$$CH_3CH_2\underset{Br}{CH}CH_3 \xrightarrow{NaNH_2}$$

Butene -1 and butene-2 (major)

The correct statement(s) are
(a) 2-butene is Saytzeff product
(b) 1-butene is Hofmann(s) product
(c) the elimination reaction follows Saytzeff rule
(d) All of the above

89. List the following alkoxide nucleophile in decreasing order of their S_N2 reactivity

1. Me_3CO^- 2. MeO^- 3. $MeCH_2O^-$

4. Me_2CHO^- 5.

(a) 2 > 3 > 5 > 4 > 1
(b) 5 > 3 > 2 > 1 > 4
(c) 1 > 5 > 2 > 3 > 4
(d) 3 > 5 > 1 > 2 > 3

90. Consider the following reactions. Which of these does not involve attack of a nucleophile in first step? **[NCERT]**

(a) $CH_3CH_2Br + HS^- \longrightarrow CH_3CH_2SH + Br^-$
(b) $(CH_3)_2C{=}CH_2 + HCl \longrightarrow (CH_3)_2CCl — CH_3$
(c) $CH_3CH_2Br + HO^- \longrightarrow CH_2{=}CH_2 + H_2O + Br^-$
(d) $(CH_3)_2C — CH_2OH + HBr \longrightarrow (CH_3)_2\ CBrCH_2CH_3 + H_2O$

Round II (Mixed Bag)

Only One Correct Option

1. In which of the compounds given below there is more than one kind of hybridisation (*sp*, sp^2, sp^3) for carbon?

(I) $CH_3CH_2CH_2CH_3$

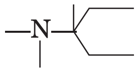
(II) $CH_3CH{=}CH-CH_3$

(III) $CH_2{=}CH-CH{=}CH_2$

(IV) $H-C{\equiv}C-H$

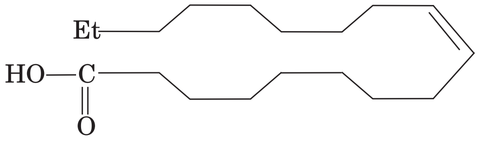
(a) (II) and (IV) (b) (I) and (IV)
(c) (II) and (III) (d) (II) only

2. The IUPAC name of following compound is



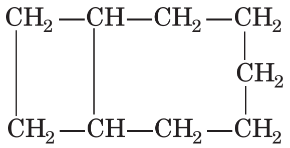
(a) N,N-dimethyl- 3-methylpentan-3-amine
(b) 3-N,N-dimethyl, 3-methyl pentanamine
(c) 3-methyl-3-N,N-dimethyl pentane
(d) 3-methyl-3-N,N-dimethyl butane

3. The compound



have its IUPAC name as
(a) octa dec-9-enoic acid
(b) oleic acid
(c) ethyl hexadec-9-enoic acid
(d) All of the above

4. The IUPAC name of the compound

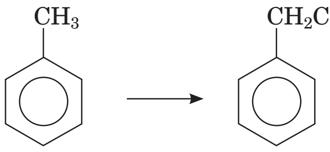


is

(a) bicyclo [2.5.0] nonane (b) bicyclo [5.0.2] nonane
(c) bicyclo [5.2.0] nonane (d) bicyclo [0.2.5] nonane

5. The nodal plane in the π-bond of ethene is located in
(a) the molecular plane
(b) a plane parallel to the molecular plane
(c) a plane perpendicular to the molecular plane which bisects the carbon-carbon sigma bond at right angle
(d) a plane perpendicular to the molecular plane which contains the carbon-carbon sigma bond

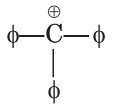
6.



The above reaction proceeds through
(a) free radical substitution
(b) nucleophilic substitution
(c) electrophilic substitution
(d) None of the above

7. Which of the following species is paramagentic in nature?
(a) Carbonium ion (b) Free radical
(c) Carbene (d) Nitrene

8. (1)

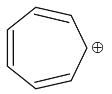


$\phi-\underset{\substack{|\\ \phi}}{\overset{\oplus}{C}}-\phi$

(2) $\phi-\overset{\oplus}{C}H_2$

(3) $CH_2{=}CH-\overset{\oplus}{C}H_2$

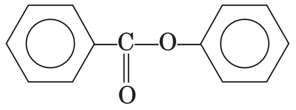
(4)



Correct order of stability is
(a) 1 > 4 > 2 > 3
(b) 1 > 2 > 3 > 4
(c) 1 > 2 > 4 > 3
(d) 1 > 3 > 4 > 2

9. Formation of ethylene from acetylene is an example of
(a) elimination reaction (b) substitution reaction
(c) condensation reaction (d) addition reaction

10. In



electrophilic substitution occurs at
(a) *ortho*/*para* at first ring
(b) *meta* at first ring
(c) *ortho* /*para* at second ring
(d) *meta* at second ring

11. An S_N2 reaction at an asymmetric carbon of a compound always gives
(a) a mixture of diastereomers
(b) a single stereoisomer
(c) an enantiomer of the substrate
(d) a product with opposite optical rotation

12. Identify the most stable species in the following sets of ions. **[NCERT Exemplar]**

(i) $\overset{\oplus}{C}H_3, \overset{\oplus}{C}H_2Br, \overset{\oplus}{C}HBr_2, \overset{\oplus}{C}Br_3$

(ii) $\overset{\ominus}{C}H_3, \overset{\ominus}{C}H_2Cl, \overset{\ominus}{C}HCl_2, \overset{\ominus}{C}Cl_3$

(a) $\overset{+}{C}Br_3, \overset{-}{C}Cl_3$ (b) $\overset{+}{C}H_3, \overset{-}{C}H_3$
(c) $\overset{+}{C}H_2Br, \overset{-}{C}H_3$ (d) $\overset{+}{C}H_3, \overset{-}{C}Cl_3$

13. SO_3 acts as an electrophile because **[NCERT Exemplar]**

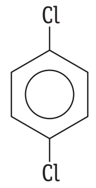
(a) S is an electron deficient element
(b) O is highly electronegative
(c) S is larger in size
(d) All of the above

14. Amino group is *ortho*/*para*- directing for aromatic electrophilic substitution. On nitration of aniline, a good amount of *m*-nitroaniline is obtained. This is due to

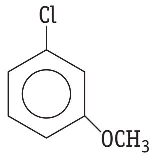
(a) the fact that in nitration mixture, *ortho, para*-activity of NH_2 group is completely lost
(b) $-NH_2$ becomes $-NH_3^+$, which is *m*-directing
(c) $-NH_2$ becomes $-NH^+SO_4^-$; which is *m*-directing
(d) $-NH_2$ becomes $-NH^-NO_2^+$, which is *m*-directing

15. Which of the following would react most readily with nucleophiles?

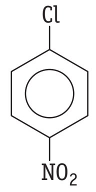
(a)



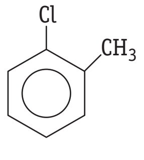
(b)



(c)



(d)



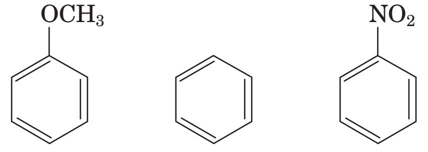
16. Which of the following statement is not characteristic of free radical chain reaction?

(a) It gives major products derived from most stable free radical
(b) It is usually sensitive to change in solvent polarity
(c) It proceeds in three main steps like initiation, propagation and termination
(d) It may be initiated by UV light

17. Arrange *p*-toluidine (I) N,N-dimethyl-*p*-toluidine (II) *p*-nitroaniline (III) and aniline (IV) in order of decreasing basicity

(a) I > IV > III > II
(b) I > II > III > IV
(c) II > I > IV > III
(d) III > I > II > IV

18. Among the following compounds (I – III) the correct order of reaction with electrophilic reagent is

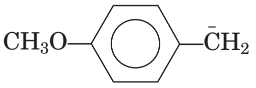


I II III

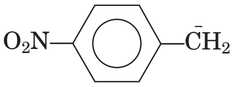
(a) II > III > I (b) III < I < II
(c) I > II > III (d) I = II > III

19. Consider the following carbanions

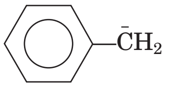
(I)



(II)



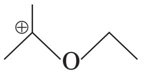
(III)



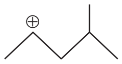
Correct order of stability is

(a) I > II > III (b) III > II > I
(c) II > III > I (d) I > III > II

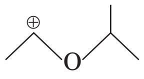
20. The correct stability order for the following species is



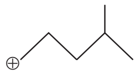
(I)



(II)



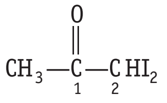
(III)



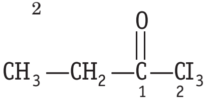
(IV)

(a) (II) > (IV) > (I) > (III) (b) (I) > (II) > (III) > (IV)
(c) (II) > (I) > (IV) > (III) (d) (I) > (III) > (II) > (IV)

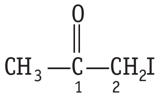
21. Which of the following compounds yields most stable carbanion after rupture of $(\underset{1}{C}-\underset{2}{C})$ bond?

(a)


$CH_3-\underset{1}{\overset{\overset{O}{\|}}{C}}-\underset{2}{C}HI_2$

(b)


$CH_3-CH_2-\underset{1}{\overset{\overset{O}{\|}}{C}}-\underset{2}{C}I_3$

(c)


$CH_3-\underset{1}{\overset{\overset{O}{\|}}{C}}-\underset{2}{C}H_2I$

(d) None of these

22. Match the following

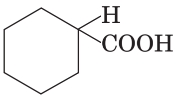
Column I

A. cyclohexane carboxylic acid
B. 2,3,5-trimethyl hexane
C. trimethyl bismuthane
D. Bicyclo [4.2.0] octane 1-ol

Column II

(i) $CH_3-CH(CH_3)CH_2-CH(CH_3)-CH(CH_3)-CH_3$

(ii)



(iii) 
(iv) $(CH_3)_3Bi$

	A	B	C	D
(a)	(iv)	(i)	(ii)	(iii)
(b)	(i)	(ii)	(iv)	(iii)
(c)	(ii)	(i)	(iv)	(iii)
(d)	(iii)	(ii)	(iv)	(i)

23. Which one of the following compounds is most acidic?

(a) $Cl—CH_2—CH_2—OH$

(b) 
(c) 
(d) 
24. Which of the following is singlet carbene?

(a) $CH_3\ddot{C}HCH_3$ (b) $C_2H_5\ddot{C}—H$

(c) $CH_2=CH—\overset{\oplus}{C}H_2$ (d) $(CH_3)_3C^+$

25. Which of the following applies in the reaction $CH_3CHBrCH_2CH_3 \xrightarrow{\text{Alco. KOH}} ?$

(I) $CH_3CH=CHCH_3$ (Major product)

(II) $CH_2=CHCH_2CH_3$ (Minor product)

(a) Hofmann's rule (b) Saytzeff's rule

(c) Kharasch effect (d) Markownikoff's rule

26. A solution of D(+)-2-chloro-2-phenylethane in toluene racemises slowly in the presence of small amount of $SbCl_5$ due to the formation of

(a) carbanion (b) carbene

(c) free radical (d) carbocation

27. Which of the following statements is incorrect?

(a) The rate of reaction increases with increase in water concentration in the hydrolysis of tertiary butyl bromide in methanol and water

(b) The relative nucleophilicity in protic solvent is

$$CN^- > I^- > \bar{O}H > Br^- > Cl^- > F^- > H_2O$$

(c) In S_N2 reactions, the order of reactivity of alkyl halides is in the order

methyl > primary > secondary > tertiary

(d) S_N2 reaction involves carbonium ions

28. Which of the following statement(s) is (are) not true?

(a) Carbanions and carbonium ions, usually exist in ion pairs or else solvated

(b) Acidity increases and basicity decreases in going from left to right across a row of periodic table

$$CH_4 < NH_3 < H_2O < HF \text{ (acidity)}$$

$$CH_3^- > NH_2^- > OH^- > F^- \text{ (basicity)}$$

(c) $RCOOH$ like $RCOR$ reacts with H_2NOH to give an oxime

(d) Decreasing order of ionizing power of solvents is

$$CF_3COOH > HCOOH > H_2O > CH_3COOH > CH_3OH > C_2H_5OH > (CH_3)_2SO > CH_3CN$$

29. Match the terms mentioned in Column I with the terms in Column II and choose the correct answer using the codes given below **[NCERT Exemplar]**

	Column I		Column II
A.	Carbocation	1.	Cyclohexane and I- hexene
B.	Nucleophile	2.	Conjugation of electrons of C—H σ bond with empty *p*-orbital present at adjacent positively charged carbon.
C.	Hyperconjugation	3.	*sp*^{2} hybridised carbon with empty *p*-orbital
D.	Isomers	4.	Ethyne
E.	*sp* hybridisation	5.	Species that can receive a pair of electrons
F.	Electrophile	6.	Species that can supply a pair of electrons

Codes

	A	B	C	D	E	F
(a)	1	2	3	4	5	6
(b)	3	6	2	1	4	5
(c)	2	3	6	5	4	1
(d)	6	3	2	1	4	5

More than One Correct Option

30. Which of the following are cyclic compounds?

(a) Borazole (b) Pyrrole

(c) Anthracene (d) Isobutylene

31. Electrophiles are electron seeking species. Which of the following groups contain only electrophiles? **[NCERT Exemplar]**

(a) BF_3, NH_3, H_2O (b) $AlCl_3, SO_3, NO_2^+$

(c) $NO_2^+, \overset{+}{C}H_3, CH—\overset{+}{C}=O$ (d) $C_2H_5^-, \dot{C}_2H_5, C_2H_5^+$

32. Hyperconjugation involves delocalisation of **[NCERT Exemplar]**

(a) electrons of carbon-hydrogen σ bond of an alkyl group directly attached to an atom of unsaturated system.

(b) electrons of carbon-hydrogen σ bond of an alkyl group directly attached to the positively charged carbon atom.

(c) π-electrons of carbon-carbon bond

(d) lone pair of electrons

33. Br has a low reactivity in $CH_2{=}CH{-}Br$ because
(a) Br is electronegative
(b) of the $+M$ effect of bromine
(c) the C—Br bond has a partial double bond character
(d) Br shows + I effect

34. Which of the following species are planar?
(a) *Iso*-propyl carbanion
(b) Nitromethyl carbanion
(c) Singlet carbene
(d) Triphenylmethyl carbocation

35. Which of the following structures have resonance stability?

(a) 
(b) 
(c) 
(d) 
Assertion and Reason

Directions (Q. Nos. 36 to 40) *Each of these questions contains two statements : Statement* I (*Assertion*) *and Statement* II (*Reason*). *Each of these questions also has four alternative choices, only one of which is the correct answer. You have to select one of the codes* (*a*), (*b*), (*c*), (*d*) *given below :*

(a) Statement I is true; Statement II is true; Statement II is a correct explanation for Statement I.
(b) Statement I is true; Statement II is true; Statement II is not a correct explanation for Statement I.
(c) Statement I is true; Statement II is false.
(d) Statement I is false; Statement II is true.

36. Statement I The IUPAC name for the compound, $NCCH_2CH_2COOH$ is 3-cyano propanoic acid.

Statement II —COOH is considered as substituent group while —CN is considered as the principal functional group.

37. Statement I All the carbon atoms in $H_2C{=}C{=}CH_2$ are sp^2-hybridised.

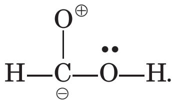
Statement II In this molecule all the carbon atoms are attached ot each other by double bonds.

38. Statement I The order of stability of carbocations are

$$R_3C^+ > R_2\overset{+}{C}H > R\overset{+}{C}H_2 > \overset{+}{C}H_3.$$

Statement II The stability of carbocations is influenced by both resonance and inductive effects.

39. Statement I 
$H{-}\underset{}{\overset{O^-}{\overset{|}{C}}}{=}\overset{+}{O}H$ is more stable than



$H{-}\underset{\ominus}{\overset{O^{\oplus}}{\overset{|}{C}}}{-}\ddot{O}{-}H.$

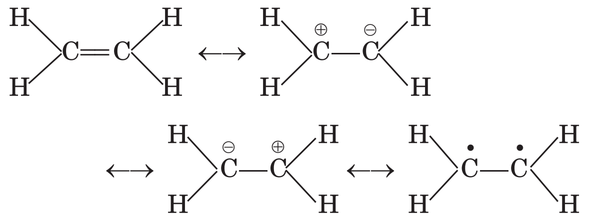
Statement II Compound in which the positive and negative charges reside on the most electropositive and most electronegative atoms of the species respectively is more stable.

40. Statement I Energy of resonance hybrid is equal to the average of energies of all canonical forms.

Statement II Resonance hybrid cannot be presented by a single structure. [**NCERT** Exemplar]

Comprehension Based Questions

Directions (Q. Nos. 41 to 43) Resonance effects are encountered mainly in molecule with multiple, *i.e.*, π bonds. Except in a few special molecules, the σ-bond framework is not involved in significant resonance interactions. This fact can be rationalized by noting that electron in π bonds are higher in energy than those in σ-bonds, making the π-bonding electrons more reactive and also more polarizable than σ-bonding electrons. For example, here four structures we might write for ethylene.



41. Which of the following compounds shows resonance?
(a) Ethyne (b) Ethane
(c) Toluene (d) Cyclohexene

42. Naphthalene is an example of
(a) alicyclic compound
(b) heterocyclic compound
(c) aliphatic compound
(d) polynuclear aromatic hydrocarbon

43. In benzene, all the C—C bonds have the same length because of
(a) isomerism
(b) tautomerism
(c) resonance
(d) inductive effect

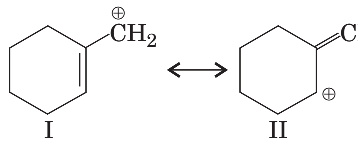
Directions (Q. Nos. 44 to 47) Stability of carbocations depends upon the electron releasing inductive effect of groups adjacent to positively charged carbon atom involvement of neighbouring groups in hyperconjugation and resonance. [**NCERT** Exemplar]

44. From the following resonance structures of $CH_3 — \ddot{\underset{\bullet\bullet}{O}} — \overset{+}{C}H_2$ predict which of the structures is more stable?

(a) $CH_3O — \overset{+}{C}H_2$ (b) $CH_3 — \underset{\bullet\bullet}{\overset{+}{O}} = CH_2$

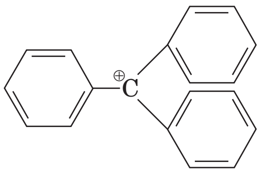
(c) $CH_2 = \overset{-}{O} — CH_3$ (d) All are equally stable

45. Which of the following ions is more stable?



(a) I
(b) II
(c) Both are equally stable
(d) Unpredictable

46. The structure of triphenylmethyl cation is given below. This is very stable and someof its salts can be stored for months. The cause of high stability of this cation, is [**NCERT** Exemplar]

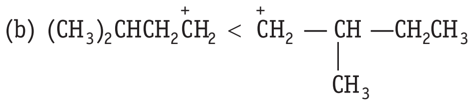


(a) hyperconjugation (b) mesomeric effect

(c) resonance (d) Both (b) and (c)

47. Arrange the various carbocations that can be obtained from 2-methylbutane in order of increasing stability. [**NCERT** Exemplar]

(a) $(CH_3)_2CHCH_2\overset{+}{C}H_2 < (CH_3)_2CH\overset{+}{C}HCH_3 < (CH_3)_2\overset{+}{C}CH_2CH_3 < \overset{+}{C}H_2(CH_3)CHCH_2CH_3$



(b) $(CH_3)_2CHCH_2\overset{+}{C}H_2 < \overset{+}{C}H_2 — \underset{\underset{CH_3}{|}}{CH} — CH_2CH_3 < (CH_3)_2H\overset{+}{C}HCH_3 < (CH_3)_2\overset{+}{C}CH_2CH_3$

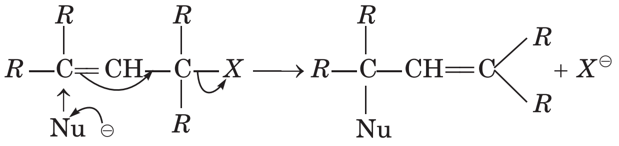
(c) $(CH_3)_2CHCH_2\overset{+}{C}H_2 < (CH_3)_2CH\overset{+}{C}HCH_3 < \overset{+}{C}H_2CH(CH_3)CH_2CH_3 < (CH_3)_2\overset{+}{C}CH_2CH_3$

(d) $(CH_3)_2CHCH_2\overset{+}{C}H_2 < (CH_3)_2\overset{+}{C}CH_2CH_3 < \overset{+}{C}H_2CH(CH_3)CH_2CH_3 < (CH_3)_2CH\overset{+}{C}HCH_3$

Directions (Q. Nos. 48 and 49) Nucleophilic substitution at an allylic carbon may also takes place by S_N2 mechanism without allylic rearrangement. This mechanism operates with primary allyl halides in the presence of polar aprotic solvents.

$$CH_2 = CH — CH_2 — Br \xrightarrow[\text{Acetone}]{\text{NaI}} CH_2 = CH — CH_2 — I$$

However, allylic rearrangement can also take place under S_N2 conditions through the following mechanism in which nucleophile attacks at the γ-carbon instead of at the usual position. This mechanism is also called S_N2 mechanism and is an allylic rearrangement. S_N2 mechanism takes place under S_N2 conditions where α-substitution sterically retards the normal S_N2 mechanism.



48. Which one of the halide is most reactive for S_N2 reaction?

(a) $C_6H_5CH_2Cl$ (b) $CH_3—O—CH_2—Cl$

(c) $CH_2 = CH—CH_2—Cl$ (d) $CH_3—CO—CH_2—Cl$

49. For the reaction,

$$CH_3 — I + Nu^{\ominus} \longrightarrow CH_3 — Nu + I^{\ominus}.$$

the rate will be maximum when $Nu^{\ominus}$ is

(a) $Br^{\ominus}$ (b) $N_3^{\ominus}$

(c) $CH_3O^{\ominus}$ (d) $C_6H_5O^{\ominus}$

Previous Years' Questions

50. Consider thiol anion ($RS^{\ominus}$) and alkoxy anion ($RO^{\ominus}$). Which of the following statements is correct? [AIEEE 2011]

(a) ($RS^{\ominus}$) is less basic and less nucleophilic than ($RO^{\ominus}$)

(b) ($RS^{\ominus}$) is less basic but more nucleophilic than ($RO^{\ominus}$)

(c) ($RS^{\ominus}$) is more basic and more nucleophilic than ($RO^{\ominus}$)

(d) ($RS^{\ominus}$) is more basic and more nucleophilic than ($RO^{\ominus}$)

51. The correct order of increasing basicity of the given conjugate bases ($R = CH_3$) is [AIEEE 2010]

(a) $RCO\bar{O} < HC \equiv \bar{C} < \bar{R} < \bar{N}H_2$

(b) $\bar{R} < HC \equiv \bar{C} < RCO\bar{O} < \bar{N}H_2$

(d) $RCO\bar{O} < \bar{N}H_2 < HC \equiv \bar{C} < \bar{R}$

(d) $RCO\bar{O} < HC \equiv \bar{C} < \bar{N}H_2 < \bar{R}$

52. Arrange the carbanions, $(CH_3)_3\bar{C}, \bar{C}Cl_3$,$(CH_3)_2\bar{C}H$, $C_6H_5\bar{C}H_2$ in order of their decreasing stability. **[AIEEE 2009]**

(a) $C_6H_5\bar{C}H_2 > \bar{C}Cl_3 > (CH_3)_3\bar{C} > (CH_3)_2\bar{C}H$
(b) $(CH_3)_2\bar{C}H > \bar{C}Cl_3 > C_6H_5\bar{C}H_2 > (CH_3)_3\bar{C}$
(c) $\bar{C}Cl_3 > C_6H_5\bar{C}H_2 > (CH_3)_2\bar{C}H > (CH_3)_3\bar{C}$
(d) $(CH_3)_3\bar{C} > \bar{C}Cl_3 > C_6H_5\bar{C}H_2 > (CH_3)_2\bar{C}H$

53. The IUPAC name of *neo*-pentane is **[AIEEE 2009]**

(a) 2-methylbutane (b) 2,2-dimethylpropane
(c) 2-methylpropane (d) 2,2-dimethylbutane

54. The correct decreasing order of priority for the functional groups of organic compounds in the IUPAC system of nomenclature is **[AIEEE 2008]**

(a) —COOH, SO_3H,—$CONH_2$,—CHO
(b) —SO_3H,—COOH,—$CONH_2$,—CHO
(c) —CHO,—COOH,—SO_3H — $CONH_2$
(d) —$CONH_2$, CHO,—SO_3H,—COOH

55. The IUPAC name of  is **[AIEEE 2007]**

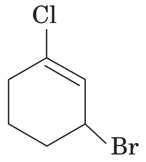
(a) 1, 1-diethyl-2, 2-dimethylpentane
(b) 4, 4-dimethyl-5, 5-diethylpentane
(c) 5, 5-diethyl-4, 4-dimethylpentane
(d) 3-ethyl-4, 4-dimethylheptane

56. Which of the following is the correct order of decreasing S_N2 reactivity? **[AIEEE 2007]**

(X = a halogen)

(a) $RCH_2X > R_3CX > R_2CHX$ (b) $RCH_2X > R_2CHX > R_3CX$
(c) $R_3CX > R_2CHX > RCH_2X$ (d) $R_2CHX > R_3CX > RCH_2X$

57. The IUPAC name of the compound shown below is **[AIEEE 2006]**



(a) 2-bromo-6-chlorocyclohex-1-ene
(b) 6-bromo-2-chlorocyclohexene
(c) 3-bromo-1-chlorocyclohexene
(d) 1-bromo-3-chlorocyclohexene

58. The increasing order of stability of the following free radicals is **[AIEEE 2006]**

(a) $(CH_3)_2\dot{C}H < (CH_3)_3\dot{C} < (C_6H_5)_2\dot{C}H < (C_6H_5)_3C$
(b) $(C_6H_5)_3\dot{C} < (C_6H_5)_2\dot{C}H < (CH_3)_3\dot{C} < (CH_3)_2\dot{C}H$
(c) $(C_6H_5)_2\dot{C}H < (C_6H_5)_3\dot{C} < (CH_3)_3\dot{C} < (CH_3)_2\dot{C}H$
(d) $(CH_3)_2\dot{C}H < (CH_3)_3\dot{C} < (C_6H_5)_3\dot{C} < (C_6H_5)_2\dot{C}H$

59. The correct order of increasing acid strength of the compounds

(*A*) CH_3CO_2H (*B*) $MeOCH_2CO_2H$

(*C*) CF_3CO_2H (*D*) 
[AIEEE 2006]

(a) $B < D < A < C$ (b) $D < A < C < B$
(c) $D < A < B < C$ (d) $A < D < C < B$

60. Due to the presence of an unpaired electron, free radicals are **[AIEEE 2005]**

(a) cations (b) anions
(c) chemically inactive (d) chemically reactive

61. Tertiary alkyl halides are practically inert to substitution by S_N2 mechanism because of **[AIEEE 2005]**

(a) steric hindrance (b) inductive effect
(d) instability (d) insolubility

62. Among the following acids which has the lowest pK_a value?

(a) CH_3CH_2COOH (b) $(CH_3)_2CH_2$—COOH
(c) HCOOH (d) CH_3COOH

63. The decreasing order of nucleophilicity among the nucleophiles

(*A*) $$CH_3\underset{\underset{O}{\|}}{C}—O^-$$
(*B*) CH_3O^-

(*C*) CN^-

(*D*)  is **[AIEEE 2005]**

(a) *C,B,A,D* (b) *B,C,A,D* (c) *D,C,B,A* (d) *A,B,C,D*

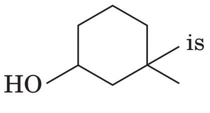
64. The reaction $$R—\overset{\overset{O}{\|}}{C}—X + Nu^{\ominus} \rightarrow R—\overset{\overset{O}{\|}}{C}—Nu + X^{\ominus}$$
is fastest when X is **[AIEEE 2005, 2004]**

(a) OCOR (b) OC_2H_5
(c) NH_2 (d) Cl

65. The IUPAC name of the compound **[AIEEE 2004]**



is

(a) 3, 3-dimethyl-1-hydroxy cyclohexane
(b) 1, 1-dimethyl-3-hydroxy cyclohexane
(c) 3, 3-dimethyl-1-cyclohexanol
(d) 1, 1-dimethyl-3-cyclohexanol

66. Which one of the following dose not have sp^2 hybridised carbon? [AIEEE 2004]
(a) Acetone (b) Acetic acid
(c) Acetonitrile (d) Acetamide

67. The IUPAC name of $CH_3COCH(CH_3)_2$ is [AIEEE 2003]
(a) *iso*-propylmethyl ketone
(b) 2-methyl-3-butanone
(c) 4-methyl *iso*-propyl ketone
(d)3-methyl-2-butanone

68. In the anion, $HCOO^-$ the two carbon-oxygen bonds are found to be of equal length . What is the reason for it? [AIEEE 2003]
(a) Electronic orbits of carbon atom are hybridised
(b) The C$=$O bond is weaker than the C—O bond
(c) The anion, $HCOO^-$ has two reasonationg structures
(d) The anion is obtained by removal of a proton from the acid molecule

69. Which of the following compounds has incorrect IUPAC nomenclature? [AIEEE 2002]

(a) $CH_3CH_2CH_2\overset{O}{\overset{\|}{C}}OC_2H_5$
ethyl butanoate

(b) $CH_3\underset{CH_3}{\underset{|}{CH}}CH_2CHO$
3-methyl butanal

(c) $CH_3\underset{CH_3}{\underset{|}{CH}}\overset{O}{\overset{\|}{C}}CH_2CH_3$
2-methyl-3-pentanone

(d) $CH_3\underset{H_3C}{\underset{|}{CH}}\underset{OH}{\underset{|}{CH}}CH_3$
2-methyl-3-butanol

70. Underlined carbon is sp^3 hybridised in [AIEEE 2002]
(a) $CH_3\underline{C}H{=}CH_2$
(b) $CH_3\underline{C}H_2NH_2$
(c) $CH_3\underline{C}ONH_2$
(d) $CH_3CH_2\underline{C}N$

71. In the following benzyl/allyl system

R—CH$=$CH$_2$ or 
(R is alkyl group)
decreasing order of inductive effect is [AIEEE 2002]
(a) $(CH_3)_3C— > (CH_3)_2CH— > CH_3CH_2—$
(b) $CH_3CH_2— > (CH_3)_2CH— > (CH_3)_3C—$
(c) $(CH_3)_2CH_2— > CH_3CH_2— > (CH_3)_3C—$
(d) $(CH_3)_2C— > CH_3CH_2— > (CH_3)_3CH—$

72. S_N1 reaction is feasible in [AIEEE 2002]

(a)  $+ \text{KOH} \longrightarrow$

(b)  $+ \text{KOH} \longrightarrow$

(c)  $+ \text{KOH} \longrightarrow$

(d)  $+ \text{KOH} \longrightarrow$

the Guidance

Round I

3. 
$$CH_3-\overset{\overset{CH_3}{|}}{\underset{\underset{CH_3}{|}}{C}}-CH_3$$

neo-pentane

The structure shows that all the hydrogen atoms are attached to primary C-atoms hence, these are primary hydrogens.

4. Carbocyclic compounds which resemble aliphatic compounds in their properties are called alicyclic compounds.

5. 
$$\underset{1}{CH_3}-\overset{\overset{CH_3}{|}}{\underset{\underset{CH_3}{|}}{\overset{}{C}_2}}-\underset{3}{CH_2}-\overset{\overset{CH_3}{|}}{\underset{\underset{CH_3}{|}}{C_4}}-\underset{5}{CH_3}$$

2, 2, 4, 4-tetramethyl pentane

There are two carbon atoms, *i.e.,* C-2 and C-4 which are tertiary in nature.

6. 
$$CH_3-CH_2-CH_2-\overset{\overset{CH_3}{|}}{\underset{\underset{CH_2-CH_3}{|}}{CH}}$$

7. 
thiophene

It is a heterocyclic compound as it contains foreign element (element other than C and H) in the cyclic chain.

8. $\underset{sp^2}{\underset{\downarrow}{CH_2}}=\underset{sp^2}{\underset{\downarrow}{CH}}-\underset{sp}{\underset{\downarrow}{C}}\equiv\underset{sp}{\underset{\downarrow}{CH}}$

9. 
$$N\underset{1\sigma}{\overset{2\pi}{\equiv}}C\overset{\sigma}{-}\underset{\underset{H}{|\sigma}}{C}\underset{\pi}{\overset{\sigma}{=}}\underset{\underset{H}{|\sigma}}{C}\overset{\sigma}{-}C\underset{2\pi}{\overset{\sigma}{\equiv}}N$$

7 sigma and 5 pi

10. 
enolic form of acetone
9σ bonds, 1π bond, 2 lone pairs

11. 
$$CH_3-\underset{sp^2}{\overset{\overset{O}{\|}}{C}}-NH_2\xrightarrow{P_2O_5}\underset{sp}{CH_3C\equiv N}$$

12. The shape of π electron cloud in acetylene is cylindrical.

13. Electronegativity depends upon *s*-character and increases with increase in *s*-character. In $CH_3-CH_2-C\equiv\overset{*}{C}H$ the *s*-character of carbon marked with asterisk is 50% (as it is *sp* hybridised). So, it is the most electronegative.

Note In sp^2, *s*-character is 33.3% and in sp^3 it is 25%.

14. Order of bond length.

$$\sigma\text{ bond }(sp^3)>\sigma\text{ bond }(sp^2)>\sigma\text{ bond }(sp)$$

C_2H_6	C_2H_4 Or $C_2H_2Br_2$	C_2H_2

15. 
The C-atoms attached to the triple bond lie in a straight line while the carbon of the CH_2 group is inclined at an angle of 120°. Therefore, only 2 carbon atoms are linearly arranged.

16. Weak base ⟶ strong conjugate acid

$$\underset{\text{(weakest base)}}{CH\equiv C^-}\longrightarrow\underset{\text{(strongest acid among the given)}}{CH\equiv CH}$$

$$\underset{\text{(strongest base)}}{CH_3-CH_2^-}\longrightarrow\underset{\text{(weakest acid)}}{CH_3CH_3}$$

17. $\underset{sp^3}{CH_3}-\underset{sp^3}{CH_2}-\underset{sp^2}{CH}=\underset{sp}{\overset{\oplus}{C}H}$

Electronegativity of different hybrid and unhybrid orbitals in decreasing order is as follows

$$s>sp>sp^2>sp^3>p$$

18. 
$$\underset{5}{CH_3}-\underset{4}{CH_2}-\underset{\underset{\underset{CH_3}{|}}{\underset{CH_2}{|3}}}{CH}-\underset{2}{CH_2}-\underset{1}{CH_3}$$

3-ethyl pentane

This compound exists.

20. According to IUPAC system, the IUPAC name of a compound is written as single word as far as possible.

21. The choice of principal functional group is made on the basis of the following order

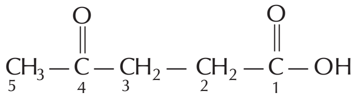
Carboxylic acid > sulphonic acid > anhydride > esters > acid halide > acid amide > nitrile > aldehyde > ketone > alcohol > amine

22. $\underset{6}{CH_3}-\underset{5}{CH_2}-\underset{4}{C}\equiv\underset{3}{C}-\underset{2}{CH}=\underset{1}{CH_2}$

hex-1-en-3-yne

[∵ Double bond is preferred over ≡ bond while naming.]

23.

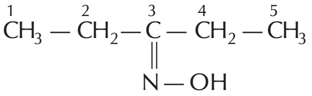


$\underset{5}{CH_3}-\underset{4}{\overset{O}{\overset{\|}{C}}}-\underset{3}{CH_2}-\underset{2}{CH_2}-\underset{1}{\overset{O}{\overset{\|}{C}}}-OH$

4-oxo pentanoic acid

24.  $-\overset{|}{\underset{|}{C}}-\overset{|}{\underset{|}{N}}$ group is called amino

while  $-\underset{|}{C}=\underset{|}{N}$ group is called imino.

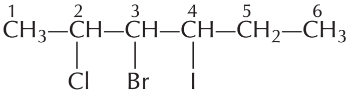


$\overset{1}{CH_3}-\overset{2}{CH_2}-\overset{3}{\underset{\underset{N-OH}{\|}}{C}}-\overset{4}{CH_2}-\overset{5}{CH_3}$

N-hydroxy-3-iminopentane

25. The decreasing order of priority of prefix in numbering the carbon chain of an organic compound is

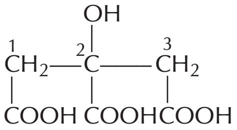
Bromo > Chloro > Iodo.



$\overset{1}{CH_3}-\underset{\underset{Cl}{|}}{\overset{2}{CH}}-\underset{\underset{Br}{|}}{\overset{3}{CH}}-\underset{\underset{I}{|}}{\overset{4}{CH}}-\overset{5}{CH_2}-\overset{6}{CH_3}$

3-bromo-2-chloro-4-iodohexane

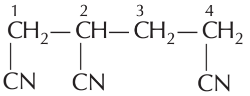
26.



$\underset{\underset{COOH}{|}}{\overset{1}{CH_2}}-\underset{\underset{COOH}{|}}{\overset{\overset{OH}{|}}{\overset{2}{C}}}-\underset{\underset{COOH}{|}}{\overset{3}{CH_2}}$

2-hydroxy propane-1,2,3-tricarboxylic acid

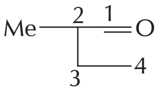
27.



$\underset{\underset{CN}{|}}{\overset{1}{CH_2}}-\underset{\underset{CN}{|}}{\overset{2}{CH}}-\overset{3}{CH_2}-\underset{\underset{CN}{|}}{\overset{4}{CH_2}}$

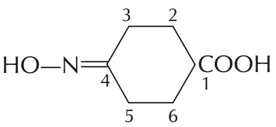
butane-1,2,4-tricarbonitrile

28.



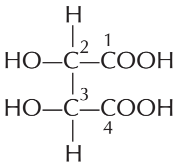
2-methylbutanal

29.



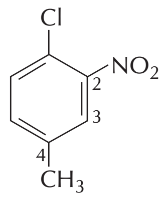
4-(N-hydroxy) imino cyclohexane-1-carboxylic acid

30. Tartaric acid is



2,3-dihydroxybutane-1,4-dioic acid

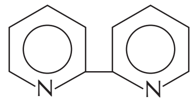
31.



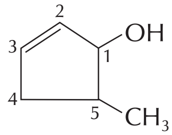
1-chloro-4-methyl-2-nitrobenzene

[Because the order of preference is $Cl > NO_2$]

33. The structure of the compound 2,2′-bipyridine is

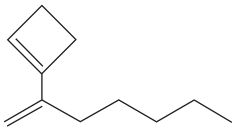


34.



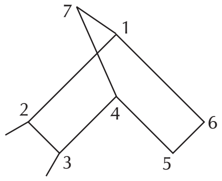
5-methyl cyclopent-2-en-1-ol

35.



2-(1-cyclobutenyl)-1-hexene

36.



2,3-dimethyl bicyclo [2.2.1] heptane

37. During the fission of a covalent bond, species that loses its electron, acquires positive charge and other one with which the electron of previous species gone, acquires a negative charge. Thus,

$$CH_3 \overset{\curvearrowright}{-} Br \longrightarrow \overset{\oplus}{C}H_3 + \overset{\ominus}{Br}$$

38. In heterolysis, the covalent bond is broken in such a way that one species (less electronegative) is deprived of its own electron, while the other species gain both the electrons.

$$CH_3CH_2CH_3 \longrightarrow \overset{\ominus}{C}H_3 + \overset{\oplus}{C}_2H_5$$

because $\overset{\oplus}{C}H_3$ is less stable than $\overset{\oplus}{C}_2H_5$.

39. Electron deficient species or electron acceptor are called electrophiles. For example

$$\dot{C}H_3, \ddot{C}H_2, \ddot{C}X_2 \qquad \text{(where, } X = Cl, Br, I)$$

40. All neutral covalent compound in which central atom has incomplete octet are electrophiles. For example

$$BF_3, BeCl_2, BH_3, ZnCl_2, AlCl_3$$

41. Nucleophiles are those substances which can donate a pair of electrons. They can be neutral or negatively charged. The nucleophilic power depends on the tendency of species to donate the electrons. Due to the presence of $+I$ effect, it increases. Hence, higher the $+I$ effect, higher the nucleophilic power.

42. CH_3NH_2 and CH_3OH are nucleophiles, CH_3-Cl is an electrophile. But $CH_3-\overset{\delta+}{C}\equiv\overset{\delta-}{N}\colon$ is a nucleophile due to the presence of a lone pair of electrons on N and is an electrophile due to the presence of a partial positive charge on C.

43. Nucleophilicity increases on moving down in a group of the Periodic Table.

$$I^{\ominus} > Br^{\ominus} > Cl^{\ominus} > F^{\ominus}$$

45. $C_6H_5\overset{+}{C}HC_6H_5$ is the most stable since the positive charge can be delocalise on both the phenyl rings.

47. It is with maximum conjugative structures (or resonating structures) among them.

48. Benzyl 
$>$ allyl $CH_2{=}CH{-}\overset{+}{C}H_2 >$ methyl CH_3 $>$ vinyl $CH_2{=}\overset{+}{C}H$

This order is based on conjugative and hyperconjugative structures.

49. Stability of alkyl carbanion $\propto \dfrac{1}{\text{magnitude of negative charge}}$

and magnitude of negative charge $\propto +I$ power of the group. Hence, acetylenic carbanion is more stable than vinylic carbanion which is more stable than alkyl carbanion.

50. $-NO_2$ group shows $-M$ effect while CH_3O- group shows $+M$ effect ($-M$ effect stabilises an anion).

51. Stability of a carbanion increases in the presence of electron withdrawing group but decreases in the presence of electron releasing group.

$O_2N-CH_2-CH_2O^-$ is expected to be more stable than $CH_3-CH_2O^-$ because $-NO_2$ group has $-I$ effect, this leads to the dispersal of negative charge. On the other hand, $-CH_3$ group has $+I$ effect, this leads to the intensification of the negative charge. Dispersal of the charge leads to the stability of ion while intensification of negative charge leads to the unstability of ion.

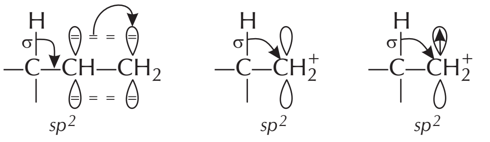
$$\underset{\text{more stable}}{O_2N\leftarrow CH_2\leftarrow CH_2\leftarrow O^-} \qquad \underset{\text{less stable}}{CH_3\rightarrow CH_2\rightarrow O^-}$$

53. The order of stability of carbanion is 1° > 2° > 3°. Moreover, III is resonance stabilised and IV also exists in two resonating forms. Thus, the order of stability is III > IV > I > II.

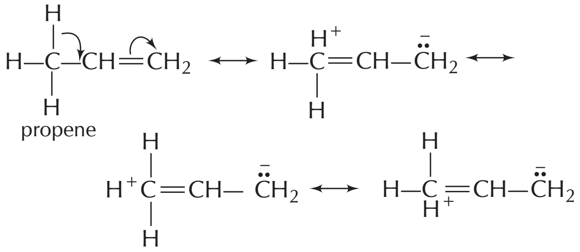
54. Stability of carbanions increase with increase in *s*-character of hybrid orbitals of carbon bearing charge therefore, the order is $sp^3 < sp^2 < sp$.

56. Cl is more electronegative than Br thus, $C-Cl$ bond is more polar and hence greatest positive charge is expected in $\overset{*}{C}H_3CH_2-Cl$.

57. Hyperconjugation is one kind of delocalisation of σ(C—H) bonded electron to unshared *p*-orbital.



58. Due to hyperconjugation, alkyl groups act as electron donors when attached to a π-system as shown below.



59. $-I$ power of groups in decreasing order with respect to the reference H is.

$$-NO_2 > -CHO > -COOR > -F > -Cl$$
$$> -Br > -I > -OH > -OR > -NH_2.$$

60. Presence of —I showing group like —Cl increases the acidic character of carboxylic acids and the acidity reduces with increase in the distance between —COOH and —I showing group.

61. In gas phase, tertiary amines are more basic than secondary amines which are more basic than ammonia.

$-I$ group present on central atom decreases electron density, hence decreases basicity. Thus, the correct order is

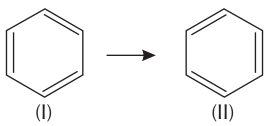
$$CH_3NH_2 > NH_3 > NF_3$$

62. As the number of hyperconjugative structures increases, stability of alkenes increases. Thus, the correct order is I > II > IV > III > V

63. Electromeric effect implies complete transfer of π-electrons in the presence of a reagent. Since, simple ethers do not contain a multiple bond, therefore, they do not show electromeric effect.

64. Stability of carbanion is not governed by hyperconjugation. Its stability depends on the $+I$ or $-I$ group.

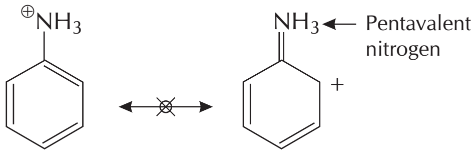
65. Delocalised electrons are present in benzene, 1,3-butadiene and 1,3,5-hexatriene.



(I) (II)

66. Benzene is the most stable and we know that resonance energy is a direct measure of the stability of a molecule.

67. If positive charge is present on nitrogen then positive charge will not be in conjugation to the ring because in this case nitrogen will become pentavalent.



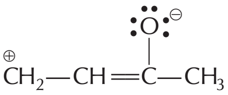
68. Due to –*R* effect of —CHO group, oxygen carries –δ charge while the terminal carbon carries +δ, *i.e.,*

$$\overset{+\delta}{C}H_2{=}CH{-}CH{=}\overset{-\delta}{O}$$

69. In the given compound four π-electrons of double bond and 1 lone pair on N atom leads to delocalisation of six electrons.

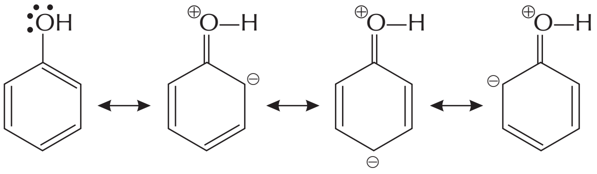
70. Two positive charges present at the adjacent place, elevates the energy, thus lowers the stability most.

71. The most stable one is that in which the positive and negative charges reside on the most electropositive and most electronegative atoms of the species respectively like



$$\overset{\oplus}{C}H_2{-}CH{=}C(\ddot{O}^{\ominus}){-}CH_3$$

72. The oxygen atom in phenol has more dominating resonance effect than inductive effect. Increase in charge separation decreases the stability of a resonating structure.



(I) (II) (III) (IV)

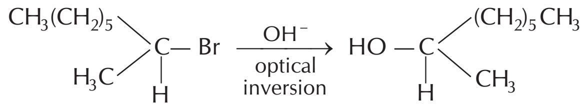
Stability of resonating structures in decreasing order will be

$$I > II \equiv IV > III$$

74. $H_3C{-}HC{=}CH_2 + H^+ \longrightarrow H_3C{-}HC^+{-}CH_3$

2° carbocation
(more stable)
+
$CH_3CH_2CH_2^+$
1° carbocation
(less stable)

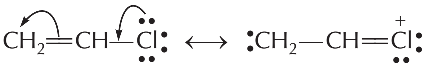
75.



$$CH_3(CH_2)_5{-}C(H_3C)(H){-}Br \xrightarrow[\text{optical inversion}]{OH^-} HO{-}C(H)((CH_2)_5CH_3)(CH_3)$$

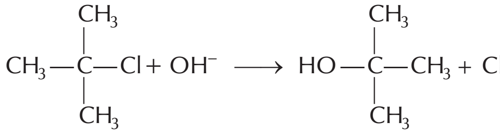
In this reaction, inversion takes place. Hence, it is an example of S_N2 reaction. In this mechanism the attack of OH^- ions take place from the back side while the Br^- ion leaves from the front side.

76. Vinyl chloride is least reactive for S_N reaction due to resonance stabilisation of C—Cl bond.



$$CH_2{=}CH{-}\ddot{\underset{..}{Cl}}{:} \longleftrightarrow {:}\bar{C}H_2{-}CH{=}\overset{+}{Cl}{:}$$

77.



$$CH_3{-}C(CH_3)_2{-}Cl + OH^- \longrightarrow HO{-}C(CH_3)_2{-}CH_3 + Cl^-$$

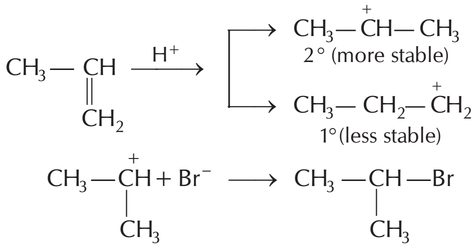
Rate ∝ [*t* - butyl chloride]

Tertiary butyl carbocation is first formed which is more stable.

78. HBr is a better source of proton. It gives H^+ and Br^- ions.

$$HBr \longrightarrow H^+ + Br^-$$

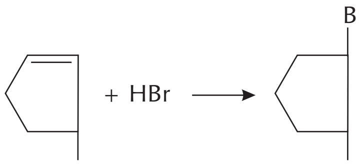
Thus, H^+ attacks the π-bond of propene to form carbonium ion as



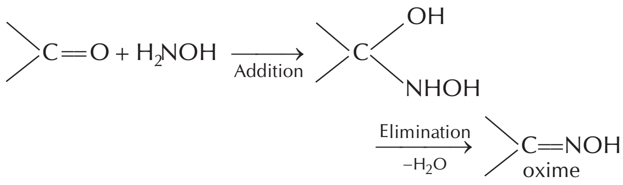
(major product)

79. With the increasing basicity of the added base, the rates of the elimination reactions have been found to increase. Thus, RO^- is most reactive.

81. A hydrogen halide containing a highly polar H—*X* bond can easily lose $\overset{\oplus}{H}$ to the pi bond of an alkene. The result of the attack of $H^{\oplus}$ is an intermediate carbocation, which quickly undergoes reaction with the negative halide ion (X^-) to yield an alkyl halide.



83. The reaction occurs as

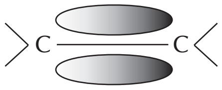


$$>C{=}O + H_2NOH \xrightarrow{\text{Addition}} >C(OH)(NHOH) \xrightarrow[-H_2O]{\text{Elimination}} >C{=}NOH$$

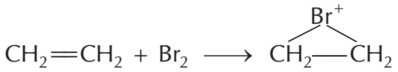
oxime

84. Primary and secondary alkyl halides give S_N2 reaction. Substrates that give stable carbocation generally undergo S_N1 reaction. Vinyl carbocation is least stable so  does not give this reaction.

85. Such a condition is seen when π-bond is formed between similar atoms *i.e.,*



86. Addition of Br_2 on ethene follow electrophilic addition.

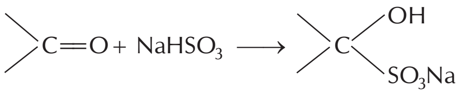


$CH_2{=}CH_2 + Br_2 \longrightarrow \overset{Br^+}{CH_2-CH_2}$

Intermediate is cyclic bromonium ion.

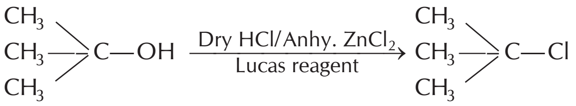
87. (a) It is Diels Alder's reaction (cyclo addition).

(b)



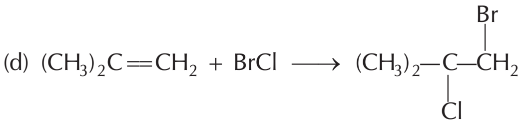
It is a nucleophilic addition reaction.

(c)



It is a nucleophilic substitution reaction.

(d)



$(CH_3)_2C{=}CH_2 + BrCl \longrightarrow (CH_3)_2-\overset{Br}{\underset{Cl}{C}}-CH_2$

It is an electrophilic addition reaction.

88. The elimination takes place according to Saytzeff rule. The most substituted alkene (butene-2) is called Saytzeff product whereas less substituted alkene (butene-1) is called Hofmann product.

89. Epoxide is ambidentate substrate for nucleophilic substitution reactions. In protonated epoxide carbon-2 and carbon-3 both aquire some positive charge due to the highly electronegative atom.

$MeO^- > MeCH_2O^- >$  $> Me_2CHO^- > Me_3CO^-$

90. (a) Nucleophilic substitution reaction

(b) Electrophilic addition reaction, involve attack of electrophile

(c) β-elimination reaction

(d) Nucleophilic substitution reaction with rearrangement.

Round II

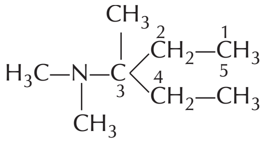
1. (I) $\overset{sp^3}{C}H_3-\overset{sp^3}{C}H_2-\overset{sp^3}{C}H_2-\overset{sp^3}{C}H_3$ only sp^3 hybridised carbon

(II) $\overset{sp^3}{C}H_2-\overset{sp^2}{C}H=\overset{sp^2}{C}H-\overset{sp^3}{C}H_3$ both sp^2 and sp^3 hybridised carbon.

(III) $\overset{sp^2}{C}H_2=\overset{sp^2}{C}H-\overset{sp^2}{C}H=\overset{sp^2}{C}H_2$ only sp^2 hybridised carbon.

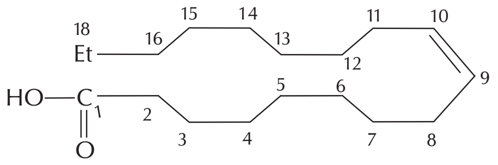
(IV) $H-\overset{sp}{C}\equiv\overset{sp}{C}-H$ only *sp*-hybridised carbon.

2.



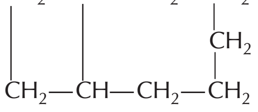
N,N-dimethyl-3-methylpentan-3-amine

3.



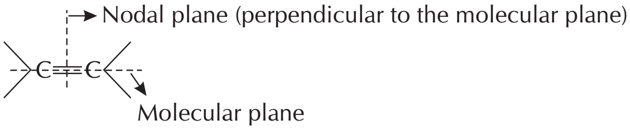
octa dec-9-enoic acid

4.

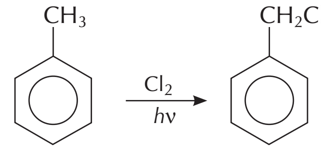


This compound contains 9 carbon atoms thus, corresponding alkane is nonane. Three bridges contain 5, 2 and 0 carbon atoms respectively. Therefore, the name of the compound is bicyclo [5.2.0] nonane.

5.

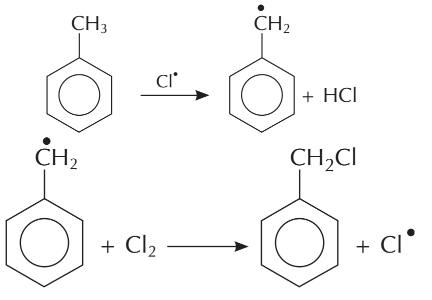


6.



This reaction proceeds through free radical substitution.

$$Cl_2 \xrightarrow{h\nu} 2Cl^\bullet$$

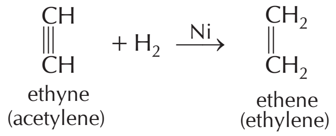


7.

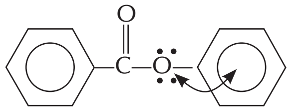
Species	Valence electrons	Magnetic behaviour
Carbonium ion	6	Diamagnetic
Free radical	7	Paramagnetic
Carbene	6	Diamagnetic
Nitrene	6	Diamagnetic

8. ϕ is phenyl group, and stability is based on the number of conjugative structures. Thus, the correct order is 1 > 4 > 2 > 3

9. Formation of ethylene from acetylene is an example of addition reaction.



10. Second ring is in conjugation with lone pair of oxygen, thus electrophilic substitution occur at *o*/*p* position of second ring.



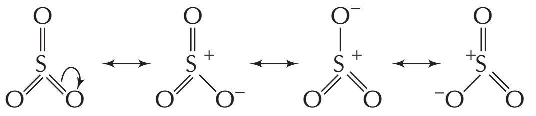
conjugation

11. In S_N2 reactions, the nucleophile attaches itself from the direction opposite to that of the nucleophile already present in the second step, the previous nucleophile is removed and a single stereoisomer is obtained.

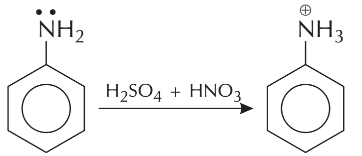
12. $\overset{\oplus}{C}H_3$ is the most stable species because the replacement of H by Br increases positive charge on carbon atom and destabilises the species.

$\overset{\ominus}{C}Cl_3$ is the most stable species because on replacing H by Cl, negative charge on carbon is reduced and species is stabilised.

13. In SO_3, three highly electronegative oxygen atoms are attached to sulphur atom. It makes sulphur atom electron deficient. Further, due to resonance, sulphur acquires positive charge. Both these factors make SO_3 an electrophile.



14. On direct nitration of aniline, lone pair of electrons present at nitrogen atom will accept proton from the nitrating mixture to give anilinium ion which is *meta*-directing.



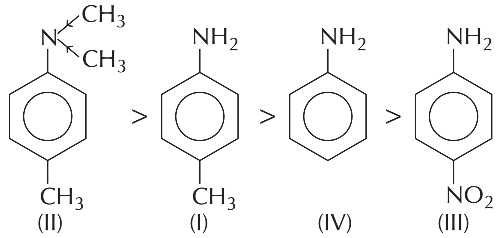
anilinium ion

15. Nucleophile always attacks on electron deficient site. Presence of electron withdrawing groups such as NO_2, CHO etc., decreases the electron density on benzene nucleus, hence such groups activate the ring towards nucleophilic attack. While presence of electron releasing groups such as *R* or O*R* increases the electron density, thus deactivates the nucleus towards nucleophilic attack.

NO_2 group activates the ring more than Cl towards nucleophilic attack, hence  reacts readily with nucleophile.

16. Free radical chain reaction is initiated by UV light. It proceeds in three main steps like initiation, propagation and termination. It gives major product derived from most stable free radical.

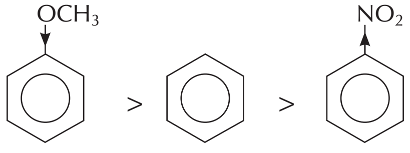
17.



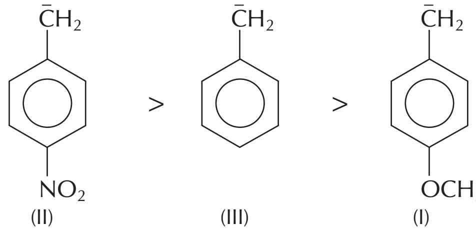
order of basicity

The reason for the above order of basicity is the presence of electron releasing —CH_3 group in II and I which facilitates the donation of lone pair by increasing electron density over N atom.

18. Methoxy group is electron releasing group so it increases electron density at benzene nucleus while —NO_2 group is electron withdrawing group, so it decreases the electron density of benzene nucleus. Thus, the order of reaction with electrophilic reagent is



19. —NO_2 group shows –*M* effect while CH_3O— group shows + *M* effect. (–*M* effect stabilises the anion).
Hence, the order of stability is



20. The correct order is I > III > II > IV

	+ *M* effect, hyperconjugation (6Hs) and + *I* effect (2–Me groups)
	+ *M* effect, hyperconjugation (3Hs) and +*I* effect (1–Me group)
 (2° carbocation)	Hyperconjugation (5Hs) and + *I* effect
 (1° carbocation)	Hyperconjugation (2Hs) and + *I* effect

21. 
$$CH_3CH_2-\overset{\overset{O}{\|}}{\underset{1}{C}}-\underset{2}{C}I_3 \xrightarrow{\text{Heterolytic fission}} CH_3CH_2-\overset{\overset{O}{\|}}{C}{}^{+} + \bar{C}I_3$$

$\bar{C}I_3$ is the most stable carbanion because of –*I* effect of I which disperses negative charge on $\bar{C}$ of  $I \leftarrow \underset{\underset{I}{\downarrow}}{\bar{C}} \rightarrow I$

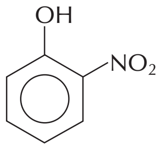
22. (A) $CH_3-CH(CH_3)-CH_2-CH(CH_3)-CH(CH_3)-CH_3$
2,3,5-trimethyl hexane

(B) 
cyclohexane carboxylic acid

(C) 
bicyclo [4.2.0] octan-1-ol

(D) $(CH_3)_3Bi$
trimethyl bismuthane

23. *Ortho* nitrophenol is the most acidic because electron withdrawing group increases acidic character due to –*I* effect of NO_2 group.



o-nitrophenol

24. An organic reaction intermediate (neutral species) having divalent carbon atom with six valence electrons, out of which two are present in same orbital with opposite spin is called singlet carbene.

25. 
$$\overset{\beta}{C}H_3\,\underset{\underset{Br}{|}}{C}H-\overset{\beta}{C}H_2CH_3 \xrightarrow{\text{alco. KOH}} \begin{cases} \underset{\text{major}}{CH_3CH=CH-CH_3} \\ \underset{\text{minor}}{CH_2=CH-CH_2CH_3} \end{cases}$$

This reaction is governed by Saytzeff's rule. According to this rule, the elimination of β-hydrogen atom take place from the carbon having the lesser number of H-atoms or in other words a stable alkene is formed. (More substituted alkene is more stable.)

26. 
The solution of D(+)-2-chloro-2-phenyl ethane in toluene racemises slowly in the presence of $SbCl_5$ due to the formation of carbocation.

27. S_N2 reaction does not involve ion formation, these infact involve formation of transition state.

28. *R*COOH does not form oxime with H_2NOH as —OH group reduces the polarity of $>C=O$ bond or reduces the positive charge on carbonyl carbon.

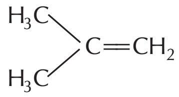
29. 
Nucleophile being electron rich can supply a pair of electrons whereas electrophile being electron deficient can receive a pair of electrons. Hyperconjugation is found when C—H bonds are in conjugation with carbon having empty *p* orbital.

 and $CH_3CH_2CH_2CH_2CH=CH_2$

Both have C_6H_{12} formula but different structures, so these are isomers.

$\overset{sp}{C}H\equiv\overset{sp}{C}H$ (Ethyne) exhibits *sp* hybridisation.

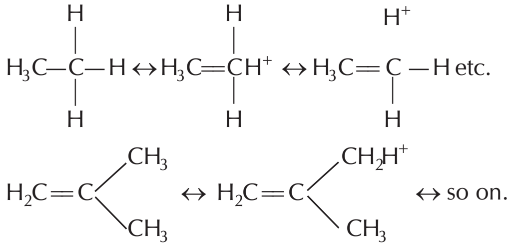
30. Only *iso*-butylene is not a cyclic compound.



31. Electron dificient species like

$AlCl_3, SO_3, NO_2^+, CH_3^+, CH_3-\overset{+}{C}=O$ are called electrophiles.

32. Conditions for hyperconjugation.



$$H_3C-\underset{\underset{H}{|}}{\overset{\overset{H}{|}}{C}}-H \leftrightarrow H_3C=\underset{\underset{H}{|}}{\overset{\overset{H}{|}}{C}}H^+ \leftrightarrow H_3C=\underset{\underset{H}{|}}{\overset{H^+}{C}}-H \text{ etc.}$$

6(hyperconjugative structures)

33. The low reactivity of a halogen bonded to an unsaturated carbon is due to the +*M* effect of the halogen. The C—Br bond in vinyl bromide has a partial double bond character due to the + *M* effect of bromine, resulting in low reactivity.

34. Singlet carbene and nitromethyl carbanion are planar species since the central carbon atom in each of them is sp^2-hybridised.

Triphenylmethyl carbocation is also in sp^2 hybrid state but it is propeller-shaped due to the repulsion between *ortho* hydrogens of the rings. However, in *iso*-propyl carbanion, C is sp^3-hybridised.

35. Charge separation structures are less important than those in which the charge is delocalised, because there is electrostatic attraction between unlike charges.

36. —COOH is the principal functional group while —CN is the substituent group.

37. In this molecule, the central C atom is *sp* hybridised.

$$H_2C\overset{\sigma}{=}C\overset{\sigma}{=}CH_2$$

2σ bonds (*sp* hybridised)

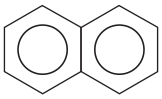
38. The stability of carbocation is explained on the basis of hyperconjugation and inductive effect hence, the stability order of carbocation is $3° > 2° > 1° >$ methyl carbocation.

39. Both the structures are resonating structures of formic acid. In $H—\overset{O^{\ominus}}{\overset{|}{C}}=\overset{+}{O}H$ negative charge is on oxygen (which is more electronegative) but in $H—\underset{\ominus}{\overset{O^{\oplus}}{\overset{|}{C}}}—\ddot{\underset{\cdot\cdot}{O}}—H$ negative charge is on carbon (which is less electronegative) therefore (I) will be more stable than the (II).

40. Energy of resonance hybrid is less than that of the canonical forms. It cannot be represented by a single structure.

41. Toluene shows resonance due to delocalisation of π-electrons.

42. Compounds containing two or more fused benzene rings are called polynuclear aromatic hydrocarbons. *e.g.*, naphthalene



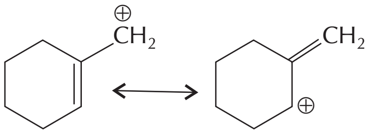
43. Due to resonance, all C—C bond distances in benzene are equal.

44. Possible structure for the given ion are

$$\underset{\text{I}}{CH_3—O—\overset{\oplus}{C}H_2} \quad \underset{\text{II}}{CH_3—\underset{\cdot\cdot}{\overset{\oplus}{O}}=CH_2}$$

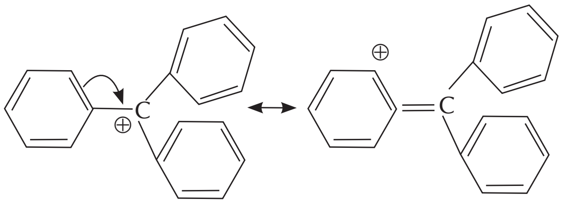
Structure II is more stable because every atom has complete octet.

45. Structure I is more stable due to resonance. (See resonance structure '*A*' and '*B*'). No resonance is possible in structure II.



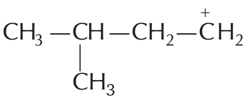
(*A*) (*B*)

46. Stabilised due to nine possible canonical structures.



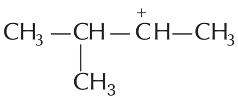
⟷ Other canonical structures

47. Four possible carbocations are



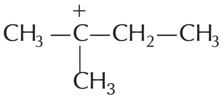
$CH_3—\underset{CH_3}{\underset{|}{CH}}—CH_2—\overset{+}{C}H_2$

(I)



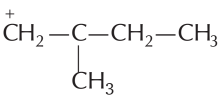
$CH_3—\underset{CH_3}{\underset{|}{CH}}—\overset{+}{C}H—CH_3$

(II)



$CH_3—\underset{CH_3}{\underset{|}{\overset{+}{C}}}—CH_2—CH_3$

(III)



$\overset{+}{C}H_2—\underset{CH_3}{\underset{|}{C}}—CH_2—CH_3$

(IV)

Order of increasing stability I < IV < II < III

48. Strong –*I* group if present on α-carbon stabilises the transition state of the S_N2 reaction. Thus, substrate having carbonyl group on β-carbon is the excellant substrate for S_N2 reaction.

49. Rate of nucleophilic substitution reaction is directly proportional to the basicity. Thus, rate is maximum when Nu^- is RO^-.

50. Nucleophilic strength increases down a column of the Periodic Table (in solvents that can have hydrogen bonds, such as water, alcohols, thio alcohols).

Nucleophilic strength $RO^- < RS^-$

Base strength $RO^{\ominus} > RS^-$

Thus, $RS^{\ominus}$ is more nucleophilic but less basic than RO^-.

51. 
$R—\overset{O}{\overset{\|}{C}}—O^- \leftrightarrow R—\overset{O^-}{\overset{|}{C}}=O$: In carboxylate ion, the negative charge is present on oxygen, a more electronegative element here, thus it is resonance stabilised.

$HC\equiv C^-$: Carbon is *sp* hybridised so its electronegativity is increased and is higher relative to the nitrogen.

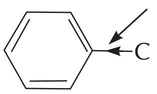
$\overset{-}{N}H_2$: Nitrogen is more electronegative than sp^3 hybridised C-atom. From the above discussion, it is clear that the order of the stability of conjugated bases is as

$RCOO^- > HC\equiv C^- > \overset{-}{N}H_2 > R^-$

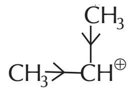
and higher is the stability of conjugated bases, lower will be basic character. Hence, the order of basic character is as

$RCOO^- < HC\equiv C^- < \overset{-}{N}H_2 < R^-$

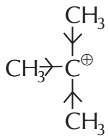
52. 
it involves $p\pi$-$d\pi$ back bonding



– *M* effect and
– *I* effect of Ph group

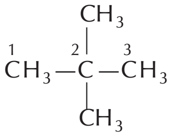


+I effect is exerted by two —CH_3 groups



+I effect is exerted by three —CH_3 groups

53. The structure *neo*-pentane is



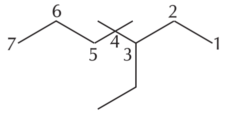
$$\overset{1}{C}H_3-\overset{\overset{CH_3}{|}}{\underset{\underset{CH_3}{|}}{\overset{2}{C}}}-\overset{3}{C}H_3$$

IUPAC name : 2,2-dimethyl propane

54. The correct decreasing order of priority for the functional groups of organic compounds in the IUPAC system is

$$—COOH > —SO_3H > —COOR > COCl > —CONH_2 > —CN > —CHO$$

55.

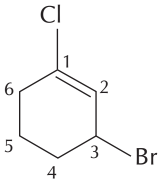


3-ethyl-4, 4-dimethylheptane

56. S_N2 reactions are greatly controlled by steric factor. $\underset{1°}{R—CH_2—X}, \underset{2°}{R_2CH—X}, \underset{3°}{R_3C—X}$,

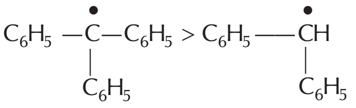
S_N2 reactivity decreases as bulkyness of alkyl group increases.

57.



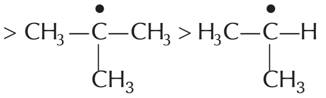
Unsaturation (double bond) is given priority over halogen. So, the correct IUPAC name is 3-bromo-1-chlorocyclohexene.

58. Order of stability of given free radicals is



$$C_6H_5-\underset{\underset{C_6H_5}{|}}{\dot{C}}-C_6H_5 > C_6H_5-\underset{\underset{C_6H_5}{|}}{\dot{C}H}$$

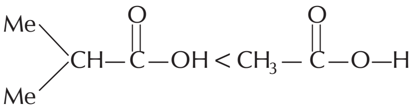
Highly stable by delocalisation



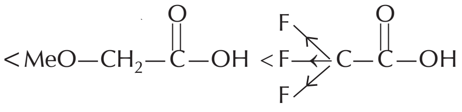
$$> CH_3-\underset{\underset{CH_3}{|}}{\dot{C}}-CH_3 > H_3C-\underset{\underset{CH_3}{|}}{\dot{C}}-H$$

9-hyperconjugative hydrogens and + I effect

59.



$$\begin{matrix}Me\\Me\end{matrix}>CH-\overset{\overset{O}{\|}}{C}-OH < CH_3-\overset{\overset{O}{\|}}{C}-O-H$$



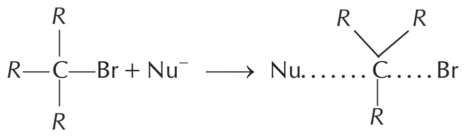
$$< MeO-CH_2-\overset{\overset{O}{\|}}{C}-OH < F_3C-\overset{\overset{O}{\|}}{C}-OH$$

–I effect increases acidity.
+ I effect decreases acidity.
–CF_3 exerting more –I effect than MeO—
Me_2CH— exerting more +I effect than —CH_3.

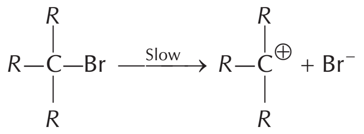
60. Free radicals have unpaired electrons, so are neutral and reactive.

$$\dot{C}H_3 + \dot{C}H_3 \longrightarrow CH_3-CH_3,$$

61. In S_N2 reaction, nucleophile and alkyl halide react in one step.



Thus, tertiary carbon is under steric hindrance, hence reaction does not take place until (C—Br) bond breaks.



which is an S_N1 reaction.

62. Out of the given acids, strongest is HCOOH. (highest K_a value)

Since, $pK_a = -\log K_a$

Thus, lowest pK_a is of HCOOH.

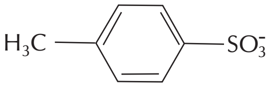
63. If acid is weak, its conjugate base (nucleophile) is strong and *vice-versa*.

(A) $CH_3-\overset{\overset{O}{\|}}{C}-O^-$ is a conjugate base of $CH_3-\overset{\overset{O}{\|}}{C}OH$ (I)

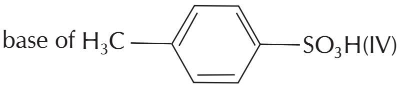
(B) CH_3O^- is conjugate base of CH_3OH (II)

(C) CN^- is a conjugate base of HCN (III)

(D)



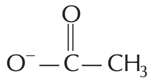
$H_3C-C_6H_4-SO_3^-$ is a conjugate base of



$H_3C-C_6H_4-SO_3H$ (IV)

Thus, order of acidic nature is D > A > C > B and of nucleophilicity is B > C > A > D.

64. Cl^- is the best leaving group as it is the weakest nucleophile out of NH_2^-, Cl^-, $O^-—C_2H_5$ and

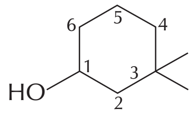


$O^- - \overset{\overset{O}{\|}}{C} - CH_3$

Note If acid HX is weak, its conjugate base X^- is strong and *vice-versa*.

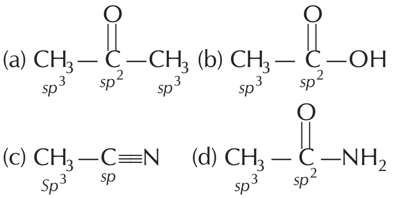
$$NH_3 < C_2H_5OH < CH_3COOH < HCl$$
$$\xrightarrow{\text{Acidic strength increases}}$$
$$NH_2^- > C_2H_5O^- > CH_3COO^- > Cl^-$$
$$\xleftarrow[\text{Basic strength of conjugate base increases}]{}$$

65.



Carbon with —OH group is given C_1, thus it is 3,3-dimethyl-1-cyclohexanol.

66.

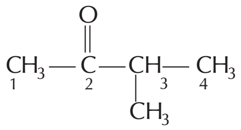


(a) $\underset{sp^3}{CH_3}-\underset{sp^2}{\overset{O}{\overset{||}{C}}}-\underset{sp^3}{CH_3}$ (b) $\underset{sp^3}{CH_3}-\underset{sp^2}{\overset{O}{\overset{||}{C}}}-OH$

(c) $\underset{Sp^3}{CH_3}-\underset{sp}{C}\equiv N$ (d) $\underset{sp^3}{CH_3}-\underset{sp^2}{\overset{O}{\overset{||}{C}}}-NH_2$

Acetonitrile does not contain sp^2-hybridised carbon.

67.

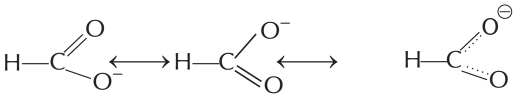


$\underset{1}{CH_3}-\underset{2}{\overset{O}{\overset{||}{C}}}-\underset{\underset{CH_3}{|}}{\overset{}{CH}}_{3}-\underset{4}{CH_3}$

3-methyl butan-2-one
or 3-methyl-2-butanone

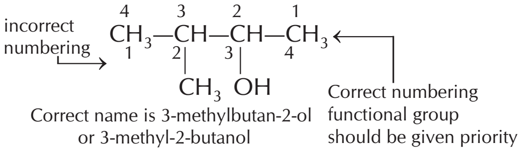
keto ($-\overset{O}{\overset{||}{C}}-$) functional group is given priority.

68.



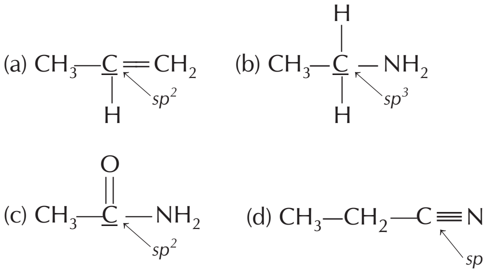
Resonating (canonical) structures of formate ion

69.



Correct name is 3-methylbutan-2-ol or 3-methyl-2-butanol

70.



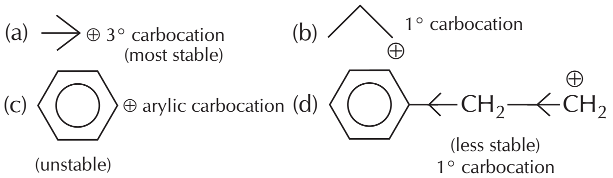
(a) $CH_3-\underset{\underset{H}{|}}{\underline{C}}=CH_2$ sp^2 (b) $CH_3-\overset{\overset{H}{|}}{\underset{\underset{H}{|}}{\underline{C}}}-NH_2$ sp^3

(c) $CH_3-\overset{\overset{O}{||}}{\underline{C}}-NH_2$ sp^2 (d) $CH_3-CH_2-C\equiv N$ sp

71. When R is attached to vinylic (≈ arylic) system, positive inductive effect occurs in the following order

$-O^{-} > -COO^{-} > (CH_3)_3C- > (CH_3)_2CH- > CH_3CH_2- > CH_3-$

72. S_N1 (unimolecular nucleophilic substitution) reaction is favoured with stability of carbocation.



14 Isomerism in Organic Compounds

JEE Main MILESTONE

- Isomerism
- Chain or Nuclear Isomerism
- Position Isomerism
- Functional Isomerism
- Metamerism
- Ring Chain Isomerism
- Geometrical Isomerism
- Optical Isomerism
- Conformations or Conformers

14.1 Isomerism

Compounds having the same molecular formula but differ in structural formula, properties and spatial arrangement are called **isomers** and the phenomenon is called **isomerism.**

Types of Isomerism

Isomerism can be of the following two types

(i) Structural isomerism (ii) Stereo isomerism

The isomers differ in properties due to different modes of combinations or arrangement of atoms within a molecule.

The relevance of isomerism may be described by assuming that atoms are arranged in a specific manner in a molecule and there is a different arrangement of each isomer.

Structural Isomerism

When the isomerism is due to difference in the sequence (connectivity) of atoms within the molecules (without any reference to space), the phenomenon is called **structural isomerism.** In other words, the structural isomers are the compounds which have same molecular formula but different structural formulae, hence different properties. The structural isomerism is also called **constitutional isomerism** and categorised to

(i) Chain isomerism
(ii) Position isomerism
(iii) Functional isomerism
(iv) Metamerism
(v) Tautomerism
(vi) Ring-chain isomerism
(vii) Isotopic isomerism.

Tautomerism and ring-chain isomerism are considered as the specialised sub-types of functional isomerism.

Stereo Isomerism

When the isomerism is caused by different arrangement of atoms or groups in space, *i.e.,* 3D-arrangement, the phenomenon is called **stereo isomerism.** In other words, the stereo isomerism is shown by those compounds which have the same structural formula (alongwith same molecular formula) but differ in configuration (the term configuration refers to three dimensional arrangement of atoms that characterise a particular compound). That's why this isomerism is also called **configurational isomerism** and can be categorised to

(i) Geometrical or *cis-trans* isomerism,

(ii) Optical isomerism

Caution Point *Neither resonance forms nor conformations constitute isomers.*

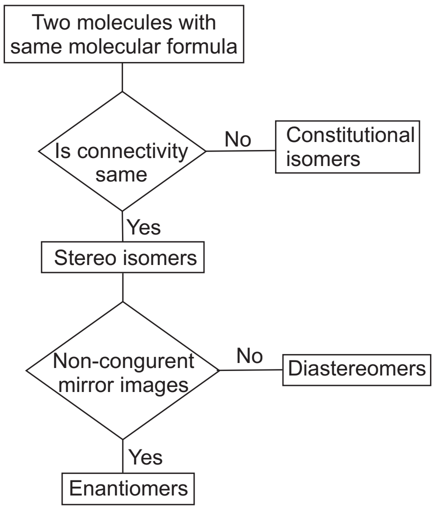


Fig 14.1 Simple flow chart representing the classification of isomers

14.2 Chain or Nuclear Isomerism

The **chain isomers** have the same molecular formula but differ in order in which the carbon atoms are bonded to each other, *e.g.*, *n*-pentane (normal chain), 2-methyl butane (*iso*-chain) and 2,2-dimethyl propane (*neo*-chain). This isomerism is also called **nuclear** or **skeletal isomerism** as different isomers differ in carbon skeleton.

Important Points Related to Chain Isomerism

1. This isomerism is seen mainly in hydrocarbons. In aliphatic hydrocarbons except alkynes a member with minimum 4 C-atoms can show this isomerism.
2. It is also possible in members of a homologous series.
3. Chain isomers may show similar or different chemical properties but definitely differ in physical properties.

Sample **Problem 1** *Which of the following are chain isomers?*

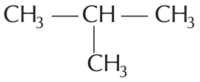
(*a*) CH_3CHCl_2 *and* CH_2ClCH_2Cl

(*b*) $CH_3(CH_2)_2CH_3$ *and* $(CH_3)_2CHCH_3$

(*c*) $CH_3(CH_2)_2OH$ *and* CH_3CH_2OH

(*d*) $CH_3CH_2CH_3$ *and* $CH_3(CH_2)_2CH_3$

Interpret (*b*) $CH_3CH_2CH_2CH_3$ and



$$CH_3-\underset{\displaystyle CH_3}{\underset{|}{CH}}-CH_3$$

both have same number of carbon atoms, *i.e.*, 4 but their parent chain is different, *i.e.*, former chain has 4 carbon atoms while later has only 3 carbon atoms. Thus, these are the examples of chain isomerism.

Sample **Problem 2** *How many chain isomers are possible for the compound* $C_5H_{11}OH$?

(*a*) 7	(*b*) 5
(*c*) 9	(*d*) 4

Interpret (*d*) The possible chain isomers for the compound are as

(i) $CH_3(CH_2)_3CH_2OH$

(ii) $CH_3CH_2CH(CH_3)CH_2OH$

(iii) $CH_3CH(CH_3)CH_2CH_2OH$

(iv) $CH_3C(CH_3)_2CH_2OH$

Thus, four chain isomers are possible for this compound.

14.3 Position Isomerism

In position isomerism, the difference lies in the position of substituent group or atom in the same chain, *e.g.*,

1. $\underset{\text{but-1-ene}}{CH_3-CH_2-CH=CH_2}$ $\underset{\text{but-2-ene}}{CH_3-CH=CH-CH_3}$

   Carbon chain length is same but position of double bond is different.

2. 
   1,2-dimethyl benzene   1,3-dimethyl benzene   1,4-dimethyl benzene

   Position of one $-CH_3$ group is differing with respect to other in the benzene ring.

Important Points Related to Position Isomerism

1. The cyanides, aldehydes, carboxylic acids and their derivatives do not exhibit position isomerism when present singly.
2. Chain and position isomerism cannot exist together *i.e.*, if two compounds are chain isomers then these will not be considered as position isomers and *vice-versa*.

3. Due to difference in the position of groups or atoms, these isomers show difference in physical as well as chemical properties.
4. Monosubstituted alicyclic compounds and aromatic compounds do not exhibit positional isomerism.

Sample **Problem 3** *Which of the following compounds, do not exhibit position isomerism?*

(a) *o-xylene* (b) *Butadiene*
(c) *Butanal* (d) *Propene*

Interpret (c) Butanal, $CH_3CH_2CH_2CHO$ do not exhibit position isomerism, as —CHO is the principal functional group and if present singly, as in this case, numbering is always started from it.

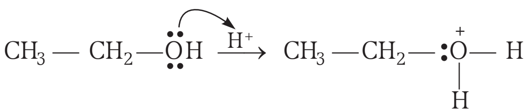
14.4 Functional Isomerism

When different functional groups are attached to the same carbon chain *i.e.,* those compounds which have same molecular formula but different structures due to difference in functional groups attached, are called **functional isomers,** *e.g.*,

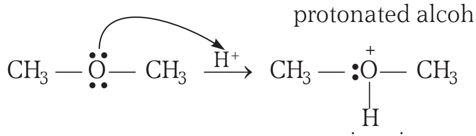
1. C_2H_6O have two functional isomers *i.e.,*
   C_2H_5OH (ethyl alcohol) and CH_3OCH_3 (dimethyl ether) Similarly
2. Similarly, $C_2H_4O_2$ have
   CH_3COOH (acetic acid) and $HCOOCH_3$ (methyl formate)

Important Facts Related to Functional Isomerism

1. If two molecules contain different functional groups, never write chain or positional isomerism, there will always be functional isomerism.
2. Functional isomers show similar approach towards a reagent as distribution of electron cloud (due to the presence of similar atoms) remains more or less same in the molecule. *e.g.*,
   CH_3CH_2OH and CH_3OCH_3 have similar approach towards H^+ as both have oxygen with high electron density around itself as central atom. *i.e.*,



protonated alcohol



oxonium ion

Similarly, just like aldehydes and ketones, oxiranes also show nucleophilic additions reactions.

3. Generally compounds having the same general formula exhibit functional isomerism *e.g.,*

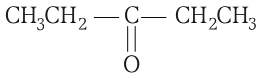
Table 14.1 **General Formula for Different Functional Groups**

S.No.	General formula	Functional isomers
1.	C_nH_{2n}	Alkene and cycloalkane
2.	C_nH_{2n-2}	Alkyne, cycloalkene and alkadiene
3.	$C_nH_{2n+2}O$	Alcohol and ether
4.	$C_nH_{2n}O$	Aldehydes, ketones and epoxides
5.	$C_nH_{2n}O_2$	Acids, ester, hydroxy aldehyde and hydroxy ketone.

14.5 Metamerism

In **metamerism** (*meta* = middle), the difference lies in nature of alkyl groups attached to the same polyvalent functional group. These isomers are called **metamers.** *e.g.,*

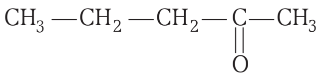
1. $>C=O$ group (carbonyl group)



$CH_3CH_2-\underset{\underset{O}{\|}}{C}-CH_2CH_3$

pentan-3-one

and



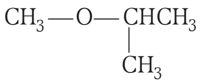
$CH_3-CH_2-CH_2-\underset{\underset{O}{\|}}{C}-CH_3$

pentan-2-one

2. —O— (ether group)

$CH_3CH_2-O-CH_2CH_3$ (diethyl ether) with $CH_3CH_2CH_2-O-CH_3$ (methyl propyl ether)

and

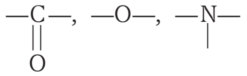


$CH_3-O-\underset{\underset{CH_3}{|}}{C}HCH_3$

methyl *iso*-propyl ether

Important Points Related to Metamerism

1. Polyvalent functional groups are those functional groups which have more than one free valency. *e.g.*,

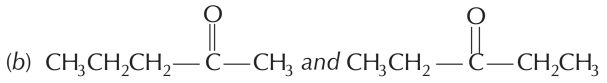


$-\underset{\underset{O}{\|}}{C}-,\ -O-,\ -\underset{|}{N}-$

2. Metamers include same class of compounds.
3. If two molecules contain same functional group (polyvalent) never write chain or position isomerism, it will always be metamerism.
4. Metamerism is never shown by alkenes or alkynes.

Sample Problem 4 *Which of the following pairs are metamers?*

(*a*) $CH_3-CH_2-CH_2-S-CH_3$ *and* $CH_3CH_2-S-CH_2CH_3$



(*b*) $CH_3CH_2CH_2-\overset{O}{\overset{\|}{C}}-CH_3$ *and* $CH_3CH_2-\overset{O}{\overset{\|}{C}}-CH_2CH_3$

(*c*) $CH_3CH_2CH_2-O-CH(CH_3)_2$ *and* $CH_3CH_2CH_2-O-CH_2CH_2CH_3$

(*d*) *All of the above*

Interpret (*d*) In each pair of compounds same functional group is present and different alkyl groups are attached to the same functional group. Thus, each pair includes metamers.

Hot Spot 1

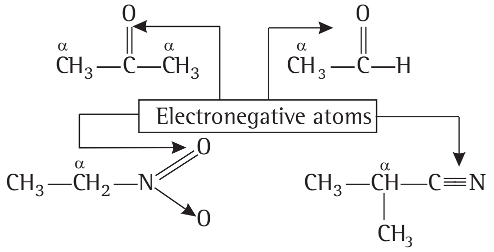
TAUTOMERISM

It is an important topic for JEE Main examination. The level of question is easy to moderate. The questions based on this topic are generally reasoning type like "Which compound exhibit tautomerism or which does not"

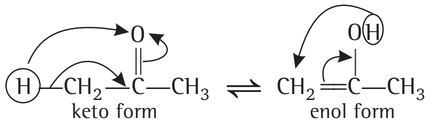
Tautomerism is a special type of functional isomerism. "When the molecules have same molecular formulae but different structural formulae due to wandering nature of hydrogen atom in between two polyvalent atoms, the isomers are called **tautomers** and their property as **tautomerism.**" The tautomerism is also called **kryptomerism** or **allelotropism** or **desmotropism** or **dynamic isomerism.**

The structural requirements for tautomerism include

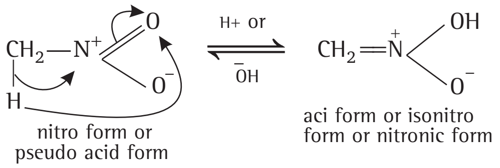
1. The compound must have at least one highly electronegative atom (*e.g.*, F, O and N) bonded with a multiple bond.
2. Compound must have at least one acidic hydrogen present on α-carbon atom of the molecule. *e.g.*,



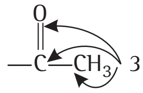
The basic cause of tautomerism is the migration of acidic hydrogen from carbon to multiple bonded electronegative atom, *e.g.*, in acetone tautomerism will be seen as



Similarly, nitroalkanes containing α-hydrogen show tautomerism as



The above examples of tautomerism comes under **TRIAD system** as these involve three molecules in tautomeric system, *i.e.*,

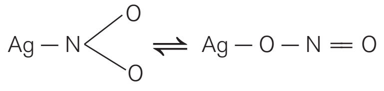


Other examples of such triad system are

(i) 
(ii) 
(iii) 
The other system of tautomers in tautomerism is **DYAD system** which involves only two atoms alongwith acidic hydrogen, *i.e.*,

$$\underset{\text{hydrocyanic acid}}{H-C\equiv N} \rightleftharpoons \underset{\text{isohydrocyanic acid}}{H-N\overset{\rightarrow}{=}C}$$

Caution Point *Silver nitrate or silver nitrite is the only compound in which tautomerism is shown by the migration of silver instead of hydrogen.*



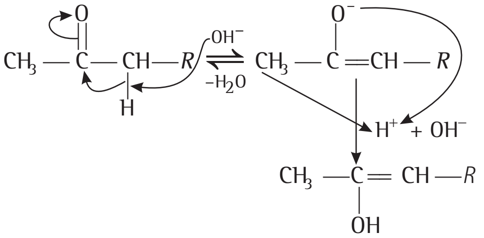
1,2-tautomerism

Important Facts Related to Tautomerism

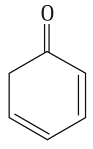
1. Tautomers always exist in **dynamic equillibrium.**
2. Number of sigma bonds, pi bonds and lone pair of electrons are always same in both the tautomers.
3. It is a chemical phenomenon which takes place only in liquids and gaseous phase. It never takes place in solid state.
4. The process can be catalysed by the acid as well as bases.

   (a) **Acid catalysed conversion**

   (b) **Base catalysed conversion**



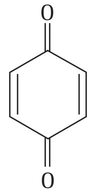
5. In most of the cases, the content of keto form is always greater than the enol form *i.e.,* keto form is more stable than the enol form. Percentage of enolic contents of some common compounds in decreasing order will be



$> C_6H_5COCH_2COCH_3 > CH_3COCH_2COCH_3$

$> CH_3COCH_2COOC_2H_5 > CH_3COCH_2CHO > CH_3COCH_3$

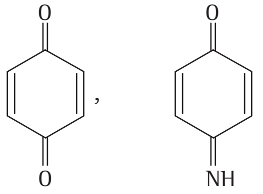
$> CH_3CHO >$



6. **Enol content** is also affected by solvents. It **increases in non-polar aprotic solvent and decreases in polar protic or polar aprotic solvent.** Enol content order in different solvents is Hexane > benzene > acetone > methanol > H_2O

   [Enol content being more volatile is separated by careful distillation of the mixture in a fused quartz apparatus.]

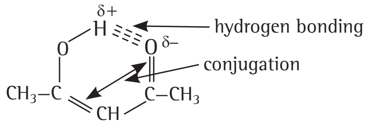
7. Compound having quinonoid structure does not show tautomerism because of the absence of free α –H atoms. For example,



8. The conversion of keto form into enol form is called **enolisation** and depends upon various factors such as structure (especially from resonance and hydrogen bonding point of view), temperature and the nature of solvent. Among these the most important aspect is the structural aspect, *e.g.*,

   (i) Ketonic form predominates in simple monocarbonyl compounds like CH_3CHO, CH_3COCH_3 etc., (due to greater bond strength of $>C{=}O$ bond in comparison to $>C{=}C<$ bond).

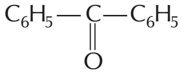
   (ii) Similarly enolic forms predominate in β-diketones due to intramolecular hydrogen bonding and resonance *i.e.,* the $CH_3COCH_2COCH_3$ will have



9. Enol content is reduced due to steric factor *e.g.,* the enol content of α-methyl acetyl acetones (44% in gaseous state) is much lower as compared to that of acetyl acetone (92% in gaseous state) due to greater internal strain in the former case.

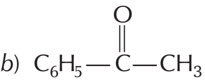
Sample Problem 5 *Keto-enol tautomerism is observed in*

(*a*)



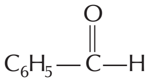
$C_6H_5-\underset{\underset{O}{\|}}{C}-C_6H_5$

(*b*)



$C_6H_5-\overset{\overset{O}{\|}}{C}-CH_3$

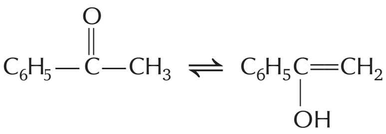
(c)



$C_6H_5-\overset{\overset{O}{\|}}{C}-H$

(*d*) *None of these*

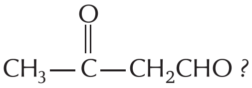
Interpret (*b*) In order to solve such problem, first find the compound which contains free α –H atoms (H atoms bonded by single bonded C atom). Among the given only $C_6H_5CO\overset{\overset{\alpha\text{-c}}{\downarrow}}{C}H_3$ contains three α –H atoms, so it will show keto-enol tautomerism.



$$C_6H_5-\overset{\overset{O}{\|}}{C}-CH_3 \rightleftharpoons C_6H_5\underset{\underset{OH}{|}}{C}{=}CH_2$$

In rest of the given compounds, migration of H-atom is not possible, due to the absence of free α-H atom.

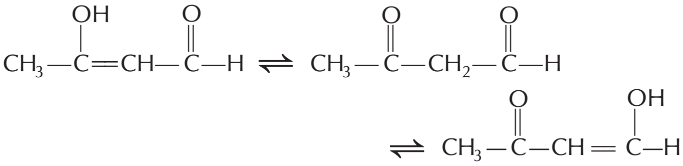
Sample Problem 6 *How many tautomeric structures are possible for the compound*



$CH_3-\overset{\overset{O}{\|}}{C}-CH_2CHO$?

(*a*) 3 (*b*) 4 (*c*) 5 (*d*) 7

Interpret (*a*) To find the number of tautomeric structures, first find the carbonyl groups attached directly to the carbons that bears α-H atoms. Now draw the tautomeric forms *e.g.*, Three tautomeric structures are possible for the given compound as



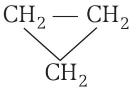
$$CH_3-\overset{\overset{OH}{|}}{C}=CH-\overset{\overset{O}{\|}}{C}-H \rightleftharpoons CH_3-\overset{\overset{O}{\|}}{C}-CH_2-\overset{\overset{O}{\|}}{C}-H \rightleftharpoons CH_3-\overset{\overset{O}{\|}}{C}-CH=\overset{\overset{OH}{|}}{C}-H$$

14.6 Ring Chain Isomerism

If one isomer has open chain structure and the other has cyclic structure then isomers are known as **ring chain isomers** and isomerism is called **ring chain isomerism,** *e.g.,*

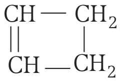
(i) Alkene and cycloalkane

C_3H_6, *i.e.*, $CH_3-CH=CH_2$ and



(ii) Cycloalkene and alkyne

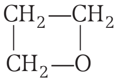
C_4H_6, *i.e.*,



and $CH_3-CH_2-C\equiv CH$

(iii) Alkenol and cyclic ether

C_3H_6O, *i.e.*, $CH_2=CH-CH_2OH$ and



Ring chain isomers are always functional isomers.

Caution Point *Alkanes and their derivatives can't show ring chain isomerism because they do not have an element of unsaturation.*

The isomerism arised due to the presence of different isotopes of an element in the compound is called **isotopic isomerism.** *e.g.,*

$$H_2O \text{ and } D_2O;\ {}^{12}CH_4 \text{ and } {}^{14}CH_4$$

Check Point 1

1. Why do aldehydes or carboxylic acids not exhibit position isomerism, when present singly?
2. Why do functional isomers show a similar approach towards the same reagent?
3. For exhibiting metamerism, presence of which type of functional groups is necessary and why?
4. In acetaldehyde, CH_3CHO keto form predominates while in $CH_3COCH_2COCH_3$ enol form predominates. Explain why?
5. Why alkanes do not exhibit ring chain isomerism?

14.7 Geometrical Isomerism

When a π-bond is present between two atoms, it restricts the free rotation of atoms around its axis. This gives rise to two different structural formulae (properties of these forms differ due to different arrangement of atoms about double bonds in alkenes or about single bonds in cyclic compounds). This isomerism which arises due to difference in spatial arrangement of groups about the

1. doubly bonded C-atoms in **alkenes,**
2. single bonded C-atoms in **cyclic compounds,**
3. doubly bonded C and N-atoms in **oximes,**
4. doubly bonded N-atoms in **diazo compounds,** is called **geometrical isomerism.**

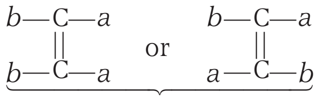
Conditions for Exhibiting Geometrical Isomerism

The conditions for exhibiting geometrical isomerism include

1. There should be frozen rotation about two atoms in the molecules *e.g.*,.
   (i) $>C=C<$, frozen rotation about C—C double bond in alkenes.
   (ii) , frozen rotation about carbon-carbon single bond in cycloalkanes.
   (iii) $>C=N$, frozen rotation about carbon-nitrogen double bond in oximes and imines.
   (iv) $-N=N-$, frozen rotation about nitrogen-nitrogen double bond in azo compounds.
2. Both the atoms of above written bonds should contain different substituents.

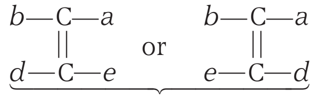
Geometrical Isomerism in Alkenes

The forms in which similar groups are present on the same side of double bond are called ***cis* forms** [Latin *cis* = same side] and the forms, in which similar groups are present on the different sides are called ***trans* forms** [Latin *trans* = across]. *e.g.,*



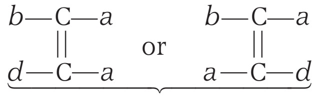
$$\underbrace{\begin{array}{c} b-\text{C}-a \\ \| \\ b-\text{C}-a \end{array} \quad \text{or} \quad \begin{array}{c} b-\text{C}-a \\ \| \\ a-\text{C}-b \end{array}}$$

(I)
non-identical



$$\underbrace{\begin{array}{c} b-\text{C}-a \\ \| \\ d-\text{C}-e \end{array} \quad \text{or} \quad \begin{array}{c} b-\text{C}-a \\ \| \\ e-\text{C}-d \end{array}}$$

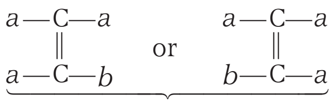
(II)
non-identical



$$\underbrace{\begin{array}{c} b-\text{C}-a \\ \| \\ d-\text{C}-a \end{array} \quad \text{or} \quad \begin{array}{c} b-\text{C}-a \\ \| \\ a-\text{C}-d \end{array}}$$

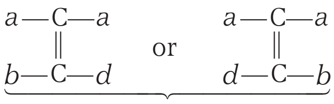
(III)
non-identical

These forms show usually similar chemical but different physical properties. However some forms may show difference in chemical properties as well. *Geometrical isomerism is not seen in those forms in which the double bonded carbon atom have same groups attached to it. e.g.,*



$$\underbrace{\begin{array}{c} a-\text{C}-a \\ \| \\ a-\text{C}-b \end{array} \quad \text{or} \quad \begin{array}{c} a-\text{C}-a \\ \| \\ b-\text{C}-a \end{array}}$$

(IV)
both the structures are identical



$$\underbrace{\begin{array}{c} a-\text{C}-a \\ \| \\ b-\text{C}-d \end{array} \quad \text{or} \quad \begin{array}{c} a-\text{C}-a \\ \| \\ d-\text{C}-b \end{array}}$$

(V)
both the structures are identical

Geometrical figures in (IV) and (V) will be identical, hence, no geometrical isomers are possible.

The conversion of *cis* isomer into *trans* isomer or *vice-versa* is possible only if either of the isomer is heated to a high temperature or absorbs light. The heat supplies the energy to break the π-bond. Some examples of geometrical isomers are as

1. Two geometrical isomers are possible for **hex-3-ene** ($CH_3CH_2CH{=}CHCH_2CH_3$). This is because each double bonded carbon atom is attached to two different groups, *i.e.,*—CH_2CH_3 and H. The *cis* and *trans* isomers of hex-3-ene are shown below

$$\begin{array}{c} C_2H_5-\text{C}-\text{H} \\ \| \\ C_2H_5-\text{C}-\text{H} \end{array} \quad \begin{array}{c} C_2H_5-\text{C}-\text{H} \\ \| \\ \text{H}-\text{C}-C_2H_5 \end{array}$$

cis hex-3-ene *trans* hex-3-ene

2. Both **fumaric** and **maleic acids** have the same molecular formula, $C_4H_4O_4$. They differ in most of their physical properties and in some of their chemical properties. Originally they were thought as structural isomers and assigned different names. Later on van't Hoff suggested them as geometrical isomers. Maleic acid, which gives anhydride at lower temperatures, is considered as *cis* acid, while fumaric acid is the *trans* variety.

$$\begin{array}{c} \text{H}-\text{C}-\text{COOH} \\ \| \\ \text{H}-\text{C}-\text{COOH} \end{array} \quad \begin{array}{c} \text{COOH}-\text{C}-\text{H} \\ \| \\ \text{H}-\text{C}-\text{COOH} \end{array}$$

maleic acid [*cis*] fumaric acid [*trans*]

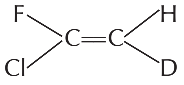
These isomers

(i) differ in physical properties such as melting point, dipole moment and acidities. The *trans* isomer has no dipole moment since it is symmetrical, unlike the *cis* isomer. The *cis* isomer is stronger acid than the *trans* isomer.

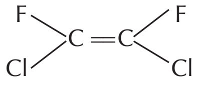
(ii) differ even in chemical properties *e.g., cis* acid undergo dehydration at 100°C and form an anhydride. However the *trans* acid does not form an anhydride until heated to 240°C. At that temperature there is sufficient thermal energy to break the double bond, so that the *cis* acid changes to *trans* and then anhydride are formed in sucession. They can be separated by conventional techniques like fractional distillations, gas chromatography etc.

Sample Problem 7 *Which of the following will not show geometrical isomerism ?* **[NCERT Exemplar]**

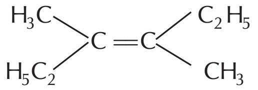
(*a*)



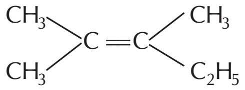
(*b*)



(*c*)



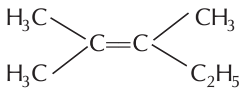
(*d*)



Interpret (*d*) To find whether a compound exhibit geometrical isomerism or not, first see is it a double bonded compound or cyclic compound. Now check the two groups attached to double bonded carbon are different or same. If a double bond or cycle is present and different groups are present at the C forming such centre, the compound exhibits geometrical isomerism.

Among the given, all have double bonds but the group present on double bonded carbon in case of (d) are same. That's why it does not exhibit geometrical isomerism.

Same group



Caution Points

(*i*) *Geometrical isomers may be considered as diastereomers as they have different physical properties.*

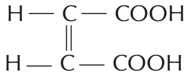
(*ii*) *Stereoisomers that are not the mirror images of each other are also called diastereomers.*

Sample **Problem 8** *Which of the following will show geometrical isomerism?*

(*a*) C_2H_5Br (*b*) $CH_2(COOH)_2$

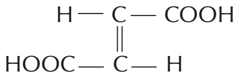
(*c*) $(CHCOOH)_2$ (*d*) C_2H_6

Interpret (*c*) Presence of at least one double bond and different groups at double bonded carbon atoms are two essential conditions for exhibiting geometrical isomerism. $(CHCOOH)_2$ fulfils both the conditions thus, exists in *cis* and *trans* forms as



$\begin{array}{c}H-C-COOH\\ \|\\ H-C-COOH\end{array}$

cis-form
(maleic acid)

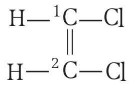


$\begin{array}{c}H-C-COOH\\ \|\\ HOOC-C-H\end{array}$

trans–form
(fumaric acid)

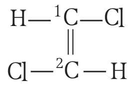
Distinction Between *cis* and *trans* Isomers

1. The *trans* forms are more stable than the corresponding *cis* isomer. This is because, in the *cis* isomer, the bulky groups are on the same side of double bond. The steric repulsion of the groups makes the *cis* isomer less stable than the *trans* isomer in which the bulky groups are far apart (they are on the opposite sides of the double bond).
2. Melting point of *trans* form is higher than the melting point of *cis* form because of symmetrical packing of *trans*-compounds in its crystal lattice.
3. Boiling point of *cis* form is higher than that of the *trans* form because of steric hindrance in *cis*- compound and high polarity of *cis*- compound.
4. Solubility of *cis*-isomer is higher as compared to *trans*-isomer, as molecules of *trans*- isomer are more tightly held in the crystal lattice than the corresponding *cis*-isomer and hence, it is easier to break the crystal lattice of *cis*- isomer as compared to *trans*- isomer.
5. Generally, a *cis*-isomer (*e.g.*, maleic acid) cyclises on heating to form the corresponding anhydride, while a *trans*-isomer does not form its anhydride at all.
6. The *cis*-isomer of a symmetrical alkene (alkene in which both the carbon atoms have similar groups) has a definite dipole moment, while the *trans*- isomer has zero dipole moment. *e.g.*,



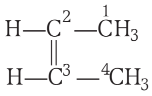
$\begin{array}{c}H-{}^1C-Cl\\ \|\\ H-{}^2C-Cl\end{array}$

cis–dichloroethene
(μ = 1.9D)



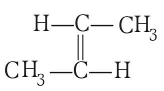
$\begin{array}{c}H-{}^1C-Cl\\ \|\\ Cl-{}^2C-H\end{array}$

trans–dichloroethene
(μ = 0.0D)



$\begin{array}{c}H-C^2-\overset{1}{C}H_3\\ \|\\ H-C^3-{}^4CH_3\end{array}$

cis–but–2–ene
$\mu \neq 0$

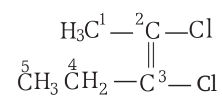


$\begin{array}{c}H-C-CH_3\\ \|\\ CH_3-C-H\end{array}$

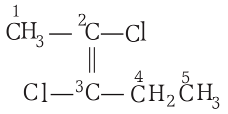
trans-but–2–ene
μ=0.0D

In *trans*-isomers of symmetrical alkenes, the effect produced in one half of the molecule is cancelled by that in the other half of the molecule.

In case of unsymmetrical alkenes, the *cis*- isomer has higher dipole moment than the corresponding *trans*-isomer. *e.g.*,



$\begin{array}{c}H_3C^1-{}^2C-Cl\\ \|\\ \overset{5}{C}H_3\,\overset{4}{C}H_2-C^3-Cl\end{array}$



$\begin{array}{c}\overset{1}{C}H_3-\overset{2}{C}-Cl\\ \|\\ Cl-{}^3C-\overset{4}{C}H_2\overset{5}{C}H_3\end{array}$

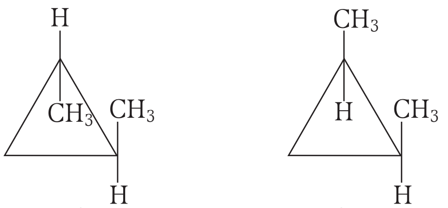
cis–2,3–dichloropent–2–ene
(high dipole moment)

trans–2,3 dichloropent–2 –ene(less dipole moment)

Geometrical Isomerism in Cyclic Compounds

Geometrical isomerism is also possible in cyclic compounds as no free rotation is possible about carbon-carbon single bonds in such compounds. Thus, for rotation, bond breaking is required which results in the ring cleavage. *e.g.*,

1,2-dimethyl cyclopropane exists in the following two isomeric forms

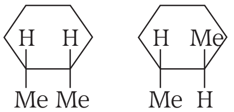


trans form *cis* form

1,2-dimethyl cyclopropane

Other examples of cyclic compounds exhibiting geometrical (*cis-trans*) isomerism are as

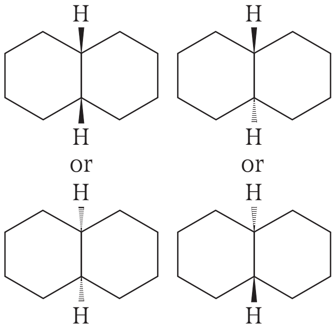
I.



cis *trans*

1,2-dimethyl cyclohexane

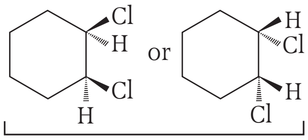
II.



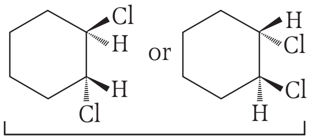
cis *trans*

decalin or bicyclo (4. 4. 0) decane or decahydro naphthalene

III.

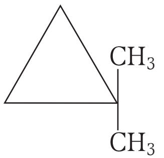


cis-1,2-dichloro cyclohexane



trans-1,2-dichloro cyclohexane

A requirement for geometrical isomerism in cyclic compounds is that there must be at least two other groups besides hydrogen on the ring and these must be on different C-atoms of the ring. For example no geometrical isomers are possible for 1, 1-dimethylcyclopropane.



1,1-dimethyl cyclopropane (no isomers possible)

Geometrical Isomerism in Nitrogen Compounds

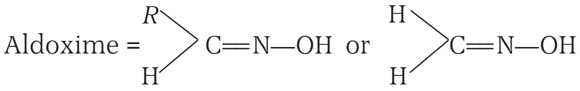
Geometrical isomerism is also seen in oximes, imines and azo compounds (all of them are nitrogen compounds). The oximes are formed by the reaction of carbonyl compounds ($>C{=}O$ compounds *i.e.,* aldehydes and ketones) with NH_2OH (hydroxyl amine) as :

$$>C{=}\boxed{O + H_2}N{-}OH \longrightarrow \underset{\text{oxime}}{>C{=}N{-}OH} + H_2O$$

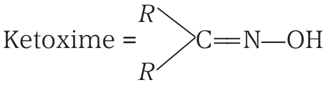
If $>C{=}O$ is aldehyde then oxime is aldoxime.

If $>C{=}O$ is ketone then oxime is ketoxime.

Hence,



$$\text{Aldoxime} = \begin{matrix} R \\ H \end{matrix}\!\!>C{=}N{-}OH \text{ or } \begin{matrix} H \\ H \end{matrix}\!\!>C{=}N{-}OH$$

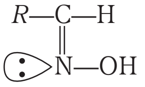


$$\text{Ketoxime} = \begin{matrix} R \\ R \end{matrix}\!\!>C{=}N{-}OH$$

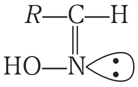
In nitrogen compounds, the steric repulsion occurs between the lone pair of nitrogen with bond pair of larger group (*i.e.,* in oximes and imines) or between the two lone pairs of two nitrogens (*i.e.,* in azo compounds) resulting to *syn* (corresponding to *cis*) and *anti* (corresponding to *trans*) forms, *e.g.*,

(a) **In oximes**

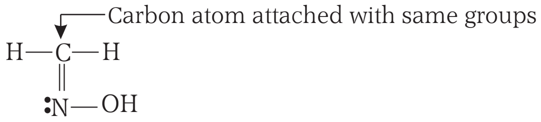
(i) In aldoximes



syn oxime

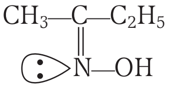


anti oxime



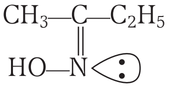
Thus, the first member of aldoximes does not show any geometrical isomer.

(ii) **In ketoximes**



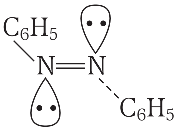
This compound is *syn* for ethyl group and *anti* for methyl group or this can be called *anti* compound.

Similarly,



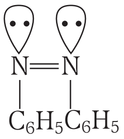
This compound is *anti* for ethyl group and *syn* for methyl group or this can be called *syn* compound.

(b) **In azo compounds**



anti oxime

and

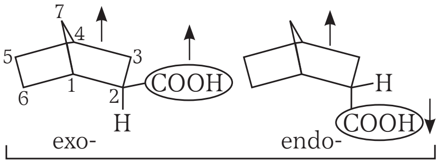


syn oxime

Exo and Endo in Bicyclic Compounds

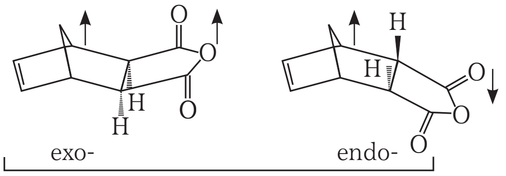
exo and endo terms are used in case of bicyclic compounds. When two rings or a ring and a group are in *cis*-position, it is called exo-stereoisomer, when two rings or a ring and a group are in *trans*-position, it is called endo-stereoisomer; *e.g.,*

I.



bycyclo (2. 2. 1) heptane-2-carboxylic acid

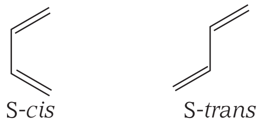
II.



endo-stereoisomer is more stable than exo-stereoisomer

Geometrical Isomerism Across a Single Bond

Cis-and *trans*-isomerism is also possible across a single bond. *e.g.,* in buta-1,3-diene.



S-*cis* form of butadiene undergoes Diels Alder reaction with dienophile while S-*trans* does not.

Calculation of Number of Geometrical Isomers

The number of geometrical isomers of a compound can be calculated with the help of following formulae.

(i) In compounds with n number of π bonds and different ends, number of geometrical isomers = 2^n.

(ii) In compounds with n number of π bonds and same ends.

Case I When n = even number

Then, number of geometrical isomers $= 2^{(n-1)} + 2^{\left(\frac{n}{2}-1\right)}$

Case II When n = odd number

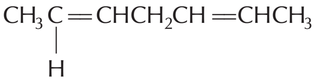
Then, number of geometrical isomers

$$= 2^{(n-1)} + 2^{\left(\frac{n+1}{2}-1\right)}$$

Sample **Problem 9** *The number of geometrical isomers possible for 2, 5- heptadiene is*

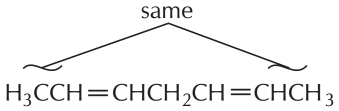
(*a*) 2 (*b*) 3 (*c*) 4 (*d*) 5

Interpret (*b*) To solve such problem, first draw the structure of given compound, if not given,



$\mathrm{CH_3\underset{|\atop H}{C}{=}CHCH_2CH{=}CHCH_3}$

Now find whether the two ends (terminals) are same or different.



$$\overset{\text{same}}{\mathrm{H_3CCH{=}CHCH_2CH{=}CHCH_3}}$$

Now n = no. of double bone = 2 *i.e.,* even.

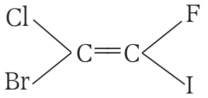
So, no. of geometrical isomers $= 2^{2-1} + 2^{\left(\frac{2}{2}-1\right)}$

$= 2 + 2^0$

$= 2 + 1 = 3$

E, Z-System of Geometrical Isomers

Cis and *trans* system of geometrical isomerism cannot work in compounds which do not have identical groups on the sides of double bond, *e.g.*,

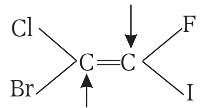


1-bromo-1-chloro-2-fluoro-2-iodoethene

The configuration of these compounds can be specified by using the notations *E* (from German *Entgegen* = opposite) and *Z* (from German *Zusammen* = together). For determining *E* and *Z* configurations, we have to assign priority to the groups attached to the doubly bonded C-atoms. The rules for assigning the priority are as follows

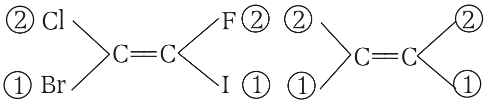
1. The priority can be assigned on the basis of the atomic number of the group attached (in fact the atomic number of that atom of the group is considered which is attached directly to the atom). *The group with higher atomic number will get the first priority*, *e.g.*,

Second C-atom according to IUPAC nomenclature



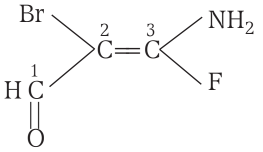
First C-atom according to IUPAC nomenclature

Out of chlorine and bromine attached to first C-atom, the atomic number of Br is higher, thus, Br gets priority over Cl. Similarly out of fluorine and iodine attached, the atomic number of iodine is greater thus iodine will get priority over F. Thus, the compound looks like



Now as it is very clear that the bulky groups are at the same side of double bond, hence the form is ***Z* form** (analogous to *cis* form)

2. Similarly, in the compound



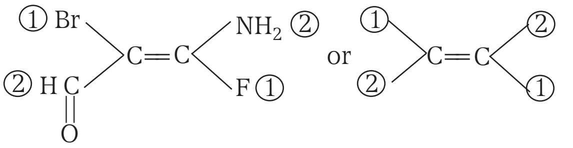
3-amino-2-bromo-3-fluoroprop-2-en-1-al

The priorities are given as

(i) Out of two groups *i.e.,* Br and — CHO attached to the C-atom number 2, the atomic number of Br is greater than the C-atom of — CHO group (as written earlier that if the functional group contains more than one atom then the atomic number of that atom is considered which is attached directly to the doubly bonded C-atom). Hence, in this case Br gets priority over — CHO group.

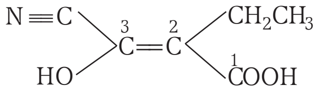
(ii) Out of the two groups attached to the C-atom number 3 *i.e.,* F and —NH_2, the atomic number of F is greater than that of the N of —NH_2 group, thus F gets priority over —NH_2.

Hence, the compound looks like



Now, as it is very clear that the bulky groups are at the opposite side of double bond, hence the form is called ***E* form** (it is analogous to *trans* form).

3. Now, if two or more atoms are attached to doubly bonded C-atoms with the same atomic number, then the priority is given according to the atomic number of next atom as in the compound written below

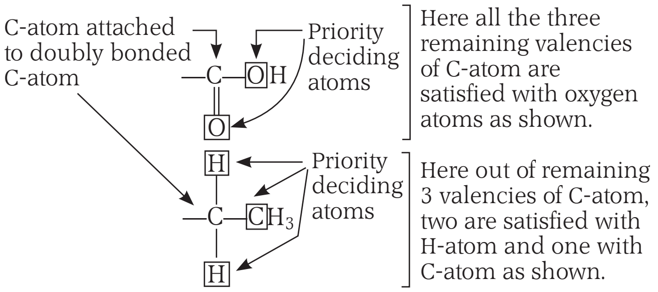


2-ethyl-3-cyano-3-hydroxy prop-2-en-1-oic acid

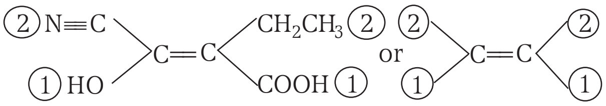
Here,

(i) out of the — OH and — CN groups attached to the 3rd C-atom, the atomic number of oxygen of — OH group is greater than the atomic number of C-atom of — CN group. Hence, — OH gets priority over —C≡N.

(ii) On the other hand, out of the two groups attached to C-atom number 2, each one begins with C-atom. Here, the — COOH group is given priority over —CH_2CH_3 group due to following reason.



Thus, oxygen of first case is preferred over C or H of second case and the compound looks like



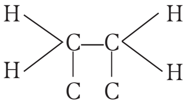
i.e., the compound is in ***Z*-form.**

From the above point (3) *the two things are clear*

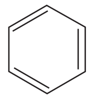
(i) If atoms attached to doubly bonded C-atoms are same, the priority is determined by going next away to such atoms.

(ii) Multiple bonds are treated as each atom of the multiple bond is attached to multiple atoms.

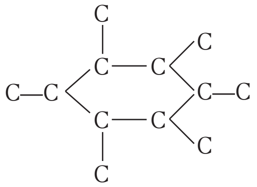
e.g., $H_2C{=}CH_2$ will be treated as



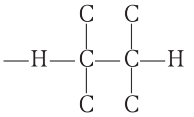
or



will be as

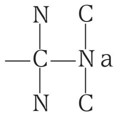


or HC≡CH will be as



$$-H-\underset{\substack{|\\C}}{\overset{\substack{C\\|}}{C}}-\underset{\substack{|\\C}}{\overset{\substack{C\\|}}{C}}-H$$

Similarly, —C≡N as

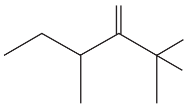


$$-\underset{\substack{|\\N}}{\overset{\substack{N\\|}}{C}}-\underset{\substack{|\\C}}{\overset{\substack{C\\|}}{N}}$$

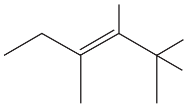
and so on.

Sample Problem 10 *Which of the following alkenes shown below has the Z-configuration of its double bond?*

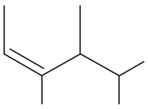
(*a*)



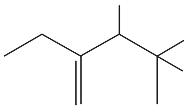
(*b*)



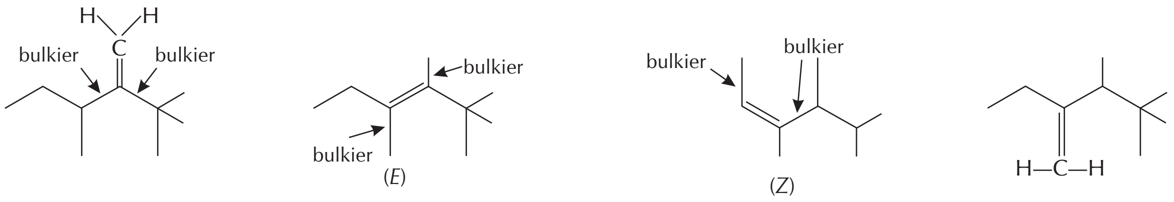
(*c*)



(*d*)



Interpret (c) *Z*-configuration shows the presence of bulkier groups at the same side of double bond.



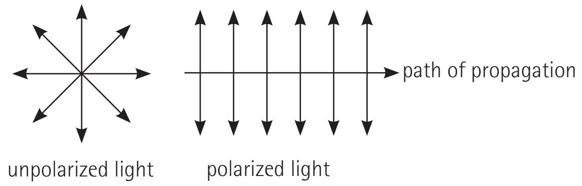
14.8 Optical Isomerism

Compounds with similar physical as well as chemical properties and with difference only in their behaviour towards plane polarized light are called *optical isomers* and this property is called *optical isomerism*.

Important Terms Related to Optical Isomerism

Before going in detail it is better to understand some terms related to this isomerism.

(a) **Plane polarized light** According to wave theory, an ordinary ray of light is considered to have particulate vibrations in all possible planes perpendicular to its path of propagation. However, in polarized light the particulate vibrations occur in one plane only.



(b) **Optical activity** The property of a compound by virtu of which it can rotate the plane of polarized light, is called optical activity.

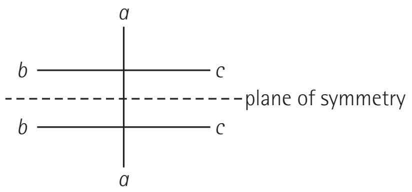
(c) **Asymmetric C-atom** C-atom having 4 different groups or atoms attached separately to its four valencies is called asymmetric carbon atom or stereocentre.

(d) **Chiral molecule** A molecule completely lacking plane of symmetry is called chiral molecule. In other words, it can also be defined as the one which is not superimposable on its mirror reflection or the one in which line of symmetrisation is lacking. An asymmetric C-atom will generally be considered as chiral and we can say that

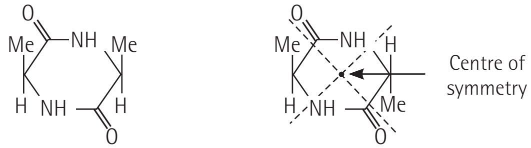
(1) A chiral molecule mostly possess at least 1-chiral carbon atom.

(2) A chiral molecule does not possess any element of symmetry like.

(i) **Plane of symmetry**



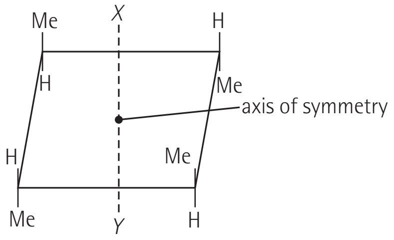
(ii) **Centre of symmetry**



no centre of symmetry (*cis* form)

trans form (has centre of symmetry)

(iii) **Axis of symmetry**



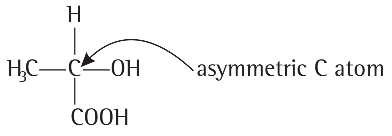
(e) **Achiral molecule** A molecule which is superimposable on its mirror image is called achiral.

Hot Spot 2

OPTICAL Isomers of Different Types

It is an important topic for JEE Main point of view. Most of the times, questions belong to this topic. A small practice of the topic can help you to solve the problem.

Usually the compounds having atleast one asymmetric C-atom (the C atom all the four valencies of which are satisfied by four different groups or atoms) are capable to exhibit optical isomerism.*e.g.*, Lactic acid.



$H_3C—C(H)(COOH)—OH$

optically active

The optical isomers can be categorised into the following two types

(a) Optically Active Compounds

Those compounds which have the ability to rotate the plane of polarised light are called **optically active compounds.** These compounds are infact chiral *i.e.*, have absence of elements of symmetry.

Among the optically active compounds following types are included

1. **Dextrorotatory** or ***d*-or (+) forms** which rotate the plane of polarised light to the right (clockwise).
2. **Laevorotatory** or ***l* or (–) forms** which rotate the plane of polarised light to the left (anticlockwise).

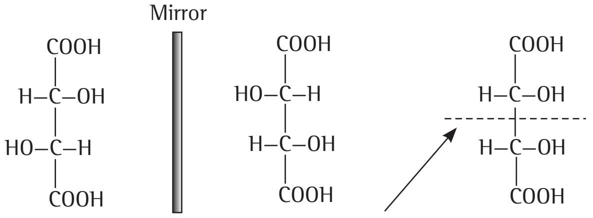
(b) Optically Inactive Compounds

Those compounds which do not have such an ability *i.e.*, which do not rotate the plane of polarised light are called **optically inactive compounds.** The reasons for the inactivity of these compounds are

(i) presence of element of symmetry
(ii) presence of *d* and *l*-forms in equal amounts.

On the basis of above reasons, optically inactive compounds can be of two types

1. ***Meso* form** It has the plane of symmetry within the molecule *i.e.*, **the one half of the molecule is dextrorotatory and rest half is laevorotatory.** Thus, within the molecule both halves show equal and opposite optical activity. As a result, the molecule becomes optically inactive. **This phenomenon of optical inactivation in which the rotation produced by one half of the molecule is cancelled by its another half is called internal compensation** *i.e.*, *meso* **forms are said to be optically inactive due to the phenomenon of internal compensation.** *e.g.*, the optically active and inactive forms of tartaric acid are as follows



optically active forms   line of symmetrization   *meso* tartaric acid

2. **Racemic mixture** The equimolar mixture of two optically active forms (*d* and *l* forms) of a compound is called **racemic mixture.** The mixture is optically inactive as both the forms neutralizes the effect of one another. Such a neutralizing effect is called **external compensation,** thus **racemic mixtures are optically inactive due to the process of external compensation.**

   The formation of racemic mixture is called **racemisation** while separation of these forms from the mixture is called **resolution.** Resolution can be achieved by mechanical method, biological method using enzymes, chemical methods (by making their diastereomers) or by chromatographic separation (by using special adsorbents).

Sample Problem 11 *Which of the following are optically inactive compounds?*

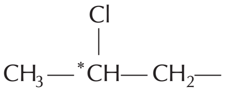
(a) Butan-1-ol (b) 2-chlorobutane
(c) Lactic acid (d) 3-chlorobutane

Interpret (*a*, *d*) In order to solve out such problems, first draw the structures of all the given compounds (in case structure are not given).

Now find the chiral or asymmetric centre and also find the presence or absence of symmetry elements. If structure contains chiral centre and have absence of symmetry elements then it will be optically active, otherwise not as

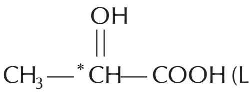
The structural formulae of the given compounds are as under

(i) $CH_3CH_2CH_2CH_2OH$ (Butan-1ol) It is not optically active since it does not contain any asymmetric carbon atom. Hence, the molecule is **achiral**.



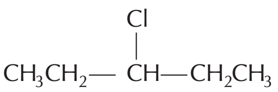
(ii) $CH_3—{}^*CH(Cl)—CH_2—CH_3$ (2-chlorobutane)

It is a chiral molecule, since it contains an asymmetric carbon atom marked with an asterisk. Hence, it is optically active.



(iii) $CH_3—{}^*CH(OH)—COOH$ (Lactic acid)

It contains one asymmetric carbon atom and its molecule is **chiral**. Thus, it shows **optical activity**.



(iv) $CH_3CH_2—CH(Cl)—CH_2CH_3$ (3-chloropentane)

It is a symmetrical molecule since it does not contain an asymmetric carbon atom. Hence, it does not show optical activity.

Enantiomers and Diastereomers

Optically active compounds which are non-superimposable mirror images of each other are called *enantiomers*. *e.g.*, in tartaric acid, first two figures written are called *enantiomers*. *Remember, an asymmetrical object can have only single mirror image, thus an optically active compound* (being asymmetrical) *can have only one enantiomer always. Secondly this mirror image is always non-superimposable.*

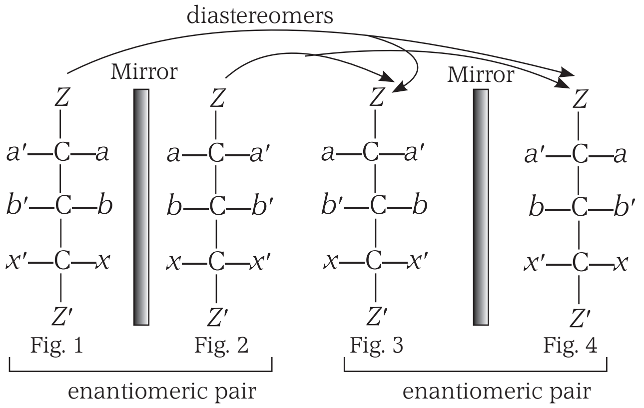
The properties of the enantiomers include

(i) These are stable compounds that differ from one another in three dimensional spatial arrangements.

(ii) These cannot be interconverted under ordinary conditions.

(iii) These have identical properties in all respects except in their interaction with plane of polarised light.

Optical isomers which are not the mirror images of each other are called **diastereomers**. *e.g.,* in the following compounds



The structure of all the four figures is same but spatial arrangement of groups differ as fig. (1) and (2) are enantiomeric, similarly fig. (3) and (4) are enantiomeric. However, Fig. (1) is diastereomeric with fig. (3) and (4) (same molecular formula, different optical behaviour and not the mirror images of each other). Similarly fig. (2) is diastereomeric with fig. (3) and (4).

Contrary to enantiomers, two diastereomers have different melting points, boiling points and solubilities. They will have different chemical reactivities towards most reagents *i.e.*, show difference in physical as well as in chemical properties.

Calculation of Number of Optical Isomers

The number of optical isomers depends upon the number of asymmetric centres and can be calculated with the help of following general relations

1. In molecules which are not divisible into two equal halves and have n number of asymmetric C-atoms
   - (i) Number of optically active forms = $2^n = a$
   - (ii) Number of enantiomeric pairs = $a/2$
   - (iii) Number of racemic mixtures = $a/2$
   - (iv) Number of *meso* forms = 0
2. In molecules which are divisible into two equal halves.

***Case* I** When n = even number,

(i) Number of optically active forms = $(a) = 2^{n-1}$

(ii) Number of enantiomeric forms = $a/2$

(iii) Number of racemic mixtures = $a/2$

(iv) Number of *meso* forms = $(m) = 2^{\left(\frac{n}{2}-1\right)}$

(v) Total number of configurational isomers = $a + m$

***Case* II** When n = odd number,

(i) Number of optically active forms $= (a) = 2^{(n-1)} - 2^{\left(\frac{n-1}{2}\right)}$

(ii) Number of enantiomeric pairs = $a/2$

(iii) Number of racemic mixtures = $a/2$

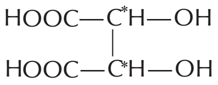
(iv) Number of *meso* forms = $(m) = 2^{\left(\frac{n-1}{2}\right)}$

(v) Total number of configurational isomers = $a + m$.

Sample **Problem 12** *The number of opitcal isomers for the compound* $(CH(OH)COOH)_2$ *is*

(a) 1
(b) 2
(c) 3
(d) 4

Interpret (c) The structure of the compound can also be written as



$$\begin{array}{c} HOOC—\overset{*}{C}H—OH \\ | \\ HOOC—\overset{*}{C}H—OH \end{array}$$

∴No. of asymmetric C atoms $(C^*) = 2$ but the two ends are similar or the molecule is divisible into equal values.

Hence, $a = 2^{n-1} = 2^{2-1} = 2$

$$m = 2^{\frac{n}{2}-1} = 2^{\frac{2}{2}-1} = 2^{\circ} = 1$$

No. of optical isomers = 2 + 1 = 3

Note Here structure is given, but if structure is not given first of all draw the structure.

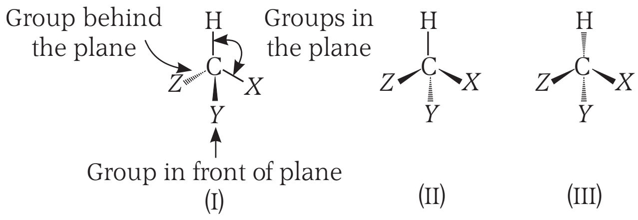
Projection Formulae

Different projection formulae have been given to define the structure a molecule completely. These can be converted into each other.

These are as follow

(a) Wedge-Dash formula

The configuration of organic molecules can be visualised by three-dimensional (3D) structures, which may be depicted by any of the following representations



Here the thick solid (solid wedge) line represents the bonds lying above the plane of paper (projecting towards the viewer), thin lines indicate the bonds lying within the plane of paper; while the dotted line indicates the bonds lying below the plane of paper. Such a representation is called Wedge-Dash formula.

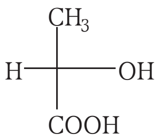
(b) Fischer Projection Formulae

A planar representation of the three dimensional structure is called **Fischer projection formulae.**

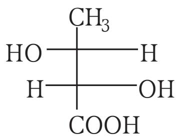
Following guidelines are used to draw it.

1. The chain of carbon atoms in arranged vertically in such a way that the most oxidised carbon occupy the top position.
2. The asymmetric carbon atom lies in the plane of paper and is represented at the interaction of crossed lines.
3. The bonds going away from you are represented by vertical lines. In other words, vertical lines represent the groups present behind the plane of paper.
4. The bonds coming towards you are represented by horizontal lines. In other words, group attached to the horizontal lines are understood to be present above the plane of the paper.

Using the above guidelines, the Fischer projection formulae for lactic acid and tartaric acid are shown as



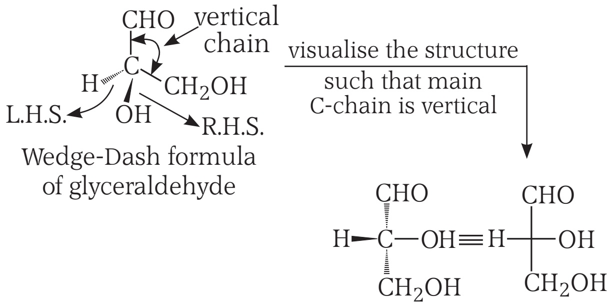
lactic acid



tartaric acid

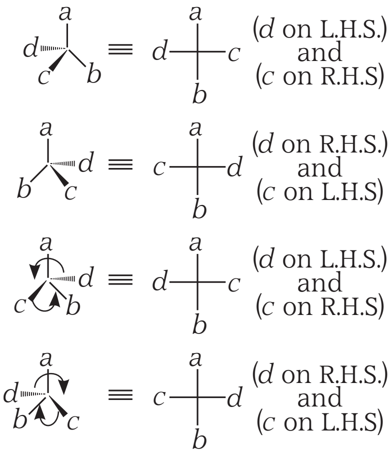
(c) Interconversion of Wedge-Dash Formula to Fischer Formula

In case of molecules having several C atoms, it is customary to orient the molecule in such a way that the C-chain is vertical. Substituents which are left and right of the viewer are written at left and right, respectively, and other two substituents which appear above and below are written at top and bottom positions, *e.g.*,

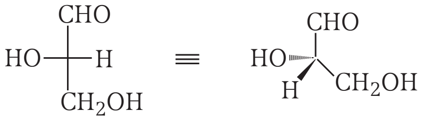


Fischer projection formula

Although the Fischer projections are planar structures, these can be rotated end-for-end on the plane of paper only in multiples of 180° but not 90° at a time. Also a Fischer projection formula may not be taken out of the plane of paper and flipped over.



(d) Interconversion of Fischer Formula to Wedge-Dash Formula



Fischer formula Wedge-Dash formula

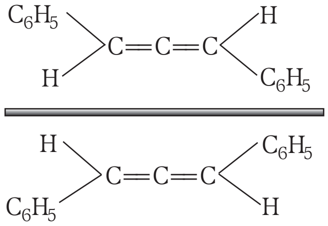
When drawing the 3D formulae from the corresponding Fischer formula, it is better to draw the group at the lower end of the vertical line towards right hand side.

Optical Isomerism in Compounds having Lack of Asymmetric C-atoms

Besides such compounds which have asymmetrical C-atoms, there are also certain compounds which are optically active but lack any asymmetric C-atom. These compounds show optical activity just because of the fact that their molecule is chiral, *e.g.*,

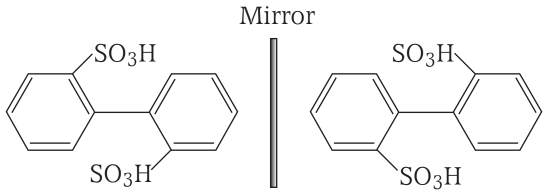
(a) Allene Derivative

Some of the allene derivatives show optical activity as 1, 3-diphenyl propadiene. In this compound the central atom forms two $sp-sp^2$ σ bonds. The central atom also has two π orbitals, which are mutually perpendicular to each other and form π bonds with the p-orbitals of other C-atoms. As a result the substituents at one end of the molecule are in a plane which is perpendicular to that of the substituents at the other end. Thus, the compound exists in two forms which are non-superimposable mirror images and are optically active.



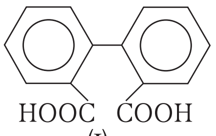
(b) Biphenyl Derivatives

Substituted biphenyls show optical isomerism, when substituent in the 2-positions are large enough to prevent rotation about the bond joining the two benzene rings, *e.g.*, biphenyl-2, 2′ -disulphonic acid exists in two forms. These two forms are non-superimposable mirror images. They do not interconvert at room temperature because the energy required to twist one ring through 180° relative to the other is too high. This is so because during the twisting process, the two $-SO_3H$ groups must come into very close proximity when the two benzene rings become coplanar and strong repulsive forces are introduced.

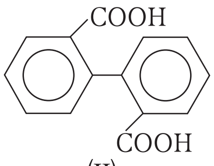


Caution Point *This type of stereoisomerism arising from restricted rotation about a single bond (and where the stereoisomers can be isolated) is called* **atrop isomerism** *and the isomers are called* **atrop isomers.**

Diphenic acid is not optically active. In configuration (I) , the molecule has a plane of symmetry and in configuration (II) , it has a centre of symmetry. Further, I is less stable than (II) because of the repulsion between two (—COOH) groups.



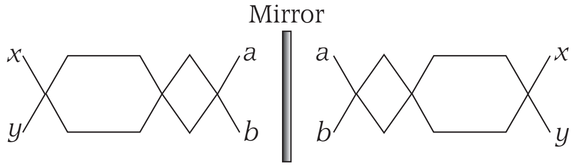
(I)



(II)

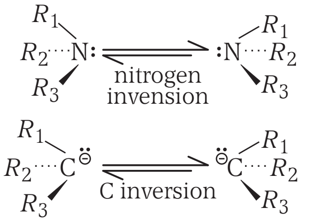
(c) Spiranes

When two double bonds in allenes are replaced by two cycloalkane rings, the resulting system also show optical isomerism.



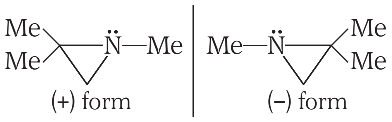
(d) *t*-amines, Amine Salts and *t*-carbanion

Amine and carbanion with a lone pair of electrons (being) considered a fourth different group) are chiral as they have pyramidal geometry, but they are optically inactive. A rapid 'Umbrella' type inversion converts either of the enantiomers to a racemic mixture.The energy required for this inversion is very low at room temperature, since this inversion does not involve bond breaking and bond formation. Thus, racemisation occurs and enantiomers cannot be isolated.



But amine salts are optically active. Nitrogen inversion is not possible *e.g.*, $[R_1R_2R_3N^{\oplus}H]Cl^{\ominus}$

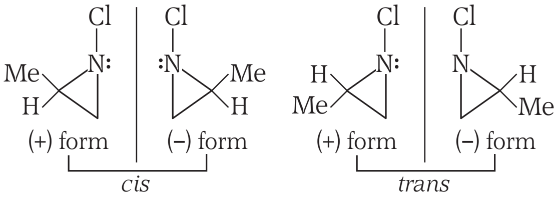
Some more examples of optically active N-containing compounds are



(+) form (–) form

1,2,2-trimethyl aziridine

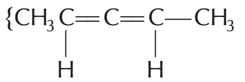
1-chloro-2-methyl aziridine shows four stereoisomers.



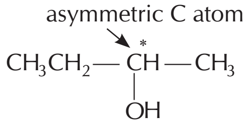
Sample Problem 13 *Which of the following does not exhibit optical isomerism?*

(a) 2,3-*pentadiene* (b) *sec-butyl alcohol*
(c) 1,2-*propadiene* (d) *All of these*

Interpret (c) The structures of the given compounds are as different groups are attached to chiral centre



$\{CH_3\underset{|}{\underset{H}{C}}=C=\underset{|}{\underset{H}{C}}-CH_3$



$CH_3CH_2-\underset{OH}{\overset{*}{C}H}-CH_3$

The attached H groups are same $\{CH_2=C=CH_2$

The mirror images of 1,2-propadiene is superimposable while those of 2,3-pentadiene and *sec*-butyl alcohol are non-superimposable. Hence, 1,2- propadiene does not exhibit enantiomerism or optical isomerism.

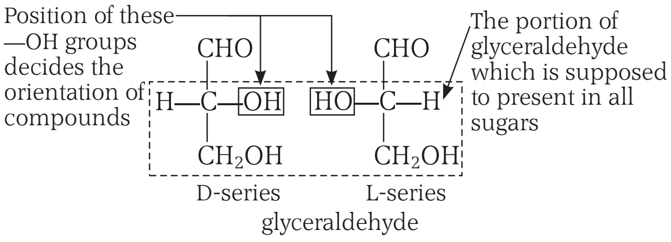
Systems of Nomenclature of Optical Isomers

The nomenclature of optical isomers canbe done in accordance with

(a) Dee-Eel (D,L) system of nomenclature
(b) *Erythro* and *threo* system of nomenclature
(c) The *R,S* (Rectus, sinister) system of nomenclature or system of absolute configuration.

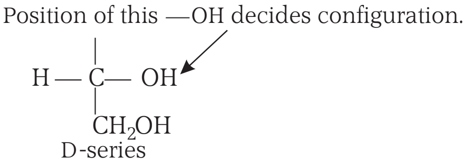
(a) D, L System of Nomenclature of Partial Configuration

The D, L system of nomenclature is used for optically active polyhydroxy carbonyl compounds (carbohydrates) mainly. This nomenclature was given by **Emil Fischer** who considered glyceraldehyde as the parental sugar.



All sugars whose Fischer projection formula shows the —OH group on the right hand side on chiral C-atom adjacent to the terminal —CH_2OH group (*i.e.*, second last C-atom) are called the sugars of D-series.

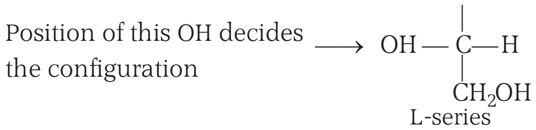
Hence, all sugars having below written structure at their terminus will belong to the **D-series.**



$H-\underset{CH_2OH}{\overset{|}{C}}-OH$

(Here D stands for dextro *i.e.*, right hand side and not dextrorotatory).

Similarly, if the —OH group is positioned left then it looks like



$OH-\underset{CH_2OH}{\overset{|}{C}}-H$

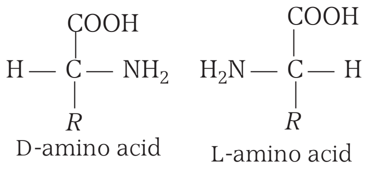
(Here, L stands for laevo *i.e.*, left hand side and not laevo rotatory).

All such sugars having this configuration are suppose to belong to the **L-series.**

As a whole we can say that any compound that can be prepared from or converted into D(+) glyceraldehyde will belong to D-series and similarly any compound that can be prepared from or converted into L(–) glyceraldehyde will belong to the L-series.

It must be noted that there is no relation between the sign of rotation (*i.e.*, +, – or *d*, *l*) and the configuration (D and L) of the enantiomer.

This nomenclature is also used for α-amino acids. *e.g.*,

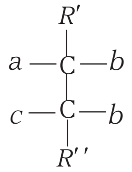


$H-\underset{R}{\overset{COOH}{C}}-NH_2 \quad H_2N-\underset{R}{\overset{COOH}{C}}-H$

(b) *Erythro* and *Threo* System

The *erythro* and *threo* system of nomenclature is used in those compounds which have

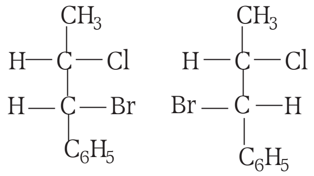
(i) only two chiral carbons and
(ii) the following structure



$a-\overset{R'}{C}-b$
$c-\underset{R''}{C}-b$

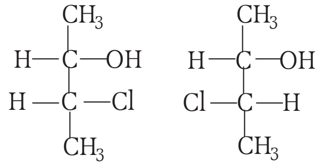
i.e., out of the 6 *substituents on two asymmetric carbons at least two should be same.*

When two like groups in Fischer projection formulae are drawn on the same side of vertical line, the isomer is called ***erythro* form** while if these are placed on the opposite sides, the isomer is said to be ***threo* form**. *e.g.*,



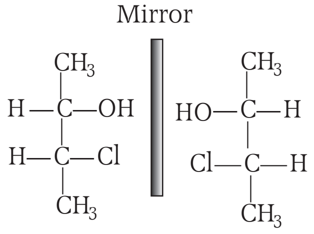
erythro form *threo* form

Similarly,

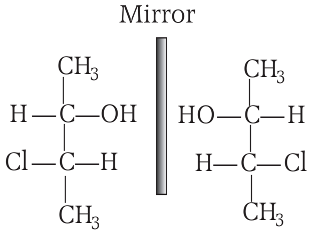


erythro form *threo* form

The *erythro* and *threo* enantiomers are also seen, *e.g.*,



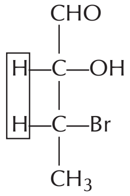
erythro enantiomers



threo enantiomers

Sample **Problem 14** *Which of the following compounds is erythro form?*

(a) 
(b) 
(c) 
(d) 
Interpret (*b*) When two like groups is Fischer projection formula are drawn on the same side of the vertical line, the isomer is called *erythro* form, *i.e.,*



erythro form

Hot Spot 3

R'S SYSTEM
or Absolute Configuration

It is an important topic for JEE Main examination as the question may be directly asked from the topic or may be based on the configuration of product of any reaction. The level of questions is average, but deep focus on the topic is required for solving problems. Here also remember if you have Wadge-Dash formula, convert it into Fischer projection to assign configuration (for better results)

R,S system is more important as compared to previous two. The actual three dimensional arrangement of groups in an asymmetrical molecule is called its **absolute configuration.** We can specify the configuration by using the *R,S* system *i.e.*, *rectus* and *sinister* system [Here, *rectus* = right hand side, *sinister* = left hand side].

This nomenclature was proposed by Cahn, Ingold and Prelog and involves two steps in it.

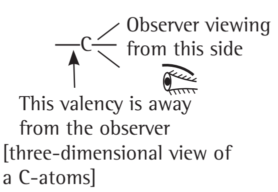
Step I Following a set of sequence rules, a sequence of priority is assigned to four different groups or atoms attached to a chiral C-atom. The most acceptable criterion of priority is based on atomic numbers *i.e.*, **atom with higher atomic number will get higher priority,** *e.g.*, in the case of bromochloroiodomethane the sequence of priority is I, Br, Cl, and H.

Step II The molecule is next visualised so oriented that the group of lowest priority is directed away from you and the arrangement of remaining groups observed. While observing you have to proceed from the group of highest priority to the group of second priority and then to the third.

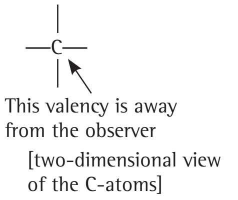
(i) If your eye travels in a clockwise direction, the configuration is called *R* [Latin *rectus* = right]

(ii) If your eye travels anticlockwise, the configuration is called *S* [Latin *sinister* = left]

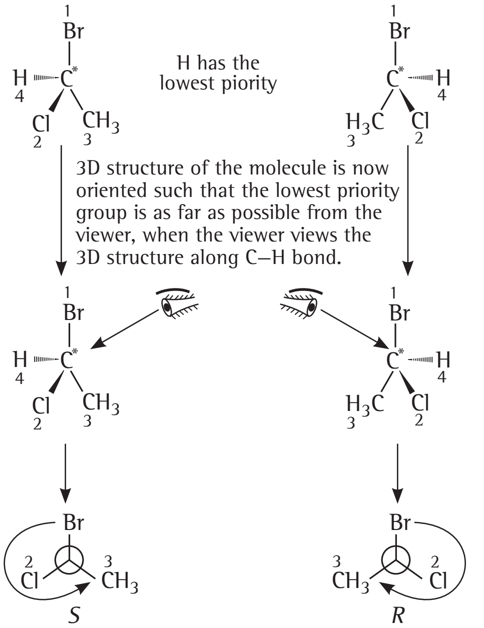
Two positioning of the lowest priority group down and away from the observer can be assumed easily in three dimensions but difficult a bit in two dimensions. *e.g.*,



You can easily position the group of lowest priority away from you if you see the C-atom three dimensionally



For positioning the group of lowest priority away from you, you have to perform pair inter changes among the groups attached to asymmetric C-atom



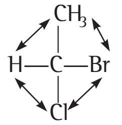
S
Highest to lowest priority is counter clockwise, hence, *S* configuration

R
Highest to lowest priority is clockwise, hence, *R* configuration

While studying, it is not possible always to keep the three dimensional view of C-atom, we perform and learn the complete exercise in accordance with two dimensional view. Thus, we have to learn the pair interchanging in detail which can be done easily if we keep following 4 points in our mind.

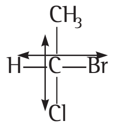
(i) Our target is to position the group with lowest priority to the valency away from the observer.

(ii) This target can be achieved by pair interchanges that will always be diagonal. That means



The interchange operations are shown by double headed arrows

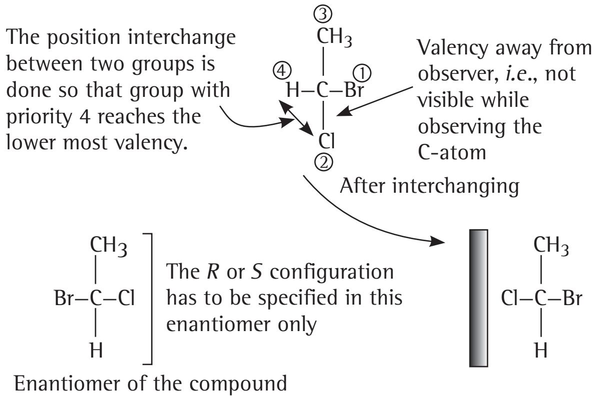
The possible ways of pair interchanging



These ways of interchanging are not possible

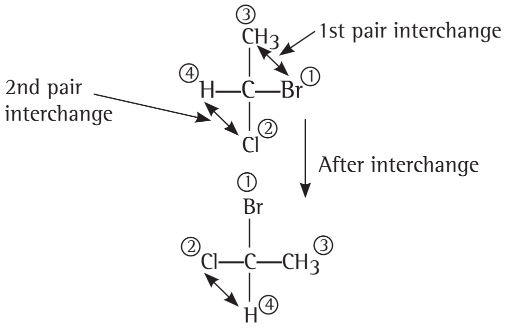
(iii) The single pair (or odd number) interchanging in Fischer projection inverts the configuration.

That means, now the enantiomer of the compound formed will give the absolute configuration of compound, *e.g.,*



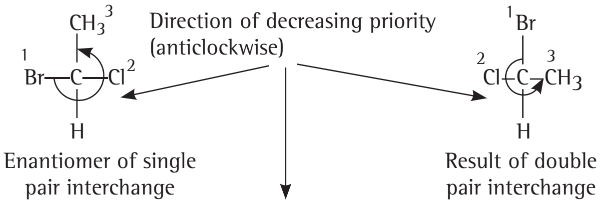
(iv) The two pair interchanges (or even number interchanges) retains the original configuration.

That is if we perform 2 pair exchanges then there is no need of enantiomer formation as seen above, *e.g.*, in the compound written above



Step III Specify the direction of decreasing priority of the three groups (1 → 2 → 3) after ignoring 4th one.

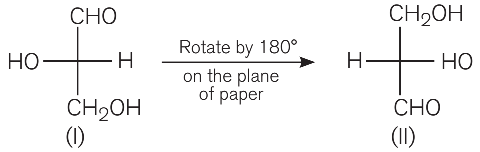
If the groups are arranged in clockwise fashion then the configuration is *R* and if these occur in anticlockwise manner, the configuration is *S*. *e.g.,* if we look at the result of single pair and double pair interchanges *i.e.,*



Hence, the configuration of the C-atom in compound is *S*.

Thus, in the above example the configuration is *S* because the groups 1, 2 and 3 are arranged in anticlockwise fashion (shown by circular arc).

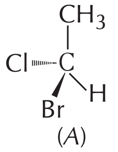
Caution Point *Rotation of Fischer projection by 180° on the plane of paper results in the equivalent Fischer projection.*



(I) and (II) are equivalent Fischer projections.

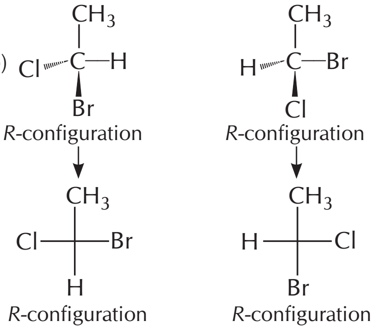
Sample Problem 15

In which of the following representations given below spatial arrangement of group/atom same from that given in structure 'A'? **[NCERT Exemplar]**



(A)

(a) 
(b) 
(c) 
(d) 
Interpret (b)



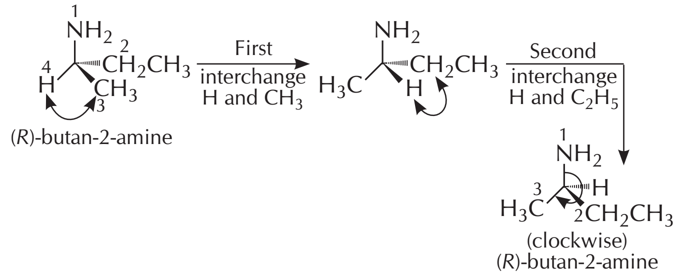
Sample Problem 16

The configuration of which of the following is not R?

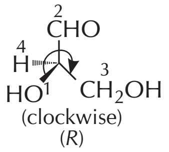
(a) 
(b) 
(c) 

(d) *None of these*

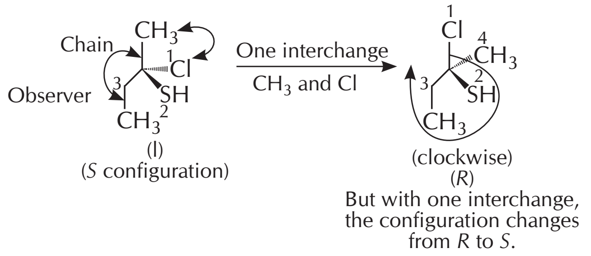
Interpret (c) The lowest priority ligand (H) is in the plane (*i.e.*, not on the dotted line) so it makes two interchanges such that H is projected away from the observer. (Priority order: —NH$_2$ > —CH$_2$CH$_3$ > — CH$_3$ > — H)



The lowest priority ligand (H) is on the dotted line. *R* and *S* can be assigned directly from the priority rule. (—OH > —CHO > — CH$_2$OH > — H)

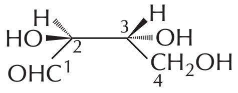


Lowest priority ligand (—CH$_3$) is in the plane (*i.e.*, not on the dotted line). So make one interchange so that (—CH$_3$) is projected away from the observer.
(Priority order.—Cl > —SH > — CH$_2$CH$_3$ > — CH$_3$



Sample Problem 17

Assign R-S configuration to the following compound



(a) C – 2 (*R*), C – 3(*S*)
(b) C – 2 (*S*), C – 3(*R*)
(c) C – 2 (*S*), C – 3(*S*)
(d) C – 2 (*R*), C – 3(*R*)

Interpret (b) Priority order at C2

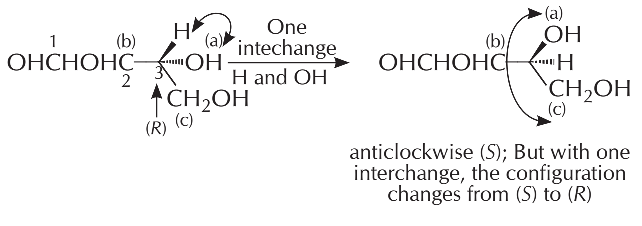
$$\underset{a}{—\text{OH}} > \underset{b}{—\text{CHO}} > \underset{c}{\text{CH(OH)CH}_2\text{OH}} > \underset{d}{—\text{H}}$$

Written as $a > b > c > d$

First assign *R/S* at C-2. Here, the lowest ligand is in the plane. (*i.e.*, on the dotted line). Priority sequence is anticlockwise hence the configuration at C-2 is *S*.

Priority order at C-3 : —OH > —CHOHCHO > CH$_2$OH > H.

Here, H is not on the dotted line, so make one interchange of H and — OH so that — OH is projected away from the observer.



So, the configuration is (2*S*, 3*R*).

Caution Point *R and S are the only configurations assigned to a particular three dimensional arrangement and these are not related to the optical rotation of the compound.*

If the absolute configuration about an asymmetric carbon is R then it is not necessary that it will rotate the plane of polarized like clockwise, it may rotate it anticlockwise also.

Measurement of Optical Activity

The optical activity of a compound can be detected and measured by means of a **polarimeter.** When a solution of a known concentration of an optically active compound is placed in a polarimeter, the beam of polarised light is rotated through a certain number of degrees either to the right (clockwise) or to the left (anticlockwise). This degree is measured and called **rotation** produced by the solution.

The degree of rotation depends upon the number of molecules of the compound encountered by light along its path. This degree of rotation, if measured, is called **specific rotation** and can be defined as the rotation produced by a solution of 10 cm length and unit concentration (1 g/mL) for the given λ of light at the given temperature. Thus, for a system in which plane of polarised light is rotated through α degrees at a temperature of t°C and using the sodium-D lines as the source, the specific rotation $[\alpha]_D^t$ is given by

$$[\alpha]_D^t = 100\,\alpha / l \times c$$

Here, l = length of the fluid filled tube in decimeters
(10 cm = 1 decimetre)
c = number of grams per 100 mL of solution

The specific rotation varies both with light wavelength and temperature.

Sample Problem 18 *The specific rotation of a pure enantiomer is +10°. Its observed rotation if it is isolated from a reaction with*

(*i*) *30% racemisation and 70% retention,*
(*ii*) *70% racemisation and 30% inversion are respectively*

(*a*) 7, 3	(*b*) 3, 7
(*c*) +7, −3	(*d*) −7, −3

Interpret (*c*) (i) $[\alpha]_{\text{obs}} = 0.70 \times +(10^\circ) = +7.0^\circ$

(ii) 30% inversion, with inversion specific rotation is (−10°)

$$\therefore \qquad [\alpha]_{\text{obs}} = 0.30 \times (-10^\circ) = -3.0^\circ$$

Sample Problem 19 *What is the percentage composition of (–) form a mixture of two enantiomers whose rotation is −10°? The specific rotation of pure enantiomers is −20°.*

(*a*) 25% (*b*) 10% (*c*) 50% (*d*) 15%

Interpret (*d*) Optical purity (OP) of sample $= \dfrac{[\alpha]_{\text{obs}}}{[\alpha]_D}$

$$= \frac{-10^\circ \times 100}{-20^\circ} = 50\%$$

So, 50% of the mixture consists of (–) enantiomer and 50% is the racemate [*i.e.*, 25% (+) and 25% (–) form].
Total percentage of (–) form = 50% + 25% = 75%
Total percentage of (+) form = 25%

Sample Problem 20 *An aqueous solution containing 10 g of optically pure fructose was diluted to 500 mL water and placed in a polarimeter tube 20 cm long. The measured rotation was −5.0°. To this solution, 500 mL of a solution containing* 10 g of racemic fructose is added. What will be the change in specific rotation?

(*a*) −62.5° (*b*) +62.5° (*c*) −12.5° (*d*) +12.5°

Interpret (*b*) As we know, 20 cm = 2 dm

$$[\alpha]_D = \frac{\theta}{l \times C} = \frac{-5.0^\circ}{2\text{ dm} \times 10\text{ g}/500\text{ mL}} = -125$$

Total volume of solution = 500 + 500 = 1000 mL

Mass per mL of pure fructose = 10 / 1000 = 0.01 g mL^{-1}

Mass per mL of mixture = (10 + 10 = 20) = 20 / 1000 = 0.02 g mL^{-1}

$$\text{OP (optical purity)} = \frac{[\alpha]_{\text{obs}}\text{ of mixture}}{[\alpha]_D\text{ of pure form}} \propto \frac{\text{Mass per mL of pure form}}{\text{Mass per mL of mixture}}$$

$$= \frac{0.01}{0.02} = 0.5 \qquad (\because l \text{ is constant})$$

New, $[\alpha]_D = -125^\circ \times 0.5 = -\,62.5^\circ$

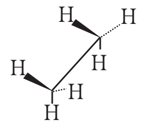
Change in specific rotation = −62.5 − (−125) = 62.5°

Check Point 2

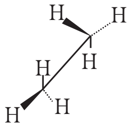
1. *Trans* form is more stable as compared to *cis* form and has zero dipole moment. Explain why?
2. Geometrical isomerism is usually exhibited by the compounds having at least one double bond between two atoms. Cyclic compounds, however, have no double bond, but exhibit geometrical isomerism. Explain.
3. Do all biphenyl derivatives are optically active? If not, mention the condition for optical activity.
4. Is presence of asymmetric carbon atom, the main condition for exhibiting optical isomerism?

14.9 Conformations or Conformers

The σ electron cloud joining the carbon atoms in alkanes is cylindrically symmetrical about a line joining the two carbon nuclei; hence bond strength should be the same for all possible arrangements. Different arrangements of atoms that can be converted into one another by rotation about single bonds are called *conformations*. Arrangement I is called the *eclipsed conformation*; arrangement II is called the *staggered conformation*. (The infinite intermediate conformations in between the above two are called **skew conformations).**



arrangement I



arrangement II

Caution Point *Conformers are also termed as rotamers and conformational isomerism as rotamerisms.*

Conformations of Ethane

In ethane molecule ($CH_3—CH_3$), the two carbon atoms are bonded by a single covalent bond. If one of the carbon atoms (methyl group) is kept fixed and the other is rotated about the C—C bond, an infinite number of arrangements of the hydrogen atoms attached to one carbon atom with respect to other are possible. These infinite number of different arrangements are called **conformations.**

To represent these conformations we can draw three dimensional pictures.

However, chemists represent conformations in two simple ways as shown below

(a) Saw Horse Representation

In it, we view carbon-carbon bond from an oblique angle and indicate spatial arrangements by showing all the C—H bonds as shown in figure 14.2.

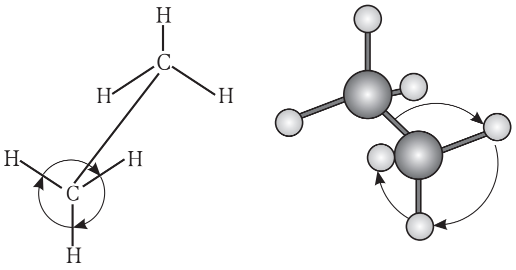


Fig. 14.2 Saw Horse representation showing rotation around C—C single bond in ethane

(b) Newmann Projection

It is a simple method to represent the conformations. In this method, the two carbon atoms forming the σ-bond are represented by two circles; one behind the other so that only the front carbon is seen. The C—H bonds of the front carbon are depicted from the centre of the circle while C—H bonds of the back carbon are drawn from the circumference of the circle.

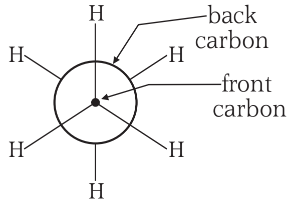

Fig. 14.3 Newmann projections of ethane

Out of all the conformations possible for ethane, only two extreme conformations are important i.e.,

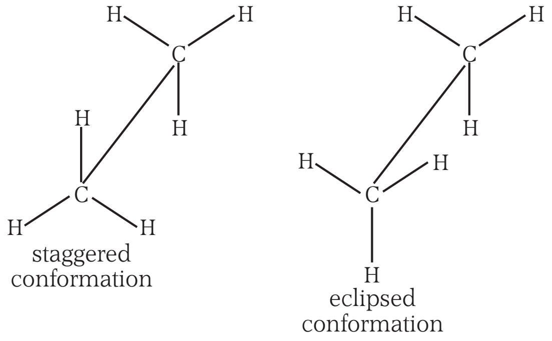
(a) Staggered Conformation

In this arrangement, the hydrogens of the two carbon atoms are staggered with respect to one another. As a result, they are at maximum distance apart and have minimum repulsion between them.

(b) Eclipsed Conformation

In this conformation, the hydrogens of one carbon atom are directly behind those of the other. Consequently, the repulsion in these atoms is maximum.

The saw horse projections of these conformations are represented in the figure below.

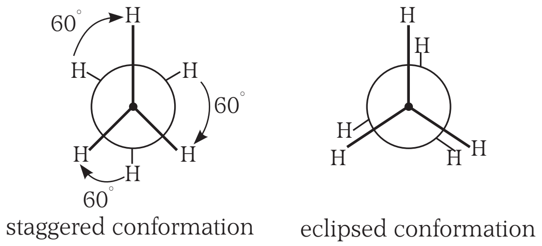


staggered conformation

eclipsed conformation

Fig. 14.4 Saw Horse representation of staggered and eclipsed conformations of ethane

The Newmann projections for staggered and eclipsed conformations of ethane are shown in figure below. It is clear that when the staggered conformation is rotated through an angle of 60°, it changes to eclipsed conformation and similarly, when eclipsed conformation is rotated through the same angle, it gives back the staggered conformation.



staggered conformation

eclipsed conformation

Fig. 14.5 Newmann projections of staggered and eclipsed conformations of ethane

Relative Stabilities of the Conformations of Ethane

The two conformations of ethane differ in their relative stabilities. The staggered conformation has minimum repulsions between the H-atoms attached tetrahedrally to the two carbon atoms. On the other hand, the eclipsed conformation has maximum force of repulsion between H-atoms. Therefore, **the staggered conformation is more stable than the eclipsed conformation.** The difference in the energy contents of the staggered and eclipsed conformations is 12.5kJ mol^{-1}. This small barrier to rotation is also called torsional barrier of the single bond. However, this energy difference is not large enough to prevent rotation Even at ordinary temperatures the molecules have thermal or kinetic energy to overcome this energy barrier. Therefore, the two conformations of ethane go on changing from one form to another thus consequently, it is not possible to isolate the different conformations of ethane.

The variation of energy *versus* rotation about the C—C bond has been shown in the following figure.

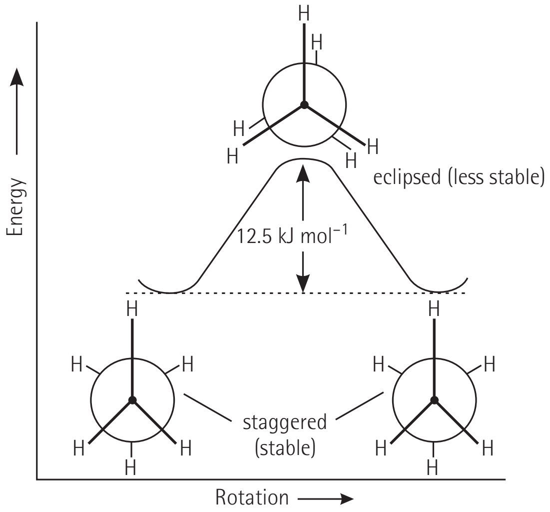


Fig. 14.6 The variation of energy *versus* rotation about C—C bond

The difference in the energy of various conformations constitutes an energy barrier in rotation. For free rotation energy barrier is 0.6 kcal/mol.

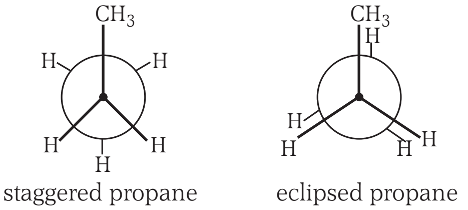
For restricted rotation, energy barrier is in between > 0.6 and < 16 kcal/mol.

For frozen rotation, energy barrier is ≥ 16 kcal/mol.

Caution Point *The dihedral angle between the* C—H *bonds on adjacent carbons in staggered and eclipsed conformations of ethane are* 180° *and* 0° *respectively whereas between the two methyl groups in the gauche and anti conformations of n-butane, these are* 60° *and* 180° *respectively.*

Conformations of Propane

The next higher member in alkane series, *i.e.,* propane ($CH_3CH_2CH_3$) also has two extreme conformations, *i.e..*, **staggered conformation** and **eclipsed conformation.** In figure only Newmann projections are shown for simplicity. However, the energy barrier in propane is 14 kJ mol^{-1}, which is slightly higher than that in ethane.



staggered propane eclipsed propane

Fig. 14.7 Newmann projections of propane

In the eclipsed conformation of propane, there are two ethane type H—H interactions and an additional interaction between C—H bond and C— C bond (of methyl group). The variation of energy *versus* rotation about C— C bond is shown in the figure.

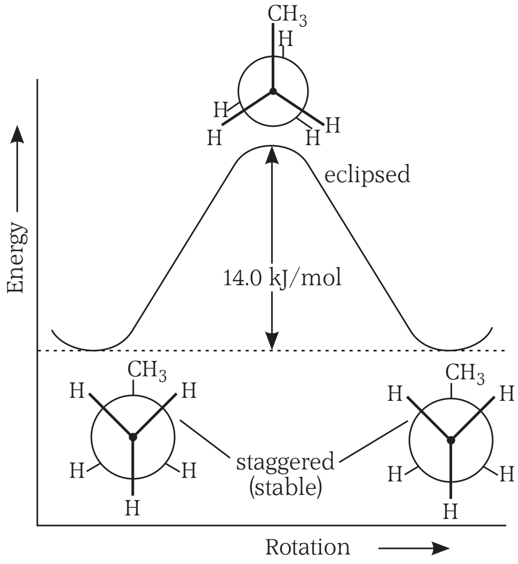


Fig. 14.8 The variation of energy *versus* rotation about C—C bond in propane

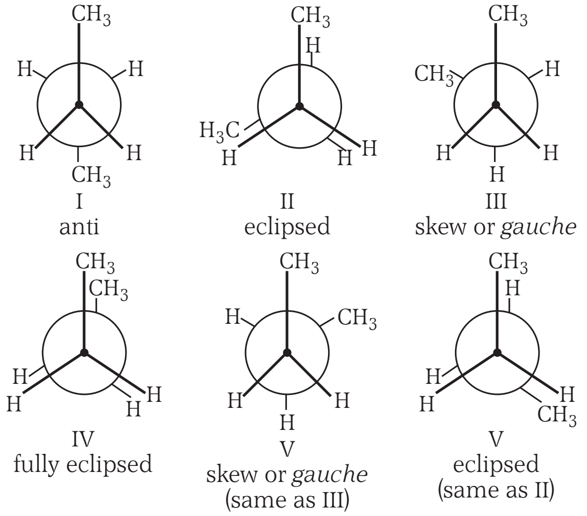
Conformations of Butane

As the alkane molecule becomes larger, the conformation situation becomes more complex. As in butane ($CH_3CH_2CH_2CH_3$), for example, the rotation about the single bond between two inner carbon atoms (C_2 and C_3) is considered. In this case, all the staggered as well as eclipsed conformations will not have same stability and energy because of different types of interaction between C—C (of methyl) and C—H bonds.

The lowest energy conformation will be the one, in which the two methyl groups are as far apart as possible *i.e.,* 180° away from each other. The conformation will be maximum staggered and is called anti conformation (marked I). Other conformations can be obtained by rotating one of the C_2 or C_3 carbon atoms roughly at an **angle of 60°** as shown below.



I
anti

II
eclipsed

III
skew or *gauche*

IV
fully eclipsed

V
skew or *gauche*
(same as III)

V
eclipsed
(same as II)

Fig. 14.9 Different conformations of butane

As is clear from the above Newmann projections, the gauche or skew conformations (II and V) are also staggered. However, in these conformations, the methyl groups are so close that they repel each other. This repulsion causes *gauche* conformations to have about 3.8 kJ mol^{-1} more energy than anti conformation. The conformations II and V are eclipsed conformations. These are unstable because of repulsions. They have 14.6 kJ mol^{-1} energy and are less stable than anti conformation. Conformation IV is also eclipsed and it is least stable having energy 18.4 kJ mol^{-1} more than anti conformation. This is because of repulsion between methyl-methyl groups which are very close together. It is called fully eclipsed conformation.

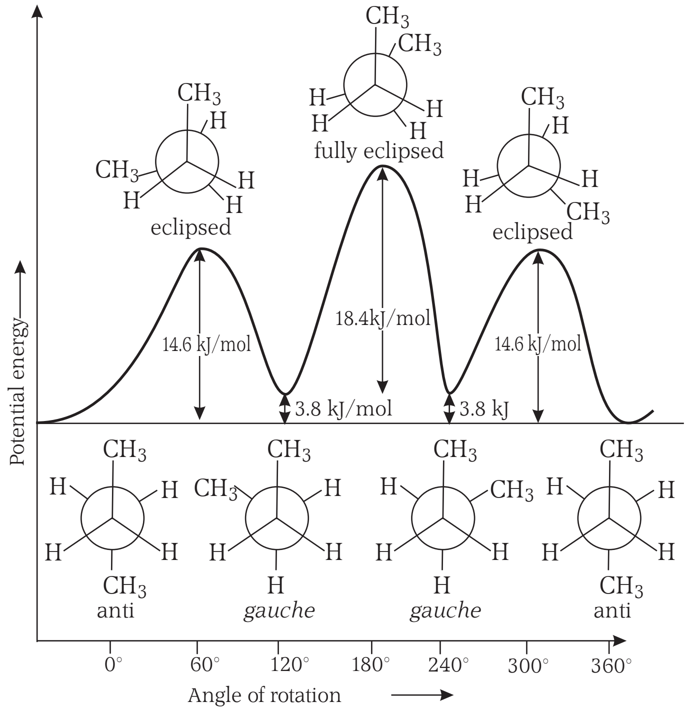


Fig. 14.10 Energy change during rotation about $C_2 - C_3$ bond of *n*-butane

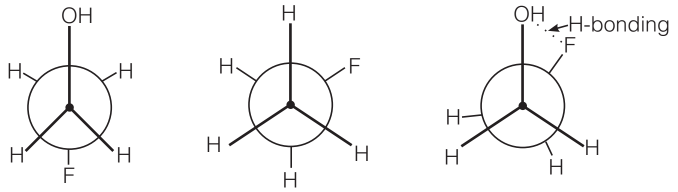
$$\overset{1}{C}H_3-\overset{2}{C}H_2-\overset{3}{C}H_2-\overset{4}{C}H_3$$

The order of stability of these conformations is

Anti > Skew or *Gauche* > Eclipsed > Fully eclipsed

The energy differences between various conformations is shown fig. 14.10.

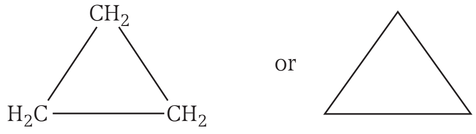
Caution Point *If there exist a possibility of H-bonding or any other such interaction then gauche form may become more stable than anti (staggered) due to H-bonding as shown below.*



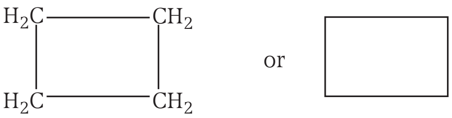
less stable
less stable
most stable

Conformations in Cycloalkanes

Conformational isomerism has also been observed in cycloalkane molecules. Cyclopropane and cyclobutane are planar molecules having bond angles of 60° and 90° respectively.



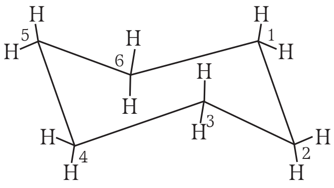
cyclopropane (bond angle = 60°)



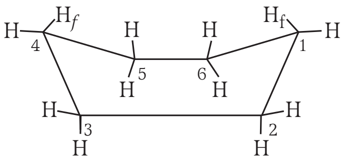
cyclobutane (bond angle = 90°)

The bond angles in these molecules are quite different from the normal tetrahedral bond angle of 109.5°, which is a normal angle for sp^3 hybridised carbon atoms. As a result of deviation from normal bond angle, there is a considerable strain in the molecules of these compounds. Therefore, these are quite reactive. Obviously, cyclopropane with a bond angle of 60° is more strained and reactive than cyclobutane (bond angle 90°).

In cyclopentane, the bond angle is 108° which is quite close to normal tetrahedral angle. Therefore, cyclopentane has very less strain and is, therefore, stable. Similarly, the bond angle in cyclohexane ring is 120° and is expected to be quite reactive and strained. However, cyclohexane is quite stable.



chair conformation

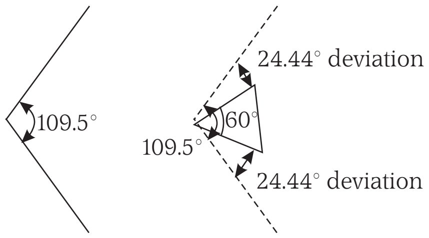


boat conformation

The stability of cyclohexane indicates that the molecule avoids strain by assuming conformation in which all the bond angles between carbon atoms are close to tetrahedral angle of 109.5°. Therefore, cyclohexane adopts a non-planar structure. *The two important conformations for cyclohexane are the chair form and the boat form as shown in the figure above.* These structures are also called **puckered ring structures**. The names of these forms are due to resemblance of their shapes with chair and boat respectively.

Baeyer's Strain Theory

The German chemist **Baeyer** was the first to suggest that the instability of small ring compounds was due to angle strain. This theory is known as **Baeyer's strain theory**. Baeyer strain theory was based upon the assumption that when an open chain organic compound having the normal bond angle 109.5° is converted into a cyclic compound, a definite distortion of this normal angle takes place leading to the development of a strain in the molecule.



Baeyer assumed that cyclic rings are planar. Assuming this, the amount of strain in various cycloalkanes can be expressed in terms of angle of deviation (d).

$$\text{Angle strain} \propto d \propto \frac{1}{\text{inner angle } (\alpha)}$$

$$\text{Stability} \propto \frac{1}{d} \propto \text{inner angle } (\alpha)$$

where, d = angle of deviation

α = inner angle in cycloalkane ring

Stabilities of the Conformations of Cyclohexane

The chair conformation of cyclohexane is more stable than the boat conformation due to the following reasons

(i) In chair conformation, the adjacent hydrogen atoms on all the neighbouring carbon atoms are quite staggered and the force of repulsion in between them is the minimum. However, in the boat conformation, the adjacent hydrogen atoms on C_2 — C_3 and C_5 — C_6 atoms are eclipsed.

(ii) The two hydrogen atoms (marked as H_f) bonded to the C_1 and C_4 atoms in boat conformation are quite close (distance = 183 pm) and repel each other. These are called **flag pole hydrogens.** Therefore, the energy of the boat conformation is more than that of chair conformation.

The energy of the boat conformation of cyclohexane is about 44 kJ mol^{-1} more than that chair conformation. Therefore, cyclohexane exists mainly in the chair form.

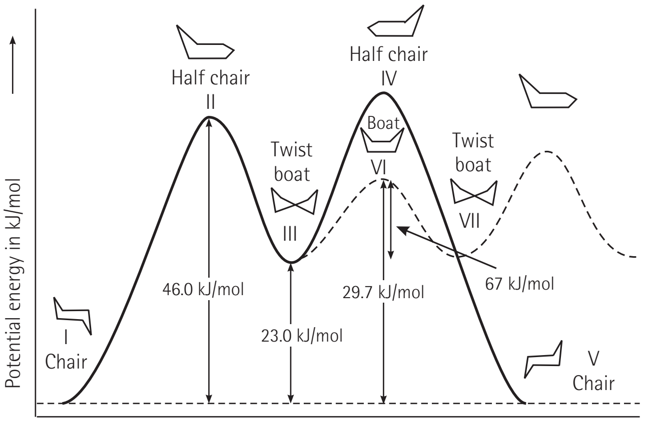


Fig. 14.11 Relative potential energies of the various conformations of cyclohexane

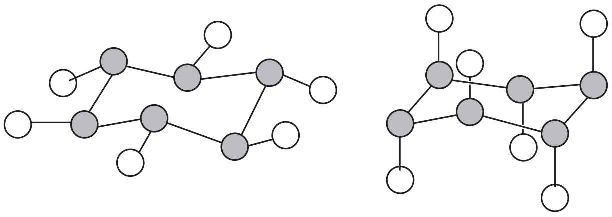
Caution Point *The two twist boat conformations are just mirror images of each other and are called enantiomeric formations.*

Sample Problem 21 *In the boat conformation of cyclohexane, the most destabilising interaction is*

(a) 1,3-*diequatorial*
(b) *eclipising*
(c) *flagpole-flagpole*
(d) 1,3-*diaxial*

Interpret (c) Boat conformation of cyclohexane has two types of destabilizing interaction, *i.e.*, eclipsing and flagpole-flagpole. Out of these flagpole-flagpole interaction is the most destabilizing.

Let us return to the model of the chair conformation of cyclohexane. Although the cyclohexane ring is not flat,

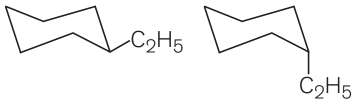


equatorial bonds axial bonds

Fig. 14.12 Chair cyclohexane : equatorial and axial bonds

we can consider that the carbon atoms lie roughly in a plane. If we look at the molecule in this way, we see that the hydrogen atoms occupy two kinds of position : six hydrogens lie in the plane, while six hydrogens lie above or below the plane. The bonds holding the hydrogens that are in the plane of the ring lie in a belt about the "equator" of the ring, and are called **equatorial bonds**. The bonds holding the hydrogen atoms that are above and below the plane are pointed along an axis perpendicular to the plane and are called **axial bonds**. In the chair conformation each carbon atom has one equatorial bond and one axial bond.

Caution Point *The structure of cyclohexane in which two or more bulkier groups ocupy equatorial positions is more stable e.g.,*



(more stable) (less stable)

Check Point 3

1. Which conformation in *n*-propane is more stable and why?
2. Draw Newmann's projection for the less stable staggered form of butane. Also give the reason for the less stability of this form.
3. Cyclohexane is expected to be quite reactive and strained but it is stable. Explain, why?
4. Why *gauche* conformation of 2-amino-3-hydroxybutane is more stable as compared to its anti form?

WORKED OUT Examples

Example 1 *Number of isomers represented by molecular formula* $C_4H_{10}O$ *is*

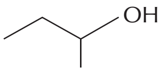
(a) 4 (b) 6
(c) 7 (d) 8

Solution (c) The following structures are possible for the molecular formula $C_4H_{10}O$.

(i)

(ii)

(iii)

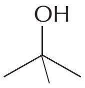


(iv)

(v)

(vi)

(vii)

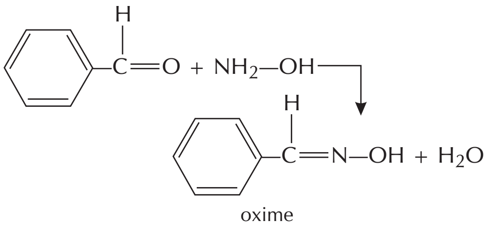


Out of these, four are alcohols and three are ethers.

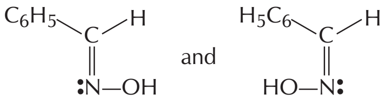
Example 2 *Types of isomerism shown by the product of the reaction between benzaldehyde and hydroxyl amine is*

(a) *syn-anti* (b) *cis-trans*
(c) *E-Z* (d) *d and l*

Solution (a)



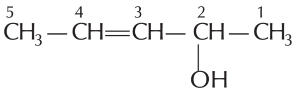
Oximes show *syn* and *anti* isomers as



Example 3 *The number of stereoisomers for pent-3-en-2-ol is*

(a) 3 (b) 4 (c) 5 (d) 2

Solution (b)



$$\overset{5}{C}H_3-\overset{4}{C}H=\overset{3}{C}H-\underset{OH}{\overset{2}{C}H}-\overset{1}{C}H_3$$

The number of stereoisomers = number of optical isomers + number of geometrical isomers

In this compound,

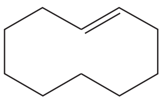
the number of optical isomers $= 2^1 = 2$

the number of geometrical isomers $= 2^1 = 2$

Thus, the number of stereoisomers $= 2 + 2 = 4$

Example 4 *Which of the following will show geometrical isomerism?*

(a) *Methyl cyclohexane* (b)



(b) $(CH_3)_2C{=}NOH$ (d) $CH_3CH{=}NOH$

Solution (d) Since, the molecules given in option (a), (b) and (c) are symmetrical, they do not exhibit geometrical isomerism.

Example 5 *The number of enantiomers and meso forms for the compound,*

$HOOC—CH(CH_3)—CHOH—CHBr—CHOHCH(CH_3)—COOH$

are respectively,

(a) 12, 2 (b) 12, 4 (c) 8, 4 (d) 8, 2

Solution (b) Since, the compound can be divided into two equal halves and has five asymmetric carbon atoms, the number of

$$\text{enantiomers} = 2^{n-1} - 2^{\left(\frac{n-1}{2}\right)}$$

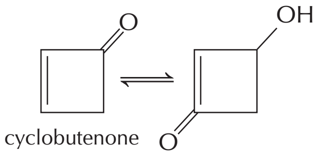
$$= 2^{5-1} - 2^2 = 2^4 - 2^2 = 16 - 4 = 12$$

$$\text{Number of } meso \text{ forms} = 2^{\left(\frac{n-1}{2}\right)} = 2^2 = 4$$

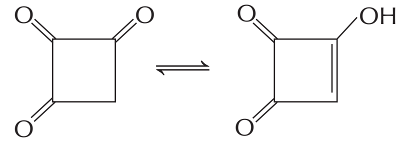
Example 6 *Which of the following is more easily enolised?*

(a) *Cyclobutenone* (b) *Triketocyclobutane*
(c) *Both are equally enolised* (d) *Nothing can be said*

Solution (b)



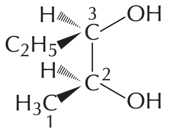
It doesn't enolise because its enol is a flat ring with $4n\pi\,\bar{e}$' s (*i.e.*, $4n\pi\,\bar{e}$'s $n = 1$) and is antiaromatic.



triketocyclobutane

It enolises because its enol has $(4n+2)\ \pi$ (*i.e.*, $2\pi\ \bar{e}'s\ n=0$) and is stabilised by aromaticity.

Example 7

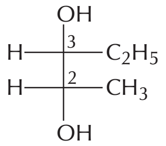


In the above compound, the configuration of C_2 and C_3 are, respectively

(*a*) *R*, *R* (*b*) *S*, *S*

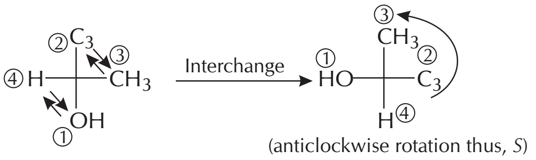
(*c*) *R*, *S* (*d*) *S*, *R*

Solution (*d*) The Fischer projection formula for the given compound is



For C_2 carbon, the order of priority is

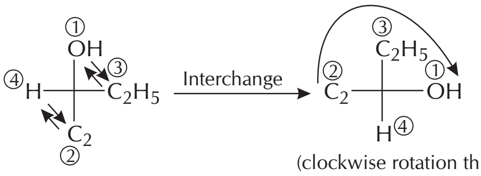
$$-OH > -C_3 > -CH_3 > -H$$



(anticlockwise rotation thus, *S*)

For C_3 carbon, the order of priority is

$$-OH > -C_2 > -C_2H_5 > -H$$

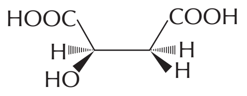


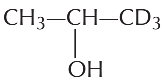
(clockwise rotation thus, *R*)

Hence, the configuration of C_2 and C_3 are respectively *S* and *R*.

Example 8 *Which of the following compounds will not show optical activity?*

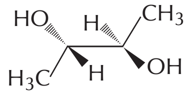
(*a*)



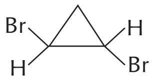
(*b*)


$CH_3-\underset{\displaystyle OH}{\underset{|}{CH}}-CD_3$

(*c*)



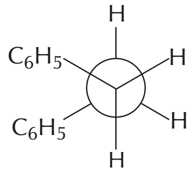
(*d*)



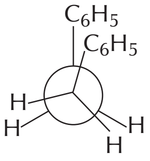
Solution (*c*) The compound given in option (*c*) is optically inactive while all others show optical activity, due to the presence of chiral carbon atom and absence of symmetry elements.

Example 9 *The most stable conformation of 1,2-diphenyl ethane is*

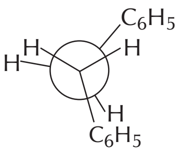
(*a*)



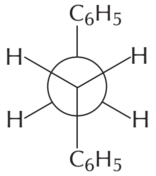
(*b*)



(*c*)



(*d*)



Solution (*d*) In conformation '*d*' the bulkier group are present as far away as possible, thus, there is minimum repulsion. Hence, this form is most stable.

Example 10 *Which of the following cycloalkanes involve maximum torsional strain?*

(*a*) *Cyclopropane* (*b*) *Cyclobutane*

(*c*) *Cyclopentane* (*d*) *Cyclohexane*

Solution (*a*) According to Baeyer's strain theory, the amount of the strain is directly proportional to the angle of deviation.

$$\text{Angle of deviation, } d = \frac{1}{2}(109°28' - \text{valency angle})$$

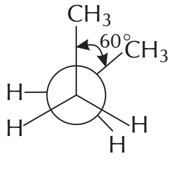
d is minimum in case of cyclohexane and maximum in case of cyclopropane, thus torsional strain is maximum in cyclopropane.

Example 11 *Dihedral angle between two methyl groups of n-butane in the gauche and anti forms are*

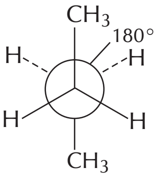
(*a*) 60°, 0° (*b*) 0°, 60°

(*c*) 60°, 180° (*d*) 180°, 60°

Solution (*c*)



gauche form



anti form

(The angle between C—C and C—H bonds on adjacent carbon atoms in any conformation is called dihedral angle.)

Hence, the dihedral angle in case of gauche is 60° and in anti form is 180°.

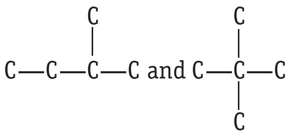
Start Practice for JEE Main

Round I (Topically Divided Problems)

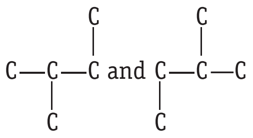
Structural Isomerism

1. Compounds having the same molecular formula but different properties are called
(a) isotopes (b) isobars
(c) isomers (d) isomorphs

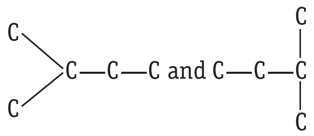
2. Which pair of carbon skeleton is an example of isomerism?

(a)


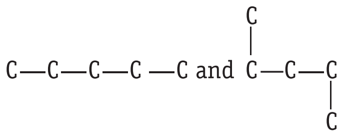
$$\mathrm{C-C-\overset{\overset{\displaystyle C}{|}}{C}-C \text{ and } C-\underset{\underset{\displaystyle C}{|}}{\overset{\overset{\displaystyle C}{|}}{C}}-C}$$

(b)


$$\mathrm{C-\underset{\underset{\displaystyle C}{|}}{C}-\overset{\overset{\displaystyle C}{|}}{C} \text{ and } \underset{\underset{\displaystyle C}{|}}{C}-\overset{\overset{\displaystyle C}{|}}{C}-C}$$

(c)


$$\mathrm{(C)_2C-C-C \text{ and } C-C-\underset{\underset{\displaystyle C}{|}}{\overset{\overset{\displaystyle C}{|}}{C}}}$$

(d)


$$\mathrm{C-C-C-C-C \text{ and } \overset{\overset{\displaystyle C}{|}}{C}-C-\underset{\underset{\displaystyle C}{|}}{C}}$$

3. Isomers have essentially identical
(a) structural formula (b) chemical properties
(c) physical properties (d) molecular formula

4. Which of the following is not isomeric with diethyl ether?
(a) Methyl *n*-propyl ether
(b) Butan-1-ol
(c) 2-methyl propan-2-ol
(d) Butan-2-one

5. Which of the following is not an isomer of but-1-yne ?
(a) But-2-yne (b) Buta-1,3-diene
(c) Methyl cyclopropene (d) But-2-ene

6. The compounds R—NO_2 and R—ONO are
(a) geometrical isomers (b) functional isomers
(c) metamers (d) optical isomers

7. Which among the following compounds will show metamerism?
(a) $CH_3COC_3H_7$ (b) $CH_3OC_2H_5$
(c) $CH_3SC_2H_5$ (d) CH_3OCH_3

8. The isomerism observed in alkanes is
(a) metamerism (b) chain isomerism
(c) position isomerism (d) geometrical isomerism

9. The molecular formula of a saturated compound is $C_2H_4Cl_2$. The formula permits the existence of two
(a) functional isomers (b) position isomers
(c) optical isomers (d) *cis-trans* isomers

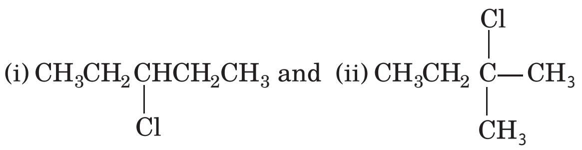
10. An alkane forms isomers if minimum number of C-atom is
(a) 1 (b) 2 (c) 3 (d) 4

11. Maximum number of open chain isomers that an alkene can have with the molecular formula C_4H_8 is
(a) 5 (b) 4 (c) 3 (d) 2

12. C_7H_8O show how many isomers?
(a) 2 (b) 3 (c) 4 (d) 5

13. Total number of isomeric alcohols with formula $C_4H_{10}O$ are
(a) 1 (b) 2
(c) 3 (d) 4

14. Compounds with following formula will show



$$\text{(i) } CH_3CH_2\underset{\underset{\displaystyle Cl}{|}}{C}HCH_2CH_3 \text{ and (ii) } CH_3CH_2\underset{\underset{\displaystyle CH_3}{|}}{\overset{\overset{\displaystyle Cl}{|}}{C}}-CH_3$$

(a) position and functional isomerism
(b) only chain
(c) chain and functional isomerism
(d) None of the above combinations

15. But-1-ene and cyclobutane exhibit
- (a) ring chain isomerism
- (b) position isomerism
- (c) tautomerism
- (d) functional isomerism

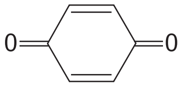
16. The type of isomerism found in urea molecule is
- (a) chain
- (b) position
- (c) tautomerism
- (d) None of these

17. Which pair of isomerism is not possible together?
- (a) Chain and position
- (b) Functional and position
- (c) Tautomerism and functional
- (d) All of the above

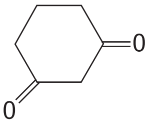
18. Tautomerism is not exhibited by

(a) $C_6H_5-CH=CH-OH$

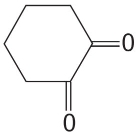
(b)



(c)



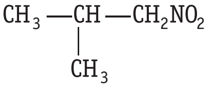
(d)



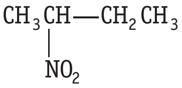
19. The type of isomerism in the molecule of compounds $CH_3CH_2COCH_2CH_3$ and $CH_3CHC(OH)CH_2CH_3$ is referred as
- (a) metamerism
- (b) chain isomerism
- (c) functional isomerism
- (d) tautomerism

20. Which of the following nitroalkane will not show tautomerism?

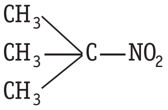
(a) $CH_3CH_2CH_2CH_2NO_2$

(b)


$CH_3-\underset{\underset{CH_3}{|}}{CH}-CH_2NO_2$

(c)


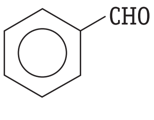
$CH_3\underset{\underset{NO_2}{|}}{CH}-CH_2CH_3$

(d)


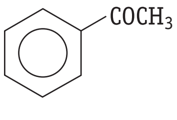
$(CH_3)_3C-NO_2$

21. Which of the following compounds can exhibit tautomerism?

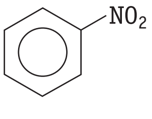
(a)

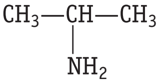


(b)



(c)

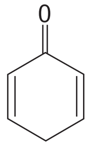


(d)


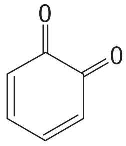
$CH_3-\underset{\underset{NH_2}{|}}{CH}-CH_3$

22. Which of the following has maximum probability of showing tautomerism?

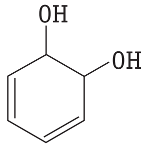
(a)



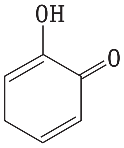
(b)



(c)



(d)



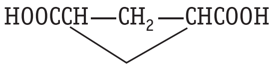
23. Enol form is more stable in
- (a) CH_3CHO
- (b) CH_3COCH_3
- (c) $CH_3COCH_2COOC_2H_5$
- (d) cyclohexanone

24. Keto form is more stable in
- (a) $CH_3COCH_2COOC_2H_5$
- (b) $CH_3COCH_2COCH_3$
- (c) CH_3COCH_3
- (d) $CH_3COCH_2COC_2H_5$

Stereoisomerism

25. Stereoisomers have different
- (a) molecular formula
- (b) structural formula
- (c) configuration
- (d) molecular mass

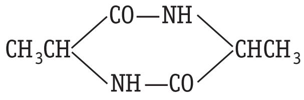
26. Which class of compounds can exhibit geometrical isomerism?
- (a) $C_6H_5CH=NOH$
- (b) $CH_3CH=CHCH_3$
- (c)



$HOOCCH-CH_2-CHCOOH$

- (d) All of the above

27. Which of the following shows geometrical isomerism?
- (a) 1, 2-dichloroethene
- (b) 1,2-dimethylcyclopropane
- (c)



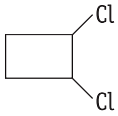
$CH_3CH\langle{}^{CO-NH}_{NH-CO}\rangle CHCH_3$

- (d) All of the above

28. The number of isomers of the compound $C_2FClBrI$ is
- (a) 3
- (b) 4
- (c) 5
- (d) 6

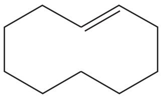
29. Which will form geometrical isomers?

(a)



(b) $CH_3CH=NOH$

(c)



(d) All of these

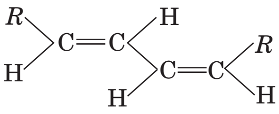
30. In  the double bonds are

(a) *cis, cis* (b) *cis, trans*
(c) *trans, cis* (d) *trans, trans*

31. The '*E*'-isomer is

(a) 
(b) 
(c) 
(d) None of the above

32. Number of geometrical isomers for the molecule



are

(a) 2 (b) 3
(c) 6 (d) 5

33. The property by virtue of which a compound can rotate the plane of polarised light is known as

(a) polarisability (b) phosphorescense
(c) optical activity (d) polarisation

34. Chiral molecules are those which are

(a) superimposable on their mirror images
(b) non-superimposable on their mirror images
(c) unstable molecules
(d) capable of showing geometrical isomerism

35. Racemic modification can be resolved by

(a) the use of enzymes
(b) fractional crystallisation
(c) fractional distillation
(d) None of the above

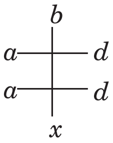
36. Racemic tartaric acid is optically inactive due to

(a) external compensation
(b) internal compensation
(c) presence of plane of symmetry
(d) All of the above

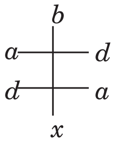
37. (+) and (–) forms of optically active compounds are different in

(a) boiling points
(b) melting points
(c) specific gravity
(d) specific rotation

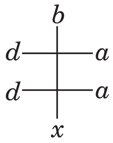
38. Which of the following is/are *threo* isomers?



(i)



(ii)



(iii)

(a) Only (i) (b) Only (ii)
(c) Only (iiii) (d) All (i), (ii) and (iii)

39. Which of the following Fischer projection formula is same as D-glyceraldehyde?

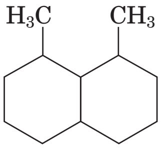
(a) 
(b) 
(c) 
(d) 
40. A compound contains 2 dissimilar asymmetric C-atoms. The number of optical isomers are

(a) 2 (b) 3 (c) 4 (d) 5

41. How many carbon atoms in the molecule HOOC—$(CHOH)_2$—COOH are asymmetric?

(a) 1 (b) 2
(c) 3 (d) None of these

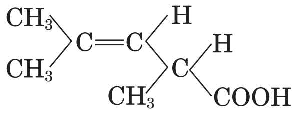
42. Number of chiral centres in



is/are

(a) 1 (b) 2 (c) 3 (d) 4

43. The following compound can exhibits



(a) tautomerism
(b) optical isomerism
(c) geometrical isomerism
(d) geometrical and optical isomerism

44. Which of the following statements is not correct ?

(a) A *meso* compound has chiral centres but exhibits no optical activity
(b) A *meso* compound has no chiral centres and thus is optically inactive
(c) A *meso* compound has molecules in which one half of molecule is superimposable on the other even through chiral centre is present in them
(d) A *meso* compound is optically inactive because the rotation caused by one half of molecule is cancelled by the rotation produced by another half

45. An enantiomerically pure acid is treated with racemic mixture of an alcohol having one chiral carbon. The ester formed will be

(a) optically active mixture
(b) pure enantiomer
(c) *meso* compound
(d) racemic mixture

46. Which of the following will exhibit geometrical isomerism?

(a) Propene
(b) Butene-2
(c) Butene-1
(d) 1,1-dichloro butane

47. During the debromination of *meso*-dibromobutane, the major compound formed will be

(a) *cis*-2-butene
(b) 1-butene
(c) *n*-butane
(d) *trans*-2-butene

48. Which statement is true?

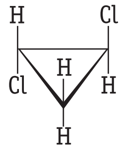
(a) A compound with *R* configuration is the (+) enantiomer
(b) If configuration changes from + to –, that essentially means inversion of configuration takes place
(c) An achiral molecule reacts always with racemic forms, to give a chiral molecule,
(d) By breaking two bonds on the chiral centre configuration changes

49. The terms stereoisomers, enantiomers and diastereomers will refer

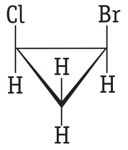
(a) only to configurational isomers including geometrical isomers
(b) only to configurational isomers
(c) to both configurational as well as conformational isomers
(d) to neither configurational nor conformational isomers

50. Which of the following compounds is not optically active?

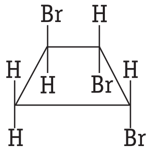
(a)



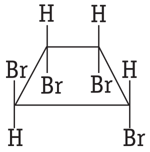
(b)



(c)

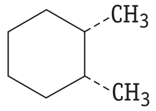


(d)

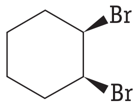


51. Mark the unidentical compound

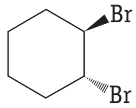
(a)



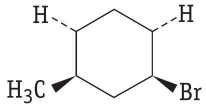
(b)



(c)



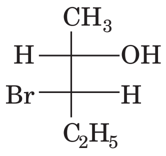
(d)

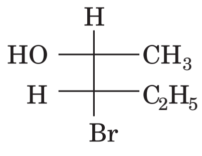


52. The functional groups —OH, —COOH, —CHO, —OCH_3 attached to a chiral carbon is in the preference order

(a) OH > COOH > CHO > OCH_3
(b) OCH_3 > OH > CHO > COOH
(c) OCH_3 > OH > COOH > CHO
(d) OCH_3 > COOH > CHO > OH

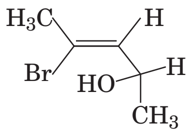
53. The molecules represented by the following two structures are





(a) epimers
(b) diastereomers
(c) enantiomers
(d) identical

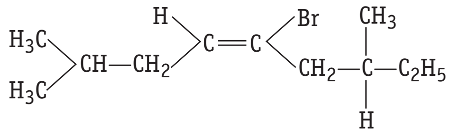
54. The compound, whose stereo chemical formula is written below, exhibits *x*-geometrical isomers and *y*-optical isomers. The value of *x* and *y* are



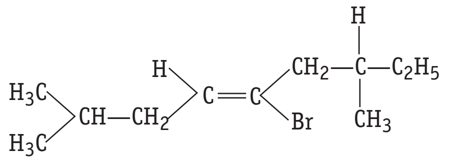
(a) 4 and 4
(b) 2 and 2
(c) 2 and 4
(d) 4 and 2

55. Correct structures of [*E*][*S*]-5-bromo-2,7-dimethyl, non-4-ene is

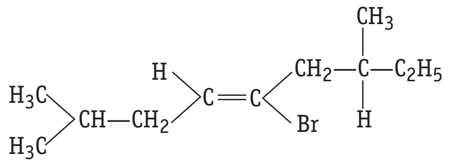
(a)



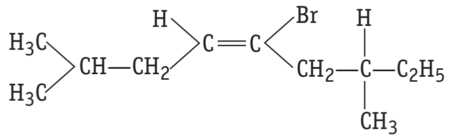
(b)



(c)



(d)



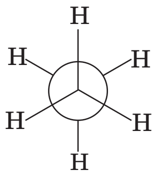
Conformations

56. Incorrect statement is
(a) ethane can have an infinite number of conformations
(b) cyclopropane molecule has considerable angle strain
(c) eclipsed form of ethane is less stable than staggered conformation
(d) staggered conformation possesses maximum energy

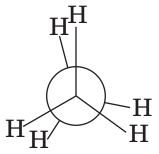
57. The dihedral angle between the two methyl groups in *gauche* conformation of *n*-butane is
(a) 120° (b) 180°
(c) 45° (d) 60°

58. The Baeyer angle strain is minimum in
(a) cyclopropane (b) cyclobutane
(c) cyclopentane (d) cyclohexane

59. Which type of conformation is shown by I and II?



(I)



(II)

(a) I is eclipsed, II is staggered
(b) II is eclipsed, I is staggered
(c) Both are eclipsed
(d) Both are staggered

60. At room temperature the eclipsed and the staggered forms of ethane cannot be isolated because
(a) both the conformers are equally stable
(b) they interconvert rapidly
(c) there is a large energy barrier of rotation about the σ-bond
(d) the energy difference between the conformers is large

61. The most unstable configuration of cyclohexane is
(a) boat (b) chair
(c) twist boat (d) half chair

62. In ethane and cyclohexane which one of the following pairs of conformations are more stable?
(a) Eclipsed and chair conformations
(b) Staggered and chair conformations
(c) Staggered and boat conformations
(d) Eclipsed and boat conformations

63. The most stable configuration of *n* butane will be
(a) skew boat (b) eclipsed
(c) *gauche* (d) staggered-anti

64. The most stable conformation of ethane chlorohydrin at room temperature is
(a) fully eclipsed
(b) partially eclipsed
(c) *gauche*
(d) staggered

65. The correct order of stability of conformations of cyclohexane is
(a) chair > twist boat > boat
(b) twist boat > chair > boat
(c) boat > chair > twist boat
(d) boat > twist boat > chair

66. Which of the following is the correct order of stability of the following four distinct conformation of *n* butane ?
(a) Staggered > *Gauche* > Partially eclipsed > Fully eclipsed
(b) *Gauche* > Staggered > Partially eclipsed > Fully eclipsed
(c) Staggered > Partially eclipsed > *Gauche* > Fully eclipsed
(d) Fully eclipsed > Staggered > Partially eclipsed > *Gauche*

Miscellaneous

67. Which of the following isomerism is shown by ethyl acetoacetate?
(a) Geometrical isomerism
(b) Keto-enol tautomerism
(c) Enantiomerism
(d) Diastereoisomerism

68. Molecular formula $C_5H_{12}O$ will show
(a) position isomerism (b) optical isomerism
(c) functional isomerism (d) All of these

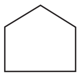
69. False statement is
(a) aprotic solvents increase the enol content in tautomerism
(b) any deviation from the normal bond angles introduces angle strain in molecule
(c) diastereomers have identical physical properties
(d) chain isomers can also be position isomers

Round II (Mixed Bag)

Only One Correct Option

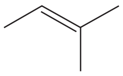
1. Select pair of chain isomers from the following.

(I)



(II)

(III)



(IV)

(a) I and II (b) I and III
(c) I and IV (d) II and III

2. Nitroethane can exhibit one of the following kind of isomerism
(a) metamerism (b) optical activity
(c) tautomerism (d) position isomerism

3. The number of isomeric pentyl alcohols possible is
(a) two (b) four
(c) six (d) eight

4. How many enantiomer pairs are obtained by monochlorination of 2,3-dimethyl butane?
(a) Four (b) Two (c) Three (d) One

5. Consider the following statements

I. Chain and position isomerism are not possible together between two isomers.
II. Tautomerism is a chemical phenomenon which is catalysed by acid as well as base.
III. Tautomers are always metamers.
IV. Tautomers are always functional isomers.

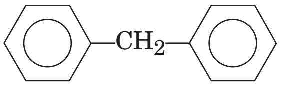
Select the correct answer by using the codes given below.
(a) only III is correct (b) III and IV are correct
(c) I, II and III are correct (d) I ,II and IV are correct

6. Increasing order of expected enol contentis
(a) $CH_3COCH_2CHO > CH_3COCH_3 > CH_3CHO > CH_3COCH_2COCH_3$
(b) $CH_3COCH_2COCH_3 > CH_3COCH_2CHO > CH_3COCH_3 > CH_3CHO$
(c) $CH_3CHO > CH_3COCH_3 > CH_3COCH_2CHO > CH_3COCH_2COCH_3$
(d) $CH_3COCH_3 > CH_3COCH_2COCH_3 > CH_3CHO > CH_3COCH_2CHO$

7. Increasing order of expected keto content
(a) $CH_3COC_2H_5 > CH_3CHO > CH_3COCH_3 > CH_3COCH_2COCH_3$
(b) $CH_3COCH_3 > CH_3CHO > CH_3COC_2H_5 > CH_3COCH_2COCH_3$
(c) $CH_3CHO > CH_3COC_2H_5 > CH_3COCH_3 > CH_3COCH_2COCH_3$
(d) $CH_3COCH_2COCH_3 > CH_3CHO > CH_3COCH_3 > CH_3COC_2H_5$

8. *Meso*-tartaric acid is optically inactive due to the presence of
(a) molecular symmetry
(b) molecular asymmetry
(c) external compensation
(d) two asymmetric C-atoms

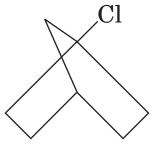
9. The molecular formula of diphenyl methane.



is $C_{13}H_{12}$.

How many structural isomers are possible when one of the hydrogen is replaced by a chlorine atom?
(a) 8 (b) 7
(c) 6 (d) 4

10. The number of chiral carbon atoms present in the molecule

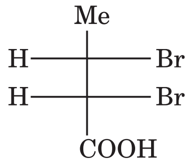


is

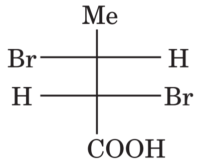
(a) 3 (b) 4
(c) 2 (d) 1

11. Which of the following are diastereomers?

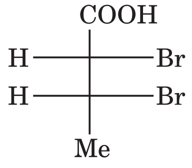
I.



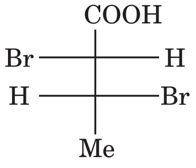
II.



III.



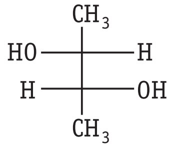
IV.



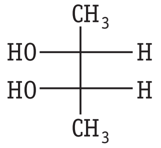
(a) (I) and (III) (b) (II) and (IV)
(c) (I) and (II) (d) None of these

12. Which of the following pairs of compounds are enantiomers?

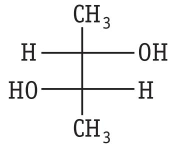
(a)



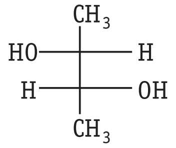
and



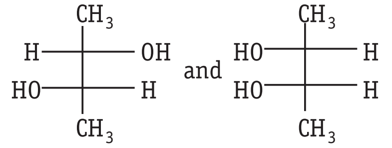
(b)



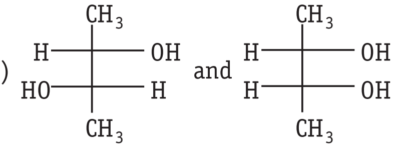
and



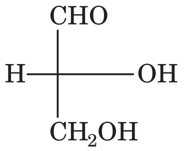
(c)



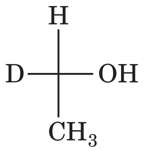
(d)



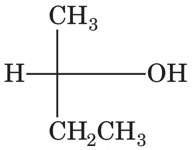
13. The *R*-isomer among the following are



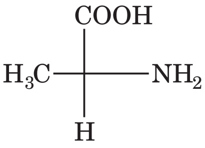
(i)



(ii)



(iii)



(iv)

(a) (i) and (ii) (b) (ii) and (iii)

(c) (iii) and (iv) (d) (i) and (iii)

14. 
Five compounds with formula $C_4H_8Br_2$.

How many structures of (*X*) are possible?

(a) 2 (b) 3 (c) 4 (d) 5

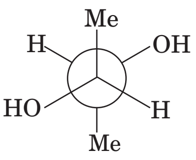
15. Which statement is true for cyclohexane?

(a) It has two possible isomers
(b) It has three conformations
(c) Boat conformation is most stable
(d) Chair and boat conformations differ in energy by 44 kJ/mol

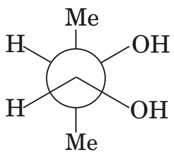
16. The number of structural and configurational isomers of a bromo compound C_5H_9Br obtained by the addition of HBr on 2-pentyne respectively are

(a) 1, 2 (b) 2, 4 (c) 4, 2 (d) 2, 1

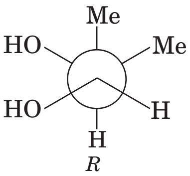
17. Among the following the Newmann projections of *meso*-2,3-butanediol are



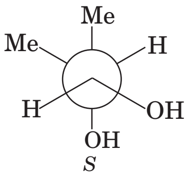
P



Q



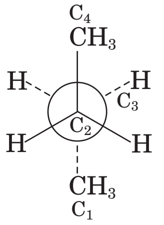
R



S

(a) *P, Q* (b) *P, R*
(c) *R, S* (d) *Q, S*

18. In the given conformation C_2 is rotated about C_2 — C_3 bond anticlockwise by an angle of 120° then the conformation obtained is



(a) fully eclipsed conformation
(b) partially eclipsed conformation
(c) *gauche* conformation
(d) staggered conformation

19. The correct order of stability of conformations of $NH_2—CH_2—CH_2—OH$ is

(a) *gauche* > eclipsed > anti
(b) *gauche* > anti > eclipsed
(c) eclipsed > *gauche* > anti
(d) anti > eclipsed > *gauche*

20. Which of the following statements is/are wrong about the more stability of chair form than boat form?

(a) In chair conformation, all the (C—H) bonds in adjacent carbons are in the skew position.
(b) In boat conformation, there are four skew interactions and two eclipsed interactions.
(c) In boat conformation, there is steric repulsion between two flag poles.
(d) In boat conformation, there are three skew interaction and three eclipsed interactions.

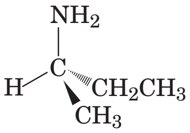
21. Which will give chiral molecule?

(a) $CH_3COCl \xrightarrow{LiAlH_4}$

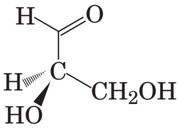
(b) $C_2H_5CHO \xrightarrow[H^+/H_2O]{CH_3MgBr}$

(c) $(CH_3)_2CHC_2H_5 \xrightarrow{Cu}$

(d) 
22. Consider the following structures and choose the correct statements.



I



II

III

(a) I and II have *R*-configuration
(b) I and III have *R*-configuration
(c) Only III has *S*-configuration
(d) Both (a) and (c) are correct

23. Configuration of  and  are

(a) *R, R* (b) *R, S*
(c) *S, S* (d) *S, R*

24. The specific rotation of a pure enantiomer is + 16°. Its observed rotation if it is isolated from a reaction with 25% racemisation and 75% retention is

(a) −12° (b) +12°
(c) +16° (d) −16°

25. An organic compound contains 66% C and 13.3% H. Its vapour density is 37. The possible number of isomers of all types for the compound is

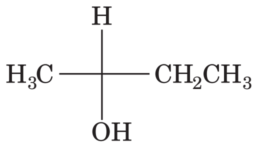
(a) 6 (b) 7
(c) 5 (d) 8

More than One Correct Option

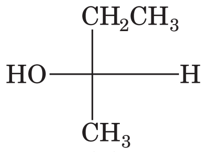
26. Which of the following statements are not correct?

(a) A *meso* compound is optically active because the rotation caused by any molecule is cancelled by an equal and opposite rotation caused by another molecules that is the mirror image of the first
(b) A *meso* compound has chiral centres but exhibits no optical activity
(c) A *meso* compound has no chiral centres and thus exhibits no optical activity
(d) A *meso* compound has molecules which are superimposable on their mirror image even though they contain chiral centres

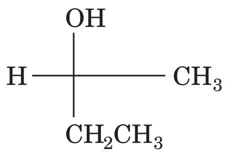
27. Consider the following compounds and choose the correct statement.



(I)



(II)



(III)

(a) structure (I) and (II) are identical
(b) all are identical
(c) structure (I) and (III) are identical
(d) structure (I) and (III) are different

28. The Fischer-projection of the molecule as represented in the wedge formula,  is/are not

(a)  (b) 
(c)  (d) 
29. Which is/are optically active?

(a) 
(b) 
(c) $CH_3-\underset{\underset{D}{|}}{CH}-COOH$

(d) 
Assertion and Reason

Directions (Q. Nos 30 to 34) *Each of these questions contains two statements : Statement* I (*Assertion*) *and Statement* II (*Reason*). *Each of these questions also has four alternative choices, only one of which is the correct answer. You have to select one of the codes* (*a*), (*b*), (*c*), (*d*) *given below :*

(a) Statement I is true; Statement II is true; Statement II is a correct explanation for Statement I.
(b) Statement I is true; Statement II is true; Statement II is not a correct explanation for Statement I.
(c) Statement I is true; Statement II is false.
(d) Statement I is false; Statement II is true.

30. **Statement I** Staggered form is less stable than the eclipsed form.

Statement II The conformation in which the bond pairs of two central atoms are very far from one another is called staggered form.

31. **Statement I** The conversion of an optically active compound into its enantiomer is called Walden inversion.

Statement II A racemic mixture is optically inactive due to internal compensation.

32. **Statement I** In keto-enol tautomerism of dicarbonyl compounds, the enol form is preferred in contrast to the keto form.

Statement II The enol form is more stable due to resonance.

33. **Statement I** A compound whose molecule has D configuration will always be dextrorotatory.

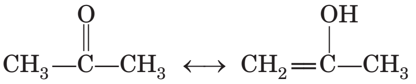
Statement II Compounds having D configuration may be dextrorotatory or levorotatory.

34. **Statement I** $CH_3—CH(Cl)OH$ is a optically active compound.

Statement II Dissymmetry arises in a chemical compound owing to the presence of chiral centre.

Comprehension Based Questions

Directions (Q. Nos 35 to 37) Tautomerism is the phenomenon in which two structural isomers differing in the relative positions of their atoms are spontaneously interconvertable and can exist in dynamic equilibrium. The two forms in tautomeric equilibrium are called tautomers of each other. The interconvertibility of tautomers is a chemical reaction which involves making and breaking of bonds. Tautomers are true isomers, and either of the individual tautomeric forms may be isolated.



$$CH_3—\overset{\overset{\displaystyle O}{\|}}{C}—CH_3 \longleftrightarrow CH_2{=}\overset{\overset{\displaystyle OH}{|}}{C}—CH_3$$

35. In the keto-enol tautomerism of dicarbonyl compounds the enol form is preferred in contrast to the keto form, this is due to
(a) rapid chemical exchange
(b) group rearrangement
(c) presence of carbonyl group on each side of the chain
(d) resonance stabilization of enol form

36. Keto-enol isomerism is exhibited by
(a) acetone
(b) benzaldehyde
(c) benzene
(d) formaldehyde

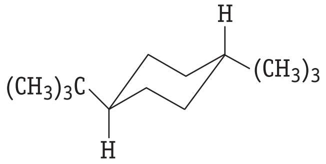
37. Acetophenone can exhibit
(a) functional isomerism
(b) chain isomerism
(c) tautomerism
(d) chain and position isomerism

Directions (Q. Nos 38 to 40) Stability of cycloalkanes can be explained on the basis of Baeyer strain theory. This theory is applicable only for cyclopropane, cyclobutane and cyclopentane. Stability of cyclohexane and its derivative can be explained by Mohr's theory. According to this theory cyclohexane exists in two forms chair and boat. The chair form is more stable than the boat form. Every carbon of chair form has an axial and equatorial bonds. Bulky groups are generally present at equatorial position. The preferred conformation of cyclohexane ring is the chain form, but when intramolecular hydrogen bonding is possible between the group 1 and 4 positions, the molecule assume a boat form.

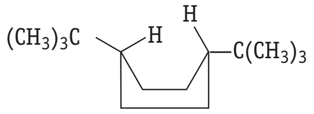
38. According to Baeyer strain theory which cycloalkane is the most stable?
(a) Cyclohexane (b) Cyclopentane
(c) Cyclopropane (d) Cyclobutane

39. Which of the following is most stable conformer of 1,4-ditert butylcyclohexane?

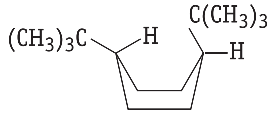
(a)



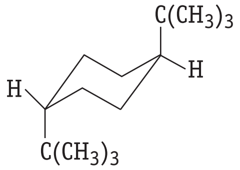
(b)



(c)

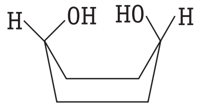


(d)

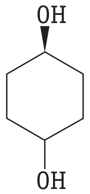


40. Which form of *trans*-1,4-cyclohexanediol is most stable?

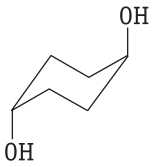
(a)



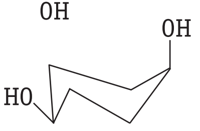
(b)



(c)



(d)



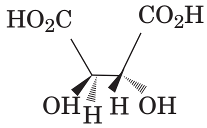
Previous Years' Questions

41. Identify the compound that exhibits tautomerism [AIEEE 2011]
(a) 2-butene (b) lactic acid
(c) 2-pentanone (d) phenol

42. Out of the following, the alkene that exhibits optical isomerism is [AIEEE 2010]
(a) 3-methyl-2-pentene (b) 4-methyl-1-pentene
(c) 3-methyl-1-pentene (d) 2-methyl-2-pentene

43. The alkene that exhibits geometrical isomerism is [AIEEE 2009]
(a) propene (b) 2-methyl propene
(c) 2-butene (d) 2-methyl-2-butene

44. The absolute configuration of



is

[AIEEE 2008]
(a) *S, S* (b) *R, R* (c) *R, S* (d) *S, R*

45. Which one of the following conformations of cyclohexane is chiral? [AIEEE 2007]
(a) Twist boat (b) Rigid (c) Chair (d) Boat

46. Which of the following molecules is expected to rotate the plane of polarised light ? [AIEEE 2007]

(a) $$\begin{array}{ccc} & CHO & \\ HO & \text{—} & H \\ & CH_2OH & \end{array}$$

(b) 
(c) 
(d) $$\begin{array}{ccc} & COOH & \\ H_2N & \text{—} & H \\ & H & \end{array}$$

47. Increasing order of stability among the three main conformations (*i.e.*, Eclipse, Anti, *Gauche*) of 2-flouro ethanol is [AIEEE 2006]
(a) eclipes, *gauche*, anti (b) *gauche*, eclipse, anti
(c) eclipes, anti, *gauche* (d) anti, *gauche*, eclipse

48. Which types of isomerism is shown by 2,3-dichlorobutane? [AIEEE 2005]
(a) Structural (b) Geometric
(c) Optical (d) Diastereo

49. For which of the following parameters the structural isomers C_2H_5OH and CH_3OCH_3 would be expected to have the same values? (Assume ideal behaviour) [AIEEE 2004]
(a) Heat of vaporisation
(b) Vapour pressure at the same temperature
(c) Boiling points
(d) Gaseous densities at the same temperature and pressure

50. Which of the following compounds is not chiral? [AIEEE 2004]
(a) 1-chloropentane
(b) 2-chloropentane
(c) 1-chloro-2-methyl pentane
(d) 3-chloro-2-methyl pentane

51. Amongst the following compounds, the optically active alkane having lowest molecular mass is [AIEEE 2004]

(a) $CH_3CH_2—CH_2CH_3$

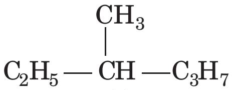
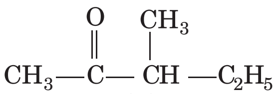
(b) $$CH_3CH_2—\overset{\displaystyle CH_3}{\overset{|}{CH}}—CH_3$$

(c) 
(d) $CH_3—CH_2—C\equiv CH$

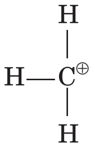
52. Among the following four structures I to IV



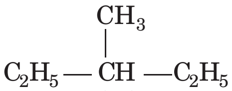
$$C_2H_5—\overset{\displaystyle CH_3}{\overset{|}{CH}}—C_3H_7$$
(I)



$$CH_3—\overset{\displaystyle O}{\overset{\|}{C}}—\overset{\displaystyle CH_3}{\overset{|}{CH}}—C_2H_5$$
(II)



$$H—\overset{\displaystyle H}{\overset{|}{\underset{\displaystyle H}{\underset{|}{C^{\oplus}}}}}$$
(III)



$$C_2H_5—\overset{\displaystyle CH_3}{\overset{|}{CH}}—C_2H_5$$
(IV)

it is true that [AIEEE 2003]
(a) all four are chiral compounds
(b) only I and II are chiral compounds
(c) only III is a chiral compound
(d) only II and IV are chiral compounds

53. Following types of compounds (as I, II)

(I) $CH_3CH = CHCH_3$ (II) $$CH_3—\underset{\displaystyle CH_2CH_3}{\underset{|}{CH}}—OH$$

are studied in terms of isomerism in [AIEEE 2002]
(a) chain isomerism (b) position isomerism
(c) conformers (d) stereoisomerism

54. Racemic mixture is formed by mixing two [AIEEE 2002]
(a) isomeric compounds
(b) chiral compounds
(c) *meso* compounds
(d) enantiomers with chiral carbon

55. Geometrical isomerism is not shown by [AIEEE 2002]
(a) 1, 1-dichloro-1-pentene
(b) 1, 2-dichloro-1-pentene
(c) 1, 3-dichloro-2-pentene
(d) 1, 4-dichloro-2-pentene

the Guidance

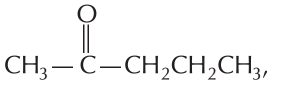
Round I

4. Butan-2-one  $CH_3-\overset{\overset{O}{\|}}{C}-CH_2-CH_3$ is not isomeric with diethyl ether $CH_3CH_2-O-CH_2-CH_3$. Because both are differing in molecular formula.

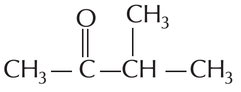
5. But-2-ene and but-1-yne do not have same molecular formula, thus are not isomers.

$CH_3-CH_2-C\equiv CH$ but-1-yne (C_4H_6) $\quad CH_3-CH=CH-CH_3$ but-2-ene (C_4H_8)

7. $CH_3COC_3H_7$ can exhibit metamerism.

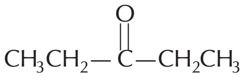


$CH_3-\overset{\overset{O}{\|}}{C}-CH_2CH_2CH_3$,



$CH_3-\overset{\overset{O}{\|}}{C}-\overset{\overset{CH_3}{|}}{CH}-CH_3$

and



$CH_3CH_2-\overset{\overset{O}{\|}}{C}-CH_2CH_3$

8. Alkanes are saturated hydrocarbons without any functional group, hence can show chain isomerism only.

9. (i)  $H-\underset{\underset{H}{|}}{\overset{\overset{H}{|}}{C}}-\underset{\underset{Cl}{|}}{\overset{\overset{H}{|}}{C}}-Cl$ (1,1-dichloro ethane)

(ii)  $H-\underset{\underset{Cl}{|}}{\overset{\overset{H}{|}}{C}}-\underset{\underset{Cl}{|}}{\overset{\overset{H}{|}}{C}}-H$ (1,2-dichloro ethane)

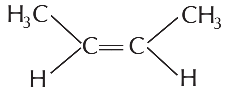
Both are position isomers.

10. Except alkynes, chain isomerism is observed when the number of carbon atoms is four or more than four.

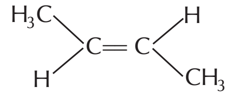
11. The following isomers the alkene have

(i) $CH_3-CH_2-CH=CH_2$ (ii) $CH_3-CH=CH-CH_3$

(iii)

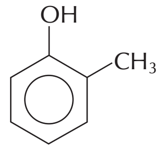


(iv)

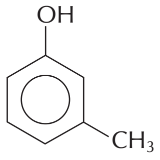


(v)  $CH_3-\overset{\overset{CH_3}{|}}{C}=CH_2$

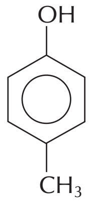
12. (i)



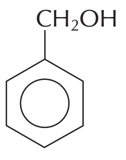
(ii)



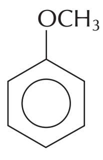
(iii)



(iv)



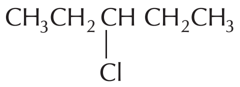
(v)



13. (i) $CH_3CH_2CH_2CH_2OH$ (ii)  $CH_3CH_2-\underset{\underset{OH}{|}}{CH}-CH_3$

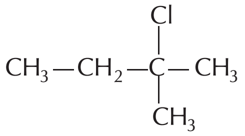
(iii)  $CH_3-\overset{\overset{CH_3}{|}}{CH}-CH_2OH$ (iv)  $CH_3-\underset{\underset{CH_3}{|}}{\overset{\overset{CH_3}{|}}{C}}-OH$

14. Isomeric substances that differ only in the arrangement of carbon atoms forming the base chain are known as chain isomers.



$CH_3CH_2\underset{\underset{Cl}{|}}{CH}CH_2CH_3$

and



$CH_3-CH_2-\overset{\overset{Cl}{|}}{\underset{\underset{CH_3}{|}}{C}}-CH_3$

15. $CH_3-CH_2-CH=CH_2$ and

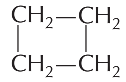


exhibit ring chain isomerism.

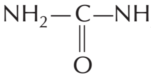
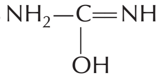
16. Urea,



$NH_2-\underset{\underset{O}{||}}{C}-NH_2$ shows tautomerism as



$NH_2-\underset{\underset{OH}{|}}{C}=NH$

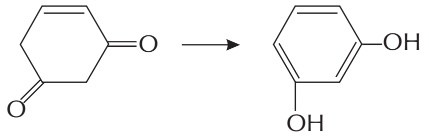
17. Tautomerism and functional isomerism is not possible together.

18. (a) shows tautomerism since aldehydes are more stable than vinyl alcohols.

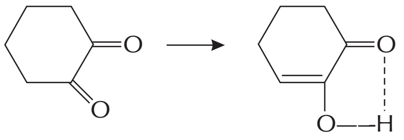
$C_6H_5-CH=CHOH \longleftrightarrow C_6H_5CH_2CH=O$

(b) does not show tautomerism because it does not have hydrogens at α-positions.

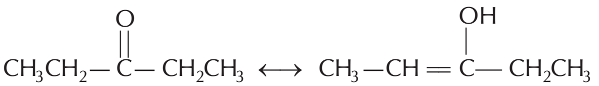
(c) shows tautomerism because enol form is stabilized by aromatic character



(d) shows tautomerism because enol form is stabilized by H-bonding.



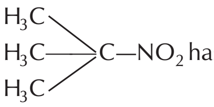
19.



$CH_3CH_2-\overset{\overset{O}{||}}{C}-CH_2CH_3 \longleftrightarrow CH_3-CH=\overset{\overset{OH}{|}}{C}-CH_2CH_3$

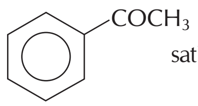
(keto form) (enol form)

20.



$(H_3C)_3C-NO_2$ has no α-hydrogen. Hence, it will not show tautomerism.

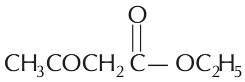
21. Presence of α –H atom along with a multi bonded functional group is an essential condition for exhibiting tautomerism.



satisfies this condition, so exhibits tautomerism.

23. The stabilising effect of enolic form is the intramolecular hydrogen bond present in enols. This provides another source of increasing bonding and hence, increased stabilisation.

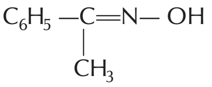
Thus,



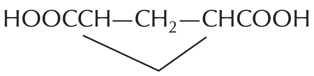
$CH_3COCH_2\overset{\overset{O}{||}}{C}-OC_2H_5$ is more stable.

24. $C=O$ double bond of a carbonyl group is a stronger bond ($>C=O$, 364 kJ/mol) than the $C=C$ bond (strength 250 kJ/mol) of the enol. Thus, CH_3COCH_3 is more stable.

26. All the compounds in which there should be restricted rotation about a bond in the molecule, show geometrical isomerism. Oximes of the type $R-CH=N-OH$,



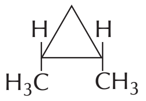
$C_6H_5-\underset{\underset{CH_3}{|}}{C}=N-OH$ and cyclic compound like



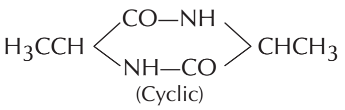
HOOCCH—CH₂—CHCOOH show geometrical isomerism.

27. Disubstituted cyclic compounds and disubstituted alkenes show geometrical isomerism.

(Non-cyclic, but have ═bond so exhibits geometrical isomerism).

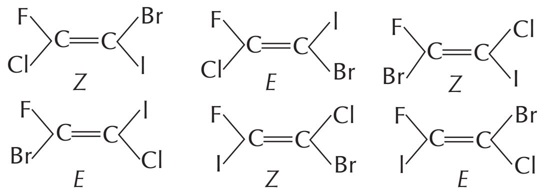


(Cyclic, two different groups at adjacent positions, so exhibits geometrical isomerism).

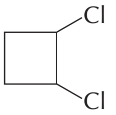


(Cyclic)

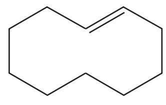
28.



29. The isomerism which arises due to restricted rotation about a bond in a molecule is known as geometrical isomerism.

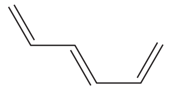


, $CH_3-CH=NOH$ and



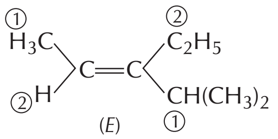
All of these form geometrical isomers.

30. In



the double bonds are *trans* and *cis*. The first and third bonds are identical

31. If the highest priority groups of two carbon atoms of the double bond are on the opposite sides, the configuration is *E*. (*Entgegen*).



(*E*)

32. When n = even number then for two identical ends, number of geometrical isomers

$$= 2^{n-1} + 2^{n/2-1}$$
$$= 2^1 + 2^0 = 3$$

35. The separation of racemic mixture back into *d* and *l* isomers is known as resolution. It can be done by

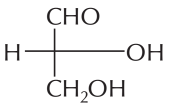
(I) mechanical method
(II) bio-chemical method using enzymes
(III) chemical method (salt formation).

36. Racemic tartaric acid is optically inactive due to external compensation. Racemic tartaric acid is an equimolar mixture of optically active *d*- and *l*- forms.

37. If a substance rotates the plane polarised light in clockwise direction, it is dextrorotatory (+). If it rotates the plane polarised light in anticlockwise direction then it is laevorotatory (–). Thus + / – form differ in specific rotation.

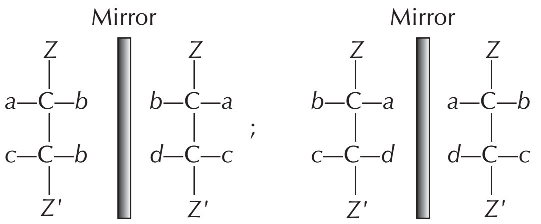
38. The prefixes *erythro* and *threo* are used in systems containing two asymmetric carbons when two of the groups are the same and the third is different. The *erythro-isomer* has identical groups on the same side when drawn in Fischer projection and *threo*-isomer has them on opposite side.

39. The configuration in the Fischer projection of which —OH group is on right hand side, H-atom is on left hand side, —CHO group is on upper side and CH_2OH is on lower side is known as D-configuration.



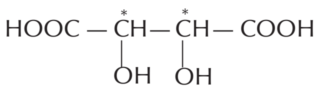
D-glyceraldehyde

40. The minimum possible isomers of compounds will be



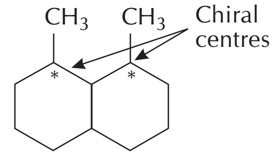
Alternative No. of optical isomers = $Z^n = 2^2 = 4$,
here n = No. of dissimilar asymmetric C-atoms.

41. A carbon atom which is attached to four different group is called an asymmetric carbon atom or chiral centre. $HOOC(CHOH)_2COOH$ has two asymmetric carbon (C^*) atoms.



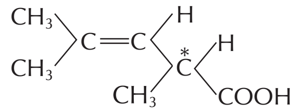
$$HOOC-\underset{OH}{\underset{|}{\overset{*}{C}H}}-\underset{OH}{\underset{|}{\overset{*}{C}H}}-COOH$$

42.



(* asymmetric C atom)

43.



The above compound has chiral centre.

Hence, it can exhibit optical isomerism while geometrical isomerism is not possible due to the presence of identical groups on double bonded carbon atoms.

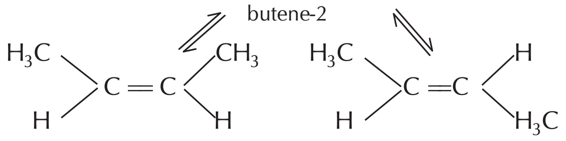
44. Compounds which do not show optical activity inspite of the presence of chiral carbon atoms are called *meso*-compounds.

45. If an enantiomerically pure acid is treated with racemic mixture of an alcohol having chiral carbon, the product formed will be optically active mixture.

46. Butene-2 exhibits geometrical (*cis*, *trans*) isomerism

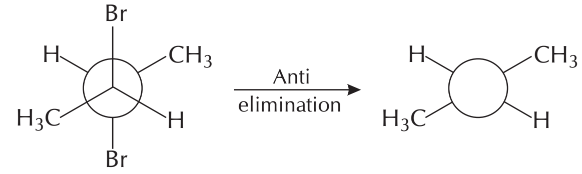
$$CH_3-CH=CH-CH_3$$

butene-2



cis-isomer *trans*-isomer

47. During debromination, *meso*-dibromobutane forms *trans*-2-butene.



meso-2,3-dibromobutane *trans*-2-butene

48. We know that by breaking two bond on the chiral centre configuration changes.

50. The compound  is symmetrical with respect to centre of the molecule.

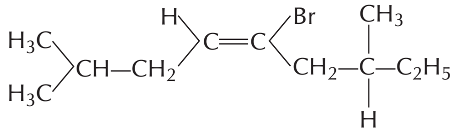
51. Compound given in option (c) is *trans* while all other have *cis* configuration.

52. If two atoms directly attached to the double bond have the same atomic number, then the relative priority of the groups is determined by a similar comparison of the atomic numbers of the next elements in the groups. Thus, the preference order of given group is

$$OCH_3 > OH > COOH > CHO$$

54. Compound  has one chiral carbon atom and one double bond thus, it has two geometrical (*cis* and *trans*) and two optical isomers.

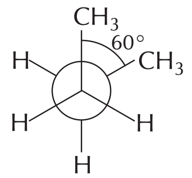
55.



[*E*][*S*]-5-bromo-2,7-dimethylnon-4-ene

56. Staggered conformation is most stable due to its minimum energy.

57. The dihedral angle is 60°.



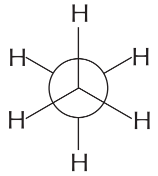
gauche conformation

58. Cyclopentane posses 0° 44′ angle strain which is minimum.

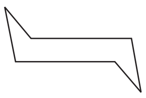
60. Staggered and eclipsed conformers cannot be physically separated because energy difference between them is so small that they most readily interconvert at room temperature.

61. Half chair is transition state conformation between the chair and boat conformations. The energy difference between the chair and half chair conformation being 44 kJ mol^{-1}. Hence, it is most unstable.

62. In ethane and cyclohexane, staggered and chair forms are more stable respectively.

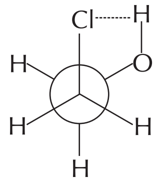


staggered form of ethane



chair form of cyclohexane

64.

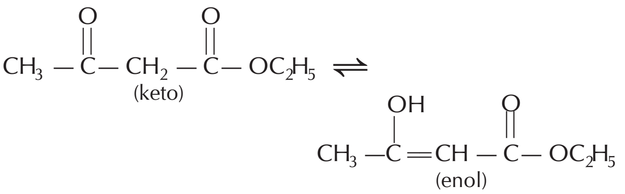


The *gauche* conformation is most stable due to the presence of H-bonding between H atom of OH and Cl.

65. The stability order of conformations of cyclohexane is

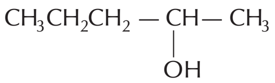
Chair > twist boat > boat

67.



$$\underset{\text{(keto)}}{CH_3-\overset{O}{\overset{\|}{C}}-CH_2-\overset{O}{\overset{\|}{C}}-OC_2H_5} \rightleftharpoons \underset{\text{(enol)}}{CH_3-\overset{OH}{\overset{|}{C}}=CH-\overset{O}{\overset{\|}{C}}-OC_2H_5}$$

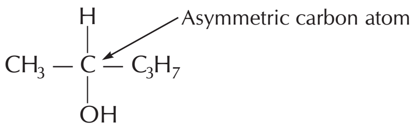
68. (i) $CH_3CH_2CH_2CH_2CH_2OH$ and



$CH_3CH_2CH_2-\underset{OH}{\underset{|}{CH}}-CH_3$

are position isomers.

(ii)



$CH_3-\underset{OH}{\underset{|}{\overset{H}{\overset{|}{C}}}}-C_3H_7$

Due to the presence of asymmetric carbon atom, optical isomerism is possible.

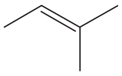
(iii) $CH_3CH_2CH_2CH_2CH_2OH$ and $CH_3CH_2OCH_2CH_2CH_3$ are functional isomerisms.

69. Diastereomers have different physical properties such as mp, bp solubilities etc.

Round II

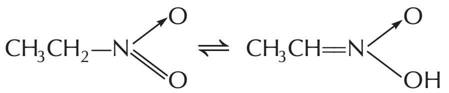
1.

and



are chain isomers.

2. Nitroethane exhibits tautomerism.



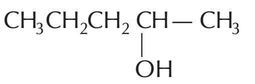
$$CH_3CH_2-N\overset{\nearrow O}{\underset{\searrow O}{}} \rightleftharpoons CH_3CH=N\overset{\nearrow O}{\underset{\searrow OH}{}}$$

nitro form aci form

3. The number of possible isomeric pentyl alcohols is eight which are as

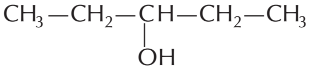
(i) $CH_3CH_2CH_2CH_2CH_2OH$ *n*-pentanol

(ii)



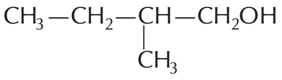
$CH_3CH_2CH_2\underset{OH}{\underset{|}{CH}}-CH_3$ 2-pentanol

(iii)



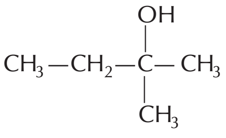
$CH_3-CH_2-\underset{OH}{\underset{|}{CH}}-CH_2-CH_3$ 3-pentanol

(iv)



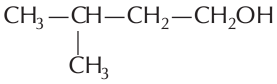
$CH_3-CH_2-\underset{CH_3}{\underset{|}{CH}}-CH_2OH$ 2-methyl butanol

(v)



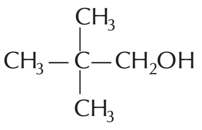
$CH_3-CH_2-\underset{CH_3}{\underset{|}{\overset{OH}{\overset{|}{C}}}}-CH_3$ 2-methyl butan-2-ol

(vi)



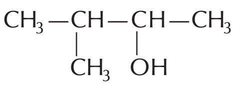
$CH_3-\underset{CH_3}{\underset{|}{CH}}-CH_2-CH_2OH$ 3-methyl butanol

(vii)



$CH_3-\underset{CH_3}{\underset{|}{\overset{CH_3}{\overset{|}{C}}}}-CH_2OH$ 2,2-dimethyl propanol

(viii)



$CH_3-\underset{CH_3}{\underset{|}{CH}}-\underset{OH}{\underset{|}{CH}}-CH_3$ 3-methyl butan-2-ol

4. 
$$CH_3-\underset{CH_3}{CH}-\underset{CH_3}{CH}-CH_3 + Cl_2 \longrightarrow CH_3-\underset{CH_3}{CH}-\underset{CH_3}{\overset{*}{CH}}-CH_2Cl$$

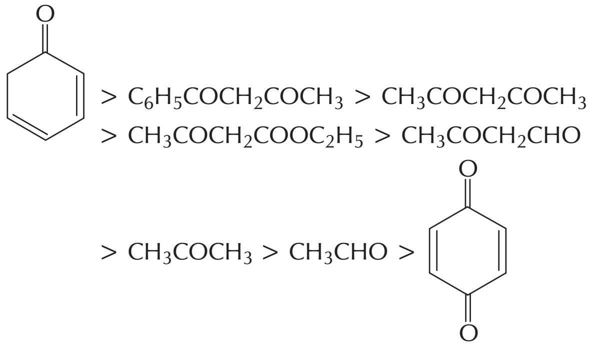
2,3-dimethyl butane 1-chloro-2,3-dimethyl butane

Due to the presence of chiral centre it shows optical activity and its mirror image are non-superimposable hence it shows one enantiomer pair.

$$CH_3-\underset{CH_3}{CH}-\underset{CH_3}{CH}-CH_2Cl \quad \Big\| \quad ClCH_2-\underset{CH_3}{CH}-\underset{CH_3}{CH}-CH_3$$

5. Tautomers may or may not be metamers. These are infact functional isomers. Tautomerism is catalysed by acid as well as base. Chain and position isomerism do not exist together.

6. The percentage of enolic contents of some common compounds in decreasing order will be



$> C_6H_5COCH_2COCH_3 > CH_3COCH_2COCH_3 > CH_3COCH_2COOC_2H_5 > CH_3COCH_2CHO > CH_3COCH_3 > CH_3CHO >$

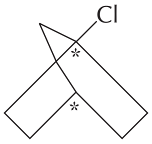
7. The reverse of enolic contents of compound is ketonic contents. Thus, the correct order of ketonic contents are

$CH_3CHO > CH_3COC_2H_5 > CH_3COCH_3 > CH_3COCH_2COCH_3$

8. 
Meso tartaric acid is optically inactive due to the presence of molecular symmetry. It is optically inactive due to internal compensation, *i.e.,* the effect of one half of the molecule is neutralised by other.

9. Four structural isomers are possible for diphenyl methane when one H-atom is replaced by a Cl-atom.

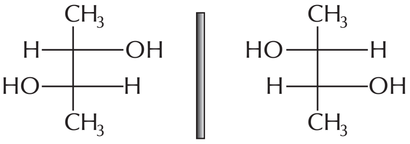
(I) 
(II) 
(III) 
(IV) 
10. Carbon bonded with four different groups is known as chiral carbon atom. In case of given compound



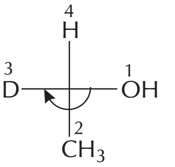
the number of chiral carbon atoms are two.

11. Superimposable compounds which are also not the mirror images of each other are called diastereomers. Thus I and II are diastereomers.

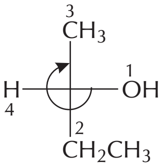
12. Optical isomers of a compound which are non-superimposable but releated to each other as an object and its mirror image are called enantiomers.



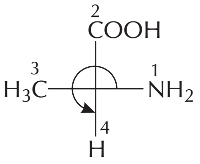
13. 
(i)
R



(ii)
R



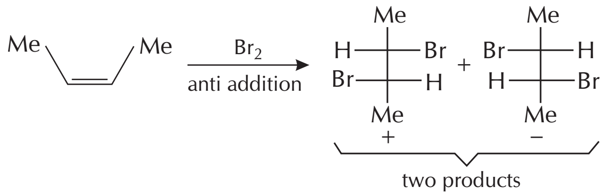
(iii)
S

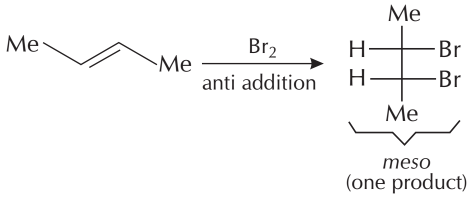


(iv)
S

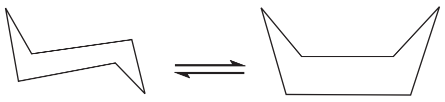
Note If H is on vertical line *R* represents clockwise and *S* represents anticlock wise rotation. Opposite is true when H or lower priority group is present on horizontal line.

14. 



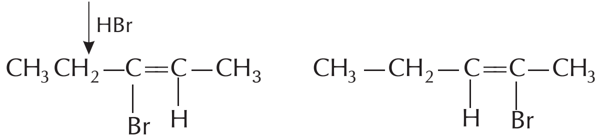


15. Chair and boat conformations of cyclohexane differ in energy by 44 kJ/mol.



chair form boat form

16. $CH_3CH_2—C\equiv C—CH_3$
2-pentyne



$CH_3CH_2—\underset{Br}{C}=\underset{H}{C}—CH_3$ $CH_3—CH_2—\underset{H}{C}=\underset{Br}{C}—CH_3$

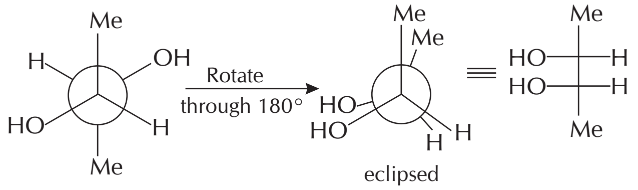
3-bromopent-2-ene
E, Z

2-bromopent-2-ene
E, Z

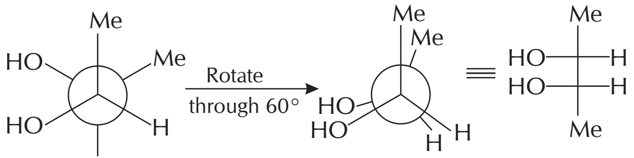
Structural isomers (position) = 2

Stereo isomers = 4

17.



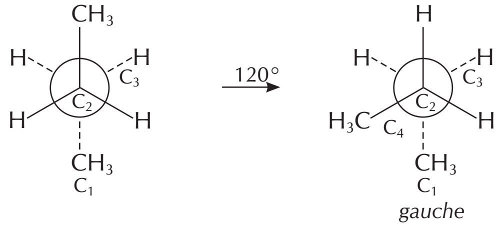
P eclipsed



R eclipsed *meso*

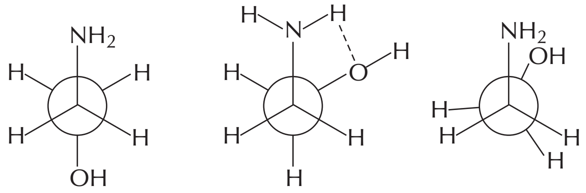
Here, *P* and *R* represent *meso*-compound.

18.



gauche conformation

19.

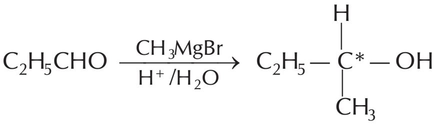


Anti *Gauche* Eclipsed

So, *gauche* form stabilized by intermolecular hydrogen bonding hence, is more stable than anti.

20. In boat conformation, there are four skew interactions and two eclipsed interactions. That's why it is less stable.

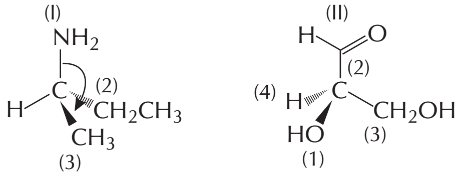
21.



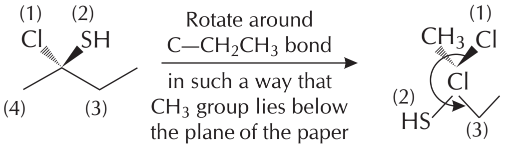
$C_2H_5CHO \xrightarrow[H^+/H_2O]{CH_3MgBr} C_2H_5—\overset{H}{\underset{CH_3}{C^*}}—OH$

(For these reactions read successive chapters.)

22.

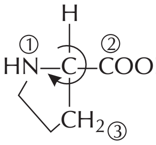


R-configuration *R*-configuration

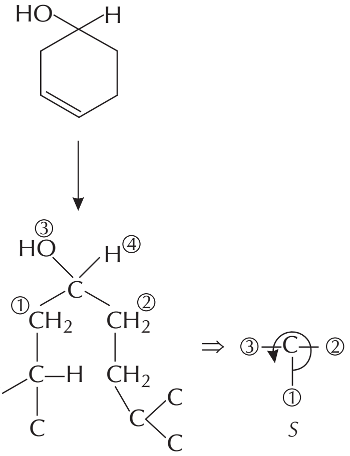


III *S*-configuration

23. Compounds in which the chiral centre is a part of the ring are handed in a analogous fashion.



R



24. % enantiomeric excess

$$= \frac{\text{observed specific rotation}}{\text{specific rotation of pure enantiomer}} \times 100$$

$$\text{Observed specific rotation} = \frac{3/4}{100} \times (+16°) \times 100$$

$$= +12°.$$

25.

Element	Percentage	At. mass	Molar ratio	Simple molar ratio
C	66%	12	$\frac{66}{12}=5.5$	4.25≈4
H	13.3%	1	$\frac{13.3}{1}=13.3$	10.3 =10
O	100–66–1 3.3 =20.7%	16	$\frac{20.7}{16}=1.29$	1 – 1

Hence, its empirical formula is $C_4H_{10}O$.

Molecular formula $=(\text{Empirical formula})_n$

$$=(C_4H_{10}O)_n$$

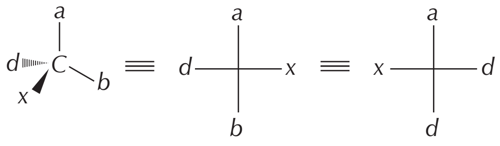
$$n=\frac{\text{emp. formula mass}}{2\times \text{VD}}=\frac{48+10+16}{2\times 37}=\frac{74}{74}=1$$

Hence, molecular formula is $C_4H_{10}O$.

Thus, this isomers have 7 isomers, out of which four are alcohols and three are ethers.

(I) 
(II) 
(III) 
(IV) 
(v) 
(VI) 
(VII) 
26. A *meso* compound has minimum two chiral centres, it has a plane of symmetry and it is optically inactive.

27. 
28. For Fischer's projection to be drawn bring the wedge-edge in correct visual point. The compound can also be represented as



and so on.

29. (b) Alkene with odd number of carbon atoms are non-planar so, these are optically active.

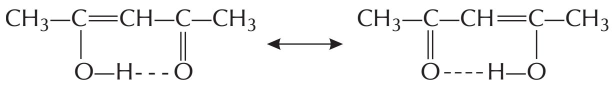
(c) $CH_3-CH(D)-COOH$ molecule contains one chiral carbon atom thus, it is optically active.

(d) 
is non-planar and does not contain any symmetry element thus, optically active.

30. The staggered form is more stable than the eclipsed form because the potential energy of staggered form, in which the bond pairs of two carbons are far away from each other, is minimum.

31. Racemic mixture is optically inactive because the two enantiomers rotate the plane polarised light equally in opposite directions and cancel each others rotation. This phenomenon is called external compensation.

32. Resonance stabilisation of enol form can be shown as

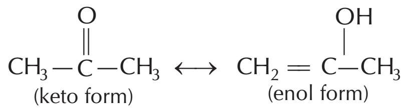


33. The configuration in a compound is independent of its physical properties like optical activity.

34. In chiral centre, chiral axis and chiral plane, if any one is present, the molecule will be optically active.

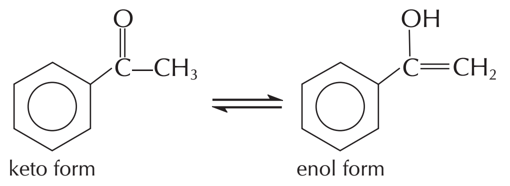
35. Due to hydrogen bonding and resonance stabilisation enol form is preferred in contrast.

36. Acetone exhibits keto-enol tautomerism.



$$\underset{\text{(keto form)}}{CH_3-\overset{\overset{O}{\|}}{C}-CH_3} \longleftrightarrow \underset{\text{(enol form)}}{CH_2=\overset{\overset{OH}{|}}{C}-CH_3}$$

37. Tautomerism in acetophenone can be represented as



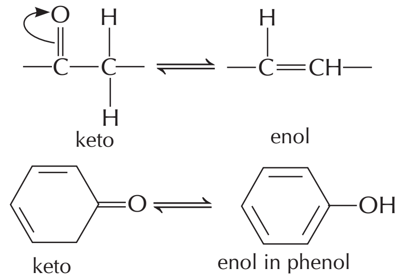
38. Baeyer predicted that a five membered ring compound would be the most stable. It has angle of deviation = 0.44°.

And we know that stability $\propto \frac{1}{d}$

39. Chair form with bulky group at equatorial position is preferred conformation when two bulky groups are present at 1,4-positions.

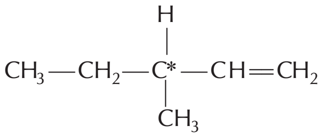
40. When intramolecular hydrogen bonding is possible between groups in 1 and 4 positions the molecule assumes a boat conformation rather than the chair conformation in which hydrogen bonding is not possible.

41. Tautomerism is due to spontaneous interconversion of two isomeric forms with different functional groups into each other. The term tautomer means constitutional isomers that undergo such rapid interconversion that can't be independently isolated.



Thus, (c) 2-pentanone and (d) phenol exhibit tautomerism.

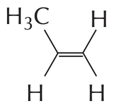
Here (c) may be considered as answer because keto form of phenol is highly unstable.

42.


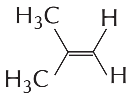
$CH_3—CH_2—\overset{H}{C^*}(CH_3)—CH{=}CH_2$

3-methyl-1-pentene

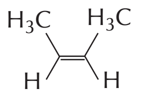
(It has one chiral centre.)

43.


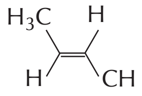
propene



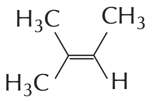
2-methyl propene



cis-2-butene

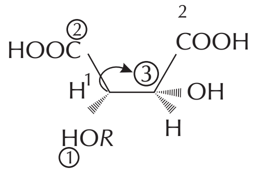


trans-2-butene

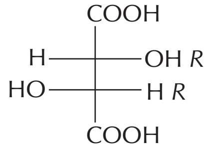


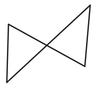
2-methyl-2-butene

44.



or

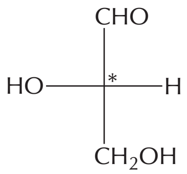


45.


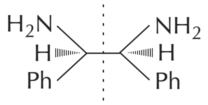
twist boat

It is chiral conformation.

46. The molecule, which is optically active, has chiral centre, is expected to rotate the plane of polarised light.

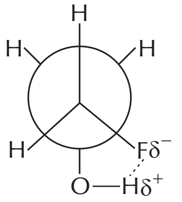


One chiral centre ⇒ optically active

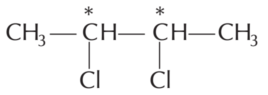


Two chiral centres, but plane of symmerty within molecule ⇒ optically inactive.

47. $HO—CH_2—CH_2—F$



Gauche conformation is comparatively more stable due to hydrogen linkage in between F and H (at O-atom), hence order is eclipse, anti (staggered), gauche.

48.


$CH_3—\overset{*}{C}H(Cl)—\overset{*}{C}H(Cl)—CH_3$

There are two chiral C-atoms (*)

Thus, optical isomerism is possible.

49. In CH_3CH_2OH, there is intermolecular H-bonding while it is absent in isomeric ether CH_3OCH_3.

Larger heat is required to vaporise CH_3CH_2OH as compared to CH_3OCH_3 thus (a) is incorrect.

CH_3CH_2OH is less volatile than CH_3OCH_3, thus vapour pressures are different, thus (b) is incorrect.

bp of $CH_3CH_2OH > CH_3OCH_3$, thus (c) is incorrect.

Density $= \frac{\text{mass}}{\text{volume}}$ Due to ideal behaviour at a given temperature and pressure volume and molar mass are same. Hence, they have same vapour density.

50. Chiral carbon has all the four different groups attached to it.

(a) $CH_3CH_2CH_2CH_2CH_2Cl$ (no chiral carbon atom)

(b) 
$CH_3\underset{\underset{Cl}{|}}{C}HCH_2CH_2CH_3$ (one chiral carbon atom)

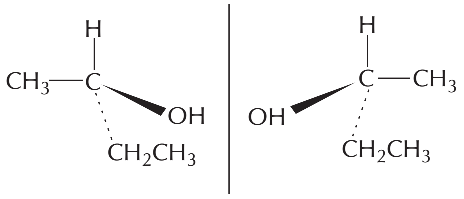
(c) 
$CH_3\,CH_2CH_2\overset{*}{\underset{\underset{CH_3}{|}}{C}}HCH_2Cl$ (one chiral carbon atom)

(d) 
$CH_3\,\overset{*}{\underset{\underset{CH_3}{|}}{C}}H - \overset{*}{\underset{\underset{Cl}{|}}{C}}HCH_2CH_3$ (two chiral carbon atom)

51. 
contains asymmetric carbon atom, thus optically active.

52. Chiral compounds are those which have one chiral centre *i.e.*, all four atoms or groups attached to same carbon are different.

53. 
geometrical isomers
(*cis-trans*)



molecules is optically active
enantiomers

Geometrical isomers and enantiomers both are stereoisomers.

54. Racemic mixture is an equimolar mixture of enantiomers.

55. 
At least two groups or atoms attached to doubly bonded carbon atoms should be different.

15 Hydrocarbons

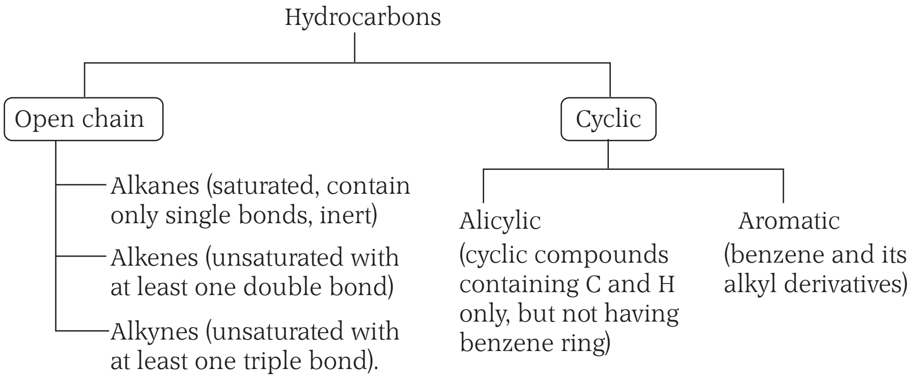
JEE Main MILESTONE

- Classification of Hydrocarbons
- Alkanes
- Alkenes
- Alkynes
- Aromaticity
- Benzene

15.1 Classification of Hydrocarbons

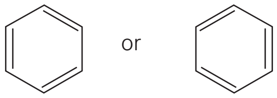
Hydrocarbons are mainly obtained from petroleum, which is the major source of commercial energy.

Hydrocarbons are classified as



*Hydrocarbons means compounds containing carbon and hydrogen only. These may contain only single bonds or double/triple bonds alongwith single bond. Only single bond containing hydrocarbons are **saturated hydrocarbons** while that have multiple bond(s) ($=$ or $\equiv$ bond) alongwith single bonds are **unsaturated compounds.***

Caution Point *Benzene ring have alternate single and double bonds.*



Such a ring is absent in alicyclic compounds.

15.2 Alkanes

Alkanes are the simplest organic compounds made up of carbon and hydrogen only. Chemically, these are almost inert that's why also called **Paraffins** (Latin, *Parum affinis* = Little affinity). The general formula for this series is C_nH_{2n+2}. Hence, the first member is CH_4 (methane).

The main sources of alkanes are **natural wax gas** and **petroleum.** The natural wax or ozokerite is found near petroleum wells and is a mixture of higher solid hydrocarbons. Bee's wax, which is mainly myricyl palmitate (an ester) also contains small quantities of $C_{27}H_{56}$ and $C_{31}H_{64}$.

Nomenclature

You have read in chapter 13 about the nomenclature of alkanes. However, names of alkanes having carbon more than 10 are tabulated below.

Table 14.1 **IUPAC Name of Higher Alkanes**

Molecular formula	Name	Molecular formula	Name
$C_{11}H_{24}$	Undecane	$C_{31}H_{64}$	Hentriacontanes
$C_{12}H_{26}$	Dodecane	$C_{40}H_{82}$	Tetracontanes
$C_{20}H_{42}$	Icosane (Eicosane)	$C_{50}H_{102}$	Pentacontanes
$C_{21}H_{44}$	Henicosane	$C_{90}H_{182}$	Nonacontanes
$C_{22}H_{46}$	Docosane	$C_{100}H_{202}$	Hectane
$C_{30}H_{62}$	Triacontanes		

Isomerism

Alkanes exhibit mainly structural (chain) and conformational isomerism. *e.g.,*

C_4H_{10} have two chain isomers as

(I) 
butane

(II) 
iso-butane
or 2-methyl propane

and C_5H_{12} have three chain isomers as

(I) 
pentane

(II) iso-pentane

(III) neo-pentane

(For details of isomerism see 'Chapter 14' Isomerism)

Methods of Preparation

Following methods are used for the preparation of alkanes.

1. By the Reduction of Different Compounds

Different reagents are used to reduce different compounds into alkanes, description of which is given below.

(i) **Reduction of alcohols, acids, acid derivatives and alkyl halides** is carried out by heating them with red P + HI but the yield is very less. *e.g.,*

$$CH_3COOH + 6HI \xrightarrow[425\text{ K}]{\text{Red P}} CH_3—CH_3 + 2H_2O + 3I_2$$

$$CH_3CH_2OH + 2HI \xrightarrow[425\text{ K}]{\text{Red P}} CH_3—CH_3 + H_2O + I_2$$

$$C_2H_5I + HI \xrightarrow{\text{Red P}} C_2H_6 + I_2$$

Here, red P is used to remove iodine as volatile PI_3, otherwise the reaction becomes reversible.

$$2P + 3I_2 \longrightarrow 2PI_3$$

(ii) **For reducing carbonyl compounds** (aldehydes and ketones) the reagents used are

(a) Red P + HI/Δ as

$$>C{=}O + 6HI \xrightarrow[425\text{ K}]{\text{Red P}} >CH_2 + H_2O + 3I_2$$

(b) Zn–Hg/conc HCl (Clemmensen reduction) *e.g.*,

$$>C{=}O + 4[H] \xrightarrow[\text{conc HCl}]{\text{Zn–Hg}} >CH_2 + H_2O$$

(c) Hydrazine followed by $C_2H_5O^-Na^+$ at 180°C (Wolff-Kishner reduction).

$$>C{=}O + NH_2NH_2 \xrightarrow[-H_2O]{} >C{=}N\cdot NH_2 \xrightarrow[-N_2]{C_2H_5ONa} >CH_2$$

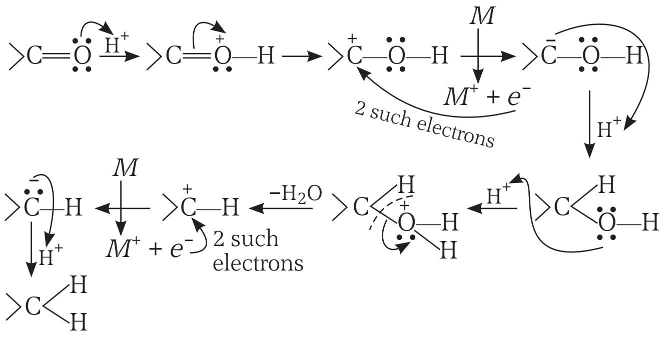
This is a specific method for reducing $>C{=}O$ *group into* $—CH_2$ *group.* N_2 *is released in the process.*

The generalised reducing agents used can be metal + proton donor and complex hydrides.

(i) Among metal + proton donor, the metal works as electron donor and the complete process looks like

$$\text{for } \boxed{>C{=}O + M \text{ with } H^+ \longrightarrow >C\begin{matrix}H\\H\end{matrix} + H_2O}$$

Here, M = metal; H^+ = any protic agent

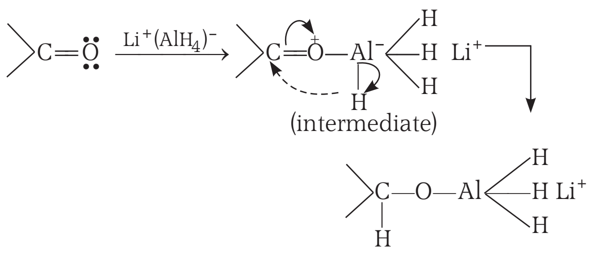


The metal used can be Na, Zn or amalgams etc., *e.g.,* Zn/HCl, Sn/HCl, Zn/CH_3COOH, Zn—Cu couple with CH_3OH, Na with ethanol etc., *e.g.,* *Alkyl halides also reduce in a similar fashion as*

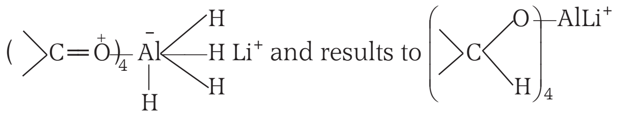
$$RX + 2\,[H] \xrightarrow[H_2O]{Zn-Cu} \underset{\text{alkane}}{R—H} + HX$$

(The order of reactivity of alkyl halides is $RI > RBr > RCl > RF$).

(ii) Among the complex hydrides, LAH (Lithium aluminium hydride, $LiAlH_4$) is the best reagent and others include $NaBH_4$, $NaAlH_4$, Ph_3SnH etc. The complex hydrides function as :



LAH is a strong reducing agent because it reduces four molecules at a time, thus the intermediate formed looks like :



The latter on acid hydrolysis with HCl yields 4 molecules of  along with $AlCl_3$ and LiCl.

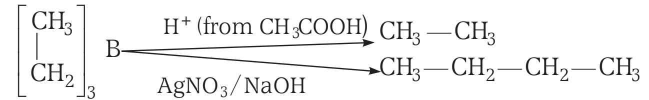
An example of such reduction is as

$$R—X \xrightarrow{LiAlH_4/NaBH_4} R—H$$

Caution Point When reducing agent is $LiAlH_4$, tertiary halides give mainly alkenes.

(iii) **Alkenes on** reduction with B_2H_6 (BH_3) in the presence of Lewis bases like THF (tetrahydrofuran), DIGLYME (diethylene glycol methyl ether) which convert dimeric B_2H_6 to BH_3 by forming acid-base complex, followed by the treatment of protic agent, form alkanes having longer chains *e.g.,*

$$3\,CH_2{=}CH_2 + BH_3 \xrightarrow[\text{DIGLYME}]{\text{THF or}}$$



trialkyl borane

Here $AgNO_3/NaOH$ is called coupling reagent that's why this reaction is also called **coupling reaction.** It also sometimes called **hydroboration reaction.**

The reaction looks like anti-Markownikoff addition but infact, it is Markownikoff addition. The difference here only is in BH_3; *the H plays the role of* (–) *ve partner while boron plays the role of* (+) *ve partner.*

2. Hydrogenation or Catalytic Reduction

The best catalyst used for hydrogenation is **Raney Ni** (an alloy containing equal amounts of Ni and Al digested with NaOH). The catalyst is very effective over normal Ni (works at 200 – 300° C) as it can work even at room temperature. Other catalysts commonly used besides Ni are Pd, Pt etc., which require a temperature between 200 – 300° C. The reduction of unsaturated hydrocarbons with Ni at temperatures between 200 – 300° C is called **Sabatier- Sanderens reaction.** The reaction looks like

$$CH\equiv CH \xrightarrow[Ni/250°C]{H_2} CH_2{=}CH_2 \xrightarrow[Ni/250°C]{H_2} CH_3{-}CH_3$$

Caution Point *Remember that* $Pd/BaSO_4$ *poisoned with S or quinoline (Lindlar's catalyst) or P-2 (Nickel boride catalyst) reduce the alkynes selectively into alkenes.*

3. Decarboxylation

Elimination of CO_2 from a carboxylic acid is called decarboxylation. Hot soda lime (NaOH/CaO) is frequently used reagent for this purpose. However, various other reagents may also be used. The reaction takes place as

$$RCOO^-Na^+ + NaOH/CaO \xrightarrow{\Delta} RH + Na_2CO_3$$

Notice that alkanes so produced, contains one less carbon atom than the original acid.

The reaction takes place by free radical mechanism and involves the formation of several byproducts like lower alkanes, hydrogen, alkenes, esters alongwith the main alkanes. The removal of these products is usually difficult. Thus, this reaction is not very useful. An example is as

$$C_2H_5COONa \xrightarrow{NaOH\ (CaO)} \underset{(44\%)}{C_2H_6} + \underset{(20\%)}{CH_4} + \underset{(33\%)}{H_2}$$
$$+ \text{ unsaturated compounds}$$

The reason of using CaO alongwith NaOH is that it keeps the NaOH (hygroscopic) dry and helps it in fusion.

Caution Point *In Kolbe's decarboxylation reaction if n is the number of carbon atoms in sodium carboxylate, the number of carbon atoms in alkane formed will be* $(n - 1)$ *while during reduction processes the number of carbon atoms in alkane formed and that in parent compound is same.*

4. Corey-House Synthesis

This method was developed in 1960 and proceed as

$$RBr + 2Li \xrightarrow{Ether} RLi + LiBr$$

$$2RLi + CuI \longrightarrow \underset{\substack{\text{lithium dialkyl}\\\text{cuperate}}}{Li(R)_2Cu} + LiI$$

$$Li(R)_2Cu + R'Br \longrightarrow R'—R + RCu + LiBr$$

This is a good method to prepare hydrocarbons (alkanes) having odd number of carbon atoms.

Caution Point *Dialkyl zinc also gives similar type of reaction but here the main product is quaternary alkane.*

$$(CH_3)_2Zn + (CH_3)_3CCl \longrightarrow (CH_3)_4C + CH_3ZnCl$$

5. From Grignard's Reagent

Grignard's reagent on treatment with compounds like H_2O, ROH, acids etc., (protic agents) forms alkane as

$$RMgX \xrightarrow{H^+} RH, \text{ i.e.,}$$

$$RMgX + HOH \longrightarrow RH + Mg(OH)X$$

$$RMgX + R'OH \longrightarrow RH + Mg(OR')X$$

$$RMgX + R'COOH \longrightarrow RH + Mg(OOCR')X$$

$$RMgX + R'C{\equiv}CH \longrightarrow RH + Mg(C{\equiv}CR')X$$

6. Kolbe's Electrolytic Method

This method is used to create a new C—C linkage and used to prepare alkenes and alkynes as well. The reaction looks like

$$\begin{array}{l}CH_3COO^-K^+\\CH_3COO^-K^+\end{array} \xrightleftharpoons{\text{Electrolysis}} \underbrace{\begin{array}{c}CH_3\\|\\CH_3\end{array} + CO_2\uparrow}_{\text{at anode}} + \underbrace{H_2\uparrow + K^+OH^-}_{\text{at cathode}}$$

Mechanism (free radical)

$$2RCOONa \xrightarrow{\text{Electrolysis}} 2RCO\ddot{O}^{\ominus} + 2Na^{\oplus}$$

At anode (oxidation)

$$2RCOO^{\ominus} \longrightarrow 2e^{\ominus} + 2RCO\dot{O} \longrightarrow 2R^{\bullet} + 2CO_2\uparrow$$
$$\longrightarrow \underset{\text{alkane}}{R—R}$$

At cathode (reduction) Reduction of H_2O takes place since reduction potential of it is greater than that of $Na^{\oplus}$.

$$2H_2O + \lambda e^{\ominus} \longrightarrow 2O^{\ominus}H + H_2\uparrow$$

Because of the generation of OH^- ions, the solution becomes alkaline.

Caution Point CH_4 *cannot be prepared by this method.*

This method is not suitable for alkanes having odd number of carbon atoms, as in such case a mixture of hydrocarbons is formed which is difficult to separate.

7. Wurtz Reaction

When alkyl halides are treated with sodium metal in dry ether, it results in the formation of an alkane having double number of carbons as that are present in parent halide. This reaction is called Wurtz reaction.

$$R\boxed{X + 2Na + X}R \xrightarrow{\text{Dry ether}} R—R + 2NaX$$

A single product is obtained as symmetrical alkane if alkyl halides are of single type but if different alkyl halides are used, the product is non-separable mixture of alkanes, so it is more suitable for the synthesis of symmetrical alkanes. *e.g.,*

$$CH_3X + 2Na + C_2H_5X \xrightarrow[-NaX]{\text{Ether}} CH_3—CH_3 + CH_3—C_2H_5$$
$$+ C_2H_5—C_2H_5$$

(A small percentage of alkene is also obtained during this reaction).

CH_4 *cannot be prepared by this reaction*

Mechanism of this reaction may be free radical or ionic but normally free radical is preferred, which takes place as

$$R—X + Na^{\bullet} \longrightarrow R^{\bullet} + NaX$$

$$R^{\bullet} + R^{\bullet} \longrightarrow R—R$$

Moreover, free radicals have a property to disproportionate as

$$R^{\bullet} + R^{\bullet} \longrightarrow \underset{\text{(saturated)}}{R} + \underset{\text{(unsaturated)}}{R}$$

This can be best understood by the following example

$$CH_3CH_2X + Na \longrightarrow CH_3\dot{C}H_2 + Na^+X^-$$

$$2CH_3\dot{C}H_2 \longrightarrow CH_3CH_2CH_2CH_3$$

$$CH_3\dot{C}H_2 + CH_3\dot{C}H_2 \xrightarrow{\text{Disproportionation}} CH_3CH_3 + CH_2{=}CH_2$$

Caution Point *This method cannot be used to convert* 3° *halides to alkanes as here alkenes are obtained instead of alkanes.*

8. Frankland Reaction

Another similar method for preparing alkanes is Frankland method in which Zn is used in the place of Na. Here, rest of the things remain absolutely same as the Wurtz reaction. The reaction looks like :

$$R\boxed{X + Zn + X}R \xrightarrow[\text{ether}]{\text{Dry}} R—R + ZnX_2$$

9. Other Methods of Preparation

(i) From Carbides

CH_4 is prepared by treated carbides, *i.e.,* Al_4C_3 and Be_2C with water. Hence, these carbides are also called **methanides.**

$$Al_4C_3 + 12H_2O \longrightarrow 4Al(OH)_3 + 3CH_4$$

$$Be_2C + 4H_2O \longrightarrow 2Be(OH)_2 + CH_4$$

(ii) Synthesis from Constituents

Lower alkanes are also prepared by synthesis, *i.e.,* build up of a chemical compound from its constituent elements as :

$$C + 2H_2 \xrightarrow[1473\ K]{\text{Electric arc}} CH_4$$

Summary of the methods described above is shown in the following flow chart.

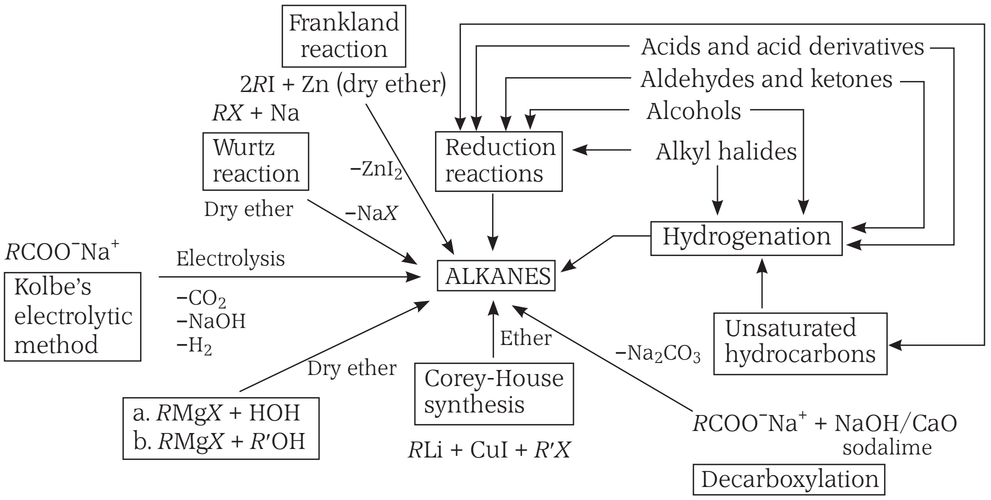


Fig. 15.1 Flow chart showing methods of preparation of alkanes

Physical Properties

Alkanes show following physical properties

1. First four alkanes are gases, next 13 are colourless liquids and all other higher ones are waxy solids.
2. These are insoluble in water but soluble in alcohol, ether, benzene etc. The solubility diminishes with increase in molecular weight.
3. As the number of carbon atoms increases, the boiling points of alkane increases because van der Waals' forces increases. However, branching results in decrease in boiling point due to decreased surface area which results in weaker van der Waals' forces.
4. The dipole moment of all alkanes, whether straight or branched chain, will be zero. However, when one H atom is replaced by another atom or group (other than alkyl group), the resultant molecule will now possess some dipole moment.
5. Melting point also increases with increase in molecular weights but alkanes with even number of carbon atoms have higher melting point than the preceding and succeeding members, due to their well packed structures.

Chemical Properties

The reaction exhibited by alkanes are as follows

1. Nitration

Higher alkanes (having more than five carbon atoms) can be nitrated when heated with fuming HNO_3. This reaction is called **liquid phase nitration,** *e.g.,*

$$C_6H_{14} + HNO_3 \longrightarrow C_6H_{13}NO_2 + H_2O$$

For nitration of lower alkanes, a technique called **vapour phase nitration** is used, in which a mixture of the lower hydrocarbons and nitric acid vapours is passed through the silica tube at highly elevated temperature (at 400–500°C). The reaction also involves cleavage of C—C linkage alongwith C—H linkage, resulting to a mixture of nitroalkanes as

$$C_2H_6 + HONO_2 \longrightarrow C_2H_5NO_2 + CH_3NO_2 + H_2O$$

Nitration (like halogenation) also follows free radical mechanism.

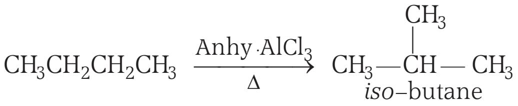
2. Sulphonation

Sulphonation is normally given by alkanes with minimum 6C-atoms onwards *i.e.,* hexane and onwards. Lower alkanes except those having tertiary hydrogen atom can't be sulphonated. Sulphonation is done by oleum (fuming H_2SO_4) *e.g.,*

$$\underset{\substack{\textit{iso}\text{-butane} \\ \text{(contains 3°C)}}}{(CH_3)_3CH} + \underset{\text{oleum}}{H_2SO_4(HSO_3OH)} \longrightarrow \underset{\substack{t\text{-butylsulphonic} \\ \text{acid}}}{(CH_3)_3CSO_3H} + H_2O$$

3. Isomerisation

This reaction is a result of molecular rearrangement involving 1,2-hydride or methyl shift. Anhydrous aluminium chloride ($AlCl_3$) is the reagent for this reaction, *e.g.,*



$$CH_3CH_2CH_2CH_3 \xrightarrow[\Delta]{\text{Anhy}\cdot AlCl_3} \underset{\textit{iso}\text{–butane}}{CH_3—\overset{\overset{\displaystyle CH_3}{|}}{C}H—CH_3}$$

This reaction does not occur unless a trace of water is present (to form HCl from $AlCl_3$) together with a trace of alkyl halide or an alkene.

Hot Spot 1

HALOGENATION

Previous years' examination paper reveals that it is an important topic for JEE Main examination. The questions are generally based on number of monochlorinated or dichlorinated products or on their yield. So, focus on these subtopics.

Halogenation is the process of replacement of one or more hydrogens of an alkane by halogen. For this reaction, order of reactivity of halogens is $I_2 < Br_2 < Cl_2 < F_2$. Reactivity decreases with decrease in the electronegativity of halogens. The reaction takes place as

$$CH_4 + Cl_2 \xrightarrow[-HCl]{h\nu \text{ or } 473-523\text{ K}} CH_3Cl + CH_2Cl_2 + CHCl_3 + CCl_4$$

This reaction follows free radical mechanism and involves the following steps

Step I (Initiation step)

$$X-X \xrightarrow{\text{UV or } \Delta} \underset{\text{free radicals}}{X^\bullet + X^\bullet}$$

Step II (Propagation step)

$$R-H + X^\bullet \longrightarrow R^\bullet + HX$$

$$R^\bullet + X-X \longrightarrow RX + X^\bullet \text{ and so on}$$

Step III (Termination step)

$$X^\bullet + X^\bullet \longrightarrow X_2$$

$$R^\bullet + X^\bullet \longrightarrow RX$$

$$R^\bullet + R^\bullet \longrightarrow R-R$$

Different halogens give this reaction under different reaction conditions as

(i) Cl_2 reacts under UV light/diffused sun light/300–400°.

(ii) Br_2 reacts less vigorously and prefers site of its selection.

(iii) With I_2, reaction is reversible and carried out in the presence of oxidising agent like HIO_3, HgO, etc.

(iv) F_2 reacts with explosion.

This reaction is mainly given by those compounds which at least have one hydrogen atom present on sp^3 hybrid C-atom. Reactivity of sp^3 hybrid C-atom is as follows
tert-benzyl carbon > *sec*-benzyl carbon > *p*-benzyl carbon > *t*-allylic carbon > *s*-allylic carbon > *p*-allylic carbon > *t*-alkyl carbon > *s*-alkyl carbon > *p*-alkyl carbon > CH_4.

A chlorine free radical is so reactive that it makes primary, secondary and tertiary radicals with almost equal ease. According to reactivity selectivity principle, the greater the reactivity of a species, lesser will be selectivity. Bromine is less reactive towards alkanes than chlorine hence bromine is more selective in the site of attack when it reacts according to reactivity selectivity principle.

Since the reaction takes place by free radical mechanism, free radical inhibitors like oxygen inhibit the reaction while free radical accelerator such as benzoyl peroxide $(C_6H_5COO)_2$, tetraethyl lead $Pb(C_2H_5)_4$ etc., accelerate the reaction.

The number of monohalogenation products obtained from any alkane depends upon the number of different types of hydrogens it contains. *e.g.*, Butane contains two types of hydrogen, so it gives two monohalogenated product on mono halogenation.

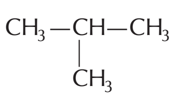
$$\underset{n\text{-butane}}{CH_3CH_2CH_2CH_3} \xrightarrow{Cl_2/h\nu} \underset{1\text{-chlorobutane}}{CH_3CH_2CH_2CH_2-Cl} + \underset{2\text{-chlorobutane}}{CH_3-CHCl-CH_2-CH_3}$$

***Sample* Problem 1** *Which of the following gives only one monohalogenated product on halogenation?*

(*a*) *Iso-propane* (*b*) *Neo-pentane*
(*c*) *Neo-hexane* (*d*) *Iso-pentane*

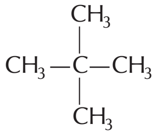
Interpret (*b*) In order to solve such problem follow the following steps

Step I Draw the structures of all the given compounds.



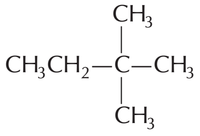
$CH_3-CH(CH_3)-CH_3$

iso-propane



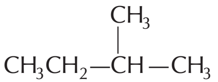
$CH_3-C(CH_3)_2-CH_3$

neo-pentane



$CH_3CH_2-C(CH_3)_2-CH_3$

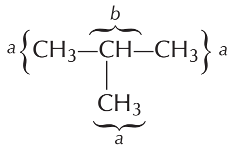
neo-hexane



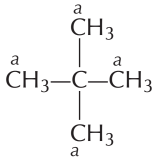
$CH_3CH_2-CH(CH_3)-CH_3$

iso-pentane

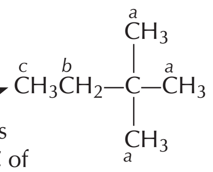
Step II Find the type of hydrogens present in each molecule.



(2 types of hydrogens)

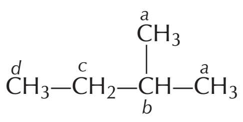


(1 type of hydrogen)



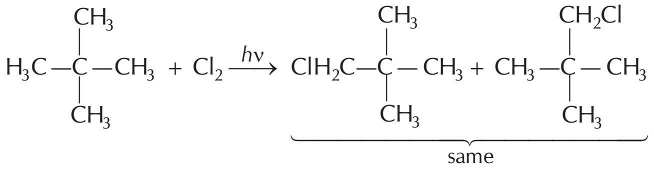
(as this C is in a different environment as compared to C of other CH_3 group)

(3 types of hydrogens)



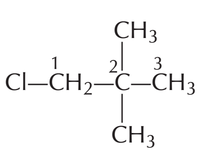
(4 types of hydrogens)

Step III The molecule having one type of H give only one monohalogenated product, so it is *neo*-pentane.



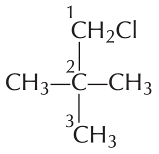
$$H_3C-\underset{CH_3}{\overset{CH_3}{C}}-CH_3 + Cl_2 \xrightarrow{h\nu} \underbrace{ClH_2C-\underset{CH_3}{\overset{CH_3}{C}}-CH_3 + CH_3-\underset{CH_3}{\overset{CH_2Cl}{C}}-CH_3}_{\text{same}}$$

Step IV Check your answer by writing IUPAC names of products obtained, as IUPAC reveals you whether the obtained products are same or different.



$$\overset{1}{Cl-CH_2}-\overset{2}{\underset{CH_3}{\overset{CH_3}{C}}}-\overset{3}{CH_3}$$

1-chloro-2,2-dimethyl propane



$$CH_3-\underset{\overset{3}{CH_3}}{\overset{\overset{1}{CH_2Cl}}{\overset{2}{C}}}-CH_3$$

1-chloro-2,2-dimethyl propane

Yield of halogenation The yield of halogenation depends upon the reactivity of H. The order of reactivity of H for chlorination is

$$\underset{(3^\circ H)}{5} > \underset{(2^\circ H)}{3.8} > \underset{(1^\circ H)}{1}$$

For bromination the order is

$$\underset{(3^\circ H)}{1600} > \underset{(2^\circ H)}{82} > \underset{(1^\circ H)}{1}$$

From the reactivity, the yield is calculated as

$$\%\ \text{yield} = \frac{\text{Number of H atom} \times \text{relative reactivity of H} \times 100}{\text{Number of } 1^\circ \text{ H} \times \text{their reactivity} + \text{Number of } 2^\circ \text{ H} \times \text{their reactivity} + \text{Number of } 3^\circ \text{ H} \times \text{their reactivity}}$$

***Sample* Problem 2** *Find the percentage yield of 2-chlorobutane when butane is halogenated with chlorine.*

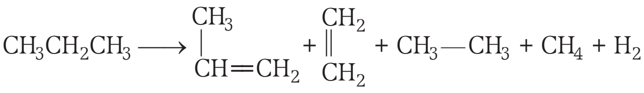
(*a*) 28.3 (*b*) 71.7 (*c*) 18.9 (*d*) 85.3

Interpret (*b*) To solve out such problems, follow the following steps.

Steps	Solution
Step I Write the structure of parent alkane	$CH_3CH_2CH_2CH_3$ butane
Step II Mark the different types of Hs as 1°, 2° or 3°	$\overset{1^\circ}{C}H_3\overset{2^\circ}{C}H_2\overset{2^\circ}{C}H_2\overset{1^\circ}{C}H_3$
Step III Count the number of 2° H as we have to find the percentage of 2-halogenated product.	Number of 2° H = 4
Step IV Calculate proportion of 2° H by multiplying their number with reactivity	$4 \times 3.8 = 15.2$
Step V Also calculate the proportions of other type of Hs.	Here only 1° H are also present. Their proportion $= 6 \times 1 = 6$
Step VI Find total proportion	$15.2 + 6 = 21.2$
Step VII Find % yield by using the formula $\% = \frac{\text{Proportion of H}}{\text{Total proportion}} \times 100$	$\% = \frac{15.2}{21.2} \times 100 = 71.7$

4. Pyrolysis

Pyrolysis (Greek, Pyro = fire, Lysis = loosening) is thermal breakage of organic molecules and when the process is applied to higher alkanes, it is called **cracking** (a word given by petroleum industry). The product is in the form of a mixture containing alkanes $(n-1)$ to CH_4, where, n = number of C atoms present in alkane undergone pyrolysis], alkenes (n to $CH_2{=}CH_2$, all possible alkenes) and H_2, *e.g.*,



$$CH_3CH_2CH_3 \longrightarrow \begin{matrix}CH_3\\ |\\ CH{=}CH_2\end{matrix} + \begin{matrix}CH_2\\ \|\\ CH_2\end{matrix} + CH_3-CH_3 + CH_4 + H_2$$

The process generally requires temperatures in the range 500 – 800° C. Some catalysts like **finely divided silica-alumina** can also be used (catalytic cracking). A free radical mechanism is favoured.

5. Aromatisation

It is applicable to alkanes from hexane to decane, *e.g.*,

$$\text{Hexane} \xrightarrow{\text{Aromatisation}} \text{Benzene}$$

$$\text{Heptane} \xrightarrow{\text{Aromatisation}} \text{Toluene, etc.}$$

The reaction conditions for aromatisation is the presence of Al_2O_3 or Cr_2O_3 and 870 K temperature.

6. Oxidation

Oxidation can be complete or partial. Complete oxidation is called **combustion** which is shown by the generalised reaction as :

$$C_nH_{2n+2} + \left(\frac{3n+1}{2}\right)O_2 \xrightarrow{\text{Flame}} nCO_2 + (n+1)H_2O + \text{Heat}$$

When alkanes are burnt in insufficient supply of oxygen, CO and carbon black are obtained.

$$C_nH_{2n+2} + O_2 \longrightarrow \underset{\substack{\text{carbon}\\ \text{black}}}{C} + H_2O$$

Alkanes are usually not affected by oxidising agents like $KMnO_4$ and $K_2Cr_2O_7$. However, alkanes having 3° hydrogen are oxidised by these oxidising agent to give corresponding alcohols.

$$(CH_3)_3CH + [O] \xrightarrow[\text{Alc.}]{KMnO_4} (CH_3)_3COH$$

Lower alkanes undergo restricted oxidation in the presence of metallic catalysts such as Cu at high temperature and pressure to form alcohols, aldehydes, ketones and acids *e.g.*,

$$\text{(i)}\ \underset{9\ :\ 1}{2CH_4 + 2[O]} \xrightarrow[100\ \text{atm}/200^\circ C]{\text{Cu- tube}} \underset{\text{methyl alcohol}}{2CH_3OH}$$

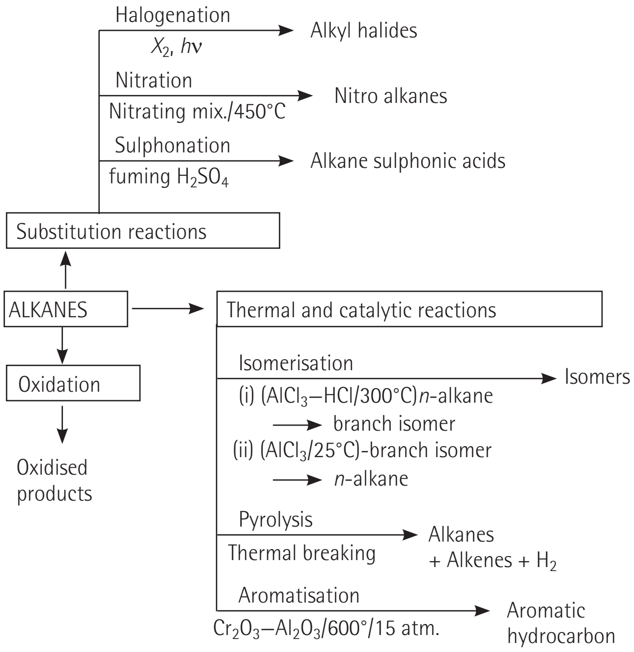
$$\text{(ii)}\ CH_4 + O_2 \xrightarrow[277^\circ C]{MoO} \underset{\text{formaldehyde}}{HCHO} + H_2O$$

$$\text{(iii)}\ HCH_3 + \frac{3}{2}O_2 \xrightarrow{(CH_3COO)_2Mn} \underset{\text{formic acid}}{HCOOH} + H_2O$$

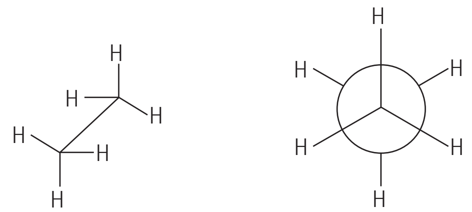
5. Methane or ethane with oxygen at high pressure and comparatively low temperatures are oxidised as

$$\begin{array}{l} CH_4 \xrightarrow{[O]} CH_3OH \xrightarrow[-H_2O]{[O]} HCHO \xrightarrow{[O]} HCOOH \\ \qquad\qquad\qquad\qquad\qquad\qquad\qquad\quad \downarrow [O] \\ \qquad\qquad\qquad\qquad\qquad\qquad\qquad H_2O + CO_2 \end{array}$$

Summary of Reactions of Alkanes



Conformations of Ethane



Saw horse projection Newmann projection

(For detail study of conformation, see chapter isomerism.)

Check Point 1

1. Alkanes are inert towards chemical reagents. Explain.
2. Why is the presence of CaO necessary during decarboxylation by NaOH?
3. Reduction with HI is usually carried out in the presence of small amounts of red P. Explain.
4. Account for the following.
   - (i) The boiling points of branched chain alkanes are lower as compared to their normal isomers.
   - (ii) Alkanes containing even number of carbon atoms have higher than expected boiling point.

15.3 Alkenes

Alkenes constitute the first series of unsaturated hydrocarbons with a π-bond proving unsaturation in them. These are characterised by the presence of a double bond between two adjacent carbons ($>C{=}C<$). Their general formula is C_nH_{2n} in comparison to C_nH_{2n+2} of alkanes. These are also called olefins (Latin, *oleum*= oil, *ficar* = to make) as their lower members form oily products on halogenation. Their main source is petroleum.

Alkenes are named by adding suffix 'ene' in the root word. These exhibit chain, position, ring-chain and geometrical isomerism. (For detail study of these topic see Chapter-13 and 14)

Methods of Preparation

Following methods are used to prepare alkenes.

1. Dehydrohalogenation

Alkyl halides when treated with alcoholic KOH/Δ gives alkenes as

$$CH_3CH_2Br \xrightarrow[\Delta]{\text{Alc. KOH}} CH_2{=}CH_2 + KBr + H_2O$$

The other reagents which can be used are high concentrations of **NaH / Δ**, **$NaNH_2$** or **KNH_2**/Δ and **sodium** or **potassium alkoxides** (for E2 reactions that occur in primary alkyl halides whose β-carbon is 1° or 2°) and **R_3N / NaOH** (for E1 reactions that occur in tertiary alkyl halides, secondary alkyl halides whose β-carbon is 3° or 4° and primary alkyl halides whose β-carbon is 3° or 4°) at room temperatures.

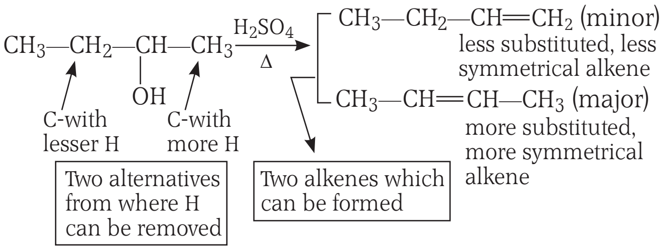
Important facts about dehydrohalogenation reaction of alkyl halides are as

1. Ease of dehydrohalogenation is 3° > 2° > 1° for alkyl halides.
2. In most of the cases **Saytzeff rule** (Zaistev rule) is followed, which was given by **A.M. Zaitsev** of university of Kazan (Russia). The rule originally was stated as "*in elimination reactions, when alternatives are available, the* H*–atom will be removed from that* C*–atom containing lesser number of hydrogens*". Two different expressions of this rule were also developed later on, which are :

   "When alternatives are available" (in elimination reactions) **:**

   (i) **More substituted alkene will be preferred.**

   (ii) **More stable** (symmetrical) **alkene will be preferred.**



2. Dehydration of Alcohols

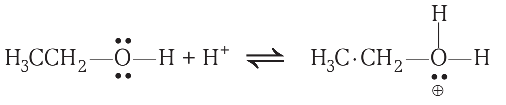
Alcohols when treated with sulphuric acid (concentrated) at 170°C, alkene is obtained.

$$CH_3CH_2OH \xrightarrow[170°C]{H_2SO_4} CH_2=CH_2 + H_2O$$

Mechanism

Step I Generation of protonated alcohol.

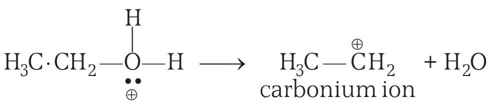
$$H_2SO_4 \rightleftharpoons H^+ + HSO_4^-$$



$$H_3CCH_2—\ddot{\underset{\cdot\cdot}{O}}—H + H^+ \rightleftharpoons H_3C\cdot CH_2—\overset{H}{\underset{\oplus}{\ddot{O}}}—H$$

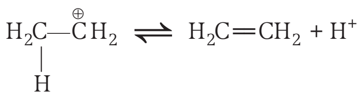
protonated alcohol

Step II Generation of carbonium ion



$$H_3C\cdot CH_2—\overset{H}{\underset{\oplus}{\ddot{O}}}—H \longrightarrow \underset{\text{carbonium ion}}{H_3C—\overset{\oplus}{C}H_2} + H_2O$$

Step III Removal of proton

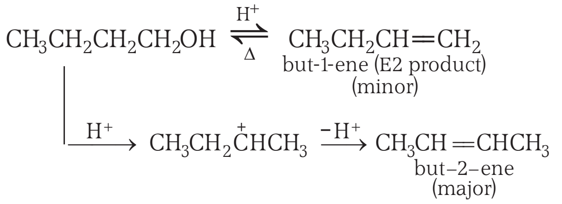


$$\underset{H}{H_2C}—\overset{\oplus}{C}H_2 \rightleftharpoons H_2C=CH_2 + H^+$$

Important facts related to dehydration are as

1. Ease of dehydration is 3° > 2° > 1° because of the involvement of carbocation intermediate.
2. The reaction can also be seen with Al_2O_3 350°C, P_2O_5, H_3PO_4, $POCl_3$ in pyridine.
3. 1° alcohols follow E2 mechanism while 3° alcohols follow E1 mechanism, 2° alcohols may follow either E2 or E1 mechanism however, E1 is preferred.

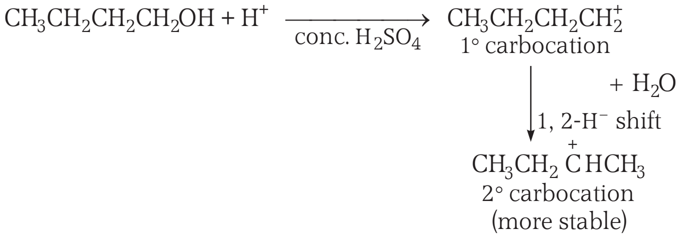
Although primary alcohols follow E2 mechanism but it is found that the yield of product is very less. The reason is the presence of H^+ ion in the reaction which works as an electrophile for alkene formed and responsible for modification or reversibility of reaction as seen in following example of butan-1-ol.



Major product (but-2-ene) formed after reaction modification due to H^+.

The rearrangement in open chain compounds in which shifting of $C_6H_5^-$ (Ph^-), CH_3^-, H^- takes place to give more stable carbocation and also the more stable product, is called *retropinacol rearrangement or Wagner rearrangement* Shifting of groups takes place in the following sequence : $C_6H_5^- > CH_3^- > H^-$

An example of such rearrangement is



This is the more stable carbocation that actually leads the formation of alkene.

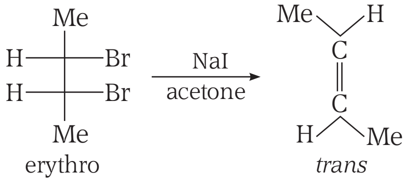
$$CH_3CH_2\overset{+}{C}HCH_3 \xrightarrow[-H^+]{} \underset{\text{2-alkene}}{CH_3CH=CHCH_3}$$

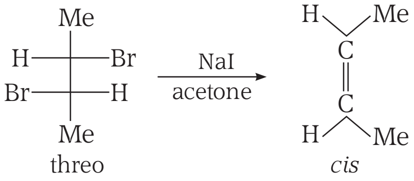
3. Dehalogenation

Only *vicinal* dihalides (in which the halogen atoms are attached to two successive C-atoms) give alkenes while *geminal* dihalides (in which the halogen atoms are attached to the same C-atoms) give alkynes when heated with a dehalogenating agent like zinc dust. The reaction takes place as

$$\underset{vic\text{-dihalide}}{BrCH_2—CH_2Br} + Zn \xrightarrow{C_2H_5OH} CH_2=CH_2 + ZnBr_2$$

Other reagents that can be used for dehalogenation are NaI in acetone and Na in dry ether (like Wurtz reaction). In the latter case elimination is associated with coupling and it is useful only for elimination from *gem* dihalides. The elimination is stereo-selective *i.e., anti* predominantly.





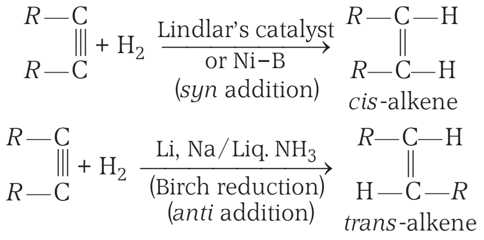
If sodium metal is used in place of zinc, the higher alkenes can be obtained.

4. Controlled Hydrogenation

Alkynes on hydrogenation with Lindlar's catalyst or nickel boride (P-2 catalyst) or with Na or Li in liquid ammonia, give alkenes.

Lindlar's catalyst is Pd poisoned with $BaSO_4$ or $CaCO_3$ in quinoline or xylene. The addition is stereo-selective and *syn* in the case of Lindlar's catalyst or nickel boride (P-2 catalyst). However, *anti*-addition is seen in the case of Na or Li in liquid NH_3. (Birch reduction)

The *syn* and *anti* additions can be seen as :

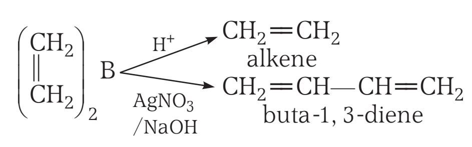


$$\begin{array}{c} R-C \\ ||| \\ R-C \end{array} + H_2 \xrightarrow[\text{or Ni–B (syn addition)}]{\text{Lindlar's catalyst}} \underset{\textit{cis}\text{-alkene}}{\begin{array}{c} R-C-H \\ \| \\ R-C-H \end{array}}$$

$$\begin{array}{c} R-C \\ ||| \\ R-C \end{array} + H_2 \xrightarrow[\text{(Birch reduction) (anti addition)}]{\text{Li, Na/Liq. }NH_3} \underset{\textit{trans}\text{-alkene}}{\begin{array}{c} R-C-H \\ \| \\ H-C-R \end{array}}$$

5. Hydroboration

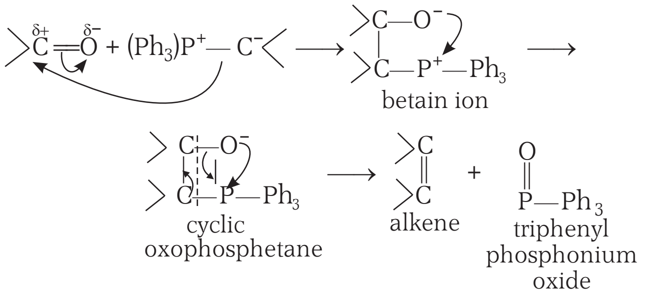
Hydroboration of alkynes can be seen as



$$3H-C\equiv C-H \xrightarrow{BH_3 \text{ in THF}} \left(\begin{array}{c} CH_2 \\ \| \\ CH_2 \end{array}\right)_2 B \begin{cases} \xrightarrow{H^+} \underset{\text{alkene}}{CH_2=CH_2} \\ \xrightarrow{AgNO_3/NaOH} \underset{\text{buta-1, 3-diene}}{CH_2=CH-CH=CH_2} \end{cases}$$

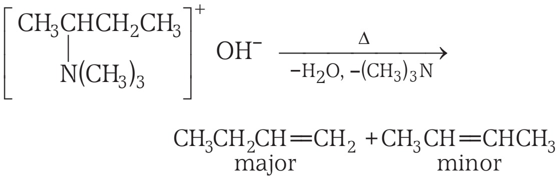
6. Wittig Reaction

In the Wittig reaction there is nucleophilic addition of triphenylphosphonium (ylide) ion which results to alkene as

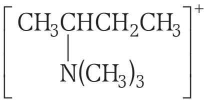


7. Pyrolysis of Quaternary Ammonium Compounds

The opposite results to Zaitsev rule were obtained by **Hofmann** while working on β-elimination in quaternary ammonium hydroxides as



$$\left[\begin{array}{c} CH_3\underset{|}{C}HCH_2CH_3 \\ N(CH_3)_3 \end{array}\right]^+ OH^- \xrightarrow[-H_2O,\ -(CH_3)_3N]{\Delta} \underset{\text{major}}{CH_3CH_2CH=CH_2} + \underset{\text{minor}}{CH_3CH=CHCH_3}$$



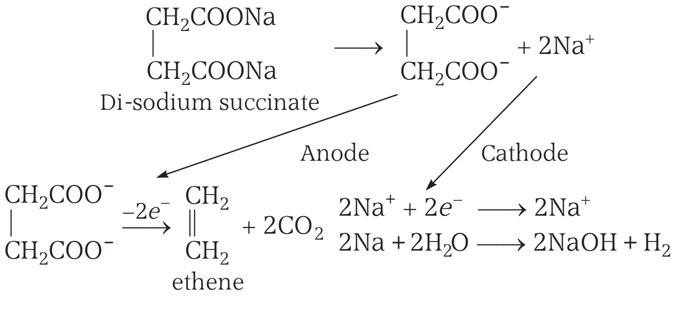
$$\left[\begin{array}{c} CH_3\underset{|}{C}HCH_2CH_3 \\ N(CH_3)_3 \end{array}\right]^+$$ X^- also gives the similar results.

He explained the difference in results on the basis of presence of bulky $N(CH_3)_3$ group in the compound, which destabilises transition state in second case. The finding of Hofmann are considered as **Hofmann rule.**

8. Kolbe's Electrolytic Method

Electrolysis of sodium or potassium salts of dicarboxylic acid, *e.g.,*

$\begin{array}{l} CH_2COO^-K^+ \\ | \\ CH_2COO^-K^+ \end{array}$ (potassium succinate) produces alkene, $\begin{array}{c} CH_2 \\ \| \\ CH_2 \end{array}$



$$\underset{\text{Di-sodium succinate}}{\begin{array}{l} CH_2COONa \\ | \\ CH_2COONa \end{array}} \longrightarrow \begin{array}{l} CH_2COO^- \\ | \\ CH_2COO^- \end{array} + 2Na^+$$

Anode

Cathode

$$\begin{array}{l} CH_2COO^- \\ | \\ CH_2COO^- \end{array} \xrightarrow{-2e^-} \underset{\text{ethene}}{\begin{array}{c} CH_2 \\ \| \\ CH_2 \end{array}} + 2CO_2$$

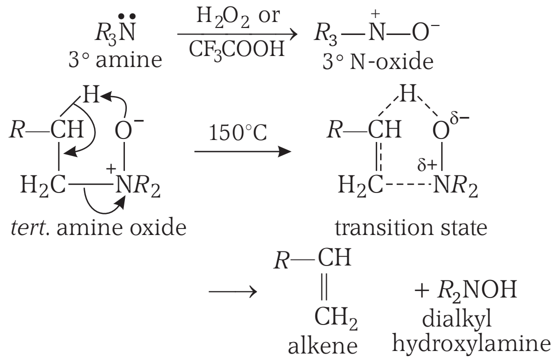
$$2Na^+ + 2e^- \longrightarrow 2Na^+$$

$$2Na + 2H_2O \longrightarrow 2NaOH + H_2$$

The method is an extension of **Kolbe's method** for the preparation of alkanes.

9. Cope Reaction

When a 3° amine oxide containing atleast one β-hydrogen is heated at 150°C, it decomposes to form an alkene and a derivative of hydroxylamine.



This reaction may also be carried out in dimethyl sulphoxide or THF at room temperature.

Summary of preparation methods of alkenes is given in the following flow diagram.

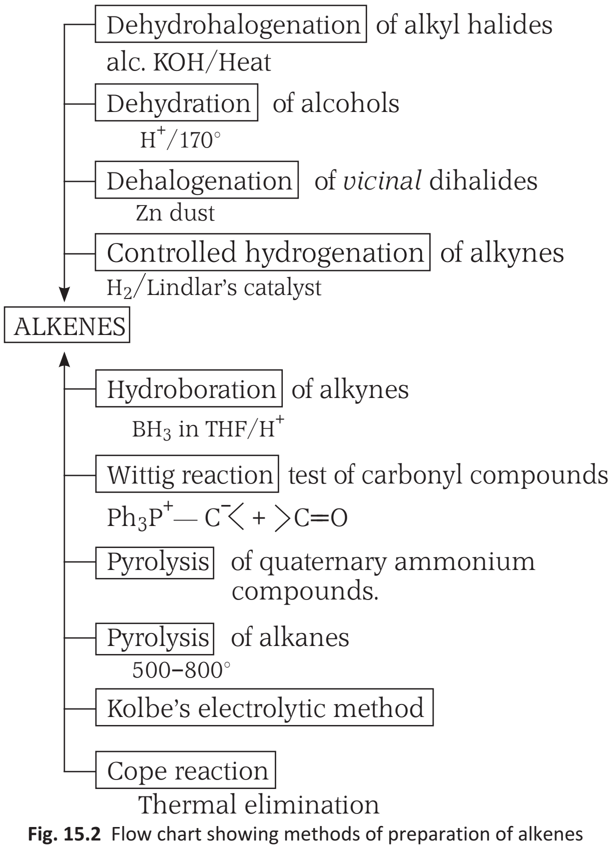


Fig. 15.2 Flow chart showing methods of preparation of alkenes

Physical Properties

1. First three alkenes are gases, next 14 are liquids and rest are solids.
2. All alkenes are colourless and odourless except ethene which has pleasent odour.
3. These are lighter than water and the density gradually increases with rise in molecular mass.
4. These also show same trend of boiling and melting points as alkanes but geometrical isomers behave differently. *cis*-alkenes have higher boiling point as compared to their *trans*-isomers. However, melting point is higher in case of *trans*-isomers.
5. In general, *trans*-form has almost zero dipole moment and thus, exhibits weaker intermolecular attractions.
6. Alkenes are insoluble in water but soluble in non-polar solvents like benzene, ether, CCl_4 etc.
7. The alkenes follows the following order of stability

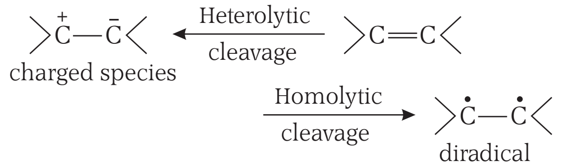
$$R_2C{=}CR_2 > R_2C{=}CHR > R_2C{=}CH_2 \approx RCH{=}CHR\ (trans > cis) > RCH{=}CH_2 > CH_2{=}CH_2$$

(On the basis of hyperconjugative structures.)

Heat of hydrogenation is also an index of stability. The *lower the heat of hydrogenation of an alkene, the more stable it is*.

Chemical Properties

Alkenes generally undergo electrophilic addition reactions because of the presence of a double bond (a strong σ and a weaker π bond), π electrons of which being loosely held are easily polarisable. These reactions involve cleavage of a π bond and formation of two new σ bonds. The cleavage may be homolytic or heterolytic.



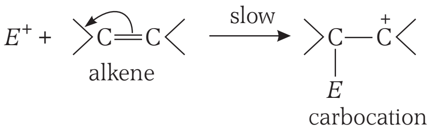
In polar solvents, addition proceeds by ionic mechanism (*i.e.,* at low temperature), whereas in the presence of light or non-polar solvents, the addition occurs by free radical mechanism (*i.e.,* at high temperature).

The steps involved in ionic mechanism are as follows

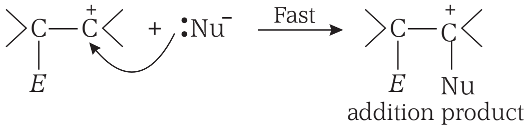
Step I Ionisation of reagent to generate electrophile and nucleophile

$$E{—}Nu \longrightarrow E^+ + :Nu^-$$

Step II Attack of electrophile on alkene



Step III Attack of nucleophile to give addition product.



Since electrophile attacks first, the reactions are called electrophilic addition reactions.

Some example of these reactions are as follows

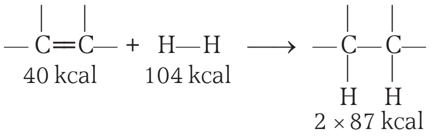
Caution Point *From the stereochemistry point of view, organic reactions can be stereoselective (i.e., one stereoisomer predominates over the other) or stereospecific (i.e., a single product is formed from both the geometrical isomers).*

While going for stereoselective reactions always remember

(i) *cis alkene + anti addition ⟶ Racemic mixture*
(ii) *trans alkene + anti addition ⟶ meso form*
(iii) *cis alkene + syn addition ⟶ meso form*
(iv) *trans alkene + syn addition ⟶ Racemic mixture*

1. Addition of Hydrogen (Hydrogenation)

Hydrogenation involves the breaking of a π-bond (about 40 kcal) and a H—H bond (104 kcal), and the formation of two C—H bonds (average value 87 kcal); the net result is the evolution of about 30 kcal of heat, which is called heat of hydrogenation.

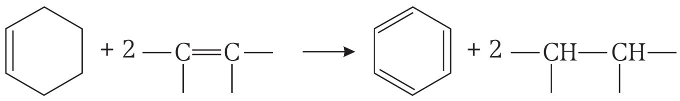


$$\underset{40\text{ kcal}}{\text{—C=C—}} + \underset{104\text{ kcal}}{\text{H—H}} \longrightarrow \underset{2\times 87\text{ kcal}}{\text{—}\underset{\text{H}}{\text{C}}\text{—}\underset{\text{H}}{\text{C}}\text{—}}$$

$$\Delta H = -30\,\text{kcal mol}^{-1}$$

For most of the alkenes, the heat of hydrogenation is approximately 30 kcal.

Wilkinson catalyst, $\mathbf{RhCl[(C_6H_5)_3P)_3]_3}$ is a good catalyst for hydrogenation (comparable with Raney Ni). Other reagents are **cyclohexene** (itself oxidises to benzene), hydrazine (itself oxidises to N_2), $NaBH_4 \cdot PtCl_2$ etc.



Birch reagent (Na in liquid NH_3 with C_2H_5OH or CH_3OH) works only on terminal double bonds in aliphatic alkenes.

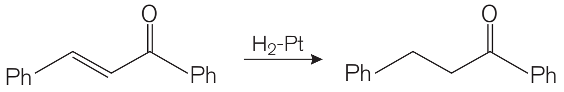
$$R\text{CH}{=}\text{CH}_2 \xrightarrow[e^-]{\text{Na}} R\text{CH}\overset{\ominus}{\ddot{\text{C}}}\text{H}_2 \xrightarrow{\text{EtOH}} R\dot{\text{C}}\text{HCH}_3$$

$$\xrightarrow[e^-]{\text{Na}} R\overset{\ominus}{\ddot{\text{C}}}\text{HCH}_3 \xrightarrow{\text{EtOH}} R\text{CH}_2\text{CH}_3$$

For hydrogenation also see alkanes (methods of preparation reaction (b).

The rate of hydrogenation of olefinic bonds (at room temperature and atmospheric pressure) is —CH$=$CH$_2$ > — CH$=$CH— or a ring double bond.

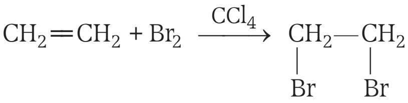
Caution Point *The C≡C bond is reduced more readily than C=C but other unsaturated groups (except nitro and acid chlorides) are reduced less readily. Catalytic hydrogenation can therefore, be used for the selective reduction of C=C in the presence of aromatic ring and carbonyl groups, whether or not the unsaturated functions are conjugated.*



Hydrogen is added in syn manner.

2. Addition of Halogens (Halogenation)

Alkenes (and also alkynes) form addition products with Cl_2 and Br_2. Br_2 water is decolourised by unsaturated hydrocarbons (hence, it is the test of unsaturation).



$$\text{CH}_2{=}\text{CH}_2 + \text{Br}_2 \xrightarrow{\text{CCl}_4} \underset{\text{Br}}{\text{CH}_2}\text{—}\underset{\text{Br}}{\text{CH}_2}$$

The reaction is stereo-selective (predominantly anti addition occurs, *i.e.,* Br atoms are on the opposite side of the plane of the molecule).

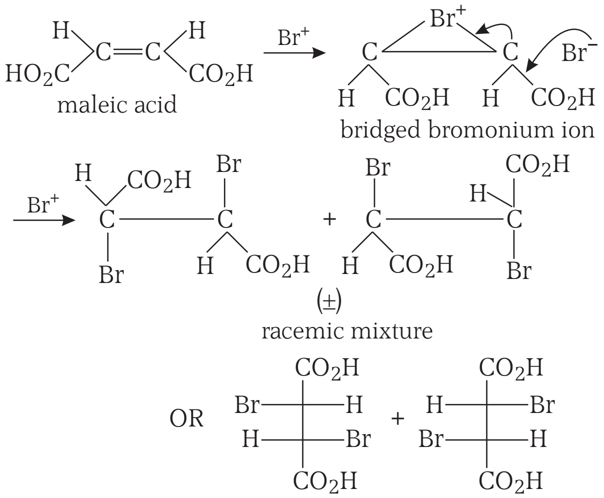
Relative rates of reaction of alkene with Br_2/CH_3OH are in order of

ethene < 1-butene < *trans*-2-butene < 2-methyl-1-butene < 2,3-dimethyl-2-butene.

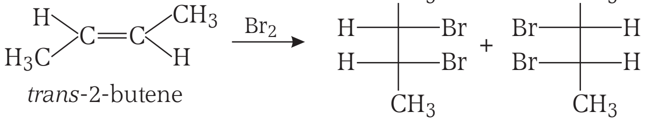
Mechanism

The reaction proceeds through the formation of a bridged bromonium ion which is more stable than carbocation followed by attack by the bromide ion.

$$\text{Br}_2 \rightleftharpoons \text{Br}^+ + \text{Br}^-$$



The attack occurs because the positively charged bromine is very electronegative and readily accepts an electron pair. With *trans*-2-butene, product of Br_2 addition is optically inactive due to the formation of symmetric *meso* compound.



identical (*meso*)

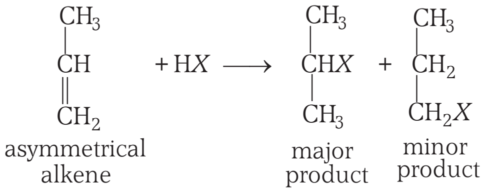
3. Reaction with Hydrogen Halides

The addition of **halogen acids** is frequently carried out by passing dry gaseous halogen acids in moderately polar solvent. In the case of asymmetric alkenes, reaction occur as per **Markownikoff rule** (given later) with exception of HBr in the presence of peroxide **(Kharasch effect)** where infact free radical mechanism is followed. The mechanism of both the reactions are seen in previous (Chapter 13).

The order of stability of carbocations is

$$3° > 2° > 1° > \overset{\oplus}{C}H_3.$$

The **Markownikoff rule** is used as a guidance for electrophilic additions in those cases where an asymmetrical reagent is added to an asymmetrical alkene or alkyne and *states that in such cases (+)ve part of the reagent goes to the* C*–atom containing more number of hydrogen or (–)ve part of the reagent goes to the* C*–atom containing lesser number of hydrogens*. If number of hydrogens are same, the (–)ve part of the reagent goes to the C-atom bearing more number of alkyl groups is also the same then addition occurs but the rule is not applicable. *e.g.,*



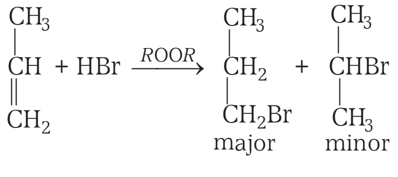
$$CH_3{-}CH{=}CH_2 + HX \longrightarrow CH_3{-}CHX{-}CH_3 + CH_3{-}CH_2{-}CH_2X$$

As the reaction is electrophilic addition thus it proceeds *via* carbonium ion formation. In the above case two carbonium ions are possible after the attack of electrophile *i.e.,*

$$(i)\ CH_3{-}CH_2{-}\overset{+}{C}H_2(1°),\quad (ii)\ CH_3\overset{+}{C}HCH_3(2°).$$

Out of these two, the latter *i.e.,* 2° carbonium ion is more stable that's why it is responsible for major product formation.

The above rule is not followed if HBr is added to an asymmetrical alkene in the presence of *ROOR* (peroxide) as :

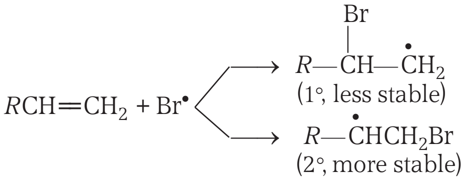


$$CH_3{-}CH{=}CH_2 + HBr \xrightarrow{ROOR} CH_3{-}CH_2{-}CH_2Br + CH_3{-}CHBr{-}CH_3$$

The main responsible factor here is organic peroxide which dissociates into free radicals and modifies the electrophilic addition to free radical addition which passes through two free radicals as their intermediates i.e.,

$$ROOR \longrightarrow 2RO^{\bullet}$$

$$RO^{\bullet} + HBr \longrightarrow R{-}OH + Br^{\bullet}$$



$$RCH{=}CH_2 + Br^{\bullet} \longrightarrow R{-}CHBr{-}\dot{C}H_2 \text{ (1°, less stable)};\quad R{-}\dot{C}HCH_2Br \text{ (2°, more stable)}$$

Now here as the 2° free radical is more stable thus it is responsible for major product formation.

$$R{-}C^{\bullet}HCH_2Br + HBr \longrightarrow RCH_2CH_2Br + Br^{\bullet}$$

The modified case of HBr in the presence of peroxide is called Kharasch effect and considered as an example of anti-Markownikoff addition as it follows an opposite course to that suggested by Markownikoff. The rule is also applicable on alkynes.

HF, HCl and HI does not give such modified reactions because

(i) The bonds between halogen and hydrogen is very strong in HF and HCl that's why $RO^{\bullet}$, free radical is unable to break them homolytically. Thus, reaction procedure is not modified.

(ii) In the case of HI, although $RO^{\bullet}$ free radical produces homolytic cleavage but $I^{\bullet}$, free radical formed has more tendency to form I_2 as compared to form free radical of carbon.

4. Reaction with Water (Hydration)

A water molecule is added when alkane it treated with dil. H_2SO_4, or subjected to hydroboration or oxymercuration-demercuration reaction.

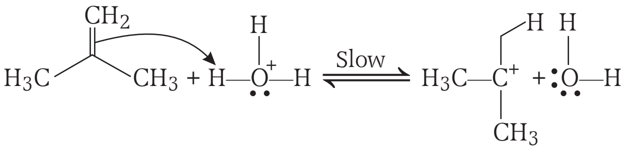
(i) **With dil. H_2SO_4** The reaction takes place as

$$CH_2{=}CH_2 \xrightarrow{\text{dil. } H_2SO_4} CH_3{-}CH_2HSO_4 \xrightarrow[\text{warm}]{H_2O} CH_3CH_2OH$$

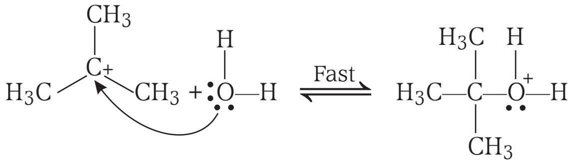
The reaction follows Markownikoff's rule.

Mechanism

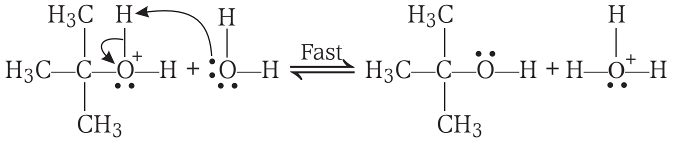
Step I The alkene accepts a proton to form more stable 3° carbocation.



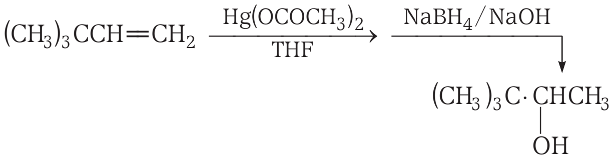
Step II The carbocation reacts with a molecule of water to form a protonated alcohol.



Step III The transfer of proton to a molecule of water leads to a product.

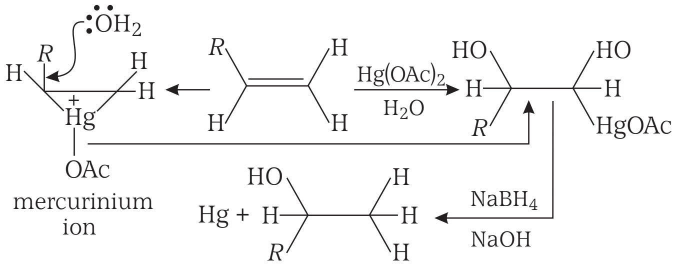


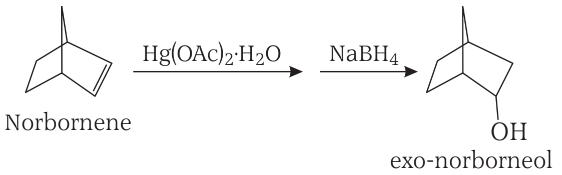
(ii) **Oxymercuration-demercuration** Mercuric acetate (in THF) followed by reduction with $NaBH_4$ /NaOH can also be used for the purpose. The reaction is called **oxymercuration-demercuration reaction** and proceeds through cyclic transition state formation involving mercury metal. It is contrary to hydration with H_2SO_4 where carbonium ion is produced. If the carbonium ion is intermediate then there always exists a possibility of rearrangement while such a possibility is not seen in the case of **oxymercuration demercuration**. *i.e.*, the addition is exactly localised here. The reaction can be seen as



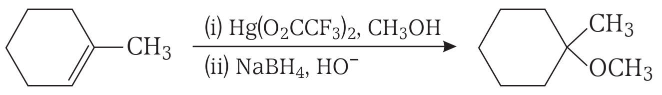
$$(CH_3)_3CCH{=}CH_2 \xrightarrow[\text{THF}]{Hg(OCOCH_3)_2} \xrightarrow{NaBH_4/NaOH} (CH_3)_3C\cdot \underset{\substack{|\\ OH}}{C}HCH_3$$

In this reaction, mercury diacetate first adds across the double bond in an oxymercuration step. Water then displaces the mercury acetate group. The mechanism involves the ring opening of a mercurinium ion by S_N2 attack of water; this result in the *anti* (or *trans*) hydroxy-substituted organomercury intermediate, which is then reduced to give the alcohol (Nucleophile attaches to the more substituted carbon from the side opposite the leaving mercury)

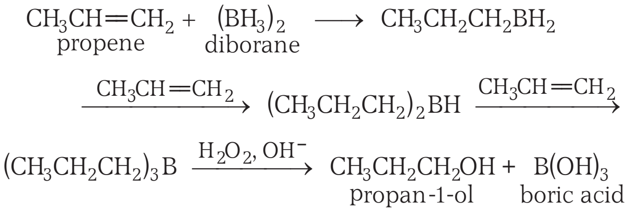




In alkoxy mercuration reaction, alcohol is the nucleophile and product formed is an ether.



(iii) **Hydroboration** A reaction of alkene with diborane followed by oxidation with alkaline H_2O_2, also give hydration product without rearrangement but in accordance with Kharash rule. This reaction looks as



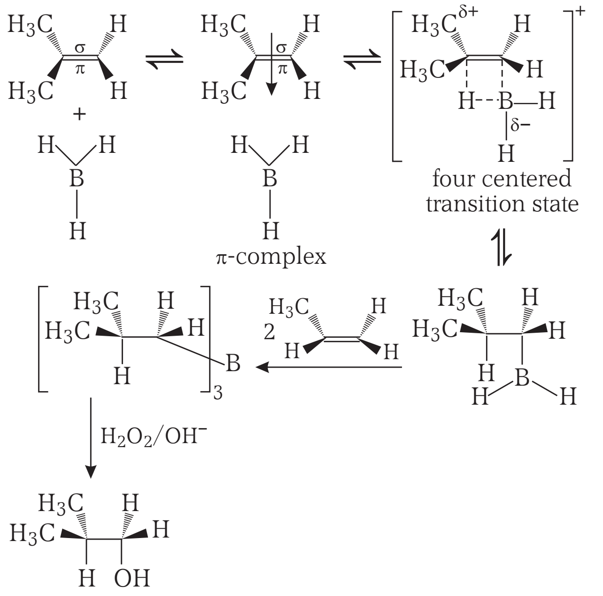
$$\underset{\text{propene}}{CH_3CH{=}CH_2} + \underset{\text{diborane}}{(BH_3)_2} \longrightarrow CH_3CH_2CH_2BH_2$$

$$\xrightarrow{CH_3CH=CH_2} (CH_3CH_2CH_2)_2BH \xrightarrow{CH_3CH=CH_2}$$

$$(CH_3CH_2CH_2)_3B \xrightarrow{H_2O_2,\, OH^-} \underset{\text{propan-1-ol}}{CH_3CH_2CH_2OH} + \underset{\text{boric acid}}{B(OH)_3}$$

This reaction involves two steps, *i.e., syn* addition of borane (BH_3) to double bond and oxidation followed by hydrolysis to give alcohol.

Mechanism



Addition takes place through the initial formation of a π-complex which changes into a cyclic four centre transition state with the boron atom adding to less hindered carbon atom. The dashed bonds in the transition state represent bonds that are partially formed or partially broken.

The overall hydration of the alkene has been shows to occur by the *syn*-addition.

Sample **Problem 3** *Alkene,* $CH_3CH_2OCH{=}CH_2$ *hydrolysed much faster as compared to ethene. The reason for this is*

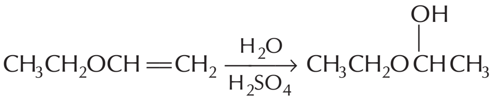
(a) *a more stable carbocation is generated in case of* $CH_3CH_2OCH{=}CH_2$

(b) $CH_3CH_2OCH{=}CH_2$ *is a more stable alkene as compared to* C_2H_4 *towards hydration.*

(c) *a more stable carbanion is generated in case of* $CH_3CH_2OCH{=}CH_2$

(d) *None of the above*

Interpret (*a*)



$$CH_3CH_2OCH{=}CH_2 \xrightarrow[H_2SO_4]{H_2O} CH_3CH_2O\overset{\overset{OH}{|}}{C}HCH_3$$

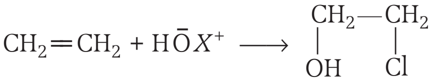
$$CH_3CH_2OCH{=}CH_2 \xrightarrow{H_3O^+} \underset{\text{carbocation } A \text{ (more stable)}}{CH_3CH_2O\overset{\oplus}{C}HCH_3}$$

$$CH_2{=}CH_2 \xrightarrow{H_3O^+} \underset{\text{carbocation } B \text{ (less stable)}}{CH_3\overset{\oplus}{C}H_2}$$

Stability of 2° carbocation is further increased by electron repelling ethoxy (CH_3CH_2O) group. Greater the stability of carbocation, easier is its formation, hence faster the reaction.

5. Reaction with Hypohalous Acid (HO*X*)

Halohydrins are obtained in the reaction. Halohydrins are the compounds containing —OH and —*X* groups at successive C–atoms. The hypohalous acid breaks as OH^- and X^+ and it is the halonium ion (X^+) which attacks on π bond. Reaction is **stereo-selective** (*anti*-addition is seen) and seen as

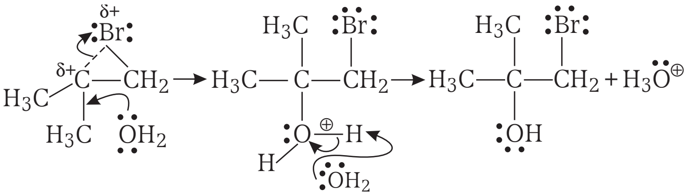


$$CH_2{=}CH_2 + H\bar{O}X^+ \longrightarrow \underset{OH}{\underset{|}{C}H_2}{-}\underset{Cl}{\underset{|}{C}H_2}$$

Markownikoff's rule is followed in the case of unsymmetrical alkenes.

The order of reactivity of different X_2/H_2O is $Cl_2/H_2O > Br_2/H_2O > I_2/H_2O$.

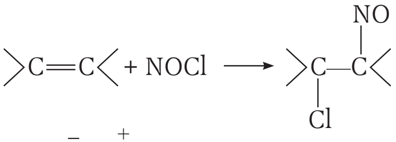
Mechanism



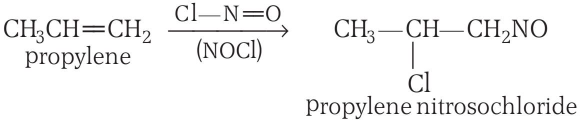
6. Addition of Nitrosyl Chloride (Tildens Reagent)

Nitrosyl chloride (NOCl) or bromide adds to a carbon-carbon double bond to yield halonitroso derivatives.

$$(NOCl \longrightarrow {}^-Cl{-}{}^+N{=}O);\ (NOBr \longrightarrow {}^-Br{-}{}^+NO)$$



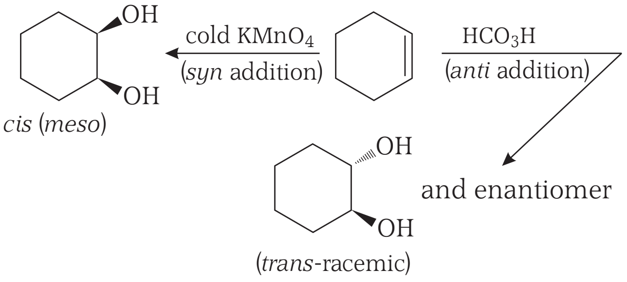
$$>C{=}C< + NOCl \longrightarrow >\underset{Cl}{\underset{|}{C}}{-}\overset{NO}{\overset{|}{C}}<$$

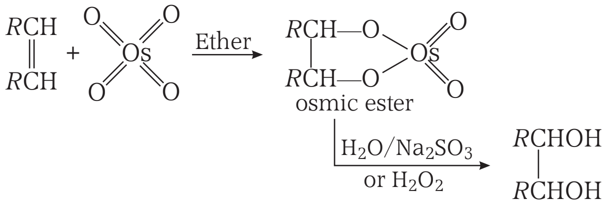


$$\underset{\text{propylene}}{CH_3CH{=}CH_2} \xrightarrow[(NOCl)]{\bar{C}l{-}\overset{+}{N}{=}O} \underset{\text{Propylene nitrosochloride}}{CH_3{-}\underset{Cl}{\underset{|}{C}H}{-}CH_2NO}$$

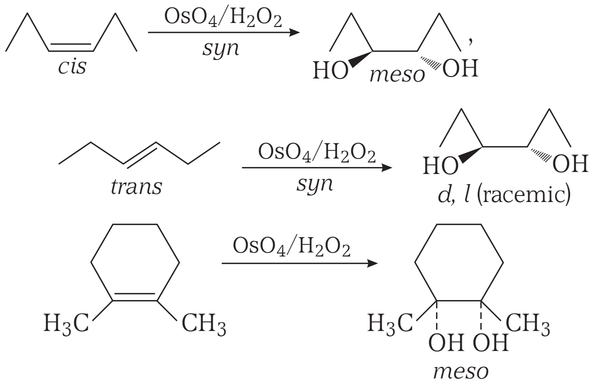
7. Hydroxylation (Insertion of —OH Group)

Hydroxylation with **Baeyer's reagent** ($KMnO_4$/NaOH or $KMnO_4$ cold or $KMnO_4$) and OsO_4 is *syn*-addition (stereo-selective) while with peroxyacids it is an *anti*-addition. Infact with peroxy acids oxiranes are produced in the beginning and peroxyformic acid (HCOOOH) is strong enough to break them into glycols. That means with rest peroxyacids oxiranes are the last product.

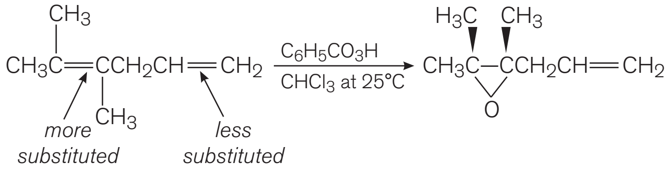




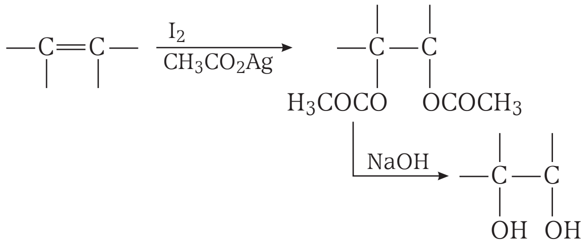
Like $KMnO_4$, in this case also, addition is *syn*.



Caution Point *If peroxybenzoic acid, $C_6H_5CO_3H$ or peroxy acetic acid CH_3CO_3H is used, oxiranes (epoxides) are formed. The more highly substituted double bond is more nucleophilic and therefore, reacts faster with the peroxy acid than the less substituted double bond.*

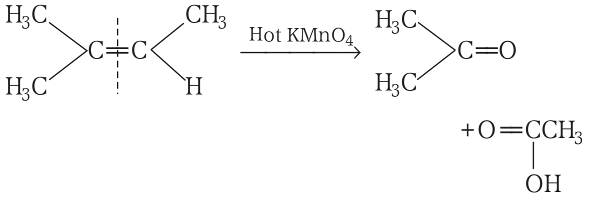


Besides, I_2 with silver acetate can also be used as hydroxylating agent and in this case also the addition is of *syn* type.



8. **Oxidation by Hot or Acidic** $KMnO_4$

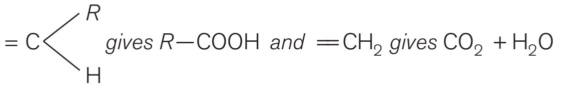
With hot or acidic $KMnO_4$, complete cleavage occurs at $>C{=}C<$ bond resulting to acids or ketone as



Caution Points

(*i*) *During oxidation of alkene with hot* $KMnO_4$.

$= CR_2$ *gets converted into* $O{=}CR_2$

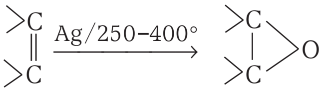


$=C\begin{matrix} R \\ H \end{matrix}$ *gives* $R{-}COOH$ *and* $=CH_2$ *gives* $CO_2 + H_2O$

(*ii*) *If* HCOOH *is formed in the above cleavage, it is further oxidised to* CO_2.

9. **Catalytic Oxidation**

This reaction produces cyclic ethers as



10. **Waker's Process**

In this process alkene is oxidised by treating it with Pd and $CuCl_2$ at 50°C, *e.g.*,

$$\underset{\text{ethene}}{H_2C{=}CH_2} + PdCl_2 + H_2O \xrightarrow{50°C} \underset{\text{acetaldehyde}}{CH_3CHO} + Pd + 2HCl$$

$$\left[\begin{array}{rcl} Pd + 2CuCl_2 & \longrightarrow & PdCl_2 + Cu_2Cl_2 \\ Cu_2Cl_2 + 2HCl + 1/2\,[O]_2 & \longrightarrow & 2CuCl_2 + H_2O \end{array}\right]$$

With propene, acetone is formed.

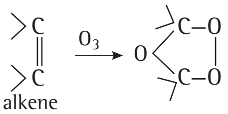
$$\underset{\text{propene}}{CH_3CH{=}CH_2} + PdCl_2 + H_2O \longrightarrow \underset{\text{acetone}}{CH_3COCH_3} + Pd + 2HCl$$

Hot Spot 2

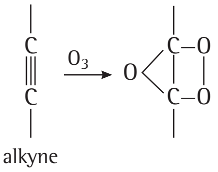
OZONOLYSIS

It is the most important topic for JEE Main examination. The importance of the topic is revealed by the fact that the question are not very difficult and with a small practice, you get mastery in it.

Ozonolysis is oxidation with O_3 (ozonide formation) followed by hydrolysis. In ozonide formation two bonds between carbon atoms are used as



Similarly,

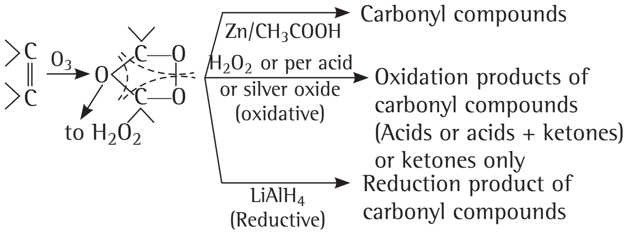


The normal products of this reaction are carbonyl compounds which are formed if hydrolysis is carried out in the presence of mild reducing agents like Zn / CH_3COOH which nullify the oxidising tendency of H_2O_2 formed as the by product of this reaction and have the tendency to oxidise carbonyl product formed.

The hydrolysis may be of oxidation type or reductive type

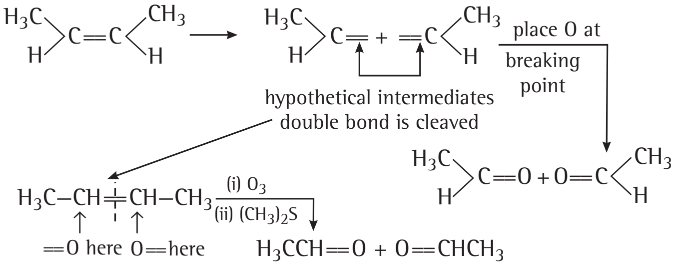
(i) The **oxidative type** hydrolysis results in oxidation products of carbonyl compounds *i.e.,* acids in the presence of oxidising agents like silver oxide or peroxy acids. H_2O_2 produced may also auto-oxidise the products. Among the carbonyl compounds, ketones are not easily oxidised. Thus, we may get either only **acids** or **acid + ketones** or only **ketones** as the product of oxidative hydrolysis.

(ii) The hydrolysis may be **reductive type** also with reagents like $LiAlH_4$ (strong reducing agents) and results to primary and secondary alcohols (reduction products of carbonyl compounds).

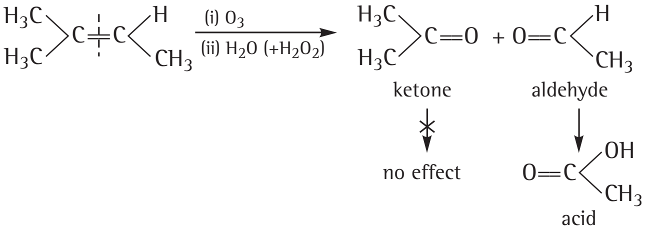


Thus, complete reaction looks as :

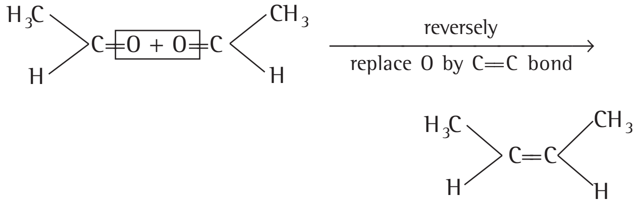
To determine product by ozonolysis of alkenes, break C═C bond and place oxygen at breaking point



If the ozonide is simply treated with water, H_2O_2 is formed as a by product. Under these conditions (or H_2O_2 is added from outside), aldehydes are converted into carboxylic acids, but ketones remain unaffected.



To decide the structure of alkene from ozonolysis products, bring the products together in such a way that O atoms are face to face, replace O by C═C bond. Thus,



Sample **Problem 4** *An alkene ' A' contains three C—C, eight C—H σ-bonds and one C—C π-bond. ' A' on ozonolysis gives two moles of an aldehyde of molar mass 44 u. Write the IUPAC name of ' A'.* [**NCERT**]

(*a*) *but*-1-*ene*

(*b*) 2-*methyl prop*-1-*ene*

(*c*) 2-*methyl prop*-2-*ene*

(*d*) *but*-2-*ene*

Interpret (*d*) To solve such problems, first identify the structure of aldehyde, *R*CHO from the molar mass (44 u) to find the structure of *A*. Join two molecules of aldehyde to find the structure of *A*. Count the number of σ and π-bonds in *A*. Are they satisfy the given data.

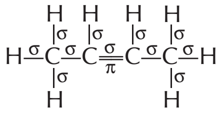
General formula for aldehyde is *R*CHO. Let mass of *R* is *x*.

$$x + 12 + 1 + 16 = 44$$

$$x = 15$$

Mass of CH_3 group is 15, so $R = CH_3$ and aldehyde is CH_3CHO.

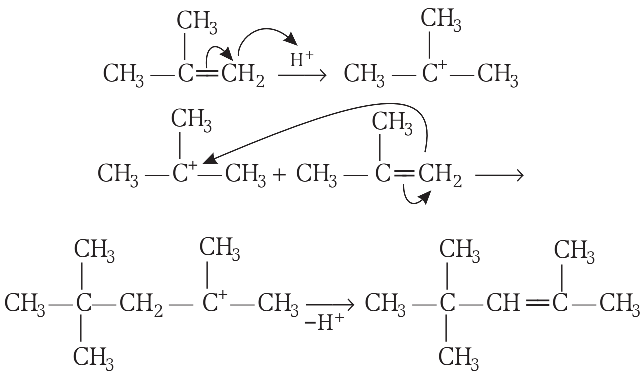
Now,



Hence, alkene (*A*), *i.e.,* but-2-ene contains three C—C, eight C—H,σ-bonds and one C—C π-bond (as given in the question).

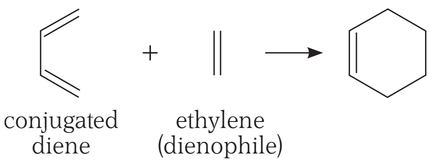
11. Dimerisation

Dimerisation have the similarity with alkylation.The first two steps are common for both the reactions. In the absence of branched alkane and at high temperature, the carbonium ion formed eliminates H^+ resulting to alkene formation again. Due to the presence of H^+ in the reaction yield of product is low. Thus, dimerisation looks as



12. Diels-Alder Reaction

The reaction is also called **cycloaddition** as a new cycle is generated in this reaction. Basically in the reaction a conjugated diene is attacked by an olefin which is called **dienophile.** The reaction looks like as



No other conditions are specified but it is seen that

(i) Attachment of electron attracting groups in dienophile or electron releasing groups in conjugated diene increases the rate of reaction.

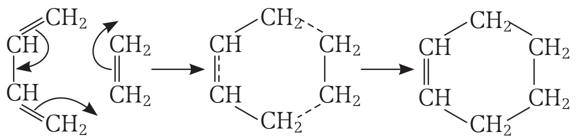
(ii) Besides olefins, alkynes, benzyne  and allenes ($>C═C═C<$) can be used as dienophiles.

(iii) 
can be used as conjugated dienes.

(iv) Benzene, naphthalene and phenanthrene are quite unreactive.

(v) The reaction is strictly **stereospecific** *i.e.*, orientation of groups does not change from reactants to products.

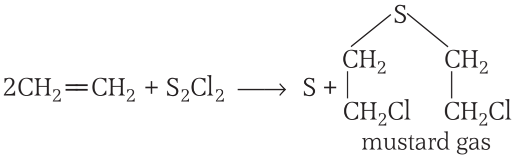
The mechanism of the reaction can be seen as



The bond breakage and formation may be **stepwise** or simultaneous (it is not definite).

13. With S_2Cl_2

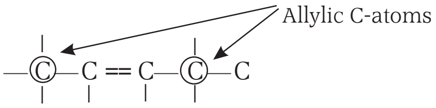
Ethylene on reaction with sulphur monochoride (S_2Cl_2) forms mustard gas which is highly poisonous and used in chemical warfare.



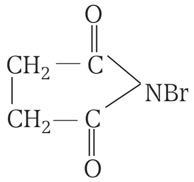
$$2CH_2{=}CH_2 + S_2Cl_2 \longrightarrow S + \underset{\text{mustard gas}}{S(CH_2CH_2Cl)_2}$$

14. Allylic Substitution

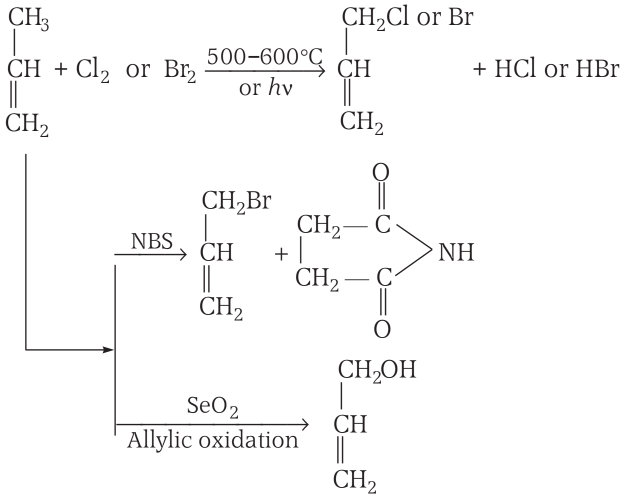
The C–atoms present alternate to carbon-carbon double bond are called **allylic C–atoms** *i.e.*,



NBS is called N–bromo succinimide with the structure



The reaction looks like



15. Polymerisation

When a large number of monomers combine to give a molecule bearing high molecular mass, called the polymer, the process is called polymerisation. The polymerisation reactions can be seen as

(i) $\underset{\text{ethene}}{nCH_2{=}CH_2} \longrightarrow \underset{\text{polyethene}}{\left[CH_2{-}CH_2\right]_n}$

(ii) $\underset{\text{butadiene}}{CH_2{=}CH{-}CH{=}CH_2} \longrightarrow \underset{\text{polybutadiene}}{\left[CH_2{-}CH{=}CH{-}CH_2\right]_n}$

(iii) 
$$\underset{\text{isoprene}}{CH_2{=}\overset{CH_3}{\overset{|}{C}}{-}CH{=}CH_2} \longrightarrow \underset{\substack{cis\text{-polyisopropene}\\ \text{(natural rubber)}}}{\left[CH_2{-}\overset{CH_3}{\overset{|}{C}}{=}CH{-}CH_2\right]_n}$$

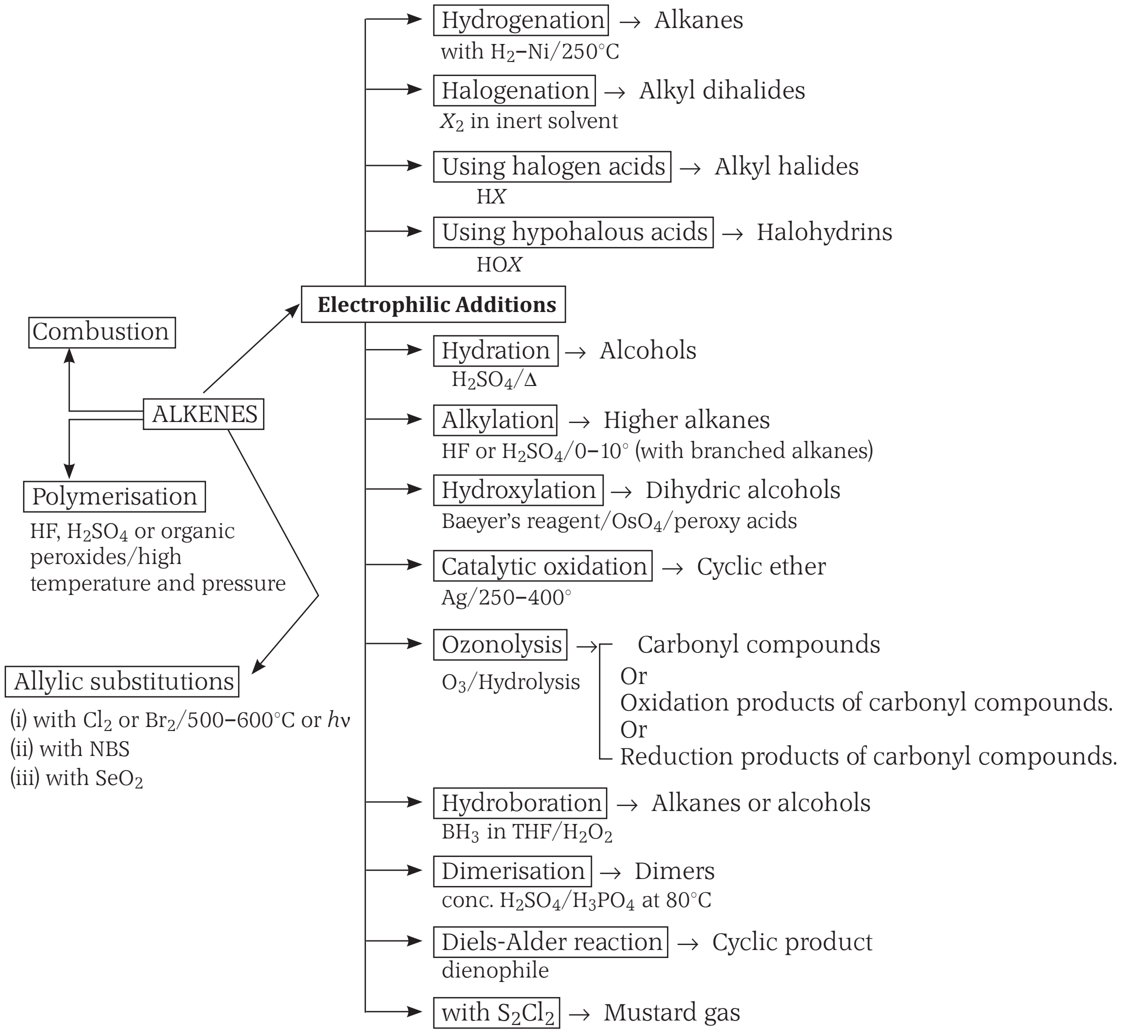
16. Combustion

The generalised combustion reaction can be seen as

$$C_nH_{2n} + \frac{3n}{2}O_2 \longrightarrow nCO_2 + nH_2O + \text{Heat}$$

Note All hydrocarbons on complete combustion gives CO_2 and H_2O.

The outline of the chemical properties of alkenes looks as



Check Point 2

1. The melting point of *cis* but-2-ene is lower than that of *trans* but-2-ene. Explain why?
2. The solubility of *cis*-alkenes is higher than the corresponding *trans* alkenes in a particular solvent. Explain.
3. Peroxide effect is not applicable in case of HF, HCl etc. Explain why?
4. Hydroxylation with $KMnO_4$ gives *syn*-addition whereas with peracid gives *anti*-addition why?
5. Hydration of propene with dilute H_2SO_4 gives 2-propanol but its hydroboration gives 1-propanol. Why?

15.4 Alkynes

These form the second series of **unsaturated hydrocarbons** with highest possible degree of unsaturation. Their general formula is C_nH_{2n-2}, with two π-bonds and one σ-bond between two C–atoms *i.e.*, total 3 bonds. This group of three bonds is often called **acetylenic bond.** (Acetylene is the first and most important member).

These are named by adding suffix 'yne' to the root word. These exhibit chain and functional isomerism (For details see Chapter 13 and 14).

Methods of Preparation

General methods of preparation of alkynes are as follows

1. By Hydrolysis of Metal Carbides

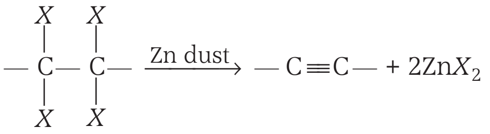
The metal carbides of group IInd elements give alkynes on reaction with H_2O

$$\text{(i)}\ \left.\begin{array}{l} MgC_2 \\ CaC_2 \\ SrC_2 \\ BaC_2 \end{array}\right\} + 2H_2O \longrightarrow C_2H_2 + \text{Metal hydroxide } [M(OH)_2]$$

$$\text{(ii)}\ Mg_2C_3 + 4H_2O \longrightarrow CH_3C{\equiv}CH + 2Mg(OH)_2$$

2. Dehalogenation

Dehalogenation of tetrahalides with Zn dust can be seen as



$$-\overset{X}{\underset{X}{C}}-\overset{X}{\underset{X}{C}}- \xrightarrow{\text{Zn dust}} -C{\equiv}C- + 2ZnX_2$$

In case of trihalides Ag is used.

$$CH\boxed{X_3 + 6Ag + X_3}CH \xrightarrow{\Delta} CH{\equiv}CH + 6AgX$$

3. Dehydrohalogenation

For dehydrohalogenation see alkenes (methods of preparation) and remember KNH_2, $NaNH_2$ in liquid NH_3 and NaH etc., are better dehydrohalogenating agents than alcoholic KOH.

4. Kolbe's Electrolytic Method

Electrolysis of potassium fumerate $\left(\begin{array}{l} CHCOO^-K^+ \\ \| \\ CHCOO^-K^+ \end{array}\right)$ produces acetylene with the liberation of CO_2 and H_2 at anode and cathode respectively.

5. From Sodium Acetylide

Reaction of sodium acetylide with alkyl halides is used to prepare higher alkynes from lower alkynes as

$$\begin{tikzcd} HC{\equiv}CH + Na \arrow[r, "\text{liquid}", "NH_3"'] & HC{\equiv}C^-Na^+ \arrow[r, "RX", "-NaX"'] & HC{\equiv}CR \arrow[d, "\text{Na in liquid}\ NH_3"] \\ R'{-}C{\equiv}C{-}R & & Na^+C^-{\equiv}CR \arrow[ll, "R'X"', "-NaX"] \end{tikzcd}$$

The reaction is seen only in acidic alkynes *i.e.,* the alkynes in which triply bonded C-atom contain atleast one replaceable H, for example acetylene and terminal alkynes.

6. From Grignard's Reagent

Grignard reagents also help in preparing higher alkynes from lower alkynes as

$$\begin{tikzcd} HC{\equiv}CH + RMgX \arrow[r] & HC{\equiv}C^-Mg^+X^- \arrow[d, "RX"] \\ & HC{\equiv}C{-}R + MgX_2 \end{tikzcd}$$

7. Other Methods

These are used to prepare acetylene and include

(i) By passing an electric discharge through graphite electrodes in the atmosphere of hydrogen.

$$\underset{\text{(graphite)}}{2C} + H_2 \xrightarrow{1200°C} CH{\equiv}CH$$

(ii) By the controlled oxidation of methane as

$$3CH_4 + 3O_2 \xrightarrow{1500°C} CH{\equiv}CH + CO + 5H_2O$$

The outline of the methods of preparation of alkynes are as

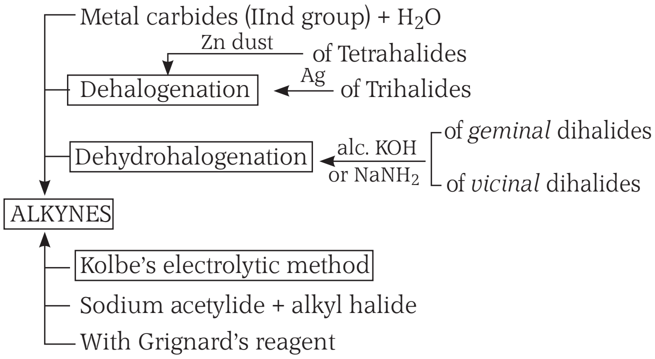


Fig. 15.3 Flow chart showing general methods of preparation of alkynes

Physical Properties

1. First three members of alkynes are gases, next eight are liquids and higher alkynes are solids.
2. All alkynes are colourless and odourless except acetylene which has garlic odour.
3. Melting and boiling points and densities of alkynes are slightly higher than that of corresponding alkenes and alkanes. These properties generally increases with increase in molecular mass.
4. These are lighter than water and also insoluble in it. However, they are soluble in non-polar solvents like benzene, ether etc.

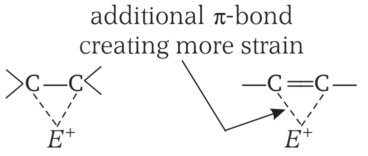
5. Acetylene and terminal alkynes $\left[\begin{array}{c}CH\\ |||\\ CH\end{array}\ \text{and}\ \begin{array}{c}CR\\ |||\\ CH\end{array}\right]$ are acidic in nature. *The acidic nature of alkynes is due to sp-hybridisation present in them because of which the electrons of* C—H *bond are held more strongly by* C–*nucleus*. Alkynes like $R—C\equiv C—R$ are non-acidic as these lack replaceable hydrogen in them.

Chemical Properties

Alkynes exhibit following chemical properties

1. Electrophilic Addition Reactions

As far as **electrophilic additions** are concerned in general alkenes are more reactive than alkynes. The reason is more strained (less stable) cyclic intermediate in the case of alkynes due to the presence of additional π-bond in alkynes.



less strained, more stable cyclic intermediate of alkenes

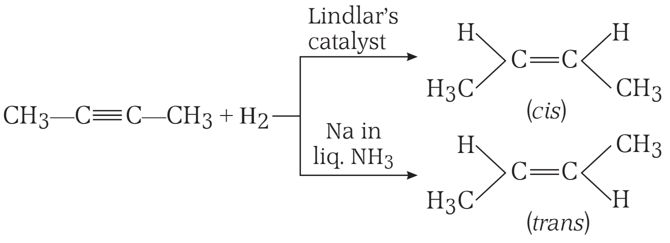
more strained, less stable cyclic intermediate of alkynes

(i) **Hydrogenation** For hydrogenation see alkene (Chemical properties;) and alkanes (Methods of preparation).

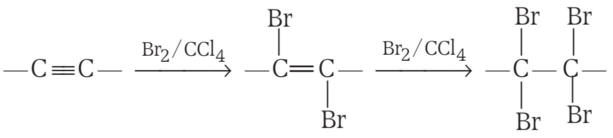
$$CH_3—C\equiv CH + 2H_2 \xrightarrow{\text{Ni or Pt or Pd}} CH_3CH_2CH_3$$

$$CH_3—C\equiv CH + H_2 \xrightarrow{\text{Lindlar's catalyst}} CH_3—CH=CH_2$$

2-butyne when reduced with Lindlar's catalyst gives nearly 100% *cis*-isomer while with Na in liquid ammonia gives nearly 100% *trans*-isomer.

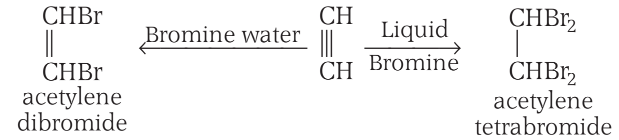


(ii) **Halogenation** Halogenation can be seen as :



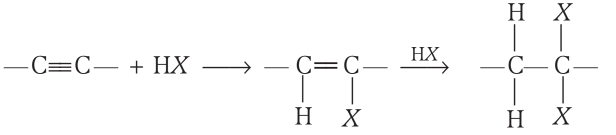
$$—C\equiv C— \xrightarrow{Br_2/CCl_4} —\overset{Br}{\overset{|}{C}}=\underset{Br}{\underset{|}{C}}— \xrightarrow{Br_2/CCl_4} —\overset{Br}{\overset{|}{\underset{Br}{\underset{|}{C}}}}—\overset{Br}{\overset{|}{\underset{Br}{\underset{|}{C}}}}—$$

Liquid bromine yields tetrabromo derivative while bromine water or Br_2/CCl_4 forms dibromo derivative.



$$\underset{\text{acetylene dibromide}}{\begin{array}{c}CHBr\\ \|\\ CHBr\end{array}} \xleftarrow{\text{Bromine water}} \begin{array}{c}CH\\ |||\\ CH\end{array} \xrightarrow[\text{Bromine}]{\text{Liquid}} \underset{\text{acetylene tetrabromide}}{\begin{array}{c}CHBr_2\\ |\\ CHBr_2\end{array}}$$

(iii) **Addition of Halogen Acids**

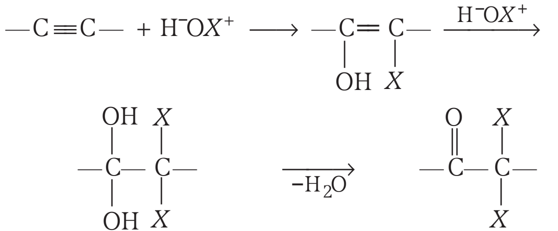


$$—C\equiv C— + HX \longrightarrow —\underset{H}{\underset{|}{C}}=\underset{X}{\underset{|}{C}}— \xrightarrow{HX} —\overset{H}{\overset{|}{\underset{H}{\underset{|}{C}}}}—\overset{X}{\overset{|}{\underset{X}{\underset{|}{C}}}}—$$

(*gem*-dihalide)

(also see alkene properties)

(iv) **Addition of Hypohalous Acids**



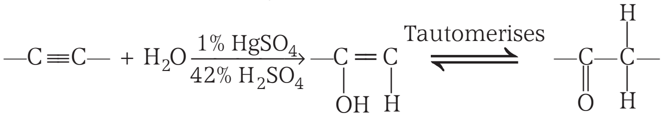
$$—C\equiv C— + H^-OX^+ \longrightarrow —\underset{OH}{\underset{|}{C}}=\underset{X}{\underset{|}{C}}— \xrightarrow{H^-OX^+}$$

$$—\overset{OH}{\overset{|}{\underset{OH}{\underset{|}{C}}}}—\overset{X}{\overset{|}{\underset{X}{\underset{|}{C}}}}— \xrightarrow{-H_2O} —\overset{O}{\overset{\|}{C}}—\overset{X}{\overset{|}{\underset{X}{\underset{|}{C}}}}—$$

(Alkynes exhibit following chemical properties)

halogen derivative of carbonyl compound

(v) **Hydration** Hydration occurs in the presence of 1% $HgSO_4$ and 42% H_2SO_4 as

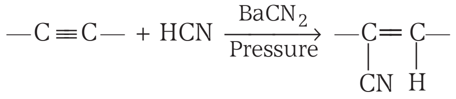


$$—C\equiv C— + H_2O \xrightarrow[42\%\ H_2SO_4]{1\%\ HgSO_4} —\underset{OH}{\underset{|}{C}}=\underset{H}{\underset{|}{C}} \overset{\text{Tautomerises}}{\rightleftharpoons} —\underset{O}{\underset{\|}{C}}—\overset{H}{\overset{|}{\underset{H}{\underset{|}{C}}}}—$$

carbonyl compound

Among the alkynes only acetylene gives aldehydes, rest all the alkynes gives ketones as the final product of this reaction.

(vi) **Addition of HCN** Addition of HCN occurs in the presence of $BaCN_2$ under pressure as



$$—C\equiv C— + HCN \xrightarrow[\text{Pressure}]{BaCN_2} —\underset{CN}{\underset{|}{C}}=\underset{H}{\underset{|}{C}}—$$

Acetylene gives vinyl cyanide (acrylonitrile) on the polymerisation of which synthetic fibre **orlon** is obtained.

$$HC\equiv CH + HCN \xrightarrow[\text{Pressure}]{BaCN_2} \underset{\text{acrylonitrile}}{CH_2=CH—CN}$$

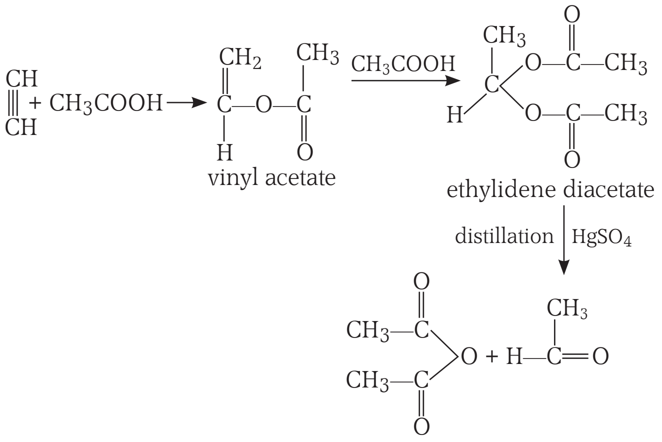
Some Addition Reactions Given by Acetylene

Only Acetylene (CH≡CH) especially undergo some more addition reactions which are

(i) **Addition of alcohols** Ethers are produced as

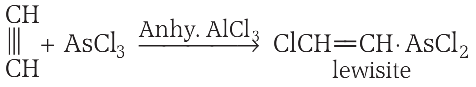
$$HC\equiv CH + ROH \xrightarrow[\substack{120\text{–}180°\\ \text{high pressure}}]{KOH\ \text{or}\ CH_3O^-K^+} \underset{\text{alkyl vinyl ether}}{CH_2=CH—OR}$$

(ii) **Addition of CH_3COOH** It is a very useful reaction used in the preparation of acetic anhydride. Ethylidene diacetate is produced in the beginning, which on distillation in the presence of $HgSO_4$, gives acetaldehyde and acetic anhydride as



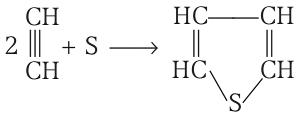
Vinyl acetate is used in the manufacture of synthetic rubber and plastic.

(iii) **Addition of arsenic trichloride** Reaction occur in the presence of $AlCl_3$ (anhydrous) to yield **lewisite** (a poisonous gas) used in chemical war as



$$CH\equiv CH + AsCl_3 \xrightarrow{\text{Anhy. }AlCl_3} \underset{\text{lewisite}}{ClCH{=}CH\cdot AsCl_2}$$

(iv) **Addition of sulphur** When acetylene is passed over heated iron pyrites (FeS_2) at 300°C, it combines with sulphur of iron pyrites to form **thiophene** as

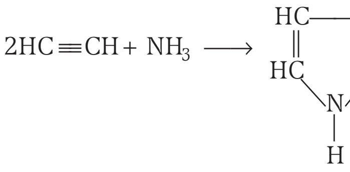


thiophene

(v) **Addition of N_2** When an electric spark is passed through a mixture of acetylene and nitrogen, HCN is produced as

$$HC\equiv CH + N_2 \xrightarrow[\text{spark}]{\text{Electric}} 2H{-}C\equiv N$$

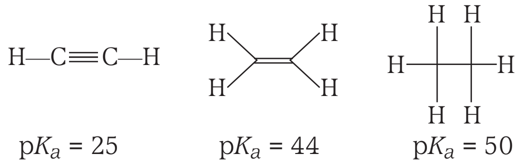
(vi) Addition of NH_3 At high temperatures, NH_3 combines with acetylene to form **pyrrole** as



pyrrole

2. Acidic Character of Alkynes

The hydrogen bonded to the carbon of terminal alkyne is considerably more acidic than those bonded to carbons of alkenes and alkanes. The pK_a values for ethyne, ethene and ethane illustrate this point.



Due to the presence of this acidic H atom, alkynes (terminal) exhibit the following reactions.

(i) **Reaction with Na in liquid NH_3** The reaction with Na in liquid NH_3 is considered as test of acidity. H_2 is released in the reaction as

$$H{-}C\equiv C{-}R + Na \xrightarrow[NH_3]{\text{In liquid}} Na^+C^-\equiv C{-}R + \frac{1}{2}H_2\uparrow$$

(ii) **Reaction with Tollen's reagent** With Tollen's reagent (ammoniacal $AgNO_3$), a white precipitate, of silver salt is obtained. The reaction is used to differentiate between terminal (acidic) alkynes with rest of the alkynes *i.e.*, helpful in detecting the position of triple bond (interstitial or terminal).

$$H{-}C\equiv C{-}H + 2AgNO_3 + 2NH_4OH \longrightarrow \underset{\substack{\text{silver acetylide}\\ \text{(white ppt.)}}}{Ag{-}C\equiv C{-}Ag} + 2NH_4NO_3 + 2H_2O$$

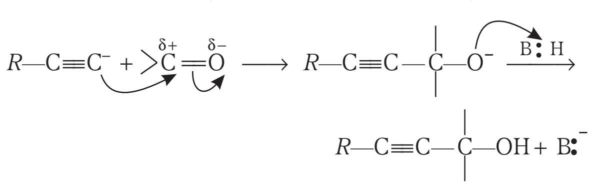
(iii) **Fehling's solution** It is also used for the same purpose as that Fehling's solution is used. Terminal alkynes with Fehling's solution give red precipitate of their copper salts.

$$H{-}C\equiv C{-}H + Cu_2Cl_2 + 2NH_4OH \longrightarrow \underset{\substack{\text{copper acetylide}\\ \text{(red ppt)}}}{Cu{-}C\equiv C{-}Cu} + 2NH_4Cl + 2H_2O$$

$$R{-}C\equiv C{-}H + Cu_2Cl_2 + 2NH_4OH \longrightarrow \underset{\text{copper alkynide}}{R{-}C\equiv C{-}Cu} + 2NH_4Cl + 2H_2O$$

3. Ethinylation

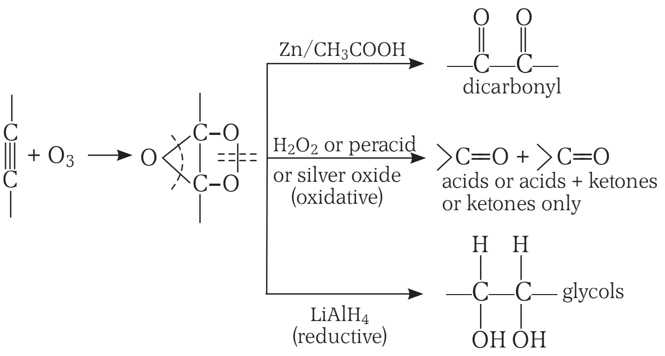
In this reaction terminal alkynes work as nucleophile, thus add to $>C{=}O$ group through nucleophilic addition, in the presence of base as :



Here, B$\colon^-$ is a base. The reaction is seen as a modification of **Aldol condensation.**

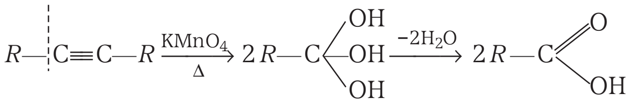
4. Ozonolysis

The ozonolysis in the case of alkynes can be seen as

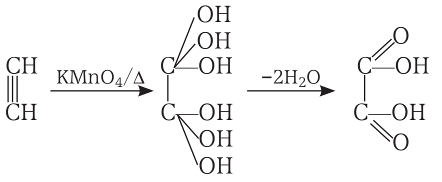


5. Oxidation with $KMnO_4$

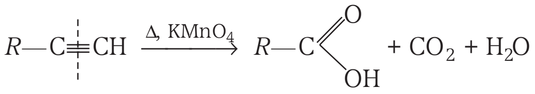
Oxidation with hot $KMnO_4$ produces carboxylic acids as



CH≡CH under these conditions gives oxalic acid as

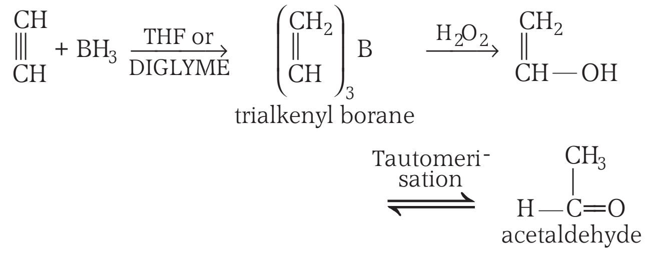


Rest of acidic alkynes produce CO_2 also along with acid as

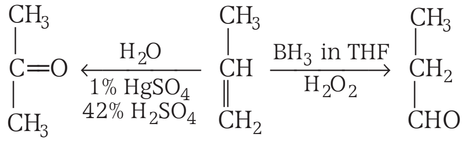


6. Hydroboration-oxidation

Hydroboration oxidation of alkyne can be seen as

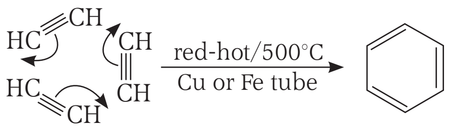


Contrary to hydration in this case all alkynes give aldehydes *i.e.,*



7. Polymerisation

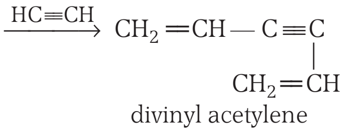
In the polymerisation reactions of alkynes, aromatic compounds are produced when their vapours are passed through red hot Cu or Fe tube as



When acetylene is passed through cuprous chloride solution containing NH_4Cl, linear polymerisation occurs resulting to mono vinyl and divinyl acetylene as

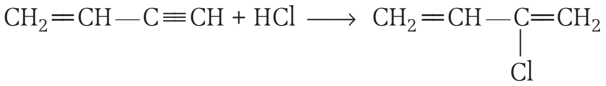
$$2HC\equiv CH \xrightarrow[NH_4Cl]{Cu_2Cl_2} CH_2{=}CH{-}C\equiv CH$$

monovinyl acetylene



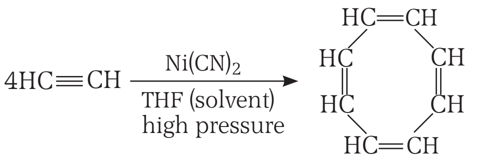
divinyl acetylene

Monovinyl acetylene is used for the synthesis of **chloroprene,** the constituent of **neoprene** (the synthetic rubber) as



chloroprene

In the presence of $Ni(CN)_2$ and under high pressure, acetylene dissolves in THF and polymerises to give cyclooctatetraene as



cyclooctatetraene

When acetylene is heated in the presence of spongy copper or its oxides, a cork like substance is produced which is called **cuprene.** It is used in the manufacture of linoleum.

Summary of the reactions of alkynes is given in the following flow chart.

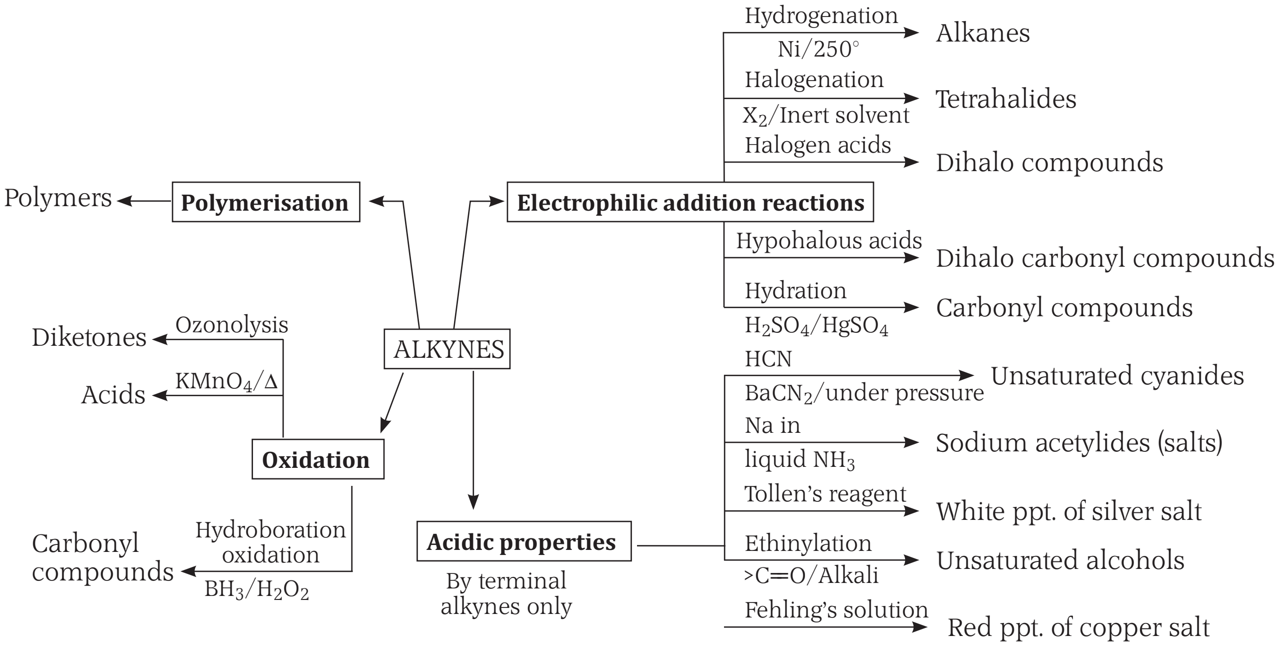


Fig. 15.4 Flow chart showing reactions of alkynes

Check Point 3

1. Explain why are alkynes less reactive than alkenes towards electrophilic addition reactions?
2. Explain why alkynes undergo nucleophilic addition reactions while simple alkenes do not?
3. $CH_2{=}CH^-$ is more basic than $HC{\equiv}C^-$. Explain.
4. Why does HF form H-bonding with ethyne even though it is non-polar in nature?

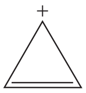
Aromatic Hydrocarbons

Aromatic hydrocarbons are specialised cyclic compounds which are known for their characteristic unique smell (*Aroma* = fragrance). The group is also called **arenes.** Although the name aromatic was given for their pleasant odour, but today, it is used for a class of compounds having a characteristic stability despite having unsaturation.

15.5 **Aromaticity**

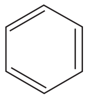
A compound can be considered as aromatic if it follows following three rules :

(i) An aromatic compound must be cyclic and planar.
(ii) An aromatic compound must have the conjugated system in it.
(iii) An aromatic compound must follow **Huckel rule** which states that the number of π-electrons = $(4n + 2)$; where n = integer 0, 1, 2, 3 etc. For example, in



number of π-electrons = 2.

$(4n + 2) = 2$ and $n = 0$ thus Huckel rule is followed.



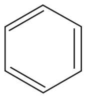
, Number of π-electron = 6.

$(4n + 2) = 6$ and $n = 1$ thus Huckel rule is followed.

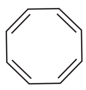
Those compounds which does not follow the above 3 rules are called **non-aromatic.** These non-aromatic compounds may be cyclic with conjugated system, for example,  (cyclooctatetraene) is cyclic with conjugated system but it does not follow Huckel rule and its plane is also distorted that's why it is non-aromatic.

Compounds which are monocyclic and contain ($4n$) π-electrons are much more reactive than expected even more reactive than their acyclic analogues. This decreased stability in ($4n$) molecules has been called *anti-aromaticity* (Breslow, 1967) for example, cyclooctatetraenide salts.

The name **annulene** has been proposed as a general name for monocyclic compounds having alternating single and double bonds (conjugated system of bonds) and the ring size is indicated with in brackets as a number before annulene as



benzene or [6] annulene
(aromatic)



cyclooctatetraene or
[8] annulene (non-aromatic)

15.6 Benzene

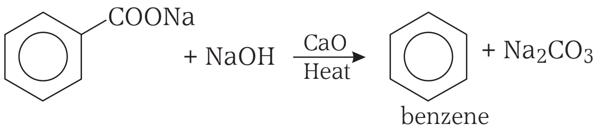
It is the first member of aromatic hydrocarbon series.

Methods of Preparation of Benzene

Following methods can be used to prepare benzene

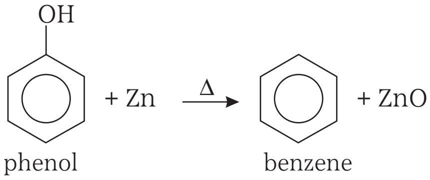
(i) Decarboxylation

It is prepared by heating the mixture of sodium benzoate and sodalime.



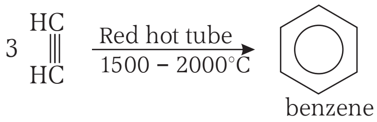
(ii) Dehydroxylation

Benzene is obtained by dehydroxylation of phenol with red hot zinc powder.



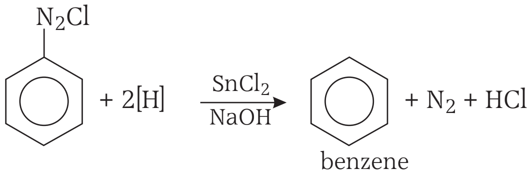
(iii) Polymerisation

When acetylene is passed through a red hot metallic tube, cyclic polymerisation takes place and benzene is formed.



(iv) Reduction of Benzene Diazonium Chloride

Benzene diazonium chloride is reduced to benzene by $SnCl_2$ and NaOH or absolute ethyl alcohol or hypophosphorous acid (H_3PO_2).



(v) Distillation

Distillation of coal-tar gives following fractions

(a) **Light oil** Below 200°C–contains BTX (Benzene, toluene and xylene) as its chief components.

(b) **Middle oil** 200–240°C–contains phenols, cresols and naphthalene.

(c) **Heavy oil** 245–280°C–contains cresols and naphthalene.

(d) **Anthracene oil** (green oil) 280–405°C-contains anthracene, phenanthrene and carbazole.

(e) **Pitch** The residue containing 5 and 6 membered fused rings and tar oils.

Benzene is obtained from light oil fraction as

$$\text{Light oil fraction} \xrightarrow[\substack{\text{(i) } H_2SO_4 \text{ (basic impurity remover)} \\ \text{(ii) NaOH (acidic impurity remover)}}]{\text{washed}} \text{Light oil fraction without impurities}$$

$$\downarrow \text{Washed with water, dried and distilled}$$

$$\text{Almost pure benzene between 80–82°C with traces of thiophene} \xleftarrow{\text{Refractioned}} \text{110°C fraction contains benzene, toluene and thiophene}$$

$$\downarrow \begin{array}{l} H_2 / 400°C \\ \text{Ni under pressure} \end{array}$$

Pure benzene + H_2S

(vi) Cracking of Petroleum

From petroleum, benzene is obtained through aromatisation or platforming of C_6-C_{10} fraction of petroleum naphtha as

$$\text{Hexane} \xrightarrow[500^\circ\text{C } 15 \text{ atm}]{\text{Pt, Al}_2\text{O}_3} \text{Benzene}$$

$$\text{Heptane} \xrightarrow[500^\circ\text{C, } 15 \text{ atm}]{\text{Pt, Al}_2\text{O}_3} \text{Toluene}$$

The reaction is the modified form of aromatisation reaction of alkanes (see properties of alkanes; reaction 6)

Summary of the methods of preparation of benzene is given below.

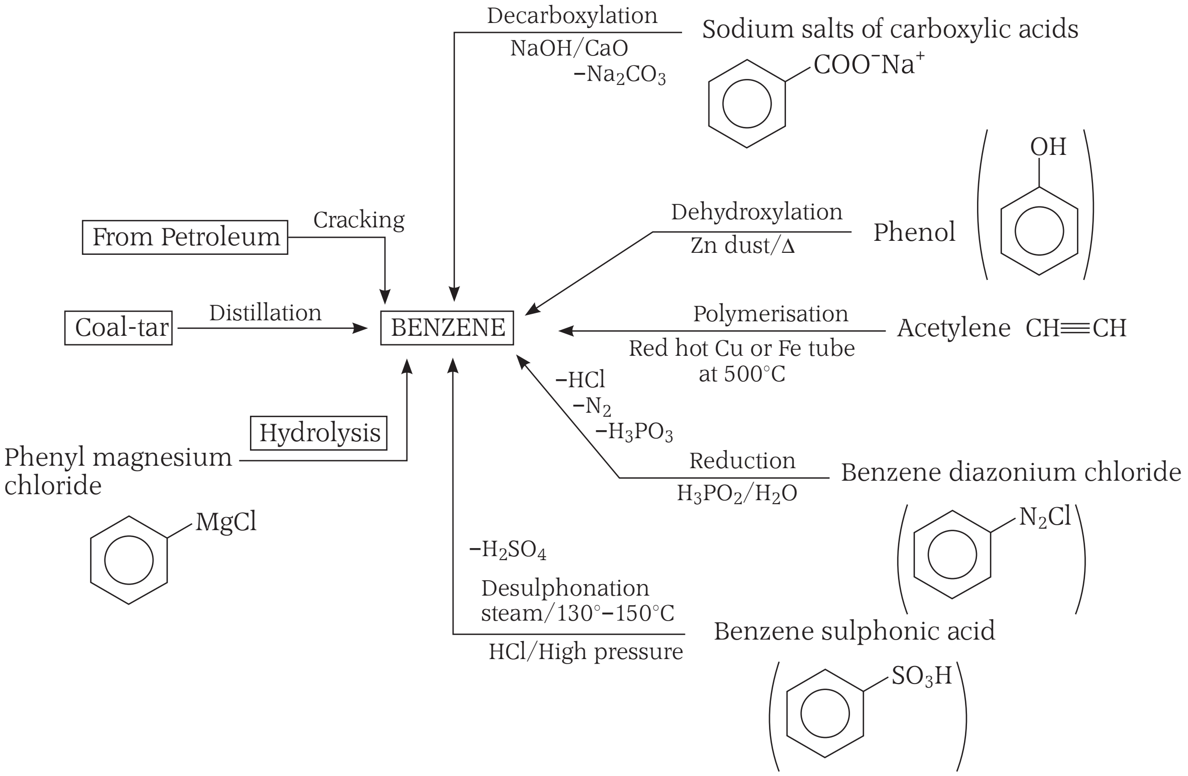


Fig. 15.5 Flow chart showing methods of preparation of benzene

Physical Properties of Benzene

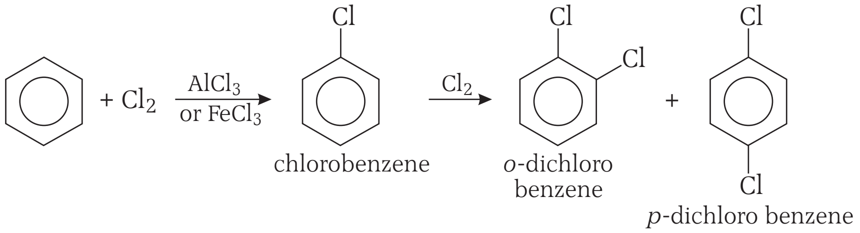
Benzene is a colourless liquid, b.p. 80.1°C, m.p. 5.5°C, insoluble in water, miscible with alcohol, ether and chloroform, itself a good solvent, vapours highly toxic, burns with a luminous sooty flame.

Chemical Properties of Benzene

Important chemical reactions exhibited by benzene are given below.

(i) Halogenation

Benzene undergo chlorination when it is treated with chlorine in the presence of catalyst aluminium chloride or ferric chloride and in the absence of light.



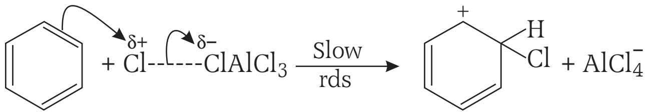
This reaction follows the following mechanism

Step I Generation of an electrophile

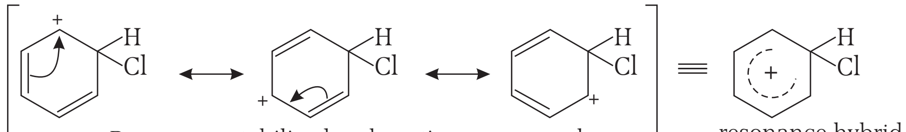
$$\mathrm{Cl{-}Cl + AlCl_3 \longrightarrow \overset{\delta+}{Cl}\text{------}\overset{\delta-}{Al}Cl_3}$$

electrophile

Step II Formation of σ-complex or carbocation intermediate.



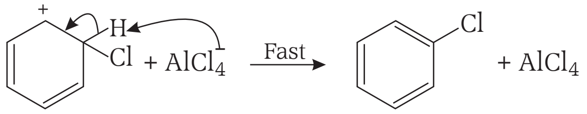
σ-complex



Resonance stabilized carbocation or σ-complex

resonance hybrid

Step III Loss of a proton from the carbocation intermediate.

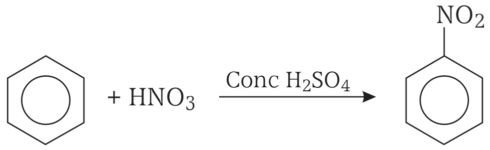


chlorobenzene

(This step is fast and hence, does not affect the rate of the reaction).

(ii) Nitration

Benzene undergoes nitration when treated with conc HNO_3 in the presence of conc sulphuric acid.

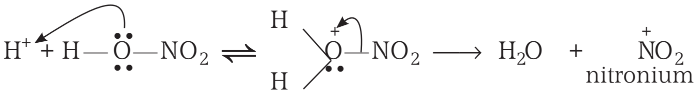


nitrobenzene

The steps involved during this reaction are as follows

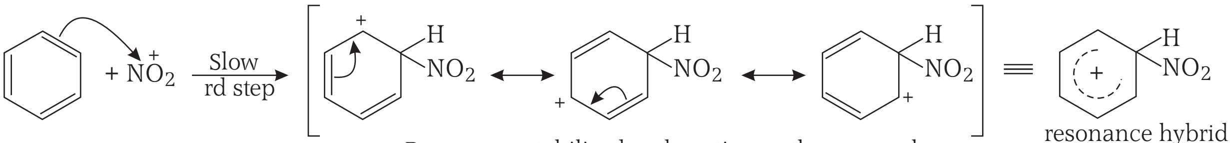
Step I Generation of an electrophile, *i.e.*, NO_2^+ (nitronium ion).

$$H_2SO_4 \longrightarrow H^+ + HSO_4^-$$



nitronium ion

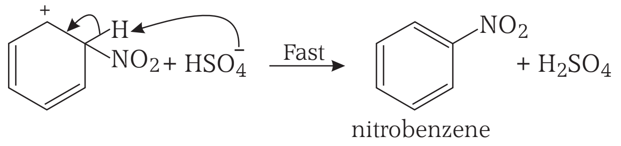
Step II Formation of σ-complex or carbocation intermediate.



Resonance stabilized carbocation or the σ-complex

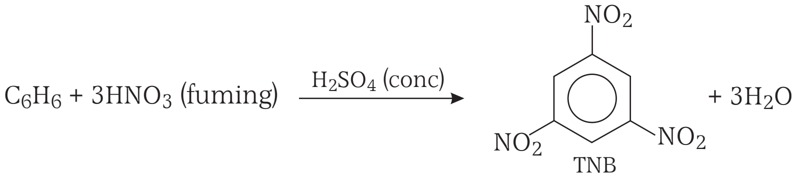
resonance hybrid

Step III Loss of a proton from the carbocation intermediate.



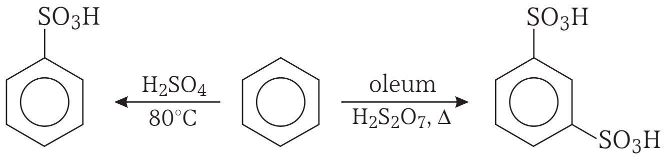
(This step is fast and hence does not affect the rate of the reaction.)

On heating benzene with fuming nitric acid and conc H_2SO_4, 1,3,5-trinitrobenzene (TNB) is formed



(iii) **Sulphonation**

Benzene forms benzene sulphonic acid with hot conc H_2SO_4, while with fuming H_2SO_4 or oleum at high temperature, *m*-benzene disulphonic acid is formed.



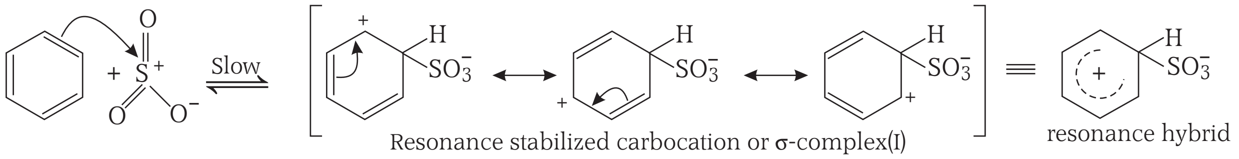
For sulphonation the attacking species is SO_3 or $\overset{+}{S}O_3H$.

This reaction involves the following mechanism

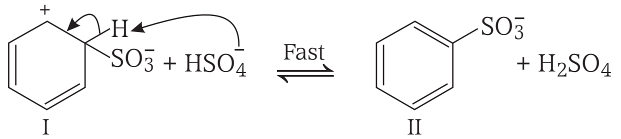
Step I Generation of an electrophile, *i.e.,* sulphur trioxide (SO_3).

$$2H_2SO_4 \rightleftharpoons SO_3 + HSO_4^- + H_3O^+$$

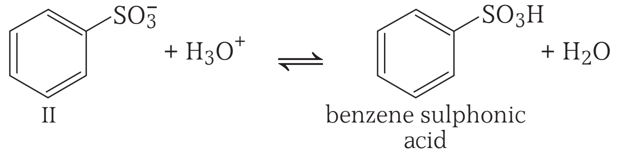
Step II Formation of σ-complex or carbocation intermediate.



Step III Loss of a proton from the carbocation.



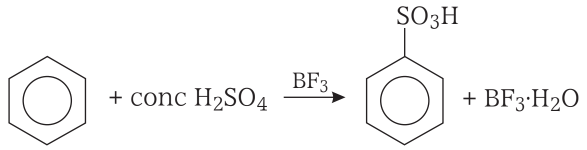
Step IV Addition of proton to the benzenesulphonic acid anion (II) gives the final product.



This equilibrium lies far to the left since sulphonic acid is a strong acid.

It may be pointed out here that unlike other electrophilic aromatic substitution reactions, sulphonation is reversible.

Sulphonation can also be carried out at room temperaure in the presence of BF_3 catalyst.



(iv) Friedel-Crafts Alkylation, Acylation or Carboxylation

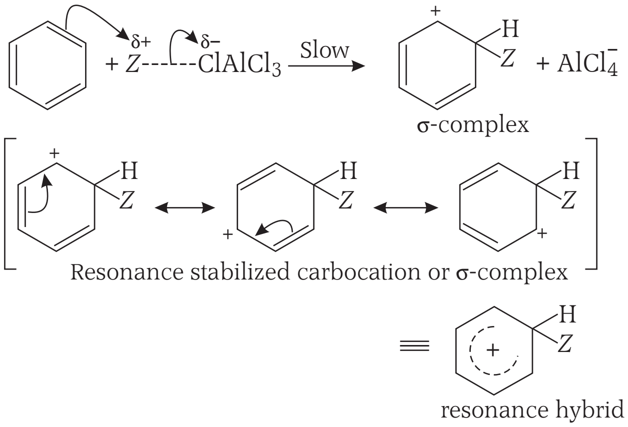
Lewis acids can be used for these reactions are $AlCl_3$, $FeCl_3$, $SnCl_2$, $SnCl_4$, BF_3, HF etc.

These reactions involve the following step

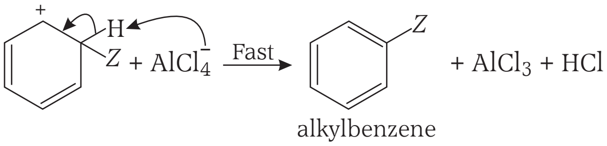
Step I Generation of an electrophile

$$Z\text{—}Cl + AlCl_3 \longrightarrow \underset{\text{electrophile}}{\overset{\delta+}{Z}\text{------}\overset{\delta-}{Cl}AlCl_3}$$

Step II Formation of σ-complex or carbocation intermediate.



Step III Loss of a proton from the carbocation intermediate.



(This step is fast and hence does not affect the rate of the reaction)

(where, $Z = -R$, —COR)

(v) Formylation

The attacking electrophile is $\overset{\overset{\displaystyle O}{\|}}{C^+}\text{—}H$, which is produced as

$$CO + HCl \rightleftharpoons H\text{—}\underset{\underset{\displaystyle O}{\|}}{C}\text{—}Cl$$

$$H\text{—}\underset{\underset{\displaystyle O}{\|}}{C}\text{—}Cl + AlCl_3 \rightleftharpoons H\text{—}\underset{\underset{\displaystyle O}{\|}}{C^+} + AlCl_4^-$$

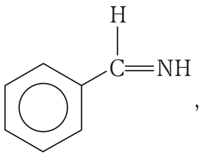
Gattermann synthesis

(a) The attacking electrophile is $\overset{+}{C}H{=}NH$, which is produced as

$$HC{\equiv}N + HCl \rightleftharpoons H\text{—}\underset{\underset{\displaystyle Cl}{|}}{C}{=}NH$$

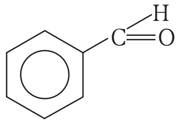
$$H\text{—}\underset{\underset{\displaystyle Cl}{|}}{C}{=}NH + AlCl_3 \rightleftharpoons H\text{—}C^+{=}NH + AlCl_4^-$$

(b) The product formed initially is



,

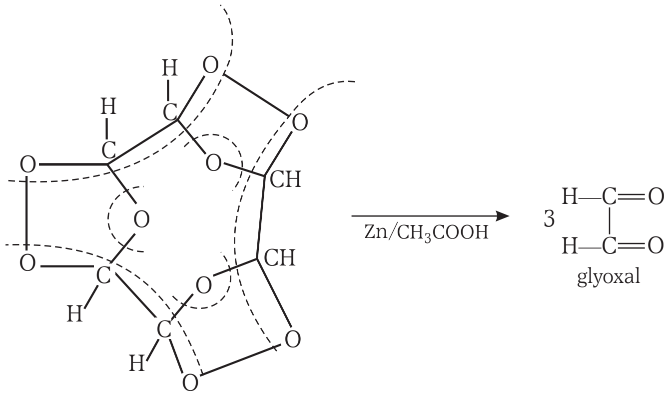
which on hydrolysis gave



and NH_3.

(vi) Ozonolysis

The ozonide formed in this reaction looks like

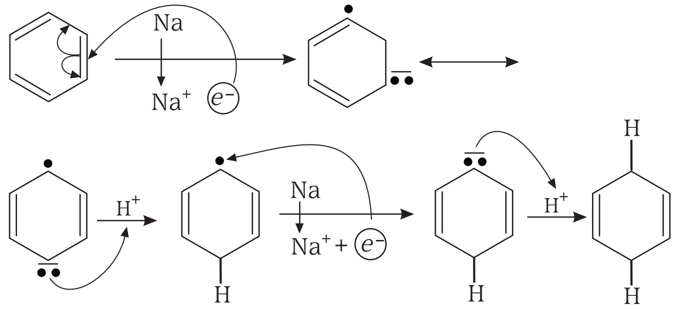


(vii) Vapour Phase Oxidation

Maleic acid $\left(\begin{array}{l}CHCOOH\\ \|\\ CHCOOH\end{array}\right)$ is first produced in the reaction which looses water at such a high temperature and converted into anhydride.

(viii) Addition Reactions

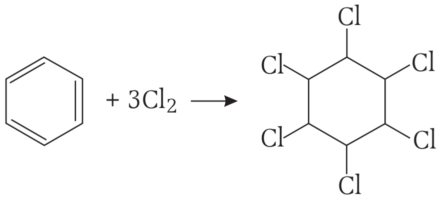
(a) Halogenation and hydrogenation operate through free radical mechanisms while in **Birch reduction** the metal used is of Ist group *i.e.*, Li, Na (mostly Na) and alcohol normally CH_3OH (or C_2H_5OH). Here metal works for electron donation and alcohol for proton donation as :



The H^+ is provided here by alcohol. At high temperature even alcohol is not needed. NH_3 provides H^+ at high temperatures and the product at high temperatures is .

The uniqueness of pathway here is that the addition is throughout 1,4-addition, *i.e.*, initially  is formed which on further 1,4-addition gave .

(b) The product of halogenation is $C_6H_6Cl_6$ (Benzene hexachloride or BHC). It is also called **Lindane** or **Gammexane** or 666 and is used as insecticide.



Sample **Problem 7** *Benzene undergoes electrophilic substitution reactions easily and nucleophilic substitution with difficulty. This is because* **[NCERT]**

(*a*) *of* $6\pi e^-s$
(*b*) *benzene is* e^- *deficient*
(*c*) *benzene is* e^- *rich*
(*d*) *both* (a) *and* (c)

Interpret (*d*) Due to the presence of delocalized 6π-electrons, benzene acts as a rich source of electrons. So, it attracts the electrophilic reagent (electron deficient species) towards itself but repels the nucleophilic reagents. That's why benzene gives electrophilic substitution reactions easily and nucleophilic substitution reactions with difficulty.

The outline of chemical properties of benzene looks like

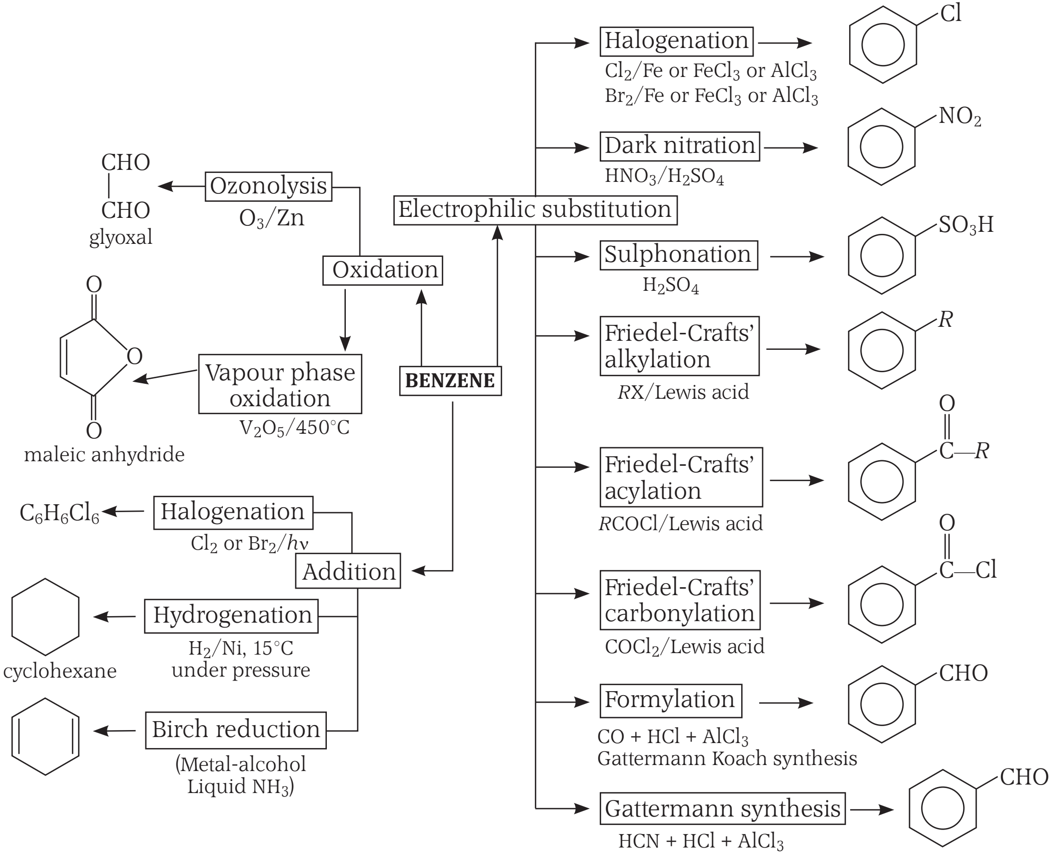


Fig. 15.6 Flow chart showing chemical reactions of benzene

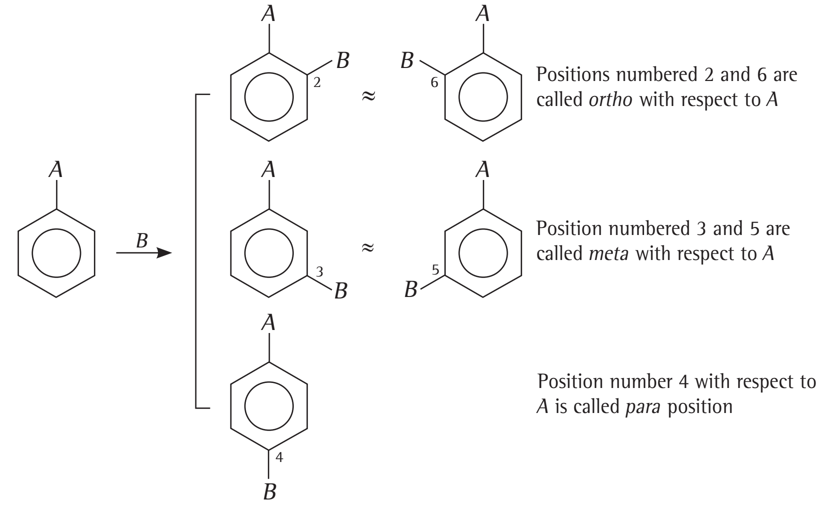
Hot Spot 3

DIRECTIVE Influence of Groups

It is also an important topic for JEE Main point of view and also a simple topic. So small practice may help you to score high marks. The questions are generally 'find the product' type.

All H-atoms of benzene ring are equivalent, thus only one monosubstitution product is possible.
For the second substituent following 3 positions are possible, i.e.



Positions numbered 2 and 6 are called *ortho* with respect to *A*

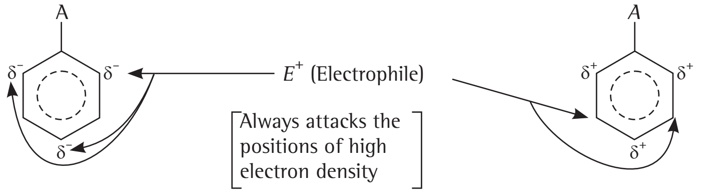
Position numbered 3 and 5 are called *meta* with respect to *A*

Position number 4 with respect to *A* is called *para* position

The first substituent (after monosubstitution) directs the next substituent as follows

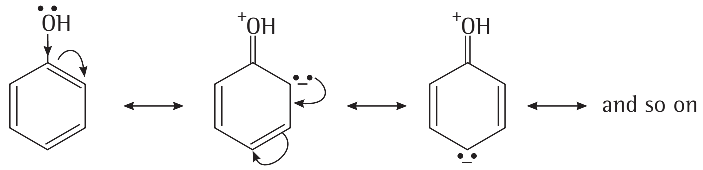
(i) if electron density at *ortho* and *para* position is increased due to first substituent *i.e.*,

(ii) if electron density at *ortho* and *para* position is decreased due to first substituent *i.e.*,



A is *ortho* and *para* **directing as electron density is highest at these positions**

A is *meta* **directing as now electron density is maximum at these positions**



The substituent which increases electron density at the ring is called **ring activator** for further electrophilic substitution while the group which decreases electron density on the ring is called **ring deactivator** for further electrophilic substitution. Thus, normally *ortho* and *para* directing groups are ring activators and *meta* directing groups are ring deactivators. (With halogens as exception because these are *ortho* and *para* directing but ring deactivators)**. The *ortho* and *para* directive influence of halogens is attributed to their ability of donating lone pair while their ring deactivation influence is attributed to their high electronegativity.**

Of all the haloarenes, fluorobenzene deviates the benzene ring to the least extent towards further electrophilic substitution reactions because the electron-donating resonance effect of F is only slightly outweighted by its electron withdrawing inductive effect.

The various ring activator and deactivator groups in the order of their activity are given below

***o/p* directing group or activating group**

(i) strongly activating $—NH_2 > —NHR > —NR_2 > —OH > —OR$

(ii) moderately activating $—NHCOR > —OCOR$,

(iii) weakly activating $—R > —Ar > —CH{=}CR_2$

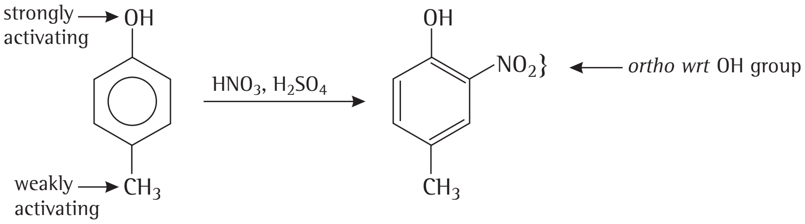
***m*-directing or deactivating**

(i) weakly deactivating $—F > —Cl > —Br > —I$

(ii) moderately deactivating $—CHO > —COR > —COOR > —COOH$

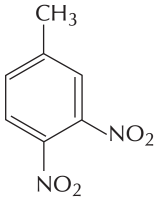
(iii) strongly deactivating $—CN < —SO_3 < \overset{+}{N}H_3 < \overset{+}{N}H_2R_2 < \overset{+}{N}HR_2 < \overset{+}{N}R_3 < —NO_2$ most deactivating.

Remember that if two groups are present, the strongly activating groups generally win over the deactivating or weakly activating group. *e.g.*,

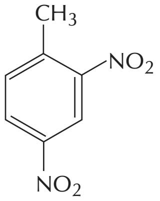


***Sample* Problem 7** *p-nitrotoluene on further nitration gives*

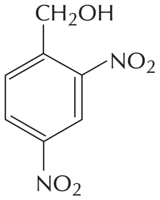
(*a*)



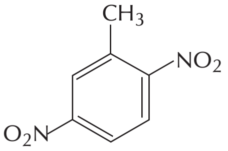
(*b*)



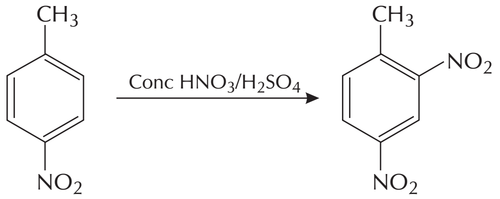
(*c*)



(*d*)



Solution (*b*) $—CH_3$ is a *o*/*p* directing group and $—NO_2$ is a *m*- directing group, thus the electrophile attacks at the position which is *ortho* to CH_3 and *meta* to NO_2 as *p*-position is already occupied.



Caution Point *When ethyl benzene or propyl benzene is chlorinated in the presence of sunlight at high temperature, the reaction proceeds through the formation of benzenylic radical, not by 1° radical.*

Check Point 4

1. Nitrobenzene does not undergo Friedel-Crafts alkylation. Explain it.
2. Why does tertiary butyl benzene not give benzoic acid on oxidation with acidic $KMnO_4$?
3. In the nitration reaction of benzene, HNO_3 acts as a base. Explain.

WORKED **OUT**
Examples

Example 1 *When bromoethane is subjected to Wurtz reaction, the hydrocarbon mixture so obtained consists of*

(*a*) *butane only*
(*b*) *butane and ethane*
(*c*) *butane and ethene*
(*d*) *butane, ethane and ethene*

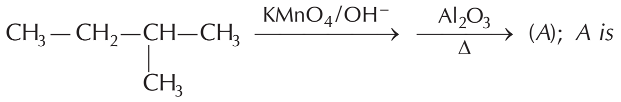
Solution (*d*) Butane is formed by Wurtz reaction whereas ethane and ethene are formed by a bimolecular elimination reaction.

$$2C_2H_5Br + 2Na \xrightarrow{\text{Dry ether}} C_2H_5-C_2H_5 + 2NaBr$$

$$C_2H_5Br + Na \longrightarrow C_2H_5^-Na^+$$

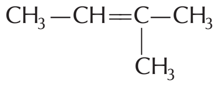
$$C_2H_5^-Na^+ + C_2H_5Br \xrightarrow[-NaBr]{} C_2H_6 + CH_2{=}CH_2$$

Example 2 *In the given sequence*



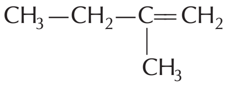
$$CH_3-CH_2-\underset{\underset{CH_3}{|}}{CH}-CH_3 \xrightarrow{KMnO_4/OH^-} \xrightarrow[\Delta]{Al_2O_3} (A);\ A \text{ is}$$

(*a*)



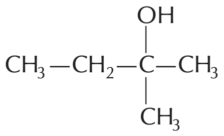
$$CH_3-CH{=}\underset{\underset{CH_3}{|}}{C}-CH_3$$

(*b*)



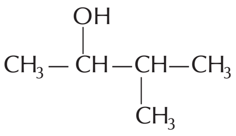
$$CH_3-CH_2-\underset{\underset{CH_3}{|}}{C}{=}CH_2$$

(*c*)



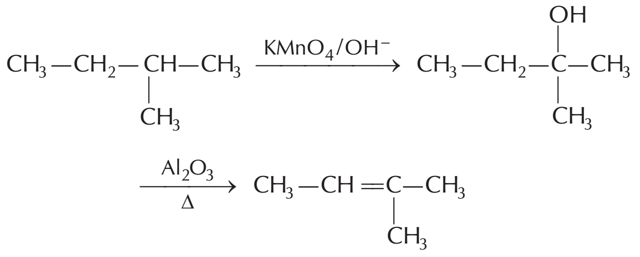
$$CH_3-CH_2-\overset{\overset{OH}{|}}{\underset{\underset{CH_3}{|}}{C}}-CH_3$$

(*d*)



$$CH_3-\overset{\overset{OH}{|}}{CH}-\underset{\underset{CH_3}{|}}{CH}-CH_3$$

Solution (*a*) The reaction is oxidation followed by Saytzeff elimination, as the compound contains 3° H atom.



$$CH_3-CH_2-\underset{\underset{CH_3}{|}}{CH}-CH_3 \xrightarrow{KMnO_4/OH^-} CH_3-CH_2-\overset{\overset{OH}{|}}{\underset{\underset{CH_3}{|}}{C}}-CH_3$$

$$\xrightarrow[\Delta]{Al_2O_3} CH_3-CH{=}\underset{\underset{CH_3}{|}}{C}-CH_3$$

(*A*)

Example 3 *1-butene and 2-butene can be distinguished by their reaction with*

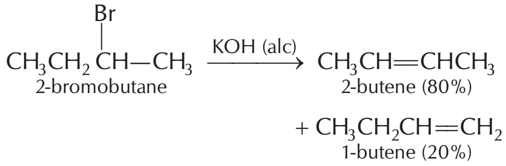
(*a*) *ammoniacal solution of* $AgNO_3$
(*b*) *alkaline solution of* $KMnO_4$
(*c*) *ammoniacal solution of* Cu_2Cl_2
(*d*) *None of the above*

Solution (*d*) In but-2-ene there is symmetry and in case of symmetrical alkenes *anti*-Markownikoff's rule is not obeyed.

Example 4 *Elimination of bromine from 2-bromobutane results in the formation of*

(*a*) *predominantly* 1-*butene*
(*b*) *predominantly* 2-*butyne*
(*c*) *predominantly* 2-*butene*
(*d*) *equimolar mixture of* 1 *and* 2-*butene*

Solution (*c*)



$$\underset{\text{2-bromobutane}}{CH_3CH_2\overset{\overset{Br}{|}}{CH}-CH_3} \xrightarrow{\text{KOH (alc)}} \underset{\text{2-butene (80\%)}}{CH_3CH{=}CHCH_3} + \underset{\text{1-butene (20\%)}}{CH_3CH_2CH{=}CH_2}$$

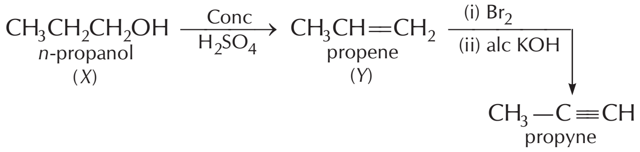
(∵ The elimination takes place according to Saytzeff's rule)

Example 5 *In the following reaction, what is X?*

$$X \xrightarrow[H_2SO_4]{\text{Conc}} Y \xrightarrow[\text{(ii) alc KOH}]{\text{(i) }Br_2} CH_3C{\equiv}CH$$

(*a*) $CH_3CH_2CH_3$
(*b*) $CH_3CH_2CH_2OH$
(*c*) $(CH_3)_2CHBr$
(*d*) CH_3CH_2Br

Solution (*b*) Since, the final product is alkyne which is obtained by dehydrohalogenation of respective halide which in turn obtained by the addition of halogen over double bond, thus, *Y* must be an alkene having three carbon atoms and alkene is obtained by dehydration of alcohols having the same number of carbon atoms. Thus, alcohol is propanol. The reactions are as follows



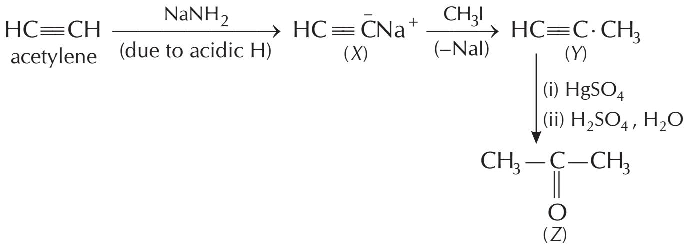
$$\underset{(X)}{\underset{n\text{-propanol}}{CH_3CH_2CH_2OH}} \xrightarrow[H_2SO_4]{\text{Conc}} \underset{(Y)}{\underset{\text{propene}}{CH_3CH{=}CH_2}} \xrightarrow[\text{(ii) alc KOH}]{\text{(i) }Br_2} \underset{\text{propyne}}{CH_3-C{\equiv}CH}$$

Example 6 *In the series,*

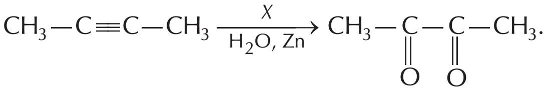
$$C_2H_2 \xrightarrow{NaNH_2} X \xrightarrow{CH_3I} Y \xrightarrow[H_2SO_4,\ H_2O]{HgSO_4} Z, \text{ the compound } Z \text{ is}$$

(*a*) $CH_3CH_2CH{=}CH_2$
(*b*) CH_3COCH_3
(*c*) CH_3CHO
(*d*) $CH_3CH_2CH_2CHO$

Solution (*b*)



Example 7



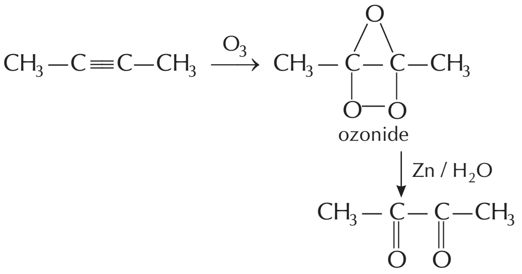
$$CH_3-C\equiv C-CH_3 \xrightarrow[H_2O,\ Zn]{X} CH_3-\underset{\underset{O}{\|}}{C}-\underset{\underset{O}{\|}}{C}-CH_3.$$

In the given reaction reagent X will be

(*a*) $KMnO_4$ (*b*) HIO_4

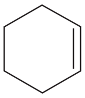
(*c*) O_3 (*d*) O_2

Solution (*c*) The reagent is O_3 as it is the reagent that introduces two O atoms at the successive triple bonded carbon atoms.

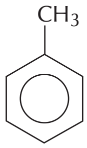


Example 8 *Which one of the following on ozonolysis followed by oxidation will give adipic acid?*

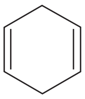
(*a*)



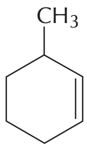
(*b*)



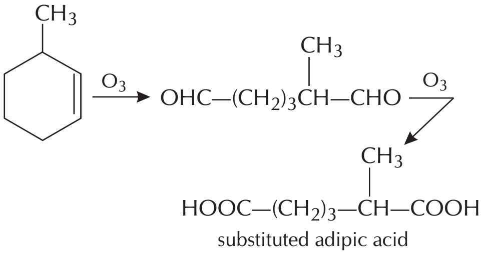
(*c*)



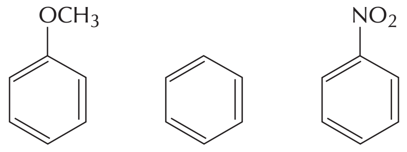
(*d*)



Solution (*d*)



Example 9 *Among the following compounds* (I – III) *the correct order of reaction with electrophile is*

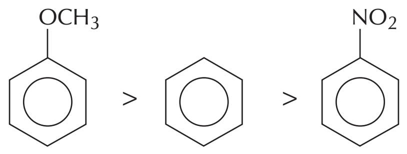


I II III

(*a*) $II > III > I$ (*b*) $III < I < II$

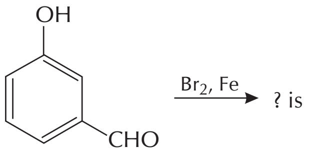
(*c*) $I > II > III$ (*d*) $I \approx II > III$

Solution (*c*) Activating groups like $—OCH_3$, —OH etc., activates the benzene ring towards electrophilic substitution while deactivating groups like NO_2, COOH etc., deactivates the benzene ring towards electrophilic substitution. Thus, order of reaction with electrophile (of the given compounds) is as

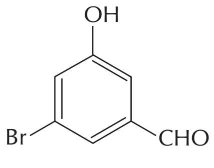


I II III

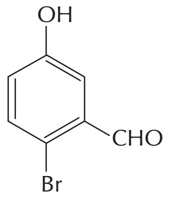
Example 10 *The product of the following reaction*



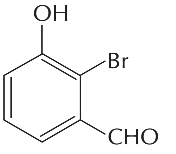
(*a*)



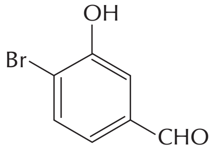
(*b*)



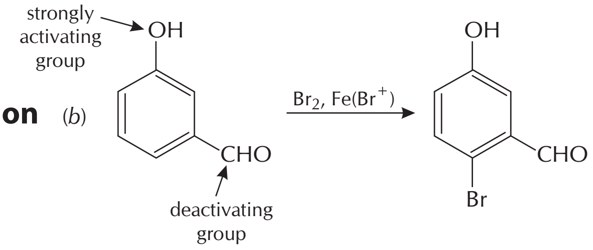
(*c*)



(*d*)



Solution (*b*)



(∵ Strongly activating group generally win over the deactivating group and —OH is a *ortho/para* directing group. *p*-product predominates.)

Start Practice *for* JEE Main

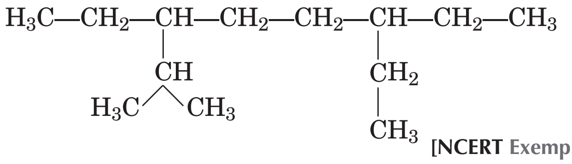
Round I (Topically Divided Problems)

Alkanes

1. In cyclopropane, cyclobutane and cyclohexane, the common group is

(a) $-\overset{|}{\underset{|}{C}}-$ (b) $\overset{|}{\underset{|}{CH_2}}$ (c) $-CH_3$ (d) $-\overset{|}{\underset{|}{CH}}$

2. The correct IUPAC name of the following alkane is



[NCERT Exemplar]

(a) 3,6-diethyl-2-methyloctane
(b) 5-*iso*-propyl-3-ethyloctane
(c) 5-ethyl-5-*iso*-propyloctane
(d) 3-*iso*-propyl-6-ethyloctane

3. Which of the following liberates methane on treatment with water?

(a) Silicon carbide (b) Calcium carbide
(c) Beryllium carbide (d) Magnesium carbide

4. Which of the following reactions of methane is incomplete combustion? **[NCERT Exemplar]**

(a) $2CH_4 + O_2 \xrightarrow{Cu/523\ K/100\ atm} 2CH_3OH$
(b) $CH_4 + O_2 \xrightarrow{Mo_2O_3} HCHO + H_2O$
(c) $CH_4 + O_2 \longrightarrow C(s) + 2H_2O(l)$
(d) $CH_4 + 2O_2 \longrightarrow CO_2(g) + 2H_2O(l)$

5. Which of the following will not produce ethane?

(a) Reduction of CH_3COOH with HI and red P
(b) Reduction of CH_3COCH_3 with HI and red P
(c) Sodalime decarboxylation of sodium propionate
(d) Hydrogenation of ethane in the presence of Raney-Ni

6. Which of the following reactions can be used to prepare methane?

(a) Clemmensen reduction
(b) Wurtz reaction
(c) Reduction of $CH_2{=}CH_2$ by $LiAlH_4$
(d) Reduction of methyl iodide by using a zinc-copper couple

7. Which of the following compounds cannot be prepared singly by the Wurtz reaction?

(a) C_2H_6
(b) $(CH_3)_2CHCH_3$
(c) $CH_3CH_2CH_2CH_3$
(d) All can be prepared

8. Both methane and ethane may be obtained by a suitable one-step reaction from

(a) CH_3I (b) C_2H_5I
(c) CH_3OH (d) C_2H_5OH

9. Arrange the halogens F_2, Cl_2, Br_2, I_2 in order of their increasing reactivity with alkanes **[NCERT Exemplar]**

(a) $I_2 < Br_2 < Cl_2 < F_2$ (b) $Br_2 < Cl_2 < F_2 < I_2$
(c) $F_2 < Cl_2 < Br_2 < I_2$ (d) $Br_2 < I_2 < Cl_2 < F_2$

10. The increasing order of reduction of alkyl halides with zinc and dilute HCl is **[NCERT Exemplar]**

(a) $R{-}Cl < R{-}I < R{-}Br$
(b) $R{-}Cl < R{-}Br < R{-}I$
(c) $R{-}I < R{-}Br < R{-}Cl$
(d) $R{-}Br < R{-}I < R{-}Cl$

11. An alkyl bromide, RBr of molecular weight 151 is the exclusive product of bromination of which hydrocarbon?

(a) Dodecane
(b) 2,2-dimethylpropane
(c) 2,2-dimethylhexane
(d) 2,2,3-trimethylheptane

12. Several hydrocarbon radicals can be formed as intermediates during monochlorination of 2-methylpropane. Which of them is the most stable? **[NCERT Exemplar]**

(a) $(CH_3)_2\dot{C}CH_3$ (b) $(CH_3)_2CH\dot{C}H_2$
(c) $(CH_3)\dot{C}HCH_2CH_3$ (d) All are equally stable

13. The products obtained in the reaction of sodium with a mixture of 1-iodo-2-methylpropane and 2-iodopropane is/are **[NCERT Exemplar]**

(a) 2,5-dimethyl hexane (b) 2,3-dimethylbutane
(c) 2,4-dimethyl pentane (d) All of these

14. Hydrocarbon which is liquid at room temperature is

(a) pentane (b) butane
(c) propane (d) ethane

15. On mixing a certain alkane with chlorine and irradiating it with UV light, it forms one monochloro alkane. The alkane could be

(a) *neo*-pentane (b) propane
(c) pentane (d) *iso*-pentane

16. Which of the following react with Cl_2 and Br_2 at room temperature and in the absence of diffused sunlight to produce dihalogen derivatives?

(a) Cyclobutane (b) Cyclopentane
(c) Cyclohexane (d) All of these

17. Which of the following alkanes can be easily sulphonated?

(a) *n*-butane (b) *iso*-butane
(c) *n*-pentane (d) *n*-hexane

18. $CH_3CH_2CH_3 \xrightarrow{400-600^\circ C} X + Y$

X and Y are

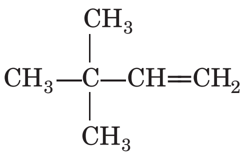
(a) hydrogen, methane (b) methane, ethylene
(c) hydrogen, ethylene (d) ethylene, ethane

Alkenes

19. The best method to prepare cyclohexene from cyclohexanol is by using

(a) conc. HCl + $ZnCl_2$ (b) conc. H_3PO_4
(c) HBr (d) conc. HCl

20. Which of the following reactions is not expected to give



$CH_3-\underset{CH_3}{\overset{CH_3}{C}}-CH=CH_2$

in yields of more than 50%?

(a) 
$CH_3-\underset{CH_3}{\overset{CH_3}{C}}-\underset{OH}{CH}-CH_3 \xrightarrow[\Delta]{H_2SO_4}$

(b) 
$CH_3-\underset{CH_3}{\overset{CH_3}{C}}-\underset{Br}{CH}-CH_3 \xrightarrow[\Delta]{(CH_3)_3CO^-K^+}$

(c) 
$CH_3-\underset{CH_3}{\overset{CH_3}{C}}-\underset{Br}{CH}-CH_3 \xrightarrow[\text{acetone}]{Zn}$

(d) None of the above

21. Allene (C_3H_4) contains

(a) one double bond, one triple bond and one single bond
(b) one triple and two double bonds
(c) two triple and one double bond
(d) two double and four single bonds

22. Which of the following compounds is the most stable?

(a) 
(b) 
(c) 
(d) 
23. Which one of the following has the smallest heat of hydrogenation per mole?

(a) 1-butene (b) *Trans*-but-2-ene
(c) *Cis*-but-2-ene (d) Buta-1,3-diene

24. The addition of HCl to 3,3,3-trichloropropene gives

(a) $Cl_3CCH_2CH_2Cl$
(b) $Cl_3CCH_2CHCl_2$
(c) $Cl_2CHCH_2CHCl_2$
(d) $Cl_2CHCH(Cl)CH_2Cl$

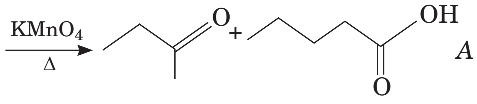
25. Arrange the following hydrogen halides in the order of their decreasing reactivity with propene. **[NCERT Exemplar]**

(a) HCl > HBr > HI (b) HBr > HI > HCl
(c) HI > HBr > HCl (d) HCl > HI > HBr

26. The addition of HBr to an alkene in the presence of peroxide is the example of

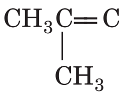
(a) electrophilic addition reaction
(b) nucleophilic addition reaction
(c) free radical addition reaction
(d) the formation of carbocation as an intermediate

27. Alkene (*A*)



A is

(a) 
(b) 
(c) 
(d) 
28. The treatment of



$CH_3\underset{\substack{|\\ CH_3}}{C}=CHCH_3$ with $NaIO_4$ or boiling $KMnO_4$ produces

(a) $CH_3COCH_3 + CH_3COOH$

(b) $CH_3COCH_3 + CH_3CHO$

(c) $CH_3CHO + CO_2$

(d) CH_3COCH_3 only

29.  on ozonolysis gives

(a) 
(b) 
(c)  + HCHO

(d) None of these

30. Propanal and pentan-3-one are ozonolysis product of an alkene. What is the structural formula of the alkene? **[NCERT]**

(a) $CH_3CH_2CH{=}C(C_2H_5)_2$ (b) $CH_3CH{=}CHCH(C_2H_5)_2$

(c) $CH_3CH_2CH{=}CHCH_2C_3H_7$ (d) 
$CH_3CH_2CH{=}C\begin{matrix} CH_3 \\ C_3H_7 \end{matrix}$

31. An unsaturated hydrocarbon '*A*' adds two molecules of H_2 and on reductive ozonolysis gives butane-1,4-dial, ethanol and propanone. Give the IUPAC name of *A*. **[NCERT Exemplar]**

(a) 3-methylocta-2,6-diene

(b) 2-methylocta-2,5-diene

(c) 2-methylocta-2,6-diene

(d) 2-methylocta-3,5-diene

32. The alkene which on hydrogenation give 2-methyl butane is **[NCERT]**

(a) 2-methylbut-1-ene

(b) 2-methylbut-2-ene

(c) 3-methylbut-1-ene

(d) All of the above

33. The reaction of propene with HOCl proceeds *via* the addition of

(a) Cl^+ and OH^- in a single step

(b) Cl^+ in the first step

(c) H^+ in the first step

(d) OH^- in the first step

34. $CH_3{-}CH{=}CH_2 + NOCl \longrightarrow P$

Identify the adduct.

(a) 
$CH_3{-}\underset{\substack{|\\ Cl}}{CH}{-}\underset{\substack{|\\ NO}}{CH_2}$

(b) 
$CH_3{-}\underset{\substack{|\\ NO}}{CH}{-}\underset{\substack{|\\ Cl}}{CH_2}$

(c) 
$CH_3{-}CH_2{-}\overset{\substack{NO\\ |}}{\underset{\substack{|\\ Cl}}{CH}}$

(d) 
$\underset{\substack{|\\ NO}}{CH_2}{-}CH_2{-}\underset{\substack{|\\ Cl}}{CH_2}$

35. $A\,(C_4H_6) \xrightarrow[\text{1 mole}]{H_2,\,Ni} B\,(C_4H_8) \xrightarrow{O_3/H_2O/Zn} CH_3CHO.$

Thus, *A* and *B* are

(a) 
(b) 
(c) $CH_3CH_2C{\equiv}CH,\ CH_3CH{=}CHCH_3$

(d) $CH_2{=}CH{-}CH{=}CH_2,\ CH_3CH{=}CH{-}CH_3$

Alkynes

36. The number of possible alkynes with molecular formula C_5H_8 is

(a) 3	(b) 4
(c) 5	(d) 6

37. $CaC_2 + H_2O \longrightarrow A \xrightarrow{H_2SO_4/HgSO_4} B$

Identify *A* and *B* in the given reaction.

(a) C_2H_2 and CH_3CHO	(b) CH_4 and HCOOH
(c) C_2H_4 and CH_3COOH	(d) C_2H_2 and CH_3COOH

38. The reduction of 4-octyne with H_2 in the presence of $Pd/CaCO_3$ quinoline gives

(a) *trans*-4-octene

(b) *cis*-4-octene

(c) a mixture of *cis*-and *trans*-4-octene

(d) a completely reduced product C_8H_{18}

39. Water can be added across a triple bond in the presence of

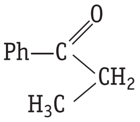
(a) acidic medium	(b) alkaline medium
(c) neutral medium	(d) acid and $HgSO_4$

40. The product(s) obtained *via* oxymercuration ($HgSO_4 + H_2SO_4$) of but-1-yne would be

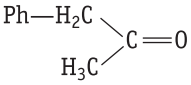
(a) $CH_3CH_2COCH_3$	(b) $CH_3CH_2CH_2CHO$
(c) $CH_3CH_2CHO + HCHO$	(d) $CH_3CH_2COOH + HCOOH$

41. $Ph—C\equiv C—CH_3 \xrightarrow{Hg^{2+}/H^+} A$,

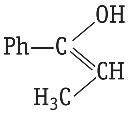
(a)



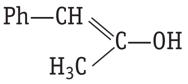
(b)



(c)



(d)



42. The final product in the following sequence of reaction is

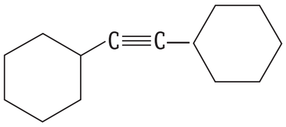
$$CH\equiv CH \xrightarrow{NaNH_2} A \xrightarrow{CH_3Br} B$$

(a) $CH_2{=}CH—CH{=}CH_2$ (b) $HC\equiv C—CH_3$
(c) $CH_2{=}CH—CH_3$ (d) $CH_3—CH_2—CH_3$

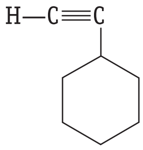
43. Acetylene and HCHO reacts in the presence of copper acetylide catalyst to form
(a) 1-butyne-1, 4-diol (b) 2-butyne-1, 2-diol
(c) 2-butyne-1, 4-diol (d) None of these

44. Which of the following form alkynide?

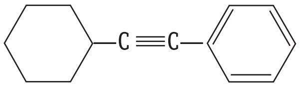
(a)



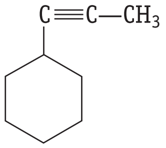
(b)



(c)



(d)



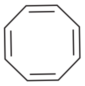
45. Ammoniacal silver nitrate form a white precipitate easily with
(a) $CH_3C\equiv CH$ (b) $CH_3C\equiv C—CH_3$
(c) $CH_3CH{=}CH_2$ (d) $CH_2{=}CH_2$

Aromatic Hydrocarbons

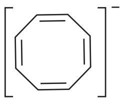
46. Which among the following is aromatic?

(a)

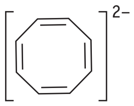
(b)



(c)

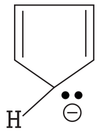


(d)

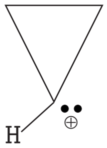


47. Which of the following species will be aromatic?

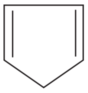
(a)



(b)



(c)

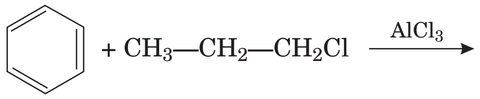


(d) None of these

48. Which of the following annulenes is anti-aromatic?
(a) Benzene
(b) Cyclobutadiene
(c) Cyclodecapentene
(d) Cyclooctatetraene

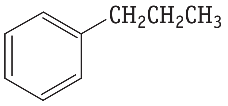
49. An activating group
(a) activates only *ortho* and *para* positions
(b) deactivates *meta* position
(c) activates *ortho* and *para* more than *meta*
(d) deactivates *meta* more than *ortho* and *para*

50. What will be the product obtained as a result of the following reaction and why? **[NCERT Exemplar]**

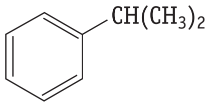


$$+ CH_3—CH_2—CH_2Cl \xrightarrow{AlCl_3}$$

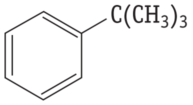
(a)



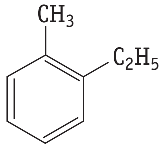
(b)



(c)



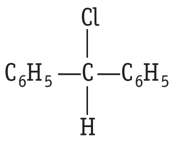
(d)



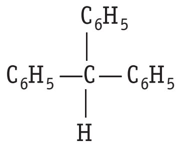
51. The treatment of benzene with benzoyl chloride in the presence of $AlCl_3$ gives
(a) benzaldehyde (b) benzophenone
(c) diphenyl (d) cyclohexane

52. A Friedel-Crafts reaction of benzene with chloroform produces

(a) $C_6H_5CHCl_2$

(b)


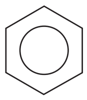
$$C_6H_5—\underset{H}{\overset{Cl}{C}}—C_6H_5$$

(c)


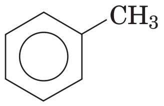
$$C_6H_5—\underset{H}{\overset{C_6H_5}{C}}—C_6H_5$$

(d) All of these

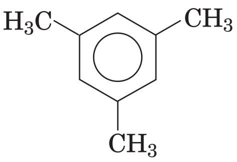
53. Arrange the following in the order of decreasing boiling point.



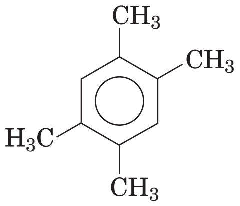
I



II



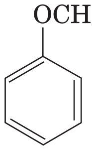
III



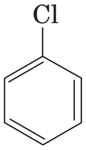
IV

(a) I > II > III > IV (b) IV > III > II > I
(c) I > III > IV > II (d) II > III > I > IV

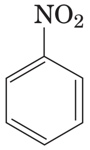
54. Arrange the following set of compounds in the order of their decreasing relative reactivity with an electrophile. **[NCERT Exemplar]**



I



II



III

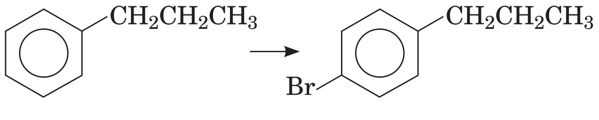
(a) I > II > III
(b) I > III > II
(c) II > I > III
(d) II > III > I

55. Among the following statements on the nitration of aromatic compounds, the false one is
(a) the rate of nitration of benzene is almost the same as that of hexadeuterobenzene
(b) the rate of nitration of toluene is greater than that of benzene
(c) the rate of nitration of benzene is greater than that of hexadeuterobenzene
(d) nitration is an electrophilic substitution reaction

56. Among the following, the compound that can be most readily sulphonated is
(a) benzene (b) nitrobenzene
(c) toluene (d) chlorobenzene

57. Toluene, when treated with Br_2/Fe, gives *p*-bromotoluene as the major product because the —CH_3 group

58. The conversion



can be achieved by using
(a) Br_2/CCl_4 (b) Br_2/H_2O
(c) Br_2/Fe (d) Br_2/benzoyl peroxide

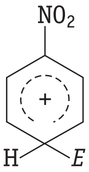
59. Nitrobenzene can be prepared from benzene by using a mixture of concentrated HNO_3 and concentrated H_2SO_4. In the nitrating mixture, HNO_3 acts as
(a) base (b) acid
(c) reducing agent (d) catalyst

60. The reaction of toluene with chlorine in the presence of ferric chloride gives predominantly
(a) benzoyl chloride (b) *m*-chlorotoluene
(c) benzyl chloride (d) *o*-and *p*-chlorotoluene

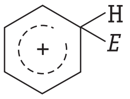
61. Benzyl chloride ($C_6H_5CH_2Cl$) can be prepared from toluene by chlorination with
(a) SO_2Cl_2 (b) $SOCl_2$
(c) Cl_2 (d) NaOCl

62. The electrophile, $E^{\oplus}$ attacks the benzene ring to generate the intermediate σ-complex of the following, which σ-complex is of lowest energy?

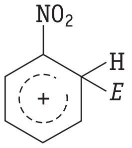
(a)



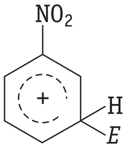
(b)



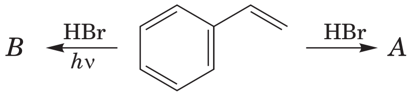
(c)



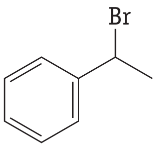
(d)



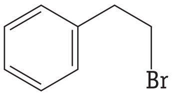
63. Observe the following reactions and predict the nature of *A* and *B*

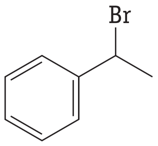


(a) *A* and *B* both are

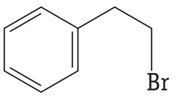


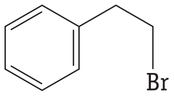
(b) *A* and *B* both are



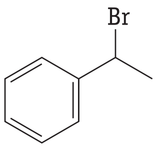
(c) *A* is


and *B* is



(d) *A* is


and *B* is



64. Arrange the following set of compounds in the order of their decreasing relative reactivity with an electrophile, E^+

I. chlorobenzene
II. 2,4-dinitrochlorobenzene
III. *p*-nitrochlorobenzene
IV. toluene
V. *p*-$H_3C—C_6H_4—NO_2$, **[NCERT]**

(a) I > II > III > IV > V (b) IV > V > I > III > II
(c) V > IV > III > II > I (d) I > III > II > V > IV

Miscellaneous

65. Which of the following will react with sodium metal?
(a) Ethene (b) Propyne (c) But-2-yne (d) Ethane

66. The treatment of aluminium carbide with water or dilute acid produces
(a) acetylene (b) ethene (c) methane (d) ethane

67. The reactivities of ethane, ethylene and acetylene are of the order
(a) ethane < ethene < ethyne
(b) ethane < ethyne < ethene
(c) ethyne = ethene > ethane
(d) Any of the above

68. Which of the following statements is true for ethane, ethene and acetylene?
(a) Acetylene is the weakest acid and has the longest C—H bond distance
(b) Acetylene is the strongest acid and has the shortest C—H bond distance
(c) Ethane is the strongest acid and has the shortest C—H bond distance
(d) Ethene is the strongest acid and has the shortest C—H bond distance

69. Compound (*A*) on oxidation with $OsO_4/NaIO_4$ gives hexanedinal. Structure of compound (*A*) will be

(a) (b) (c) 
(d) 
70. Choose the correct statement.
(a) Acetylene is more reactive than ethylene to an electrophilic attack
(b) Acetylene and ethylene show similar reactivities towards an electrophilic attack with different rates
(c) The reactivities of acetylene and ethylene towards an electrophilic attack depend on the electrophilic reagent
(d) Acetylene is less reactive than ethylene to an electrophilic attack

Round II (Mixed Bag)

Only One Correct Option

1. What would be the product formed when 1-bromo-3-chloro cyclobutane reacts with two equivalents of metallic sodium in ether?

(a) 
(b) 
(c) (d) 
2. An alkene, C_8H_{18} is obtained as the only product on subjecting a primary alkyl halide to Wurtz reaction. On monobromination this alkane yields a single isomer of a tertiary bromide. The primary alkyl halide is **[NCERT Exemplar]**
(a) 1-chloro butane
(b) *iso*-butyl halide
(c) *iso*-pentyl halide
(d) *neo*-pentyl halide

3. The relative reactivity of 1°, 2°, 3° hydrogen's towards chlorination is 1 : 3.8 : 5. The percentages of 2° monochlorinated products obtained from 2-methylbutane is **[NCERT Exemplar]**
(a) 41.67 (b) 35.18 (c) 23.15 (d) 48.5

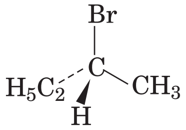
4. $C_8H_{10}(A) \xrightarrow{O_3/H_2O} \text{acid } (B)$

$C_3H_5MgBr(C) \xrightarrow{CO_2,\, H_3O^+} \text{acid } B$

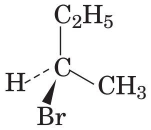
Identify *A*, *B* and *C*.

(a) , , 
(b) , $CH_3CH_2CH_2COOH$,
$CH_2{=}CH—CH_2MgBr$

(c) $CH_3—CH_2—CH_2—CH_3$, $CH_3CH_2CH_2COOH$, $CH_2{=}CH—CH_2MgBr$
(d) $CH_3CH_2CH_2CH_3$, , 
5. The addition of HBr to 1-butene gives a mixture of products *A*, *B* and *C*



(*A*)



(*B*)

$CH_3CH_2CH_2CH_2Br$
(*C*)

The mixture consists of **[NCERT Exemplar]**

(a) *A* and *B* as major and *C* as minor products
(b) *B* as major, *A* and *C* as minor products
(c) *B* as minor, *A* and *C* as major products
(d) *A* and *B* as minor and *C* as major products

6. Alkyne, C_7H_{12}, when reacted with alkaline $KMnO_4$ followed by acidification with HCl gives a mixture of $(CH_3)_2CHCOOH + CH_3CH_2COOH$. The alkyne C_7H_{12} is

(a) 3-hexyne (b) 2-methyl-2-hexene
(c) 2-methyl-3-hexyne (d) 3-methyl-2-hexyne

7. The reagent(s) for the following conversion,

is/are

(a) alcoholic KOH
(b) alcoholic KOH followed by $NaNH_2$
(c) aqueous KOH followed by $NaNH_2$
(d) Zn/CH_3OH

8. $$A \xleftarrow[\text{(ii) } H_2O_2,\ OH^-]{\text{(i) } BH_3,\ THF} CH_3C{\equiv}CH \xrightarrow[H_2SO_4]{HgSO_4} B$$

Identify *A* and *B*.

(a) CH_3CHO, CH_3COCH_3
(b) CH_3CH_2CHO, CH_3COCH_3
(c) CH_3CH_2CHO, $CH_3COCH_2CH_3$
(d) HCHO, CH_3COCH_3

9. 
Identify *A* and *B*.

(a) 
(b) 
(c) 
(d) 
10. Propyne and propene can be distinguished by

(a) conc. H_2SO_4
(b) Br_2 in CCl_4
(c) alk. $KMnO_4$
(d) $AgNO_3$ in NH_3

11. Arrange benzene, *n*-hexane and ethyne in the decreasing order of acidic behaviour. **[NCERT]**

(a) Ethyne > benzene > hexane
(b) Hexane > benzene > ethyne
(c) Ethyne > hexane > benzene
(d) Benzene > hexane > ethyne

12. 
Identify the *X* in the above reaction

(a) 
(b) 
(c) 
(d) 
13. When excess of C_6H_6 reacts with CH_2Cl_2 in the presence of anhydrous $AlCl_3$, the following compound is obtained

(a) 
(b) 
(c) 
(d) 
14. Which of the following compounds are aromatic according to Huckel's rule? **[NCERT Exemplar]**

I. 
II. 
III. 
IV. 
V. 
VI. 
(a) I, II, IV, V
(b) II, IV, V, VI
(c) II, III, V only
(d) IV, V and VI

15. 896 mL vapour of a hydrocarbon '*A*' having carbon 87.80% and hydrogen 12.19% weighs 3.28 g at STP. Hydrogenation of '*A*' gives 2-methylpentane. Also '*A*' on hydration in the presence of H_2SO_4 and $HgSO_4$ gives a ketone '*B*' having molecular formula $C_6H_{12}O$. The ketone '*B*' gives a positive iodoform test. Find the structure of '*A*'. **[NCERT Exemplar]**

(a) $(CH_3)_3CC{\equiv}C{-}CH_2CH_3$
(b) $(CH_3)_2CHCH_2C{\equiv}CH$
(c) $CH_3CH_2C{\equiv}CCH_2CH_2CH_2CH_3$
(d) $(CH_3)_2CHCH_2CH_2C{\equiv}CH$

16. Match the reagent from Column I which on reaction with $CH_3{-}CH{=}CH_2$ gives some product given in Column II as per the codes given below **[NCERT Exemplar]**

	Column I		Column II
A.	$O_3/Zn + H_2O$	1.	Acetic acid and CO_2
B.	$KMnO_4/H^+$	2.	Propan-1-ol
C.	$KMnO_4/OH^-$	3.	Propan-2-ol
D.	H_2O/H^+	4.	Acetaldehyde and formaldehyde
E.	B_2H_6/NaOH and H_2O_2	5.	Propane-1,2- diol

Codes

	A	B	C	D	E
(a)	4	1	5	2	3
(b)	4	5	1	2	3
(c)	3	2	1	5	4
(d)	4	1	5	3	2

17. Match the following reactants in Column I with the corresponding reaction products in Column II. **[NCERT Exemplar]**

	Column I		Column II
A.	Benzene + $Cl_2 \xrightarrow{AlCl_3}$	1.	Benzoic acid
B.	Benzene + $CH_3Cl \xrightarrow{AlCl_3}$	2.	Methyl phenyl ketone
C.	Benzene + $CH_3COCl \xrightarrow{AlCl_3}$	3.	Toluene
D.	Toluene $\xrightarrow{KMnO_4/NaOH}$	4.	Chlorobenzene
		5.	Benzene hexachloride

Codes

	A	B	C	D
(a)	4	3	2	1
(b)	1	2	3	4
(c)	4	3	1	5
(d)	1	5	2	3

More than One Correct Option

18. Some oxidation reactions of methane are given below. Which of them is/are controlled oxidation reactions? **[NCERT Exemplar]**

(a) $CH_4(g) + 2O_2(g) \longrightarrow CO_2(g) + 2H_2O(l)$
(b) $CH_4(g) + O_2(g) \longrightarrow C(s) + 2H_2O(l)$
(c) $CH_4(g) + O_2(g) \xrightarrow{Mo_2O_3} HCHO + H_2O$
(d) $2CH_4(g) + O_2(g) \xrightarrow{Cu/523/100\ atm} 2CH_3OH$

19. Nitration of propane with concentrated HNO_3 gives
(a) CH_3NO_2
(b) $CH_3CH_2CH_2NO_2$
(c) $CH_3{-}CH(NO_2){-}CH_3$
(d) $CH_3CH_2NO_2$

20. Which of the following alkenes on ozonolysis give a mixture of ketones only? **[NCERT Exemplar]**

(a) $CH_3{-}CH{=}CH{-}CH_3$
(b) $CH_3{-}CH(CH_3){-}CH{=}CH_2$
(c) (d) 
21. The molecules having dipole moment are …… . **[NCERT Exemplar]**

(a) 2,2-dimethylpropane
(b) *trans*-pent-2-ene
(c) *cis*-hex-3-ene
(d) 2,2,3,3-tetramethylbutane

22. For an electrophilic substitution reaction, the presence of a halogen atom in the benzene ring …… . **[NCERT Exemplar]**

(a) deactivates the ring by inductive effect
(b) deactivates the ring by resonance
(c) Increases the charge density at *ortho* and *para* position relative to *meta* position by resonance
(d) directs the incoming electrophile to *meta* position by increasing the charge density relative to *ortho* and *para* position.

Assertion and Reason

Directions (Q. Nos. 23 to 27) *Each of these questions contains two statements : Statement* I (*Assertion*) *and Statement* II (*Reason*). *Each of these questions also has four alternative choices, only one of which is the correct answer. You have to select one of the codes* (*a*), (*b*), (*c*), (*d*) *given below :*

(a) Statement I is true; Statement II is true; Statement II is a correct explanation for Statement I.
(b) Statement I is true; Statement II is true; Statement II is not a correct explanation for Statement I.
(c) Statement I is true; Statement II is false.
(d) Statement I is false; Statement II is true.

23. **Statement I** Cycloalkenes decolourise the purple colour of dilute and cold $KMnO_4$ or red colour of bromine in carbon tetrachloride.

Statement II Cycloalkenes undergo the electrophilic addition reactions which are characteristic of alkenes.

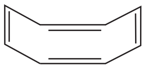
24. **Statement I** Among isomeric pentanes, 2,2-dimethylpropane has the lowest boiling point.

Statement II Branching does not affect the boiling point. **[NCERT Exemplar]**

25. **Statement I** Acetylene is more reactive than ethylene.

Statement II In acetylene, there is greater strain.

26. **Statement I** The compound cyclooctane has the following structural formula



It is cyclic and has conjugated 8π-electron system but it is not an aromatic compound.

Statement II $(4n+2)\,\pi$ electrons rule does not hold good and ring is not planar. **[NCERT Exemplar]**

27. **Statement I** The repalcement of hydrogen atom by sulphonic acid group (—SO_3H) is known as sulphonation.

Statement II Sulphonation follows free radical mechanism.

Comprehension Based Questions

Directions (Q. Nos. 28 to 30) Dehydration of 1-butanol and 2-butanol with conc H_2SO_4 gives the same mixture of 1-butene and 2-butene in which the more highly substituted alkene, *i.e.,* 2-butene predominates (Saytzeff rule). The formation of this mixture from 1-butanol can be explained by the rearrangement of the initially formed less stable 1° carbocation to the more stable 2° carbocation, which then loses a proton in accordance with Saytzeff rule to afford a mixture of 2-butene and 1-butene.

28. In the acid catalysed dehydration of alcohols to alkenes, the reactive intermediate involved is a

(a) carbene
(b) free radical
(c) carbocation
(d) carbanion

29. When ethyl alcohol is heated with conc H_2SO_4 at 443 K, ethylene is formed by

(a) intermolecular dehydration
(b) intramolecular dehydration
(c) intermolecular hydration
(d) intramolecular hydration

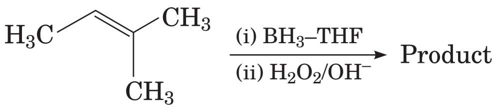
30. Which one of the following heptanols can be dehydrated to hept-3-ene only?

(a) Heptan-3-ol
(b) Heptan-4-ol
(c) Heptan-2-ol
(d) Heptan-1-ol

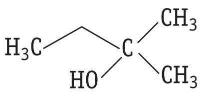
Directions (Q. Nos. 31 to 33) Acid catalysed hydration of alkene gives alcohol. In this reaction addition of water takes place according to Markownikoff's rule. Since intermediate carbocation is formed in this reaction, rearrangement of carbocation takes place. In oxymercuration-demercuration reaction hydration of alkene takes place according to Markownikoff's rule. Oxymercuration-demercuration is a better process than the catalytic hydration of alkene because in oxymercuration-demercuration, no rearrangement is possible. In hydroboration oxidation, (HBO) hydration of alkene takes place according to anti-Markownikoff's addition. In HBO reaction rearrangement is not possible. Both in oxymercuration-demercuration and hydroboration oxidation intermediate carbocation are not formed.

31. 2-phenyl propene on acidic hydration gives
- (a) 2-phenyl-2-propanol
- (b) 2-phenyl-1-propanol
- (c) 3-phenyl-1-propanol
- (d) 1-phenyl-2-propanol

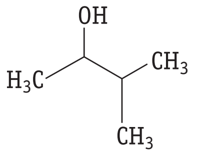
32. The product formed in the following reaction is



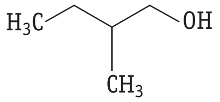
(a)



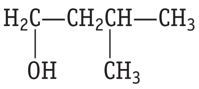
(b)



(c)



(d)



$\underset{OH}{H_2C}—CH_2\underset{CH_3}{CH}—CH_3$

33. $CH_3—C≡C—H \xrightarrow[\text{(ii) } H_2O_2/OH^-]{\text{(i) } B_2H_6} A$, A is
- (a) $CH_3—CH_2—CHO$
- (b)  $H_3C—\underset{\underset{O}{\|}}{C}—CH_3$
- (c) $CH_3—CHO$
- (d) $CH_3—CH_2—CH_2—OH$

Previous Years' Questions

34. How many chiral compounds are possible on monochlorination of 2-methyl butane? **[AIEEE 2012]**
- (a) 8
- (b) 2
- (c) 4
- (d) 6

35. Which branched chain isomer of the hydrocarbon with molecular mass 72 u gives only one isomer of mono substituted alkyl halide? **[AIEEE 2012]**
- (a) *Tert*-butyl chloride
- (b) *Neo*-pentane
- (c) *Iso*-hexane
- (d) *Neo*-hexane

36. 2-hexyne gives *trans*-2-hexene on treatment with **[AIEEE 2012]**
- (a) Pt/H_2
- (b) Li/NH_3
- (c) $Pd/BaSO_4$
- (d) $LiAlH_4$

37. Ozonolysis of an organic compound gives formaldehyde as one of the products. This confirms the presence of **[AIEEE 2011]**
- (a) two ethylenic double bonds
- (b) a vinyl group
- (c) an *iso* propyl group
- (d) an acetylenic triple bond

38. Ozonolysis of an organic compound *A* produces acetone and propionaldehyde in equimolar mixture. Identify *A* from the following compounds. **[AIEEE 2011]**
- (a) 2-methyl-1-pentene
- (b) 1-pentene
- (c) 2-pentene
- (d) 2-methyl-2-pentene

39. One mole of a symmetrical alkene on ozonolysis gives two moles of an aldehyde having a molecular mass of 44 u. The alkene is **[AIEEE 2010]**
- (a) propene
- (b) 1-butene
- (c) 2-butene
- (d) ethene

40. In the following sequence of reactions, the alkene affords the compound '*B*'

$$CH_3CH{=}CHCH_3 \xrightarrow{O_3} A \xrightarrow[Zn]{H_2O} B.$$

The compound *B* is **[AIEEE 2008]**
- (a) CH_3CH_2CHO
- (b) CH_3COCH_3
- (c) $CH_3CH_2COCH_3$
- (d) CH_3CHO

41. The hydrocarbon which can react with sodium in liquid ammonia is **[AIEEE 2008]**
- (a) $CH_3CH_2CH_2C≡CCH_2CH_2CH_3$
- (b) $CH_3CH_2C≡CH$
- (c) $CH_3CH{=}CHCH_3$
- (d) $CH_3CH_2C≡CCH_2CH_3$

42. The treatment of CH_3MgX with $CH_3C≡C—H$ produces **[AIEEE 2008]**
- (a) $CH_3—CH{=}CH_2$
- (b) $CH_3C≡C—CH_3$
- (c)  $CH_3—\overset{\overset{H}{|}}{C}{=}\overset{\overset{H}{|}}{C}—CH_3$
- (d) CH_4

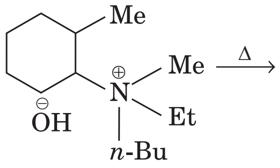
43. Which of the following reactions will yield 2, 2-dibromopropane? **[AIEEE 2007]**
- (a) $CH_3—C≡CH + 2HBr \longrightarrow$
- (b) $CH_3CH{=}CHBr + HBr \longrightarrow$
- (c) $CH≡CH + 2HBr \longrightarrow$
- (d) $CH_3—CH{=}CH_2 + HBr \longrightarrow$

44. Presence of a nitro group in a benzene ring **[AIEEE 2007]**
- (a) activates the ring towards electrophilic substitution
- (b) renders the ring basic
- (c) deactivates the ring towards nucleophilic substitution
- (d) deactivates the ring towards electrophilic substitution

45. HBr reacts with $CH_2{=}CH{-}OCH_3$ under anhydrous conditions at room temperature to give **[AIEEE 2006]**

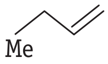
(a) CH_3CHO and CH_3Br (b) $BrCH_2CHO$ and CH_3OH
(c) $BrCH_2{-}CH_2{-}OCH_3$ (d) $H_3C{-}CHBr{-}OCH_3$

46.



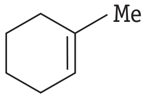
The alkene formed as a major product in the above elimination reaction is **[AIEEE 2006]**

(a)

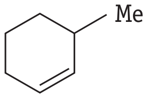


(b) $CH_2{=}CH_2$

(c)



(d)



47. Of the five isomeric hexanes , the isomer which can give two monochlorinated compounds, is **[AIEEE 2005]**

(a) 2-methylpentane
(b) 2, 2-dimethylbutane
(c) 2, 3-dimethylbutane
(d) *n*-hexane

48. Reaction of one molecule of HBr with one molecule of 1, 3-butadiene at 40°C gives predominantly **[AIEEE 2005]**

(a) 1-bromo-2-butene under kinetically controlled conditions
(b) 3-bromobutene under thermodynamically controlled conditions
(c) 1-bromo-2-butene under thermodynamically controlled conditions
(d) 3-bromobutene under kinetically controlled conditions

49. Which one of the following has the minimum boiling point? **[AIEEE 2004]**

(a) *n*-butane (b) 1-butyne
(c) 1-butene (d) *Iso*-butene

50. Butene-1 may be converted to butane by reaction with **[AIEEE 2003]**

(a) Zn-HCl (b) Sn-HCl
(c) Zn-Hg (d) Pd/H_2

51. Acetylene does not react with **[AIEEE 2002]**

(a) Na (b) ammoniacal $AgNO_3$
(c) HCl (d) NaOH

the Guidance

Round I

2. 
longest chain with eight carbons

3,6-diethyl-3-methyloctane

Note Name of the substituent are given alphabetically when more than one substituent are present.

3. Beryllium carbide gives CH_4, magnesium carbide (MgC_2) and calcium carbide (CaC_2) give acetylene on hydrolysis while silicon carbide being covalent does not undergo hydrolysis.

4. Incomplete combustion of methane results in the formation of carbon black C(s).

5. Reduction of CH_3COCH_3 with HI and red P will give propane.

$$CH_3COCH_3 \xrightarrow{\text{HI, Red P}} CH_3CH_2CH_3$$

7. If two different alkyl halides (R_1—X and R_2—X) are used, a mixture of three alkanes is obtained which is difficult to separate.

8. $$CH_3I + 2[H] \xrightarrow{\text{Zn–Cu}} \underset{\text{methane}}{CH_4} + HI$$

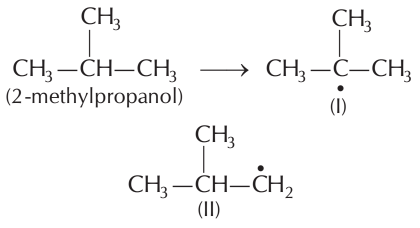
$$2CH_3I \xrightarrow{\text{Na}} \underset{\text{ethane}}{CH_3CH_3}$$

9. Among the halogens, fluorine being most electronegative is highly reactive and reactivity decreases on moving down the group. Thus, the correct order is $I_2 < Br_2 < Cl_2 < F_2$.

10. As the size of halogen atom increases, R—X bond length increases, thus, reactivity of RX increases.

11. 
$$\underset{\text{2,2-dimethyl propane}}{CH_3-\overset{CH_3}{\underset{CH_3}{C}}-CH_3} \xrightarrow{Br_2} \underset{(C_5H_{11}Br = 151)}{CH_3-\overset{CH_3}{\underset{CH_3}{C}}-CH_2Br}$$

12. 2-methylpropane gives two types of radicals.



$$\underset{\text{(2-methylpropanol)}}{CH_3-\overset{CH_3}{CH}-CH_3} \longrightarrow \underset{\text{(I)}}{CH_3-\overset{CH_3}{\underset{\bullet}{C}}-CH_3}$$

and $$\underset{\text{(II)}}{CH_3-\overset{CH_3}{CH}-\dot{C}H_2}$$

Radical (I) is more stable because it is 3° and stabilized by nine hyperconjugative structures (as it has 9α-hydrogens).

Radical (II) is less stable because it is 1° and stabilized by only one hyperconjugative structure (as it has only 1α-hydrogen).

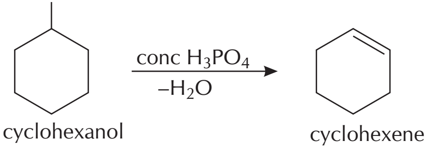
13. 
2,4-dimethyl pentane

15. All H-atoms in *neo*-pentane are equivalent thus, it will yield monochloro product.

18. The thermal decomposition of alkanes is known as cracking. It leads to the formation of lower alkanes, alkenes and hydrogen.

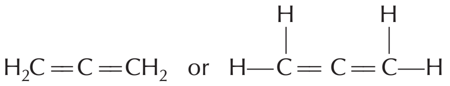
$$\underset{\text{propane}}{CH_3CH_2CH_3} \xrightarrow{400\text{–}600°C} \underset{\underset{(X)}{\text{ethylene}}}{CH_2=CH_2} + \underset{\underset{(Y)}{\text{methane}}}{CH_4}$$

19. The best method to prepare cyclohexene from cyclohexanol is by using conc. H_3PO_4 because among given options dehydrating agent is only conc. H_3PO_4.



20. 
$$CH_3-\overset{CH_3}{\underset{CH_3}{C}}-\underset{OH}{CH}-CH_3 \xrightarrow[\Delta]{H_2SO_4} \underset{\text{(major)}}{CH_3-\overset{CH_3}{C}=\underset{CH_3}{C}-CH_3}$$

$$+ \underset{\text{(minor)}}{CH_3-\overset{CH_3}{\underset{CH_3}{C}}-CH=CH_2}$$



21. $H_2C{=}C{=}CH_2$ or $H{-}\overset{H}{C}{=}C{=}\overset{H}{C}{-}H$

allene (C_3H_4)

It has two double and four single bonds.

22. Conjugate dienes are more stable than the other dienes.

23. Heat of hydrogenation $\propto \dfrac{1}{\text{stability}}$

Among the given buta-1,3-diene is resonance stabilised, *i.e.*, more stable, thus it has the lowest heat of hydrogenation.

24. $Cl_3C{-}CH{=}CH_2 \xrightarrow[\text{anti-Markownikoff's rule}]{HCl} Cl_3C{-}CH_2{-}CH_2Cl$

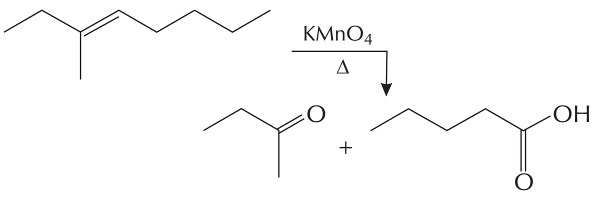
($\because$ CCl_3 is highly electron attracting group.)

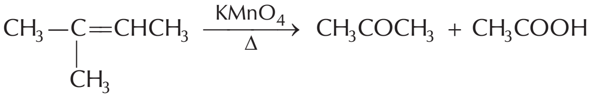
25. Reactivity of halogen acids towards addition reactions increases with increase in the size of halogen atoms as this reaction involves dissociation of H—*X* bond.

26. Addition of HBr to an alkene in the presence of peroxide is the example of free radical addition reaction.

$$R{-}O{-}O{-}R \longrightarrow 2R{-}O^{\bullet}$$
$$R{-}O^{\bullet} + HBr \longrightarrow R{-}OH + Br^{\bullet}$$
$$R{-}CH{=}CH_2 + Br^{\bullet} \longrightarrow R{-}\dot{C}H{-}CH_2Br$$
$$R{-}\dot{C}H{-}CH_2Br \xrightarrow{HBr} RCH_2CH_2Br + Br^{\bullet}$$
$$Br^{\bullet} + Br^{\bullet} \longrightarrow Br_2$$

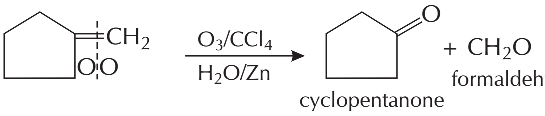
27.



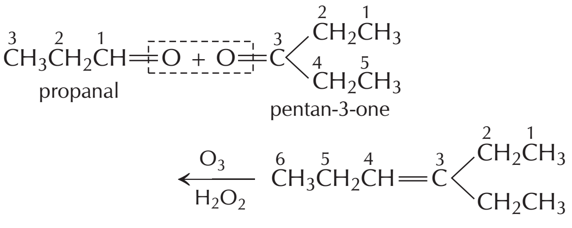


28. $CH_3{-}\underset{CH_3}{\underset{|}{C}}{=}CHCH_3 \xrightarrow[\Delta]{KMnO_4} CH_3COCH_3 + CH_3COOH$

29.



cyclopentanone formaldehyde



30. $\overset{3}{C}H_3\overset{2}{C}H_2\overset{1}{C}H{=}\boxed{O + O}{=}\overset{3}{C}(\overset{2}{C}H_2\overset{1}{C}H_3)(\overset{4}{C}H_2\overset{5}{C}H_3)$

propanal pentan-3-one

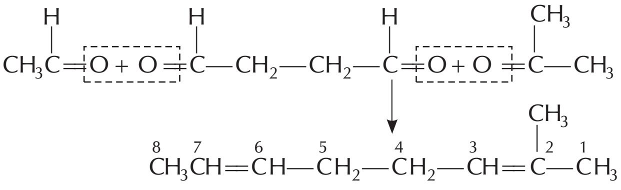
$\xleftarrow[H_2O_2]{O_3}$ $\overset{6}{C}H_3\overset{5}{C}H_2\overset{4}{C}H{=}\overset{3}{C}(\overset{2}{C}H_2\overset{1}{C}H_3)(CH_2CH_3)$

3-ethylhex-3-ene

31. $OHC{-}CH_2{-}CH_2{-}CHO$, CH_3CHO and CH_3COCH_3

(butane-1,4-dial) (ethanal) (propanone)

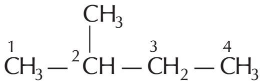
Hence, the structure of compound *A* is



$$CH_3\overset{H}{C}{=}\boxed{O + O}{=}\overset{H}{C}{-}CH_2{-}CH_2{-}\overset{H}{C}{=}\boxed{O + O}{=}\overset{CH_3}{C}{-}CH_3$$
$$\downarrow$$
$$\overset{8}{C}H_3\overset{7}{C}H{=}\overset{6}{C}H{-}\overset{5}{C}H_2{-}\overset{4}{C}H_2{-}\overset{3}{C}H{=}\overset{CH_3}{\overset{2}{C}}{-}\overset{1}{C}H_3$$

(*A*) 2-methylocta-2,6-diene

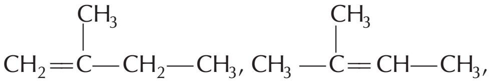
32. Structure of 2-methyl butane is



$$\overset{1}{C}H_3{-}\overset{CH_3}{\overset{2}{C}H}{-}\overset{3}{C}H_2{-}\overset{4}{C}H_3$$

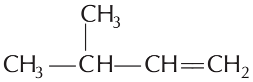
2-methyl butane

The structures of the given alkenes are as



$$CH_2{=}\overset{CH_3}{C}{-}CH_2{-}CH_3,\ CH_3{-}\overset{CH_3}{C}{=}CH{-}CH_3,$$

2-methylbut-1-ene 2-methylbut-2-ene

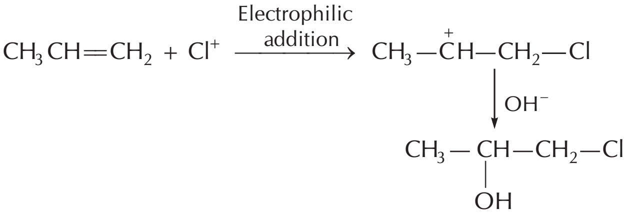


$$CH_3{-}\overset{CH_3}{C}H{-}CH{=}CH_2$$

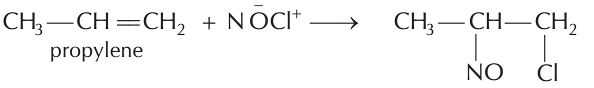
3-methylbut-1-ene

Thus, all give 2-methyl butane on hydrogenation.

33. HOCl has Cl^+ and OH^- ions.



$$CH_3CH{=}CH_2 + Cl^+ \xrightarrow[\text{addition}]{\text{Electrophilic}} CH_3{-}\overset{+}{C}H{-}CH_2{-}Cl$$
$$\downarrow OH^-$$
$$CH_3{-}\underset{OH}{\underset{|}{C}H}{-}CH_2{-}Cl$$



34. $CH_3{-}CH{=}CH_2 + N\overset{-}{O}Cl^+ \longrightarrow CH_3{-}\underset{NO}{\underset{|}{C}H}{-}\underset{Cl}{\underset{|}{C}H_2}$

propylene propylene nitroso chloride

35. $CH_2{=}CH{-}CH{=}CH_2 \xrightarrow[\text{1 mole}]{H_2,\ Ni} CH_3CH{=}CH{-}CH_3$

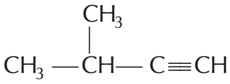
1,3-butadiene (*A*) 1,4-addition product (*B*)

$\xrightarrow[\text{(ii) } H_2O/Zn]{\text{(i) } O_3} CH_3CHO$

36. C_5H_8 has three possible alkynes. These are

$CH_3CH_2CH_2C{\equiv}CH$, $CH_3CH_2C{\equiv}C{-}CH_3$,

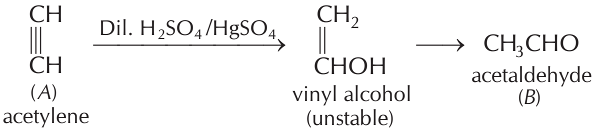
pent-1-yne pent-2-yne



$$CH_3{-}\overset{CH_3}{C}H{-}C{\equiv}CH$$

3-methylbut-1-yne

37. $CaC_2 + 2H_2O \longrightarrow \underset{(A)}{C_2H_2} + Ca(OH)_2$

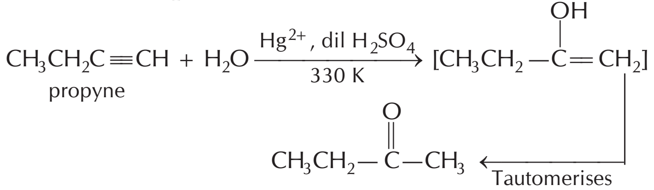


$$\begin{matrix}CH\\ |||\\ CH\end{matrix} \xrightarrow{\text{Dil. } H_2SO_4/HgSO_4} \begin{matrix}CH_2\\ ||\\ CHOH\end{matrix} \longrightarrow CH_3CHO$$

(*A*) acetylene vinyl alcohol (unstable) acetaldehyde (*B*)

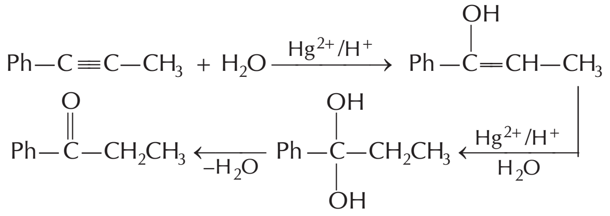
38. Reaction of 4-octyne and H_2 can be arrested at the alkene stage only by using palladium partially inactivated with trace of quinoline. The product is *cis*-alkene.

40. In the presence of dil H_2SO_4 and mercury salts, alkynes add a molecule of H_2O to form aldehydes or ketones.



$$\underset{\text{propyne}}{CH_3CH_2C\equiv CH} + H_2O \xrightarrow[330\text{ K}]{Hg^{2+},\ \text{dil }H_2SO_4} [CH_3CH_2-\overset{OH}{\overset{|}{C}}=CH_2] \xrightarrow{\text{Tautomerises}} CH_3CH_2-\overset{O}{\overset{\|}{C}}-CH_3$$

41.

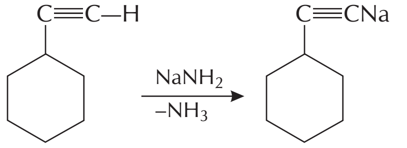


$$Ph-C\equiv C-CH_3 + H_2O \xrightarrow{Hg^{2+}/H^+} Ph-\overset{OH}{\overset{|}{C}}=CH-CH_3 \xrightarrow[H_2O]{Hg^{2+}/H^+} Ph-\underset{OH}{\overset{OH}{C}}-CH_2CH_3 \xrightarrow{-H_2O} Ph-\overset{O}{\overset{\|}{C}}-CH_2CH_3$$

42. $CH\equiv CH \xrightarrow{NaNH_2} \underset{'A'}{CH\equiv C^-Na^+} \xrightarrow[-NaBr]{CH_3Br} \underset{'B'}{CH\equiv C-CH_3}$

43. $\underset{\text{acetylene}}{CH\equiv CH} + 2HCHO \longrightarrow \underset{\text{2-butyne-1, 4-diol}}{OHH_2C-C\equiv C-CH_2OH}$

44. Only terminal alkynes when heated with sodamide ($NaNH_2$ in liq. NH_3), result in the formation of alkynide



sodium alkynide

45. C_2H_2 and all 1-alkynes give white precipitate with ammoniacal silver nitrate.

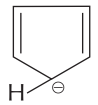
Propyne-1 ($CH_3C\equiv CH$) will give white precipitate with ammoniacal silver nitrate.

$$\underset{\text{propyne-1}}{CH_3C\equiv CH} + NH_4OH + AgNO_3 \longrightarrow \underset{\text{white ppt.}}{CH_3C\equiv CAg} + NH_4NO_3 + H_2O$$

46. Compound  has $8+2=10\pi$-electrons, hence is aromatic.

 has 4 πe^-,  has $8\pi e^-$, while  has $8+1=9\pi e^-$, hence, all these species are not aromatic.

47.



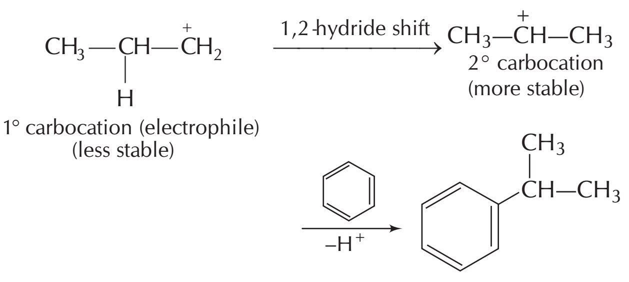
cyclopentadienyl anion

π electrons $= 4+2=6$

As it obeys Huckel rule, it is aromatic.

48. Cyclodecapentene and cyclooctatetraene both are non-aromatic. Cyclobutadiene is anti-aromatic while benzene having 6π-electrons is aromatic.

50. $CH_3-CH_2-CH_2-Cl + AlCl_3 \xrightarrow[-AlCl_4^-]{}$

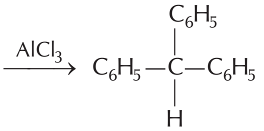


Iso-propyl benzene

51. Benzophenone (diphenyl ketone) can be prepared by the Friedel-Crafts condensation between benzoyl chloride and benzene.

$$C_6H_6 + C_6H_5COCl \xrightarrow{AlCl_3} C_6H_5COC_6H_5 + HCl(80\%)$$

52.

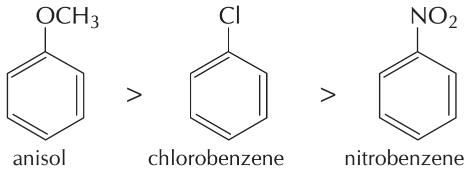


$$C_6H_6 + CHCl_3 \xrightarrow{AlCl_3} C_6H_5-\underset{H}{\overset{C_6H_5}{C}}-C_6H_5$$

53. As the number of $-CH_3$ group increases, boiling point decreases.

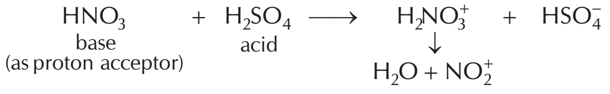
54. $-OCH_3$ (methoxy group) is an electron releasing group. It increases electron density in benzene nucleus due to resonance effect (+ *R* effect). Hence, makes anisole more reactive than benzene towards electrophiles.

In case of aryl halides, halogens are moderately deactivating because of their strong $-I$ effect and $+R$ effect thus, overall electron density on benzene ring decreases. It makes further substitution difficult. $-NO_2$ group is electron withdrawing group. It decreases the electron density in benzene nucleus due to strong $-I$ effect. Hence, makes nitrobenzene less reactive. Therefore, overall reactivity of these three compounds towards electrophiles decreases in the following order



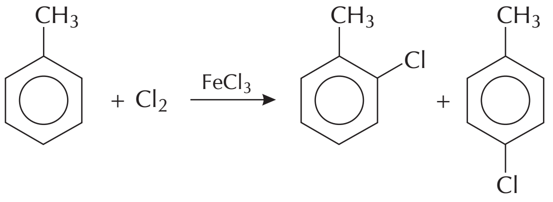
56. Reactivity towards electrophilic substitution increases as the electron density in the benzene ring increases. Since CH_3 is a strong electron donating group thus toluene ($C_6H_5CH_3$) can be most readily sulphonated.

59. In the laboratory, nitrobenzene is prepared by nitration of benzene with the mixture of nitric acid and sulphuric acid at temperature below 60°C. In which HNO_3 acts as a base.

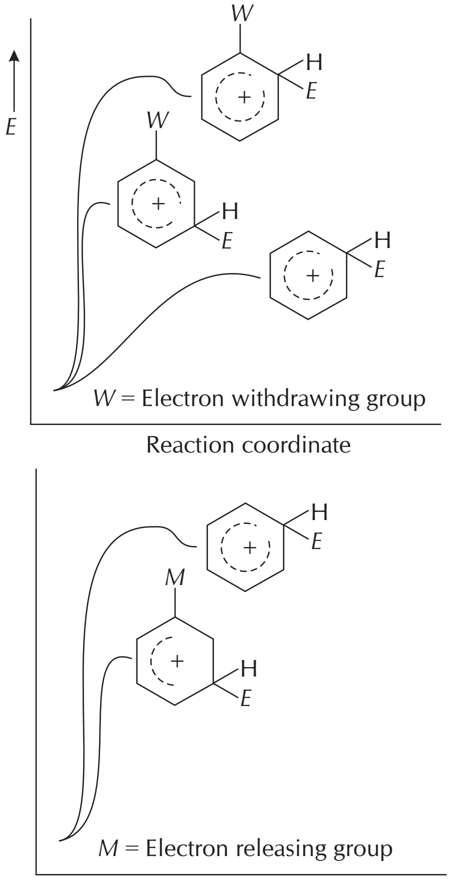


$$\underset{\substack{\text{base}\\\text{(as proton acceptor)}}}{HNO_3} + \underset{\text{acid}}{H_2SO_4} \longrightarrow \underset{\substack{\downarrow\\ H_2O + NO_2^+}}{H_2NO_3^+} + HSO_4^-$$

60.



62.



Electron withdrawing group destabilises the arenium ion σ-complex.

64. Presence of electron releasing group (or activating group) increases the electron density in benzene nucleus. Therefore, electrophile will attack benzene nucleus easily. But the presence of electron withdrawing group like $-NO_2$ decreases the electron density in benzene ring. Therefore, electrophile will attack benzene nucleus with difficulty.

The order of reactivity towards electrophile, E^+ in the order of their decreasing relative reactivity is

Toluene > $p\text{-}CH_3-C_6H_4-NO_2$

Chlorobenzene > *p*-nitrochlorobenzene
> 2,4-dinitrochlorobenzene

65. $$\underset{\substack{\text{propyne}\\ \text{(terminal alkyne)}}}{CH_3-C\equiv C-H} + Na \xrightarrow{\text{Liq. }NH_3} CH_3-C\equiv C-Na$$

$$CH_3-C\equiv C-Na + BrCH_3 \longrightarrow \underset{\text{but-2-yne}}{CH_3-C\equiv C-CH_3} + NaBr$$

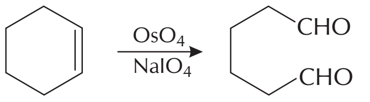
This reaction is utilised for the preparation of higher alkynes.

68. C_4H_6 may contains either two double bond or a triple bond.

$$CH_2=CH-CH=CH_2$$

or $$CH_3-CH_2-C\equiv CH$$

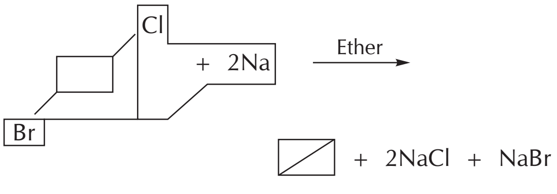
69.



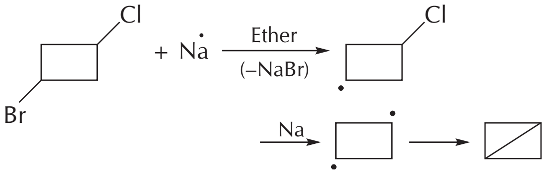
hexane-1,6-dial

Round II

1. This reaction is of Wurtz's type reaction.

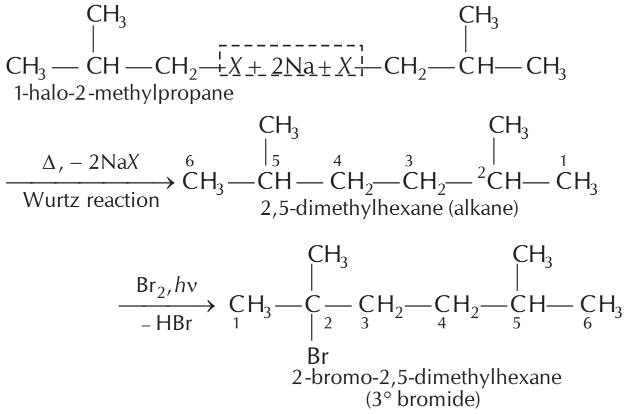


In this reaction, following mechanism is possible.



(Order of removal of halogen I > Br > Cl).

2. Since, alkane C_8H_{18} on monobromination yields a single isomer of a tertiary bromide, therefore alkane must contain tertiary hydrogen. This is possible if primary alkyl halide (which undergoes Wurtz reaction) has a tertiary hydrogen.



$$\underset{\text{1-halo-2-methylpropane}}{CH_3-\overset{CH_3}{\overset{|}{CH}}-CH_2-}\boxed{X+2Na+X}-CH_2-\overset{CH_3}{\overset{|}{CH}}-CH_3$$

$$\xrightarrow[\text{Wurtz reaction}]{\Delta,\,-2NaX} \underset{\text{2,5-dimethylhexane (alkane)}}{\overset{6}{CH_3}-\overset{CH_3}{\overset{|}{\overset{5}{CH}}}-\overset{4}{CH_2}-\overset{3}{CH_2}-\overset{CH_3}{\overset{|}{{}^2CH}}-\overset{1}{CH_3}}$$

$$\xrightarrow[-HBr]{Br_2,h\nu} \underset{\substack{\text{2-bromo-2,5-dimethylhexane}\\ (3^\circ\text{ bromide})}}{\underset{1}{CH_3}-\underset{\underset{Br}{|}}{\overset{CH_3}{\overset{|}{\underset{2}{C}}}}-\underset{3}{CH_2}-\underset{4}{CH_2}-\overset{CH_3}{\overset{|}{\underset{5}{CH}}}-\underset{6}{CH_3}}$$

3. 
$\overset{(1°)\,CH_3}{\underset{(1°)}{CH_3}—\underset{(3°)}{CH}—\underset{(2°)}{CH_2}—\underset{(1°)}{CH_3}}$

Relative amount of monochlorinated product

= Number of hydrogen × relative reactivity

For (1°) monochlorinated product $= 9 \times 1 = 9$

(2°) monochlorinated product $= 2 \times 3.8 = 7.6$

(3°) monochlorinated product $= 1 \times 5 = 5$

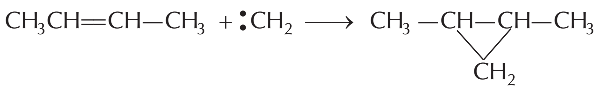
Total amount of monochlorinated compounds

$= 9 + 7.6 + 5 = 21.6$

% of 1° monochlorinated product $= \frac{9 \times 100}{21.6} = 41.67$

% of 2° monochlorinated product $= \frac{7.6 \times 100}{21.6} = 35.18$

% of 3° monochlorinated product $= \frac{5 \times 100}{21.6} = 23.15$



$CH_3CH{=}CH—CH_3 + {:}CH_2 \longrightarrow CH_3—\underset{\diagdown\ CH_2\ \diagup}{CH—CH}—CH_3$

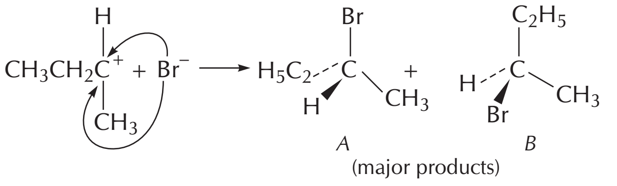
4. 
5. $CH_3CH_2CH{=}CH_2 + H^+ \longrightarrow CH_3CH_2\overset{+}{C}H—CH_3$

2° (planar)
(more stable major)

$+ CH_3CH_2CH_2—\overset{+}{C}H_2$

1°
(less stable)

$CH_3CH_2CH_2\overset{+}{C}H_2 + Br^- \longrightarrow \underset{(C)}{CH_3CH_2CH_2CH_2Br}$



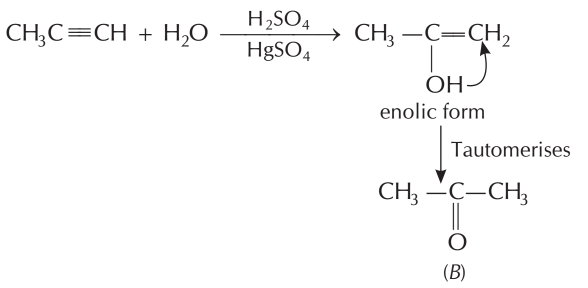
(major products)

6. $\underset{\text{2-methyl-3-hexyne}}{(CH_3)_2CH—C{\equiv}C—CH_2CH_3} \xrightarrow{[O]} (CH_3)_2CHCOOH + CH_3CH_2COOH$

7. 
vinylic bromide is more stable stronger base ($–NH_2^-$) is required to proceed elimination

8. 
$3CH_3C{\equiv}CH \xrightarrow{BH_3,\ THF} \left(CH_3CH{=}\underset{H}{C}—B\right)_3 \xrightarrow{H_2O_2,\ OH^-}$

$CH_3CH{=}CHOH \xrightarrow{\text{Tautomerises}} \underset{(A)}{CH_3CH_2CHO}$



9. 
10. The two compounds should react differently with the reagent used to distinguish them.

∵ Propyne ($CH_3—C{\equiv}CH$) and propene ($CH_3CH{=}CH_2$) both are unsaturated compounds.

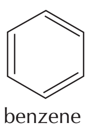
∴ Both of them decolourise alk. $KMnO_4$ and Br_2 in CCl_4 and both of them give addition reaction with conc. H_2SO_4.

∵ Propyne reacts with $AgNO_3$ in NH_3 to give white ppt. of silver acetylide and propene does not react with it. (only terminal alkynes react with $AgNO_3$ in NH_3.

$\underset{\text{(propyne)}}{CH_3—C{\equiv}CH} + AgNO_3 + NH_3 \longrightarrow \underset{\substack{\text{silver acetylide}\\ \text{(white ppt.)}}}{CH_3—C{\equiv}CAg}$

$CH_3—CH{=}CH_2 + AgNO_3 + NH_3 \longrightarrow$ No reaction

11. The hybridisation state of carbon in the given compounds is



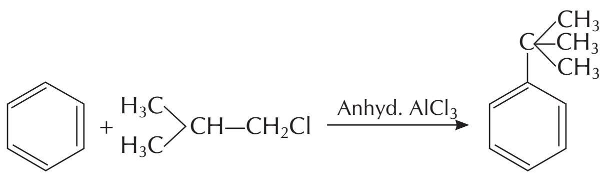
; $CH_3—(CH_2)_4—CH_3$; $HC{\equiv}CH$

	benzene	hexane	ethyne
Type of hybridisation	sp^2	sp^3	sp
s-character	33.33%	25%	50%

Acidic character increases with increase in *s*-character of the orbital. Hence, decreasing order of acidic behaviour of benzene, *n*-hexane and ethyne is as follows

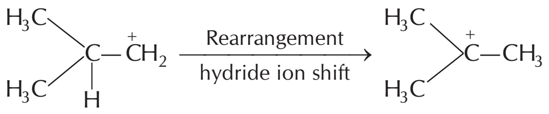
Ethyne > Benzene > Hexane

12.

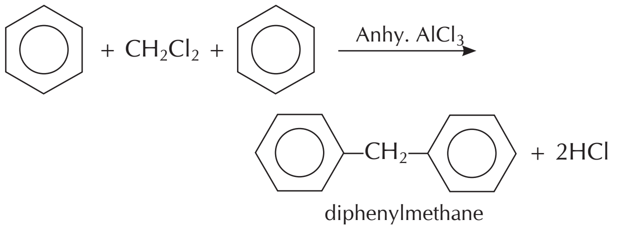


This reaction is an example of Friedel-Crafts reaction.

Mechanism



13. When excess of benzene reacts with CH_2Cl_2 in the presence of anhy. $AlCl_3$, diphenylmethane is obtained.



This reaction is an example of Friedel-Crafts reaction.

14. I. has 8π electrons, does not follow Huckel rule. Orbitals of one carbon atom are not in conjugation. It is not aromatic.

II. has 6π delocalised electrons. Hence, is aromatic.

III. has 6π electrons in conjugation but not in the ring. Non aromatic.

IV. 10π electrons in planar rings, aromatic.

V. Out of 8π electrons it has delocalised 6π electrons in one six membered planar ring, which follows Huckel's rule due to which it will be aromatic.

VI. 14π electrons are in conjugation and are present in a ring. Huckel's rule is being followed. Compound will be aromatic if ring is planar.

15. (i) Determination of empirical formula of hydrocarbon *A*

Element	Percentage	Atomic mass	Relative ratio	Relative number of atoms	Simplest ratio
C	87.8	12	$\frac{87.8}{12} = 7.31$	$\frac{7.31}{7.31} = 1$	$1 \times 3 = 3$
H	12.19	1	$\frac{12.19}{1} = 12.19$	$\frac{12.19}{7.31} = 1.66$	$1.66 \times 3 = 5$

∴ Empirical formula of hydrocarbon (*A*) = C_3H_5

Empirical formula mass $= 12 \times 3 + 5 \times 1 = 41$ u

(ii) Determination of molecular mass of hydrocarbon (*A*)

896 mL vapours of hydrocarbon (*A*) weigh at STP = 3.28 g

∴ 22400 mL vapours of *A* will weigh at STP

$$= \frac{3.28 \times 22400}{896} \text{ g mol}^{-1} = 82 \text{ g}$$

∴ Molecular mass of hydrocarbon (*A*) = 82 g mol^{-1}

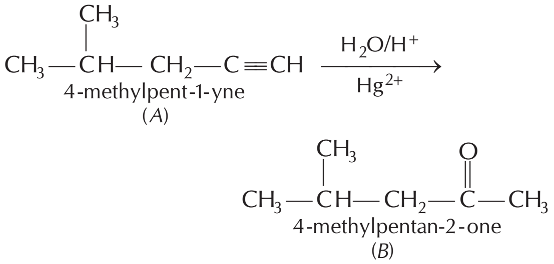
(iii) Determination of molecular formula of hydrocarbon *A*.

$$n = \frac{\text{Molecular mass}}{\text{Empirical formula mass}} = \frac{82}{41} = 2$$

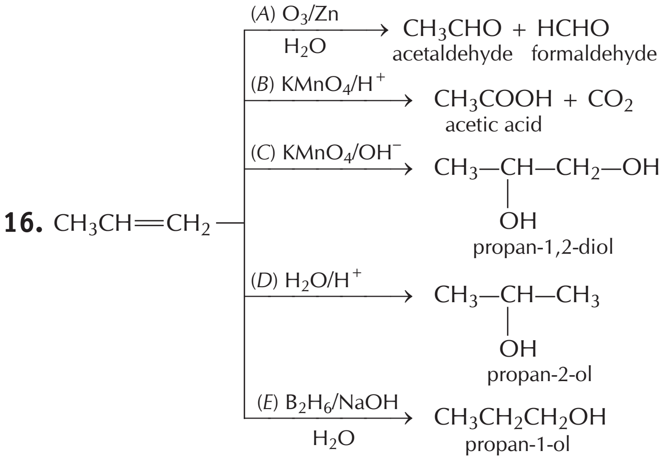
Therefore, molecular formula of hydrocarbon

$$(A) = n \times \text{Empirical formula} = 2 \times C_3H_5 = C_6H_{10}$$

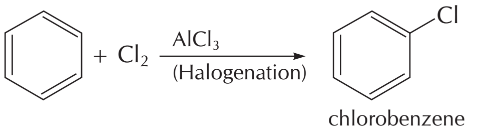
Since, hydrogenation of *A* gives 2-methyl pentane therefore compound '*A*' have 5 carbon atoms in straight chain. It should be an alkyne because compound '*A*' adds a molecule of H_2O in the presence of Hg^{2+} and H^+ to give a ketone '*B*'. Ketone '*B*' gives iodoform test so it should be a methyl ketone. Therefore, the structures of compound *A* and compound *B* are as follows



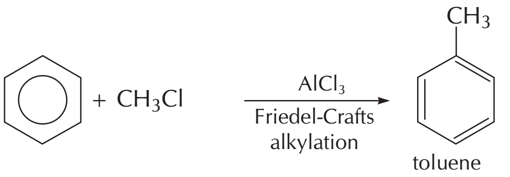
16.



17. (A)

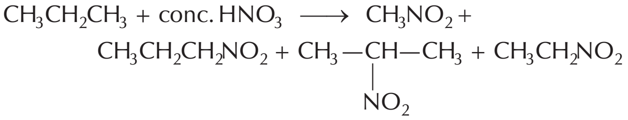


(B)



(C) 
(D) 
18. The controlled oxidation of methane results in the formation of aldehyde or alcohol.

19. The reaction occurs by a free radical mechanism and so a mixture of products is obtained.



$$CH_3CH_2CH_3 + \text{conc. } HNO_3 \longrightarrow CH_3NO_2 + CH_3CH_2CH_2NO_2 + CH_3{-}\underset{NO_2}{\underset{|}{CH}}{-}CH_3 + CH_3CH_2NO_2$$

20. (a) $CH_3CH{=}CH{-}CH_3 \xrightarrow[H_2O]{O_3/Zn} 2CH_3CHO$

two moles of aldehyde

(b) 
(c) 
(d) $(CH_3)_2C{=}C(CH_3)_2 \xrightarrow[H_2O]{O_3/Zn} 2(CH_3)_2C{=}O$

21. (a) 
symmetrical molecule
(μ = 0)

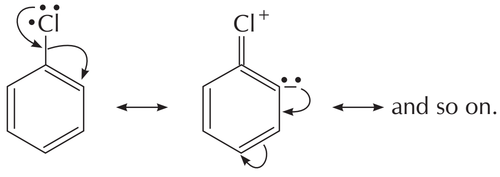
(b) 
trans-pent-2-ene
(μ ≠ 0)
(as it is unsymmetrical)

(c) 
cis hex-3-ene
(unsymmetrical μ ≠ 0)

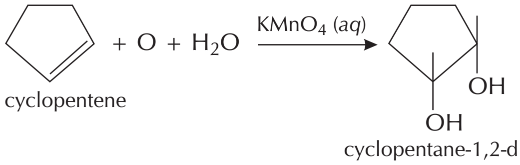
(d) 
(symmetrical so μ = 0)

22. 
Cl ← due to –*I* effect deactivate the ring towards $E^{\oplus}$.

due to electron donating resonance effect increase charge density at *o*/*p* position.



23. 



24. With branching boiling point decreases, due to decrease in van der Waals' forces.

25. When carbon atoms are linked by triple bond, the valency bonds undergo bending and are distorted from their normal directions. This bending produces strain in the molecule with the result that it becomes unstable and hence, more reactive.

26. 
8πe⁻ and non-planar
so non-aromatic

27. Lower alkanes do not undergo sulphonation but higher members are sulphonated slowly when treated with fuming sulphuric acid at about 400°C.

$$R{-}H + HOSO_3H \xrightarrow[\text{Prolonged heating}]{SO_3} R{-}SO_3H + H_2O$$

This reaction occur by free radical mechanism.

28. Dehydration of alcohols to alkene is carried out through carbocation formation.

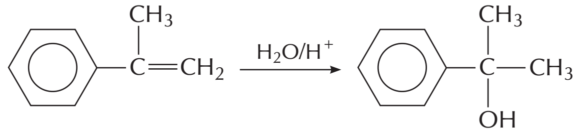
29. Intramolecular dehydration since H_2O is lost from one molecule of ethyl alcohol.

30. 
$$CH_3CH_2CH_2{-}\underset{OH}{\underset{|}{CH}}{-}CH_2CH_2CH_3 \xrightarrow[-H_2O]{\text{Dehydration}}$$

heptan-4-ol

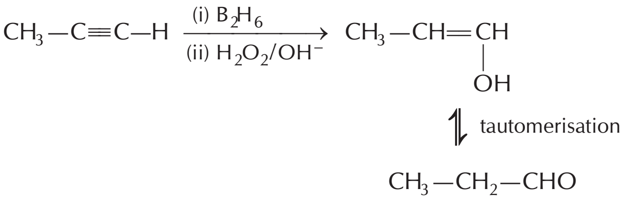
$CH_3CH_2CH{=}CHCH_2CH_2CH_3$
hept-3-ene

31.



32. Hydroboration oxidation, anti-Markownikoff's addition of water gives product.

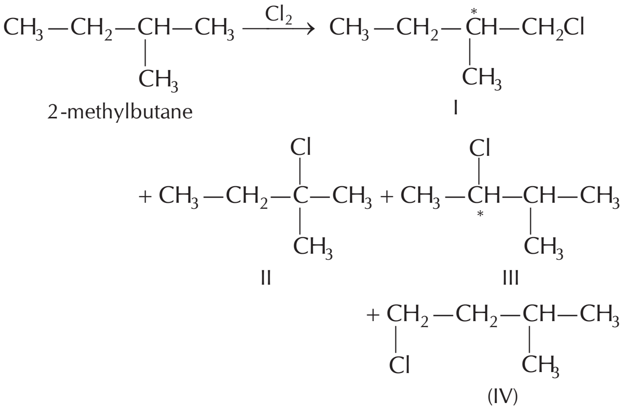
33.



$$CH_3-C\equiv C-H \xrightarrow[\text{(ii) } H_2O_2/OH^-]{\text{(i) } B_2H_6} CH_3-CH=CH(OH) \rightleftharpoons CH_3-CH_2-CHO$$

tautomerisation

34.



$$CH_3-CH_2-CH(CH_3)-CH_3 \xrightarrow{Cl_2} \underset{\text{I}}{CH_3-CH_2-\overset{*}{C}H(CH_3)-CH_2Cl} + \underset{\text{II}}{CH_3-CH_2-CCl(CH_3)-CH_3} + \underset{\text{III}}{CH_3-\overset{*}{C}HCl-CH(CH_3)-CH_3} + \underset{\text{(IV)}}{CH_2Cl-CH_2-CH(CH_3)-CH_3}$$

2-methylbutane

I and III have chirality (*). Thus, in all four (including enantiomers) optical isomers are obtained.

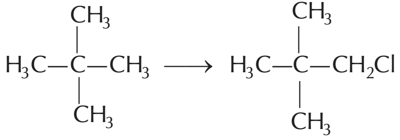
35. Molar mass = 72 = $C_nH_{2n+2} = 12n + (2n+2)$

$$n = 5$$

Thus, hydrocarbon is C_5H_{12}.

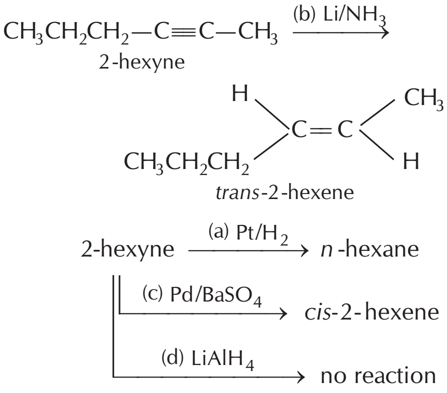
Since, it gives only single $C_5H_{11}Cl$, thus C_5H_{12} is symmetrical.

It is ***neo*-pentane**



$$H_3C-C(CH_3)_2-CH_3 \longrightarrow H_3C-C(CH_3)_2-CH_2Cl$$

36.



$CH_3CH_2CH_2-C\equiv C-CH_3 \xrightarrow{\text{(b) Li/NH}_3}$

2-hexyne

trans-2-hexene

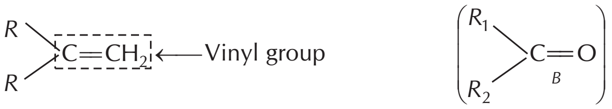
2-hexyne $\xrightarrow{\text{(a) Pt/H}_2}$ *n*-hexane

$\xrightarrow{\text{(c) Pd/BaSO}_4}$ *cis*-2-hexene

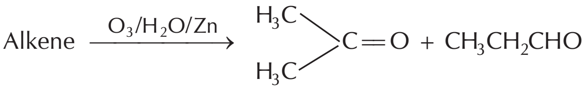
$\xrightarrow{\text{(d) LiAlH}_4}$ no reaction

37. Alkenes give carbonyl compounds on ozonolysis

$$\text{Alkene} \xrightarrow{O_3/Zn/H_2O} \underset{(A)}{HCHO} + \text{other carbonyl compound}$$

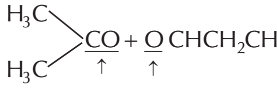


38.



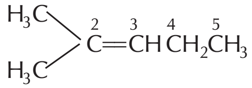
$$\text{Alkene} \xrightarrow{O_3/H_2O/Zn} (H_3C)_2C=O + CH_3CH_2CHO$$

To identify alkene (from ozonolysis products) place these products with O-atoms face to face. Replace O-atoms by = (double) bond.



$$(H_3C)_2\underline{CO} + \underline{O}\,CHCH_2CH_3$$

O-atom face to face



$$(H_3C)_2\overset{2}{C}=\overset{3}{C}H\overset{4}{C}H_2\overset{5}{C}H_3$$

2-methyl-2-pentene

39. $C_nH_{2n}O = 44$

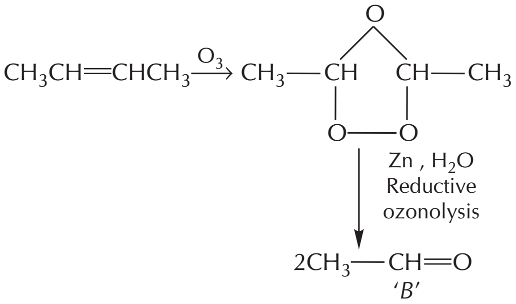
$$C_nH_{2n} = 44 - 16 = 28$$

$\therefore$ $n = 2$

So, $CH_3-CH=CH-CH_3$ is the symmetrical alkene.

Thus, $\underset{\text{2-butene}}{CH_3-CH=CH-CH_3} \xrightarrow[\text{(ii) Zn/H}_2O]{\text{(i) } O_3} \underset{\text{acetaldehyde}}{2CH_3-CH=O}$

40.



$$CH_3CH=CHCH_3 \xrightarrow{O_3} CH_3-CH(-O-O-)(-O-)CH-CH_3 \xrightarrow[\text{Reductive ozonolysis}]{Zn,\ H_2O} \underset{'B'}{2CH_3-CH=O}$$

41. $CH_3CH_2C\equiv CH \xrightarrow[\Delta]{\text{Na/Liq. NH}_3} CH_3CH_2C\equiv CNa^+$

Considering the options given it appears correct. Na/liq NH_3 is known for metal dissolved reduction. Actually it is truth that Na/liq NH_3 reduces internal triple bond and terminal double bond and do not reduce the terminal alkyne due to such alkylide formation.

42. Terminal alkyne has acidic hydrogen which is enough to protonate the Grignard reagent.

$$CH_3MgX + CH_3C\equiv CH \longrightarrow CH_4 + CH_3C\equiv CMgX$$

43. 
$$CH_3-C\equiv CH + HBr \longrightarrow CH_3-\underset{\underset{Br}{|}}{C}=CH_2 \xrightarrow{H^+} H_3C-\overset{+}{\underset{\underset{Br}{|}}{C}H}-CH_3 \xrightarrow{\text{Rearrangement}} CH_3-\overset{\overset{Br}{|}}{\underset{\underset{Br}{|}}{C}}-CH_3$$

2, 2-dibromopropane

$$CH_3-CH=CHBr \xrightarrow{HBr} CH_3-CH_2-CHBr_2$$

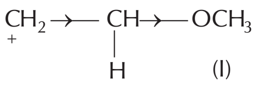
$$CH\equiv CH \xrightarrow{2HBr} CH_3CHBr_2$$

$$CH_3-CH=CH_2 \xrightarrow{HBr} CH_3-CHBr-CH_3$$

44. 
—NO_2 group withdraw electron from the ring, shows –*M* effect makes ring electron deficient, thus deactivates the ring for electrophilic substitution.

45. 
$$CH_2=CH-O-CH_3 \xrightarrow{HBr} CH_3-\underset{\underset{Br}{|}}{C}H-O-CH_3$$

First protonation occurs, two possible intermediates are



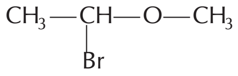
$$\overset{+}{C}H_2 \leftarrow \underset{\underset{H}{|}}{CH} \leftarrow OCH_3 \quad (I)$$

(–*I* effect destabilises carbocation)

and 
$$CH_3-\overset{+}{C}H-\ddot{O}\ CH_3 \quad II$$

(+ *M* effect stabilises carbocation)

II, is more favourable. Hence, $Br^{\ominus}$ attacks and product is



$$CH_3-\underset{\underset{Br}{|}}{C}H-O-CH_3$$

46. 
There are four β-hydrogens, in this quarternary ammonium salt.

On heating, quarternary ammonium salt gives Hofmann elimination (abstraction of most acidic hydrogen which is β^1).

Hence, major product is $CH_2=CH_2$ (least substituted alkene).

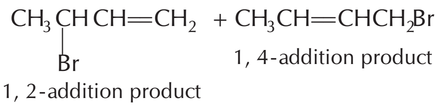
47. (A) 2-methyl pentane $\xrightarrow{Cl_2}$ five types of monochlorinated compounds

(B) 2, 2-dimethylbutane $\xrightarrow{Cl_2}$ three types...

(C) 2, 3-dimethylbutane $\xrightarrow{Cl_2}$ two types...

(D) *n*-hexane $\xrightarrow{Cl_2}$ three types ....

48. $CH_2=CHCH=CH_2 + HBr \longrightarrow$



$$\underset{\text{1, 2-addition product}}{CH_3\underset{\underset{Br}{|}}{C}H\,CH=CH_2} + \underset{\text{1, 4-addition product}}{CH_3CH=CHCH_2Br}$$

Addition is through the formation of allylic carbocation.

$$\underset{\substack{(2°\text{ allylic})\\(\text{more stable})}}{CH_2=CH\overset{\oplus}{C}HCH_3} \longleftrightarrow \underset{\substack{(1°\text{ allylic})\\(\text{less stable})}}{CH_3CH=CH\,\overset{\oplus}{C}H_2}$$

Under mild conditions (temperature ≈ – 80° C) **kinetic product** is the **1, 2-addition product** and under vigorous conditions
(temp. ≈ 40° C) **thermodynamic product** is the **1, 4-addition product.**
Thus, 1-bromo-2-butene is the major product under given condition.

49. *iso*-butene  has minimum force of attraction (due to steric hindrance). Thus, minimum boiling point.

50. $$\underset{\text{butene-1}}{CH_2=CH-CH_2CH_3} \xrightarrow[\Delta,\text{ pressure}]{Pd/H_2} \underset{\text{butane}}{CH_3-CH_2-CH_2-CH_3}$$

Other reagents are successful with polar double bonds.

51. $$CH\equiv CH + Na \longrightarrow CH\equiv C^{-}Na^{+} + \frac{1}{2}H_2$$

$$CH\equiv CH + \underset{(\text{ammoniacal})}{AgNO_3} \longrightarrow \underset{\text{white ppt.}}{CH\equiv C^{-}Ag^{+}}$$

$$CH\equiv CH + HCl \longrightarrow CH_2=CH-Cl$$

Usually occurs in the presence of Hg^{2+}

$$CH=CH + NaOH \longrightarrow \text{no reaction}$$

Because of hard acid hard base soft acid soft base (HASB) theory.

$$CH\equiv CH + NaNH_2 \longrightarrow CH\equiv C^{-}Na^{+} \text{ feasible.}$$

16 Environmental Chemistry

JEE Main MILESTONE

- Components of Environment
- Environmental Pollution
- Pollutants
- Atmospheric Pollution
- Tropospheric Pollution
- Water Pollution
- Soil Pollution
- Strategies to Control Environmental Pollution

16.1 Components of Environment

Environment includes three main components, viz.

1. Abiotic or non-living components include atmosphere, hydrosphere and lithosphere.
2. Biotic or living components include plants and animals (including human beings).
3. Energy components include various kinds of energy such as solar energy, thermal energy and nuclear energy.

Anything that environs us such as air, water, soil, sunlight etc., constitutes our environment and the branch of chemistry, which deals with the chemical phenomena happening in the environment is termed as **environmental chemistry.** *This term has come to be regarded as synonymous with environmental pollution by some scientists. However, it must be emphasised that environmental chemistry deals with a wider aspect of knowledge. The problem of pollution is just a small segment of it.*

Atmosphere

Earth is surrounded by a covering of various gases (air), called atmosphere, which extends to a height of about 1600 km above the earth surface. Dry air contains roughly (by volume) nitrogen (78.08%), oxygen (20.95)%, argon (0.93%), carbon dioxide (0.033%) and trace amount of other gases such as Ne (18 ppm), He (5.2 ppm), methane (1.3 ppm), Kr (1 ppm), H_2 (0.5 ppm), CO (0.10 ppm), O_3 (0.02 ppm), SO_2 (0.001 ppm) etc. Thus, **atmosphere is the gaseous component of the earth.** The gaseous covering (or the atmosphere) prevents the harmful radiations, coming from the sun or outer space, to reach on the earth and protects the life on earth.

The thickness of atmosphere is not same at all heights because of the presence of concentric layers of air or regions of different density. *Thus, atmosphere, can further be divided into the following regions*

(a) Troposphere

It is the lower layer of atmosphere which extends up to the height of ~ 10 to ~ 18 km from the sea level. It is a turbulent and dusty zone which contains air (N_2, O_2, CO_2, etc.), much water vapours and clouds. Therefore, this is the region that supports life. This region constitutes about 80% of the total mass of the atmosphere. Temperature of this region decreases with altitude due to decrease in pressure and density of air and it is minimum at about 11 km. This point is called **tropopause** and acts as boundary between the troposphere and the next layer, *i.e.,* stratosphere.

(b) Stratosphere

Above the troposphere is the stratosphere which lies between 18-50 km above sea level. In this region, temperature starts to rise, therefore, tropopause is the point at which temperature inversion occurs. In stratosphere, at about 20 to 40 km, there is a part of relatively high ozone concentration, called the **ozone layer.** Due to such a high concentration of ozone, this region is also known as **ozonosphere.**

Ozone is formed when UV light strikes oxygen molecule and splits it into individual oxygen atoms (O) which combine with undissociated oxygen. Since O_3 is unstable and again splits into O_2 and O, a dynamic equilibrium exists between production and dissociation of ozone molecule.

$$O_2(g) \xrightarrow{\text{UV light}} 2O(g)$$

$$O\,(g) + O_2(g) \underset{}{\overset{\text{UV light}}{\rightleftharpoons}} O_3(g)$$

Thus, this region contains dinitrogen, oxygen, ozone, and little water vapours. Ozone layer absorbs about 99.5% of harmful UV radiations coming from the sun and thus, protects human and other living things from it. The boundary between the mesosphere and stratosphere is called **stratopause.**

(c) Mesosphere

It is the region above stratosphere and extends from 50-85 km. In this region again temperature decreases with height and reaches to −100°C. That's why when any meteors enter in mesosphere, it burns up.

(d) Thermosphere

Above the mesosphere is thermosphere which extends up to 640 km. In this region, although, the temperature can rise to 1500°C, a person would not feel warm because of the extreme low pressure. The international space station orbit is also in this layer.

Caution Point *Mesosphere and thermosphere are collectively called ionosphere as in these, gases are present in their ionised form.*

(e) Exosphere

Above thermosphere, the highest region of atmosphere, known as exosphere (500-1600 km), is present which also contains ionised gases.

Beyond this region, an unbounded area, called **interstellar space** is present.

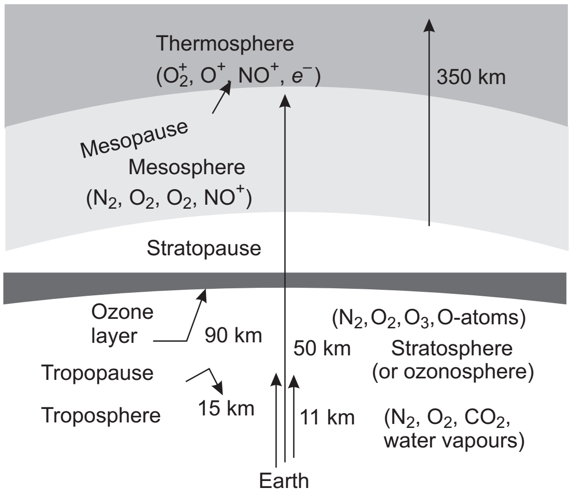


Fig. 16.1 Various regions of the Earth's atmosphere

Hydrosphere and Lithosphere

The liquid parts (the parts that contain water) of environment such as sea, oceans, rivers, lakes etc., constitute **hydrosphere** whereas the solid components of earth such as soil, rocks, mountains etc., constitute **lithosphere.**

Biosphere

It is that part of abiotic components (lithosphere, hydrosphere and atmosphere) where living organisms live and interact with these components.

Check Point 1

1. When any meteors enters in the mesosphere, it burns up. Explain, why?
2. Explain why does the temperature in troposphere decrease with altitude?
3. The composition of atmosphere is different at different heights. Explain.

16.2 Environmental Pollution

The contamination of environment (*i.e.,* air, water and soil) with any undesirable substance, obtained from either a natural source or human activity, which has adverse effect on plants, animals and human beings, is called **environmental pollution.** The biotic and abiotic components that are affected adversely, are known as **receptors or targets.** On the basis of the part of environment (*i.e.,* air, water, soil) affected, pollution may be of the following three types :

(i) Atmospheric pollution (when air gets polluted),
(ii) Water pollution,
(iii) Soil pollution

However, on the basis of nature of pollutants, pollution can be classified into following categories : Thermal pollution, noise pollution, radioactive pollution, smog pollution, plastic pollution, industrial pollution, metal toxicity pollution, acid rain pollution, oil pollution etc.

16.3 Pollutants

The substance that contaminate the environment are referred to as **pollutants.** There are several substances which in normal conditions are not pollutants but when present in excess or at a wrong place, act as pollutants and have harmful effect, *e.g.,* fertilisers act as pollutant for water. Remember that the pollutants that do not occur in nature and are introduced into the environment by human activity are called **contaminants.**

Classification of Pollutants Depending upon their State

On this basis pollutants are classified into following categories

(a) Solid Pollutants

These exist in solid state, *e.g.,* rubbish, ashes, wastes sludges, pesticides, insecticides, chemicals etc. Solid pollutants may be degradable or non-degradable. **Degradable solid pollutants** are those, which are easily decomposed either by microorganisms (biodegradable), *e.g.,* wastes sludges or by any other treatment such as chemical treatment (non-biodegradable), *e.g.,* heat while **non-degradable solid pollutants** are those which do not degrade, *e.g.,* DDT, plastics etc. Soil pollution is mainly caused by solid pollutants.

(b) Liquid Pollutants

These exist in liquid state, *e.g.,* sewage, wastes which contain faecal matter, urine and some bacteria and industrial wastes. These are the main source of water pollution. However, these also cause soil pollution.

(c) Gaseous Pollutants

These exist in gaseous form. Examples of such pollutants are CO, NO, CO_2, SO_3, O_3, NO_2 etc. These are the main source of atmospheric pollution. However, these also cause soil and water pollution.

(d) Invisible Pollutants

Heat, noise and radiations are the examples of such pollutants. These are the main source of thermal, noise and radioactive pollutions.

Classification of Pollutants on the Basis of their Formation

On this basis pollutants are of following two types

(a) Primary Pollutants

These are simple molecules that persist in the environment in the form, they are formed. *e.g.,* oxides of carbon, nitrogen, sulphur such as SO_2, NO_2, CO, hydrocarbons etc.

(b) Secondary Pollutants

These are the products of reactions of primary pollutants. These are more harmful than primary pollutants, *e.g.,* PAN (peroxyacetyl nitrate) which is formed when hydrocarbons react photochemically with oxides of nitrogen, ozone, aldehydes, phenols etc.

16.4 Atmospheric Pollution

Atmospheric pollution is defined as *the presence or addition of some undesirable substances, which have adverse effect on plants and animals including human being, into the atmosphere either due to some natural phenomenon or due to human activity.* Although atmosphere comprises several regions, atmospheric pollution is related to only tropospheric pollution (pollution of air) and stratospheric pollution (pollution of stratosphere, *i.e.,* depletion of ozone layer).

16.5 Tropospheric Pollution

Tropospheric pollution is defined as **the contamination of air by undesirable solid or gaseous particles.** The major sources of tropospheric pollution are of two types

(a) Gaseous air pollutants such as oxides of nitrogen, sulphur, carbon, hydrocarbons, ozone and other oxidants.
(b) Particulate air pollutants such as dust, mist, fumes, smoke.

Major Gaseous Air Pollutants

Major gaseous pollutants along with their sources and harmful effects are as follows

(a) Oxides of Carbon

Carbon forms two oxides, *viz*, carbon monoxide (CO) and carbon dioxide (CO_2). Out of these two oxides, carbon monoxide is most harmful. Under normal conditions, carbon dioxide does not act as air pollutant but when present in large excess, has an adverse effect on our climate.Carbon monoxide is obtained by incomplete combustion of fossil fuels in automobiles, metallurgical operations,forest fire or burning of agricultural waste and volcanic eruption. Cigarette smoke also contains CO. However, about 70% carbon monoxide is obtained only from automobiles.

Carbon monoxide *is highly poisonous to living beings because it has an ability to form more stable carboxyhaemoglobin complex with haemoglobin due to which the delivery of oxygen to the organs and tissues is blocked.* The carboxyhaemoglobin complex is about 200 times more stable than the oxygen haemoglobin complex. If the concentration of carboxy-haemogobin complex, in blood, reaches about 3-4%, the oxygen carrying capacity of blood is reduced greatly which results in headache, nervousness, muscular weakness, weak eyesight and asphyxia. *Microorganisms present in the soil act as a sink for carbon monoxide.*

On exposing the victim (person) suffering from CO poisoning to 2-2.5 atm oxygen, under a high pressure, the CO of carboxyhaemoglobin is substituted by oxygen and transport of oxygen to the different parts of the body starts again.

$$\text{HbCO} + \underset{\text{2-2.5 atm}}{O_2} \xrightleftharpoons{\text{High pressure}} \text{HbO}_2 + \text{CO}$$

$$\text{HbO}_2 \longrightarrow \text{Hb} + \underset{\substack{\text{(goes to the different}\\ \text{body parts)}}}{O_2}$$

Respiration, burning of fossil fuels for energy, decomposition of lime stone for cement manufacturing, volcanic eruptions etc., all p rocesses proceed with the liberation of carbon dioxide into the atmosphere. Thus, a large amount of carbon dioxide is released into the atmosphere which is removed by green plants on account of photosynthesis and in turn they release oxygen and maintain an appropriate level of CO_2 (*i.e.,* 0.03%) in the troposphere (or atmosphere). But deforestation and excessive burning of fossil fuels increase the level of CO_2 and disturb the atmospheric balance. This increased level of CO_2 may be expected to result in fast growing of plant, if climate is warm with adequate rainfall. Excessive concentration of CO_2 in atmosphere also causes headache, mild narcotic effect and global warming.

Caution Point *Ocean acts as sink for* SO_2, CO_2 *and nitrogen oxides and remember that* NO *has greater affinity towards haemoglobin than* CO.

(b) Oxides of Nitrogen

Among the oxides of nitrogen, nitric oxide (NO), a colourless, odourless gas and nitrogen dioxide (NO_2), a brown gas with pungent odour act as tropospheric pollutants. At high altitudes when lightning strikes or thunderstrome, the two major constituents of air, *i.e.,* dinitrogen and dioxygen combine to give these oxides. Other sources of these oxides are combustion of fossil fuels such as coal, oil, gasoline etc., in automobile engines, tobacco smoke, denitrifying bacteria and many industrial processes.

$$N_2(g) + O_2(g) \xrightarrow{1210°\text{C}} 2\,\text{NO}(g)$$

Actually NO, itself, is not a pollutant but it reacts readily with oxygen in the troposphere and with ozone in the stratosphere, to give NO_2.

NO_2 is highly toxic for living tissues. Its higher concentration causes leaf fall and retards the rate of photosynthesis. It is a corrosive oxide and helps in the formation of smog. NO_2 produces irritation in eyes and can injure liver and kidneys. In the presence of oxygen, NO_2 reacts with water or moisture and produces HNO_3 which is an important factor for making rain acidic.

(c) Oxides of Sulphur

SO_2 is the most harmful gaseous pollutant. In atmosphere, it is released by volcanic eruptions. It is also released by the combustion of sulphur containing materials. A part of SO_2, present in the atmosphere, is oxidised to SO_3 by photolytic or catalytic oxidation. Thus, atmospheric SO_2 also contains some SO_3, although the quantity of SO_3 is not high.

SO_2 is highly toxic for both animals and plants. Its very low concentration can cause several respiratory diseases such as bronchitis, asthma, emphysema. It also causes eye and throat irritation and breathlessness. In plants, it reduces the rate of formation of chloroplast and thus, causes chlorosis. SO_2 is highly corrosive and damages buildings, marbles (Taj Mahal) and textiles. In the presence of particulate matter and NO_2 or H_2O_2 (promoter), SO_2 is oxidised to SO_3 which reacts with water to give H_2SO_4. H_2SO_4 remains suspended in the air as droplets or come down in the form of acid rain.

$$2SO_2(g) + O_2(g) \xrightarrow[\text{NO}_2 \text{ or } \text{H}_2\text{O}_2]{\text{Particulate matter}} 2SO_3(g)$$

$$SO_3(g) + H_2O \longrightarrow H_2SO_4$$

Lime stone reacts with H_2SO_4 (formed from SO_2 and SO_3) *and removes oxides of sulphur from atmosphere. Therefore,* $CaCO_3$ *acts as sink for oxides of sulphur.*

(d) Hydrocarbons

These are the compounds of only carbon and hydrogen. These are obtained by the incomplete combustion of fuels in automobile engines and by anaerobic decomposition of organic matter. Out of the hydrocarbons, methane (CH_4) is the most abundant hydrocarbon pollutant. High concentrations of hydrocarbons have carcinogenic effect, *i.e.*, are cancer producing. They cause ageing of plants, breakdown of plant tissues and shedding of leaves. Hydrocarbons react with oxides of nitrogen to form secondary pollutants.

Caution Points

(*i*) *The atmospheric pollution is mainly caused by* CO (≃ 52%) *and the order of other pollutants (to cause atmospheric pollution) is as* SO_2 (18%) > *hydrocarbons* (12%) > *particulates* (9%), *nitrogen oxides* (6%). *A rememberable point here is that spraying of DDT causes all; air, water and soil pollutions.*

(*ii*) *Bhopal gas tragedy* (*on December* 1984) *in which about* 3000 *people were on killed and about* 50000 *are still suffering from respiratory, lung and eye diseases, was due to leakage of methyl isocyanate* (*MIC*) *vapours.*

Consequences of Air Pollution Caused by Gaseous Pollutants

Global warming, caused by more heating of green house (earth's atmosphere and surface) and acid rain are the two important consequences of gaseous air pollutants.

Hot Spot 1

GREEN HOUSE

Effect and Global Warming

Although the chapter is not very important for JEE Main examination, but the question, if asked, may be based on this topic. The question is general and easy.

When sunlight containing UV rays, IR rays and visible rays falls on earth, the UV rays are absorbed by ozone, present in the stratosphere and visible and IR rays (short wavelength) reach on the earth. IR rays, having heating effect, heat up the earth and its various objects. As a result, the earth and its objects also begin to emit IR rays (but of higher wavelength). The CO_2 layer present in the air (atmosphere) traps these IR rays and does not allow them to go out of the earth's atmosphere. This is because CO_2 absorbs only IR rays of longer wavelengths. Consequently, the earth and its atmosphere remains warm. **This heating up of earth and its objects because of the trapping of IR radiations by** CO_2 (mainly) **and other green house gases such as methane, NO,** O_3**, CFCs, water vapour etc., in the atmosphere is called green house effect.** Green house effect is very essential for existence of life because in its absence, the earth would be converted into extremely cold planet.

When concentration of green house gases increases, these trap excess IR rays and increases the temperature of earth too much, i.e., increases the green house effect, which is termed as global warming. Thus, global warming is the main consequence of disturbance of green house effect. Global warming had a drastic effect on climatic conditions. It may cause melting of ice caps and glaciers which result in floods of low lying areas. Moreover global warming also increases the incidence of several infectious diseases such as malaria, sleeping sickness etc.

The name 'green house effect' is come from the fact that at cold places, plants, flowers are grown in a glass covered area, called green house because the glass walls are transparent for incoming radiations but not transparent for outgoing IR radiations. Thus, required temperature is maintained. Similarly, earth atmosphere is also transparent for incoming visible and IR radiations but not for outgoing IR radiations and thus, keeps the earth warmth.

Sample **Problem 1** *What would have happened if the green house gases were totally missing in the earth's atmosphere?* **[NCERT]**

(a) *The plant leaves turn yellow*
(b) *All plants turn yellow*
(c) *No vegetation or life exists*
(d) *Earth becomes warm*

Interpret (c) Carbon dioxide, methane, water vapour, nitrous oxide, CFCs and ozone are green house gases. These gases trap some of the heat radiated by the earth's object near the earth's surface and keep it warm. This is called natural green house effect because it maintains the temperature and makes the earth perfect for life. If there were no green house gases, there would have no vegetation and life on our earth (because the earth would convert into a cold planet).

(b) **Acid Rain**

The pH of normal rain water is 5.6 due to the dissolution of carbon dioxide from atmosphere which furnish H^+ ions to the rain water.

$$H_2O + CO_2 \rightleftharpoons \underset{\text{carbonic acid}}{H_2CO_3}$$

$$H_2CO_3 \rightleftharpoons H^+ + HCO_3^-$$

When the pH of rain water drops below 5 *because of the presence of certain acids, it is called acid rain.* The term "acid rain" was putforth by *'Robert Augus'. Oxides of nitrogen and sulphur, released into the atmosphere from thermal power plants, industries and automobiles, are the main sources of acid rain.* These oxides on oxidation followed by hydrolysis (*i.e.,* reaction with water) give sulphuric acid and nitric acid that along with HCl are responsible for the acidity of rain., The oxidation reaction is catalysed by particulate matter present in the polluted atmosphere.

$$2SO_2 + O_2 + 2H_2O \longrightarrow 2H_2SO_4$$

$$4NO_2 + O_2 + 2H_2O \longrightarrow 4HNO_3$$

In acid rain, concentration of these acids follows the order $H_2SO_4 > HNO_3 > HCl$.

Acid rain damages the buildings and other structures made up of lime stone or marble, *i.e.,* $CaCO_3$, *e.g.,* Due to acid rain the marble of a wonderful monument Taj Mahal, situated at Agra, is getting discoloured and lustreless. Acid rain also corrodes metal pipes, as a result of which heavy metals such as Fe, Pb and Cu get leached into the drinking water and make it toxic. The nutrients required for growth and development of plants and trees are dissolved in acid rain, so it is very harmful for agriculture, trees and plants. In human beings and animals, it causes several respiratory diseases. When acid rain water is mixed with river or lakes, it adversely affect the aquatic life.

Some important facts related to acid rain are as follows

1. The most acidic rain with a pH of 1.7 has occurred over West Virginia, USA.
2. The historic marble statue, in Greece and Itlay also have been damaged by acid rain.
3. In order to save Taj Mahal, Government of India announced a plan in early 1995. According to this plan, it was decided to clear the air in the "Taj Trapezium", an area which includes the towns of Agra, Mathura, Firozabad and Bharatpur.

   The main points of this plan are as follows

   (i) Industries lying in the Trapezium would be allowed to use only natural gas or LPG instead of coal or oil. For this purpose a new natural gas pipeline would be laid.
   (ii) Peoples living in these area would be encouraged to use LPG or a low sulphur containing fuel.
   (iii) Vehicles plying in the nearby areas would be encouraged to use low sulphur content fuel.

Control of Pollution Caused by Gaseous Pollutants

The tropospheric pollution, caused by the gaseous air pollutants, can be prevented by following methods

1. Catalytic converters are used in automobile exhaust pipes to prevent formation and release of oxides of nitrogen.These convert oxides of nitrogen to free nitrogen or to a small amount of ammonia.
2. esnareshratoaeFlue gases, obtained from power plants and many industrial units, are made free from NO_2 and SO_2 by treating them with either sulphuric acid or alkaline solutions such as $Ca(OH)_2$, $Mg(OH)_2$. The process is called **scrubbing process.**
3. SO_2 pollution can also be prevented either by desulphurisation of coal or by using natural gas instead of coal for heating purposes, since natural gas does not produce SO_2 on burning.
4. Production of CO and unburnt hydrocarbons from automobiles can be prevented by fitting catalytic converters and tune-ups (for high air-fuel ratio) in automobiles exhaust pipes.
5. CO and hydrocarbons production can also be controlled by using a modified internal combustion engine with an extra combustion chamber where fuel undergoes complete combustion.
6. CO pollution can be completely controlled by using LPG and CNG instead of gasoline, coal etc.
7. Another way to reduce CO pollution is using leaded petrol (the petrol mixed with tetraethyl lead). *The addition of tetraethyllead to the petrol minimise the CO and unburnt hydrocarbon pollution, but it leads to the lead pollution.* (metal pollution).
8. Keeping the vehicle properly tuned for the optimum combustion of fuel is another way to reduce CO and unburnt hydrocarbon pollution.
9. Use of tall chimney in the kitchen can minimise the pollution of air at ground level.
10. The increasing concentration of carbon dioxide can be controlled by growing more plants and using LPG instead of coal and such fuels. In other words, global warming can be minimised by growing more plants and reducing the use of fossil fuels.

Particulate Air Pollutants

Minute solid particles and liquid droplets dispersed in air are called **particulate matter.** Particulate present in the atmosphere may be viable and non-viable. The viable particulates are minute living organisms, such as bacteria, fungi, algae, moulds, etc., that are dispersed into the atmosphere. Some of the fungi, present in air are allergic for human beings and can also cause many plant diseases. The disintegration of large size materials or condensation of small size particles or droplets result in the formation of non-viable particulates. Indeed, **non-viable particulates** are non-living, small size particles or condensed droplets that are dispersed in the atmosphere. Examples of non-viable particulates are flyash, fur, spores, pollen grains, dusts of various kinds, fumes, smoke etc.

On the basis of particle size, the non-viable particulate matter may further be differentiated into two types, *viz*, settleable particulates having particle size larger than $10\,\mu m$ and suspended particulates having particle size less than $10\,\mu m$. While on the basis of nature, non-viable particulates may be classified into following four types

(a) Smoke

These particulates are composed of solid particles or mixture of solid and liquid particles which are formed during the burning of organic matter. Since smoke contains unburnt carbon particles, it pollutes the air. It spoils clothes, blacken the buildings, monuments, causes several diseases of lungs. Examples of smoke are oil smoke, tobacco smoke and carbon smoke. Clouds of smoke over big industries unable the Sun rays to reach every corner of the city and thus, lead several infectious diseases. **A clusture of smoke particles is called soot.**

(b) Dusts

It consist of fine solid particles (> $1\,\mu m$ in diameter) that are produced during some industrial operations such as crushing and grinding of solid materials, *e.g.,* coal, cement, flyash and silica dust (from factories), sand (from sand blasting), saw dust (from wood works) etc. Dust, in the air, causes poor visibility. It deposits on plants leaves and inhibits photosynthesis by blocking stomata. Dust deteriorates the quality of articles, reflects sun rays back and thus causes cooling of the earth. Dust produces allergic reactions and can cause several diseases on the basis of particles present, *e.g.,* **Pneumoconiosis,** a lung disease, is caused due to inhalation of coal dust from coal mining industry. **Silicosis** is caused due to inhalation of free silica or SiO_2 from dust.In this disease, person suffers from chronic cough and pain in chest. Bronchial asthma and lung cancer are also caused by dust. Coal miners usually suffer from black lung disease whereas textile workers suffer from white lung disease due to inhalation of dust of corresponding particles. Asbestosis and byssinosis are caused due to inhalation of asbestos dust and cotton fibres dust respectively.

(c) Fumes

These are condensed vapours present in air. These are generally obtained by condensation of vapours during boiling, distillation, sublimation and other such processes. These are also obtained from metals, metallic oxides and organic solvents. Fumes, when mixed with air, inhaled by the people and cause several dangerous diseases, *e.g.,* inhalation of beryllium compounds causes beryllosis. Similarly, lead particulates are highly poisonous as lead interferes in the development and maturation of RBC. Moreover, it adversely affect the children's brain and causes cancer.

(d) Mists

These are obtained by particles of spray liquids and by condensation of vapours in air, *e.g.,* herbicides and insecticides, while spray travel through air and form mists. Other examples of mists are sulphuric acid mist, nitric acid mist etc.

Hot Spot 2

SMOG

It is also an important topic of the chapter for JEE Main examination, if question is from this chapter. The level of question is easy.

Smog is an important example of air pollution which can be seen in many cities throughout the world. Actually, the word "smog" is obtained by combining two words, *viz.*, smoke and fog.

Smogs are mainly of two types

(a) Classical or London Type Smog

It occurs in cool humid climate when carbon soot particles combine with gaseous oxides of sulphur, present in atmosphere. Since, it was first observed in London (in 1952), it is also called **London smog.** The main source for the formation of this type of smog, is combustion of industrial and household fuels (coal and petroleum). Usually, it is formed in the early morning hours of winter months. However, shortly after sunrise it increases because of the oxidation of SO_2 and subsequent combination with moisture to give sulphuric acid aerosol.

$$2SO_2 + O_2 \longrightarrow 2SO_3 \text{ (oxidation)}$$

$$SO_3 + H_2O \longrightarrow \underset{\substack{\text{aerosol}\\ \text{(increases the smog)}}}{H_2SO_4}$$

Due to the presence of carbon particles and SO_2, it is **reducing in nature.** This smog causes lung and throat irritation and in higher concentrations, it leads to death.

(b) Photochemical or Los Angeles Smog

It occurs in warm, dry and sunny climate, generally during the day time from its components, which are obtained by the action of sunlight on unsaturated hydrocarbons and nitrogen oxides (produced by automobiles and factories). The following reactions take place during the formation of components of photochemical smog.

$$N_2 + O_2 \xrightarrow[\substack{\text{or in petrol and}\\ \text{diesel engines)}}]{\text{(At high altitudes}} 2NO$$

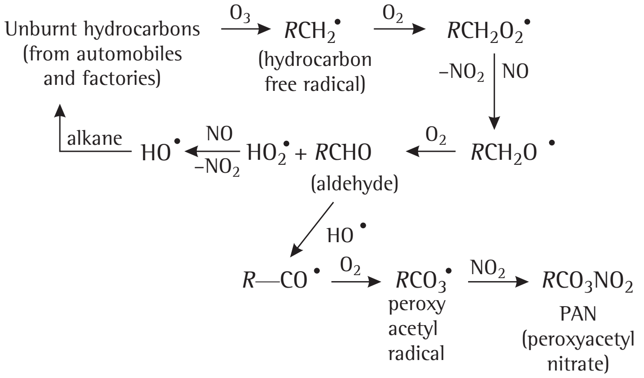
$$\underset{\substack{\text{in high}\\ \text{concentration}}}{2NO} + O_2 \xrightarrow{\text{Sunlight}} 2NO_2$$

$$NO_2 \xrightarrow{h\nu} NO + \underset{\substack{\text{nascent oxygen}\\ \text{(very reactive)}}}{[O]}$$

$$[O] + O_2 \rightleftharpoons \underset{\substack{\text{(reacts rapidly}\\ \text{with NO)}}}{O_3}$$

$$O_3 + NO \longrightarrow \underset{\substack{\text{(brown gas)}\\ \text{(in high concentration}\\ \text{forms haze)}}}{NO_2} + O_2$$

Since, O_3 and NO_2 are strong oxidising agent, they react with unburnt hydrocarbons to give following compounds (secondary pollutants).



(where, R = H, CH_3, C_6H_5)

(If R = H, acrolein and formaldehyde are obtained.)

Due to the presence of high concentration of oxidising agents, photochemical smog is **oxidising in nature.**

Photochemical smog due to the presence of ozone, PAN and nitric oxide, irritates eyes, nose, lungs, causes headache, chest pain etc. It also leads to the cracking of rubber and extensive harm to plant life. It corrodes metals, stones and even painted surfaces.

Its formation can be prevented by controlling the formation and release of primary precursors such as oxides of nitrogen, hydrocarbons etc., by their usual methods. Other method of its prevention is plantation of certain plants such as pyrus, pinus, juniparus and vitis that have an ability to metabolise nitrogen oxide. Spraying of suitable free radical generating compounds also reduce photochemical smog.

Sample **Problem 2** *Photochemical smog occurs in warm, dry and sunny climate. One of the following is not amongst the components of photochemical smog, identify it.*

- (*a*) NO_2
- (*b*) O_3
- (*c*) SO_2
- (*d*) *Unsaturated hydrocarbon*

Interpret (*c*) SO_2 is reducing in nature and not obtained in sunny, dry climate. So, it is not a component of photochemical smog. It is a component of classical smog.

Control of Pollution Caused by Particulates

The particulates, present in the atmosphere, can be removed by following methods.

1. Larger particulate particles from air are removed by using gravity settling chamber.
2. Particulates such as soluble gases and particles are removed by fine spray of water or alkaline fluid, which are called **wet scrubbers.**
3. Cyclone collectors are used to remove the particulates of 5-20 μm. This method is based on centrifugation.
4. Particulate matters are also removed by using bag filters, a porous bag made up of teflon or other polyester.
5. The most effective and efficient method to remove particulates especially aerosol particles, is the use of electrostatic precipitators, a charged plate.
6. A broad strip of vegetation also reduces particulate pollution.

Hot Spot 3

OZONE LAYER DEPLETION
or Stratospheric Pollution

It is more important as compared to other topic of the chapter and questions, if asked, may be generally from this topic. The level of question may be easy to average.

Stratospheric pollution is mainly concerned with **ozone layer depletion.** In stratosphere, there is a region of high concentration of ozone (10 ppm), at a height of 23 km, called **ozone layer.** This layer does not allow the UV rays coming from the sun to reach on the earth. Thus, protects us from harmful effects of UV rays.

Sources of Stratospheric Pollution

In recent years, it has been reported that the ozone layer is getting thin at some places. Thinning of ozone layer has mainly observed over Antarctica and north pole. Depletion of ozone layer is being caused by certain compounds such as chlorofluorocarbon compounds (CFCs), oxides of nitrogen etc., obtained from various human activities.

Nitric oxide is released into upper atmosphere from engine of supersonic transport planes. When it reaches into the stratosphere, it reacts with ozone and causes its depletion.

$$NO + O_3 \longrightarrow NO_2 + O_2$$

$$O_2 \xrightarrow{\text{UV light}} [O] + [O]$$

$$NO_2 + [O] \longrightarrow NO + O_2$$

Since, chlorofluorocarbon compounds, *i.e.,* freons (CFCs) are non-reactive, non-inflammable, non-toxic organic molecules, these are widely used in air conditioners, refrigerators, in electronic industry for cleaning computer parts. Due to very long life time (CF_2Cl_2— 12 : 139 yr and $CFCl_3$ —11 : 77 yr), these compounds ultimately reach the stratosphere where they get broken down by powerful UV radiations and release chlorine free radical. The chlorine free radicals react with ozone and cause its depletion.

$$CF_2Cl_2 \xrightarrow{h\nu} \dot{Cl} + \dot{C}F_2Cl$$

$$CFCl_3 \xrightarrow{h\nu} CFCl_2 + \dot{Cl} \qquad \text{(free radical)}$$

$$\underset{\substack{\text{(chlorine}\\ \text{free radical)}}}{\dot{Cl}} + O_3 \longrightarrow Cl\dot{O} + O_2$$

$$Cl\dot{O} + O \longrightarrow \dot{Cl} + O_2$$

The reaction, once start, continues for a long time. Thus, a single chlorine free radical is able to convert about one lakh ozone molecules into oxygen. Due to this, a massive **ozone hole** has been created in the ozone layer.

Other compounds that are responsible for ozone layer depletion are carbon tetrachloride, halons and methyl chloroform. They react with ozone in the same manner as chlorofluorocarbons.

Caution Point *Because of ozone depletion ability, chlorofluorocarbons (CFCs) are being replaced by hydrofluorocarbons and hydrochlorofluorocarbons (HCFCs).*

Causes of Formation of Ozone Hole over Antarctica

Although the above reactions of depletion of ozone take place all over the stratosphere yet ozone hole has mainly been observed in the stratosphere over Antarctica. This is because, in other parts of the stratosphere, nitrogen dioxide and methane react with chlorine monoxide radicals and chlorine radicals respectively. Thus, these act as a sink for chlorine free radicals and prevent the depletion of ozone.

$$Cl\dot{O} + NO_2 \longrightarrow ClONO_2$$

$$\dot{Cl} + CH_4 \longrightarrow \dot{C}H_3 + HCl$$

Moreover, a unique set of conditions was responsible for the ozone hole over Antarctica. In Antarctica during summer season, there exist nitrogen dioxide and methane which act as sink for chlorine free radicals and prevent much ozone depletion, whereas, in winters, there exist special type of clouds, called polar stratospheric clouds (PSCs) over Antarctica.

These clouds are of two types

(i) Type I clouds that are formed at about −77°C, have some solidified nitric acid trihydrate ($HNO_3 \cdot 3H_2O$).

(ii) Type II clouds that are formed at about −85°C, contains some ice. These clouds convert chlorine nitrate ($ClONO_2$) and hydrochloric acid (HCl) formed in the above reactions, into HOCl and Cl_2.

$$ClONO_2 + H_2O \longrightarrow HOCl + HNO_3$$
$$ClONO_2 + HCl \longrightarrow Cl_2 + HNO_3$$

During spring season, *i.e.,* in the months of September and October, the sunlight returns to the Antarctica and breaks up the clouds and photolysis HOCl and Cl_2.

$$HOCl \xrightarrow{h\nu} \dot{O}H + \dot{C}l$$
$$Cl_2 \xrightarrow{h\nu} 2\,\dot{C}l$$

The chlorine free radicals, thus formed, again start the chain reaction for ozone depletion.

Further, in the stratosphere, polar vortex (a tight whirlpool of wind) is formed due to the presence of PSCs over Antarctica which unables the ozone rich air of the non-polar regions to reach in Antarctica. Consequently the ozone hole remains unfilled. But after spring, the high intensity sunlight breaks down these vortex and ozone rich air from surroundings rushes in and replenishes the ozone hole.

Consequences of Stratospheric Pollution

Due to the depletion of ozone layer, harmful UV radiations reach the earth surface. These radiations can cause skin cancer, sunburn, ageing of skin, cataract or even blindness. These also lead to the harmful mutation of cells in plants, depletion of plants and crops. These decrease the moisture content of soil, thereby increasing the evaporation of surface water.

Sample **Problem 3** *Ozone is a toxic gas and is a strong oxidising agent even then its presence in the stratosphere is very important. What would happen if ozone from this region is completely removed?* **[NCERT Exemplar]**

(*a*) *Skin infection*
(*b*) *Sun burn*
(*c*) *Harmful mutation of cells in plants*
(*d*) *All of the above*

Interpret (*d*) Ozone prevents harmful UV radiations of the Sun from reaching to the earth's surface, thereby it protects life from bad effects of UV radiations. If ozone is removed completely from the stratosphere, the UV rays will reach to the earth and leads to several diseases like sun burn, skin infection etc.

Check Point 2

1. What is the difference between a contaminant and a pollutant?
2. Carbon monoxide gas is more dangerous than carbon dioxide gas, why?
3. Why 'photochemical smog' is so called?
4. How do particulates help in the cloud formation?
5. What would have happened, if the green house gases were totally missing in the earth's atmosphere?

16.6 Water Pollution

The contamination of water by foreign substances such as solid particles, soluble salts, sewage, algae etc., which make it injurious for living organisms and unfit for domestic, agricultural and industrial use, is called **water pollution.** The pollution of water can be checked by one or more of the following parameters : taste of water, its odour, colour presence of oil or grease on its surface. These foreign substance are termed as **'water pollutants'.**

Types of Sources of Water Pollutants

The sources from which these pollutants are obtained and released, are of two types :

(a) Point Sources

These are easily identified sources or places of pollution. These, discharge pollutants directly into the water source. Examples of such sources are factories, power plants, underground coal mines and oil wells situated near the water source. Therefore, the pollutants obtained by these sources can be treated easily before entering in the water source.

(b) Non-point Sources

Such sources cannot be easily identified. These sources are usually scattered and are difficult to monitor, regulate and treat. These sources include run off from field lawns, construction sites, acid rain, storm water drainage etc.

Major Water Pollutants

The major water pollutants are of three types, *i.e.,* pathogens such as bacteria, organic wastes such as leaves, grass, phytoplankton and chemical pollutants such as metals from industrial wastes, petroleum etc.

(a) **Pathogens**

Bacteria and other microorganisms are disease causing agents. These enter into the water bodies from domestic sewage and animal excreta. These are the most serious water pollutants because these are transmitted from one living being to another through water supplies. These cause various water borne diseases such as typhoid, cholera, dysentry, hepatitis, jaundice etc., in human beings. To control pathogen pollution, domestic sewage and animal excreta should not be drained directly to any water body. These should be drained after proper treatment.

(b) **Organic Wastes**

Leaves, grass, sewage, oxygen demanding wastes (from industries and agriculture) etc., are other major water pollutants. Water gets polluted as a consequence of run off of organic wastes. Water gets also polluted by excessive phytoplankton growth. All of these wastes are biodegradable, *i.e.,* degraded by microorganisms. The microbes require oxygen for the decomposition of organic matter, that they get from water.

Water contains some dissolved oxygen (DO) but in limited amount. The concentration of DO in water is very important because, if it is below 5 ppm, the growth of the fishes is inhibited. Generally, in cold water, the concentration of dissolved oxygen (DO) can reach upto 10 ppm (parts per million). The aquatic plants and animals use this dissolved oxygen for respiration.

Thus, organic matter, if present in excess, the microorganisms require a large amount of oxygen. But due to absence of such a large amount, anaerobic bacteria (without using oxygen) begin to decompose organic matter and give foul smelling compounds which are also harmful to human beings. However, aerobic bacteria also decompose these organic matter.

In water of good quality, the optimum value of DO is 5-6 ppm. This also ensures healthy aquatic life in water body. The lower the concentration of DO in a water sample, the more polluted is the water sample.

Degree of Water Pollution Due to Organic Matter

It is measured in terms of biochemical oxygen demand (BOD), mainly and chemical oxygen demand (COD).

1. **Biochemical oxygen demand** (BOD) is defined as the total amount of oxygen in milligrams required by microbes to decompose the organic matter present in 1 L of water sample. Whereas the term BOD_5 refers to the total amount of oxygen required for five days by microbes to decompose the organic matter. Thus,

$$\text{BOD} = \frac{\text{amount of oxygen required (in mg)}}{\text{volume of water sample (in L)}}$$

For clean water, the BOD value is less than 5 ppm while highly polluted water could have a BOD value of 17 ppm or more. The value of BOD_5 can be 100-400 ppm for untreated sewage. To find the BOD value of a water sample, it is first saturated with oxygen and then incubated at 20°C for five days. Oxidation of organic matter takes place and remaining amount of dissolved oxygen is determined. Thus, BOD is obtained by subtraction.

2. **Chemical oxygen demand** (COD) It is the total amount of oxygen in ppm that would be consumed by the pollutants, in a given water sample. For pure water COD value is 4 ppm. For COD determination, the given water sample is treated with a known quantity of oxidising agent such as $K_2Cr_2O_7$ in acidic medium. The reagent oxidises most of the organic matters. The remaining amount of $K_2Cr_2O_7$ is determined by titrating the water sample against a suitable reducing agent such as Mohr's salt. From the amount of $K_2Cr_2O_7$ used, the amount of oxygen used can be obtained (in ppm) by the following equation

$$K_2Cr_2O_7 + 4H_2SO_4 \longrightarrow K_2SO_4 + Cr_2(SO_4)_3 + 4H_2O + 3[O]$$

Due to the presence of organic matter in water, its colour gets brown. This water has an unpleasent odour due to the formation of secondary pollutants such as CH_4, NH_3, H_2S. These waste also produce scum and sludge in water. These lead oxygen dependent aquatic life to die. Sewage also increases the growth of phytoplankton and thus, reduces the amount of DO in water and leads to eutrophication, *a process of enrichment of water by nutrients to support a dense plant population, which affect the fish population and also kills other aquatic animals.*

Organic matter pollution is also controlled by drainning these matter into water body after proper treatment.

Sample **Problem 5** *A large number of fish are suddenly found floating dead on a lake. There is no evidence of toxic dumping but you find an abundance of phytoplankton. Suggest a reason for the fish kill.* **[NCERT]**

(a) *Low BOD* (b) *Low DO*
(c) *Low COD* (d) *None of these*

Interpret (*b*) Large quantities of phosphates and nitrates increases the growth of phytoplankton. These phytoplankton use so much oxygen that it is not enough available for other organisms to use in respiration. Moreover a large population of bacteria decomposes organic matter such as leaves, grass, etc., in water. During this process, they consume the oxygen dissolved in water. Microorganisms may become so abundant that they form a mat covering on the water surface and preventing sunlight from penetrating the surface and thereby preventing photosynthesis. In all these processes concentration of dissolved oxygen in water decreases. When the concentration of dissolved oxygen of water is below 6 ppm, the growth of fish gets inhibited and they cannot survive.

(c) Chemical Pollutants

These include inorganic minerals, heat, chemical compounds, petroleum (oil), pesticides, detergents (surfactants), fertilizers etc. Since, water is an excellent solvent, all these substance dissolve in it and pollute it.

(i) **Fertilizers** They contain phosphates and nitrates. When added to crop fields, a part of these fertilizers is passed down to water bodies by rain water through surface run off. Since, the contaminated water becomes rich in these nutrients, it increases the growth of algae and other aquatic plants, *i.e.,* causes eutrophication which leads to organic loading, lack of dissolved oxygen, death of animals and bad odour of water. The water containing nitrate is unfit for drinking purposes. Moreover, it cannot be purified for drinking. After a long period, these nutrients convert the lakes and slow moving waters in swamps and marshes. Compost should be used instead of fertilizers to control fertilizers pollution.

(ii) **Municipal and industrial waste water** It contains various toxic elements which are very dangerous to humans as our body does not excrete them. If their concentration is quite high, these cause several diseases. Some metals, their sources and harmful effects are tabulated below.

Table 16.1 **Toxic Metals, their Sources and Harmful Effect**

Element	Sources	Harmful effect
Mercury	Pesticides, coal, industrial waste, mining.	(i) Highly toxic in CH_3Hg^- form. (ii) Causes *minamata* (*minimata*) disease which is characterised by diarrhoea, haemolysis, meningitis and death.
Chromium	Metal plating industries.	Carcinogenic, causes gastrointestinal ulcers and nervous system disorder.
Cadmium	Industrial wastes, Ni-Cd batteries.	(i) High blood pressure, kidney malfunctioning, disorder of bone marrow. (ii) *Itai-itai* disease.
Lead	Plumbing, mining, coal gasoline	(i) Anaemia, kidney malfunctioning, nervous disorder. (ii) Interferes with haem synthesis and glucose metabolism.
Zinc	Industrial wastes	Vomiting, cramps, renal damage and toxic to plants.
Arsenic	Chemical wastes, pesticides	Carcinogenic, *i.e.,* cancer producing.
Copper	Industrial waste, leaching process	Not very toxic to animals but toxic to plants and algae.

Caution Point *When polluted water contains acids or alkalies, self purification process is hindered due to the absence of microorganisms because microorganisms are destroyed by acids or alkalies.*

(iii) **Detergents** They contain alkyl benzene sulphonates (ABS), a surfactant (surface active agent) which is non-biodegradable and thus, forms stable foam, stabilise colloidal impurities and create several problems during the treatment of waste water. However, most of the detergents, available now a days, are biodegradable but they can cause other problems. PCBs (polychlorinated biphenyls), a chemical, used as fluids in transformers and capacitors, have been found to be carcinogenic.

(iv) **Oil** It mainly pollutes sea water, when spilled accidently or intentionally into it. Oil may form a thin layer on the surface of water, called oil spill or a thick layer on the surface of sea water, called oil slick. It checks the growth of phytoplanktons and disrupts the entire marine life cycle. The oil film may catch fire and harms to the aquatic life. *Oil pollution greatly affects the flight and swimming capability of sea-birds.*

(v) **Pesticides** When pesticides (such as DDT) is mixed with water, they pollute it and cause several problems such as cerebral haemorrhage, hypertension, softening of brain. However, microorganisms capable of degrading these chlorinated hydrocarbons have been discovered recently. These degrade chlorinated compounds due to secretion of enzyme dehalogenase. Pesticides are generally broad spectrum (used widely) and function as biocides. When persistant pesticides such as DDT passes from lower tropic level to higher one, through food chain, the amount of pesticides per unit weight of organism increase due to their accumulation in fat. This phenomenon is called **biomagnification.**

(vi) **Thermal and Nuclear power plants** The waste water, discharged from **thermal** and **nuclear power plants,** is at a raised temperature which has several adverse effect. The warm water has lower density and viscosity, thus suspended solids settle faster. Moreover, warm water has less DO, lower rate of putrescibility which results in organic loading and replacement of green algae (aerobic) by blue-green algaes (an-aerobic). The rate of evaporation also rises with rise in temperature which results in greater wastage of water in the form of vapours. At high temperature, many animals fail to reproduce, *e.g.,* salmon.

(vii) **Elements** Some elements, when present within prescribed concentration are not harmful but when their concentration exceeds it, these have several adverse effect. Some such elements with their sources, prescribed concentration and adverse effect of higher amount are tabulated below :

Table 16.2 **Prescribed Concentration and Harmful Effects of Different Elements**

Element/ion	Sources	Prescribed concentration		Adverse effect of higher concentration
		by WHO	by EV	
Fluorides (F)	Added externally	1.5 ppm (or 1.5 mg dm^{-3})	1.5 ppm	(i) Converts enamel (hydroxyapatite, $[3Ca_3(PO_4)_2 \cdot Ca(OH)_2]$ to more harder fluorapatile, $[3Ca_3(PO_4)_2 \cdot CaF_2]$. (ii) Concentration (> 2 ppm) causes brown mottling of teeth. (iii) High concentrations (> 10 ppm) are harmful for bones and teeth.
Lead (Pb)	Lead pipes	0.01 ppm	0.01 ppm	Damage kidney, liver and reproductive system.
Sulphate (SO_4^{2-})	Acid rain, industries	500 ppm	250 ppm	Has laxative effect.
Nitrate (NO_3^-)	Fertilizers	50 ppm	50 ppm	Methemoglobinemia (blue baby syndrome).
Other metals :				
(i) Iron (Fe)	—	No guideline	0.2 ppm	
(ii) Manganese (Mn)	—	0.5 ppm	0.05 ppm	
(iii) Copper (Cu)	—	2 ppm	2 ppm	
(iv) Aluminium (Al)	—	0.2 ppm	0.2 ppm	
(v) Zinc (Zn)	—	3 ppm	not given	
(vi) Cadmium (Cd)	—	0.003 ppm	0.005 ppm	
(vii) Sodium (Na)	—	200 ppm	200 ppm	

Sample **Problem 6** *A person was using water supplied by municipality. Due to shortage of water he started using underground water. He felt laxative effect. Its cause is high concentration of* **[NCERT** Exemplar**]**

(*a*) CO_2 (*b*) SO_4^{2-} (*c*) CO_3^{2-} (*d*) S^{2-}

Interpret (*b*) The laxative effect is observed only when the sulphates present in water have concentration greater than 500 ppm. Otherwise at moderate levels it is harmless.

16.7 Soil Pollution

Soil pollution is alteration in soil caused by addition or removal of such substances or factors that deteriorates the quality, texture and mineral content of the soil or that disturbs the biological balance of the organisms in the soil and has a lethal effect on plant growth. The substances or factors are called **soil pollutants.**

Types of Soil Pollution

Soil pollution can be classified into following types

(a) Positive Soil Pollution

Reduction in soil productivity because of the addition of undesirable substances such as fertilizers, pesticides, industrial wastes, air pollutants etc., is termed as positive soil pollution.

(b) Negative Soil Pollution

The reduction in the productivity of soil due to soil erosion and over use is termed as **negative soil pollution.**

(c) Landscape Pollution

If the fertile land gets converted into barren land by dumping wastes such as rubbish, industrial wastes, broken cans, bottles, plastics etc., the pollution is termed as **landscape pollution.**

Sources of Soil Pollution

Major source of soil pollution is indiscriminate use of pesticides and fertilizers. Accumulation of excreta of grazing animals, dumping of urban, industrial and radioactive wastes are some other sources of soil pollution.

(a) Pesticides

The chemical substances, used to control the growth of pests, are called **pesticides**. These are usually insoluble in water and non-biodegradable. However, a few biodegradable pesticides have been synthesised now a days. Being water insoluble, these transfer from lower tropical level to higher one through food chain. Pesticides are basically toxic chemicals but their repeated use make the pest more resistant towards pesticides. These have adverse effect on human health, when reach in the body. Studies have shown that a single pesticide can not elimiate all species of a target pest. Due to this, the number of commercial pesticides is increasing tremendously. Depending upon their target, *i.e.,* insects, weeds, fungi etc. *Pesticides are classified into following classes :*

(i) **Insecticides** are the chemical substances which are used to kill crops destroying insects. A very small amount of such chemicals is toxic to insects. Organochlorine group compounds such as DDT (dichlorodiphenyl trichloro ethane), BHC (benzene hexa chloride), aldrin, dieldrin were widely used as insecticides but because of their high insolubility and persistant nature, their use is being restricted. Now a days, a series of organophosphate and carbamates, which are more biodegradable, are used as insecticides. However, these chemicals are nerve toxic and more harmful to humans.

(ii) **Herbicides** are used to kill weeds. Sodium chlorate ($NaClO_3$) and sodium arsinite (Na_3AsO_3) are used as herbicides. These are also toxic to mammals but are not as persistant as organochlorine compounds. These chemicals take a few months to decompose. Some herbicides cause birth defects. Now a days, organic compounds such as triazines are widely used as herbicides, especially for the corn-fields.

(iii) **Fungicides** are used to stop growth of fungi and to check plant diseases. Fungi, due to the lack of chlorophyll, depend upon other plants for their food and consequently, retard their growth. Organomercury compounds are commonly used as fungicides but their dissociation in soil produces mercury which is highly toxic.

(b) Soil Conditioners

Compounds of some toxic metals such as As, Pb, Hg, Cd etc., called **soil conditioners,** are used for killing the insects and to protect the soil fertility. After the decomposition of these compounds, the obtained metals accumulate in the soil, from where they reach the growing crops and from crops to animals.

Caution Point *Loam soil because of the presence of equal amounts of sand, slit and clay alongwith humus and* 34% *air,* 66%, *water, is best for growing plants.*

(c) Solid Wastes

Solid wastes such as industrial wastes, urban wastes, farm waste, radioactive wastes etc., also cause soil or land pollution.

(d) Soil Salination

Halomorphic soil contains a large concentration of salts. The process by which salt concentration in soil is increased is called **soil salination.** There is a white incrustation over the soil surface after salination, thus soil becomes barren. The sources/processes that lead to soil salination are excessive use of fertilizers, canal water, poor drainage systems, salts blown from rocks/sea, absorption of acidic ions by plants etc. Conductivity meter is used to measure soil salinity.

16.8 Strategies to Control Environmental Pollution

Environmental pollution is mainly controlled either by waste management or by green chemistry.

Waste Management

Management of industrial and household wastes through suitable treatment plays an important role to reduce environmental pollution.

It can be done by the following methods :

(a) Recycling

It is a process in which waste materials can be used as raw materials for manufacturing many useful products again. Therefore, it is the most important technique for waste disposal, *e.g.,* agricultural wastes are used for manufacturing paper, hard board, animal feed etc., used newspapers and magazines for making paper and paper envelopes, organic wastes for making compost or in biogas plants. Plastics and metals are also recycled now.

(b) Digestion

This process involves, the degradation of toxic organic wastes by anaerobic microorganisms, *i.e.,* in the absence of oxygen. In this process, CO_2 and methane are obtained.

$$2(CH_2O) \longrightarrow CO_2 + CH_4$$

Methane is used as fuel.

(c) Incineration

It involves combustion of a substance into its ash at a high temperature ($\approx 1000°C$) and in a plentiful supply of oxygen. Therefore, waste materials can be converted into their ash by incineration and the obtained ash can be used to fill the low lying lands. Exhaust gases must be filtred. It is an important method for the disposal of polychlorinated biphenyls (PCBs) because in presence of high temperature, C—Cl bonds get ruined. The major disadvantage of this process is the production of highly toxic chloro compounds due to incomplete combustion of PCBs.

(d) Dumping

Dumping of sewage sludge into ocean has been widely used in all countries. However, dumping of sludge into land is preferred, now a days. This is because of the presence of compounds of nitrogen and phosphorus in sludge that act as soil fertilizers.

(e) Sewage Treatment

The treatment of sweage involves the following steps

1. Large size materials are filtered off and used to fill low lying land.
2. Then, the residual water is allowed to stand in tanks, by which many solid materials settle down as primary sludge but oil and grease float on the surface from where these are removed.
3. The organic content of residual water are allowed to undergo oxidation by aerobic microorganisms. By this secondary sludge is formed which is mixed with primary sludge and subjected to anaerobic oxidation (by anaerobic microbes).
4. Finally, phosphate is removed from waste water by treating it with lime followed by coagulation, filtration and disinfectant (such as chlorine). The sludge obtained in this process is dried and then may be incinerated, digested or dumped.

Green Chemistry

The concept of green chemistry was introduced in 1990. It is an alternative tool for reducing pollution. Indeed, **green** *chemistry is a branch of chemistry in which chemicals of daily needs are produced by using such reactions or processes that neither use toxic chemicals nor emit such chemicals into the atmosphere*. In this, various reactions are carried out in the presence of mild and environment friendly reagents such as ultraviolet light (photochemistry), sound waves (sonic chemistry), enzymes and microwaves so that harmful chemicals are neither used up nor released.

Applications of Green Chemistry

Some uses of the green chemistry in day to day life are

1. Use of liquefied carbon dioxide with suitable detergents for drycleaning clothes which replaces tetrachloroethene, a pollutant and suspected carcinogen (used earlier for drycleaning).
2. Use of hydrogen peroxide for bleaching clothes, in laundary and paper.
3. Catalytic dehydrogenation of diethanolamine without using formaldehyde and cyanide.
4. Preparation of ethanol from oxidation of ethene in the presence of ionic catalyst.
5. Synthesis of ibuprofen by using smaller quantities of solvents.
6. Replacement of organotins by sea-nine.
7. Replacement of chlorofluorocarbons (CFCs) and used in manufacturing polystyrene foam sheets, by CO_2.

Metathesis is an example that exhibits the importance of application of basic science for human welfare.

Sample **Problem 7** *For which of the following you apply green chemistry?*

I. To control photochemical smog.
II. To avoid use of halogenated solvents in dry cleaning and that. of chlorine in bleaching.
III. To reduce use of synthetic detergents.
IV. To reduce the consumption of petrol and diesel.

The correct choice is/are **[NCERT Exemplar]**

(a) *I and II only*
(b) *II and III only*
(c) *I and III only*
(d) *I, II, III and IV*

Interpret (*d*)

I. Certain plants, e.g., *Pinus*, *Janiparus*, *Quercus*, *Pyrus* and *Vitis* can metabolize nitrogen oxide (NO) and therefore, their plantation could help in reducing photochemical smog.
II. Liquefied CO_2 with a suitable detergent is used for dry cleaning and H_2O_2 (hydrogen peroxide) is used for the purpose of bleaching clothes in the process of laundry which gives better results and makes use of lesser amount of water.
III. Soaps are 100% biodegradable so they should be used in place of detergents. Now a day biodegradable detergents are available. Therefore, they should be used in place of non-biodegradable hard detergents.
IV. CNG (compressed natural gas), should be used as it causes much less pollution. Moreover, electrical vehicles should be used to reduce the consumption of petrol and diesel.

WORKED **OUT**
Examples

Example 1 *Ozone is formed in the upper atmosphere from oxygen by the action of*

(*a*) *thermal radiation from sunlight*
(*b*) *cosmic rays*
(*c*) *ultraviolet rays*
(*d*) *infrared rays*

Solution (*c*) Ozone is formed when UV light strikes oxygen molecules and splits it into individual oxygen atom (O) which combine with undissociated oxyen.

$$O_2(g) \xrightarrow{\text{UV light}} 2O(g)$$

$$O(g) + O_2(g) \overset{\text{UV light}}{\rightleftharpoons} O_3(g)$$

Example 2 SO_2 *and* NO_2 *cause pollution by increasing*

(*a*) *alkalinity* (*b*) *neutrality*
(*c*) *acidity* (*d*) *buffer action*

Solution (*c*) SO_2 and NO_2 when dissolve in water, form H_2SO_4 and HNO_3, (strong acids) respectively.

$$4NO_2 + 2H_2O + O_2 \longrightarrow 4HNO_3$$

$$2SO_2 + O_2 \xrightarrow{\text{Particulate}} 2SO_3$$

$$SO_3 + H_2O \longrightarrow H_2SO_4$$

Thus, they cause the pollution by increasing acidity.

Example 3 *In acid rain, the acid present in highest concentration is*

(*a*) *nitric acid* (*b*) *hydrochloric acid*
(*c*) *sulphuric acid* (*d*) *carbonic acid*

Solution (*c*) In acid rain, the percentage of various acids is as

$$H_2SO_4 > HNO_3 > HCl$$

Example 4 *Which of the following statements is not true?*

(*a*) *London smog is a mixture of smoke and fog*
(*b*) *London smog is oxidising in nature*
(*c*) *Photochemical smog causes irritation in eyes*
(*d*) *Photochemical smog results in the formation of PAN*

Solution (*b*) Smogs either London or photochemical, are the mixture of smoke and fog. London smog is formed in cool humid climate when carbon soot particles combine with gaseous oxides of sulphur. Since in this type of smog, C particles and SO_2 are present, it is reducing in nature. Photochemical smog, on the other hand, occurs in warm, dry and sunny climate. It results in the formation of PAN. Since in photochemical smog, O_3 is present, it irritates the eyes, nose, lungs etc.

Example 5 *Which causes water pollution?*

(*a*) *Smoke-flyash* (*b*) 2,4-*D*
(*c*) *Automobile exhaust* (*d*) *Cars*

Solution (*b*) Pathogenes, organic wastes and chemical pollutants are the sources of water pollution. Hence, 2, 4-D being a chemical pollutant, causes water pollution.

Example 6 *Which one of the following is considered as point source for water pollution?*

(*a*) *Factories* (*b*) *Construction site*
(*c*) *Acid rain* (*d*) *Field lawns*

Solution (*a*) Point source means the sources that can be easily identified. Among the given, factories can be considered as point source for water pollution.

Example 7 *Match Column* I *with Column* II *and select the correct answer using the codes given below.*

Column I (Pollutant)	Column II (Source)
A. Microorganisms	*1. Chemical fertilizers*
B. Plant nutrients	*2. Abandoned coal mines*
C. Sediments	*3. Domestic sewage*
D. Mineral acids	*4. Erosion of soil by strip mining*
	5. Detergents

Codes

	A	B	C	D
(*a*)	2	5	3	1
(*b*)	3	1	4	2
(*c*)	4	2	5	1
(*d*)	1	3	2	4

Solution (*b*) Microorganisms are present in domestic sewage. Chemical fertilizers are also known as plant nutrients. Sediments are obtained by the erosion of soil by strip mining and abandoned coal mines are the source of mineral acids. Thus, the correct match is

A-3, *B*-1, *C*-4, *D*-2.

Start Practice for JEE Main

Round I (Topically Divided Problems)

Components of Environment and General Terms Related to Pollution

1. Which of the following is a living component of atmosphere?

(a) Lithosphere (b) Biosphere
(c) Hydrosphere (d) Troposphere

2. Atmospheric content of CO_2 is

(a) 0.0034% (b) 0.034%
(c) 0.34% (d) 3.4%

3. The gaseous envelope around the earth is known as atmosphere. The lowest layer of this is extended upto 10 km from sea level, this layer is **[NCERT Exemplar]**

(a) stratosphere (b) troposphere
(c) mesosphere (d) hydrosphere

4. Ozone layer is present in

(a) troposphere (b) stratosphere
(c) mesosphere (d) exosphere

5. Region/regions of the atmosphere where temperature decreases with altitude is/are

(a) thermosphere (b) stratosphere
(c) troposphere (d) ozonosphere

6. Which of the following region is the coldest?

(a) Stratosphere (b) Troposphere
(c) Mesosphere (d) Thermosphere

7. The elements present in the core of earth are collectively known as

(a) lithophiles (b) nucleophiles
(c) chaleophiles (d) siderophiles

8. Dinitrogen and dioxygen are main constituents of air but these do not react with each other to form oxides of nitrogen because **[NCERT Exemplar]**

(a) the reaction is endothermic and requires very high temperature
(b) the reaction can be initiated only in the presence of a catalyst
(c) oxides of nitrogen are unstable
(d) N_2 and O_2 are unreactive

9. Pollution is

(a) removal of top soil
(b) release of toxic/undesirable materials in environment
(c) conservation of energy
(d) All of the above

10. Which of the following is a primary pollutant?

(a) CO (b) PAN (c) Aldehydes (d) H_2SO_4

11. The pollutants which come directly in the air from sources are called primary pollutants. Primary pollutants are sometimes converted into secondary pollutants. Which of the following belongs to secondary air pollutants? **[NCERT Exemplar]**

(a) CO
(b) Hydrocarbon
(c) Peroxyacetyl nitrate (PAN)
(d) NO

12. Which of the following is a biodegradable pollutant?

(a) Plastic (b) Sewage
(c) Asbestos (d) Mercury

Gaseous Air Pollution

13. Oxides of sulphur and nitrogen are important pollutants of

(a) water (b) air
(c) soil (d) All of these

14. Gas released during Bhopal gas tragedy was

(a) methyl isocyanate
(b) potassium isothiocyanate
(c) sodium isothiocyanate
(d) ethyl isothiocyanate

15. Which among the given is not a natural source of air pollution?
(a) Automobile exhausts
(b) Vegetation decay
(c) Forest fire
(d) Volcanic eruptions

16. Carbon monoxide, emitted by automobiles, prevents transport of oxygen in the body due to
(a) combining with oxygen to form carbon dioxide
(b) destruction of haemoglobin
(c) preventing reaction between oxygen and haemoglobin
(d) forming stable compound with haemoglobin

17. Taj Mahal is threatened by pollution from
(a) chlorine (b) sulphur dioxide
(c) hydrogen (d) oxygen

18. Most hazardous metal pollutant of automobile exhaust is
(a) mercury (b) lead
(c) cadmium (d) copper

19. Which of the following gases is not a green house gas? **[NCERT Exemplar]**
(a) CO (b) O_3
(c) CH_4 (d) H_2O vapour

20. Acid rains are produced by
(a) excess NO_2 and SO_2 from burning fossil fuels
(b) excess production of NH_3 by industry and coal gas
(c) excess release of carbon monoxide by incomplete combustion
(d) excess formation of CO_2 by combustion and animal respiration

Particulate Pollution

21. Which of the following is a viable particulate?
(a) Algae (b) Smoke
(c) Mist (d) Fumes

22. Pneumoconiosis is caused by inhalation of
(a) coal dust (b) silica dust
(c) cotton fibre dust (d) asbestos dust

23. White lung cancer is caused by
(a) asbestos (b) silica
(c) paper (d) textiles

24. Oxidation of sulphur dioxide into sulphur trioxide in the absence of a catalyst is a slow process but this oxidation occurs easily in the atmosphere. Which substance here catalyse the reaction? **[NCERT Exemplar]**
(a) Oxygen
(b) Particulate
(c) UV rays
(d) IR rays

25. Photochemical smog always contains
(a) O_3 (b) CO
(c) CO_2 (d) CH_4

26. Which of the following statements is not true about classical smog? **[NCERT Exemplar]**
(a) Its main components are produced by the action of sunlight on emissions of automobiles and factories
(b) Produced in cold and humid climate
(c) It contains compounds of reducing nature
(d) It contains smoke, fog and sulphur dioxide

27. Which of the following statements about photochemical smog is wrong? **[NCERT Exemplar]**
(a) It has high concentration of oxidising agents
(b) It has low concentration of oxidising agents
(c) It can be controlled by controlling the release of NO_2, hydrocarbons, ozone etc
(d) Plantation of some plants like pinus helps in controlling photochemical smog

28. PAN stands for
(a) CH_2O (b) $CH_2{=}CH{-}CHO$
(c) $CH_3CH_2O{-}N{=}O$ (d) $CH_3{-}\underset{\underset{O}{\|}}{C}{-}OONO_2$

Stratospheric Pollution

29. Which of the following statements is correct? **[NCERT Exemplar]**
(a) Ozone hole is a hole formed in stratosphere from which ozone oozes out
(b) Ozone hole is a hole formed in the troposphere from which ozone oozes out
(c) Ozone hole is thinning of ozone layer of stratosphere at some places
(d) Ozone hole means vanishing of ozone layer around the earth completely

30. Which of the following statements is wrong? **[NCERT Exemplar]**
(a) Ozone is not responsible for green house effect
(b) Ozone can oxidise sulphur dioxide present in the atmosphere to sulphur trioxide
(c) Ozone hole is thinning of ozone layer present in stratosphere
(d) Ozone is produced in upper stratosphere by the action of UV rays on oxygen

31. Ozone layer of stratosphere requires protection from indiscriminate use of
(a) pesticides
(b) atomic explosions
(c) aerosols and high flying jets
(d) balloons

32. Which of the following is responsible for peeling of ozone umbrella?

(a) PAN (b) Coal burning
(c) CFCs (d) CO_2

33. Chlorofluorocarbons (CFCs) are widely used in air conditioners, refrigerators etc., because of being

(a) highly reactive (b) flammable
(c) non-reactive (d) All of these

34. Result of ozone hole is

(a) green house effect (b) global warming
(c) acid rain (d) UV rays reach the earth

35. Ozone is an important constituent of stratosphere because it

(a) prevents the formation of smog over large cities
(b) removes poisonous gases of the atmosphere by reacting with them
(c) absorbs ultraviolet radiations which is harmful to human life
(d) destroys bacteria which are harmful to human life

36. Ozone hole is maximum over

(a) Europe (b) Antarctica
(c) India (d) Africa

37. Which of the following acts as a sink for chlorine free radicals?

(a) Nitrogen dioxide (b) Methane
(c) Carbon dioxide (d) Both (a) and (b)

38. Some time ago formation of polar stratospheric clouds was reported over Antarctica. What happens when such clouds break up by warmth of sunlight? **[NCERT Exemplar]**

(a) Ozone layer depletion stops
(b) Ozone layer depletion starts
(c) HOCl and Cl_2 are obtained
(d) Both (a) and (c)

Water and Soil Pollution

39. Which of the following statements is false?

(a) The main reason for river water pollution is industrial and domestic sewage discharge
(b) Surface water contains a lot of organic matter, mineral nutrients and radioactive materials
(c) Oil spill in sea water causes heavy damage to fishery
(d) Oil slick in a sea water increases DO value

40. Biochemical Oxygen Demand, (BOD) is a measure of organic material present in water. BOD value less than 5 ppm indicates a water sample to be **[NCERT Exemplar]**

(a) rich in dissolved oxygen
(b) poor in dissolved oxygen
(c) highly polluted
(d) not suitable for aquatic life

41. What does BOD_5 represent?

(a) Biological ozone depletion in five days
(b) Dissolved oxygen left after five days
(c) Dissolved oxygen consumed in five days
(d) Microorganisms killed by ozone in sewage treatment plants in five hours

42. Drawback of DDT as pesticides is that

(a) it is less effective than others
(b) it becomes ineffective after some time
(c) it is a non-degradable substance
(d) it is very costly

43. The sources of dissolved oxygen in water **[NCERT Exemplar]**

(a) photosynthesis
(b) natural aeration
(c) mechanical aeration
(d) All of the above

44. Phosphate pollution is caused by

(a) weathering of phosphate rocks only
(b) agricultural fertilizers only
(c) phosphate rocks and sewage
(d) sewage and agricultural fertilizers

45. Sewage containing organic waste should not be disposed in water bodies because it causes major water pollution. Fishes in such a polluted water die because of **[NCERT Exemplar]**

(a) large number of mosquitoes
(b) increase in the amount of dissolved oxygen
(c) decrease in the amount of dissolved oxygen in water
(d) clogging of gills by mud

46. Negative soil pollution is

(a) reduction in soil productivity due to erosion and over use
(b) reduction in soil productivity due to addition of pesticides and industrial wastes
(c) converting fertile land into barren land by dumping ash, sludge and garbage
(d) None of the above

Strategies to Control Pollution and Green Chemistry

47. Modes of controlling pollution in large cities include

(a) less use of insecticides
(b) proper disposal of organic wastes, sewage and industrial effluents
(c) shifting of factories out of the residential area
(d) All of the above

48. Which one of the following is not an application of green chemistry?
- (a) Replacement of CFCs by CO_2 as blowing agent in the manufacture of polystyrene foam sheets
- (b) Reacting methylamine and phosgene to produce methyl isocyanate
- (c) Replacement of organotins by 'sea-nine' as anti fouling compound in sea marines
- (d) Catalytic dehydrogenation of the diethanol amine without using cyanide and formaldehyde

49. Proper management of disposal of household and industrial wastes can be done by
- (a) recycling the waste material to give useful products again
- (b) burning and incineration of combustible waste
- (c) sewage treatment
- (d) All of the above

50. Green chemistry involves
- (a) production of chemicals of our daily use from green house gases
- (b) such chemical processes in which green plants are used
- (c) those reactions which are of biological origin
- (d) use of non-toxic reagents and solvents to produce environment friendly products

Round II (Mixed Bag)

Only One Correct Option

1. Temperature of troposphere decreases with altitude. This is because of
- (a) high pressure of air
- (b) gases present in air
- (c) lower density of air
- (d) All of these

2. The greatest affinity for haemoglobin is shown by
- (a) NO
- (b) CO
- (c) O_2
- (d) CO_2

3. Which of the following is not regarded as a pollutant?
- (a) NO_2
- (b) CO_2
- (c) O_3
- (d) Hydrocarbons

4. Match the Column I and II and pick the correct matching from the codes given below.

Column I	Column II
(A) Polycyclic aromatic hydrocarbons	1. Global warming
(B) Dioxins	2. Photochemical smog
(C) IR active molecules	3. Carcinogens
(D) Peroxy acetyl nitrate	4. Waste incineration

Codes

	A	B	C	D
(a)	3	4	1	2
(b)	4	3	2	1
(c)	3	4	2	1
(d)	1	2	3	4

5. Ultraviolet light causes
- (a) formation of pyrimidines
- (b) sticky metaphases
- (c) photodynamic action
- (d) destruction of hydrogen bonds between complementary DNA strands

6. Cyclone collector is used for minimising
- (a) radioactive pollution
- (b) air pollution
- (c) noise pollution
- (d) water pollution

7. Which of the following statements is not true?
- (a) Ammonia acts as sink for NO_x
- (b) Limestone acts as sink for SO_x
- (c) The average residence time of NO is one month
- (d) SO_x can be removed from flue gases by passing through a solution of citrate ions

8. Among the following statements which one is incorrect?
- (a) Suspended particulate matter (SPM) is an important pollutant released by diesel vehicles
- (b) Soot particles (size $< 5\ \mu$) cause fibrosis of the lung lining
- (c) H_2SO_4 particulates have size of 500-1000 nm
- (d) Photochemical smog is formed by oxides of sulphur, smoke and dust particles

9. Pick up the correct statement.
- (a) CO plays a major role in photochemical smog
- (b) London smog has an oxidising character whereas Los Angeles smog is reducing in nature
- (c) Classical smog is good for health but photochemical somg not
- (d) Los Angeles smog forms in day time whereas London smog forms in early morning hours

10. Which of the following statements about control of particulate pollution is false?
- (a) Gravity settling chamber removes larger particles from the air
- (b) Cyclone collector removes fine particles in the diameter range 5-20 microns

(c) Wet scrubbers are used to wash away all types of particulates

(d) In electrostatic precipitator, the particulates are made to acquire positive charge which are then attracted by the negative electrode and removed

11. Which of the following statements about polar stratospheric clouds (PSCs) is not correct?

(a) Type I clouds are formed at about −77°C and contain solid $HNO_3 \cdot 3H_2O$

(b) Type II clouds are formed at about −85°C and contains some ice

(c) A tight whirlpool of wind called polar vortex is formed which surrounds Antarctica

(d) PSCs do not react with chlorine nitrate and HCl

12. As it passes into food chain, the concentration of DDT

(a) remains same
(b) decreases
(c) increases
(d) unpredictable

13. For dry cleaning, in the place of tetrachloroethane, liquefied carbon dioxide with suitable detergent is an alternative solvent. What type of harm to the environment will be prevented by stopping use of tetrachloroethane? **[NCERT Exemplar]**

(a) It results in tropospheric pollution

(b) It causes depletion of ozone layer

(c) It causes particulate pollution

(d) Both (a) and (b)

14. Match the activity given in Column I with the type of pollution created by it given in Column II.

	Column I (Activity)		Column II (Effect)
A.	Releasing gases to the atmosphere after burning waste material containing sulphur.	1.	Water pollution
B.	Using carbamates as pesticides.	2.	Photochemical smog, damage to plant life, corrosion to building material, induce breathing problems, water pollution
C.	Using synthetic detergents for washing clothes	3.	Damaging ozone layer
D.	Releasing gases produced by automobiles and factories in the atmosphere.	4.	May cause nerve diseases in human.
E.	Using chlorofluorocarbon compounds for cleaning computer parts.	5.	Classical smog, acid rain, water pollution, induce breathing problems, damage to buildings, corrosion of metals.

[NCERT Exemplar]

Codes

	A	B	C	D	E
(a)	5	4	3	2	1
(b)	5	4	2	1	3
(c)	5	4	1	2	3
(d)	4	5	2	3	1

15. Select the incorrect statement.

(a) Water is considered pure if it has BOD less than 5 ppm

(b) In COD determination, the pollutants resistant to microbial oxidation are not oxidised by oxidising agent like $K_2Cr_2O_7$

(c) The lower the concentration of DO, the more polluted is the water sample

(d) The tolerable limit of lead in drinking water is 50 ppm

16. Which of the following practices will not come under green chemistry? **[NCERT Exemplar]**

(a) If possible, making use of soap made of vegetable oils instead of using synthetic detergents

(b) Using H_2O_2 for bleaching purpose instead of using chlorine based bleaching agents

(c) Using bicycle for travelling small distances instead of using petrol/diesel based vehicles

(d) Using plastic cans for neatly storing substances

More than One Correct Option

17. Non-degradable solid pollutants are

(a) domestic waste

(b) DDT

(c) plastics

(d) cow dung

18. The acids present in acid rain are … . **[NCERT Exemplar]**

(a) peroxyacetylnitrate
(b) H_2CO_3
(c) HNO_3
(d) H_2SO_4

19. The consequences of global warming may be … **[NCERT Exemplar]**

(a) increase in average temperature of the earth

(b) melting of Himalayan Glaciers

(c) increased biochemical oxygen demand

(d) eutrophication

20. Which of the following conditions shows the polluted environment? **[NCERT Exemplar]**

(a) pH of rain water is 5.6

(b) Amount of carbondioxide in the atmosphere is 0.03%

(c) Biochemical oxygen demand 10 ppm

(d) Eutrophication

21. Phosphate containing fertilisers cause water pollution. Addition of such compounds in water bodies causes …… **[NCERT Exemplar]**

(a) enhanced growth of algae
(b) decrease in amount of dissolved oxygen in water
(c) deposition of calcium phosphate
(d) increase in fish population

Assertion and Reason

Directions (Q. Nos. 22 to 27) *Each of these questions contains two statements : Statement* I (*Assertion*) *and Statement* II (*Reason*). *Each of these questions also has four alternative choices, only one of which is the correct answer. You have to select one of the codes* (*a*), (*b*), (*c*), (*d*) *given below :*

(a) Statement I is true, Statement II is true; Statement II is a correct explanation for Statement I.
(b) Statement I is true, Statement II is true; Statement II is not a correct explanation for Statement I.
(c) Statement I is true; Statement II is false.
(d) Statement I is false; Statement II is true.

22. **Statement I** Green house effect was observed in houses used to grow plants and these are made of green glass.

Statement II Green house name has been given because glass houses are made of green glass. **[NCERT Exemplar]**

23. **Statement I** Presently, the global atmosphere is warming up.

Statement II The depletion of stratospheric ozone layer has resulted in increase in ultraviolet radiations reaching the earth.

24. **Statement I** The pH of acid rain is less than 5.6.

Statement II Carbon dioxide present in the atmosphere dissolves in rain water and forms carbonic acid. **[NCERT Exemplar]**

25. **Statement I** Photochemical smog is oxidising in nature.

Statement II Photochemical smog contains NO_2 and O_3, which are formed during the sequence of reactions. **[NCERT Exemplar]**

26. **Statement I** Excessive use of chlorinated synthetic pesticides causes soil and water pollution.

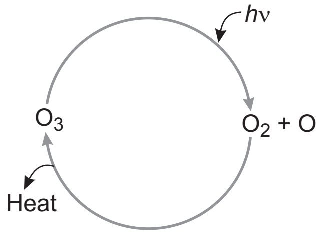
Statement II Such pesticides are non-biodegradable. **[NCERT Exemplar]**

27. **Statement I** If BOD level of water in a reservoir is less than 5 ppm it is highly polluted.

Statement II High biological oxygen demand means low activity of bacteria in water. **[NCERT Exemplar]**

Comprehension Based Questions

Directions (Q. Nos. 28 to 30) When healthy, earth's stratosphere contains a low concentration of ozone (O_3) that absorbs potentially harmful ultraviolet (UV) radiations by the cycle shown :



Chlorofluoro carbon refrigerants, such as freon-12 (CF_2Cl_2), are stable in lower atmosphere, but in the stratosphere, they absorb high energy UV radiation to generate chlorine radicals.

$$CF_2Cl_2 \longrightarrow \dot{C}F_2Cl + \dot{C}l$$

The presence of small number of chlorine radicals appears to lower ozone concentrations dramatically. The following reactions are all known to be exothermic (except the one requiring light) and to have high rate constants.

A. $Cl—O—O—Cl \xrightarrow{h\nu} O_2 + 2Cl^{\bullet}$
B. $Cl—O^{\bullet} + O \longrightarrow O_2 + Cl^{\bullet}$
C. $Cl^{\bullet} + O_3 \longrightarrow Cl—O^{\bullet} + O_2$
D. $2\ Cl—O^{\bullet} \longrightarrow Cl—O—O—Cl$

28. Which of the following reactions is harmful to ozone layer?
(a) A (b) B (c) C (d) D

29. Ozone has the ability to absorb
(a) UV radiations (b) electromagnetic radiations
(c) CFC (d) green house gases

30. Increased UV radiations due to hole in ozone layer
(a) will cause increase in cases of skin diseases
(b) will cause more ice to melt
(c) will cause summer to be more warmer
(d) will cause more rain

Direction (Q. Nos. 31 to 33) Water is one of the most common substances on earth.It covers 72% of the earth's surface. Water is essential for life and its pollution can cause serious problems. The effect of water problems on health can be anything from an upset stomach to severe illness leading to death. Eutrophication is another source of water pollution. It is the process that results when large quantities of phosphates and nitrates are released into aquatic ecosystem. High concentration of phosphates and nitrates causes rapid growth in the populations of bacteria and algae. These microorganisms use so much oxygen that there is not enough oxygen, available for other organisms to use in respiration.

31. Which of the following does not cause water pollution?
(a) Heavy metals such as Cd, Pb, Hg
(b) Detergents
(c) Polychlorobiphenyls
(d) Freons

32. Eutrophication of a lake means, it
(a) is low in nutrients
(b) is high in nutrients
(c) has excess amount of organic matter
(d) has a high temperature

33. Fish die in water bodies polluted by sewage due to
(a) pathogens (b) reduction in oxygen
(c) foul smell (d) None of these

Previous Years' Questions

34. Identify the incorrect statement from the following. [AIEEE 2011]
(a) Oxide of nitrogen in the atmosphere can cause the depletion of ozone layer
(b) Ozone absorbs the intense ultraviolet radiations of the sun
(c) Depletion of ozone layer is because of its chemical reaction with chlorofluoro alkanes
(d) Ozone absorbs infrared radiations

35. Identify the wrong statements in the following. [AIEEE 2008]
(a) Chlorofluoro carbons are responsible for ozone layer depletion
(b) Green house effect is responsible for global warming
(c) Ozone layer does not permit infrared radiation from the sun to reach the earth
(d) Acid rain is mostly because of oxides of nitrogen and sulphur

36. The smog is essentially caused by the presence of [AIEEE 2007]
(a) O_2 and O_3
(b) O_2 and N_2
(c) oxides of sulphur and nitrogen
(d) O_3 and N_2

37. When rain is accompanied by a thunderstorm, the collected rain water will have a pH value [AIEEE 2003]
(a) slightly lower than that of rain water without thunderstorm
(b) slightly higher than that when the thunderstorm is not there
(c) uninfluenced by occurrence of thunderstorm
(d) which depends on the amount of dust in air

the Guidance

Round I

1. Biosphere is a living component of atmosphere.

3. The gaseous envelope around the earth is known as atmosphere. The lowest layer of this which is extended upto 10 km from sea level, is called troposphere.

4. In stratosphere at about 20 to 40 km, there is a part of relatively high ozone concentration, called the ozone layer.

6. Mesosphere is the coldest region having −100°C temperature.

7. The elements present in the earth's core are collectively called siderophiles. These are found in their native state. These elements generally have low reactivity and exhibit an affinity to form metallic bond, *e.g.,* Pt, Pu, Ru, Pd, Ir, Os etc.

8. Dinitrogen (N_2) and dioxygen (O_2) are main constituents of air but these do not react with each other to form oxides of nitrogen because the reaction of dinitrogen with dioxygen is endothermic and requires very high temperature while in this reaction air does not provide such a high temperature.

11. The pollutants which come directly in the air from sources are known as primary pollutants. SO_2, CO and nitrogen oxide (NO_x) are the example of primary pollutants.

Primary pollutants are sometimes converted into secondary pollutants. Ozone (O_3) and peroxyacetyl nitrate (PAN) belong to the secondary air pollutants.

12. Sewage is a biodegradable pollutant because it is easily decompose by microorganism.

14. Methyl isocyanate (MIC) gas was released during Bhopal gas tragedy.

16. Carbon monoxide is highly toxic to living being because it has an ability to form more stable carboxyhaemoglobin complex with haemoglobin due to which the delivery of oxygen to the organs and tissues is blocked.

19. CO gas is not a green house gas. CH_4, CO_2, N_2O, O_3 and H_2O vapour gases are the green house gases.

22. Pneumoconiosis is caused by inhalation of coal dust.

24. The presence of particulate matter in polluted air catalyses the oxidation of SO_2 to SO_3.

$$2SO_2 + O_2 \xrightarrow{\text{Particulates}} 2SO_3$$

26. Classical smog contains smoke, fog, sulphur dioxide (SO_2). and compounds of reducing nature. It is produced in cold and humid climate. But its main components are not produced by the action of sunlight on emissions of automobiles and factories.

27. Photochemical smog has high concentration of oxidising agents and it can be controlled by controlling the release of NO_2, hydrocarbons, ozone (O_3) etc. Plantation of some plants like pinus helps in controlling photochemical smog..

30. Ozone is responsible for green house effect.

31. Aerosols and high flying jets release nitric oxide into the upper atmosphere which leads to the destruction of ozone layer.

33. Chlorofluorocarbons *i.e.,* freons are non-reactive, non-inflammable, non-toxic organic molecules, that's why these are widely used in air conditioners, refrigerators etc.

36. Ozone hole is maximum over Antarctica.

37. Nitrogen dioxide and methane which act as sink for chlorine free radicals and prevent much ozone depletion.

38. In summer season, nitrogen dioxide and methane react with chlorine monoxide and chlorine atoms forming chlorine sinks, preventing much ozone depletion, whereas in winter, special type of clouds called polar stratospheric clouds are formed over Antarctica. These polar stratospheric clouds provide surface on which chlorine nitrate gets hydrolysed to form hypochlorous acid. It also reacts with hydrogen chloride to give molecular chlorine.

$$Cl\dot{O}(g) + NO_2(g) \longrightarrow ClONO_2(g)$$
$$\dot{Cl}(g) + CH_4(g) \longrightarrow \dot{C}H_3(g) + HCl(g)$$
$$ClONO_2(g) + H_2O(g) \longrightarrow HOCl(g) + HNO_3(g)$$
$$ClONO_2(g) + HCl(g) \longrightarrow Cl_2(g) + HNO_3(g)$$

When sunlight returns to the Antarctica in the spring, the sun's warmth breaks up the clouds and HOCl and Cl_2 are photolysed by sunlight.

$$HOCl(g) \xrightarrow{h\nu} \dot{O}H(g) + \dot{Cl}(g)$$

$$Cl_2(g) \xrightarrow{h\nu} 2\,\dot{Cl}(g)$$

The chlorine radicals thus formed, initiate the chain reaction for ozone depletion.

39. Oil slick causes water pollution, thus it decreases DO value (dissolved oxygen value) of sea water.

40. Biochemical oxygen demand (BOD) is a measure of organic material present in water. BOD value less than 5 ppm indicates a water sample to be rich in dissolved oxygen. For fresh water, the value of BOD is less than 5 ppm while for polluted water the value of BOD is 17 ppm or more than 17 ppm.

41. BOD_5 means dissolved oxygen consumed in five days.

43. Sources of dissolved oxygen in water are (i) photosynthesis (ii) natural aeration and (iii) mechanical aeration.

45. Sewage containing organic waste should not be disposed in water bodies because it causes major water pollution. So, fishes in such a polluted water die because it decrease in the amount of dissolved oxygen in water.

Round II

1. In troposphere, as we move towards the altitude, the density and pressure of air decreases. Due to which temperature also decreases.

2. Nitrous oxide (NO) has the highest affinity towards haemoglobin. However, due to its larger size, it cannot be inhaled.

3. Carbon dioxide, being limiting factor, when present in small amount (*i.e.,* 0.033%), has no adverse effect but when its concentration is slightly higher than 0.033%, it has an adverse effect on our climate. Thus, in normal conditions, CO_2 is not regarded as a pollutant.

4. Polycyclic aromatic hydrocarbons are carcinogens, *i.e.,* cancer producing dioxins are waste incineration, IR active molecules such as CO_2 are related with global warming. PAN (peroxy acetyl nitrate) forms photochemical smog.

5. The hydrogen bonds present between complementary strands of DNA are destructed by UV light.

6. Cyclone collector is used to remove particulate particles, thus it minimises air pollution.

7. The average residence time of NO is 4 days.

8. When climate is warm, dry and sunny, the oxides of nitrogen and unsaturated hydrocarbons are converted in the components such as PAN, formaldehyde which form photochemical smog, by the action of sunlight.

9. Classical or London type smog is formed by the combination of soot particles with oxides of sulphur while climate is cool and humid. Due to presence of soot and oxides of sulphur, it is reducing in nature.

Photochemical smog or Los Angeles smog is obtained from nitrogen oxides when climate is warm, dry and sunny. Due to the presence of O_3 and NO_2 (strong oxidising agents), it is oxidising in nature.

CO does not play any role in the formation of photochemical smog.

10. In electrostatic precipitator, the electrode plate is positively charged. Thus, the particulates acquire negative charge and are attracted by the negative electrode plate.

11. PSCs (polar stratospheric clouds) of type II provide a surface for the conversion of chlorine nitrate ($ClONO_2$) and HCl into HOCl and Cl_2.

$$ClONO_2 + H_2O \xrightarrow{PSCs} HOCl + HNO_3$$
$$ClONO_2 + HCl \longrightarrow Cl_2 + HNO_3$$

12. When a pesticide such as DDT passes from lower tropic level to higher level, through food chain, the amount of pesticide per unit weight of organism increases due to accumulation in fat. This process is called biomagnification.

13. Tetrachloroethane, $Cl_2C{=}CCl_2$ is suspected to be carcinogenic and also contaminates the ground water. This harmful effect will be prevented by using liquefied CO_2 along with suitable detergent.

Note Use of liquefied CO_2 along with detergent will not be completely safe because most of the detergents are non-biodegradable and they cause water pollution. Moreover, liquefied CO_2 will ultimately enter into the atmosphere and contribute to the green house effect.

14. Sulphur dioxide is a component of classical smog, acid rain, water pollution etc., and obtained by burning S.

Carbamates causes nerve diseases in human.

Synthetic detergents cause water pollution. Gases releasing from automobiles and factories contains oxides of N which is a part of photochemical smog.

CFCs are responsible for damaging ozone layer.

15. In COD determination, the pollutants, which are resistant to microbial oxidation, are also oxidised by strong oxidising agents such as $K_2Cr_2O_7$.

16. Using plastic cans for neatly storing substances will not come under green chemistry.

17. Non-degradable solid pollutants are those which do not degrade, *e.g.,* DDT, plastic etc.

18. The acids present in acid rain are H_2CO_3, HNO_3 and H_2SO_4 as the CO_2, SO_2 and NO_2 gases present in the atmosphere dissolve in water to give these acids.

19. The consequences of global warming may be increase in average temperature of the earth and melting of Himalayan Glaciers.

BOD and eutrophication are the result of water pollution.

20. 10 ppm value of biochemical oxygen demand (BOD) and eutrophication show that the environment is polluted.

21. Phosphate containing fertilizers cause water pollution. Addition of such compounds in water bodies causes enhanced growth of algae and hence, results in decreased amount of dissolved oxygen in water. Due to lack of dissolved oxygen, fish population greatly reduces.

22. Green house effect was observed in houses used to grow plants in colder regions. Since the houses were made up of green glasses, these are called green houses.

Note Similar phenomenon is also seen in our environment which keep our earth warm and make life possible on it. This effect is called green house effect.

23. Presently, the global atmosphere is warming up, because the concentration of green house gases increases constantly.

Ozone layer is non-permeable for UV rays, so its depletion resulted in increase in UV radiation reaching the earth.

24. Generally the pH of rain water is 5.6 because of the dissolution of CO_2 from the atmosphere into rain water.

When some other gases, like SO_2, NO_2 etc., also dissolve, the pH goes below 5.6 due to the presence of strong acids like H_2SO_4, HNO_3, etc. This rain now referred as acid rain.

25. Because of the presence of oxidising substance like NO_2, O_3, etc., photochemical smog is oxidising in nature.

26. Pesticides being non-biodegradable result in soil as well as water pollution.

27. If BOD is less than 5 ppm, the water is considered as clear.

High BOD represent less activity of bacteria.

28. Reaction of $ClO^{\bullet}$ with atomic O generates more $Cl^{\bullet}$. These $Cl^{\bullet}$ can continue to destroy ozone by the following reaction.

$$Cl^{\bullet} + O_3 \longrightarrow ClO^{\bullet} + O_2$$

It has been calculated that one molecule of CFC can destroy more than thousand of O_3.

29. Ozone has the ability to absorb harmful UV radiations.

30. UV radiations posses high energy and are harmful to men's life, cause skin cancer.

31. Freons do not cause water pollution.

32. Eutrophication means high concentration of phosphate and nitrates from fertilizer and detergents in aquatic ecosystem.

33. Fish die in water bodies polluted by sewage because of the decrease in the dissolved oxygen in water.

34. $NO + O_3 \longrightarrow NO_2 + O_2$

$O_3 + h\nu \longrightarrow O_2 + O$

$NO_2 + O \longrightarrow NO + O_2$

Net reaction : $2O_3 + h\nu \longrightarrow 3O_2$

Thus, ozone layer is depleted by oxides of nitrogen.

Thus, (a) is corrrect statement.

(b) Ozone layer is a protective layer and absorbs harmful UV rays from the sun.

Thus, (b) is also correct statement.

(c)
$$Cl + O_3 \longrightarrow Cl\dot{O} + O_2$$
$$O_3 + h\nu \longrightarrow \dot{O} + O_2$$
$$Cl\dot{O} + \dot{O} \longrightarrow Cl + \dot{O}_2$$

Net reaction $2O_3 + h\nu \longrightarrow 3O_2$

Thus, ozone layer is also depleted by reaction with freons.

Thus, (c) is also correct statement.

(d) is a incorrect statement as ozone layer is permeable for IR rays.

35. Ozone layer permits the infrared radiation to pass through but does not permit the higher range of ultraviolet radiation to pass through.

36. NO, NO_2, SO_2 and SO_3 are responsible for smog (environmental pollution).

37. During thunderstorm there is formation of NO which changes to NO_2 and ultimately to HNO_3 (acid-rain).

$$N_2 + O_2 \longrightarrow NO \xrightarrow{O_2} NO_2$$
$$\longrightarrow N_2O_5 \xrightarrow{H_2O} HNO_3 \text{ (pH} < 7)$$

Chapters from Class 12th Syllabus

1 States of Matter : Solid State

JEE Main MILESTONE

- Solid State
- External Features of Crystals
- Bragg's Law : (Determination of Crystal Structure by X-ray Diffraction)
- Crystal Lattice and Unit Cells
- Packing of Particles in a Solid
- Structures of Ionic Crystals
- Radius Ratio Rules
- Imperfections in Solids
- Electrical Properties of Solids
- Magnetic Properties of Solids
- Dielectric Properties of Solids

1.1 Solid State

A solid is defined as that form of matter which has rigidity and due to which possesses a definite volume and a definite shape. These characteristics are due to the existence of very strong forces of attraction among the constituent species of the solid. Due to these strong forces, the structural units of the solid do not possess any translatory motion but can have only vibrational motion about their mean positions.

Classification of Solids

The solids can be classified into the following two types

(A) Amorphous Solids

The solids which do not have any definite shape geometrically are called amorphous (Morpha = form) solids. Infact these have a random and disordered arrangement of atoms. These solids are also called **supercooled liquids** and are without sharp melting points *i.e.,* these have **short range order** of their constituent atoms like that in the liquids. *e.g.,* glass, rubber, plastics, etc.

Amorphous solids are **isotropic** *i.e.,* have same physical properties in all directions. Actually, here the particles are randomly arranged and disordered due to which all the directions are equivalent, hence all the properties remain same in all the directions.

Amorphous solids soften over a range of temperature and can be moulded and blown into various shapes. On heating they become crystalline at some temperature. Some glass objects from ancient civilisations are found to become milky in appearance because of some crystallisation.

Moreover, solids posses high density and low compressibility as compared to liquids and gases, because of strong intermolecular forces of attraction.

Caution Point *Glass panes fixed to windows or doors of old buildings are invariably found to be slightly thicker at the bottom than at the top. This is because the glass flows down very slowly and makes the bottom portion slightly thicker.*

(B) Crystalline Solids

A crystalline solid is composed of atoms arranged in an orderly repetitive array, *i.e.,* it is a **homogeneous anisotropic substance** having a definite geometrical shape with surfaces that are usually plane with sharp edges. These have sharp melting points.

In many solids, we may not clearly see the shape of crystals because several small or micro-sized crystals are tightly packed together without any specific order. Such a substance which is infact crystalline but is superfine to be seen as crystals is called **micro-crystalline** or **polycrystalline solid** *e.g.,* many metals and alloys. A copper wire have micro-crystalline structure.

Table 1.1 **Distinction between Crystalline and Amorphous Solids**

Property	Crystalline solids	Amorphous solids
Shape	They have definite characteristic geometrical shape.	They have irregular shape.
Melting point	They melt at a sharp and characteristic temperature.	They gradually soften over a range of temperature.
Cleavage property	When cut with a sharp edged tool, they split into two pieces and the newly generated surfaces are plain and smooth.	When cut with a sharp edged tool, they split into two pieces with irregular surfaces.
Anisotropy/ isotropy	Anisotropic in nature	Isotropic in nature
Also called	True solids	Pseudo solids or supercooled liquids
Heat of fusion	They have a definite and characteristic heat of fusion.	They do not have definite heat of fusion.
Order in arrangement of constituents	Long range order.	Short range order.

On the basis of nature of bonding, the crystalline solids have been classified into following four types

(i) Ionic Crystals

These have (+)ve and (–)ve ions as constituent particles which are bonded together by strong electrostatic forces of attraction, *e.g.,* NaCl, KNO_3, etc.

These solids are hard and brittle in nature. They have high melting and boiling points. Since, the ions are not free to move about, they are electrical insulators in the solid state. However, in the molten state or when dissolved in water, the ions become free to move about and they conduct electricity.

(ii) Molecular Crystals

These have molecules as constituent particles which are bonded by van der Waals' forces, *e.g.,* I_2, dry ice (solid CO_2), solid CH_4, ice, etc.

These are further sub divided into the following categories

(a) **Non-polar molecular solids** which comprise of either atoms, *e.g.,* argon and helium or the molecules formed by non-polar covalent bonds *e.g.,* H_2, Cl_2 and I_2. In these solids, the atoms or molecules are held by weak dispersion forces or London forces. They have low melting points and are usually in liquid or gaseous state at room temperature and pressure. These solids are soft and non-conductors of electricity.

(b) **Polar molecular solids** are those in which the molecules are held together by relatively stronger dipole-dipole interactions. These solids are soft and non-conductors of electricity. Their melting points are higher than those of non-polar molecular solids yet most of these are gases or liquids under room temperature and pressure. *e.g.,* solid SO_2, solid NH_3 etc.

(c) **Hydrogen bonded molecular solids** are those in which the molecules contain polar covalent bonds between H and F, O or N atoms. Strong hydrogen bonding binds molecules of such solids like H_2O (ice). They are non-conductors of electricity. Generally they are volatile liquids or soft solids under room temperature and pressure.

(iii) Covalent Crystals

These have atoms as constituent particles (bonded together by covalent bonds), *e.g.,* diamond, graphite, silicon etc. Such solids are very hard and brittle because of the presence of strong and directional covalent bonds which hold the constituents very strongly at their positions. Moreover, melting points of such solids are extremely high, even they may decompose before melting. They are insulator (*i.e.,* do not conduct electricity).

Graphite is soft and conductor of electricity. Its exceptional behaviour is because of the presence of loosely held layers and free electrons.

Free electrons make graphite a good conductor of electricity. Different layers can slide one over the other. This makes graphite a soft solid and a good solid lubricant.

(iv) Metallic Crystals

These have positive metal ions (Kernels) and free electrons as constituent particles (bonded together by metallic bonds), *e.g.,* all metals and alloys. Each metal atom contributes one or more electrons towards this sea of mobile electrons. These free and mobile electrons are responsible for high electrical and thermal conductivity of metals. When an electric field is applied, these electrons flow through the network of positive ions.

Similarly, when heat is supplied to one portion of a metal, the thermal energy is uniformly spread throughout by free electrons. Another important characteristic of metals is their lustre and colour in certain cases. This is also due to the presence of free electrons in them. Metals are highly malleable and ductile.

Sample **Problem 1** *Iodine molecules are held in the crystals lattice by* **[NCERT Exemplar]**

(a) *London force* (b) *dipole-dipole interactions*
(c) *covalent bonds* (d) *coulombic forces*

Interpret (*a*) Iodine is a molecular solids, thus in it the constituent particles, *i.e.,* molecules are held together by weak London forces.

Sample **Problem 2** *Graphite cannot be classified as* **[NCERT Exemplar]**

(a) *conducting solid* (b) *network solid*
(c) *covalent solid* (d) *ionic solid*

Interpret (*d*) Because of the absence of ions, graphite is not an ionic solid. It is a network or covalent solid which has high conductivity due to the presence of free electrons.

Sample **Problem 3** *Which of the following solids is not an electrical conductor?* **[NCERT Exemplar]**

(*A*) Mg(*s*) (*B*) TiO(*s*)
(*C*) $I_2(s)$ (*D*) $H_2O(s)$
(a) *only* (*A*) (b) *only* (*B*)
(c) (*C*) *and* (*D*) (d) (*B*), (*C*) *and* (*D*)

Interpret (*c*) Metallic and ionic solids (in molten state) because of the presence of free electrons and free ions respectively, conduct electricity. Thus, Mg (metallic solid) and TiO are conductor of electricity.

$I_2(s)$ and $H_2O(s)$ are molecular solids and do not have charge carrier like free electrons or ions. That's why these are non-conductor of electricity.

Crystalline and Amorphous Silica

Silica (SiO_2) can be crystalline (quartz) as well as amorphous. *Main differences are given below*

Table 1.2 **Difference between Quartz and Amorphous Silica**

S.N.	Quartz	Amorphous silica
1.	Crystalline.	Light white powder.
2.	All four corners of SiO_4^{4-} tetrahedron are shared by others to give a network solid.	The SiO_4^{4-} tetrahedra are randomly joined giving rise to polymeric chains, sheets or three-dimensional units.
3.	High and sharp melting point (1710°C).	Does not have sharp melting point. On heating softens gradually to liquid.

1.2 External Features of Crystals

The external features of crystals include

1. Faces
2. Forms
3. Edge
4. Solid angle
5. Interfacial angle
6. Zone and zone-axis.

The crystals are bounded by surfaces which are usually planar and arranged in definite pattern. These surfaces are called **faces.** Faces are of two types namely like and unlike faces. The crystals with all similar surfaces is said to have like faces, *e.g.,* alums, fluorspar, etc., while galena crystal has unlike faces, *i.e.,* it has a combination of cubical and octahedral faces.

All the faces corresponding to a crystal are said to constitute a form. The forms may be **simple** (with like faces) or in **combination** (with unlike faces). In a crystal, when two adjacent faces intersect, we get an **edge** and when three or **more** edges intersect, we get a **solid angle.** The angle between the normals to the two intersecting faces is called an **interfacial angle** *i.e.,*

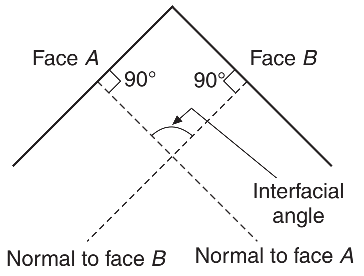

Fig. 1.1 Representation of interfacial angle

The faces, edges and interfacial angles are related as,

$$f + c = e + 2$$

where, f = number of faces
e = number of edges
c = number of interfacial angles

The faces of a crystal occur in sets. These sets are called **zones.** Each zone forms a complete belt around a crystal. A line drawn through the centre of a crystal in a direction parallel to the edges of a zone is known as **zone axis.**

1.3 **Bragg's Law :** (Determination of Crystal Structure by X-ray Diffraction)

The size of the unit cell and arrangement of atoms in a crystal is determined with the help of measurement of diffraction of X-rays by the crystal. W.H. Bragg pointed out that the scattering of X-rays by crystals could be considered as reflection from successive planes of atoms in the crystals.

The process was based upon the principle that a crystal may be considered to be made up of a number of parallel equidistant atomic planes as represented by lines *AB, CD* and *EF* in figure shown below.

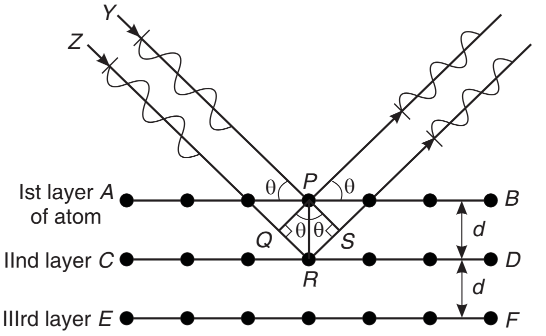

Fig. 1.2 X-ray diffraction by crystal particles

Assume two waves *Y* and *Z* of X-ray beams which are in phase, fall on the surface of the crystal. If ray *Y* gets reflected from the first layer, *i.e., AB* line and ray *Z* is reflected from the second layer of atoms, *i.e., CD* line, then it is evident that as compared to ray *Y*, ray *Z* has to travel a longer distance, equal to *QRS* in order to emerge out of the crystal. If waves *Y* and *Z* are in-phase (for the intensity of the reflected beam to be maximum) after reflection, the difference in distance travelled by the two rays must be equal to the integral multiple of wavelength, *i.e.,* $n\lambda$ (for constructive interference).

Thus, distance $QRS = n\lambda$ ...(i)

It is obvious from the figure that $QR = RS = PR \sin\theta$

$\therefore$ $QRS = 2PR \sin\theta$ ...(ii)

If the distance between the successive atomic planes is *d*, then, $PR = d$. ...(iii)

So, from Eq. (i), (ii), and (iii), we have

$$\boxed{n\lambda = 2d \sin\theta}$$

This is **Bragg's equation.**

Thus, Bragg gave a mathematical equation to establish a relationship between the wavelength of the incident X-ray, the distance between the layers, and the angle of diffraction, where

λ = wavelength of X-ray used

θ = angle between incident X-rays and the plane of the crystal. The diffracted beam makes an angle 2θ.

d = distance between planes of the constituent particles in a crystal.

n = an integer (1, 2, 3, 4, ...) which represents the serial order of diffracted beams.

Applications of Bragg's Law

Bragg diffraction (also referred as Bragg's formulation of X-ray diffraction) is an important application of Bragg's law. The concept of Bragg diffraction applies equally to neutron diffraction and electron diffraction. Electron diffraction provides a basis for studying the structure of crystals and of identifying materials. Metal tend to give a very strong electron diffraction patterns whereas biological specimens generally diffract quite weakly.

In X-ray diffraction, a diffraction pattern is obtained by measuring the intensity of scattered waves as a function of scattering angle. Very strong intensities known as Bragg peaks are obtained in the diffraction pattern when scattered waves satisfy the Bragg's law.

Sample **Problem 4** *The X-ray powder pattern of potassium chloride shows a cone at $\theta = 90°$, using X-rays of wavelength 1.54×10^{-8} cm. What is the spacing between the planes?*

(*a*) 7.5×10^{-5} *cm* (*b*) 7.7×10^{-9} *cm*

(*c*) 3.6×10^{-8} *cm* (*d*) 1.54×10^{-8} *cm*

Interpret (*b*) Using Bragg's equation, we have

$$d = \frac{1.54 \times 10^{-8}}{2 \times \sin 90°} \text{ cm}$$

$$= \frac{1.54 \times 10^{-8}}{2 \times 1} \text{ cm}$$

$$= 7.7 \times 10^{-9} \text{ cm}$$

Sample **Problem 5** *When an electron in an excited* Mo *atom falls from L to K shell, an X-ray is emitted. These X-rays are diffracted at angle of 7.75 by planes with a separation of 2.64 Å. What is the difference in energy between K-shell and L-shell in* Mo *assuming a first order diffraction* (sin 7.75 = 0.1349) ?

(*a*) 36.38×10^{-14} *J* (*b*) 27.88×10^{-16} *J*

(*c*) 45.34×10^{-16} *J* (*d*) 31.46×10^{-15} *J*

Interpret (*b*) Bragg's equation,

$$n\lambda = 2d \sin\theta$$

$$\lambda = \frac{2d \sin\theta}{n}$$

$$= \frac{2 \times 2.64 \times 10^{-10} \times \sin 7.75}{1}$$

$$= 0.7123 \times 10^{-10} \text{ m}$$

Also, we know that

$$E = \frac{hc}{\lambda} = \frac{6.62 \times 10^{-34} \times 3 \times 10^{8}}{0.7123 \times 10^{-10}}$$

$$= 27.88 \times 10^{-16} \text{ J}$$

Check Point 1

1. Why do solids have a definite volume?
2. Why are pseudo solids anisotropic?
3. Why is glass considered a super cooled liquid?
4. Refractive index of solid is observed to have the same value along all directions. Comment on the nature of this solid. Would it show cleavage property?
5. Ionic solids conduct electricity in molten state but not in solid state. Explain.

1.4 Crystal Lattice and Unit Cells

The regular arrangement of the constituent particles of a crystalline solid in the three dimensional space is called the space lattice or crystal lattice.

The smallest portion of the complete space which when repeated again and again in different directions produces the complete space lattice, is called the unit cell.

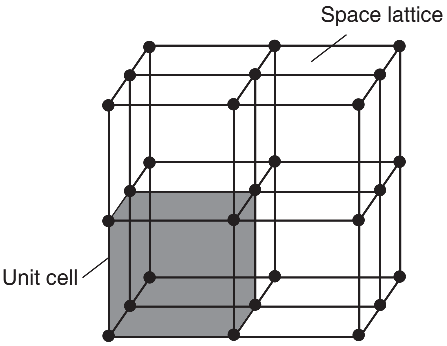

Fig. 1.3 Space lattice and unit cell

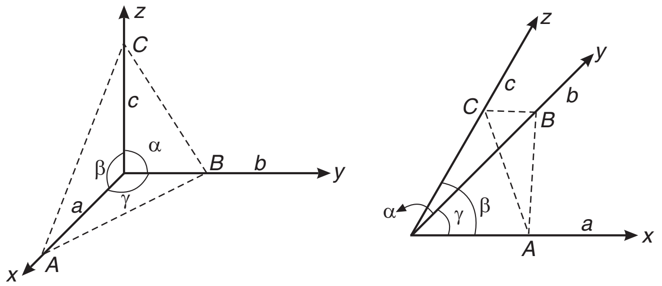
Crystal Parameters

The geometry of a crystal can be best described in terms of 3 non-coplanar coordinate axes, called the **crystallographic axes.** These axes namely x, y and z may be mutually at right angles to each other or may be inclined to each other at different angles. As per convention, the angle between y and z-axes is called α, between z and x is called β and between x and y is called γ.



(a) α, β, and γ when perpendicular to each other *i.e.*, $\alpha = \beta = \gamma = 90°$

(b) α, β, γ, when inclined at different angle

Fig. 1.4 Crystallographic axes showing angles

Any face of the crystal may cut into one or more crystallographic axes. The face which cuts all the three axes is called **standard** or **unit plane.** The distances of the points where the standard plane cuts the three axes from the origin are called intercepts. The intercepts a, b and c and axes x, y and z respectively are called crystal parameters. In actual practice, the ratio $a : b : c$ is called the axial ratio and it depends upon the point where all the three axes meet.

On the basis of different possible values of α, β and γ and different axial distances or edge lengths a, b and c following 7 types of three dimensional primitive cells or crystal systems are as follows

Table 1.3 **Seven Crystal Systems and their Unit Cell Parameters**

S.N.	Crystal systems	Bravais lattices	Unit cell parameters		Examples
			Intercepts	Crystal angles	
1.	Cubic	Primitive, Face centred, Body centred	$a = b = c$	$\alpha = \beta = \gamma = 90°$	NaCl, KCl, diamond, copper, zinc blende etc.
2.	Rhombohedral (Trigonal)	Primitive	$a = b = c$	$\alpha = \beta = \gamma \neq 90°$	$NaNO_3, CaCO_3$, HgS, etc.
3.	Orthorhombic	Primitive, Face centred, Body centred, End centred	$a \neq b \neq c$	$\alpha = \beta = \gamma = 90°$	Rhombic sulphur, $BaSO_4$ (baryta), $PbCO_3$ etc.
4.	Triclinic (most asymmetric)	Primitive	$a \neq b \neq c$	$\alpha \neq \beta \neq \gamma \neq 90°$	$K_2Cr_2O_7, H_3BO_3, CuSO_4 \cdot 5H_2O$ etc.
5.	Monoclinic	Primitive, End centred	$a \neq b \neq c$	$\alpha = \gamma = 90°, \beta \neq 90°$	$Na_2SO_4 \cdot 10H_2O, Na_2B_4O_7 \cdot 10H_2O$, monoclinic S etc.
6.	Tetragonal	Primitive, Body centred	$a = b \neq c$	$\alpha = \beta = \gamma = 90°$	Cassiterite, white tin, rutile etc.
7.	Hexagonal	Primitive	$a = b \neq c$	$\alpha = \beta = 90°, \gamma = 120°$	Mg, beryl, ZnO (zincite) PbI_2, graphite etc.

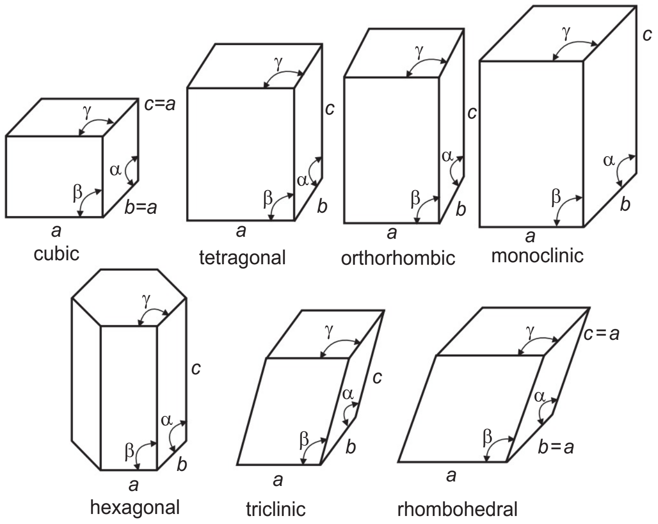


Fig. 1.5 Three dimensional primitive crystal systems

Caution Point *As there are 5 possible two dimensional lattice, similarly there are only 14 possible three dimensional lattices. These are called* Bravais lattices *(after the French mathematician who first described them).*

Sample **Problem 6** *Match box belongs to*

(a) *tetragonal system* (b) *orthorhombic system*
(c) *hexagonal system* (d) *triclinic system*

Interpret (*b*) In match box, all the sides are unequal, *i.e.,*

$$a \neq b \neq c$$

but all the angles are 90°, *i.e.,* $\alpha = \beta = \gamma = 90°$.

Thus, it belongs to orthorhombic crystal system.

Types of Unit Cells

The unit cells are of the following two types

(a) Simple or primitive unit cell

(b) Non-primitive or multiple unit cell.

(a) Simple or Primitive Unit Cell

The **simplest unit cell** has the lattice points at the corners or in other words we can say, when particles are present only at the corners of the unit cell, it is called simplest type. It is denoted by *P*.

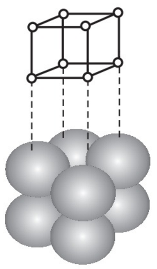

Fig. 1.6 (a) Simple cubic unit cell

(b) Non-primitive or Multiple Unit Cell

When a unit cell contains more than one additional lattice points (additional to those defined in simple unit cell), it is called non-primitive or multiple unit cell. It is further sub-divided into

(i) Face-centred unit cell (*F*)

(ii) End face-centred unit cell (*C*)

(iii) Body-centred unit cell (*I*)

When the particles or lattice points are present at the centre of each face in addition to particles at the corner, the unit cell is called **face centred.**

When in the unit cell, besides the points or particles at the corner of cell, the points or particles are located at the centre of any two parallel faces of the unit cell, it is called **side-centred** or **end face centred unit cell.**

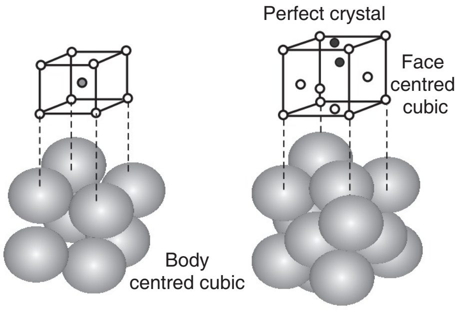

Fig. 1.6 (b) Multiple unit cell types

In a unit cell when, besides the points or particles at the corner there is single particle located at the centre within its body; it is called body centred arrangement and the unit cell is called **body centred unit cell.**

Effective Number of Atoms in a Unit Cell

In a crystal, atoms located at the corner and face center of a unit cell are shared by other cells and only a portion of such an atom actually lies within a given unit cell.

1. A point that lies at the corner of a unit cell is shared among eight unit cells and therefore, only one eighth of each such point lies within the given unit cell.
2. A point along an edge is shared by four unit cells and only one-fourth of it lies within any one cell.
3. A face-centred point is shared by two unit cells and only one half of it is present in a given unit cell.
4. A body-centred point lies entirely within the unit cell and contributes one complete point to the cell. Thus,

Table 1.4 **Contribution of Different Atoms per Unit Cell**

Type of lattice point	Contribution to one unit cell (in Cubic Unit Cell)
Corner	1/8
Edge	1/4
Face centre	1/2
Body centre	1

Calculation of Number of Atoms in Different Unit Cells

In different types of unit cell, the number of atoms per unit cell can be calculated as follows

(a) Primitive or Simple Cubic Unit Cell

From the given figure, it is clear that here eight atoms which are present at 8 corners are shared by 8 unit cells. Hence, contribution of each atom present at the corner $= \frac{1}{8}$

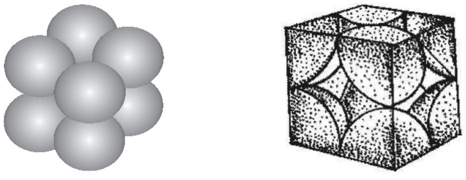

Fig. 1.7 Simple cubic unit cell

Thus, total number of atoms present per unit cell $= 8 \times \frac{1}{8}$

$= 1$ atom

(b) Body Centred Cubic Unit Cell

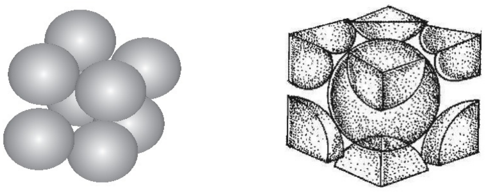

Fig. 1.8 Body centred cubic unit cell

From the above figure, it is clear that this unit cell has 1 complete atom additional to that present in simple cubic unit cell. Hence, the total number of atoms present $= 1 + 1 = 2$ atoms per unit cell.

(c) Face Centred Cubic Unit Cell

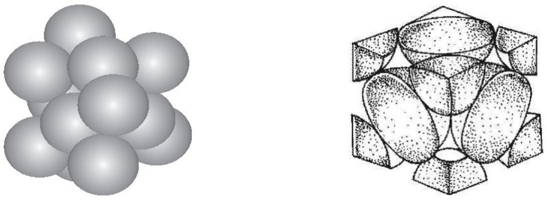

Fig. 1.9 Face centred cubic unit cell

From the above figure it is clear that here

(i) 8 corner atoms $\times \frac{1}{8}$ atoms per unit cell = 1 atom

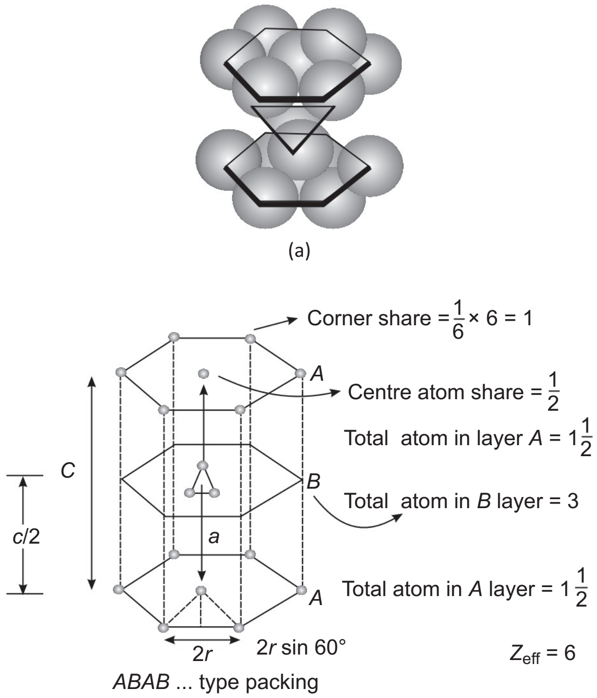
(ii) 6 face atoms (with representation of 1/2 atom per face) per unit cell, thus $6 \times \frac{1}{2} = 3$ atoms

Total atoms present per unit cell = 1 + 3 = 4 atoms

(d) End Face Centred Cubic Unit Cell

Similarly, end face centred cubic unit cell have 1 instead of 3 face atoms present in face centred cubic unit cell. Rest distribution is same (because here only 2 parallel faces have one atom each at the centre of face shared by two unit cells). Thus, the total number of atoms present per unit cell here is $1 + 1 = 2$ atoms per unit cell.

(e) Hexagonal Close Packed Unit Cell



(a)

(b)

Fig. 1.10 Hexagonal close packed unit cell

Three atoms in B layer exclusively belong to this prism (*i.e.,* in the body centre of hexagonal)

In layer A

1. One atom in the centre is shared by two prisms.
2. There are 12 atoms in two A layers and each is shared amongst six prisms of this type $= 12 \times \frac{1}{6} = 2$

   Effective number of atoms in both A layers = 2 + 1 = 3.
3. Effective number of atoms in two A layers + Effective number of atoms in B layer = 3 + 3 = 6

   ∴ Effective number of atoms in hcp = 6

   Alternatively

   Effective number of atoms unit cell $= 12 \times \frac{1}{6}$ (corner) (from both A layer)

   $+ 2 \times \frac{1}{2}$ (in the centre of both A layers)

   + 3 (in the body in layer B) = 6

Table 1.5 **Number of Atoms in Different Unit Cells**

S. No.	Cubic unit cell	n_c	n_f	n_i	Total atoms in unit cell
1.	Simple cubic	8	0	0	1
2.	Body-centred cubic	8	0	1	2
3.	Face centred cubic	8	6	0	4

General Formula for Calculating Number of Atoms

The number of atoms per unit cell can also be determined by the simplest relation

$$Z = \frac{n_c}{8} + \frac{n_f}{2} + \frac{n_i}{1}$$

where, n_c = number of atoms at the corners of the cube

n_f = number of atoms at six faces of the cube

n_i = number of atoms inside the cube

Sample **Problem 7** *A compound formed by elements X and Y has a cubic structure in which X atoms are at the corner of the cube and Y atoms are at the face centres. One atom X is missing from the corner. The formula of the compound is*

(a) X_2Y_4 (b) X_7Y_{24}
(c) $X_{24}Y_7$ (d) X_7Y_3

Interpret (*b*) In a cube there are 8 atoms. Since, one atom *X* is missing from the corner.

The number of *X* atoms at the corners = 7

$$\text{Number of effective } X \text{ atoms} = 7 \text{ corners} \times \frac{1}{8} \text{ per corner atom share}$$

$$= \frac{7}{8} \text{ atom/unit cell}$$

$$\text{Number of effective } Y \text{ atoms} = 6 \text{ faces} \times \frac{1}{2} \text{ per face atom share}$$

$$= 3 \text{ atoms/unit cell}$$

Thus, formula of the compound is $X_{7/8}Y_3$.

Simplifying = X_7Y_{24}.

Sample **Problem 8** *If in the above sample problem, all the atoms are removed from one of the faces of the cube containing atoms at the corners, find the formula of the compound.*

(a) X_7Y_{24} (b) X_6Y_{24} (c) X_3Y_{20} (d) Y_3Y_5

Interpret (c) Atoms removed from one face of the cube, containing all atoms at corners = 4 corners + 1 face-centred atom

= 5 atom/unit cell

Corner atom left = 7 − 4 = 3 atoms at corner

Face-centre atom left = 6 − 1 = 5 atoms at face centre.

Formula of compound

$$Z_{\text{eff }(X)} = \frac{3}{8}, \; Z_{\text{eff }(Y)} = \frac{5}{2}.$$

Formula $X_{3/8}Y_{5/2}$

Simplifying = X_3Y_{20}

1.5 Packing of Particles in a Solid

To understand the packing of particles in a crystal, it is assumed that these particles are hard spheres of identical size. *The number of spheres surrounding a particular sphere is called the coordination number* (CN) *of that sphere i.e.,* in simple words, coordination number is the number of atoms or ions or molecules surrounding a particular atom in a crystal lattice.

Caution Point *In crystals with directional bonds, coordination number is lower than that of crystals with non-directional bonds such as metals and ionic compounds.*

The packing can be seen in one of the following ways

Close Packing in One Dimension

It is the simplest close packing here spheres are placed in a horizontal row, touching each other as shown below

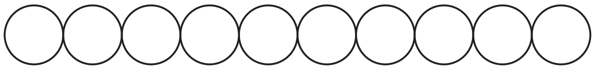


Fig. 1.11 One dimensional packing of spheres

Thus, an edge of crystal is formed.

Here, each sphere is in contact of two other spheres, so its coordination number is 2.

Close Packing in Two Dimensions

When the above written rows combine, two types of combinations are possible

(i) With a horizontal as well as vertical alignment as shown below

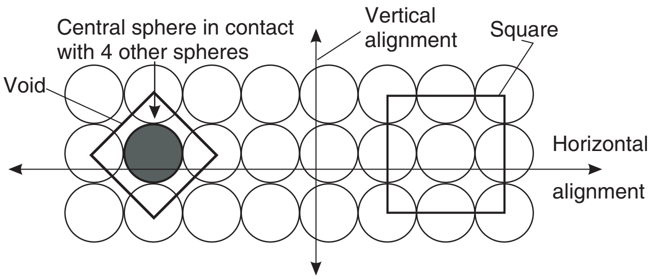

Fig. 1.12 Square close packing of spheres in two dimensions

Here, particles form square and the packing is called **square close packing.** The coordination number of each sphere in such packing is 4. The empty space between the particles in a close packing is called void as seen above.

(ii) With the particles in every next row are placed in the depressions between the particles of first row. The particles of third row will show vertical alignment with the first row as shown below

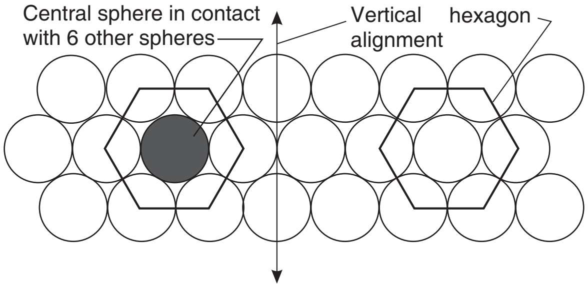

Fig. 1.13 Hexagonal close packing of spheres in two dimensions

Such a packing gives hexagonal pattern, thus called **hexagonal close packing.** Here coordination number is 6.

Caution Point *The hexagonal close packing is more efficient than square close packing as here more space is occupied by spheres.*

Close Packing in Three Dimensions

As among two dimensional packings hexagonal close packing is more efficient, the three dimensional packings are based upon the hexagonal close packing patterns.

Three dimensional close packing from two dimensional square close packed layers, results in the formation of simple cubic lattice.

The two dimensional hexagonal close packing observation shows two types of voids in it as shown below

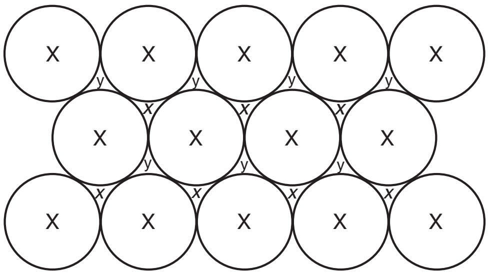

Fig. 1.14 Two dimensional hexagonal close packing

Placing of Second Layer

Keeping both the types of voids in mind, in three dimensional packing, the IInd row of spheres is placed in such a way that its spheres find place above the voids marked x of first row (voids marked y left unoccupied) as shown in the figure

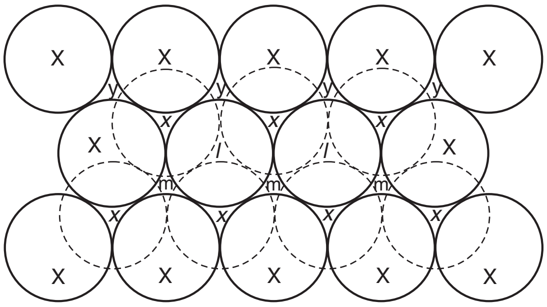

Fig. 1.15 A stack of two layers of close packed spheres and voids

In the second layer, two types of voids are seen again

(i) Those which lie above the spheres of first layer (marked l in above diagram).

(ii) Those which lie above the voids y of first layer (marked m in above diagram).

Placing of Third Layer

There are two possible ways by which the third layer can be placed over the second.

These two ways are as follows

(i) When the third layer is placed in such a way that the spheres cover the l voids of second layer, a three dimensional cubic packing is obtained where the spheres in every 3rd or alternate layer are vertically aligned *i.e.,* 3rd layer is directly above Ist or 4th layer is directly above 2nd. The arrangement is also called as $A\,B\,A\,B$ ...., if we designate first layer as A and second layer as B as seen as below

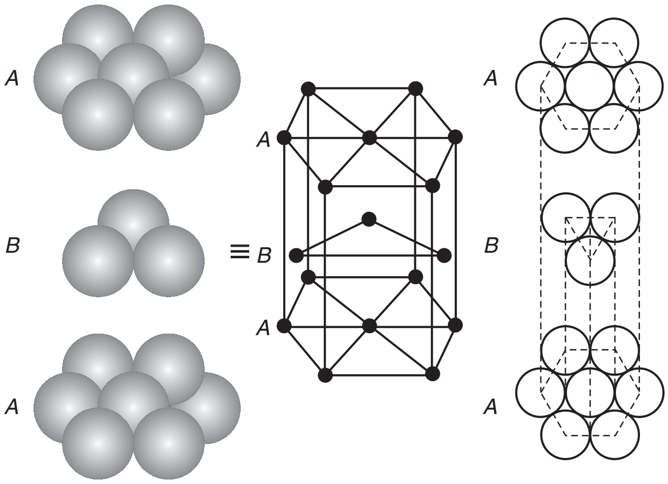

Fig. 1.16 Hexagonal close packing in three dimensions

Such a $A\,B\,A\,B$ ... packing is called **hexagonal close packing** (three dimensional) *e.g.,* Be, Mg crystals, etc.

(ii) Consider the same arrangement described above till 2nd layer, and if a 3rd layer is placed in such a way that spheres cover the void m of second layer, a layer different from A and B described above, is seen. Let us call it as layer C. Continuing further, if the 4th layer is placed over the 3rd layer in such a way that each sphere of it align vertically with the first layer, the packing is called **cubic close packing** with *ABC*, *ABC* ... pattern of layers as shown in the figure

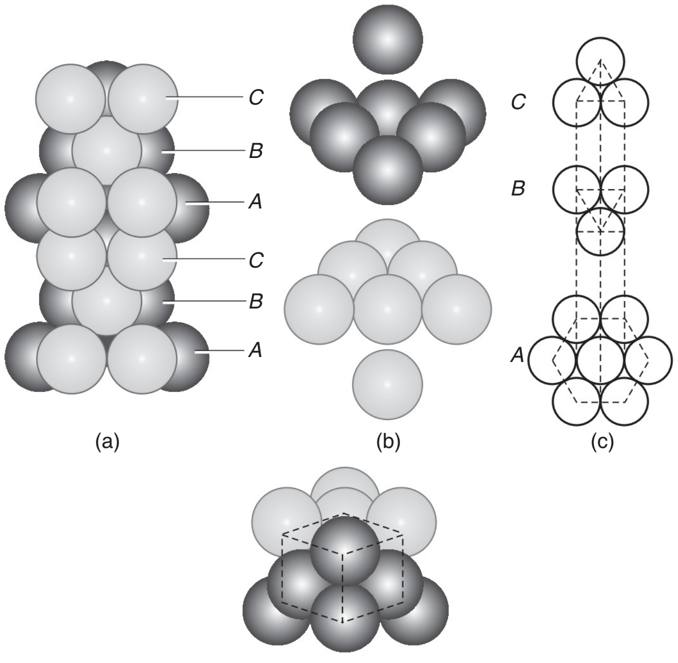

Fig. 1.17 Cubic close packing in three dimensions

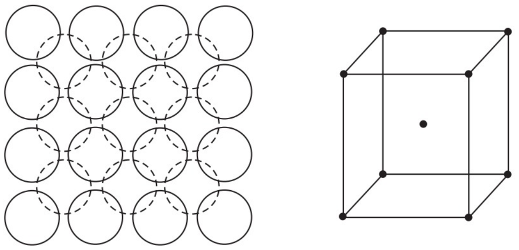
The packing is also called face centred cubic packing (fccp). The example of fccp include Fe, Ni, Cu, Ag, Au and Al, etc.

Both the above patterns are almost equally efficient and occupy maximum possible space i.e., about 74% *of the available volume with variable coordination numbers from* 4 *to* 12*, i.e.,* 4, 6, 8 *and* 12.

Body Centred Cubic Close Packing

Body centred cubic (bcc) arrangement is obtained when the spheres of the first layer are opened up and the spheres of second layer are placed at the top of the hollows in the first layer. The spheres of the third layer are placed exactly above the spheres of first layer.



(a) bcc packing of spheres (b) bcc arrangement

Fig. 1.18 Body centred close packing in three dimensions

From the figure, it is clear that each sphere in this arrangement is in contact with 8 spheres, thus, the coordination number is 8. Here, the space occupancy is only 68%. *e.g.,* Li, Na, K, Rb, Cs, etc.

Packing Pattern of Different Metals

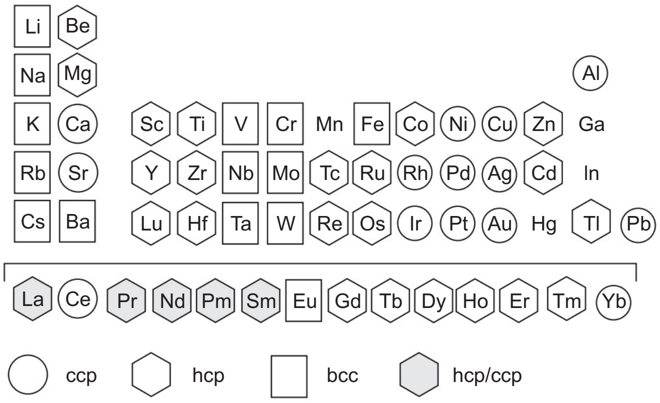


Fig. 1.19 Packing pattern among the metals

Caution Point *The space occupied by hard spheres in fcc and hcp is* 74%*, in bcc it is* 68%*, in simple cubic it is* 52% *and in diamond it is* 34%*. Thus, only fcc and hcp are close packed structures.*

Voids

In closely packed structures, the empty space is called interstitial site or void. The void can be a simple triangular space in the case of two dimensional packing and called the **trigonal void.**

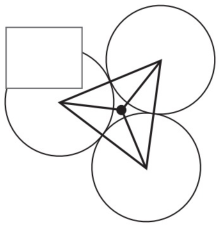

Fig. 1.20 Trigonal void

In three dimensional close packing patterns, the voids can be

(a) Tetrahedral (b) Octahedral

(a) Tetrahedral Void

A tetrahedral void is a simple triangular space surrounded by 4 spheres as shown below

Location and number of tetrahedral voids Number of ions (or atoms) in a close packed structure (fcc or ccp)

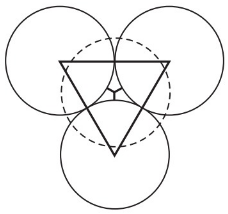

Fig. 1.21 Tetrahedral void

$$= 8 \text{ corner} \times 1/8 \text{ per corner share} + 6 \text{ faces} \times 1/8 \text{ per face share}$$
$$= 1 + 3 = 4/\text{unit cell}$$

2 tetrahedral voids are present on each body diagonal of a cube.

$\therefore$ Number of tetrahedral voids $= 2 \times 4$ body diagonal $= 8/\text{unit cell}$

or the number of tetrahedral voids in a close packed structure $= 8/\text{unit cell}$ or $8/4 = 2/\text{atom}$.

(b) Octahedral Void

An octahedral void is a double triangular void surrounded by 6 spheres as shown below

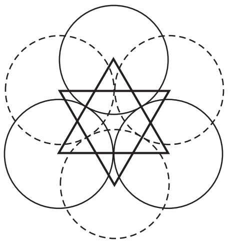

Fig. 1.22 Octahedral void

Location and number of octahedral void Octahedral voids are present on the edge centre of a cube and at body centre of a cube.

$\therefore$ Number of octahedral void $= 12$ edge centre $\times \frac{1}{4}$ per edge centre share $+ 1$ body centre
$$= 3 + 1 = 4/\text{unit cell}$$

Thus, number of octahedral void $= 4/\text{unit cell}$ or
$$\frac{4}{4} = 1/\text{atom}$$

The sum of radius of the atom of host lattice (r_h) and the radius of atom occupying void $(r_{f(t)}$ or $r_{f(0)})$ is given by

For octahedral void, $r_h + r_{f(0)} = \dfrac{a}{2}$

and for tetrahedral void, $r_h + r_{f(t)} = \dfrac{\sqrt{3}a}{4}$

The sizes of above written voids can be seen in increasing order as

Trigonal < Tetrahedral < Octahedral

The actual sizes of the voids can be calculated on the basis of sizes of spheres involved in the formation of solids.

1. The size of trigonal void is 0.115 times of the radius of bigger sphere involved.
2. The size of tetrahedral void is 0.2247 times of the radius of bigger sphere involved.
3. The size of octahedral void is 0.414 times of the radius of bigger sphere involved.

In a closely packed structure containing X spheres (i.e., atoms, molecules or ions), there are 8X trigonal, 2X tetrahedral and X octahedral voids.

Sample Problem 9 *The total number of tetrahedral voids in the face centred unit cell is* **[NCERT Exemplar]**

(*a*) 6 (*b*) 8 (*c*) 10 (*d*) 12

Interpret (*b*) In fcc unit cell.

Number of atoms = 4

$\therefore$ Total number of tetrahedral voids $= 2 \times$ number of atoms $= 2 \times 4 = 8$

Sample Problem 10 *A compound is formed by two elements M and N. The element N forms ccp and atoms of M occupy $\frac{1}{3}$rd of tetrahedral voids. What is the formula of the compound?* **[NCERT]**

(*a*) MN_3 (*b*) M_3N (*c*) M_3N_2 (*d*) M_2N_3

Interpret (*d*) To solve such problems follow the following steps

Step I Find the number of tetrahedral voids as number of tetrahedral voids $= 2 \times$ number of atoms present in the lattice.

Step II Calculate the number of atoms (or ratio) of elements *M* and *N* as a chemical formula represents the number of atoms of different elements present in a compound. Derive the formula.

Suppose atoms of element *N* present in ccp $= x$

Then, number of tetrahedral voids $= 2x$

Since, $\frac{1}{3}$ rd of the tetrahedral voids are occupied by atoms of element *M*.

Therefore, number of atoms of element $M = \dfrac{1}{3} \times 2x = \dfrac{2x}{3}$

Ratio of $M : N = \dfrac{2x}{3} : x = 2 : 3$

Hence, formula of the compound $= M_2N_3$.

Sample Problem 11 *In a crystalline solid, having formula AB_2O_4, oxide ions are arranged in cubic close packed lattice while cations A are present in tetrahedral voids and cations B are present in octahedral voids. The percentage of tetrahedral voids occupied by A is*

(*a*) 50% (*b*) 25%
(*c*) 75% (*d*) 12.5%

Interpret (*d*) In a cubic close packed lattice of oxide ions, there would be two tetrahedral and one octahedral void per oxide ion.

Since, the formula shows the presence of 4 oxide ions, the number of tetrahedral voids is eight and that of octahedral voids is four.

Out of the eight tetrahedral voids one is occupied by *A*.

$\therefore$ Percentage of tetrahedral voids occupied $= \dfrac{1}{8} \times 100 = 12.5\%$

Hot Spot 1

CALCULATIONS Involving Unit Cell Parameters

Questions based on unit cell parameters like radius, edge length, packing efficiency, empty space and density have been frequently seen in JEE Main examination which reveal the importance of the topic for this examination. The questions of this topics are simple formula based and their level may vary from easy to average.

1. Relation Between Radius (r) and Edge Length (a)

(a) **For Simple Cubic Unit Cell**

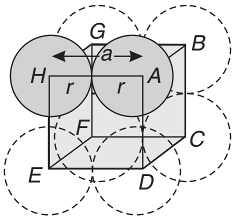

Fig. 1.23 Simple cubic unit cell

$$a = 2r$$

or $a = r_+ + r_-$ (if r_+ and r_- are not equal)

(r_+ radius of cation and r_- radius of anion)

or $\boxed{r = \frac{a}{2}}$

(b) **For Body Centred Cubic Arrangement,**

In ΔEFD,

$$b^2 = a^2 + a^2 = 2a^2$$

$$b = \sqrt{2}a$$

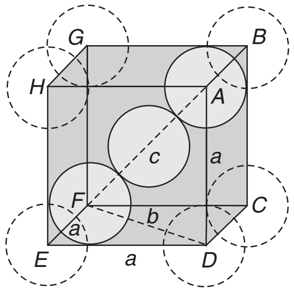

Fig. 1.24 Body centred cubic unit cell

Now in ΔAFD

$$c^2 = a^2 + b^2 = a^2 + 2a^2 = 3a^2$$

$$c = \sqrt{3}a$$

Therefore, $\sqrt{3}a = 4r$ or $\sqrt{3}a = 2r_+ + 2r_-$ (if $r_+ \neq r_-$)

$$a = \frac{4r}{\sqrt{3}}$$

Also we can write, $\boxed{r = \frac{\sqrt{3}}{4}a}$

(c) **For fcc Arrangement**

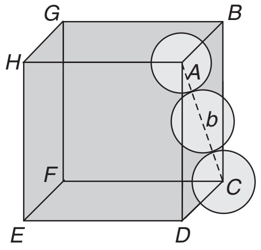

Fig. 1.25 Cubic closed pack unit cell

In ΔABC

$$AC^2 = BC^2 + AB^2$$

$$b^2 = a^2 + a^2 = 2a^2$$

or $b = \sqrt{2}a$

If r is the radius of the sphere,

we find

$$b = 4r = \sqrt{2}a$$

or $2r_+ + 2r_- = \sqrt{2}a$ (if $r_1 \neq r_-$)

or $a = \frac{4r}{\sqrt{2}} = 2\sqrt{2}\,r$

we can also write, $\boxed{r = \frac{a}{2\sqrt{2}}}$

(d) **For hcp Arrangement**

Base area of hexagon $= 6\sqrt{3}r^2$

Height of hexagon $= 4r \times \sqrt{\frac{2}{3}}$

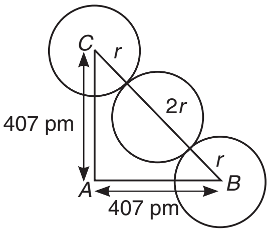
$= 2a \times \sqrt{\frac{2}{3}}$ $(\because\ a = 2r)$

Volume of unit cell of hexagon $= 24\sqrt{2}r^3$

Sample **Problem 12** Ag *metal crystallises in a cubic closest packed arrangement with the edge of the unit cell having a length a* = 407 *pm. The radius of the similar atom is*

(a) 203.5 (b) 176.23
(c) 143.9 (d) 287.7

Interpret (c) $AC^2 + AB^2 = BC^2$



$$a^2 + a^2 = (4r)^2$$

$$r = \frac{a}{\sqrt{8}}$$

$$= \frac{407}{\sqrt{8}}$$

$$= 143.9 \text{ pm}$$

2. Packing Fraction

It is the ratio of total volume of spheres to the volume of the unit cell. In other words, it shows the fraction of volume occupied by spheres.

$$\text{Packing density} = \frac{\text{total volume of spheres}}{\text{volume of the unit cell}}$$

(i) In a **simple cubic unit cell**, packing fraction

$$= \frac{4/3\pi r^3}{8r^3} \times 100 = 52.4\%$$

Here, $\frac{4}{3}\pi r^3$ = volume of one sphere and

for sc,

no. of atoms = 1

$a = 2r$

∴ $a^3 = 8r^3$ = volume of cube (unit cell)

(ii) In **hexagonal close packing** and **face centred cubic** structure, packing fraction $= \frac{16\pi r^3/3}{32 r^3/\sqrt{2}} \times 100 = 74\%$

Here, $\frac{32}{\sqrt{2}} r^3$ = volume of the unit cell

$$\left[\because\ a = \frac{4r}{\sqrt{2}} \text{ and } a^3 = \left(\frac{4r}{\sqrt{2}}\right)^3\right]$$

$\frac{16}{3}\pi r^3$ = total volume of spheres

$$\left[\text{fcc unit cell have 4 particle } \therefore 4 \times \frac{4}{3}\pi r^3\right]$$

(iii) In **body-centred** cubic structure,

$$\text{packing fraction} = \frac{\frac{8}{3}\pi r^3}{\frac{64r^3}{3\sqrt{3}}} \times 100 = 68\%$$

Here, $\frac{64r^3}{3\sqrt{3}}$ = volume of the unit cell

$$\left[\because\ a = \frac{4r}{\sqrt{3}} \text{ and } a^3 = \left(\frac{4r}{\sqrt{3}}\right)^3\right]$$

$\frac{8}{3}\pi r^3$ = total volume of spheres as bcc have two atoms $\left(\therefore 2 \times \frac{4}{3}\pi r^3\right)$

(iv) In hcc, packing fraction $= \frac{6 \times \frac{4}{3}\pi r^3}{24\sqrt{2}\, r^3} = 74\%$

Sample Problem 13 *The percentage of empty space in a body centred cubic arrangement is* **[NCERT Exemplar]**

(a) 74 (b) 68 (c) 32 (d) 26

Interpret (c) In case of body centred cubic arrangement,

$$\text{packing fraction} = \frac{\frac{8}{3}\pi r^3}{\frac{64r^3}{3\sqrt{3}}} \times 100$$

$$= 68\%$$

∴ Fraction of empty space = 100 − 68 = 32%

Sample Problem 14 *The density of solid argon is 1.65 g/mL at −233°C. If the argon atom is assumed to be sphere of radius* 1.54×10^{-8} *cm, what percentage of solid argon is apparently empty space? (At. wt. of* Ar = 40)

(a) 54% (b) 82%

(c) 62% (d) 48%

Interpret (c) Volume of one atom of Ar $= \frac{4}{3}\pi r^3$

Also, number of atoms in 1.65 g per mL $= \frac{1.65}{40} \times 6.023 \times 10^{23}$

∴ Total volume of all the atoms of Ar in solid state

$$= \frac{4}{3}\pi r^3 \times \frac{1.65}{40} \times 6.023 \times 10^{23}$$

$$= \frac{4}{3} \times \frac{22}{7} \times (1.54 \times 10^{-8})^3 \times \frac{1.65}{40} \times 6.023 \times 10^{23}$$

$$= 0.380 \text{ cm}^3$$

Volume of solid Ar = 1 cm^3

$$\therefore \quad \%\text{ empty space} = \frac{1 - 0.381}{1} \times 100 = 62\%$$

3. Density of the Crystal

If we know the type of crystal structure possessed by the cubic crystal, so that the number of particles per unit cell are known and the edge length for it is known by X-ray studies, the density of the crystal can be determined. It is given by the formula

$$d = \frac{Z \times M}{a^3 \times N_A \times 10^{-3}} \text{ g/cm}^3$$

$$d = \frac{Z \times M}{a^3 \times N_A} \text{ kg/cm}^3$$

Here, Z = Number of particles present per unit cell *i.e.,* 1 for simple, 2 for bcc, 4 for fcc

M = Atomic mass of element

a = Edge of the unit cell

N_A = Avogadro number

For ionic crystals, the formula used is same and the difference lies in

1. Z = number of formula units in one unit cell.
2. M = formula mass (molecular mass) of the compound.
3. a = edge which is $2x$ distance between Na$^+$ and Cl$^-$ in NaCl crystal.

Sample **Problem 15** *An element with molar mass* 2.7×10^{-2} *kg mol*$^{-1}$ *forms a cubic unit cell with edge length 405 pm. If its density is* 2.7×10^{3} *kg m*$^{-3}$ *, what is the nature of the cubic unit cell?* **[NCERT Exemplar]**

(*a*) *sc* (*b*) *fcc* (*c*) *bcc* (*d*) *end centred*

Interpret (*b*) To solve out such problems, first calculate the number of atoms present in the unit cell $(Z) = \dfrac{d \times a^3 \times N_A}{M}$ and then find the type of the cubic unit cell as $Z = 1$ for sc, 2 for bcc and 4 for fcc as.

Density $(d) = \dfrac{Z \times M}{a^3 \times N_A}$ so, $Z = \dfrac{d \times a^3 \times N_A}{M}$

Given, $M = 2.7 \times 10^{-2}$ kg mol^{-1}

$a = 405$ pm $= 405 \times 10^{-12}$ m $= 4.05 \times 10^{-10}$ m

$d = 2.7 \times 10^{3}$ kg m^{-3}

$N_A = 6.022 \times 10^{23}$ mol^{-1}

Hence,

$$Z = \frac{(2.7 \times 10^{3}\ \text{kg m}^{-3})\,(4.05 \times 10^{-10}\text{m})^3 \times (6.022 \times 10^{23}\ \text{mol}^{-1})}{(2.7 \times 10^{-2}\ \text{kg mol}^{-1})}$$

$= 3.99 = 4$

Since, there are four atoms per unit cell, the cubic unit cell must be **face-centred**.

Sample **Problem 16** *Niobium crystallises in body-centred cubic structure. If density is* 8.55 *g cm*$^{-3}$ *calculate atomic radius of niobium using its atomic mass* 93 *u.* **[NCERT Exemplar]**

(*a*) 200 *pm* (*b*) 185 *pm*
(*c*) 143 *pm* (*d*) 129 *pm*

Interpret (*c*) Since, we know density, but not radius and radius (*r*) of unit cell is related to *a* for bcc structure as $r = \dfrac{\sqrt{3}\,a}{4}$. So,

We first calculate the edge length of unit cell and then calculate the radius of unit cell

Step I **Calculation of edge length of unit cell** (*a*)

Atomic mass of the element $(M) = 93$ g mol^{-1}

Number of particles in bcc type unit cell $(Z) = 2$

$$\text{Mass of the unit cell} = \frac{Z \times M}{N_A} = \frac{2 \times (93\ \text{g mol}^{-1})}{(6.022 \times 10^{23}\ \text{mol}^{-1})}$$

$= 30.89 \times 10^{-23}$ g

Density of unit cell $(d) = 8.55$ g cm^{-3}

$$\text{Volume of unit cell } (a^3) = \frac{\text{Mass of unit cell}}{\text{Density of unit cell}}$$

$$= \frac{(30.89 \times 10^{-23}\,\text{g})}{(8.55\ \text{g cm}^{-3})}$$

$= 36.16 \times 10^{-24}$ cm^3

Edge length of unit cell $(a) = (36.13 \times 10^{-24}\ \text{cm}^3)^{1/3}$

$= 3.31 \times 10^{-8}$ cm

Step II **Calculation of radius of unit cell** (*r*)

For bcc structure, $r = \dfrac{\sqrt{3}\,a}{4}$

$$= \frac{\sqrt{3} \times (3.31 \times 10^{-8}\ \text{cm})}{4}$$

$= 1.43 \times 10^{-8}$ cm

$= 143$ pm

1.6 Structures of Ionic Crystals

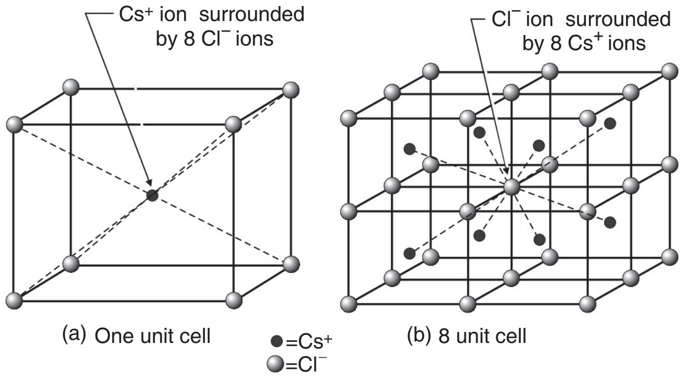
The ionic crystals may be

(i) *AB* type structures,

(ii) AB_2 or A_2B type structures

AB Type Ionic Crystals

The *AB* type structures designate equality in number of cations and the number of anions. The example of this type of structures include NaCl with coordination number 6–6, CsCl with coordination number 8–8 and ZnS with coordination number 4–4.



(a) One unit cell (b) 8 unit cell

Fig. 1.26 Structure of CsCl (8 : 8 coordination)

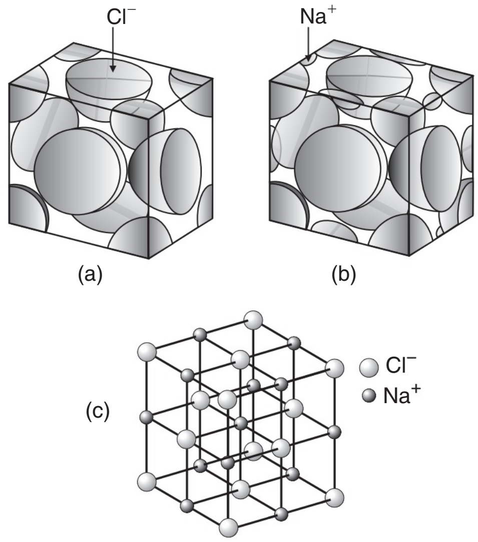


Fig. 1.27 The sodium chloride structure (6 : 6 coordination) : (a) the fcc Cl^- ions array (b) The Na^+ ions enter the voids (c) the resulting two interpenetrating arrays

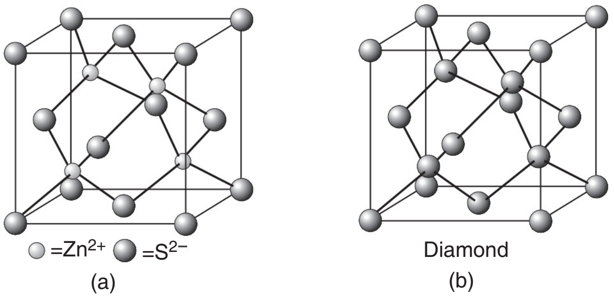

Fig. 1.28 (a) ZnS structure (b) Diamond structure
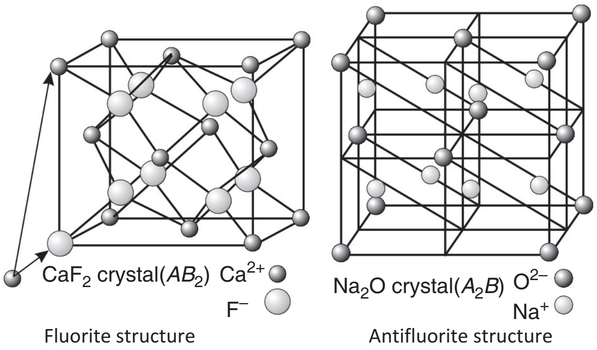
Both structures are identical (4 : 4 coordination)

AB_2 or A_2B Type Ionic Crystals

The AB_2 or A_2B type of ionic crystals contain the ions in the ratio 1 : 2 or 2 : 1 respectively. *e.g.*, CaF_2 popularly called to have **fluorite structure** with other examples like SrF_2, BaF_2, PbF_2 and $BaCl_2$, etc. The coordination number of Ca^{2+} in CaF_2 is 8 while that of F^- is 4. On the contrary, Na_2O have **antifluorite structure** *i.e.*, here the place of cations is occupied by anions and *vice-versa*.



Fluorite structure Antifluorite structure

Fig. 1.29 Fluorite and antifluorite structure

Caution Point *Pressure and temperature also influence the structure of ionic solids. The structures of chlorides, bromides and iodides of sodium, potassium and rubidium having* 6 : 6 *coordination at normal temperature and pressure. It will change to* 8 : 8 *coordination like* CsCl *structure at high pressure, and reverse takes place at high temperature.*

Sample Problem 17 MgO *has a structure of* NaCl, *the coordination number of* O^{2-} *in* MgO *is*

(*a*) 6 (*b*) 3 (*c*) 12 (*d*) 8

Interpret (*a*) Since MgO have NaCl (rock salt) structure, and in NaCl the coordination number of ions are 6 and 6 respectively. Thus, in MgO, O^{2-} also have coordination number 6.

Remember that in the ionic crystals, the bigger ions (usually anions) form the close packed structure and the smaller ion (usually cation) occupy the voids. *e.g.*,

Table 1.6 **Different Ionic Crystals**

Ionic crystal type	Cations occupy	Anions form
NaCl	All octahedral voids	fcc unit cell
CsCl	Body centre	Simple cubic unit cell
ZnS	Alternate tetrahedral voids	fcc unit cell
CaF_2	Alternate body centre	Simple cubic
Na_2O	All tetrahedral sites	fcc unit cell

Sample Problem 18 *In which of the following structures coordination number for cations and anions in the packed structure will be same?* **[NCERT Exemplar]**

(*a*) Cl^- *ion form fcc lattice and* Na^+ *ions occupy all octahedral voids of the unit cell*

(*b*) Ca^{2+} *ions form fcc lattice and* F^- *ions occupy all the eight tetrahedral voids of the unit cell*

(*c*) O^{2-} *ions form fcc lattice and* Na^+ *ions occupy all the eight tetrahedral voids of the unit cell.*

(*d*) S^{2-} *ions form fcc lattice and* Zn^{2+} *ions go into alternate tetrahedral voids of the unit cell*

Interpret (a) NaCl is 6 : 6 coordinated crystal, thus in it coordination number of cations = coordination number of anion.

Note CaF_2 is 8 : 4, Na_2O is 4 : 8 and ZnS is 4 : 4 coordinated crystals.

Sample Problem 19 *Which of the following is not true about the ionic solids?* **[NCERT Exemplar]**

(*a*) *Bigger ions form the close packed structure*

(*b*) *Smaller ions occupy either the tetrahedral or the octahedral voids depending upon their size*

(*c*) *Occupation of all the voids is not necessary*

(*d*) *The fraction of octahedral or tetrahedral voids occupied depends upon the radii of the ions occupying the voids*

Interpret (*d*) Fraction of voids depends upon the number of constituent particles.

Other given statements are true.

Structure of Diamond

Solids which follow the structure of diamond are called diamond cubic. Diamond has fcc structure with four more atoms that are found to be present in the alternate tetrahedral voids.

So, Z_{eff} of C-atoms in diamond cubic

$$= Z_{\text{eff}} \text{ in fcc unit cell} + Z_{\text{eff}} \text{ in alternate tetrahedral voids}$$

$$= \underbrace{\left[\frac{1}{8}\times 8+\frac{1}{2}\times 6\right]}_{\text{fcc unit cell}} + \underbrace{[1\times 4]}_{\text{Alternate TV's}} = 8$$

The C-atom in tetrahedral voids touches its four surrounding atoms (nearest neighbours), so the coordination number = 4.

The carbon atoms in an fcc lattice do not touch atoms at all. But C-atoms which are present in tetrahedral voids touch the surrounding four atoms. So, the centre-to-centre distance between two C-atoms is

$$2r = \frac{\sqrt{3}}{4}a,$$

where a is the length of the unit cell and r is the radius of C-atom.

Packing Efficiency (PE) of Diamond Cubic (dc)

$$\text{PE} = \frac{Z_{\text{eff}} \times \text{Volume of C-atom}}{a^3} \times 100$$

$$= \frac{8\times\frac{4}{3}\pi r^3 \times 100}{a^3}$$

$$= \frac{8\times\frac{4}{3}\pi\left(\frac{\sqrt{3}}{8}\right)^3 a^3 \times 100}{a^3} \qquad \left(\because r = \frac{\sqrt{3}a}{8}\right)$$

$$= \frac{32}{3}\pi\left(\frac{\sqrt{3}}{8}\right)^3 \times 100 = 34\%$$

Germanium, silicon, and grey tin also crystallize in the same way as diamond does.

Spinel Structures

Spinels are the compounds which have two different cations A^{2+} and B^{3+} and oxide (O^{2-}) as the anion, with the general formula $A^{2+}B_2^{3+}O_4^{2-}$.

Caution Point *Many substances of the type* $(A^{4+}B_2^{2+}O_4^{2-})$ *also have spinel-type structure.*

(a) Normal Spinel Structures

In such structures, O^{2-} anions form the fcc packing and 1/8th of tetrahedral voids are occupied by divalent metal ion A^{2+} and half of the octahedral voids are occupied by trivalent metal ions (B^{3+}).

Let Z_{eff} of O^{2-} anion in fcc packing = 1/atom

Number of tetrahedral void = 2/atom

Number of octahedral void = 1/atom

Therefore,

$$\text{Number of } A^{2+} \text{ ions} = \frac{1}{8}\times\text{tetrahedral void} = \frac{1}{8}\times 2 = \frac{1}{4}$$

$$\text{Number of } B^{3+} \text{ ions} = \frac{1}{2}\times\text{octahedral void} = \frac{1}{2}\times 1 = \frac{1}{2}$$

General formula $A^{2+}_{1/4}B^{3+}_{1/2}O^{2-}_{1}$

On simplifying, we get the formula AB_2O_4.

(b) Inverse Spinel Structures

In such structures, O^{2-} anions form the fcc packing and 1/8th of the tetrahedral voids are occupied by divalent metal ion A^{2+}. Trivalent metal ions B^{3+} are present in $\left(\frac{1}{8}\text{ th tetrahedral void} + \frac{1}{4}\text{ th octahedral void}\right)$

Let Z_{eff} of O^{2-} anion in fcc packing = 1/atom

Number of tetrahedral void = 2/atom

Number of octahedral void = 1/atom

Therefore,

$$\text{Number of } A^{2+} \text{ ions} = \frac{1}{8}\times\text{tetrahedral void} = \frac{1}{8}\times 2 = \frac{1}{4}$$

$$\text{Number of } B^{3+} \text{ ions} = \frac{1}{8}\times\text{tetrahedral void} + \frac{1}{4}\times\text{octahedral void}$$

$$= \frac{1}{8}\times 2 + \frac{1}{4}\times 1$$

$$= \frac{1}{4} + \frac{1}{4} = \frac{2}{4} = \frac{1}{2}$$

So, general formula

$$A^{2+}_{1/4}B^{3+}_{1/2}O^{2-}_{1}$$

Simplifying, formula = AB_2O_4.

Corrundum Structure

In this structure, O^{2-} anions form hcp and cations A^{3+} are present in two-third of the octahedral voids. The general formula of a compound is A_2O_3. Examples are Fe_2O_3, Al_2O_3, Cr_2O_3. From the formula, the ligancy of $(A^{3+} : O^{2-})$ in A_2O_3 is 3 : 2 or 6 : 4.

1.7 Radius Ratio Rules

The structure of many ionic solids can be accounted by considering the relative sizes of the cation and anion, and their relative numbers. By simple calculations, we can work out as how many ions of a given size can be in contact with a smaller ion. Thus, we can predict the coordination number from the relative size of the ions.

The ionic radius ratios (of cation and anion) play a very important role in giving clue to the nature of crystal structure of the ionic substance. This can be clear from the table given below

Table 1.7 **Coordination Number and Shape from Radius Ratio**

S.N.	Limiting radius ratio (r_+/r_-)	Coordination number	Shape	Structure type	Example
1.	Less than 0.225	2 or 3	Linear for 2, triangular planar for 3	same as shape	B_2O_3
2.	0.225 – 0.414	4	Tetrahedral	Sphalerite (ZnS)	CuCl, CuBr, CuI, HgS, BaS
3.	0.414 – 0.732	4 or 6	Square planar for 4 Octahedral for 6	NaCl	MgO, NaBr, CaS, MnO, KBr, CaO, AgCl
4.	0.732 or more	8	Cube	CsCl	CsI, CsBr, TlBr, NH_4Br

Sample Problem 20 *The radius of a divalent cation M^{2+} is 94 pm and that of divalent anion X^{2-} is 146 pm. Thus, $M^{2+}X^{2-}$ has*

(*a*) NaCl *structure* (*b*) *linear structure*
(*c*) CsCl *structure* (*d*) ZnS *structure*

Interpret (*a*) For $M^{2+}X^{2-}$,

$$\frac{r_+}{r_-} = \frac{94}{146} = 0.6438$$

Since, the radius ratio is in between 0.414 to 0.732, it has NaCl structure.

Sample Problem 21 *The structure of* TiCl *is similar to* CsCl. *The radius ratio in* TiCl *is*

(*a*) 0.155 – 0.225
(*b*) 0.225 – 0.414
(*c*) 0.414 – 0.732
(*d*) 0.732 – 1.000

Interpret (*d*) For CsCl structure, the radius ratio is 0.732 – 1.000. Thus, for TiCl, it is also 0.732 – 1.000

Check Point 2

1. The distance between the NaI and LiI is 0.007 nm and that between NaCl and LiCl is 0.03 nm. Suggest why there is such a small difference in internuclear distance between LiI and NaI as compared to that between LiCl and NaCl?
2. Explain in fcc arrangement, there are four atoms per unit cell.
3. Explain why the coordination number for bcc packing is 8?

1.8 Imperfections in Solids

In actual practice, it is difficult to grow a perfect crystal. Even single crystals grown with all care are found to contain many internal irregularities. These irregularities are called **crystal defects** and can be defined as *"Any departure from perfectly ordered arrangement of atoms in a crystal is called imperfection or defect"*. These imperfections not only modify the properties but also sometimes impart new properties to the solids.

If a graph is plotted between Gibb's free energy and defect concentration, Gibb's free energy has a minimum value at non-zero concentration. This shows that defect formation is a spontaneous process.

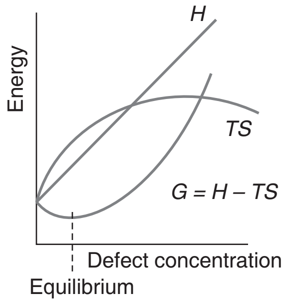


Fig. 1.30 Variation of enthalpy and entropy with defects

In an ionic crystal, the electrons are mostly concentrated around the electronegative component. Some of these electrons have the tendency of thermal release, *i.e.*, the property of losing its position on increase in temperature. These thermally released electrons become mobile resulting in increase in conductivity of solid.

When an electron is thermally removed from its position the electron deficient site thus formed is called a hole. Holes also impart electrical conductivity but their movement is opposite in direction to which the electrons move. The electrons and holes in solids give rise to **electronic imperfections.**

The defect discussed above is/are called point defects as these are found around a point or an atom. These can be categorised into following three types as stoichiometric, non-stoichiometric and impurity defects.

Hot Spot 2

STOICHIOMETRIC Defects

It is also an important topic of the chapter for JEE Main examination. The questions are generally based on Schottky and Frenkel defects.

If imperfection in crystals are such that the ratio between the cations and the anions remain the same as described in its molecular formula, the defect will be called **stoichiometric defects.** They are also called intrinsic or **thermodynamic defects.** Basically these are of two types, vacancy defects and interstitial defects.

(a) Vacancy Defect

When some of the lattice sites are vacant, the crystal is said to have vacancy defect. This results in decrease in density of the substance. This defect can also develop when a substance is heated.

(b) Interstitial Defect

When some constituent particles (atoms or molecules) occupy an **interstitial** site, the crystal is said to have interstitial defect. This defect increases the density of the substance.

Vacancy and interstitial defects as explained above can be shown by non-ionic solids. Ionic solids must always maintain electrical neutrality. Rather than simple vacancy or interstitial defects, they show these defects as **Frenkel and Schottky defects.**

(i) Schottky Defect

In an ionic crystal of A^+B^- type, if equal number of cations and anions are missing from their lattice sites, the defect is called Schottky defect. In this defect electrical neutrality is maintained due to disappearance of similar number of cations and anions (lattice vacancy). It is shown by highly ionic compounds having

(i) high coordination number

(ii) small difference in the size of cations and anions.

e.g., NaCl, KCl, KBr, CsCl, etc.

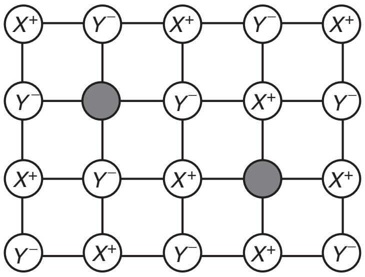

Fig. 1.31 Schottky Defect

Because of the missing of ions from the lattice, this defect results in decrease in density.

(ii) Frenkel Defect

In an ionic crystal, when an ion is missing from its lattice site (causing a hole or vacancy there) and occupies interstitial site, the defect is called Frenkel's defect. It is also called **dislocation defect.** In this defect the electrical neutrality and stoichiometry of the compound is maintained as ion does not leave the crystal completely.

This type of defect is seen in those crystals where the difference in the size of cations and anions is very large and their coordination number is low, *e.g.,* AgCl, AgBr, ZnS, etc., as Zn^{2+} and Ag^+ ions have small size. Due to such a defect the density of the solid remains unchanged because no ion is missing from the lattice.

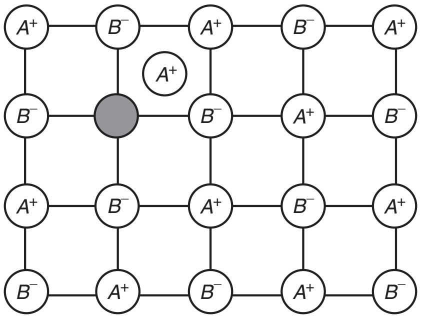

Fig. 1.32 Frenkel defect

Caution Point AgBr *is a compound in which both Schottky and Frenkel defects are found because* AgBr *is highly ionic but there is a great difference in the size of* $Ag^{\oplus}$ *and* $Br^{\ominus}$*.*

Calculation of Number of Schottky/Frenkel Defects

The number (n) of Schottky defects present in an ionic crystal containing N ions at temperature T is given by :

$$n = Ne^{-E/2KT}.$$

where, E is the energy required to create these n Schottky defects and K is the Boltzmann constant $= R/N_A$

$$= 1.38 \times 10^{23} \text{ JK}^{-1}$$

The number (n) of Frenkel defects in an ionic crystal containing N ions and N_i is the number of interstitial sites at a temperature T is given by

$$n = (N/N_i)^{1/2} e^{-E/2KT}$$

where, E is the energy required to create n Frenkel defects.

In NaCl, there are 10^{22} ions and 10^6 Schottky pairs/cm^3 at room temperature, *i.e.,* there is one Schottky pair defect per 10^{16} ions.

Non-Stoichiometric Defects

When the ratio of cations and anions, due to imperfection, differ from that indicated by their molecular formula, the defects are called non-stoichiometric defects. These defects results in either **excess of metal atom** or **excess of non-metal atom.**

(a) Metal Excess Defects

The metal excess may occur in either of the following two ways

(i) **Due to missing of a negative ion from its lattice site,** thus leaving a hole which is occupied by an electron. The electrons thus, trapped in the anion vacancies are called *F*-**centres** (*F* = *Farbe* = German word for colour) as these are responsible for imparting colour to the crystals.

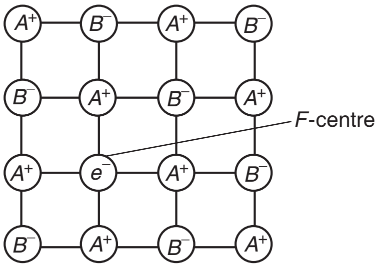

Fig. 1.33 (a) Metal excess defect due to missing of anion

e.g., NaCl when heated in Na vapour atmosphere, the excess Na atom deposit on the surface. Now, $Cl^{\ominus}$ diffuse to the surface where they combine with Na atoms which lose the electrons. The electrons diffuse into the vacant sites created. The electrons absorb some energy from the visible light and re-emit the complimentary yellow colour to NaCl crystal. Excess of Li in LiCl gives a pink colour. Excess of K in KCl make it violet.

This defect is similar to Schottky defect.

(ii) **Due to the presence of extra cations in the interstitial sites.** Here, electrical neutrality is maintained by an electron present in another interstitial site.

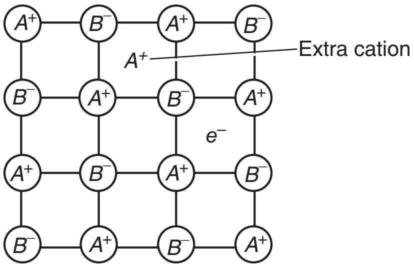

Fig. 1.33 (b) Metal excess defect due to the presence of extra cation

e.g., Zinc oxide is white in colour at room temperature. On heating it loses oxygen and turns yellow.

$$ZnO \xrightarrow{\text{heating}} Zn^{2+} + \frac{1}{2}O_2 + 2e^-$$

Now, there is excess of zinc in the crystal and its formula becomes $Zn_{1+x}O$. The excess Zn^{2+} ions move to interstitial sites and the electrons to neighbouring interstitial sites.

This defect is similar to Frenkel defect.

(b) Metal Deficiency Defect

Metal deficiency or non-metal excess occurs where the metal shows variable valency *i.e.,* transition metals. The defect usually occur due to missing of a cation from its lattice site and presence of the cation having higher charge at different lattice site thus, balancing the loss as seen above, *e.g.,* FeO, FeS, NiO, etc.

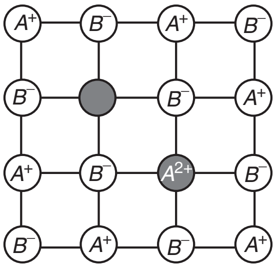

Fig. 1.34 Metal deficiency defect

FeO is mostly found with a composition of $Fe_{0.95}O$. It may actually range from $Fe_{0.93}O$ to $Fe_{0.96}O$. In crystals of FeO some Fe^{2+} cations are missing and the loss of positive charge is made up by the presence of required number of Fe^{3+} ions.

Impurity Defects

Another common method of introducing defects in ionic solids is by adding impurity ions having different charge than host ion. These foreign atoms are present at lattice site in **substitutional solids** and at vacant interstitial sites in **interstitial solids.**

Formation of substitutional solids depends upon the electronic structure of impurity while that of latter on the size of impurity.

The number (n) of defects per cm^3 is given by

$$n = N \times e^{-W/2RT}$$

where, N = number of sites per cm^3

W = work or energy required to produce a defect,
T = absolute temperature
R = gas constant, e = base of natural logarithm

If molten NaCl containing a little amount of $SrCl_2$ is crystallised, some of the sites of Na^+ ions are occupied by Sr^{2+}.

Each Sr^{2+} replaces two Na^+ ions. It occupies the site of one ion and the other site remains vacant. The cationic vacancies thus produced are equal in number to that of

Sr^{2+} ions. Another similar example is the solid solution of $CdCl_2$ and AgCl.

Sample Problem 22 *If* NaCl *is doped with* 10^{-3} *mol% of* $SrCl_2$, *calculate the concentration of cation vacancies* **[NCERT]**

(a) 6.02×10^{18} mol^{-1} (b) 6.02×10^{24} mol^{-1}
(c) 6.02×10^{20} mol^{-1} (d) 6.02×10^{16} mol^{-1}

Interpret (a) Due to addition of $SrCl_2$, each Sr^{2+} ion replaces two Na^+ ions, but occupies only one Na^+ lattice point. This makes one cationic vacancy.

Number of moles of cation vacancies in 100 mol of NaCl $= 10^{-3}$

Number of moles of cation vacancies in 1 mol $= \dfrac{10^{-3}}{100} = 10^{-5}$

Total cationic vacancies $= 10^{-5} \times N_A$

$$= 10^{-5} \times 6.023 \times 10^{23}$$

$$= 6.023 \times 10^{18} \text{ mol}^{-1}$$

Sample Problem 23 *The composition of a sample of wustite is* $Fe_{0.93}O$. *What percentage of the iron is present in the form of* Fe (III)?

(a) 84.95% (b) 45.64%
(c) 15.05% (d) 44.36%

Interpret (c) From the valency of Fe(II) and Fe(III), it is clear that three Fe(II) ions will be replaced by two Fe(III) causing a loss of one iron ion. Total loss of iron from one molecule of FeO $= 1 - 0.93 = 0.07$

Hence, total Fe(III) present in one molecule of

$$FeO = 2 \times 0.07 = 0.14$$

Total number of Fe(II) and Fe(III) present in one molecule of

$$FeO = 0.93$$

Hence, percentage of Fe(III) $= \dfrac{0.14}{0.93} \times 100 = 15.05\%$

Sample Problem 24 *Which of the following point defects are shown by* AgBr(*s*) *crystals?* **[NCERT Exemplar]**

(*A*) *Schottky defect* (*B*) *Frenkel defect*
(*C*) *Metal excess defect* (*D*) *Metal deficiency defect*

(a) (*A*) and (*B*) (b) (*C*) and (*D*)
(c) (*A*) and (*C*) (d) (*B*) and (*D*)

Interpret (a) AgBr crystal exhibits Schottky as well as Frenkel defects because it is ionic in nature and have a large difference in the size of ions.

1.9 Electrical Properties of Solids

Solids are classified into three groups on the basis of conduction power, namely

(i) **Conductors** with conductivity range of the order of $10^7 (\Omega \text{ m})^{-1}$ *e.g.,* metals.

(ii) **Semiconductors** with conductivity range $10^{-6} - 10^{-4} (\Omega \text{ m})^{-1}$ *e.g.,* semi-metals.

(iii) **Insulators** with conductivity range $10^{-10} - 10^{-20} (\Omega \text{ m})^{-1}$, *e.g.,* non-metals.

In most of the solids, conduction is through electrons, however in some ionic solids the conduction is through ions. In metals, conductivity strongly depends upon the number of valence electrons available per atom. The atomic orbitals form molecular orbitals which are so close to each other as to form a **band.**

The conductivity of solids can be better explained on the basis of energy gap present between the conduction band (just higher unoccupied band) and the valence band (Band theory).

Conductors

In conductors, the conduction band is almost overlapping with the valence band, *i.e.,* there is no energy gap present between these two bands or valence band is not completely filled. Then, electrons can flow easily under the influence of electric field, in both the cases.

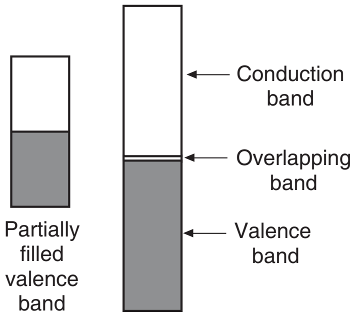

Fig. 1.35 Conductor

Semiconductors

In the case of semiconductors, the gap between valence band and conduction band is small and therefore, some of the electrons may jump from valence band to conduction band and some conductivity is observed. The conductivity here increases with increase in temperature. The reason for such an increase is lowering of energy gap as shown in the figure.

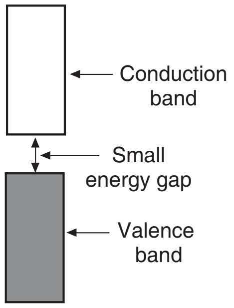

Fig. 1.36 Semiconductor

(a) Intrinsic Semiconductors

Here heat is responsible for ejection of electrons thus, leaving a (+)**ve charge** (positive hole). The crystal can now conduct electricity because on applying the electric field the electrons and holes migrate in opposite directions. This type of conductance is called intrinsic conductance and the semiconductors showing this type of conductivity are called **undoped** or **intrinsic semiconductors**, *e.g.*, Si, Ge, etc.

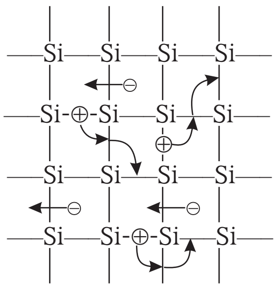

Fig. 1.37 Electrical conduction in an intrinsic semiconductor

(b) Extrinsic Semiconductor

For practical purposes the conductivity of pure Si and Ge is very low at room temperature. In order to increase their conductance, the pure substances are carefully doped (introduced with small amount of impurities in the form of elements of the 13 and 15 group of the Periodic Table). Such conductance is called **extrinsic conductance.** Depending upon the nature of the elements used for doping, the extrinsic semiconductor can be of two types, *viz*, *n*-types semiconductors and *p*-type semiconductors.

The group 15 elements have 1 electron excess to Si or Ge, after forming 4 covalent bonds with group 14 member (Si or Ge). This excess free electron is responsible for electrical conductivity in them. *Group* 14 *elements when doped with group* 15 *elements are called n-type semiconductors*. Here, *n* specifies that negative charge flows in them.

The group 13 elements have 1 electron short to group 14 elements, thus giving rise to electron deficient band or a hole. Here, such holes are responsible for electrical conductivity. Thus, *group* 14 *elements when doped with elements of group* 13 *are called p-type semiconductors*. Here, *p* specifies that conduction is through positive holes in them.

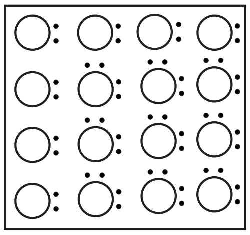

Fig. 1.38 (a) Normal silicon atom

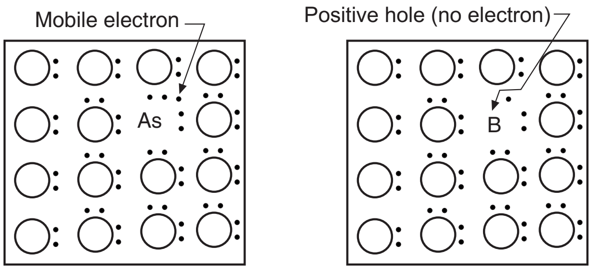

Fig. 1.38 (b) *n* and *p*-type semiconductors

Various combinations of *n*-type and *p*-type semiconductors are used to make electronic components. *e.g.,* diode is a combination of *p* and *n*-type semiconductors and used as rectifier. Transistors which are **pnp** or **npn** sandwich semiconductor, are used to detect or amplify radio or audio signals.

Germanium and silicon, group 14 elements, have a characteristic valence of four and form four bonds as in diamond. A large variety of solid state materials have been prepared by combination of groups 13 and 15 or 12 and 16 to simulate average valence of four as in Ge or Si. Typical compounds of **groups 13–15** are InSb, AlP and GaAs. Gallium arsenide (GaAs) semiconductors have very fast response and have revolutionised the design of semiconductor devices. ZnS, CdS, CdSe and HgTe are examples of **groups 12–16 compounds.** In these compounds, the bonds are not perfectly covalent and the ionic character depends on the electronegativities of the two elements.

Caution Point TiO, CrO_2 *and* ReO_3 *behave like metals. Rhenium oxide,* ReO_3 *is like metallic copper in its conductivity and appearance. Certain other oxides like* VO, VO_2, VO_3 *and* TiO_3 *show metallic or insulating properties depending on temperature*.

Insulators

In case of **insulators,** the energy gap between valence band and conduction band is so large that it cannot even covered up by supplying energy in the form of heat.

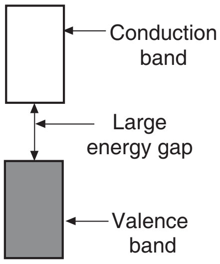

Fig.1.39 Insulators

Sample Problem 25 *To get a n-type semiconductor from silicon, it should be doped with a substance with valence ....*

[NCERT Exemplar]

(*a*) 2	(*b*) 1
(*c*) 3	(*d*) 5

Interpret (*d*) To get a *n*-type semiconductor, Si (tetravalent) should be doped with a pentavalent element (element having five valence electrons) like N, P, As, etc.

Sample Problem 26 *Which of the following oxides behaves as conductor or insulator depending upon temperature?* **[NCERT Exemplar]**

(*a*) TiO	(*b*) SiO_2
(*c*) TiO_3	(*d*) MgO

Interpret (*c*) Oxides like VO, VO_2, VO_3 and TiO_3 exhibit metallic or insulating properties depending on temperature.

1.10 Magnetic Properties of Solids

Every substance has some magnetic properties associated with it. The origin of these properties lies in the electrons. Each electron in an atom behaves like a tiny magnet. Its magnetic moment originates from two types of motions (i) its orbital motion around the nucleus and (ii) its spin around its own axis. Electron being a charged particle and undergoing these motions can be considered as a small loop of current which possesses a magnetic moment. Thus, each electron has a permanent spin and an orbital magnetic moment associated with it. Magnitude of this magnetic moment is very small and is measured in the unit called Bohr magneton, μ_B. It is equal to 9.27×10^{-24} Am^2.

Classification of Substances on the Basis of their Magnetic Properties

On this basis substances can be categorised as

(a) Diamagnetic

These are feebly repelled by magnetic field. These have the characteristic absence of unpaired electrons in them, *i.e.,* their all electrons are paired. *e.g.,* some non-metallic elements (except O_2 and S), inert gases and species with paired electrons *e.g.,* TiO_2, V_2O_5, C_6H_6, NaCl, etc.

(b) Paramagnetic

These are attracted by magnetic field due to the presence of atoms, ions or molecules with unpaired electron in them (*e.g.,* O_2, Cu^{2+}, Fe^{3+} etc). In magnetic field, these tend to orient themselves parallel to the direction of magnetic field. These are used in electronic appliances.

(c) Ferromagnetic

These substances show magnetism even in the absence of magnetic field. Fe, Co, CrO_2 and Ni are 3 elements which show ferromagnetism at room temperature. A spontaneous alignment of magnetic moments in the same direction gives rise to ferromagnetism. The ferromagnetism is not seen above a temperature, called **Curie temperature.**

(d) Antiferromagnetic

These substances have net magnetic moment zero due to compensatory alignment of magnetic moments. *e.g.,* MnO, MnO_2, FeO, NiO, Cr_2O_3, etc.

(e) Ferrimagnetic

They have a net dipole moment due to unequal parallel and antiparallel alignment of magnetic moments. *e.g.,* Fe_3O_4, ferrites of the formula $M^{2+}Fe_2O_4$, where, M = Mg, Cu, Zn, etc.

Caution Point *All ferroelectric crystals are piezoelectric but reverse is not true.*

The details of the above magnetic properties are summarised in the following table.

Table 1.8 **Magnetic Properties of Solids**

S.N.	Properties	Description	Alignment of magnetic dipoles	Examples	Application
1.	Diamagnetic	Feebly repelled by the magnetic fields. Non-metallic elements (except O_2,S) inert gases and species with paired electrons are diamagnetic.	All paired electrons ↑↓ ↑↓ ↑↓	TiO_2, V_2O_5, NaCl, C_6H_6 (benzene)	Insulator
2.	Paramagnetic	Attracted by the magnetic field due to the presence of permanent magnetic dipoles (unpaired electrons). In magnetic field, these tend to orient themselves parallel to the direction of the field and thus, produce magnetism in the substances.	↑↓ ↑ ↑ At least one unpaired electron	O_2, Cu^{2+}, Fe^{3+}, TiO, Ti_2O_3, VO, VO_2, CuO	Electronic appliances
3.	Ferromagnetic	Permanent magnetism even in the absence of magnetic field. Above a temperature, called **Curie temperature,** there is no ferromagnetism.	Dipoles are aligned in the same direction ↑ ↑ ↑ ↑ ↑	Fe, Ni, Co, CrO_2	CrO_2 is used in audio and video tapes
4.	Antiferromagnetic	This arises when net dipole alignment is zero due to equal and opposite alignment.	↑ ↓ ↑ ↓ ↑ ↓	MnO, MnO_2, Mn_2O_3, FeO, Fe_2O_3; NiO, Cr_2O_3, CoO, Co_3O_4	—
5.	Ferrimagnetic	This arises when there is net dipole moment.	↑ ↓ ↓ ↓ ↑ ↓	Fe_3O_4, ferrites	—

Effect of temperature on the magnetic properties is shown by the following graphs

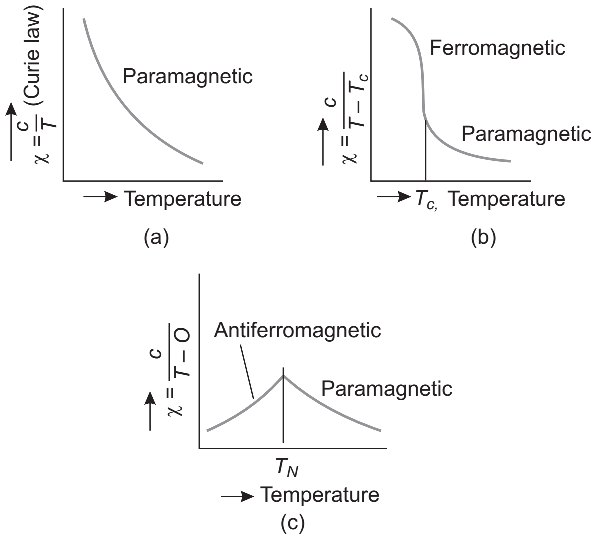

Fig. 1.40 Graphs showing effect of temperature on magnetic properties

1.11 Dielectric Properties of Solids

The dielectric properties are seen in insulators, which, when are placed in an electric field, show generation of dipoles in them due to the pulling of electrons and nuclei of atoms or molecules in opposite directions. These dipoles,

(i) may align themselves in an ordered manner so that there is a net dipole moment in the crystal.

(ii) may align themselves in such a manner that dipole moments may cancel each other.

(iii) It is also possible that there are no dipoles in the crystal but only ions are present.

The crystals where situation (i) is found exhibit **peizoelectricity** or **pressure electricity,** which is the production of electricity by a polar crystal when mechanical stress is applied to it.

Peizoelectric crystals also show development of mechanical stress when electric field is applied to them, thus acting as a mechanical-electrical transducer.

1. Peizoelectric crystals with permanent dipoles are said to have **ferroelectricity** *e.g.*, Rochelle's salt, $BaTiO_3$, KH_2PO_4 etc.
2. Peizoelectric crystals with zero dipole moment have **antiferroelectricity.**
3. Some peizoelectric crystals, when heated produce small electric potential or **pyroelectricity.**

The phenomenon where electricity passes through a material without resistance is called **superconductivity.** The material showing this property is said to be **superconductor.** It was **Kammerlingh Onnes** of Netherlands who first reported the case of Hg as superconductor at a very low temperature of 4.2 K. Afterwards, some metal alloys and certain organic solids have been reported to be superconducting but at very low temperatures. Now a days, superconductors are also reported at comparatively higher temperatures. *e.g.,* : $YBa_2Cu_3O_7$ at 90 K, $Bi_2Ca_2Sr_2Cu_3O_{10}$ at 105 K, and $Tl_2Ca_2Ba_2Cu_3O_{10}$ at 125 K, etc.

Check Point 3

1. Explain why does Schottky defect lower the density of related solids?
2. Frenkel defects are not found in alkali metal halides. Explain why?
3. Impurity doped silicon is a semiconductor. Explain.
4. Which type of defect can arise when a solid is heated?

WORKED OUT Examples

Example 1 *How many number of atoms are there in a cube based unit cell having one atom on each corner and two atoms on each body diagonal of cube?*

(*a*) 4 (*b*) 9 (*c*) 12 (*d*) 14

Solution (*b*) There are four body diagonals. Atoms on the body diagonals are not shared by any other unit cell. Contribution by atoms on corners $= 8 \times \frac{1}{8} = 1$

and contribution by atoms on body diagonal $= 2 \times 4 = 8$

Total number of atoms $= 8 + 1 = 9$

Example 2 *The first order reflection of a beam of X-ray from a given crystal occurs at 5°15′. At what angle will the third-order reflection occur?*

(*a*) 15°55.9′ (*b*) 18°48.9′

(*c*) 20°55.2′ (*d*) None of these

Solution (*a*)

$$n_1\lambda = 2d \sin\theta_1$$

$$n_2\lambda = 2d \sin\theta_2$$

$$\frac{n_1}{n_2} = \frac{\sin\theta_1}{\sin\theta_2}$$

$$\frac{1}{3} = \frac{\sin 5°15'}{\sin\theta_2}$$

$$\therefore \quad \theta_2 = 15°\,55.9'$$

Example 3 *A solid AB has the* NaCl *structure. If radius of cation A^+ is* 120 pm, *the maximum possible value of the radius of the anion B^- is*

(*a*) *240 pm* (*b*) *60 pm* (*c*) *49.6 pm* (*d*) *290 pm*

Solution (*d*) For NaCl crystal,

Radius of cation/radius of anion = 0.414

$$\frac{r_{A^+}}{r_{B^-}} = 0.414$$

$$r_{B^-} = \frac{r_{A^+}}{0.414} = \frac{120}{0.414} = 290 \text{ pm}$$

Example 4 CsCl *crystallises in a cubic lattice that has a* Cl^- *at each corner and* Cs^+ *at the centre of the unit cell. If* $(r_{Cs^+}) = 1.69\,Å$ *and* $(r_{Cl^-}) = 1.81\,Å$, *what is the value of edge length a of the cube?*

(*a*) 4.04 (*b*) 3.50 (*c*) 3.03 (*d*) 1.95

Solution (*a*) The closest Cs^+ to Cl^- distance = sum of ionic radii of Cs^+ and Cl^-

$= 1.69 + 1.81$

$= 3.50$ Å

The distance in one-half of the cubic diagonal $= \frac{a\sqrt{3}}{2}$

$$\frac{a\sqrt{3}}{2} = 3.50 \text{ Å}$$

$$a = 4.04 \text{ Å}$$

Example 5 KCl *crystallises in the same type of lattice as does* NaCl. *Given,* $\frac{r_{Na^+}}{r_{Cl^-}} = 0.5$ *and* $\frac{r_{Na^+}}{r_{K^+}} = 0.7$

The ratio of the side of the unit cell for NaCl *to that for* KCl *is*

(*a*) 1:1.172 (*b*) 1 : 1.143

(*c*) 1 : 1.1413 (*d*) 1 : 1.732

Solution (*b*) NaCl crystallises in the face centred cubic unit cell such that

$$r_{Na^+} + r_{Cl^-} = \frac{a}{2}$$

Given, $\frac{r_{Na^+}}{r_{Cl^-}} = 0.5, \quad \frac{r_{Na^+}}{r_{K^+}} = 0.7$

Thus, we have, $\frac{r_{Na^+} + r_{Cl^-}}{r_{Cl^-}} = 1.5$

$$\frac{r_{K^+}}{r_{Cl^-}} = \frac{r_{K^+}}{r_{Na^+}/0.5} = \frac{0.5}{r_{Na^+}/r_{K^+}} = \frac{0.5}{0.7}$$

Therefore, $\frac{r_{K^+} + r_{Cl^-}}{r_{Na^+} + r_{Cl^-}} = \frac{1.2}{0.7} \times \frac{1}{1.5}$

$$\therefore \quad \frac{a_{KCl/2}}{a_{NaCl/2}} = \frac{1.2}{0.7 \times 1.5} = \frac{a_{KCl}}{a_{NaCl}} = 1.143$$

or $\frac{a_{NaCl}}{a_{KCl}} = 1 : 1.143$

Example 6 *Edge length of M^+X^- (fcc structure) is 7.2 Å. Assuming $M^+ - X^-$ contact along the cell edge, radius of X^- ion is (r_{M^+} = 1.6 Å)*

(*a*) 2.0 Å (*b*) 5.6 Å

(*c*) 2.8 Å (*d*) 3.8 Å

Solution (*a*)
$$2(r_{M^+} + r_{X^-}) = 7.2$$
$$2(1.6 + r_{X^-}) = 7.2$$
$$\therefore \qquad r_{X^-} = 2.0\ \text{Å}$$

Example 7 *Gold (at. wt. 197 g mol^{-1}) crystallises in a cubic closest packed structures (the face-centred cubic) and has a density of 19.3 g/cm^3. Its atomic radius is*

(*a*) 144.17 pm (*b*) 407.8 pm
(*c*) 128.32 pm (*d*) 203.4 pm

Solution (*a*) Density $d = \dfrac{MZ}{a^3 N_A}$
$$a = \sqrt[3]{\frac{197 \times 4}{6.023 \times 10^{23} \times 19.3}}$$
$$a = 407.8 \times 10^{-10}\ \text{cm} = 407.8\ \text{pm}$$
$$r = \frac{407.8}{\sqrt{8}} = 144.18\ \text{pm}$$

Example 8 *Calcium metal crystallises in fcc lattice with edge length 556 pm. Calculate the density (in g cm^{-3}) of metal if it contains 0.2% Schottky defects.*

(*a*) 3.992 (*b*) 1.5455 (*c*) 1.5427 (*d*) 1.4987

Solution (*c*) Due to 0.2% Schottky defect, number of atoms
$$= 4 - \frac{0.2}{100} \times 4 = 3.992$$
$$d = \frac{Z \times M}{a^3 \times N_A} = \frac{40 \times 3.992}{(0.556 \times 10^{-7})^3 \times 6.023 \times 10^{23}}$$
$$= 1.5427\ \text{g cm}^{-3}$$

Example 9 *An element occurs in two crystalline forms α and β. The α-form has an fcc with $a = 3.68$ Å and β- form has a bcc with $a = 2.92$ Å. Calculate the ratio of their densities.*

(*a*) 1 : 1 (*b*) 1 : 2 (*c*) 2 : 1 (*d*) 2 : 3

Solution (*a*) Z_{eff} for fcc = 4, Z_{eff} for bcc = 2
$$\text{Atomic volume of } \alpha\text{-form} = \frac{(3.68 \times 10^{-8})^3 \times N_A}{4}$$
$$\text{Atomic volume of } \beta\text{-form} = \frac{(2.92 \times 10^{-8})^3 \times N_A}{2}$$
(As *Aw* is same, element is same), so the density ratio is
$$\rho_\alpha : \rho_\beta = V_\beta : V_\alpha = \frac{(2.92)^3}{2} : \frac{(3.68)^3}{4}$$
$$= 12.448 : 12.459 = 1 : 1$$

Example 10 *A compound forms hexagonal close-packed structure. What is the total number of voids in 0.5 mole of it?*

(*a*) 3.011×10^{23} (*b*) 6.022×10^{23}
(*c*) 9.033×10^{23} (*d*) 1.802×10^{24}

Solution (*c*) To find total number of voids, we have to calculate the number of octahedral and tetrahedral voids which depend upon the number of atoms in 0.5 mole (*N*), so first calculate the number of atoms in 0.5 mole and then find number of octahedral voids (= *N*),

Number of tetrahedral voids (= 2 *N*) and total voids.

Total number of atoms (*N*) in a closed packed structure (0.5 mol)
$$= 0.5 \times 6.022 \times 10^{23}$$
$$= 3.011 \times 10^{23}$$
Number of octahedral voids $= N = 3.011 \times 10^{23}$

Number of tetrahedral voids $= 2N = 2 \times 3.011 \times 10^{23}$
$$= 6.022 \times 10^{23}$$
$$\text{Total number of voids} = 3.011 \times 10^{23} + 6.022 \times 10^{23}$$
$$= 9.033 \times 10^{23}$$

Start **Practice** *for* JEE Main

Round I (Topically Divided Problems)

Solids and their Classification

1. Which of the following conditions favours the existence of a substance in the solid state? **[NCERT** Exemplar]

(a) High temperature
(b) Low temperature
(c) High thermal energy
(d) Weak cohesive forces

2. Why are solids rigid? **[NCERT]**

(a) Because of large intermolecular forces
(b) Because of vibrating motion
(c) Because of large intermolecular space
(d) All of the above

3. Which of the following is an amorphous solid? **[NCERT** Exemplar]

(a) Graphite (C) (b) Quartz glass (SiO_2)
(c) Chrome alum (d) Silicon carbide (SiC)

4. Which of the following statement is not true about amorphous solids? **[NCERT** Exemplar]

(a) On heating they may become crystalline at certain temperature
(b) They may become crystalline on keeping for long time
(c) Amorphous solids can be moulded by heating
(d) They are anisotropic in nature

5. Which of the following is not a characteristic of a crystalline solid? **[NCERT** Exemplar]

(a) Definite and characteristic heat of fusion
(b) Isotropic nature
(c) A regular periodically repeated pattern of arrangement of constituent particles in the entire crystal
(d) A true solid

6. Which among the following will show anisotropy?

(a) Glass (b) Plastic
(c) Barium chloride (d) Wood

7. Which type of solid crystals will conduct heat and electricity?

(a) Ionic (b) Covalent
(c) Molecular (d) Metallic

8. Solid carbon dioxide is an example of

(a) metallic crystal (b) covalent crystal
(c) molecular crystal (d) ionic crystal

9. Which of the following is not the characteristic of ionic solids? **[NCERT** Exemplar]

(a) Very low value of electrical conductivity in the molten state
(b) Brittle nature
(c) Very strong forces of interactions
(d) Anisotropic nature

10. Which of the following is a network solid? **[NCERT** Exemplar]

(a) SO_2 (Solid) (b) I_2
(c) Diamond (d) H_2O (Ice)

11. Graphite is a good conductor of electricity due to the presence of …… . **[NCERT** Exemplar]

(a) lone pair of electrons (b) free valence electrons
(c) cations (d) anions

Crystal Lattice, Unit Cells and their Parameters

12. How many space lattices are obtainable from the different crystal systems?

(a) 7 (b) 14
(c) 32 (d) 230

13. Monoclinic crystal has dimension

(a) $a \neq b \neq c, \alpha = \gamma = 90^\circ, \beta \neq 90^\circ$
(b) $a = b = c, \alpha = \beta = \gamma = 90^\circ$
(c) $a = b = c, \alpha = \beta = 90^\circ, \gamma = 120^\circ$
(d) $a \neq b = c, \alpha = \beta = \gamma = 120^\circ$

14. The most unsymmetrical crystal system is

(a) hexagonal (b) triclinic

(c) cubic (d) orthorhombic

15. How much portion of an atom located at corner and body centre of a cubic unit cell is part of its neighbouring unit cell respectively? **[NCERT]**

(a) $1, \frac{1}{2}$ (b) $\frac{1}{2}, 1$

(c) $\frac{1}{8}, 1$ (d) $\frac{1}{8}, \frac{1}{2}$

16. The edge lengths (a) of the unit cells in terms of the radius of spheres constituting fcc, bcc and simple cubic unit cell are respectively …… . **[NCERT Exemplar]**

(a) $2\sqrt{2}r, \frac{4r}{\sqrt{3}}, 2r$ (b) $\frac{4r}{\sqrt{3}}, 2\sqrt{2}r, 2r$

(c) $2r, 2\sqrt{2}r, \frac{4r}{\sqrt{3}}$ (d) $2r, \frac{4r}{\sqrt{3}}, 2\sqrt{2}r$

17. If the distance between Na^+ and Cl^- ions in NaCl crystal is 'a' pm what is the length of the cell edge?

(a) $4a$ pm (b) $\frac{a}{4}$ pm

(c) $2a$ pm (d) $\frac{a}{2}$ pm

18. Gold (atomic radius $= 0.144$ nm) crystallises in a face-centred unit cell. What is the length of a side of the cell? **[NCERT Exemplar]**

(a) 0.414 (b) 0.407

(c) 1.414 (d) 1.407

19. The edge of unit cell of fcc Xe crystal is 620 pm. The radius of Xe atom is

(a) 189.37 pm (b) 209.87 pm

(c) 219.25 pm (d) 235.16 pm

20. Calculate the ionic radius of a Cs^+ ion, assuming that the cell edge length for CsCl is 0.4123 nm and that the ionic radius of a Cl^- ion is 0.181 nm.

(a) 0.352 nm (b) 0.116 nm

(c) 0.231 nm (d) 0.176 nm

21. An fcc lattice has a lattice parameter $a = 400$ pm. Calculate the molar volume of the lattice including all the empty space.

(a) 7.6 mL (b) 6.5 mL

(c) 10.8 mL (d) 9.6 mL

22. A metal has bcc structure and the edge length of its unit cell is 3.04 Å. The volume of the unit cell in cm^3 will be

(a) 1.6×10^{21} cm^3 (b) 2.81×10^{-23} cm^3

(c) 6.02×10^{-23} cm^3 (d) 6.6×10^{-24} cm^3

23. Aluminium crystallises in a cubic close-packed structure. Its metallic radius is 125 pm. How many unit cells are there in 1.00 cm^3 of aluminium? **[NCERT Exemplar]**

(a) 4.42×10^{22} (b) 2.36×10^{21}

(c) 2.26×10^{22} (d) 3.92×10^{18}

24. A compound is formed by elements A and B. This crystallises in the cubic structure when atoms A are at the corners of the cube and atoms B are at the centre of the body. The simplest formula of the compound is

(a) AB (b) AB_2

(c) A_2B (d) AB_4

25. X-ray analysis shows that the unit cell length in NaCl is 562.8 pm. Calculate the density you would expect on this basis, $N_A = 6.023 \times 10^{23}$ mol^{-1}.

(a) 0.3216 g cm^{-3} (b) 2.179 g cm^{-3}

(c) 1.859 g cm^{-3} (d) 2.346 g cm^{-3}

Packing in Solids and Bragg's Law

26. For a given crystal, the lattice parameter 'a' is 318 pm. The d-spacing for a (III) plane is

(a) 318 pm (b) 184 pm

(c) 390 pm (d) 225 pm

27. The vacant space in the bcc unit cell is

(a) 23% (b) 26%

(c) 32% (d) None of these

28. The correct order of the packing efficiency in different types of unit cells is **[NCERT Exemplar]**

(a) fcc < bcc < simple cubic

(b) fcc > bcc > simple cubic

(c) fcc < bcc > simple cubic

(d) bcc < fcc > simple cubic

29. What is the coordination number in a square close packed structure in two dimensions? **[NCERT Exemplar]**

(a) 2 (b) 3

(c) 4 (d) 6

30. The arrangement ABC, ABC, ABC …… is referred as

(a) cubic close packing

(b) tetrahedral close packing

(c) octahedral close packing

(d) hexagonal close packing

31. The coordination number of atoms in a cubic-packed structure and in a body-centred cubic structure respectively is **[NCERT Exemplar]**

(a) 6, 8 (b) 8, 6

(c) 12, 6 (d) 12, 8

32. The number of octahedral sites per sphere in a fcc structure is
(a) 1
(b) 2
(c) 4
(d) 8

33. Which of the following statement is not true about the hexagonal close packing? **[NCERT** Exemplar**]**
(a) The coordination number is 12
(b) It has 74% packing efficiency
(c) Tetrahedral voids of the second layer are covered by the spheres of the third layer
(d) In this arrangement spheres of the fourth layer are exactly aligned with those of the first layer

34. A solid is made of two elements X and Z. The atoms Z are in ccp arrangement while the atom X occupy all the tetrahedral sites. What is the formula of the compound?
(a) XZ
(b) XZ_2
(c) X_2Z
(d) X_2Z_3

35. An alloy of Cu, Ag and Au is found to have Cu forming the simple cubic close packed lattice. If the Ag atoms occupy the face centres and Au is present at the body centre, the formula of the alloy will be
(a) Cu_4Ag_4Au
(b) $CuAg_3Au$
(c) CuAgCu
(d) Cu_4Ag_2Au

36. Bragg's law is given by the equation
(a) $n\lambda = 2\,\theta \sin\theta$
(b) $n\lambda = 2d \sin\theta$
(c) $2n\lambda = d \sin\theta$
(d) $n\frac{\theta}{2} = \frac{d}{2} \sin\theta$

37. The number of equidistance oppositely charged ions in a sodium chloride crystal is
(a) 2
(b) 4
(c) 6
(d) 8

38. In which of the following crystals alternate tetrahedral voids are occupied?
(a) NaCl
(b) CaF_2
(c) Na_2O
(d) ZnS

39. Which of the following statements is not true about NaCl structure?
(a) Cl^- ions are in fcc arrangement
(b) Na^+ ions has coordination number 4
(c) Cl^- ions has coordination number 6
(d) Each cell contains 4 NaCl molecules

40. The structure of Na_2O crystal is
(a) NaCl type
(b) CsCl type
(c) ZnS type
(d) antifluorite type

41. In A^+B^- ionic compound, radii of A^+ and B^- ions are 180 pm and 187 pm respectively. The crystal structure of this compound will be
(a) NaCl type
(b) CsCl type
(c) ZnS type
(d) similar to diamond

42. In the calcium fluoride structure, the coordination number of the cation and anion are respectively
(a) 4, 4
(b) 6, 6
(c) 4, 8
(d) 8, 4

43. Iron oxide crystallises in a hexagonal close-packed array of oxide ions with two out of every three octahedral holes occupied by iron ions. Derive the formula of the iron oxide. **[NCERT** Exemplar**]**
(a) FeO
(b) Fe_2O_3
(c) Fe_3O_4
(d) All are possible

44. Potassium fluoride has NaCl type structure. What is the distance between K^+ and F^- ions if cell edge is a cm?
(a) $\frac{a}{2}$ cm
(b) $\frac{a}{4}$ cm
(c) $2a$ cm
(d) $4a$ cm

45. For cubic coordination, the value of radius ratio is
(a) 0.000 – 0.225
(b) 0.225 – 0.414
(c) 0.414 – 0.732
(d) 0.732 – 1.000

46. If the radius ratio is in the range of 0.414 – 0.732, then the coordination number will be
(a) 2
(b) 4
(c) 6
(d) 8

47. The maximum radius of sphere that can be fitted in the octahedral hole of cubical closed packing of sphere of radius r is
(a) $0.732\,r$
(b) $0.414\,r$
(c) $0.225\,r$
(d) $0.155\,r$

48. The ratio of cationic radius to anionic radius in an ionic crystal is greater than 0.732. Its coordination number is
(a) 1
(b) 4
(c) 6
(d) 8

49. If the value of ionic radius ratio $\left(\frac{r_c}{r_a}\right)$ is 0.52 in an ionic compound, the geometrical arrangement of ions in crystal is
(a) planar
(b) pyramidal
(c) tetrahedral
(d) octahedral

Imperfections in Solids

50. Which defect causes decrease in the density of crystal?
(a) Frenkel
(b) Schottky
(c) Interstitial
(d) F-centre

51. Schottky defect is observed in crystals when **[NCERT Exemplar]**

(a) some cations move from their lattice site to interstitial sites
(b) equal number of cations and anions are missing from the lattice
(c) some lattice sites are occupied by electrons
(d) some impurity is present in the lattice

52. Which of the following defects is also known as dislocation defect? **[NCERT Exemplar]**

(a) Frenkel defect
(b) Schottky defect
(c) Non-stoichiometric defect
(d) None of the above

53. Which one of the following has Frenkel defect?

(a) NaCl (b) AgBr
(c) Graphite (d) Diamond

54. Cations are present in the interstitial sites in **[NCERT Exemplar]**

(a) Frenkel defect (b) Schottky defect
(c) Vacancy defect (d) Metal deficiency defect

55. Which kind of defects are introduced by doping? **[NCERT Exemplar]**

(a) Dislocation defect (b) Schottky defect
(c) Frenkel defects (d) Electronic defects

56. The correct statement regarding *F*-centre is

(a) electron are held in the voids of crystals
(b) *F*-centre produces colour to the crystals
(c) conductivity of the crystal increases due to *F*-centre
(d) All of the above

57. What type of defect can arise when a solid is heated? **[NCERT Exemplar]**

(a) Interstitial defect (b) Vacancy defect
(c) Impurity defect (d) None of these

58. The flame colours of metal ions are due to

(a) Schottky defect (b) Frenkel defect
(c) metal excess defect (d) metal deficiency defect

59. An example of a non-stoichiometric compound is

(a) PbO (b) NiO_2
(c) Al_2O_3 (d) Fe_3O_4

60. In AgBr crystal, the ion size lies in the order $\text{Ag}^+ << \text{Br}^-$. The AgBr crystal should have the following characteristics

(a) defect less (perfect) crystal
(b) Schottky defect
(c) Frenkel defect
(d) Both Schottky and Frenkel defect

Properties of Solids

61. Silicon doped with electron-rich impurity forms **[NCERT Exemplar]**

(a) *p*-type semiconductor
(b) *n*-type semiconductor
(c) intrinsic semiconductor
(d) insulator

62. Which of the following is true about the charge acquired by *p*-type semiconductors? **[NCERT Exemplar]**

(a) Positive
(b) Neutral
(c) Negative
(d) Depends on concentration of *p* impurity

63. A ferromagnetic substance becomes a permanent magnet when it is placed in a magnetic field because **[NCERT Exemplar]**

(a) all the domains get oriented in the direction of magnetic field
(b) all the domains get oriented in the direction opposite to the direction of magnetic field
(c) domains get oriented randomly
(d) domains are not affected by magnetic field

64. Which of the following arrangements shows schematic alignment of magnetic moments of antiferromagnetic substances? **[NCERT Exemplar]**

(a) ↑ ↑ ↑ ↑ ↑ ↑
(b) ↓ ↓ ↓ ↓ ↓ ↓
(c) ↑ ↑ ↓ ↑ ↑ ↓
(d) ↑ ↓ ↑ ↓ ↑ ↓

65. Which of the following statements is not true? **[NCERT Exemplar]**

(a) Paramagnetic substances are weakly attracted by magnetic field
(b) Ferromagnetic substances cannot be magnetised permanently
(c) The domains in antiferromagnetic substances are oppositely oriented with respect to each other
(d) Pairing of electrons cancels their magnetic moment in the diamagnetic substances

66. Which of the following is ferroelectric compound?

(a) $BaTiO_3$ (b) Pb_2O_3
(c) $PbZrO_3$ (d) $K_4[Fe(CN)_6]$

67. Which one of the following metal oxides is antiferromagnetic in nature?

(a) MnO_2 (b) VO_2
(c) TiO_2 (d) CrO_2

68. Which of the following oxides shows electrical properties like metals? **[NCERT Exemplar]**
(a) SiO_2 (b) MgO
(c) $SO_2(s)$ (d) CrO_2

69. Piezoelectric crystals are used in
(a) TV (b) radio
(c) freeze (d) record player

70. Which of the following represents correct order of conductivity in solids? **[NCERT Exemplar]**
(a) $\kappa_{\text{metals}} >> \kappa_{\text{insulators}} < \kappa_{\text{semiconductors}}$
(b) $\kappa_{\text{metals}} << \kappa_{\text{insulators}} < \kappa_{\text{semiconductors}}$
(c) $\kappa_{\text{metals}} ; \kappa_{\text{semiconductors}} > \kappa_{\text{insulators}} = \text{zero}$
(d) $\kappa_{\text{metals}} < \kappa_{\text{seminconductors}} > \kappa_{\text{insulators}} \neq \text{zero}$

Round II (Mixed Bag)

Only One Correct Option

1. Amorphous substances show
(i) short and long range order
(ii) short range order
(iii) long range order
(iv) have no sharp melting point
(a) (i) and (iii) are correct
(b) (i) and (ii) are correct
(c) (ii) and (iii) are correct
(d) (ii) and (iv) are correct

2. The following is not a function of an impurity present in a crystal
(a) establishing thermal equilibrium
(b) having tendency to diffuse
(c) contributing to scattering
(d) introducing new electronic energy levels

3. The incorrect statement in the following is
(a) the ionic crystal of AgBr has Schottky defect
(b) the coordination number of Na^+ ion in NaCl is 4
(c) in ionic compounds having Frenkel defect, the ratio $\frac{r_+}{r_-}$ is high
(d) the unit cell having crystal parameters, $a = b \neq c$, $\alpha = \beta = 90°$, $\gamma = 120°$ is hexagonal

4. The number of atoms in 100 g of an fcc crystal with density, $d = 10 \text{ g/cm}^3$ and cell edge equal to 100 pm, is equal to
(a) 1×10^{25} (b) 2×10^{25}
(c) 3×10^{25} (d) 4×10^{25}

5. The pyknometric density of sodium chloride crystal is $2.165 \times 10^3 \text{ kg m}^{-3}$, while its X-rays density is $2.178 \times 10^3 \text{ kg m}^{-3}$. The fraction of unoccupied sites in sodium chloride crystal is
(a) 5.96 (b) 5.96×10^{-1}
(c) 5.96×10^{-2} (d) 5.96×10^{-3}

6. When a certain crystal was studied by the Bragg technique using X-rays of wavelength 229 pm, an X-ray reflection was observed at an angle of 23° 20′. What is the corresponding interplanar spacing? $[\sin(23°20') = 0.396]$
(a) 375.6 pm (b) 256.5 pm
(c) 289.2 pm (d) 315.4 pm

7. An element occurring in the bcc structure has 12.08×10^{23} unit cells. The total number of atoms of the element in these cells will be
(a) 6.04×10^{23} (b) 12.08×10^{23}
(c) 24.16×10^{23} (d) 36.18×10^{23}

8. In a solid '*AB*' having the NaCl structure, '*A*' atoms occupy the corners of the cubic unit cell. If all the face-centred atoms along one of the axes are removed then the resultant stoichiometry of the solid is
(a) AB_2 (b) A_2B
(c) A_3B_4 (d) A_4B_3

9. The number of unit cells in 58.5 g of NaCl is nearly
(a) 0.5×10^{24} (b) 1.5×10^{23}
(c) 3×10^{22} (d) 6×10^{20}

10. Ferrous oxide has a cubic structure and each edge of the unit cell is 5.0 Å. Assuming density of the oxide as 4.0 g cm^{-3} the number of Fe^{2+} and O^{2-} ions present in each unit cell will be
(a) two Fe^{2+} and four O^{2-}
(b) three Fe^{2+} and three O^{2-}
(c) four Fe^{2+} and two O^{2-}
(d) four Fe^{2+} and four O^{2-}

11. A solid has a structure in which 'W' atoms are located at the corners of a cubic lattice 'O' atoms at the centre of edges and Na atoms at the centre of the cube. The formula for the compound is
(a) Na_2WO_3 (b) Na_2WO_2
(c) $NaWO_2$ (d) $NaWO_3$

12. A metallic element has a cubic lattice. Each edge of the unit cell is 2 Å. The density of the metal is 2 g cm^{-3}. The unit cells in 200 g of the metal are

(a) 1×10^{25} (b) 1×10^{24}

(c) 1×10^{22} (d) 1×10^{20}

13. If the pressure on a NaCl structure is increased, then its coordination number will

(a) increase (b) decrease

(c) either (a) or (b) (d) remain the same

14. In orthorhombic lattice, the value of a, b and c are respectively 4.2 Å, 8.6 Å and 8.3 Å. Given the molecular mass of the solute is 155 g mol^{-1} and its density is 3.3 g/cc, the number of formula units per unit cell is

(a) 2 (b) 3

(c) 4 (d) 6

15. Analysis shows that nickel oxide has the formula $Ni_{0.98}O_{1.00}$. What fraction of nickel exist as Ni^{2+}? **[NCERT Exemplar]**

(a) 4% (b) 95%

(c) 98% (d) 90%

16. A sample of ferrous oxide has actual formula $Fe_{0.93}O_{4.00}$. What type of non-stoichiometric defect is present in this sample? **[NCERT Exemplar]**

(a) Schottky defect

(b) Frenkel defect

(c) Metal deficiency defect

(d) Metal excess defect

17. Match the type of packing given in Column I with the items given in Column II.

Column I	Column II
A. Square close packing in two dimensions	1. Triangular voids
B. Hexagonal close packing in two dimensions	2. Pattern of spheres is repeated in every fourth layer
C. Hexagonal close packing in three dimensions	3. Coordination number 4
D. Cubic close packing in three dimensions	4. Pattern of sphere is repeated in alternate layers

[NCERT Exemplar]

Codes

	A	B	C	D
(a)	3	1	4	2
(b)	1	2	3	4
(c)	3	2	1	4
(d)	4	3	2	1

18. Match the items given in Column I with the items given in Column II.

Column I	Column II
A. Mg in solid state	1. *p*-type semiconductor
B. $MgCl_2$ in molten state	2. *n*-type semiconductor
C. Silicon with phosphorus	3. Electrolytic conductors
D. Germanium with boron	4. Electronic conductors

[NCERT Exemplar]

Codes

	A	B	C	D		A	B	C	D
(a)	4	3	2	1	(b)	4	3	1	2
(c)	3	4	2	1	(d)	3	4	1	2

19. Match the type of unit cell given in Column I with the features given in Column II.

Column I	Column II
A. Primitive cubic unit cell	1. Each of the three perpendicular edges compulsorily have the different edge length, *i.e.*, $a \neq b \neq c$.
B. Body centred cubic unit cell	2. Number of atoms per unit cell is one.
C. Face centred cubic unit cell	3. Each of the three perpendicular edges compulsorily have the same edge length, *i.e.*, $a = b = c$
D. End centred orthorhombic unit cell	4. In addition to the contribution from the corner atoms the number of atoms present in a unit cell is one.
	5. In addition to the contribution from the corner atoms the number of atoms present in a unit cell is three.

[NCERT Exemplar]

Codes

	A	B	C	D		A	B	C	D
(a)	1	3	2	5	(b)	2	4	3	1
(c)	2	4	5	1	(d)	1	2	3	5

More than One Correct Option

20. An excess of potassium ions makes KCl crystals to appear violet or lilac in colour since **[NCERT Exemplar]**

(a) some of the anionic sites are occupied by an unpaired electron

(b) some of the anionic sites are occupied by a pair of electrons

(c) there are vacancies at some anionic sites

(d) *F*-centres are created which impart colour to the crystals

21. Under the influence of electric field, which of the following statements is true about the movement of electrons and holes in a p-type semiconductor? **[NCERT** Exemplar**]**

(a) Electron will move towards the positively charged plate through electron holes
(b) Holes will appear to be moving towards the negatively charged plate
(c) Both electrons and holes appear to move towards the positively charged plate
(d) Movement of electrons is not related to the movement of holes

22. For the spinel structure ($MgAl_2O_4$), the correct statement is/are

(a) 50% octahedral voids are occupied by ions
(b) Al^{3+} is equally distributed in tetrahedral voids and octahedral voids
(c) oxide ions occupy ccp lattice
(d) 12.5% tetrahedral voids are occupied by ions

23. For which of the following cases, answer is 4?

(a) Coordination number of Zn^{2+} in zinc blende
(b) Number of body diagonal planes in a cube
(c) Formula units in rock salt structure
(d) Formula units in CsCl structure

24. Which of the following statements are true about metals? **[NCERT** Exemplar**]**

(a) Valence band overlaps with conduction band
(b) The gap between valence band and conduction band is negligible
(c) The gap between valence band and conduction band cannot be determined
(d) Valence band may remain partially filled

Assertion and Reason

Directions (Q. Nos. 25 to 29) *Each of these questions contains two statements : Statement* I *(Assertion) and Statement* II *(Reason). Each of these questions also has four alternative choices, only one of which is the correct answer. You have to select one of the codes (a), (b), (c), (d) given below*

(a) Statement I is true, Statement II is true; Statement II is a correct explanation for Statement I.
(b) Statement I is true, Statement II is true; Statement II is not a correct explanation for Statement I.
(c) Statement I is true; Statement II is false.
(d) Statement I is false; Statement II is true.

25. **Statement I** Crystalline solids are anisotropic.

Statement II Crystalline solids are not as closely packed as amorphous solids.

26. **Statement I** Total number of octahedral voids present in the unit cell of cubic close packing including the one that is present at the body centre, is four.

Statement II Besides the body centre there is one octahedral void present at the centre of each of the six faces of the unit cell and each of which is shared between two adjacent unit cells. **[NCERT** Exemplar**]**

27. **Statement I** The packing efficiency is maximum for the fcc structure.

Statement II The coordination number is 12 in fcc structures. **[NCERT** Exemplar**]**

28. **Statement I** Semiconductors are solids with conductivities in the intermediate range from $10^{-6} - 10^{4}$ ohm^{-1} m^{-1}.

Statement II Intermediate conductivity in semiconductor is due to partially filled valence band. **[NCERT** Exemplar**]**

29. **Statement I** The conductivity of semiconductors increases with increase in temperature.

Statement II Semiconductors conduct electricity due to the presence of ions.

Comprehension Based Questions

Directions (Q. Nos. 30 to 32) In a unit cell, atoms (A) are present at all corner lattices, (B) are present at alternate faces and all edge centres. Atom (C) are present at face centres left from (B) and one at each body diagonal at distance of 1/4th of body diagonal from corner.

30. Formula of the given solid is

(a) $A_3B_8C_7$
(b) AB_4C_6
(c) $A_6B_4C_8$
(d) $A_2B_9C_{11}$

31. A tetrad axis is passed from the given unit cell and all the atoms touching the axis are removed. The possible formula of the compound left is

(a) AB_3C_6 and AB_4C_5
(b) $A_3B_6C_7$ and $A_3B_6C_5$
(c) $A_4B_5C_8$ and $A_4B_5C_7$
(d) AB_2C and ABC_2

32. Total fraction of voids occupied are

(a) 0.58
(b) 0.25
(c) 0.48
(d) 0.86

Directions (Q. Nos. 33 to 35) In hexagonal systems of crystals, a frequently encountered arrangement of atoms is described as a hexagonal prism. Here, the top and bottom of the cell are regular hexagons and three atoms are sandwitched in between them. A space filling model of this structure, called hexagonal closed packed (HCP), is constituted of a sphere on a flat surface surrounded in the same plane by six identical spheres as closed as possible.

Three spheres are then placed over the first layer so that they touch each other and represent the second layer. Each one of these sphere touches three spheres of the bottom layer. Finally, the second layer is covered with a third layer that is identical to the bottom layer in relative position. Assume radius of every sphere to be 'r'.

33. The number of atoms in the HCP unit cell is

(a) 4 (b) 6
(c) 12 (d) 17

34. The volume of this HCP unit is

(a) $24\sqrt{2}r^3$ (b) $16\sqrt{2}r^3$
(c) $12\sqrt{2}r^3$ (d) $\frac{64}{3\sqrt{3}}r^3$

35. The empty space in this HCP unit cell is

(a) 74% (b) 47.6%
(c) 32% (d) 26%

Previous Years' Questions

36. In a face centred cubic lattice, atom A occupies the corner positions and atom B occupies the face centre positions. If one atom of B is missing from one of the face centred points, the formula of the compound is **[AIEEE 2011]**

(a) A_2B (b) AB_2 (c) A_2B_2 (d) A_2B_5

37. Copper crystallises in fcc lattice with a unit cell edge of 361 pm. The radius of copper atom is **[AIEEE 2011, 2009]**

(a) 181 pm (b) 108 pm (c) 128 pm (d) 157 pm

38. The edge length of a face centred cubic cell of an ionic substance is 508 pm. If the radius of the cation is 110 pm, the radius of the anion is **[AIEEE 2010]**

(a) 288 pm (b) 398 pm
(c) 618 pm (d) 144 pm

39. Percentage of free space in cubic close packed structure and in body centred packed structure are respectively **[AIEEE 2010]**

(a) 30% and 26% (b) 26% and 32%
(c) 32% and 48% (d) 48% and 26%

40. In a compound, atoms of element Y form ccp lattice and those of element X occupy 2/3rd of tetrahedral voids. The formula of the compound will be **[AIEEE 2008]**

(a) X_4Y_3 (b) X_2Y_3 (c) X_2Y (d) X_3Y_4

41. Total volume of atoms present in a face-centred cubic unit cell of a metal is (r is atomic radius) **[AIEEE 2006]**

(a) $\frac{20}{3}\pi r^3$ (b) $\frac{24}{3}\pi r^3$
(c) $\frac{12}{3}\pi r^3$ (d) $\frac{16}{3}\pi r^3$

42. An ionic compound has a unit cell consisting of A ions at the corners of a cube and B ions on the centres of the faces of the cube. The empirical formula for this compound would be **[AIEEE 2005]**

(a) A_3B (b) AB_3
(c) A_2B (d) AB

43. What type of crystal defect is indicated in the diagram shown below ? **[AIEEE 2004]**

Na^+ Cl^- Na^+ Cl^- Na^+ Cl^-
Cl^- Cl^- Na^+ Na^+
Na^+ Cl^- Cl^-, Na^+ Cl^-
Cl^- Na^+ Cl^- Na^+ Na^+

(a) Frenkel defect
(b) Schottky defect
(c) Interstitial defect
(d) Frenkel and Schottky defects

44. How many unit cells are present in a cube shaped ideal crystal of NaCl of mass 1.00 g?

[Atomic mass : Na = 23, Cl = 35.5] **[AIEEE 2003]**

(a) 2.57×10^{21}
(b) 5.14×10^{21}
(c) 1.28×10^{21}
(d) 1.71×10^{21}

45. Number of atoms in the unit cell of Na (bcc type crystal) and Mg (fcc type crystal) are, respectively **[AIEEE 2002]**

(a) 4, 4 (b) 4, 2
(c) 2, 4 (d) 1, 1

the Guidance

Round I

1. At low temperature, molecular motion are slow, thus constituents are close together. Moreover, strong cohesive forces also holds the constituents together. These two conditions shows the existence of a substance in solid state.

2. In solid state the constituent particles are not free to move. They can only oscillate about their mean positions due to strong attraction forces between the particles. That is why solids have a closely packed arrangement and rigid structure.

3. Quartz glass is an amorphous solid because in it short range order of constituents is found.

4. Amorphous solids are isotropic in nature. These can be moulded by heating. Moreover, they become crystalline on standing for a long time or on heating.

5. Crystalline solids are anisotropic in nature, *i.e.,* have different properties in different directions.

6. Crystalline solids such as NaCl, $BaCl_2$ etc., will show anisotropy.

7. Metallic crystals are good conductor of heat and current due to the presence of free electrons in them.

9. Ionic solids are hard and brittle because of the presence of very strong forces of attraction. Because of highly ordered arrangement of particles, these are anisotropic in nature. In molten state or in aqueous solution, these are good conductor of electricity because of the presence of free ions.

10. In diamond, the constituent atoms are held together by strong covalent bonds. It is a giant molecule. Thus, classified as network solid.

Note *SO_2, H_2O and I_2 are examples of molecular solids.*

11. In graphite each C atom is sp^2 hybridised. One electron of each C atom remains free and make graphite, a good conductor of electricity.

15. (i) A point lying at the **corner** of a unit cell is shared equally by eight unit cells and therefore, only one-eighth $\left(\frac{1}{8}\right)$ of each such point belongs to the given unit cell.

(ii) **A body centred point** belongs entirely to **one** unit cell since, it is not shared by any other unit cell.

17. Length of the edge of NaCl unit cell,

$$= 2 \times \text{distance between } Na^+ \text{ and } Cl^-$$

$$= 2 \times a = 2a \text{ pm}$$

18. For a face-centred cubic unit cell (fcc),

$$\text{Edge length } (a) = 2\sqrt{2}\, r$$

$$= 2 \times 1.4142 \times 0.144 \text{ nm}$$

$$= 0.407 \text{ nm}$$

19. $r = \frac{a}{2\sqrt{2}} = \frac{620}{2\sqrt{2}} = 219.25$ pm.

20. CsCl has a bcc lattice. So, $d_{\text{body}} = a\sqrt{3}$

or $\quad d_{\text{body}} = \sqrt{3} \times 0.4123 \text{ nm} = 0.7141 \text{ nm}$

The sum of the ionic radii of Cs^+ and Cl^- ions is half of this distance *i.e.,*

$$r_{Cs^+} + r_{Cl^-} = \frac{d_{\text{body}}}{2} = \frac{0.7141}{2} \text{ nm} = 0.3571 \text{ nm}$$

Ionic radius of $Cs^+ = 0.3571 - 0.181 = 0.1761 \text{nm}$

21. Volume $= a^3 = (400 \times 10^{-10} \text{ cm})^3 = 64 \times 10^{-24} \text{ cm}^3$

$$V_{\text{total}} = VN_A = 64 \times 10^{-24} \times 6.02 \times 10^{23} = 38.4$$

Molar volume $= \frac{1}{4} \times V_{\text{total}} = \frac{38.4}{4} = 9.6$ mL

22. Volume of unit cell $(V) = a^3$.

$$\therefore \quad = (3.04 \times 10^{-8} \text{ cm})^3$$
$$= 2.81 \times 10^{-23} \text{ cm}^3$$

23. For an fcc unit cell, $r = \frac{a}{2\sqrt{2}}$ [Given, $r = 125$ pm]

$$a = 2\sqrt{2} \times r = 2 \times 1.414 \times 125$$
$$= 353.5 \text{ pm} \simeq 354 \text{ pm}$$

Volume of unit cell $= a^3 = (353.5 \times 10^{-10} \text{cm})^3$

$$= 442 \times 10^{-25} \text{ cm}^3$$

Number of unit cell $= \frac{1.00 \text{ cm}^3}{442 \times 10^{-25} \text{ cm}^3}$

$$= 2.26 \times 10^{22} \text{ unit cells}$$

24. *A* atoms are at eight corners of the cube. Therefore, the number of *A* atoms in the unit cell $= \frac{8}{8} = 1$,

Atoms *B* per unit cell = 1.

Hence, the formula is *AB*.

25. Density, $d = \frac{ZM}{a^3 N_A} = \frac{4(58.5) \text{ g mol}^{-1}}{(5.628 \times 10^{-8} \text{ cm})^3 (6.023 \times 10^{23} \text{ mol}^{-1})}$

$$= 2.179 \text{ g cm}^{-3}$$

26.

$$d_{hkl} = \frac{a}{\sqrt{h^2 + k^2 + l^2}}$$

$$d_{(111)} = \frac{a}{\sqrt{(1)^2 + (1)^2 + (1)^2}} = \frac{a}{\sqrt{3}}$$

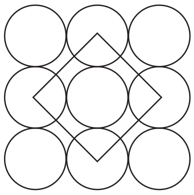
$$d_{(111)} = \frac{318}{\sqrt{3}} = 184 \text{ pm}$$

27. In bcc structure 68% of the available volume is occupied by spheres. Thus, vacant space is 32%.

28. Packing efficiency,
for sc unit cell = 5%
for bcc unit cell = 68%
for fcc unit cell = 74%

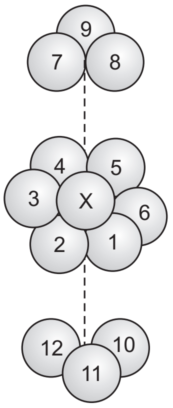
Thus, the order of packing efficiency is fcc > bcc > sc

29. Square close packing in two dimension can be shown as

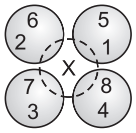


Thus, coordination number is 4 as each atom is sorrounded by four other atoms.

31.



ccp structure



bcc structure

(a) 12 (as each atom is attached with 12 other atoms.)

(b) 8 (because each atom is attached with 8 other atoms.)

32. Number of octahedral sites = Number of sphere in the packing.

∴ Number of octahedral sites per sphere = 1.

33. In hexagonal close packing, it is the third layer, spheres of which are exactly aligned with those of the first layer. Other given statements are true.

34. Tetrahedral sites are double comparable to number of atom then ratio of *X* and *Z* respectively 2 : 1, since formula of the compound X_2Z.

35. Cu atoms are at eight corners of the cube. Therefore, the number of Cu atoms in the unit cell $= \frac{8}{8} = 1$.

Ag atoms are at the face-centre of six faces. Therefore, its share in the unit cell $= \frac{6}{2} = 3$.

Au atoms are at the body centre, so the number of Au atoms = 1

∴ The formula of the alloy is $CuAg_3Au$.

40. Na_2O has antifluorite (A_2B) type structure.

41. $\frac{r_+}{r_-} = \frac{180}{187} = 0.962$, which lies in the range of 0.732 – 1.000, hence, coordination number is 8, *i.e.,* the structure is CsCl type.

43. There is one octahedral hole for each atom in hexagonal close packed arrangement. If the number of oxide ions (O^{2-}) per unit cell is 1, then the number of Fe^{3+} ions $= 2/3 \times$ octahedral holes $= 2/3 \times 1 = 2/3$. Thus, the formula of the compound $= Fe_{2/3}\ O_1$ or Fe_2O_3.

44. Distance between K^+ and $F^- = \frac{1}{2} \times$ length of the edge.

45. For body centred cubic arrangement coordination number is 8 and radius ratio $\left(\frac{r_+}{r_-}\right)$ is $0.732 - 1.000$.

46. The radius ratio for coordination number 4, 6 and 8 lies in between the ranges 0.225 – 0.414, 0.414 – 0.732 and 0.732 – 1.000 respectively.

48. When radius ratio is in between 0.732 – 1.000, then coordination number is 8 and the structural arrangement is body centred cubic.

49. The value of ionic radius ratio is 0.52 which is in between 0.414 – 0.732, then the geometrical arrangement of ions in crystal is octahedral.

50. More is the Schottky defect in crystal, more is the decrease in density.

51. Schottky defect is observed when equal number of cations and anions are missing from their lattice sites.

52. Frenkel defect, which is a stoichiometric defect, is also known as dislocation defect because in it some of the ions dislocated from their position and occupy interstitial spaces.

53. AgBr exhibits Frenkel defect due to large difference in the size of Ag^+ and Br^- ions.

54. In Frenkel defect, the smaller ions, which is generally the cation, leave its place and occupy the interstitial site. That's why this defect is also called interstitial defect.

55. Doping introduces electronic defects as it results in the formation of holes or free electrons.

56. All the given statements are correct about *F*-centres.

57. When a solid is heated, a vacancy is created in the crystal. On heating, some of the lattice sites are vacant and the density of the solid decreases as the number of ions per unit volume decreases.

58. In metal excess defect when holes created by missing of anions are occupied by electrons, these sites are called *F*-centres and are responsible for the colour of the crystal.

59. Fe_3O_4 is a non-stoichiometric compound because in it, the ratio of the cations to the anions becomes different from that indicated by the chemical formula.

61. When Si is doped with an electron rich impurity, the resulting crystal have an extra electron, which makes the crystal conducting. Since an electron (negative charge) is responsible for the conductivity of crystal, it is called *n*-type semiconductor.

62. In case of *p*-type semiconductors, holes are created but the crystal as a whole remains neutral.

63. In the presence of magnetic field, all the domains of a ferromagnetic substance get oriented in the direction of magnetic field. That's why it becomes a permanent magnet.

64. The domains of antiferromagnetic substance are oppositely oriented and cancel out each other's magnetic moment, thus, it is represented as

$$\uparrow\downarrow\uparrow\downarrow\uparrow\downarrow$$

65. Ferromagnetic substances can be magnetised permanently. Other given statements are true.

66. The dipoles in certain solids are spontaneously aligned in a particular direction, even in the absence of electric field. Such substances are called ferroelectric substances. Barium titanate ($BaTiO_3$) and potassium hydrogen phosphate (KH_2PO_4) are ferroelectric solids.

68. TiO, CrO_2 and ReO_3 behave as metal, thus, shows electrical properties similar to metals.

70. Conductivity of metals are much higher than the semiconductors and insulators. Insulators are non-conductor of electricity.

Thus, the order of conductivities of solids is

$$\kappa_{metals} >> \kappa_{insulator} < \kappa_{semiconductors}.$$

Round II

1. Amorphous solids have short range order and no sharp melting point.

2. Addition of impurity does not establish equilibrium.

3. Coordination number of Na^+ in NaCl is 6.

4. $$M = \frac{\rho \times a^3 \times N_A \times 10^{-30}}{Z}$$

$$= \frac{10 \times (100)^3 \times 6.02 \times 10^{23} \times 10^{-30}}{4} = 1.505$$

$\therefore$ Number of atoms in 100 g $= \frac{6.02 \times 10^{23}}{1.505} \times 100$

$$= 4 \times 10^{25}$$

5. Difference $= 2.178 \times 10^3 - 2.165 \times 10^3$

$$= 0.013 \times 10^3$$

Fraction unoccupied $= \frac{0.013 \times 10^3}{2.178 \times 10^3}$

$$= 5.96 \times 10^{-3}$$

6. Given that, $\lambda = 229$ pm and $\theta = 23°20'$

Substituting these values in the Bragg's equation, we have

$$d_{hkl} = \frac{\lambda}{2\sin\theta} = \frac{229\text{ pm}}{2\sin(23°20')}$$

$$= \frac{229\text{ pm}}{2\times 0.396} = 289.2\text{ pm}$$

7. There are two atoms in a bcc unit cell.

So, number of atoms in 12.08×10^{23} unit cells

$$= 2\times 12.08\times10^{23}$$

$$= 24.16\times10^{23}\text{ atoms}$$

8. There are 6 *A* atoms on the face centres. Removing face centred atoms along one of the axes means removal of 2 *A* atoms.

Now, number of *A* atoms per unit cell

$$= \underset{\text{(corners)}}{8\times\frac{1}{8}} + \underset{\text{(face-centred)}}{4\times\frac{1}{2}} = 3$$

Number of *B*-atoms per unit cell

$$= \underset{\text{(edge centred)}}{12\times\frac{1}{4}} + \underset{\text{(body centred)}}{1} = 4$$

Hence, the resultant stoichiometry is A_3B_4.

9. 58.5 g NaCl = 1 mol NaCl = 6.023×10^{23} NaCl units.

One unit cell contains 4 NaCl units.

Hence, number of unit cell present

$$= \frac{6.023\times10^{23}}{4} = 1.5\times10^{23}$$

10. Let the units of ferrous oxide in a unit cell = *n*.

Molecular weight of ferrous oxide (FeO)

$$= 56 + 16 = 72\text{ g mol}^{-1}$$

$$\text{Weight of } n \text{ units} = \frac{72\times n}{6.023\times10^{23}}$$

Volume of one unit = (length of corner)^3

$$= (5\text{ Å})^3 = 125\times10^{-24}\text{ cm}^3$$

$$\text{Density} = \frac{\text{wt. of cell}}{\text{volume}}$$

$$\therefore \quad 4.09 = \frac{72\times n}{6.023\times10^{23}\times125\times10^{-24}}$$

$$\text{Hence,} \quad n = \frac{3079.2\times10^{-1}}{72} = 42.7\times10^{-1}$$

$$= 4.27 \approx 4$$

11. In a unit cell, W atoms at the corner $= \frac{1}{8}\times 8 = 1$

O atoms at the centre of edges $= \frac{1}{4}\times 12 = 3$

Na atoms at the centre of the cube = 1

W : O : Na = 1 : 3 : 1

Hence, formula = $NaWO_3$

12. Edge length of the unit cell = 2 Å = 2×10^{-8} cm

$$\text{Volume of the unit cell} = (2\times10^{-8})^3\text{ cm}^3$$

$$= 8\times10^{-24}\text{ cm}^3$$

$$\text{Mass of unit cell} = \text{volume}\times\text{density}$$

$$= 8\times10^{-24}\times2.5\text{ g}$$

No. of unit cells in 200 g of the metal

$$\frac{\text{mass of metal}}{\text{mass of unit cell}} = \frac{200}{8\times10^{-24}\times2.5} = 1\times10^{25}$$

13.

$$\underset{\text{(6 : 6 coordination no.)}}{\text{NaCl structure}} \underset{760\text{ K}}{\overset{\text{High pressure}}{\rightleftharpoons}} \underset{\text{(8 : 8 coordination no.)}}{\text{CsCl structure}}$$

14. $Z = \frac{a^3\times N_A\times\rho}{M}$

$$= \frac{4.2\times8.6\times8.3\times10^{-24}\times6.023\times10^{23}\times3.3}{155}$$

$$= 3.84 \approx 4$$

15. The ratio of Ni and O atoms in pure nickel oxide (NiO) = 1 : 1

Let *x* be the number of Ni (II) atoms replaced by Ni (III) atoms in the oxide.

$\therefore$ Number of Ni (II) atoms present = $(0.98 - x)$

Since, the oxide is neutral in nature,

Total charge on Ni atoms = Charge on oxygen atoms

$$2(0.98 - x) + 3x = 2$$

$$1.96 - 2x + 3x = 2$$

$$x = 2 - 1.96 = 0.04$$

% of Ni (III) atoms in nickel oxide

$$= \frac{\text{Number of Ni (III) atoms}}{\text{Total number of Ni atoms}}\times100$$

$$= \frac{0.04}{0.98}\times100 = 4.01\%$$

% of Ni (II) atoms in nickel oxide = 100 − 4.01

= 95.99%

16. Metal deficiency defect is present in the sample because iron is less in amount than that required for stoichiometric composition.

17. Coordination number is 4 in square close packing in two dimensions.

Two dimensional hexagonal close packing contains triangular voids.

Three dimensional hexagonal close packing have *ABAB* .... arrangement whereas, ccp have *ABCABC* ...... type arrangement.

18. Mg in solid state is an electronic conductor as electrons are responsible for its conductivity. $MgCl_2$ in molten state is an electrolytic conductor as ions are responsible for its conductivity. Si with P is a *n*-type semiconductor and Ge with B is a *p*-type semiconductor.

19. For primitive unit cell number of atoms $= 1$

For bcc, number of atoms $= 1 + 1 = 2$

For fcc, number of atoms $= 1 + 3 = 4$

For end centred orthorhombic unit cell $a \neq b \neq c$

20. The colour of KCl is violet or lilac because of the presence of unpaired electrons, called the *F*-centre, at some of the anionic sites.

21. In *p*-type semiconductors, holes move towards the positively charged plate and electrons towards the negatively charged plate.

22. For spinel structure, O^{2-} ions from ccp arrangement.

$\therefore$ Number of O^{2-} ions = 4.

Numbr of tetrahedral void $= 8$,

Number of octahedral void = 4

$$\text{Number of } Mg^{2+} \text{ ions} = \frac{1}{8} \times \text{tetrahedral void} = \frac{1}{8} \times 8 = 1$$

$$\text{Number of } Al^{3+} \text{ ions} = \frac{1}{2} \times \text{tetrahedral void} = \frac{1}{2} \times 4 = 2$$

So, 50% octahedral voids are occupied and 1/8th, *i.e.*, 12.5% tetrahedral voids are occupied.

23. (a) CN of Zn^{2+} ion in ZnS = 4.

(b) Number of body diagonal planes in a cube $= 6$.

(c) Formula unit in rock salt structure = 4.

(d) Formula unit in CsCl structure $= 1$.

24. In metals valence bond overlaps with the conduction band, thus the gap between these two in negligible. In these, the valence band may also remain partially filled.

25. Crystalline solids possess the properties of rigidity. They are anisotropic and undergo a clean cleavage. The constituent particles are arranged in a definite and orderly pattern through the entire three dimensional space.

26. Statement II is wrong.

27. Both the statements are correct.

28. Intermediate conductivity of semiconductors is due to small energy gap between valence band and conduction band.

29. Semiconductors conduct electricity not due to presence of ions but due to presence of defects.

30. Number of *A* atoms $= 8 \text{ (corner)} \times \frac{1}{8} \text{ (per corner share)} = 1$

$$\text{Number of } B \text{ atoms} = 2 \text{ (alternate face)} \times \frac{1}{2} \text{ (face centre share)}$$
$$+ 12 \text{ (edge)} \times \frac{1}{4} \text{ (edge centre share)}$$
$$= 1 + 3 = 4$$

$$\text{Number of } C \text{ atoms} = 4 \text{ (face centres left from B)} \times \frac{1}{2} \text{ (face centre share)}$$
$$+ 1 \text{ (at body diagonal)} \times 4 \text{ (body diagonal)}$$
$$= 2 + 4 = 6$$

Formula AB_4C_6.

31. ***Case I*** If the tetrad axis passes through the face centres where *B* lies, then

$$\text{Number of } B \text{ atoms} = 4 - \left(\frac{1}{2} \times 2\right) = 3$$

The formula of the compound left is AB_3C_6.

Case II If the tetrad axis passes through the face centres where C lies, then

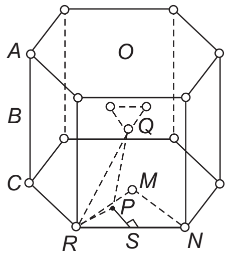
$$\text{Number of C atoms} = 6 - \left(\frac{1}{2} \times 2\right) = 5$$

The formula of the compound left is AB_4C_5.

32. There are 8 effective tetrahedral voids, out of which 4 are occupied (one at each body diagonal) and 4 effective octahedral voids such that one is not filled (body centre). So, out of 12 (8 tetrahedral voids + 4 octahedral voids), only 7 are filled (4 tetrahedral voids + 3 octahedral voids).

$$\text{Therefore, fraction of void occupied} = \frac{7}{12} = 0.58$$

33.



In hcp unit cell

$$\text{Contribution of atoms from corner} = \frac{1}{6}$$

$$\text{Contribution from face centre} = \frac{1}{2}$$

$$\Rightarrow \text{Total number of atoms per unit cell} = 12 \times \frac{1}{6} + 2 \times \frac{1}{2} + 3 = 6$$

34. In close packed arrangement, side of the base $= 2r$

$$\Rightarrow \quad RS = r$$

Also *MNR* is equilateral triangle, $\angle PRS = 30°$

$$\text{In triangle } PRS, \cos 30° = \frac{RS}{PR} = \frac{\sqrt{3}}{2}$$

$$\Rightarrow \quad PR = \frac{2}{\sqrt{3}} RS = \frac{2}{\sqrt{3}} r$$

In right angle triangle $PQR : PQ = \sqrt{QR^2 - PR^2} = 2\sqrt{\frac{2}{3}}\,r$

$\Rightarrow$ Height of hexagon $= 2PQ = 4\sqrt{\frac{2}{3}}\,r$

$\Rightarrow$ Volume = area of base × height $= 6\,\frac{\sqrt{3}}{4}(2r)^2 \times 4\sqrt{\frac{2}{3}}\,r$

$$= 24\sqrt{2}r^3$$

35. Packing fraction $= \dfrac{\text{volume occupied by atoms}}{\text{volume of unit cell}}$

$$= 6 \times \frac{4}{3}\pi r^3 \times \frac{1}{24\sqrt{2}r^3} = 0.74$$

$\Rightarrow$ Fraction of empty space $= 1 - 0.74 = 0.26 = 26\%$

36. Number of atoms (A) per unit cell $= 8 \times \frac{1}{8} = 1$

Number of atoms (B) per unit cell $= (6-1) \times \frac{1}{2} = \frac{5}{2}$

(one atom B is missing)

Thus, formula is $A_1B_{5/2} = A_2B_5$

37. Copper crystallises in fcc lattice.

If r = radius

a = edge length

then $r = \dfrac{a}{2\sqrt{2}} = \dfrac{361}{2\sqrt{2}}$ pm

$= 127.633$ pm ≈ 128 pm

38. For fcc arrangement

$$2(r^+ + r^-) = \text{edge length}$$

$$2(110 + r^-) = 508$$

So, $r^- = 144$ pm

39. Packing fraction of ccp $= \dfrac{\pi}{3\sqrt{2}} = 0.74 \Rightarrow 74\%$

% free space in ccp $= 26\%$

Packing fraction of bcc $= \dfrac{\pi\sqrt{3}}{8} = 0.68 = 68\%$

% free space in bcc $= 32\%$

40. Suppose atoms of element Y in ccp $= 100$

Number of tetrahedral voids $= 2 \times 100$

Number of atoms of element

$$X = \frac{2}{3} \times 200 = \frac{400}{3}$$

$$\frac{X}{Y} = \frac{400}{300}$$

Formula $= X_4Y_3$

41. Total number of atoms in face centred cubic unit cell = 4

At corner $= 8 \times \frac{1}{8} = 1$

On faces $= 6 \times \frac{1}{2} = 3$

Total = 4

Total volume $= 4 \times \dfrac{4\pi r^3}{3}$

$$= \frac{16}{3}\pi r^3$$

42. Unit cell consists of A ions at the corners. Thus, number of ions of the type $A = \frac{8}{8} = 1$

Unit cell consists of B ions at the centre of the six faces.

Thus, number of ions of the type $B = \frac{6}{2} = 3$

[Each corner is shared by 8 cubes and each face is shared by 2 faces]

Thus, formula is AB_3.

43. When equal number of cations and anions (such that charges are equal) are missing ($1Na^+$, $1Cl^-$ /1 Fe^{2+}, $2Cl^-$) then it is a case of Schottky defect.

44. Mass of one unit cell (m) = volume × density

$$= a^3 \times d = a^3 \times \frac{Mz}{N_0a^3} = \frac{Mz}{N_0}$$

$$m = \frac{58.5 \times 4}{6.02 \times 10^{23}}\ \text{g}$$

$\therefore$ Number of unit cells in 1g $= \dfrac{1}{m}$

$$= \frac{6.02 \times 10^{23}}{58.5 \times 4}$$

$$= 2.57 \times 10^{21}$$

45. In Na unit cell (body centred cubic)

8 (corner atoms) $\times \frac{1}{8} = 1$

Atoms placed inside the unit cell = 1

Total atoms = 2 .

In Mg unit cell (face centred cubic)

8 (corner atoms) $\times \frac{1}{8} = 1$

6 (face atoms) $\times \frac{1}{2} = 3$

Total atoms = 4.

2 Solutions

JEE Main MILESTONE

- Types of Solutions
- Solubility
- Concentration of Solution
- Vapour Pressure of Solutions and Raoult's Law
- Ideal Solutions
- Non-Ideal or Real Solutions
- Colligative Properties
- Abnormal Colligative Properties : van't Hoff Factor

2.1 Types of Solutions

In case of binary solutions, each component may be solid, liquid or in gaseous state and on this basis different types of solutions are summarised, in the following Table.

Table 2.1 **Different Types of Solutions**

Types of solution	Solute	Solvent	Common example
Gaseous solutions	Gas	Gas	Mixture of oxygen and nitrogen gases
	Liquid	Gas	Chloroform mixed with nitrogen gas
	Solid	Gas	Camphor in nitrogen gas
Liquid solutions	Gas	Liquid	Oxygen dissolved in water
	Liquid	Liquid	Ethanol dissolved in water
	Solid	Liquid	Glucose dissolved in water
Solid solutions	Gas	Solid	Solution of hydrogen in palladium
	Liquid	Solid	Amalgam of mercury with sodium
	Solid	Solid	Copper dissolved in gold

Solution is a homogeneous mixture of two or more substances on molecular level. A solution of two substances is called a ***binary solution.*** *The substances forming the solution are called* ***components*** *of the solutions. As a generalisation, the component present in smaller amount is called* ***solute*** *and the other present in larger amount is called* ***solvent.***

Caution Point *A solution in which water is the solvent is called an* ***aqueous solution.*** *The solutions in which solid is present in larger proportion are called solid solutions. Amalgam is a solution of liquid in solid. Alloys are solution of a solid is another solid.*

2.2 Solubility

The maximum amount of a solute that can be dissolved in a given amount of solvent (generally 100 g) at a given temperature is termed as **solubility** at that temperature.

Solubility of Gas in Liquid

All gases are soluble in water as well as in other liquids to a greater or lesser extent.

The solubility of a gas in liquids depends upon the following factors

(a) Nature of the Gas

The gases which can be easily liquified, are more soluble in common solvents, *e.g.*, CO_2 is more soluble than H_2 and O_2 in water.

(b) Nature of the Solvent

The gases which are capable of forming ions in aqueous solutions are much more soluble in water than in other solvents, *e.g.*, gases like HCl and NH_3 are highly soluble in water but not in organic solvents in which they do not ionise.

(c) Temperature

The solubility of most gases in liquids decreases with increase of temperature. When a solution of a gas is heated, the gas is usually expelled. However, some gases are more soluble at higher temperature than at lower.

(d) Pressure

The solubility of a gas in liquid is also influenced by pressure. The relation between the solubility and pressure is given by **Henry's law.** According to this law

$$m \propto p \text{ or } m = K_H p \qquad \text{...(i)}$$

where, m = mass of the gas dissolved per unit volume of a solvent

p = pressure of the gas at equilibrium with the solution

K_H = Henry's constant

Thus, Henry's law can also be stated as, the pressure of a gas over a solution in which the gas is dissolved is equal to the amount fraction of the dissolved gas multiplied by Henry's constant.

Different gases have different K_H values at the same temperature. This suggests that K_H is a function of the nature of the gas. Table 2.2 gives K_H values of some common gases at specified temperature.

Table 2.2 **Values of Henry's law Constant** (K_H) **for Some Selected Gases in Water**

Gas	Temp (K)	K_H (k bar)	Gas	Temp (K)	K_H (k bar)
He	293	144.97	Argon	298	40.3
H_2	293	69.16	CO_2	298	1.67
N_2	293	76.48	HCHO	298	1.83×10^{-5}
N_2	303	88.84	CH_4	298	0.413
O_2	293	34.86	Vinyl chloride	298	0.611
O_2	303	46.82	$(CH_2{=}CH{-}Cl)$		

It is obvious from Eq. (i) that *higher the value of K_H at a given pressure, the lower is the solubility of the gas in the liquid*. It can be seen from Table 2.2 that the K_H value for both N_2 and O_2 increases with increase of temperature indicating that *the solubility of gases decreases with increase of temperature*. It is due to this reason that aquatic species are more comfortable in cold water rather than in warm water.

Sample Problem 1 *The partial pressure of ethane over a solution containing 6.56×10^{-3} g of ethane is 1 bar. If the solution contains 5.00×10^{-2} g of ethane, then what shall be the partial pressure of gas?* **[NCERT]**

(a) 4.2 bar (b) 7.6 bar
(c) 8.9 bar (d) 9.8 bar

Interpret (*b*) According to Henry's law,

Mass of the gas (m) dissolved in solution $\propto$ Partial pressure (p) (At constant temperature)

$$\therefore \quad (6.56 \times 10^{-3} \text{ g}) \propto 1 \text{ bar}$$

$$(5.00 \times 10^{-2} \text{ g}) \propto p$$

$$\text{or} \quad p = \frac{(5.0 \times 10^{-2} \text{ g})}{(6.56 \times 10^{-3} \text{ g})} \times (1 \text{ bar})$$

$$= 7.62 \text{ bar}$$

Sample Problem 2 H_2S*, a toxic gas with rotten egg like smell, is used for the qualitative analysis. If the solubility of* H_2S *in water at STP is* 0.195 *m, calculate Henry's law constant.* **[NCERT]**

(a) 152 bar (b) 100 bar
(c) 200 bar (d) 282 bar

Interpret (*d*) Since molality is given and molality is the moles present in 1000 g of water so first we find the moles of H_2S, if molality is 0.195 m and then calculate the moles of water n_{H_2O} as we know from molality its mass is 1000 g.

Now, we calculate the mole fraction of H_2S using the formula,

$$X_{H_2S} = \frac{n_{H_2S}}{n_{H_2S} + n_{H_2O}} \text{ from which we can easily}$$

calculate Henry's law constant.

Calculation of mole fraction of H_2S 0.195 m means that 0.195 mole of H_2S are dissolved in 1000 g of water.

Number of moles of water in 1000 g, (n_{H_2O})

$$= \frac{(1000\text{ g})}{(18\text{ g mol}^{-1})} = 55.55\text{ mol}$$

$$\text{Mole fraction } H_2S\ (x_{H_2S}) = \frac{n_{H_2S}}{n_{H_2S} + n_{H_2O}}$$

$$= \frac{(0.195\text{ mol})}{(0.195 + 55.55)\text{ mol}}$$

$$= \frac{(0.195\text{ mol})}{(55.745\text{ mol})} = 0.0035$$

Calculation of Henry's Law Constant

According to Henry's law

$$x_{H_2S} = \frac{\text{partial pressure of } H_2S}{K_H \text{ for } H_2S} \text{ at STP}$$

$$K_H \text{ for } H_2S = \frac{\text{partial pressure of } H_2S}{x_{H_2S}}$$

$$= \frac{(0.987\text{ bar})}{(0.0035)} = 282\text{ bar}$$

Solubility of Liquid in Liquid

A liquid may or may not be soluble in another liquid. Depending upon the relative solubility of a liquid in another, the following three cases are possible

(a) Miscible

When two substances dissolve in each other, they are said to be completely miscible, *e.g.,* water and alcohol, benzene and toluene.

(b) Immiscible

Two chemically different liquids such as water and oil, water and mercury, do not dissolve in each other and are said to be completely immiscible.

(c) Partially Miscible

Certain liquids like water and phenol, water and ether, which dissolve only to a limited extent are known as partially miscible.

Caution Point *In general "like dissolves like" e.g., water and* NaCl *both being ionic are completely miscible. Similarly, benzene and chloroform being covalent are miscible.*

Solubility of Solid in Liquid

On the basis of solubility of solid (solute) in a liquid (solvent), solution may be of the following types

(a) Unsaturated Solution

A solution in which more solute can be dissolved without raising temperature is called an *unsaturated solution*.

(b) Saturated Solution

A solution in which no solute can be dissolved further at a given temperature is called a saturated solution.

(c) Supersaturated Solution

When the solution contains more solute than would be necessary to saturate it then it is termed as supersaturated solution. Supersaturated solutions are not in equilibrium with the solid substance. Thus, if a small crystal of solute (say sodium thiosulphate) is added to its supersaturated solution, the excess immediately crystallises out, which is usually quite fast (and dramatic too).

Check Point 1

1. Explain how can you increase the solubility of a gas in liquid?
2. State the condition in which an electrolyte can dissolve in water.
3. What happens when a crystal of solute is introduced into a supersaturated solution of the solute?
4. What happens when a saturated solution is heated?
5. Why true solutions are homogeneous in nature?

2.3 Concentration of Solution

The **concentration** of a solution is defined as the relative amount of a solute present in a solution . It is generally expressed as the amount of solute present in a unit volume of solution. Solutions with relatively low concentration are called **dilute solutions,** while those with relatively high concentration are called **concentrated solutions.**

Various expression for the concentrations of solutions can be summarised as

Per cent by Weight or Mass Per cent

It is the amount of solute present in 100 g of the solution.

$$\text{Per cent by weight } (w/W) = \frac{\text{weight of solute (in g)}}{\text{weight of solution (in g)}} \times 100$$

Per cent by Volume

The volume of solute (in mL) present in 100 mL of the solution is called **volume per cent.**

$$\text{Per cent by volume } (v/V) = \frac{\text{volume of solute (in mL)}}{\text{volume of solution (in mL)}} \times 100$$

Mole Fraction (χ)

It is the ratio of the number of moles of one component (*i.e.,* solute or solvent) to the total number of moles of solute and solvent (*i.e.,* moles of solution).

$$\chi_{\text{solute}} = \frac{\text{moles of solute}}{\text{moles of solute + moles of solvent}}$$

$$\chi_{\text{solvent}} = \frac{\text{moles of solvent}}{\text{moles of solute + moles of solvent}}$$

$$\chi_{\text{solute}} + \chi_{\text{solvent}} = 1$$

Sample Problem 3 *The mole fraction of benzene in a solution containing* 30% *by mass in carbon tetrachloride is* **[NCERT]**

(*a*) 0.46 (*b*) 0.54 (*c*) 0.64 (*d*) 0.45

Interpret (*a*) For 100 g of the solution, mass of benzene = 30 g

Mass of carbon tetrachloride = 100 − 30 = 70 g

$$\text{Molar mass of benzene } (C_6H_6) = (12 \times 6) + (6 \times 1)$$
$$= 72 + 6 = 78 \text{ g mol}^{-1}$$

$$\text{Moles of benzene, } n_{C_6H_6} = \frac{\text{Mass}}{\text{Molar mass}} = \frac{30}{78} = 0.385 \text{ mol}$$

Molar mass of carbon tetrachloride

$$(CCl_4) = 12 + (35.5 \times 4)$$
$$= 12 + 142.0 = 154 \text{ g mol}^{-1}$$

$$\text{Moles of } CCl_4, n_{CCl_4} = \frac{70 \text{ g}}{(154 \text{ g mol}^{-1})} = 0.454 \text{ mol}$$

$$\text{Mole fraction of benzene, } \chi_{C_6H_6} = \frac{n_{C_6H_6}}{n_{C_6H_6} + n_{CCl_4}}$$
$$= \frac{0.385 \text{ mol}}{(0.385 + 0.454) \text{ mol}} = 0.459$$

Parts Per Million (ppm)

When the amount of solute (in g) is present in one million mL (1 million = 10^6) per mL of solution, the concentration of the solution is expressed in **ppm.**

$$\text{ppm} = \frac{\text{weight of solute (in g)}}{\text{total volume of solution (in mL)}} \times 10^6$$

In case of gases, ppm refers to volumes rather than masses, *i.e.,* 1 ppm means 1 cm^3 of gaseous components is present in 1000 L.

Strength or Concentration in Gram Per Litre

It represents the number of grams present in 1 L of solution.

$$\text{Strength of solution} = \frac{\text{mass of solute (g)}}{\text{volume of solution (in L)}}$$

Molarity (M)

It is the number of moles of solute present in one litre of the solution.

$$\text{Molarity } (M) = \frac{\text{number of moles of solute}}{\text{volume of solution (in L)}}$$
$$= \frac{\text{mass of solute (in g)}}{\text{mol. wt. of solute} \times \text{volume of solution (in L)}}$$
$$= \frac{\text{number of millimoles of solute}}{\text{volume of solution (in mL)}}$$
$$= \frac{\text{per cent of solute} \times 10}{\text{molecular weight of solute}}$$
$$= \frac{\text{weight \% of solute} \times \text{sp. gravity of the solution} \times 10}{\text{molecular weight of the solute}}$$

Molarity varies with temperature due to accompanied change in volume of the solution.

Unit of molarity = g-mol/L

Relation between molarity and strength in g/L

$$\text{Molarity } (M) = \frac{\text{weight of solute (in g)}}{\text{molecular weight of solute} \times \text{volume of solution (in L)}}$$

$$\text{Molarity } (M) = \frac{\text{strength in g / L}}{\text{molecular weight of solute}}$$

Relation between molarity (M) *and mole fraction of the solute* (χ)

$$\chi = \frac{MM_1}{M(M_1 - M_2) + d}$$

where, d = density of the solution
M_1 = molar mass of solvent
M_2 = molar mass of solute
M = molarity of solution

Dilution Law

If molarity and volume of solution are changed from M_1, V_1 to M_2, V_2 then

$$M_1V_1 = M_2V_2 \quad \text{(Molarity equation)}$$

If n_1 moles of reactant '1' react with n_2 moles of reactant '2' then

$$\frac{M_1V_1}{n_1} = \frac{M_2V_2}{n_2}$$

If two solutions of the same solute are mixed then molarity of the resulting solution,

$$M = \frac{M_1V_1 + M_2V_2}{V_1 + V_2}$$

Volume of water added to get a solution of molarity M_2 from V_1 mL of molarity M_1 is

$$V_2 - V_1 = \left(\frac{M_1 - M_2}{M_2}\right) V_1$$

Sample Problem 4 *Calculate the molarity of* KI *if the density of* 20% *(mass/mass) aqueous* KI *is* 1.202 g mL^{-1}. **[NCERT]**

(*a*) 0.04 *M* (*b*) 1.25 *M* (*c*) 0.25 *M* (*d*) 1.45 *M*

Interpret (*d*) Since density is given, so first we calculate volume and then molarity.

$$\begin{aligned}
\text{Weight of the solution} &= 100\ \text{g}\\
\text{Density of the solution} &= 1.202\ \text{g mL}^{-1}\\
\text{Volume of the solution} &= \frac{\text{weight of solution}}{\text{density}}\\
&= \frac{(100\ \text{g})}{(1.202\ \text{g mL}^{-1})}\\
&= 83.19\ \text{mL} = 0.083\ \text{L}\\
\text{Molarity of the solution } (M) &= \frac{\text{number of gram moles of KI}}{\text{volume of solution in litres}}\\
&= \frac{(20\ \text{g})/(166\ \text{g mol}^{-1})}{(0.083\ \text{L})}\\
&= 1.45\ \text{mol L}^{-1} = 1.45\ \text{M}
\end{aligned}$$

Alternate Method

$$\begin{aligned}
\text{Molarity} &= \frac{\%\ \text{by mass} \times \text{density} \times 10}{\text{molar mass of KI}}\\
&= \frac{20 \times 1.202 \times 10}{166} = 1.45\ \text{M}
\end{aligned}$$

Molality (*m*)

It is the number of moles of the solute dissolved in 1000 g of the solvent.

$$\begin{aligned}
\text{Molality } (m) &= \frac{\text{number of moles of solute}}{\text{mass of solvent (in g)}} \times 1000\\
&= \frac{\text{mass of solute (in g)} \times 1000}{\text{molecular weight of solute} \times \text{mass of solvent (in g)}}\\
&= \frac{10 \times \text{solubility}}{\text{molecular weight of solute}}
\end{aligned}$$

Molality is independent of temperature.

Unit of molality = g moles/kg of solvent.

Relation between molality and weight percentage of solute (x)

$$= \frac{1000 \times \text{weight \% of solute } (\chi)}{(100 - x) \times \text{molecular weight of solute}}$$

Relation between molality (m) *and mole fraction of the solute* (χ)

$$\chi = \frac{mM_1}{1 + mM_1}$$

where, M_1 = molecular mass of the solvent

Relation between molality (m) *and molarity* (M)

$$\text{Molality } (m) = \frac{M}{d - MM_2} \quad (\text{If } d \text{ in kg/L and } M_2 \text{ in kg/mol})$$

$$\text{Molality } (m) = \frac{M}{1000d - MM_2} \times 1000$$

(If d in g/L and M_2 in g/mol)

$$\text{Molarity } (M) = \frac{m \times d}{1 + \dfrac{m \times M_2}{1000}}$$

where, M_2 = molar mass of the solute

d = density of the solution.

Sample Problem 5 *If the density of some lake water is* 1.25 g mL^{-1} *and contains* 92 g *of* Na$^+$ *ions per kg of water, calculate the molality of* Na$^+$ *ions in the lake.* **[NCERT]**

(*a*) 2 *m* (*b*) 4 *m* (*c*) 8 *m* (*d*) 10 *m*

Interpret (*b*) Molality of Na$^+$ ions (m)

$$\begin{aligned}
&= \frac{\text{number of moles Na}^+ \text{ ions}}{\text{mass of water in kg}}\\
&= \frac{(92\ \text{g})/(23\ \text{g mol}^{-1})}{(1\ \text{kg})}\\
&= 4\ \text{mol kg}^{-1} \text{ or } 4\ \text{m}
\end{aligned}$$

Sample Problem 6 *A solution of glucose in water is labelled as* 10% *w/ w. What should be the molality of the solution, if the density of solution is* 1.2 g mL^{-1}? **[NCERT]**

(*a*) 0.45 (*b*) 0.62

(*c*) 0.82 (*d*) 0.19

Interpret (*b*) 10% means

$$\begin{aligned}
W_B &= \text{Mass of glucose} = 10\ \text{g}\\
&\quad\ \text{Mass of solution} = 100\ \text{g}\\
W_A &= \text{Mass of water (solvent)}\\
&= 100 - 10 = 90\ \text{g} = 0.09\ \text{kg}\\
M_B &= \text{Molar mass of glucose } (C_6H_{12}O_6)\\
&= (12 \times 6) + (1 \times 12) + (16 \times 6)\\
&= 72 + 12 + 96 = 180\ \text{g mol}^{-1}
\end{aligned}$$

$$\begin{aligned}
\text{Molality of solution } (m) &= \frac{W_B/M_B}{W_A} = \frac{(10\ \text{g})/(180\ \text{g mol}^{-1})}{(0.09\ \text{kg})}\\
&= \frac{(10\ \text{g})}{(180\ \text{g mol}^{-1}) \times (0.09\ \text{kg})}\\
&= 0.617\ \text{mol kg}^{-1} \text{ or } 0.617\ \text{m}
\end{aligned}$$

Sample Problem 7 *An 'm' molal solution of a compound in benzene has mole fraction of solute equal to* 0.2. *The value of 'm' is*

(*a*) 0.018 (*b*) 0.14

(*c*) 0.040 (*d*) 0.0032

Interpret (*d*) Mole fraction of solute is given by

$$\chi = \frac{mM_1}{1 + mM_1}$$

where, M_1 = molecular mass of the solvent, *i.e.*, benzene = 78

$$0.2 = \frac{m \times 78}{1 + m \times 78}$$

$$0.2 + 0.2 \times 78\, m = 78\, m$$

or $$(78 - 15.6)\, m = 0.2$$

or $$62.4\, m = 0.2$$

or, $$m = \frac{0.2}{62.4} = 0.0032$$

Normality (N)

Normality is the number of gram equivalents of substance dissolved per litre of the solution.

$$\text{Normality } (N) = \frac{\text{number of g-equivalent of solute}}{\text{volume of solution (in L)}}$$

$$= \frac{\text{mass of solute (in g)}}{\text{equivalent weight} \times \text{volume (in L)}}$$

$$N = \frac{\text{mass of solute } (w) \text{ (in g)}}{\text{equivalent weight } (E) \times \text{volume } (V) \text{ (in mL)}} \times 1000$$

or $$N = \frac{w \times 1000}{E \times V}$$

or $$w = \frac{NEV}{1000} = \frac{\text{per cent of solute}}{\text{equivalent weight of the solute}} \times 10$$

$$\text{Again, Normality } (N) = \frac{\text{per cent of solute}}{\text{equivalent weight of the solute}} \times 10$$

$$= \frac{\text{weight per cent of solute} \times \text{sp. gravity of the solution} \times 10}{\text{equivalent weight of the solute}}$$

Relation between normality and strength in g/L

$$\text{Normality } (N) = \frac{\text{mass of solute (in g)}}{\text{equivalent weight} \times \text{volume (in L)}}$$

$$= \frac{\text{strength in g / L}}{\text{equivalent weight}}$$

Relation between normality and molarity

$$\text{Normality} = \frac{\text{number of g-equivalents of solute}}{\text{volume of solution (in L)}}$$

and, $$\text{Molarity} = \frac{\text{number of moles of solute}}{\text{volume of solution (in L)}}$$

$$\therefore \quad \frac{\text{Normality}}{\text{Molarity}} = \frac{\text{number of g-equivalent of solute}}{\text{number of moles of solute}}$$

$$= \frac{\text{molecular weight}}{\text{equivalent weight}}$$

$$\Rightarrow \textit{normality} \times \textit{equivalent weight} = \textit{molarity} \times \textit{molecular weight}$$

For an acid, $$\frac{\text{molecular weight}}{\text{equivalent weight}} = \text{basicity}$$

$$\therefore \quad \text{Normality of an acid} = \text{molarity} \times \text{basicity}$$

For a base, $$\frac{\text{molecular weight}}{\text{equivalent weight}} = \text{acidity}$$

$$\therefore \quad \text{Normality of a base} = \text{molarity} \times \text{acidity}$$

Relation between normality and percentage of solute

$$N = \frac{x \times d \times 10}{E}$$

where, x = % of the solute by mass

d = density of solution in g/mL

E = equivalent mass of solute

Dilution Law

If normality and volume of solution are changed from N_1, V_1 to N_2, V_2 then

$$N_1V_1 = N_2V_2 \quad \text{(Normality equation)}$$

If n_1 moles of reactant '1' react with n_2 moles of reactant '2', then

$$\frac{N_1V_1}{n_1} = \frac{N_2V_2}{n_2}$$

If two solutions of the same solute are mixed then normality of the resulting solution,

$$N = \frac{N_1V_1 + N_2V_2}{V_1 + V_2}$$

Volume of water added to get a solution of normality N_2 from V_1 mL of normality N_1 is

$$V_2 - V_1 = \left(\frac{N_1 - N_2}{N_2}\right) V_1$$

Normality changes with temperature since it involves volume.

When a solution is diluted x times, its normality also decreased by x times.

Unit of normality = gram equivalents per litre.

Sample Problem 8 *The amount of* H_2SO_4 *in* 150 *mL of* $\frac{N}{7}$ H_2SO_4 *is*

(*a*) 15 g
(*b*) 2.10 g
(*c*) 1.05 g
(*d*) 51.45 g

Interpret (*c*) $$w = \frac{NEV}{1000} = \frac{1}{7} \times \frac{49 \times 150}{1000}$$

($\because$ Eq. weight of H_2SO_4 = 49)

$$= 1.05 \text{ g}$$

Sample Problem 9 *What will be the normality of a solution obtained by mixing* 0.45 *N and* 0.60 *N* NaOH *in the ratio* 2 : 1 *by volume ?*

(a) 0.15 *N* (b) 0.8 *N* (c) 0.5 *N* (d) 0.45 *N*

Interpret (c) g-equivalents $= 0.45 \times 2V + 0.60 \times V$

Total volume $= 2V + V = 3V$

$\Rightarrow$ g-equivalents of NaOH solution obtained $= N \times 3V$

$$\therefore \quad N \times 3V = 0.45 \times 2V + 0.6V$$

$$3NV = 0.9V + 0.6V$$

$$N = \frac{1.5V}{3V} = \frac{1}{2} = 0.5$$

Formality (*F*)

This is the concentration unit for ionic compounds which dissolve in a polar solvent to give pair of ions. This represents number of gram-formula weight of the substance dissolved per litre of the solution. It is almost the same as molarity. It describes the solute that is mixed in a liquid rather than the solute present in solution after the dissolution process.

$$\text{Formality} = \frac{\text{moles of substance added to solution}}{\text{volume of solution (in L)}}$$

If formula weight is equal to molecular weight, formality and molarity will be same.

Formality is also dependent on temperature.

Demal (*D*)

It is equal to molar concentration at 0°C, *i.e.,* 1D represents one mole of the solute present in one litre of the solution at 0°C.

Caution Point *Normality and molarity changes with temperature because they involve volumes while molarity, mole fraction and mass fraction do not change with temperature because they involve weights.*

Check Point 2

1. In which mode of expression, the concentration of the solution remains independent of temperature and why?
2. What is the difference between molality and molarity?
3. What is the difference between normality and formality?
4. Why molarity is affected by changes in temperature?
5. At same temperature, oxygen in found to be more soluble in water as compared to hydrogen. Which of these have higher K_H value and why?

2.4 Vapour Pressure of Solutions and Raoult's Law

The pressure exerted by the vapours of a solvent while in equilibrium with pure solvent, at a given temperature, is called vapour pressure.

Factors Affecting Vapour Pressure

Vapour pressure gets affected by following factors.

(a) Purity of the Liquid

Pure liquid always has a vapour pressure higher than its solution.

(b) Nature of the Liquid

Liquids which have weak intermolecular forces are volatile and have greater vapour pressure.

(c) Temperature

The vapour pressure of a liquid increases with increase in temperature. This is because on increasing the temperature the kinetic energy of molecules increases that results into the fact that more molecules of the liquid can go into vapour phase.

(d) Effect of Adding Solute

When a liquid contains a solute, some of the solvent molecules are replaced by the solute particles on the liquid surface and therefore, the available surface area for the escape of solvent molecule decreases.

Due to the less available area on the surface of liquid for escape, rate of evaporation and hence, the rate of condensation both lowers.

The vapour pressure of liquid in solution is known as its **partial vapour pressure** and is less than the vapour pressure of the pure liquid at the same temperature.

If p° be the vapour pressure of pure liquid and p_s be that of liquid in solution then lowering of vapour pressure of the liquid $= p^\circ - p_s$

$$\therefore \quad \text{Relative lowering in pressure} = \frac{p^\circ - p_s}{p^\circ}$$

Hot Spot 1

RAOULT'S Law

Questions based on Raoult's law have been frequently asked in the JEE Main examination, so it is an important topic for the examinations. The nature of questions is numerical type and their level vary from moderate to difficult.

Raoult's law states, "For a solution of two miscible liquids, the vapour pressure of each liquid in the solution is less than the respective vapour pressure of the pure liquid and at the equilibrium, partial vapour pressure of the liquid is directly proportional to its mole fraction in solution."

For a solution containing two liquids *A* and *B*, the partial vapour pressure of liquid *A* is

$$p_A \propto \chi_A \quad \text{or} \quad p_A = k\chi_A$$

where, $\chi_A = \dfrac{n_A}{(n_A + n_B)}$ = the **mole fraction of liquid *A***

The proportionality constant *k* is obtained by considering the pure liquid when $\chi_A = 1$, then $k = p_A{}^\circ$, (the vapour pressure of pure liquid), hence,

$$p_A = p_A{}^\circ\, \chi_A$$

Similarly, $$p_B = p_B^\circ\, \chi_B$$

According to **Dalton's law of partial pressure,** the total pressure (p_{total}) over the solution phase in the container will be the sum of the partial pressures of the components of the solution and is given as

$$p_{\text{total}} = p_A + p_B$$

Substituting the values of p_A and p_B, we get

$$\begin{aligned} p_{\text{total}} &= \chi_A p_A^\circ + \chi_B p_B^\circ \\ &= (1 - \chi_B)p_A^\circ + \chi_B p_B^\circ \\ &= p_A^\circ + (p_B^\circ - p_A^\circ)\chi_B \end{aligned}$$

Following conclusions can be drawn from the equation

(i) Total vapour pressure over the solution can be related to the mole fraction of any one component.

(ii) Total vapour pressure over the solution varies linearly with the mole fraction of component *B*.

(iii) Depending on the vapour pressures of the pure components *A* and *B*, total vapour pressure over the solution decreases or increases with the increase of the mole fraction of component.

The composition of vapour phase in equilibrium with the solution is determined by the partial pressures of the components. If y_1 and y_2 are the mole fractions of the component 1 and 2 respectively in the vapour phase then, using Dalton's law of partial pressures :

$$p_1 = y_1\, p_{\text{total}}$$

$$p_2 = y_2\, p_{\text{total}}$$

In general

$$p_i = y_i\, p_{\text{total}}$$

Raoult's Law as a Special Case of Henry's Law

According to Raoult's law, the vapour pressure of a volatile component in a given solution is given by $p_i = x_i\, p_i^\circ$. In the solution of a gas in a liquid, one of the components is so volatile that it exists as a gas and we have already seen that its solubility is given by Henry's law which states that

$$p = K_{\text{H}} x$$

If we compare the equations for Raoult's law and Henry's law, it can be seen that the partial presssure of the volatile component or gas is directly proportional to its mole fraction in the solution. Only the proportionality constant K_{H} differs from p_i°, Thus, Raoult's law becomes a special case of Henry's law in which K_{H} becomes equal to p_i°.

Sample **Problem 10** *At 40°C, the vapour pressure in torr, of methyl alcohol-ethyl alcohol solution is represented by the equation.* $p = 119X_A + 135$ *where* X_A *is mole fraction of methyl alcohol, then the value of* $\lim\limits_{X_A \to 1} \dfrac{p_A}{X_A}$ *is*

(*a*) *254 torr* (*b*) *135 torr*
(*c*) *119 torr* (*d*) *140 torr*

Interpret (*a*) $p = 119X_A + 135$;

$$\lim_{X_A \to 1} \frac{p_A}{X_A} = 119 + 135 = 254 \text{ torr}$$

Sample **Problem 11** *The vapour pressure of a pure liquid A is 40 mm* Hg *at 310 K. The vapour pressure of this liquid in a solution with liquid B is 32 mm* Hg. *Calculate the mole fraction of A in the solution if it obeys the Raoult's law.*

(*a*) 0.5 (*b*) 0.6 (*c*) 0.7 (*d*) 0.8

Interpret (*d*) Vapour pressure of pure *A* = 40 mm Hg

Vapour pressure of *A* in solution = 32 mm Hg

According to Raoult's law

$$p_A = p_A^\circ \chi_A$$

or $$\chi_A = \frac{p_A}{p_A^\circ} = \frac{32 \text{ mm Hg}}{40 \text{ mm Hg}} = 0.8$$

Sample **Problem 12** *Heptane and octane form an ideal solution. At 373 K, the vapour pressure of the two liquid components are 105.2 kPa and 46.8 kPa respectively. What* *will be the vapour pressure of a mixture of 26.0 g of heptane and 35 g of octane?* **[NCERT]**

(a) 82.8 *kPa* (b) 73.5 *kPa*
(c) 39.2 *kPa* (d) 88.2 *kPa*

Interpret (*b*) Number of moles of octane

$$(n_A) = \frac{\text{Mass}}{\text{Molar mass}} = \frac{35\ \text{g}}{114\ \text{g mol}^{-1}}$$

$$= 0.307\ \text{mol}$$

[Molar mass of octane

$$C_8H_{18} = (12 \times 8) + (1 \times 18) = 114\ \text{g mol}^{-1}]$$

Number of moles of heptane

$$(n_B) = \frac{26\ \text{g}}{100\ \text{g mol}^{-1}} = 0.26\ \text{mol}$$

[Molar mass of heptane $C_7H_{16} = (12 \times 7) + 16 = 100\ \text{g mol}^{-1}$]

Mole fraction of octane

$$(\chi_A) = \frac{n_A}{n_A + n_B} = \frac{(0.307\ \text{mol})}{(0.307 + 0.26)\ \text{mol}} = 0.541$$

Mole fraction of heptane

$$(\chi_B) = \frac{n_B}{n_A + n_B} = \frac{(0.26\ \text{mol})}{(0.307 + 0.26)\ \text{mol}} = 0.458$$

Vapour pressure of pure heptane $(p_B^\circ) = 105.2$ kPa

Vapour pressure of pure octane $(p_A^\circ) = 46.8$ kPa

In the mixture of 26.0 *g heptane and* 35.0 *g octane*

(i) Vapour pressure of heptane $(p_B) = p_B^\circ\ \chi_B$

$$= (105.2\ \text{kPa} \times 0.458)$$
$$= 48.18\ \text{kPa}$$

(ii) Vapour pressure of octane

$$(p_A) = p_A^\circ\ \chi_A = (46.8\ \text{kPa} \times 0.541)$$
$$= 25.32\ \text{kPa}$$

(iii) Total vapour pressure of the mixture

$$(p) = p_A + p_B$$
$$= 25.32 + 48.18 = 73.5\ \text{kPa}$$

Sample **Problem 13** *The vapour pressure of chloroform* ($CHCl_3$) *and dichloromethane* (CH_2Cl_2) *at 298 K is 200 mm* Hg *and 415 mm* Hg*, respectively. If a solution is prepared by mixing 25.5 g of* $CHCl_3$ *and 40 g of* CH_2Cl_2 *at 298 K, calculate the mole fractions of chloroform in vapour phase.*

[NCERT Exemplar]

(a) 0.18 (b) 0.82 (c) 0.34 (d) 0.48

Interpret (*a*) Molar mass of $CH_2Cl_2 = 12 \times 1 + 1 \times 2 + 35.5 \times 2$

$$= 85\ \text{g mol}^{-1}$$

Molar mass of $CHCl_3 = 12 \times 1 + 1 \times 1 + 35.5 \times 3$

$$= 119.5\ \text{g mol}^{-1}$$

$$\text{Moles of } CH_2Cl_2 = \frac{40\ \text{g}}{85\ \text{g mol}^{-1}} = 0.47\ \text{mol}$$

$$\text{Moles of } CHCl_3 = \frac{25.5\ \text{g}}{119.5\ \text{g mol}^{-1}} = 0.213\ \text{mol}$$

Total number of moles $= 0.47 + 0.213 = 0.683$ mol

$$\chi_{CH_2Cl_2} = \frac{0.47\ \text{mol}}{0.683\ \text{mol}} = 0.688$$

$$\chi_{CHCl_3} = 1.00 - 0.688 = 0.312$$

$$p_{\text{total}} = p^\circ_{CHCl_3} + (p^\circ_{CH_2Cl_2} - p^\circ_{CHCl_3})\ \chi_{CH_2CH_2}$$
$$= 200 + (415 - 200) \times 0.688$$
$$= 347.9\ \text{mm Hg}$$

To calculate the mole fraction of component in vapour phase,

$$\chi_i^V = p_i / p_{\text{total}}$$

$$\therefore \quad p_{CH_2Cl_2} = 0.688 \times 415\ \text{mm Hg} = 285.5\ \text{mm Hg}$$

$$p_{CHCl_3} = 0.312 \times 200\ \text{mm Hg} = 62.4\ \text{mm Hg}$$

$$\chi^V_{CH_2Cl_2} = \frac{285.5}{347.9} = 0.82$$

$$\chi^V_{CHCl_3} = \frac{62.4}{347.9} = 0.18$$

Note Since CH_2Cl_2 is more volatile component than $CHCl_3$ [$p^\circ_{CH_2Cl_2} = 415$ mm Hg and $p^\circ_{CHCl_3} = 200$ mm Hg] and the vapour phase is also richer in CH_2Cl_2 [$\chi^V_{CH_2Cl_2} = 0.82$ and $\chi^V_{CHCl_3} = 0.18$], it may be concluded that at equilibrium, vapour phase will be always rich in the component which is more volatile.

Limitations of Raoult's Law

1. It is applicable only to very dilute solutions.
2. It is applicable only to solutions containing non-volatile and non-electrolytic solutes which exist as a single molecule.
3. It is not applicable to solutes which dissociate or associate in the particular solution.

2.5 Ideal Solutions

Ideal solutions are those, which obey Raoult's law with overall concentration ranges at a given temperature. The total vapour pressure of an ideal solution containing components *A* and *B* is given by

$$p = p_A + p_B = p_A{}^\circ\ \chi_A + p_B{}^\circ\ \chi_B$$

In an ideal solution of two components say *A* and *B*, all cohesive forces (*A*—*A*, *B*—*B* and *A*—*B*) must be identical. *Two liquids on mixing will form an ideal solution if following conditions be satisfied*

(i) both have similar structure,
(ii) both have similar molecular sizes,
(iii) both have identical intermolecular forces.

Characteristics of an Ideal Solution

The mixture of two liquids results in an ideal solution when

(i) they obey Raoult's law.

(ii) $\Delta H_{\text{mixing}} = 0$, *i.e.,* no energy evolved or absorbed on mixing.

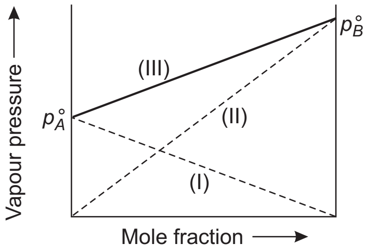
(iii) $\Delta V_{\text{mixing}} = 0$, *i.e.,* on mixing no expansion or contraction occurs.

Examples of the Ideal Solutions

Benzene-toluene, *n*-hexane-*n*-heptane; ethyliodide-ethyl bromide, chlorobenzene- bromobenzene.

Graphical Representation of Ideal Solutions

The curve I (straight line) gives variations of vapour pressure of liquid *A* and the curve II gives that of liquid *B* with their respective mole fractions.



The resultant graph III (representing $p = p_A^\circ \chi_A + p_B^\circ \chi_B$) is the plot for solution and is a straight line joining p_A° and p_B°. Hence, the vapour pressure at various compositions of ideal solutions is intermediate between the values of p_A° and p_B°.

2.6 Non-Ideal or Real Solutions

Solutions, which do not obey Raoult's law, are called **non-ideal solutions.** Hence, for such solutions $p_A \neq p_A^\circ \chi_A$ and $p_B \neq p_B^\circ \chi_B$.

For such mixtures,

$$\Delta H_{\text{mixing}} \neq 0$$

and $$\Delta V_{\text{mixing}} \neq 0;$$

Non-ideal solutions show the following two types of deviations from ideal behaviour

1. Solution Showing Positive Deviation

The vapour pressure of each component in such a mixture is more than what would be expected on the basis of Raoult's law of components *A* and *B* alone.

If the attraction between *A* and *B* molecules is less than the attractive forces between *A* to *A* and *B* to *B*, the escaping tendency in solution is higher than in either of the pure components.

For such a deviation

$$p_A > p_A^\circ \chi_A\ ,\ p_B > p_B^\circ \chi_B$$

and hence, $$p_{\text{total}} > p_A^\circ \chi_A + p_B^\circ \chi_B$$

also $$\Delta H_{\text{mixing}} > 0$$

as the new bonds formed are weaker and energy is absorbed.

$\Delta V_{\text{mixing}} > 0$ *i.e.*, there is increase in volume.

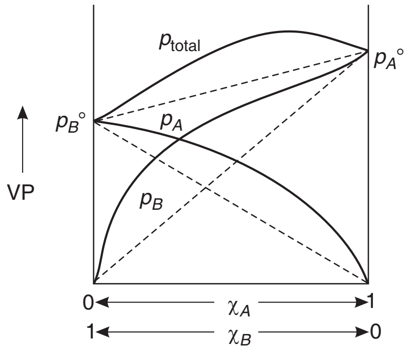


Fig. 2.1 Graph of solution showing positive deviation from Raoult's law

Examples Ethanol-water, ether-acetone, carbon disulphide-acetone, carbon tetrachloride-methanol, cyclohexane-ethanol, water-methanol, carbon tetrachloride-benzene, carbon tetrachloride-toluene, acetone-benzene.

2. Solutions Showing Negative Deviation

For such solutions, the partial vapour pressure of each component is less than what would be expected on the basis of Raoult's law.

In such a mixture, the attraction between molecules of *A* and *B* is greater than the force between *A*—*A* molecules or *B*—*B* hence the escaping tendencies of both the components are lowered.

For a mixture showing negative deviation

$$p_A < p_A^\circ \chi_A$$

or $$p_B < p_B^\circ \chi_B,$$

hence, $$p_{\text{total}} < p_A^\circ \chi_A + p_B^\circ \chi_B$$

$\Delta H_{\text{mixing}} < 0$, *i.e.*, heat is evolved due to the formation of stronger bonds.

$\Delta V_{\text{mixing}} < 0$, *i.e.,* there is decrease in volume.

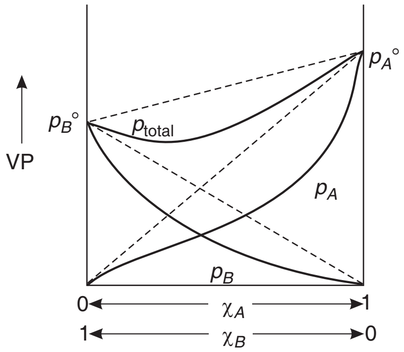

Fig. 2.2 Graph of solution showing negative deviation from Raoult's law

Examples Acetic acid-methanol, acetic acid-pyridine acetone-aniline, acetone-chloroform, benzene-chloroform, water-hydrochloric acid, water-nitric acid etc.

Azeotropic Mixtures

A mixture of two liquids which boils at a constant temperature and distils over without any change in composition is called azeotropic mixture.

Azeotropic mixtures are of two types

(a) Minimum Boiling Azeotropes

These are the mixture of two liquids boiling point of which is less than either of the two pure components. They are formed by non-ideal solutions showing positive deviations.

(b) Maximum Boiling Azeotropes

These are the mixtures of two liquids boiling point of which is more than either of the two pure components. They are formed by non-ideal solutions showing negative deviations.

2.7 Colligative Properties

The properties of a dilute solution which depends only upon the number of particles present in a solution and their concentration are called colligative properties. These depend on the dative fraction of solute and solvent particles but not on the chemical nature of solute *i.e.,* these are proportional to the number of solute particles in the solution.

These properties have their origin from the fact that the chemical potential of a species in an ideal solution is lower than the chemical potential of pure component.

Factors Affecting Colligative Properties

1. Fraction of solute and solvent particles in solution.
2. Nature of solvent.
3. Extent of association and dissociation of solute particles in solution.

There are four colligative properties, i.e.,

(i) Relative lowering of vapour pressure
(ii) Elevation in boiling point of the solvent
(iii) Depression in freezing point
(iv) Osmotic pressure

Caution Points

(*i*) *The freezing point and boiling point depend on the type of salt that's why these are not considered as colligative properties.*

(*ii*) *When a non-volatile solute is added to the solvent, vapour pressure and freezing point decrease whereas boiling point increases.*

Hot Spot 2

RELATIVE Lowering of Vapour Pressure

It is also an important topic of the chapter from JEE Main examination point of view. The nature of question is numerical type and their level vary from easy to moderate.

When a non-volatile solute is added to a solvent, the vapour pressure is lowered. So, vapour pressure of a solution (p) is always less than the vapour pressure of pure solvent (p°) at that temperature. Therefore, ($p^\circ - p$) is called the **lowering in vapour pressure** and the ratio $\left(\dfrac{p^\circ - p}{p^\circ}\right)$ is known as the **relative lowering in vapour pressure.**

According to **Raoult's law,** "the relative lowering in vapour pressure of a dilute solution is equal to the mole fraction of the solute present in the solution. *i.e.,*

$$\frac{p^\circ - p}{p^\circ} = \chi_B$$

where, χ_B = mole fraction of solute

Determination of Molecular Mass

If n moles of solute be dissolved in N moles of the solvent, the mole fraction of the solute $= \dfrac{n}{n + N}$

Then, according to Raoult's law,

$$\therefore \qquad \frac{p^\circ - p_s}{p^\circ} = \frac{n}{n + N}$$

$$\frac{p^\circ - p_s}{p^\circ} = \frac{\dfrac{w}{m}}{\dfrac{w}{m} + \dfrac{W}{M}} \qquad \left[\because \; n = \frac{w}{m} \text{ and } N = \frac{W}{M}\right]$$

For very dilute solutions

$$n <<< N$$

$$\therefore \qquad \frac{p^\circ - p_s}{p^\circ} = \frac{n}{N}$$

$$\text{or} \qquad \boxed{\frac{p^\circ - p_s}{p^\circ} = \frac{w \times M}{m \times W}}$$

This expression is used to find the molecular weight of an unknown solute dissolved in a given solvent.

Alternate Formula for the Relative Lowering of Vapour Pressure When the solution is not Dilute

$$\frac{p^\circ - p_s}{p^\circ} = \frac{n_B}{n_A + n_B} \qquad \text{...(i)}$$

On reversing Eq. (i), we get

$$\frac{p^\circ}{p^\circ - p_s} = \frac{n_A + n_B}{n_B} = 1 + \frac{n_A}{n_B}$$

$$\Rightarrow \qquad \frac{p^\circ}{p^\circ - p_s} - 1 = \frac{n_A}{n_B}$$

$$\Rightarrow \qquad \frac{p^\circ - p^\circ + p_s}{p^\circ - p_s} = \frac{n_A}{n_B}$$

$$\Rightarrow \qquad \frac{p_s}{p^\circ - p_s} = \frac{n_A}{n_B}$$

$$\text{or} \qquad \boxed{\frac{p^\circ - p_s}{p_s} = \frac{n_B}{n_A}}$$

Caution Point *This equation can be used to solve the problem quickly, whether the solution is dilute or not.*

Sample Problem 14 *Calculate the mass of a non-volatile solute (molar mass 40 g mol^{-1}) which should be dissolved in 114 g octane to reduce its vapour pressure to 80%.*

(*a*) 20 g (*b*) 10 g (*c*) 30 g (*d*) 45 g

Interpret (*b*) According to Raoult's law, relative lowering of vapour pressure,

$$\frac{p_A^\circ - p_S}{p_A^\circ} = \chi_B \qquad \text{...(i)}$$

$$\chi_B = \frac{n_B}{n_B + n_A} = \frac{W_B/M_B}{\dfrac{W_B}{M_B} + \dfrac{W_A}{M_A}} \qquad \text{...(ii)}$$

Given vapour pressure is reduced to 80% when non-volatile solute is dissolved in octane. It means

If $p_A^\circ = 1$ atm then $p_S = 0.8$ atm; $p_A^\circ - p_S = 0.2$ atm;
M_A (C_8H_{18}) = 114 g mol^{-1}; W_A = 114 g; M_B = 40 g mol^{-1}; W_B = ?

Applying Eq. (ii)

$$\frac{0.2}{1} = \frac{W_B/40}{\dfrac{W_B}{40} + \dfrac{114}{114}} = \frac{W_B/40}{\dfrac{W_B}{40} + 1}$$

$$0.2 = \frac{W_B}{W_B + 40}$$

$$0.2W_B + 8 = W_B$$

$$W_B = 10$$

Sample Problem 15 *The vapour pressure of 100 g water reduces from 17.53 mm to 17.22 mm when 17.10 g substance 'X' is dissolved in it. Substance X can be*

(*a*) *methanol* (*b*) *glucose*
(*c*) *carbon dioxide* (*d*) *cannot predict*

Interpret (*b*) $$\frac{p^\circ - p_s}{p^\circ} = \frac{n}{n+N} = \frac{\frac{w}{m}}{\frac{w}{m} + \frac{W}{M}}$$

$$\because \quad \frac{w}{m} <<< \frac{W}{M}$$

$$\therefore \quad \frac{p^\circ - p_s}{p^\circ} = \frac{w/m}{W/M} = \frac{w}{m} \times \frac{M}{W}$$

$$\Rightarrow \quad \frac{17.53 - 17.22}{17.53} = \frac{17.10}{m} \times \frac{18}{100}$$

$$\Rightarrow \quad m = \frac{17.10 \times 18 \times 17.53}{0.31 \times 100}$$

$$m = 174.05$$

174 is nearest to the molecular weight of glucose ($C_6H_{12}O_6$), thus the substance '*X*' can be glucose.

Experimental Method of Calculation of Relative Lowering in Vapour Pressure

Relative lowering in vapour pressure is experimentally calculated by Ostwald and Walker method. The experimental setup for determining relative lowering in vapour pressure is shown in the figure. It consists of two sets of bulbs. The first set of three bulbs is filled with solution, to half of their capacity and the second set of another three bulbs is filled with the pure solvent.

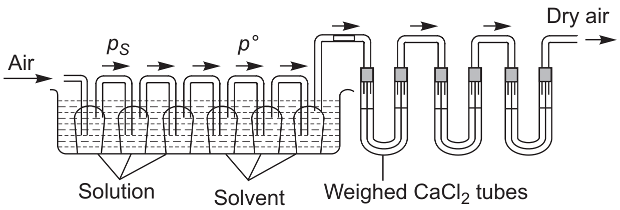

Fig. 2.3 Ostwald and Walker method

Each set is separately weighed accurately. Both sets are connected to each other and then with the accurately weighed set of guard tubes which contain anhydrous calcium chloride or some other dehydrating agents such as P_2O_5, concentrated H_2SO_4, etc. The bulbs of solution and pure solvent are kept in a thermostat maintained at a constant temperature.

A current of pure dry air is bubbled through the series of bulbs as shown in the figure. The air gets saturated with the vapour in each set of bulbs. The air takes up an amount of vapours proportional to the vapour pressure of the solution first and then it takes up more amount of vapour from the solvent which is proportional to the difference in the vapour pressure of solvent and the vapour pressure of solution, *i.e.*, $p^\circ - p_s$. The two sets of bulbs are weighed again. The guard tubes are also weighed.

Loss in mass in the solution bulbs $\propto p_s$

Loss in mass in the solvent bulbs $\propto (p^\circ - p_s)$

Total loss in the both sets of bulbs $\propto [p_s + (p^\circ + p_s)]$

$\propto p^\circ$

Total loss in the mass of both sets of bulbs is equal to gain in the mass of guard tubes.

$$\text{Thus,} \quad \frac{p^\circ - p_s}{p^\circ} = \frac{\text{loss in mass in solvent bulbs}}{\text{total loss in mass in both sets of bulbs}}$$

$$= \frac{\text{loss in mass in solvent bulbs}}{\text{gain in mass of guard tubes}}$$

Further we know from Raoult's law,

$$\frac{p^\circ - p_s}{p^\circ} = \frac{W_B/M_B}{W_A/M_A + W_B/M_B}$$

$$\text{Hence,} \quad \frac{\text{loss in mass in solvent bulbs}}{\text{gain in mass of guard tubes}} = \frac{W_B/M_B}{W_A/M_A + W_B/M_B}$$

The above relationship is used for the calculation of molecular masses of non-volatile solutes.

For very dilute solutions, the following relationship can be applied

$$\frac{p^\circ - p_s}{p^\circ} = \frac{\text{loss in mass in solvent bulbs}}{\text{gain in mass of guard tubes}} = \frac{W_B/M_B}{W_A/M_A}$$

Sample **Problem 16** *A current of dry air was bubbled through a bulb containing* 26.66 *g of an organic compound in* 200 *g of water, then through a bulb at the same temperature, containing water and finally through a tube containing anhydrous calcium chloride. The loss of mass in the bulb containing water was* 0.087 *g and the gain in the mass of calcium chloride tube was* 2.036 *g. Calculate the molecular mass of the organic substance.*

(*a*) 35.23 (*b*) 53.75

(*c*) 40.21 (*d*) 21.15

Interpret (*b*) $$\frac{p^\circ - p_s}{p^\circ} = \frac{\text{loss in the mass of solvent bulb}}{\text{gain in the mass of } CaCl_2 \text{ tube}}$$

$$= \frac{0.087}{2.036}$$

Let the molecular mass of the organic substance be M_2.

According to Raoult's law,

$$\frac{p^\circ - p_s}{p^\circ} = \frac{W_2/M_2}{\frac{W_2}{M_2} + \frac{W_1}{M_1}}$$

$$\frac{0.087}{2.036} = \frac{\frac{26.66}{M_2}}{\frac{26.66}{M_2} + \frac{200}{18}} = \frac{26.66}{26.66 + \frac{200}{18} M_2}$$

$$M_2 = 53.75 \text{ g mol}^{-1}$$

Elevation in Boiling Point of the Solvent

(Ebullioscopy)

The boiling point of a liquid may be defined as the temperature at which vapour pressure becomes equal to the atmospheric pressure (760 mm). As the vapour pressure of a solution is decreased due to the presence of a non-volatile solute, the solution boils at a higher temperature as compared to the pure solvent. The boiling point of the solution is therefore higher than the boiling point of the pure solvent. If $T_b°$ is the boiling point of pure liquid and T_b is the boiling point of solution then,

Elevation in boiling point, $\Delta T = T_b - T_b°$

The elevation in boiling point is proportional to the molality of the solution, i.e.,

$$\Delta T_b \propto m$$

or $$\Delta T_b = k_b m$$

Determination of Molecular Mass from Elevation in Boiling Point

We know that molality,

$$m = \frac{\text{weight of solute} \times 1000}{\text{mol. wt. of solute} \times \text{mass of solvent}}$$

$$= \frac{w \times 1000}{m' \times W}$$

On putting the value of m in expression of elevation in boiling point, we get

or $$\Delta T_b = \frac{k_b \times w \times 1000}{m' \times W}$$

or $$m' = \frac{k_b \times w \times 1000}{\Delta T_b \times W}$$

where, k_b = molal boiling point elevation constant or ebullioscopic constant of the solvent

w = weight of the solute

W = weight of solvent

m' = molecular weight of the solute

Sometimes the value of k_b is given per 0.1 kg (100 g), in such case the expression becomes

$$m = \frac{100 \times k_b \times w}{\Delta T_b \times W}$$

Definition of k_b

If $\frac{m}{w} = 1$ (*i.e.*, $m' = w$)

and, $w = 1$ kg = 1000 g

Then, $k_b = \Delta T_b$

Therefore, k_b is defined as the elevation in boiling point produced when 1 mole of the solute is dissolved in 1 kg of the solvent.

Unit of k_b $= \text{K (mol / kg)}^{-1}$

$= \text{K kg mol}^{-1}$

Molal boiling point elevation constant (k_b) can be calculated from molar enthalpy of vaporisation (ΔH_{vap}) of the solvent using the expression,

$$k_b = \frac{MR(T_b°)^2}{(\Delta H_{\text{vap}} \times 1000)}$$

where, M = molar mass of solvent,

$T_b°$ = boiling point of solvent

R = gas constant .

Molal boiling point elevation constant (k_b) can also be calculated from latent heat of evaporation (l_v) of pure solvent using the expression.

$$k_b = \frac{0.002\,(T°)^2}{l_v}$$

where, $T°$ = normal boiling point of the pure solvent

l_v = latent heat of evaporation in cal/g of pure solvent

Caution Point *k_b for water is 0.52 K-kg mol^{-1}.*

Sample Problem 17 *Calculate the boiling point of a solution containing 0.456 g of camphor (molar mass = 152) dissolved in 31.4 g of acetone (b.p. = 56.30°C), if the molecular elevation constant per 100 g of acetone is 17.2°C.*

(a) 56.46°C (b) 36.56°C

(c) 56.14°C (d) 72.52°C

Interpret (a) We know that

$$\Delta T_b = \frac{100 k_b \times w}{W \times m'} = \frac{100 \times 17.2 \times 0.456}{31.4 \times 152}$$

$$= 0.16°\text{ C}$$

∴ Boiling point of solution $(T_s) = T° + \Delta T_b$

$$= 56.30 + 0.16 = 56.46°\text{ C}$$

Hot Spot 3

DEPRESSION in Freezing Point of the Solvent (Cryoscopy)

It is a very important topic of the chapter for JEE Main examination. Most of the times, the questions are from this topic. The level of question is moderate and their nature is numerical type.

The temperature at which the liquid and solid states of a substance have the same vapour pressure is called **freezing point**. Since, the vapour pressure of a solvent is lowered by the addition of non-volatile solute, the freezing point of the solution (T_f) is always lower than the freezing point of the pure solvent (T_f°). Therefore,

depression in freezing point, $\Delta T_f = T_f^\circ - T_f$

The depression in freezing point is proportional to the molality of the solution, *i.e.*,

$$\Delta T_f \propto m$$

or $$\boxed{\Delta T_f = k_f m}$$

where, k_f = molal freezing point depression constant or cryoscopic constant of the solvent

Determination of Molecular Mass from Depression in Freezing Point

As we known, molality, $m = \dfrac{w \times 1000}{m' \times W}$

On putting this value in the expression of depression in freezing point, we get

$$\Delta T_f = \frac{k_f \times w \times 1000}{m' \times W} \quad \text{or} \quad m' = \frac{k_f \times w \times 1000}{\Delta T_f \times W}$$

where, w = weight of the solute

W = weight of the solvent

m' = molecular weight of the solute

Sometimes the value of k_f is given per 0.1 kg (100 g), in such case the expression becomes

$$m' = \frac{100 \times k_f \times w}{\Delta T_f \times W}$$

Definition of k_f

If $\dfrac{m}{w} = 1$ (*i.e.*, $m = w$), $W = 1\text{ kg} = 1000\text{ g}$

Then, $$k_f = \Delta T_f$$

Therefore, k_f is defined as the depression in freezing point produced when 1 mole of the solute is dissolved in 1 kg of the solvent.

Unit of k_f = K (mol/kg^{-1}) = K kg-mol^{-1}

Molal depression constant, k_f can be calculated from molar heat of fusion of the solvent using the expression

$$k_f = \frac{MR\,(T_f^\circ)^2}{(\Delta H_{\text{fusion}} \times 1000)}$$

where, M = molar mass of solvent, T_f° = boiling point of solvent

R = gas constant

Molal freezing point depression constant (k_f) can also be calculated from latent heat of fusion (l_f) of pure solvent using the expression

$$k_f = \frac{0.002\,(T^\circ)^2}{l_f}$$

where, T° = normal freezing point of the solvent

l_f = latent heat of fusion in cal/g of pure solvent

Caution Point *k_f for water is 1.86 K-kg mol^{-1}.*

Sample Problem 18 *Calculate the mass of ascorbic acid (Vitamin C, $C_6H_8O_6$) to be dissolved in 75 g of acetic acid to lower its melting point by 1.5° C. k_f = 3.9 K kg mol^{-1}.* **[NCERT]**

(a) 5 g (b) 4 g (c) 8 g (d) 9 g

Interpret (a) Mass of ascorbic acid $(W_A) = 75\text{ g} = 0.075\text{ kg}$

Depression in melting point $(\Delta T_f) = 1.5^\circ\text{ C} = 1.5\text{ K}$

Molar mass of ascorbic acid

$$(M_B) = (12 \times 6) + (8 \times 1) + (16 \times 6) = 176\text{ g mol}^{-1}$$

Molal depression constant $(k_f) = 3.9\text{ K kg mol}^{-1}$

Since, lowering of melting point is given, apply the formula for lowering of melting point, *i.e.*,

$$\Delta T_f = k_f \cdot m$$

$$\Delta T_f = \frac{k_f \cdot W_B}{M_B \times W_A} \quad \text{or} \quad W_B = \frac{\Delta T_f \cdot M_B \cdot W_A}{k_f}$$

$$W_B = \frac{(176\text{ g mol}^{-1}) \times (1.5\text{ K}) \times (0.075\text{ kg})}{(3.9\text{ K kg mol}^{-1})} = 5.08\text{ g}$$

Sample Problem 19 *An aqueous solution freezes at – 0.186°C (k_f = 1.86° and k_b = 0.512°). What is the elevation of boiling point?*

(a) 0.0512°C (b) 0.326°C

(c) 0.0592°C (d) 0.0256°C

Interpret (a) $\because \quad \Delta T_f = k_f \times \text{molality}$

$$\therefore \quad \text{Molality} = \frac{0.186}{1.86} = 0.1$$

Again, from, $\Delta T_b = k_b \times m = 0.512 \times 0.1 = 0.0512^\circ$

Osmosis and Osmotic Pressure

Osmosis is the spontaneous flow of the solvent molecules through semipermeable membrane from a pure solvent to a solution or from a dilute to a concentrated solution.

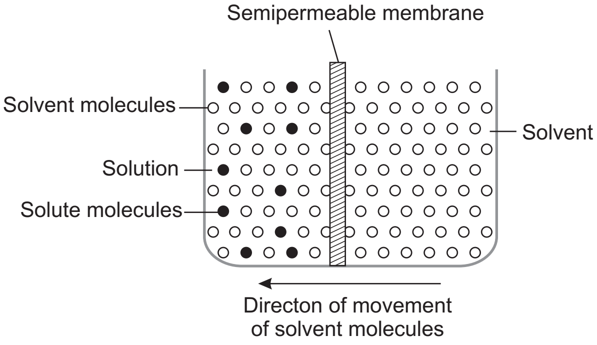

Fig. 2.4 Osmosis

Semipermeable membranes are thin sheets, which allow the passage of only solvent molecules through them. *e.g.,* egg membrane, goat's bladder, cell membrane are natural semipermeable membranes. Artifical membranes of gelatinous inorganic substances such as calcium phosphate, copper ferrocyanide, freshly prepared silicates of iron, cobalt nickel etc., are also semipermeable. Cellophane and perchment papers etc., are also used for the same purpose.

Difference Between Osmosis and Diffusion

1. Diffusion is intermingling of molecules or ion etc., resulting from the random thermal agitation thus there is no restriction to motion of any kind of particles while in osmosis only solvent molecules flow.
2. Osmosis takes place through a semipermeable membrane while for diffusion it is not required.
3. A homogeneous mixture is obtained as a result of diffusion. On the other hand no mixing is possible in osmosis.
4. Diffusion cannot be prevented while osmosis can be stopped by applying pressure to the solution.

Osmotic Pressure

The external pressure which must be applied on the solution in order to stop the flow of the solvent into the solution through semipermeable membrane is termed as osmotic pressure.

The hydrostatic pressure developed as a result of osmosis is a measure of osmotic pressure of the solution and is defined as the hydrostatic pressure built up on the solution which just stops the osmosis.

Osmotic pressure $(\pi) = hdg$ (approximate)

where, h = increase in level in the tube of unit cross-section

d = density of solution

Laws of Osmotic Pressure

van't Hoff realised that an analogy exists between the gases and solutions provided the osmotic pressure of solutions is used in place of ordinary gas pressure. He showed that for solutions of non-electrolytes the following laws hold good

(i) **Boyle-van't Hoff law** which states that the osmotic pressure (π) of a solution is directly proportional to its concentration (C), when the temperature is kept constant.

$$\pi \propto C \quad \text{(Temperature, } T \text{ is constant)}$$

If V litres of solution contain n moles of solute then

$$C = \frac{n}{V}, \text{ or } \pi \propto \frac{1}{V}$$

$$\pi V = \text{constant}$$

Caution Point *The osmotic pressure of a solution containing 1 mole of solute particles per litre (1M) at 0°C is 22.4 atm.*

(ii) **Charles'-van't Hoff law** (Gay-Lussac law) according to which the osmotic pressure of a dilute solution is directly proportional to its absolute temperature (T), when the concentration of solution is kept constant.

$$\pi \propto T \quad \text{(Concentration, } C \text{ is constant)}$$

or $$\frac{\pi}{T} = \text{constant}$$

(iii) **Avogadro-van't Hoff law** states that equal volumes of dilute solutions of different solutes, having the same temperature and osmotic pressure contain equal number of molecules, *i.e.,* isotonic solutions at a given temperature have same molar concentration.

$$\pi \propto n,$$

here, n = number of moles of solute per litres of solutions.

(iv) **General equation for dilute solutions** is obtained by combining the above three laws

$$\pi V = nRT \text{ or } \pi = CRT$$

On the basis of this analogy, van't Hoff proposed that a solute in dissolved state behave as a gas and the osmotic pressure of the solution is equal to the pressure which the solute would exert if it were a gas at the same temperature and occupying the same volume as that of solution.

These laws fail to deal with concentrated solution due to the fact that osmotic pressure is actually related to the activity and not to the concentration of the solution. Osmotic pressure is the most sensitive colligative property and its magnitude is proportional to the molality of the solution.

Sample Problem 20 *Calculate the osmotic pressure of 0.01 M solution of cane sugar at 300 K ($R = 0.0821$ L atm degree^{-1} mol^{-1}).*

(a) 0.3568 *atm* (b) 0.2463 *atm*
(c) 0.1562 *atm* (d) 0.5623 *atm*

Interpret (b) $C = 0.01\ M = 0.01$ mol / L,

$$R = 0.0821 \text{ L-atm/degree/mol}, T = 300 \text{ K}$$

$$\because \quad \pi = CRT$$

$$\therefore \quad \pi = 0.01 \times 0.0821 \times 300 = 0.2463 \text{ atm}$$

Sample Problem 21 *Osmotic pressure of a urea solution at 10°C is 500 mm. Osmotic pressure of the solution become 105.3 mm, when it is diluted and temperature is raised to 25°C. The extent of dilution is*

(a) 4 *times* (b) 3 *times*
(c) 5 *times* (d) 2 *times*

Interpret (c)

$$\pi V = nRT$$

$$\frac{500 V_1}{105.3 V_2} = \frac{nR \times 283}{nR \times 298}$$

$$\frac{V_1}{V_2} = \frac{1}{5}$$

or

$$V_2 = 5V_1$$

Determination of Molecular Mass from Osmotic Pressure

We know that number of moles $= \dfrac{\text{mass}}{\text{molar mass}}$

or

$$n = \frac{w}{m'}$$

where, w = gram of solute dissolved in V litre of the solution

m' = molecular mass of solute

$$\therefore \quad \pi V = \frac{w}{m'} RT$$

or

$$m' = \frac{wRT}{\pi V}$$

Sample Problem 22 *If 20 g of a solute was dissolved in 500 mL of water, osmotic pressure of the solution was found to be 600 mm of Hg at 15°C. The molecular weight of the solute is*

(a) 1200 (b) 1500 (c) 800 (d) 1000

Interpret (a) We know that $\pi = \dfrac{nRT}{V} = \dfrac{wRT}{V \times m}$

$$\frac{600}{760} = \frac{20 \times 0.0821 \times 288 \times 1000}{500 \times M}$$

or

$$M \simeq 1200 \text{ g mol}^{-1}$$

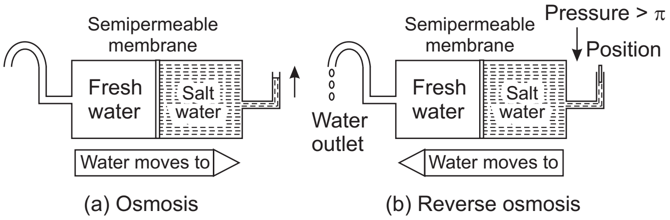
Total Osmotic Pressure

If a number of solutions are present in the solution and $\pi_1, \pi_2, \pi_3, \ldots$ are their individual osmotic pressure then

total osmotic pressure, $\pi = \pi_1 + \pi_2 + \pi_3 + \ldots$

Reverse Osmosis

When a pressure more than the osmotic pressure is applied to the solution, the solvent may pass from solution into the solvent through the semi-permeable membrane. This type of osmosis is known as **reverse osmosis.** Reverse osmosis is used for the **desalination of sea water.**



(a) Osmosis (b) Reverse osmosis

Fig. 2.5 A schematic set up for the reverse osmosis used for desalination of sea water

Caution Point *The osmotic pressure of sea water at 15°C is 25 atm.* ***Isotonic solutions*** *have the same osmotic pressure. If two solutions have different osmotic pressures, the one having lower pressure is called* ***hypotonic*** *and the other with higher pressure is* ***hypertonic solution.***

Sample Problem 23 *How many gram of glucose must be present in 0.5 L of solution for its osmotic pressure to be the same as that of 9.2 g of glucose per litre?*

(a) 4.6 g (b) 5.8 g (c) 3.6 g (d) 8.4 g

Interpret (a) For isotonic solution,

$$\frac{w_1}{m_1 V_1} = \frac{w_2}{m_2 V_2}$$

$$\frac{w_1}{180 \times 0.5} = \frac{9.2}{180 \times 1}$$

or

$$w = 4.60 \text{ g}$$

Applications of Osmotic Pressure

1. Osmotic pressure measurement provided very good method of determination of molecular mass of polymers like proteins etc., due to the following reasons
   (i) Osmotic pressure of a solution containing fewer particles is appreciable and can therefore be measured accurately as compared to ΔT_b or ΔT_f which are very small in these conditions.
   (ii) Osmotic pressure is measured at room temperature, hence the method is particularly useful for biomolecules which are generally unstable at higher temperatures.

2. Osmosis plays a vital role in biology also. *Some examples of it are*
   - (i) For normal functioning of the living systems, the fluid concentration has to be maintained in the plant and animal cells.
   - (ii) Movement of water from roots to the top of plants takes place *via* osmosis.
   - (iii) Flow of water to various parts of plants is due to osmosis.
   - (iv) Different movements of plants such as opening and closing of flowers, etc., are controlled by osmosis.
   - (v) A 0.91% solution of pure NaCl is isotonic with human red blood red cells (RBCs). Therefore, in this solution, RBCs neither swell nor undergo plasmolysis.
   - (vi) A pure NaCl solution with concentration less than 0.91% is called *hypotonic solution*. On placing RBCs in this solution, they will swell and even burst.
   - (vii) A pure NaCl solution with concentration more than 0.91% is called *hypertonic solution*. On placing RBCs in this solution, they shink due to plasmolysis.
   - (viii) People taking a lot of salt or salty food experience water osmosis. The resulting puffiness or swelling is called *edema*.
   - (ix) The use of salt and sugar as preservatives in pickels and jams has its basis in preventing growth of fungi and bacteria by osmosis.

Check Point 3

1. When two liquids *A* and *B* are mixed then their boiling points become greater than both of them. What is the nature of this solution?
2. When ethanol mixes in cyclohexane, cyclohexane reduces the intermolecular forces between ethanol molecule. Should this pair show any deviation from Raoult's law?
3. Distinguish between the boiling point of a liquid and the normal boiling point of the liquid.
4. Explain the flow of water through a semipermeable membrane during osmosis.

2.8 Abnormal Colligative Properties : van't Hoff Factor

Various relations of colligative properties hold good in dilute solutions only when there is no change in molecular state of solute. In case the total number of particles of solute changes in solution, the colligative properties also change accordingly.

This change occur in the following two ways

By Dissociation

When substance is an electrolyte, the number of particles increases in solution and the colligative property increases accordingly.

In case of dissociation suppose 1 molecule of solute *A* dissociates to give *n* ions and α is the degree of dissociation.

$$\begin{array}{ccc} A & \rightleftharpoons \; nB & \\ 1\text{ mol} & 0 & \text{initially} \\ (1-\alpha)\text{ mol} & n\alpha & \text{after dissociation} \end{array}$$

Total number of moles present in solution

$$= (1-\alpha) + n\alpha = 1 + (n-1)\,\alpha$$

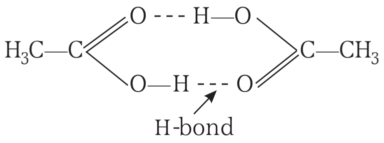
van't Hoff factor, $i = 1 + (n-1)\,\alpha > 1$ if $n \geq 2$

and $$\alpha = \frac{(i-1)}{(n-1)}$$

By Association

When substance undergoes association, the number of particles decreases in solution and consequently the value of colligative property decreases. Association of molecules is depicted as follows

$$2CH_3COOH \rightleftharpoons (CH_3COOH)_2$$



Molecules of acetic acid dimerise in benzene due to hydrogen bonding. It generally happens in solvents having low dielectric constant.

In case of association suppose *n* molecules associate to form one giant molecule and α is the degree of association.

$$\begin{array}{ccc} nA & \rightleftharpoons \; (A)_n & \\ 1\text{ mol} & 0 & \text{initially} \\ (1-\alpha)\text{ mol} & \dfrac{\alpha}{n} & \text{at equilibrium} \end{array}$$

Total number of moles in solution

$$= (1-\alpha) + \frac{\alpha}{n} = 1 + \left(\frac{1}{n} - 1\right)\alpha$$

van't Hoff factor $= 1 + \left(\dfrac{1}{n} - 1\right)\alpha < 1$ if $n \geq 2$

and $$\alpha = \frac{(i-1)}{\dfrac{1}{n} - 1}$$

van't Hoff Factor

Normal value of colligative property $\propto$ number of particles of solute taken and abnormal value of colligative property $\propto$ number of particles of solute after dissociation or association.

The ratio of two values *i.e.*,

$\dfrac{\text{abnormal colligative property}}{\text{normal colligative property}}$ is termed as van't Hoff factor (i).

Thus,

$$i = \frac{\pi_{\text{obs}}}{\pi_{\text{theo}}} = \frac{(\Delta p)_{\text{obs}}}{(\Delta p)_{\text{theo}}}$$

$$= \frac{(\Delta T_b)_{\text{obs}}}{(\Delta T_b)_{\text{theo}}} = \frac{(\Delta T_f)_{\text{obs}}}{(\Delta T_f)_{\text{theo}}}$$

$$= \frac{\text{actual number of particles in solution}}{\text{number of particles taken}}$$

Abnormal Molecular Weight

As, colligative properties $\propto \dfrac{1}{(\text{molecular weight})}$

$$\therefore \quad \frac{\text{abnormal colligative property}}{\text{normal colligative property}}$$

$$= \frac{\text{normal molecular weight}}{\text{abnormal molecular weight}}$$

$$= 1 + (n-1)\,\alpha > 1 \text{ in case of dissociation}$$

$$= 1 + \left(\frac{1}{n} - 1\right)\alpha < 1 \text{ in case of association}$$

In case van't Hoff factor is known, the various colligative properties would be given by

$$\Delta T_f = i\,k_f\,m$$

$$\Delta T_b = i\,k_b\,m$$

$$\pi V = inRT$$

$$\frac{p^\circ - p}{p^\circ} = ix_B$$

where, m is the molality of solution, $i \times m$ is sometimes referred to as **effective molality** or **colligative molality** (m_i).

$$\therefore \quad m_i = i \times m$$

$$\text{and} \quad \Delta T_f = k_f\,m_i$$

$$\Delta T_b = k_b m_i$$

Sample Problem 24 *The van't Hoff factor for sodium phosphate would be*

(*a*) 1 (*b*) 2 (*c*) 3 (*d*) 4

Interpret (*d*) van't Hoff factor is the number of ions produced

$$\text{Na}_3\text{PO}_4 \longrightarrow 3\text{Na}^+ + \text{PO}_4^{3-}$$

So, van't Hoff factor = 3 + 1 = 4

Sample Problem 25 *The freezing point depression of* 0.1 *molal solution of acetic acid in benzene is* 0.256 *K.* k_f *for benzene is* 5.12 *K kg mol*$^{-1}$*. What conclusion can you draw about the molecular state of acetic acid in benzene?*

(*a*) *Acetic acid is doubly associated*
(*b*) *Benzene is doubly associated*
(*c*) *Both are equally associated*
(*d*) *None of the above*

Interpret (*a*) $i = \dfrac{\text{observed colligative property}}{\text{calculated colligative property}} = \dfrac{0.256}{0.512} = \dfrac{1}{2}$

Also, $i = \dfrac{\text{calculated molecular mass}}{\text{observed molecular mass}}$

Calculated molecular mass of $\text{CH}_3\text{COOH} = 60$

$\therefore$ Observed molecular mass $= \dfrac{60}{1/2} = 120$

Hence, acetic acid exists as doubly associated.

Sample Problem 26 *Lowering of vapour pressure is highest for*

(*a*) 0.1 *M urea*
(*b*) 0.1 *M glucose*
(*c*) 0.1 *M* MgSO_4
(*d*) 0.1 *M* BaCl_2

Interpret (*d*) $\dfrac{p^\circ - p_s}{p^\circ} = i \times \chi_{\text{solute}}$

or $\dfrac{p^\circ - p_s}{p^\circ} \propto i$

$\therefore$ $p^\circ - p_s$ is maximum for BaCl_2.

Sample Problem 27 *Which one of the following aqueous solutions will exhibit highest boiling point?*

(*a*) 0.01 M Na_2SO_4
(*b*) 0.01 *M* KNO_3
(*c*) 0.015 *M urea*
(*d*) 0.015 *M glucose*

Interpret (a) $\Delta T \propto im$ (as k_f is a constant)

(a) $\Delta T \propto 3 \times 0.01 = 0.03$ (because it gives 3 ions)
(b) $\Delta T \propto 2 \times 0.01 = 0.02$ (because it gives 2 ions)
(c) $\Delta T \propto 0.015 \times 1 = 0.015$ (No ions are obtained)
(d) $\Delta T \propto 0.015 \times 1 = 0.015$

Since, ΔT is highest for 0.01 M Na_2SO_4 so it will exhibit highest boiling point.

WORKED OUT Examples

Example 1 *Calculate the molarity of solution of* $CaCl_2$ *if on chemical analysis it is found that 200 mL of* $CaCl_2$ *contains* 3.01×10^{22} Cl^- *ions.*

(*a*) 40 *M* (*b*) 3.01 *M* (*c*) 0.125 *M* (*d*) 0.250 *M*

Solution (*c*) $\underset{1\ \text{mol}}{CaCl_2} \longrightarrow Ca^{2+} + \underset{2 \times 6.023 \times 10^{23}\ \text{ions}}{2Cl^-}$

$2 \times 6.023 \times 10^{23}$ Cl^- ions are present in = 1 mole of $CaCl_2$

$$3.01 \times 10^{22}\ Cl^-\ \text{ions are present in } \frac{1 \times 3.01 \times 10^{22}}{2 \times 6.02 \times 10^{23}}$$

$$= 0.025 \text{ mol of } CaCl_2$$

$$M = \frac{\text{number of moles}}{\text{volume of solution (in L)}} = \frac{0.025}{200} \times 1000 = 0.125 \text{ M}$$

Example 2 *What volume of 12 N and 3 N* HCl *must be mixed to give* 1.00 *L of* 6.00 *N* HCl?

(*a*) 0.33 *L*, 0.66 *L* (*b*) 0.33 *L*, 0.33 *L*
(*c*) 0.66 *L*, 0.66 *L* (*d*) 0.8 *L*, 0.2 *L*

Solution (*a*) L-equivalents of solution

$$= 1 \text{ L} \times \left(\frac{6.00 \text{ eq.}}{\text{L}}\right) = 6.00 \text{ eq.}$$

Let x = volume of concentrated solution. Then

$1.00 - x$ = volume of dilute solution

$$(x)\left(\frac{12.0 \text{ eq}}{\text{L}}\right) + (1.00 - x)\left(\frac{3.00 \text{ eq}}{\text{L}}\right) = 6.00 \text{ eq.}$$

On solving

$x = 0.333$

∴ Volume of concentrated solution = 0.33 L

and, Volume of dilute solution = 1 − 0.33 = 0.67 L

Example 3 *How many mL of* 0.1*M* HCl *are required to react completely with* 1g *mixture of* Na_2CO_3 *and* $NaHCO_3$ *containing equimolar amounts of both?* **[NCERT]**

(a) 157.8 *mL* (*b*) 110.2 *mL* (*c*) 98.4 *mL* (*d*) 175 *mL*

Solution (*a*) ***Step I*** *Calculating mass of* Na_2CO_3 *and* $NaHCO_3$

Mass of the mixture = 1.0 g

Let the mass of Na_2CO_3 = x g

Then the mass of $NaHCO_3$ = $(1 - x)$ g

$$\text{Moles of } Na_2CO_3 = \frac{\text{mass}}{\text{molar mass}}$$

$$= \frac{x \text{ g}}{[(23 \times 2) + (12) + (16 \times 3)] \text{ g mol}^{-1}}$$

$$= \frac{x}{106} \text{ mol}$$

$$\text{Moles of } NaHCO_3 = \frac{\text{mass}}{\text{molar mass}}$$

$$= \frac{(1 - x) \text{ g}}{[(23) + (1) + (12) + (16 \times 3)] \text{ g mol}^{-1}}$$

$$= \frac{(1 - x)}{84} \text{ mol}$$

According to the question, the mixture contains equimolar amounts of Na_2CO_3 and $NaHCO_3$.

$$\text{Moles of } Na_2CO_3 = \text{Moles of } NaHCO_3$$

$$\frac{x}{106} \text{ mol} = \frac{(1 - x)}{84} \text{ mol}$$

$$84x = 106 - 106\,x;\ 106x + 84x = 106$$

$$190x = 106;\ x = \frac{106}{190} = 0.558 \text{ g}$$

∴ Mass of Na_2CO_3 = 0.558 g

Mass of $NaHCO_3$ = (1 − 0.558) = 0.442 g

Step II *Calculating total mass of* HCl *required*

$$\underset{106\ \text{g}}{Na_2CO_3(s)} + \underset{73\ \text{g}}{2HCl\,(aq)} \longrightarrow 2NaCl\,(aq) + H_2O\,(l) + CO_2\,(g)$$

According to the above equation

∵ 106 g Na_2CO_3 require HCl to react completely = 73 g

∴ 0.558 g Na_2CO_3 require HCl to react completely

$$= \frac{73 \times 0.558}{106} \text{ g}$$

$$= 0.384 \text{ g}$$

$$\underset{84\ \text{g}}{NaHCO_3(s)} + \underset{36.5\ \text{g}}{HCl\,(aq)} \longrightarrow NaCl\,(aq) + H_2O\,(l) + CO_2(g)$$

∵ 84 g $NaHCO_3$ require HCl = 36.5 g

$$\therefore\ 0.442 \text{ g } NaHCO_3 \text{ require HCl} = \frac{36.5 \times 0.442}{84} \text{ g} = 0.192 \text{ g}$$

Total mass of HCl required = (0.384 + 0.192) g = 0.576 g

Step III *Calculating volume of* HCl *required*

Mass of HCl required = 0.576 g

Molarity of HCl solution = 0.1M

$$\text{Molarity}\,(M) = \frac{\text{mass / molar mass}}{\text{volume of HCl in litres}}$$

$$(0.1\ \text{mol L}^{-1}) = \frac{(0.576\ \text{g})\,/\,(36.5\ \text{g mol}^{-1})}{\text{volume in litres}}$$

$$\text{Volume}\,(V) = \frac{0.576}{36.5 \times 0.1} = 0.1578\ \text{L} = 157.8\ \text{mL}$$

Example 4 *The volume of water to be added to* 100 cm^3 *of* 0.5 *N* H_2SO_4 *to get decinormal concentration is*

(*a*) 400 *cm*^{3} (*b*) 500 *cm*^{3} (*c*) 450 *cm*^{3} (*d*) 100 *cm*^{3}

Solution (*a*) Let the total volume of solution = *x*

$$\therefore \qquad V_2 = \frac{N_1V_1}{N_2} = \frac{0.5 \times 100}{0.1} = 500\ \text{cm}^3$$

$\therefore$ The volume of water added = 500 − 100 cm^3 = 400 cm^3

Example 5 *A dry air is passed through the solution, containing the* 10 *g of solute and* 90 *g of water and then it is passed through pure water. There is the depression in weight of solution by* 2.5 *g and in weight of pure solution by* 0.05 *g. Calculate the molecular weight of solute.*

(*a*) 25 (*b*) 50 (*c*) 100 (*d*) 180

Solution (*c*) $\because$ Lowering in weight of solution $\propto$ solution pressure (p_s)

and lowering in weight of solvent $\propto p^\circ - p_s$

($\because$ p° = vapour pressure of pure solvent)

$$\text{Thus,} \qquad \frac{p^\circ - p_s}{p_s} = \frac{\text{lowering in weight of solvent}}{\text{lowering in weight of solution}} = \frac{0.05}{2.5}$$

But according to Raoult's law,

$$\frac{p^\circ - p_s}{p_s} = \frac{w}{m} \times \frac{M}{W}$$

$$\therefore \qquad \frac{0.05}{2.5} = \frac{10 \times 18}{90 \times m} \quad \Rightarrow \quad m = \frac{10 \times 18 \times 2.5}{90 \times 0.05} = 100\ \text{g mol}^{-1}$$

Example 6 *Mark the correct relationship between the boiling points of very dilute solutions of* $BaCl_2(t_1)$ *and* KCl (t_2), *having the same molarity.*

(*a*) $t_1 = t_2$ (*b*) $t_1 < t_2$

(*c*) $t_2 < t_1$ (*d*) *cannot be calculated*

Solution (c) $BaCl_2$ furnishes more ions than KCl and thus, shows higher boiling point, *i.e.*, $t_1 > t_2$

Example 7 *A solution of urea in water has a boiling point of* 100.128°C. *Find the freezing point of the same solution. Molal constants of water* k_f *and* k_b *are* 1.86°C *and* 0.512°C *respectively.*

(*a*) −0.346°C (*b*) −0.465°C (*c*) +0.465°C (*d*) −0.256°C

Solution (*b*) $\because \quad \Delta T_b = k_b \times m$

$$m = \frac{\Delta T_b}{k_b} = \frac{0.128}{0.512} = 0.25$$

$$\text{Now,} \qquad k_f = 1.86^\circ\ \text{C}, m = 0.25$$

$$\therefore \qquad \Delta T_f = k_f \times m$$

$$\therefore \qquad \Delta T_f = 1.86 \times 0.25 = 0.465^\circ\ \text{C}$$

$\therefore$ Freezing point of the solution $(T_b) = T^\circ - \Delta T_f$

$$= 0 - 0.465 = -0.465^\circ\ \text{C}$$

Example 8 *What is the freezing point of a* 10% *(by weight) solution of* CH_3OH *in water?*

(*a*) 90°*C* (*b*) 10°*C* (*c*) 6.45°*C* (*d*) −6.45°*C*

Solution (*d*) 1.00 kg contains 0.100 kg CH_3OH (and 0.900 kg H_2O)

$$(100\ \text{g CH}_3\text{OH})\left(\frac{1\ \text{mol}}{32.0\ \text{g}}\right) = 3.12\ \text{mol}$$

$$= \frac{3.12\ \text{mol}}{0.900\ \text{kg}} = 3.47\ \text{m}$$

$$\Delta T_f = k_f \times m = (1.86^\circ\ \text{C / m})(3.47\ \text{m}) = 6.45^\circ\ \text{C}$$

Freezing point of the solution $(T_b) = T^\circ - \Delta T_f = 0 - 6.45$

$$= -6.45^\circ\ \text{C}$$

Example 9 *The osmotic pressure of blood is* 7.65 *atm at* 37°C. *How much glucose should be used per litre for an intravenous injection that is to have the same osmotic pressure as blood?*

(*a*) 54.2 *g* (*b*) 180 *g* (*c*) 12 *g* (*d*) 0.30 *g*

Solution (*a*) $\pi V = nRT$

$$n = \frac{\pi V}{RT} = \frac{(7.65\ \text{atm})(1.00\ \text{L})}{(0.0821\ \text{L atm / mol K})(310\ \text{K})}$$

$$= 0.301\ \text{mol}$$

$$= (0.301\ \text{mol})\left(\frac{180\ \text{g C}_6\text{H}_{12}\text{O}_6}{\text{mol}}\right)$$

$$= 54.2\ \text{g}$$

Example 10 *A* 1% *(w/V)* KCl *solution is ionised to the extent of* 82%. *What would be its osmotic pressure at* 291 *K?* (*R* = 0.083 *L bar K*$^{-1}$ *mol*$^{-1}$)

(*a*) 1.82 *bar* (*b*) 5.9 *bar* (*c*) 82 *bar* (*d*) 100 *bar*

Solution (*b*) $KCl \longrightarrow K^+ + Cl^-$

$$\alpha = \frac{i-1}{n-1} \quad \text{or} \quad 0.82 = \frac{i-1}{2-1} \quad \text{or} \quad i = 1.82$$

$$\pi V = i\,\frac{W_B}{M_B} \times RT$$

$$\text{Volume of solution} = 100\ \text{mL} = \frac{100}{1000}\ \text{L}$$

$$\pi \times \frac{100}{1000} = 1.82 \times \frac{1}{74.5} \times 0.083 \times 291$$

$$\pi = \frac{439.58}{74.5} = 5.9\ \text{bar}$$

Start Practice for JEE Main

Round I (Topically Divided Problems)

Different Solutions and their Concentrations

1. A beaker contains a solution of substance '*A*'. Precipitation of substance '*A*' takes place when small amount of '*A*' is added to the solution. The solution is **[NCERT Exemplar]**

(a) saturated (b) supersaturated
(c) unsaturated (d) concentrated

2. Value of Henry's constant K_H **[NCERT Exemplar]**

(a) increases with increase in temperature
(b) decreases with increase in temperature
(c) remains constant
(d) first increases then decreases

3. Low concentration of oxygen in the blood and tissues of people living at high altitude is due to **[NCERT Exemplar]**

(a) low temperature
(b) low atmospheric pressure
(c) high atmospheric pressure
(d) both low temperature and high atmospheric pressure

4. K_H value for $Ar(g), CO_2(g)$, $HCHO(g)$ and $CH_4(g)$ are 40.39, 1.67, 1.83×10^{-5} and 0.413 respectively. Arrange these gases in the order of their increasing solubility. **[NCERT Exemplar]**

(a) $HCHO < CH_4 < CO_2 < Ar$
(b) $HCHO < CO_2 < CH_4 < Ar$
(c) $Ar < CO_2 < CH_4 < HCHO$
(d) $Ar < CH_4 < CO_2 < HCHO$

5. Calculate the mass percentage of aspirin ($C_9H_8O_4$) in acetonitrile (CH_3CN) when 6.5 g of $C_9H_8O_4$ is dissolved in 450 g of CH_3CN. **[NCERT]**

(a) 1.40 (b) 1.90
(c) 2.60 (d) 2.29

6. A sample of drinking water was found to be severely contaminated with chloroform ($CHCl_3$) supposed to a carcinogen. The level of contamination was 15 ppm (by mass). Express this in per cent by mass. **[NCERT]**

(a) $15 \times 10^{-3}\%$ (b) $1.5 \times 10^{-4}\%$
(c) $1.5 \times 10^{-3}\%$ (d) $15 \times 10^{-6}\%$

7. Henry's law constant for the molality of methane in benzene at 298 K is 4.27×10^5 mm Hg. Calculate the solubility of methane in benzene at 298 K under 760 mm Hg. **[NCERT]**

(a) 1.78×10^{-4} (b) 1.78×10^{-5}
(c) 17.8×10^{-4} (d) 1.78×10^{-6}

8. 4L of 0.02 M aqueous solution of NaCl was diluted by adding 1 L of water. The molality of the resultant solution is **[NCERT Exemplar]**

(a) 0.004 (b) 0.008
(c) 0.012 (d) 0.016

9. If 5.85 g of NaCl (molecular weight 58.5) is dissolved in water and the solution is made up to 0.5 L, the molarity of the solution will be

(a) 0.1 (b) 0.2 (c) 0.3 (d) 0.4

10. Calculate the amount of benzoic acid (C_6H_5COOH) required for preparing 250 mL of 0.15 M solution in methanol. **[NCERT]**

(a) 1.89 g (b) 4.57 g
(c) 2.99 g (d) 3.54 g

11. An antifreeze solution is prepared from 222.6 g of ethylene glycol ($C_2H_6O_2$) and 200 g of water. If the density of the solution is 1.072 g mL^{-1} then what shall be the molarity of the solution? **[NCERT]**

(a) 91 M (b) 9.1 M
(c) 0.91 M (d) 0.0091 M

12. Increasing the temperature of an aqueous solution will cause

(a) decrease in molarity
(b) decrease in molality
(c) decrease in mole fraction
(d) decrease in % *w*/*w*

13. The normality of 10% (weight/volume) acetic acid is

(a) 1 N (b) 1.3 N
(c) 1.7 N (d) 1.9 N

14. 19.85 mL of 0.1 N NaOH reacts with 20 mL of HCl solution for complete neutralisation. The molarity of HCl solution is

(a) 9.9 (b) 0.99
(c) 0.099 (d) 0.0099

15. The normality of 0.3 M phosphorous acid (H_3PO_3) is

(a) 0.2 (b) 0.4
(c) 0.6 (d) 0.8

16. What is the molarity of H_2SO_4 solution that has a density 1.84 g/cc at 35°C and contains 98% solute by weight?

(a) 4.18 M (b) 1.84 M
(c) 8.41 M (d) 18.4 M

17. Molecular weight of glucose is 180. A solution of glucose which contains 18 g/L, is

(a) 0.1 molal (b) 0.2 molal
(c) 0.3 molal (d) 0.4 molal

18. If 20 mL of 0.4 N NaOH solution completely neutralizes 40 mL of a dibasic acid, the molarity of the acid solution is

(a) 0.1 M (b) 0.3 M
(c) 0.5 M (d) 0.7 M

19. Calculate the molality of 1 L solution of 93% H_2SO_4 (weight/volume). The density of the solution is 1.84 g/mL.

(a) 11.05 (b) 12.05
(c) 13.05 (d) 10.05

20. Which of the following solutions has the highest normality?

(a) 6 g of NaOH/100 mL
(b) 0.5 M H_2SO_4
(c) N phosphoric acid
(d) 8 g of KOH/L

21. 100 mL of 0.3 N HCl is mixed with 200 mL of 0.6 N H_2SO_4. The final normality of the resulting solution will be

(a) 0.3 N (b) 0.2 N
(c) 0.5 N (d) 0.1 N

22. Based on solute-solvent interactions, arrange the following in the order of increasing solubility in *n*-octane. Cyclohexane, KCl, CH_3OH, CH_3CN. **[NCERT]**

(a) KCl < CH_3OH < CH_3CN < Cyclohexane
(b) CH_3OH < KCl < CH_3CN < Cyclohexane
(c) CH_3OH < CH_3CN < KCl < Cyclohexane
(d) None of the above

Raoult's Law
(Ideal and Non-Ideal Solutions)

23. If two liquids *A* and *B* form minimum boiling azeotrope at some specific composition then **[NCERT Exemplar]**

(a) *A*–*B* interactions are stronger than those between *A*–*A* or *B*–*B*
(b) vapour pressure of solution increases because more number of molecules of liquids *A* and *B* can escape from the solution
(c) vapour pressure of solution decreases because less number of molecules of only one of the liquids escape from the solution
(d) *A*–*B* interactions are weaker than those between *A*–*A* or *B*–*B*

24. Considering the formation, breaking and strength of hydrogen bond, predict which of the following mixtures will show a positive deviation from Raoult's law? **[NCERT Exemplar]**

(a) Methanol and acetone
(b) Chloroform and acetone
(c) Nitric acid and water
(d) Phenol and aniline

25. Formation of a solution from two components can be considered as

(1) Pure solvent → separated solvent molecules; ΔH_1
(2) Pure solute → separated solute molecules; ΔH_2
(3) Separated solvent and solute molecules → solution, ΔH_3

Solution so formed will be ideal if

(a) $\Delta H_{\text{sol}} = \Delta H_1 - \Delta H_2 - \Delta H_3$
(b) $\Delta H_{\text{sol}} = \Delta H_3 - \Delta H_1 - \Delta H_2$
(c) $\Delta H_{\text{sol}} = \Delta H_1 + \Delta H_2 + \Delta H_3$
(d) $\Delta H_{\text{sol}} = \Delta H_1 + \Delta H_2 - \Delta H_3$

26. Which of the following is true when components forming an ideal solution are mixed?

(a) $\Delta H_m = \Delta V_m = 0$ (b) $\Delta H_m < \Delta V_m$
(c) $\Delta H_m = \Delta V_m = 1$ (d) $\Delta H_m > \Delta V_m$

27. When two liquids A and B are mixed then their boiling points becomes greater than both of them. What is the nature of this solution?

(a) Ideal solution
(b) Normal solution
(c) Negative deviation with non-ideal solution
(d) Positive deviation with non-ideal solution

28. For the determination of molecular weights, Raoult's law is applicable only to

(a) dilute solutions of electrolytes
(b) concentrated solutions of electrolytes
(c) dilute solutions of non-electrolytes
(d) concentrated solutions of non-electrolytes

29. Vapour pressure of CCl_4 at 25°C is 143 mm of Hg and 0.5 g of a non-volatile solute (mol. wt. = 65) is dissolved in 100 mL CCl_4. Find the vapour pressure of the solution. (Density of $CCl_4 = 1.58 \text{ g / cm}^3$).

(a) 94.39 mm
(b) 141.93 mm
(c) 134.44 mm
(d) 199.34 mm

30. The vapour pressure of pure liquids A and B are 450 and 700 mm Hg respectively, at 350 K. If total vapour pressure is 600 mm Hg, find the composition of B in vapour phase. **[NCERT]**

(a) 0.30 (b) 0.40 (c) 0.60 (d) 0.70

31. 100 g of liquid A (molar mass 140 g mol^{-1}) was dissolved in 1000 g of liquid B (molar mass 180 g mol^{-1}). The vapour pressure of pure liquid B was found to be 500 torr. Calculate the vapour pressure of pure liquid A and its vapour pressure in the solution if the total vapour pressure of the solution is 475 torr. **[NCERT]**

(a) 500, 450
(b) 280, 500
(c) 280, 32
(d) 500, 280

32. The vapour pressure of two liquids P and Q are 80 and 60 Torr, respectively. The total vapour pressure of solution obtained by mixing 3 moles of P and 2 moles of Q would be

(a) 140 Torr
(b) 20 Torr
(c) 68 Torr
(d) 72 Torr

Colligative Properties

33. Which of the following is a colligative property?

(a) Boiling point
(b) Freezing point
(c) Osmotic pressure
(d) Vapour pressure

34. Lowering of vapour pressure is highest for

(a) 0.1 M $BaCl_2$
(b) 0.1 M glucose
(c) 0.1 M $MgSO_4$
(d) Urea

35. Which one of the statements given below concerning properties of solutions, describes a colligative effect?

(a) Vapour pressure of pure water decreases by the addition of nitric acid
(b) Boiling point of pure water decreases by the addition of ethanol
(c) Boiling point of pure benzene increases by the addition of toluene
(d) Vapour pressure of pure benzene decreases by the addition of naphthalene

36. The vapour pressure of water at 20°C is 17.54 mm. When 20 g of a non-ionic substance is dissolved in 100 g of water, the vapour pressure is lowered by 0.30 mm. What is the molecular mass of the substance?

(a) 200.8
(b) 206.88
(c) 210.5
(d) 215.2

37. Vapour pressure of pure water at 298 K is 23.8 mm Hg. 50 g urea (NH_2CONH_2) is dissolved in 850 g of water. Calculate the relative lowering of vapour pressure. **[NCERT]**

(a) 0.017 (b) 0.023 (c) 0.089 (d) 0.012

38. Vapour pressure of water at 293 K is 17.535 mm Hg. Calculate the vapour pressure of water at 293 K when 25 g of glucose is dissolved in 450 g of water. **[NCERT]**

(a) 17.43 mm Hg
(b) 18.93 mm Hg
(c) 20.12 mm Hg
(d) 25.31 mm Hg

39. The unit of ebullioscopic constant is **[NCERT Exemplar]**

(a) K kg mol^{-1} or K (molality)^{-1}
(b) mol kg K^{-1} or K^{-1} (molality)
(c) $\text{kg mol}^{-1} \text{K}^{-1}$ or $\text{K}^{-1} \text{(molality)}^{-1}$
(d) K mol kg^{-1} or K (molality)

40. If the elevation in boiling point of a solution of 10 g of solute (mol. wt. = 100) in 100 g of water is ΔT_b, the ebullioscopic constant of water is

(a) 10
(b) $100T_b$
(c) ΔT_b
(d) $\frac{\Delta T_b}{10}$

41. Boiling point of water at 750 mm Hg is 99.63°C. How much sucrose is to be added to 500 g of water such that it boils at 100° C. [k_b for water is $0.52 \text{ K kg mol}^{-1}$] **[NCERT]**

(a) 121 g (b) 150 g (c) 180 g (d) 300 g

42. When 10 g of a non-volatile solute is dissolved in 100 g of benzene, it raises boiling point by 1°C then molecular mass of the solute is (k_b for $C_6H_6 = 2.53 \text{ K kg-mol}^{-1}$)

(a) 223 g (b) 233 g (c) 243 g (d) 253 g

43. If 0.15 g of a solute dissolved in 15 g of solvent is boiled at a temperature higher by 0.216°C than that of the pure solvent, the molecular weight of the substance is (molal elevation constant for the solvent is 2.16°C)

(a) 100 (b) 102 (c) 104 (d) 1.02

44. The molar freezing point constant for water is $1.86^\circ \text{C mol}^{-1}$. If 342 g of cane sugar ($C_{12}H_{22}O_{11}$) is dissolved in 1000 g of water, the solution will freeze at

(a) -1.86°C (b) -2.86°C
(c) $+1.86^\circ$C (d) $+2.86^\circ$C

45. The amount of ice that will separate out on cooling a solute containing 50 g of ethylene glycol in 200 g water to –9.3°C will be ($k_g = 1.86 \text{ K kg mol}^{-1}$)

(a) 8.37 g (b) 161.3 g
(c) 3.87 g (d) 38.7 g

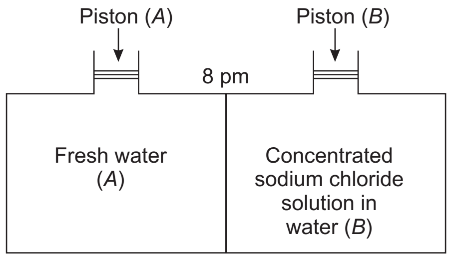
46. The molecular weight of NaCl determined by studying freezing point depression of its 0.5% aqueous solution is 30. The apparent degree of dissociation of NaCl is

(a) 0.60 (b) 0.50
(c) 0.30 (d) 0.95

47. Which of the following statements is false?
[NCERT Exemplar**]**

(a) Units of atmospheric pressure and osmotic pressure are the same
(b) In reverse osmosis, solvent molecules move through a semipermeable membrane from a region of lower concentration of solute to a region of higher concentration
(c) The value of molal depression constant depends on nature of solvent
(d) Relative lowering of vapour pressure is a dimensionless quantity

48. Consider the figure and mark the correct option.



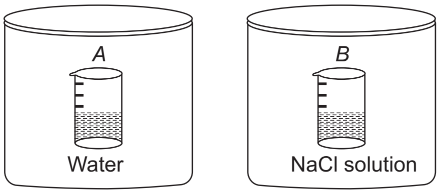
[NCERT Exemplar**]**

(a) Water will move from side (*A*) to side (*B*) if a pressure lower than osmotic pressure is applied on piston (*B*)
(b) water will move from side (*B*) to side (*A*) if a pressure greater than osmotic pressure is applied on piston (*B*)
(c) Water will move from side (*B*) to side (*A*) if a pressure equal to osmotic pressure is applied on piston (*B*)
(d) Water will move from side (*A*) to side (*B*) if pressure equal to osmotic pressure is applied on piston (*A*)

49. An unripe mango placed in a concentrated salt solution to prepare pickle, shrivels because
[NCERT Exemplar**]**

(a) it gains water due to osmosis
(b) it loses water due to reverse osmosis
(c) it gains water due to reverse osmosis
(d) it loses water due to osmosis

50. Two beakers of capacity 500 mL were taken. One of these beakers, labelled as "*A*", was filled with 400 mL water whereas the beaker labelled "*B*" was filled with 400 mL of 2 M solution of NaCl. At the same temperature both the beakers were placed in closed containers of same material and same capacity as shown in the figure. **[NCERT** Exemplar**]**



At a given temperature, which of the following statement is correct about the vapour pressure of pure water and that of NaCl solution.

(a) Vapour pressure in container (*A*) is more than that in container (*B*)
(b) Vapour pressure in container (*A*) is less than that in container (*B*)
(c) Vapour pressure is equal in both the containers
(d) Vapour pressure in container (*B*) is twice the vapour pressure in container (*A*)

51. Which of the following associated with isotonic solutions is not correct?

(a) They will have the same osmotic pressure
(b) They will have the same vapour pressure
(c) They have same weight concentrations
(d) Osmosis does not take place when the two solutions are separated by a semipermeable membrane

52. Calculate the osmotic pressure in pascals exerted by a solution prepared by dissolving 1.0 g of polymer of molar mass 185000 in 450 mL of water at 37°C.
[NCERT]

(a) 10.9 (b) 35.8
(c) 20.5 (d) 30.9

53. The relationship between osmotic pressure at 273 K when 10 g glucose (p_1), 10 g urea (p_2) and 10 g sucrose (p_3) are dissolved in 250 mL of water is
(a) $p_1 > p_2 > p_3$ (b) $p_3 > p_2 > p_1$
(c) $p_2 > p_1 > p_3$ (d) $p_2 > p_3 > p_1$

54. A 6% solution of urea is isotonic with
(a) 1 M solution of glucose
(b) 0.05 M solution of glucose
(c) 6% solution of glucose
(d) 25% solution of glucose

55. The osmotic pressure of a 5% (wt./vol) solution of cane sugar at 150°C is
(a) 3.078 atm (b) 4.078 atm
(c) 5.078 atm (d) 2.45 atm

56. A 5% solution of sugar cane (mol. wt. = 342) is isotonic with 1% solution of X under similar conditions. The molecular weight of X is
(a) 136.2 (b) 68.4
(c) 34.2 (d) 171.2

57. At 300 K, 36 g of glucose present in a litre of its solution has an osmotic pressure of 4.98 bar. If the osmotic pressure of the solution is 1.52 bar at the same temperature, what would be its concentration? **[NCERT]**
(a) 0.02 (b) 0.04 (c) 0.08 (d) 0.06

58. Which of the following units is useful in relating concentration of solution with its vapour pressure? **[NCERT Exemplar]**
(a) Mole fraction (b) Parts per million
(c) Mass percentage (d) Molality

Abnormal Colligative Properties : van't Hoff Factor

59. We have three aqueous solutions of NaCl labelled as '*A*', '*B*' and '*C*' with concentrations 0.1 M, 0.01 M and 0.001 M, respectively. The value of van't Hoff factor for these solutions will be in the order **[NCERT Exemplar]**
(a) $i_A < i_B < i_C$ (b) $i_A > i_B > i_C$
(c) $i_A = i_B = i_C$ (d) $i_A < i_B > i_C$

60. Which of the following solution in water possesses the lowest vapour pressure?
(a) 0.1 (N) $BaCl_2$ (b) 0.1 (M) NaCl
(c) 0.1 (M) KCl (d) None of these

61. Which of the following aqueous solutions should have the highest boiling point? **[NCERT Exemplar]**
(a) 1.0 M NaOH (b) 1.0 M Na_2SO_4
(c) 1.0 M NH_4NO_3 (d) 1.0 M KNO_3

62. Which has minimum osmotic pressure?
(a) 200 mL of 2 M NaCl solution
(b) 200 mL of 1 M glucose solution
(c) 200 mL of 2 M urea solution
(d) All have same osmotic pressure

63. Two solutions of KNO_3 and CH_3COOH are prepared separately. Molarity of both is 0.1 M and osmotic pressures are p_1 and p_2 respectively. The correct relationship between the osmotic pressures is
(a) $p_1 = p_2$ (b) $p_1 > p_2$
(c) $p_2 > p_1$ (d) $\frac{p_1}{p_1 + p_2} + \frac{p_2}{p_1 + p_2}$

64. When 20 g of naphthoic acid ($C_{11}H_8O_2$) is dissolved in 50 g of benzene (k_f = 1.72 K kg mol^{-1}), a freezing point depression of 2 K is observed. The van't Hoff factor (i) is
(a) 0.5 (b) 1 (c) 2 (d) 13

65. The freezing point depression of 0.001 m, $K_x[Fe(CN)_6]$ is 7.10×10^{-3} K. If for water, k_f is 1.86 K kg mol^{-1}, value of x will be
(a) 4 (b) 3 (c) 2 (d) 1

66. The elevation in boiling point of a solution of 13.44 g of $CuCl_2$ in 1 kg of water using the following information will be (molecular weight of $CuCl_2$ = 134.4 and k_b = 0.52 K $molal^{-1}$)
(a) 0.16 (b) 0.05 (c) 0.1 (d) 0.2

67. What is the freezing point of a solution containing 8.1 g HBr in 100 g water assuming the acid to be 90% ionised (k_f for water = 1.86 kg mol^{-1})?
(a) −0.35°C (b) −1.35°C
(c) −2.35°C (d) −3.53°C

68. Determine the amount of $CaCl_2$ (i = 2.47) dissolved in 2.5 L of water such that its osmotic pressure is 0.75 atm at 27°C. **[NCERT]**
(a) 1.82 g (b) 3.42 g (c) 2.98 g (d) 1.45 g

69. Determine the osmotic pressure of a solution prepared by dissolving 25 mg of K_2SO_4 in 2 L of water at 25°C, assuming that it is completely dissociated. **[NCERT]**
(a) 2.39×10^{-2} atm (b) 4.29×10^{-3} atm
(c) 5.27×10^{-3} atm (d) 1.39×10^{-4} atm

70. 19.5 g of CH_2FCOOH is dissolved in 500 g of water. The depression in the freezing point of water observed is 1.0°C. Calculate the degree of dissociation and dissociation constant of fluoroacetic acid. K_f = 1.86 K kg mol^{-1} **[NCERT]**
(a) 0.07 and 3.07×10^{-3} (b) 0.04 and 3.07×10^{-3}
(c) 0.082 and 4.23×10^{-4} (d) 0.07 and 4.23×10^{-4}

Round II (Mixed Bag)

Only One Correct Option

1. The air is a mixture of a number of gases. The major components are oxygen and nitrogen with approximate proportion of 20% and 79% by volume at 298 K. The water is in equilibrium with air at a pressure of 10 atm. At 298 K if the Henry's law constants for oxygen and nitrogen at 298 K are 3.30×10^7 mm and 6.51×10^7 mm respectively, the composition of O_2 and N_2 gases in water respectively are **[NCERT]**

(a) $4.6 \times 10^{-5}, 9.22 \times 10^{-5}$

(b) $9.22 \times 10^{-5}, 4.6 \times 10^{-5}$

(c) $4.6 \times 10^{-5}, 4.12 \times 10^{-5}$

(d) $4.12 \times 10^{-5}, 4.6 \times 10^{-5}$

2. Henry's law constant for CO_2 in water is 1.67×10^8 Pa at 298 K. Calculate the quantity of CO_2 in 500 mL of soda water when packed under 2.5 atm CO_2 pressure at 298 K. **[NCERT]**

(a) 2.82 g (b) 1.85 g

(c) 9.62 g (d) 11.2 g

3. Nalorphene ($C_{19}H_{21}NO_3$), similar to morphine, is used to combat withdrawal symptoms in narcotic users. Dose of nalorphene generally given is 1.5 mg. Calculate the mass of 1.5×10^{-3} m aqueous solution required for the above dose. **[NCERT]**

(a) 3.2×10^{-2} kg (b) 3.2×10^{-4} kg

(c) 3.2×10^{-3} kg (d) 3.2×10^{-5} kg

4. A solution is obtained by mixing 300 g of 25% solution and 400 g of 40% solution by mass. Calculate the mass percentage of solute in the resulting solution. **[NCERT]**

(a) 33.57 (b) 66.43

(c) 87.23 (d) 19.24

5. The molarity of pure water is

(a) 55.6 (b) 5.56

(c) 6.55 (d) 65.5

6. On the basis of information given below mark the correct option.

Information

(A) In bromoethane and chloroethane mixture intermolecular interactions of *A*—*A* and *B*—*B* type are nearly same as *A*—*B* type interactions.

(B) In ethanol and acetone mixture *A*—*A* or *B*—*B* type intermolecular interactions are stronger than *A*—
B type interactions.

(C) In chloroform and acetone mixture *A*—*A* or *B*—*B* type intermolecular interactions are weaker than *A*—*B* type interactions. **[NCERT Exemplar]**

(a) Solution (B) and (C) will follow Raoult's law

(b) Solution (A) will follow Raoult's law

(c) Solution (B) will show negative deviation from Raoult's law

(d) Solution (C) will show positive deviation from Raoult's law

7. When mercuric iodide is added to the aqueous solution of potassium iodide, the

(a) freezing point is raised

(b) freezing point is lowered

(c) freezing point does not change

(d) boiling point does not change

8. Which of the following aqueous solutions produce the same osmotic pressure?

(i) 0.1 M NaCl solution

(ii) 0.1 M glucose solution

(iii) 0.6 g urea in 100 mL solution

(iv) 1.0 g of a non-electrolyte solute (*X*) in 50 mL solution (molar mass of $X = 200$)

(a) (i), (ii), (iii) (b) (ii), (iii), (iv)

(c) (i), (ii), (iv) (d) (i), (iii), (iv)

9. A 0.025 M solution of monobasic acid had a freezing point of –0.060°C. The pK_a for the acid is ($k_b = 1.86 \text{ K kg mol}^{-1}$)

(a) 1.2 (b) 2 (c) 2.5 (d) 5.7

10. How many gram of sucrose (mol. wt. = 342) should be dissolved in 100 g water in order to produce a solution with a 105.0°C difference between the freezing point and boiling temperature? ($k_f = 1.860°\text{C / m}, k_b = 0.151°\text{C/m}$)

(a) 34.2 g (b) 72 g

(c) 342 g (d) 460 g

11. The vapour pressure of water is 12.3 kPa at 300 K. Calculate the vapour pressure of 1 molal solution of a non-volatile solute in it. **[NCERT]**

(a) 12 kPa (b) 10 kPa

(c) 15 kPa (d) 13 kPa

12. A 5% solution (by mass) of cane sugar in water has freezing point 271 K. Calculate the freezing point of 5% glucose in water if freezing point of pure water is 273.15 K. **[NCERT]**

(a) 250 K
(b) 269 K
(c) 310 K
(d) 275 K

13. Benzene and naphthalene form ideal solution over the entire range of composition. The vapour pressure of pure benzene and naphthalene at 300 K are 50.71 mm Hg and 32.06 mm Hg respectively. Calculate the mole fraction of benzene in vapour phase if 80 g of benzene is mixed with 100 g of naphthalene. **[NCERT]**

(a) 0.67
(b) 0.32
(c) 0.85
(d) 0.42

14. A certain substance '*A*' tetramerises in water to the extent of 80%. A solution of 2.5 g of *A* in 100 g of water lowers the freezing point by 0.3°C. The molar mass of *A* is

(a) 31
(b) 62
(c) 122
(d) 244

15. Two solutions of glucose have osmotic pressure 1.0 and 3.5 atm. If 1 L of first solution is mixed with *V* L of second solution, the osmotic pressure of the resultant solution becomes 2.5 atm. Volume of second solution is

(a) 1.0 L
(b) 1.5 L
(c) 2.5 L
(d) 3.5 L

16. A solution containing 30 g of non-volatile solute exactly in 90 g of water has a vapour pressure of 2.8 kPa at 298 K. Further, 18 g of water is then added to the solution and the new vapour pressure becomes 2.9 kPa at 298 K. Calculate the vapour pressure of water at 298 K. **[NCERT]**

(a) 3.5 kPa
(b) 8.2 kPa
(c) 4.2 kPa
(d) 1.9 kPa

17. Two elements *A* and *B* form compounds having formula AB_2 and AB_4. When dissolved in 20 g of benzene (C_6H_6), 1 g AB_2 lowers the freezing point by 2.3 K whereas 1.0 g of AB_4 lowers it by 1.3 K. The molal depression constant for benzene is 5.1 K kg mol^{-1}. The atomic masses of *A* and *B* are respectively. **[NCERT]**

(a) 25.6, 42.9
(b) 30.9, 50.2
(c) 42.64, 25.6
(d) 42.5, 25.6

18. Calculate the depression in the freezing point of water when 10 g of $CH_3CH_2CHClCOOH$ is added to 250 g of water. $K_a = 1.4 \times 10^{-3}$; $K_f = 1.86$ K kg mol^{-1}. **[NCERT]**

(a) 0.42 K
(b) 0.82 K
(c) 0.19 K
(d) 0.65 K

More than One Correct Option

19. Which of the following factor(s) affect the solubility of a gaseous solute in the fixed volume of liquid solvent? **[NCERT Exemplar]**

(i) nature of solute (ii) temperature (iii) pressure
(a) (i) and (iiii) at constant *T*
(b) (i) and (ii) at constant *p*
(c) (ii) and (iii) only
(d) (iii) only

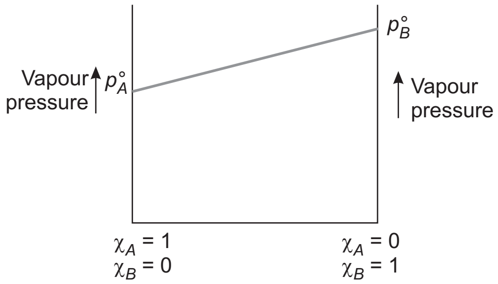
20. Which of the following is/are not affected by temperature?

(a) Molarity
(b) Molality
(c) Normality
(d) Mole fraction

21. Isotonic solutions must have the same **[NCERT Exemplar]**

(a) solute
(b) density
(c) elevation in boiling point
(d) depression in freezing point

22. The following is a graph plotted between the vapour pressure of two volatile liquids against their respective mode fractions.



Which of the following statement is/are correct?

(a) When $\chi_A = 1$ and $\chi_B = 0$, then $p = p_A^\circ$.
(b) When $\chi_B = 1$ and $\chi_A = 0$, then $p = p_B^\circ$.
(c) When $\chi_A = 1$ and $\chi_B = 0$, then $p < p_B^\circ$.
(d) When $\chi_B = 1$ and $\chi_A = 0$, then $p > p_A^\circ$.

23. Molecular weight of urea is 60. A solution of urea containing 6 g of urea in 1 L is a

(a) 1 N
(b) 0.1 M
(c) 0.1 N
(d) 1 M

Assertion and Reason

Directions (Q. Nos. 24 to 28) *Each of these questions contains two statements : Statement* I (*Assertion*) *and Statement* II (*Reason*). *Each of these questions also has four alternative choices, only one of which is the correct answer. You have to select one of the codes* (*a*), (*b*), (*c*), (*d*) *given below*

(a) Statement I is true, Statement II is true; Statement II is a correct explanation for Statement I.
(b) Statement I is true, Statement II is true; Statement II is not a correct explanation for Statement I.
(c) Statement I is true; Statement II is false.
(d) Statement I is false; Statement II is true.

24. **Statement I** Molarity of a solution in liquid state changes with temperature.

Statement II The volume of a solution changes with change in temperature. **[NCERT Exemplar]**

25. **Statement I** ΔH_{mix} and ΔV_{mix} in an ideal solution are zero.

Statement II $A - B$ interactions in ideal solutions are same as between $A - B$ and $B - B$.

26. **Statement I** When NaCl is added to water a depression in freezing point is observed.

Statement II The lowering of vapour pressure of a a solution causes depression in the freezing point. **[NCERT Exemplar]**

27. **Statement I** One molar aqueous solution has always higher concentration than one molal.

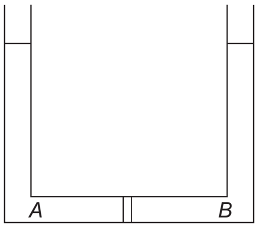
Statement II The molality of a solution depends upon the density of the solution whereas molarity does not.

28. **Statement I** The difference in the boiling points of equimolar solution of HCl and HF decreases as their molarity is decreased.

Statement II The extent of dissociation decreases steadily with increasing dilution.

Comprehension Based Questions

Directions (Q.Nos. 29 to 31)



Compartments A and B have the following combinations solution :

	A	B
1.	0.1 M KCl	0.2 M KCl
2.	0.1% (m/V) NaCl	10% (m/V) NaCl
3.	18 gL^{-1} glucose	34.2 gL^{-1} sucrose
4.	20% (m/V) glucose	10% (m/V) glucose

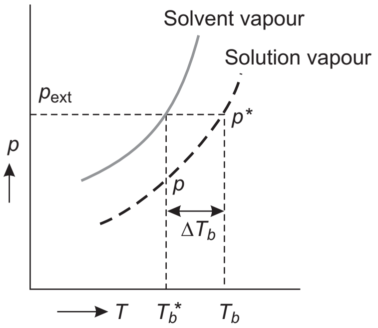
Answer the following questions

29. Indicate the number of solutions which is/are isotonic
(a) 1 only (b) 3 only
(c) 4 only (d) 2 only

30. The solutions in which compartment B is hypertonic.
(a) 1, 2 (b) 2, 3 (c) 3, 4 (d) 1, 4

31. Indicate the solution(s) in which compartment B will show an increase in volume.
(a) 1, 2, 4 (b) 1, 2 (c) 2, 3 (d) 3, 4

Directions (Q. Nos. 32 to 34) The variation of vapour pressure of the solvent and that of the solution with temperature are given by the respective solvent-vapour and solution-vapour curves of the phase diagram.

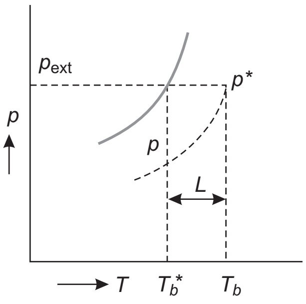


For a given value of the external pressure, the pure solvent will boil at temperature T_b^* and at temperature T_b let p_{ext} be equal to p^*, the vapour pressure of pure solvent.

Applying the Clausius-Clapeyron equation to the solution vapour equilibrium for the two values of p, T_b^* and p^*, T_b we have

$$\ln \frac{p^*}{p} = \frac{\Delta_{vap} H_{1m}}{R}\left(\frac{1}{T_b^*} - \frac{1}{T_b}\right) = \frac{\Delta_{vap} H_{1m}}{R}\,\frac{\Delta T_b}{T_b^* T_b}$$

32. The phase diagram for the pure solvent and solution are recorded below. The quantity indicated by L in the figure is



(a) Δp
(b) $k_b \cdot m$
(c) $k_f m$
(d) m

33. The vapour pressure of pure benzene and toluene are 160 and 60 torr respectively. The mole fraction of toluene in vapour phase in contact with equimolar solution of benzene and toluene is

(a) 0.50 (b) 0.93
(c) 0.6 (d) 0.27

34. At certain hill-station, pure water boils at 99.725°C. If K_b for water is 0.513°C kg mol^{-1}, the boiling point of 0.69 m solution of urea will be

(a) 100.359°C (b) 103°C
(c) 100.073°C (d) unpredictable

Previous Years' Questions

35. The density of a solution prepared by dissolving 120 g of urea (mol. mass = 60 u) in 1000 g of water is 1.15 g/mL. The molarity of this solution is **[AIEEE 2012]**

(a) 0.50 M (b) 1.78 M
(c) 1.02 M (d) 2.05 M

36. K_f water is 1.86 K kg mol^{-1}. If your automobiles radiator holds 1.0 kg of water, how many grams of ethylene glycol ($C_2H_6O_2$) must you add to get the freezing point of the solution lowered to –2.8°C? **[AIEEE 2012]**

(a) 72 g (b) 93 g
(c) 39 g (d) 27 g

37. A 5.2 molal aqueous solution of methyl alcohol, CH_3OH, is supplied. What is the mole fraction of methyl alcohol in the solution ? **[AIEEE 2011]**

(a) 0.100 (b) 0.190
(c) 0.086 (d) 0.050

38. Ethylene glycol is used as an antifreeze in a cold climate. Mass of ethylene glycol which should be added to 4 kg of water to prevent it from freezing at – 6° C will be (k_f for water = 1.86 K kg mol^{-1} and molar mass of ethylene glycol = 62 g mol^{-1}) **[AIEEE 2011]**

(a) 804.32 g (b) 204.30 g
(c) 400.00 g (d) 304.60 g

39. The degree of dissociation (α) of a weak electrolyte, A_xB_y is related to van't Hoff factor (i) by the expression **[AIEEE 2011]**

(a) $\alpha = \dfrac{i-1}{(x+y-1)}$ (b) $\alpha = \dfrac{i-1}{x+y+1}$
(c) $\alpha = \dfrac{x+y-1}{i-1}$ (d) $\alpha = \dfrac{x+y+1}{i-1}$

40. A 5% solution of cane sugar (molar mass 342) is isotonic with 1% of a solution of an unknown solute. The molar mass of unknown solute in g/mol is **[AIEEE 2011]**

(a) 136.2 (b) 171.2
(c) 68.4 (d) 34.2

41. If sodium sulphate is considered to be completely dissociated into cations and anions in aqueous solution, the change in freezing point of water (ΔT_f), when 0.01 mole of sodium sulphate is dissolved in 1 kg of water, is (k_f = 1.86 K kg mol^{-1}) **[AIEEE 2010]**

(a) 0.0372 K (b) 0.0558 K
(c) 0.0744 K (d) 0.0186 K

42. On mixing, heptane and octane form an ideal solution. At 373 K, the vapour pressures of the two liquid components (heptane and octane) are 105 kPa and 45 kPa respectively. Vapour pressure of the solution obtained by mixing 25 g of heptane and 35 g of octane will be (molar mass of heptane = 100 g mol^{-1} and of octane = 114 g mol^{-1}). **[AIEEE 2010]**

(a) 72.0 kPa (b) 36.1 kPa
(c) 96.2 kPa (d) 144.5 kPa

43. Two liquids X and Y form an ideal solution at 300 K, vapour pressure of the solution containing 1 mole of X and 3 moles of Y is 550 mm Hg. At the same temperature, if 1 mole of Y is further added to this solution, vapour pressure of the solution increases by 10 mm Hg. Vapour pressure (in mm Hg) of X and Y in their pure states will be, respectively **[AIEEE 2009]**

(a) 200 and 300 (b) 300 and 400
(c) 400 and 600 (d) 500 and 600

44. A binary liquid solution is prepared by mixing n-heptane and ethanol. Which one of the following statements is correct regarding the behaviour of the solution?

(a) The solution formed is an ideal solution
(b) The solution is non-ideal showing positive deviation from Raoult's law
(c) The solution is non-ideal showing negative deviation from Raoult's law
(d) n-heptane shows positive deviation while ethanol show negative deviation from Raoult's law

45. At 80°C, the vapour pressure of pure liquid 'A' is 520 mm Hg and that of pure liquid 'B' is 1000 mm Hg. If a mixture solution of 'A' and 'B' boils at 80°C and 1 atm pressure, the amount of 'A' in the mixture is (1 atm = 760 mmHg) **[AIEEE 2008]**

(a) 52 mol per cent (b) 34 mol per cent
(c) 48 mol per cent (d) 50 mol per cent

46. The vapour pressure of water at 20°C is 17.5 mm Hg. If 18 g of glucose ($C_6H_{12}O_6$) is added to 178.2 g of water at 20°C, the vapour pressure of the resulting solution will be [AIEEE 2008]

(a) 17.675 mm Hg (b) 15.750 mm Hg
(c) 16.500 mm Hg (d) 17.325 mm Hg

47. A mixture of ethyl alcohol and propyl alcohol has a vapour pressure of 290 mm at 300 K. The vapour pressure of propyl alcohol is 200 mm. If the mole fraction of ethyl alcohol is 0.6, its vapour pressure (in mm) at the same temperature will be [AIEEE 2007]

(a) 350 (b) 300
(c) 700 (d) 360

48. A 5.25% solution of a substance is isotonic with a 1.5% solution of urea (molar mass = 60 g mol^{-1}) in the same solvent. If the densities of both the solutions are assumed to be equal to 1.0 g cm^{-3}, molar mass of the substance will be [AIEEE 2007]

(a) 90.0 g mol^{-1} (b) 115.0 g mol^{-1}
(c) 105.0 g mol^{-1} (d) 210.0 g mol^{-1}

49. Density of a 2.05 M solution of acetic acid in water is 1.02 g/mL. The molality of the solution is [AIEEE 2006]

(a) 1.14 mol kg^{-1} (b) 3.28 mol kg^{-1}
(c) 2.28 mol kg^{-1} (d) 0.44 mol kg^{-1}

50. Two solutions of a substance (non-electrolyte) are mixed in the following manner.
480 mL of 1.5 M first solution + 520 mL of 1.2 M second solution.
What is the molarity of the final mixture ? [AIEEE 2005]

(a) 2.70 M (b) 1.34 M
(c) 1.50 M (d) 1.20 M

51. Benzene and toluene form nearly ideal solutions. At 20°C, the vapour pressure of benzene is 75 Torr and that of toluene is 22 Torr. The partial vapour pressure of benzene at 20°C for a solution containing 78 g of benzene and 46 g of toluene in Torr is [AIEEE 2005]

(a) 53.5 (b) 37.5
(c) 25 (d) 50

52. To neutralise completely 20 mL of 0.1 M aqueous solution of phosphorous acid (H_3PO_3), the volume of 0.1 M aqueous KOH solution required is [AIEEE 2004]

(a) 10 mL (b) 20 mL
(c) 40 mL (d) 60 mL

53. Which of the following liquid pairs shows a positive deviation from Raoult's law ? [AIEEE 2004]

(a) Water — hydrochloric acid
(b) Benzene — methanol
(c) Water — nitric acid
(d) Acetone — chloroform

54. Which one of the following statements is false ? [AIEEE 2004]

(a) Raoult's law states that the vapour pressure of a component over a solution is proportional to its mole fraction
(b) The osmotic pressure (π) of a solution is given by the equation $\pi = MRT$, where M is the molarity of the solution
(c) The correct order of osmotic pressure for 0.01 M aqueous solution of each compound is $BaCl_2 > KCl > CH_3COOH >$ sucrose
(d) Two sucrose solutions of same molality prepared in different solvents will have the same freezing point depression

55. 25 mL of a solution of barium hydroxide on titration with 0.1 molar solution of hydrochloric acid gave a titre value of 35 mL. The molarity of barium hydroxide solution was [AIEEE 2003]

(a) 0.07 (b) 0.14 (c) 0.28 (d) 0.35

56. A pressure cooker reduces cooking time for food because [AIEEE 2003]

(a) heat is more evenly distributed in the cooking space
(b) boiling point of water involved in cooking is increased
(c) the higher pressure inside the cooker crushes the food material
(d) cooking involves chemical changes helped by a rise in temperature

57. In a 0.2 molal aqueous solution of a weak acid HX, the degree of ionisation is 0.3. Taking k_f for water as 1.85, the freezing point of the solution will be nearest to [AIEEE 2003]

(a) $-0.480°$ C (b) $-0.360°$ C
(c) $-0.260°$ C (d) $+0.480°$ C

58. In a mixture of A and B, components show negative deviation when [AIEEE 2002]

(a) $A—B$ interaction is stronger than $A—A$ and $B—B$ interaction
(b) $A—B$ interaction is weaker than $A—A$ and $B—B$ interaction
(c) $\Delta V_{mix} > 0, \Delta S_{mix} > 0$
(d) $\Delta V_{mix} = 0, \Delta S_{mix} > 0$

Answers

the Guidance

Round I

1. Precipitation occurs when the solution is supersaturated.

2. Value of Henry's constant K_H increases with increase in temperature.

3. At high altitudes, atmospheric pressure is low and solubility of gases varies directly with pressure thus, decreases at high altitudes.

This is the reason for low concentration of oxygen in blood and tissues of people living at high altitude.

4. The order of increasing solubility are

$$\text{Ar} < \text{CO}_2 < \text{CH}_4 < \text{HCHO}$$

(As solubility increases as the values of K_H decreases)

5. Mass of aspirin $= 6.5$ g

Mass of acetonitrile $= 450$ g

$$\text{Mass of solution} = (6.5 + 450)\text{ g} = 456.5\text{ g}$$

$$\text{Mass \%} = \frac{(6.5\text{ g})}{(456.5\text{ g})} \times 100 = 1.424\%$$

6. Percentage (%) by mass of $CHCl_3$

$$= \frac{\text{mass of CHCl}_3}{\text{mass of solution}} \times 100$$

$$= \frac{(15.0\text{ g})}{(10^6\text{ g})} \times 100 = 1.5 \times 10^{-3}\%$$

7. $K_H = 4.27 \times 10^5$ mm Hg (at 298 K)

$$p = 760\text{ mm}$$

Applying Henry's law

$$p = K_H\,\chi \; [\chi = \text{Mole fraction or solubility of methane}]$$

$$x = \frac{p}{K_H} = \frac{(760\text{ mm})}{(4.27 \times 10^5\text{ mm})} = 178 \times 10^{-5} = 1.78 \times 10^{-3}$$

8.
$$M_1V_1 = M_2V_2$$
$$0.02 \times 4 = 5 \times M$$
$$M = 0.06$$

9. $$M = \frac{W}{\text{mol. wt.} \times \text{V}\,(L)} = \frac{5.85}{58.5 \times 0.5} = 0.2\text{ M}$$

10. Molarity $= 0.15$ M or 0.15 mol L^{-1}

Volume of solution $= 250$ mL $= 0.25$ L

$$\text{Molar mass of solute} = (12 \times 6) + (1 \times 5) + (12) + (16 \times 2) + (1)$$
$$= 122\text{ g mol}^{-1}$$

$$\text{Molarity} = \frac{\text{mass}}{\text{molar mass}} \times \frac{1}{\text{volume (L)}};$$

$$(0.15\text{ mol L}^{-1}) = \frac{W}{(122\text{ g mol}^{-1})} \times \frac{1}{(0.25\text{ L})}$$

$$\underset{\text{(Benzoic acid)}}{\text{Mass of solute}} = (0.15 \times 122 \times 0.25)\text{ g} = 4.575\text{ g}$$

11. Density of the solution $= 1.072 \text{ g mL}^{-1}$

$$\text{Mass of solution} = \text{Mass of solute} + \text{Mass of solution}$$
$$= 222.6 \text{ g} + 200 \text{ g} = 422.6 \text{ g}$$
$$\text{Volume} = \frac{\text{mass}}{\text{density}} = \frac{422.6 \text{ g}}{1.072 \text{ g mL}^{-1}} = 394.2 \text{ mL}$$
$$= 0.3942 \text{ L}$$
$$\text{Molarity } (M) = \frac{\text{mass of ethylene glycol/molar mass}}{\text{volume in litres}}$$
$$= \frac{(222.6 \text{ g})/(62 \text{ g mol}^{-1})}{0.3942 \text{ L}}$$
$$= 9.10 \text{ mol L}^{-1} = 9.10 \text{ M}$$

12. An increases in temperature increase the volume of the solution and thus, decreases its molarity.

13. $N = \dfrac{w \times 1000}{\text{eq. wt.} \times V \text{ (mL)}} = \dfrac{10 \times 1000}{60 \times 100} = 1.66 \text{ N}$

14. Molarity of base $= \dfrac{\text{normality}}{\text{acidity}}$

$$= \frac{0.1}{1} = 0.1$$
$$M_1V_1 = M_2V_2$$
$$0.1 \times 19.85 = M_2 \times 20$$
$$M_2 = 0.09925 \approx 0.099$$

16. Molarity $= \dfrac{\text{weight \% of solute} \times \text{density of the solution} \times 10}{\text{molecular weight of the solution}}$

$$= \frac{98 \times 1.84 \times 10}{98} = 18.4$$

17. Molality $= \dfrac{18}{180} = 0.1$ molal

18. $20 \times 0.4 = 40 \times N$ $\quad (\because N_1V_1 = N_2V_2)$

or $\quad N = 0.2$

$\therefore \quad M = \dfrac{0.2}{2} = 0.1 \text{ M}$

20. (a) 6 g of NaOH/100 mL

$$N = \frac{6 \times 1000}{40 \times 100} = 1.5 \text{ N}$$

(b) 0.5 M H_2SO_4

$$N = M \times \text{basicity} = 0.5 \times 2 = 1.0$$

(c) N phosphoric acid, normality $= 1$

(d) 8 g of KOH/L

$$\text{Normality} = \frac{\text{strength in g / L}}{\text{equivalent weight}} = \frac{8}{56} = 0.14 \text{ N}$$

21.
$$N_1V_1 + N_2V_2 = N_3V_3$$
$$0.3 \times 100 + 0.6 \times 200 = N_3 \times 300$$
$$0.3 + 1.2 = 3N_3$$
$$N_3 = 0.5$$

22. (i) Cyclohexane and *n*-octane both are non-polar. So, they mix completely in all proportions.

(ii) KCl is an ionic compound, but *n*-octane is non-polar. So, KCl does not dissolve in *n*-octane.

(iii) CH_3OH and CH_3CN both are polar but CH_3CN is less polar than CH_3OH. As the solvent is non-polar, CH_3CN will dissolve more than CH_3OH in *n*-octane.

Order of solubility is KCl < CH_3OH < CH_3CN < cyclohexane.

23. If two liquids *A* and *B* form minimum boiling azeotrope at some specific composition then *A* – *B* interactions are weaker than those between *A* – *A* or *B* – *B*.

25. For an ideal solution

$$\Delta H_{\text{solution}} = \Delta H_1 + \Delta H_2 + \Delta H_3$$

27. The one whose boiling point is more than that of either of the two pure components is known as azeotropic mixture with maximum boiling point. This is formed by non-ideal solutions showing negative deviation.

29. Relative lowering in vapour pressure,

$$\frac{p^\circ - p_s}{p^\circ} = \frac{w \times M}{m \times W}$$
$$\frac{143 - p_s}{143} = \frac{0.5}{65} \times \frac{154}{1.58 \times 100}$$

[$\because$ molecular weight of $CCl_4 = 154$ and weight = density × volume]

$$143 - p_s = 1.07 \Rightarrow p_s = 141.93 \text{ mm}$$

30. Vapour pressure of pure liquid *A* $(p_A^\circ) = 450$ mm

Vapour pressure of pure liquid *B* $(p_B^\circ) = 700$ mm

Total vapour pressure of the solution $(p) = 600$ mm

According to Raoult'a law,

$$p = p_A^\circ \chi_A + p_A^\circ \chi_B = p_A^\circ \chi_A + p_B^\circ (1 - \chi_A)$$
$$(600 \text{ mm}) = 450 \text{ mm} \times \chi_A + 700 \text{ mm} (1 - \chi_A)$$
$$= 700 \text{ mm} + \chi_A (450 - 700) \text{ mm}$$
$$= 700 - \chi_A (250 \text{ mm})$$
$$\chi_A = \frac{(600 - 700)}{-(250 \text{ mm})} = 0.40$$

Mole fraction of *A* $(\chi_A) = 0.40$

Mole fraction of *B* $(\chi_B) = 1 - 0.40 = 0.60$

$$p_A = p_A^\circ \chi_A = (450 \text{ mm}) \times 0.40 = 180 \text{ mm}$$
$$p_B = p_B^\circ \chi_B = (700 \text{ mm}) \times 0.60 = 420 \text{ mm}$$

Mole fraction of *A* in vapour phase

$$= \frac{p_A}{p_A + p_B}$$
$$= \frac{(180) \text{ mm}}{(180 + 420) \text{ mm}} = 0.30$$

Mole fraction of *B* in vapour phase

$$= \frac{p_B}{p_A + p_B} = \frac{(420) \text{ mm}}{(180 + 420) \text{ mm}} = 0.70$$

31. ***Step I* Calculation of vapour pressure of pure liquid** $A\,(p_A^\circ)$

Number of moles of liquid A

$$(n_A) = \frac{W_A}{M_A} = \frac{(100\text{ g})}{(140\text{ g mol}^{-1})} = 0.7143\text{ mol}$$

Number of moles of liquid B

$$(n_B) = \frac{W_B}{M_B} = \frac{(1000\text{ g})}{(180\text{ g mol}^{-1})} = 5.5556\text{ mol}$$

Mole fraction of A

$$(\chi_A) = \frac{n_A}{n_A + n_B} = \frac{(0.7143\text{ mol})}{(0.7143 + 5.5556)\text{ mol}}$$

$$= \frac{0.7143}{6.2699} = 0.1139$$

Mole fraction of $B\,(\chi_B) = 1 - 0.1139 = 0.8861$

Vapour pressure of pure liquid $B\,(p_B^\circ) = 500$ torr

Total vapour pressure of solution (p) = 475 torr

According to the Raoult's law

$$p = p_A^\circ \chi_A + p_B^\circ \chi_B$$

$$475\text{ torr} = p_A^\circ \times (0.1139) + 500\text{ torr} \times (0.8861)$$

$$475\text{ torr} = p_A^\circ \times (0.1139) + 443.05\text{ torr}$$

$$p_A^\circ = \frac{(475 - 443.05)\text{ torr}}{(0.1139)} = \frac{31.95}{0.1139}\text{ torr}$$

$$= 280.5\text{ torr}$$

***Step II* Calculation of vapour pressure of *A* in the solution** (p_A)

According to Raoult's law,

$$p_A = p_A^\circ \chi_A = (280.5\text{ torr}) \times (0.1139)$$

$$p_A = 32.0\text{ torr}$$

32. Mole fraction of $P = \frac{3}{3+2} = \frac{3}{5}$

Mole fraction of $Q = \frac{2}{3+2} = \frac{2}{5}$

Hence, total vapour pressure

= mole fraction of $P \times$ V.P. of P + mole fraction of $Q \times$ V.P. of Q

$$= \frac{3}{5} \times 80 + \frac{2}{5} \times 60 = 72\text{ Torr}$$

34. $\frac{p^\circ - p_s}{p^\circ}$ = molality $\times (1 - \alpha + x\alpha + y\alpha)$

The value of $p^\circ - p_s$ is maximum for $BaCl_2$.

35. Due to addition of nitric acid in water, the vapour pressure of pure water decreases.

36. Relative lowering in vapour pressure,

$$\frac{p^\circ - p_s}{p^\circ} = \frac{w}{m} \times \frac{M}{W}$$

$$\frac{0.30\text{ mm}}{17.54\text{ mm}} = \frac{20}{m} \times \frac{18}{100}$$

$$\Rightarrow \qquad m = \frac{20 \times 18 \times 17.54}{0.30 \times 100} = 210.48$$

37. According to Raoult's law,

Relative lowering in vapour pressure,

$$\frac{p_A^\circ - p_S}{p_A^\circ} = \frac{n_B}{n_A + n_B}$$

$$n_A = \frac{850}{18} = 47.22 \quad \text{and} \quad n_B = \frac{50}{60} = 0.833$$

$$\frac{p_A^\circ - p_s}{p_A^\circ} = \frac{0.833}{48.053} = 0.017$$

38. W_B (solute) = 25 g ; $M_B = 180$ g mol^{-1}; $p_A^\circ = 17.535$ mm

W_A (water) = 450 g; $M_A = 18$ g mol ; p_s = ?

$$\frac{p_A^\circ - p_s}{p_A^\circ} = \chi_B = \frac{n_B}{n_B + n_A}$$

$$n_B = \frac{W_B}{M_B} = \frac{25}{180} = 0.1389$$

$$n_A = \frac{W_A}{M_A} = \frac{450}{18} = 25$$

$$\frac{17.535 - p_s}{17.535} = \frac{0.1389}{0.1389 + 25}$$

$$\frac{17.535 - p_s}{17.535} = 0.00552$$

$$p_s = 17.535 - 0.097$$

$$p_s = 17.438\text{ mm Hg}$$

39. The unit of ebullioscopic constant is K kg mol^{-1} or K (molality)$^{-1}$.

40. We know that, $\Delta T_b = \frac{1000 \times k_b \times w}{W \times M}$

$$M = \frac{1000 \times k_b \times w}{W \times \Delta T_b}$$

$$\Delta T_b = \frac{1000 \times k_b \times 10}{100 \times 100}$$

$$\Delta T_b = k_b$$

41. Mass of water (W_A) = 500 g = 0.5 kg

Elevation in boiling point

$$(\Delta T_b) = 100°\text{ C} - 99.63°\text{ C} = 0.37°\text{ C} = 0.37\text{ K}$$

Molal elevation constant (k_b) = 0.52 K kg mol^{-1}

Molar mass sucrose $C_{12}H_{22}O_{11}$

$$(M_B) = (12 \times 12) + (22 \times 1) + (16 \times 11)$$

$$= 342\text{ g mol}^{-1}$$

$$W_B = \frac{M_B \times \Delta T_b \times W_A}{k_b} = \frac{(342\text{ g mol}^{-1}) \times (0.37\text{ K}) \times (0.5\text{ kg})}{(0.52\text{ K kg mol}^{-1})}$$

$$= 121.7\text{ g}$$

42. $\Delta T_b = \frac{k_b \times w \times 1000}{m \times W}$

$$\therefore\ m = \frac{k_b \times w \times 1000}{\Delta T_b \times W} = \frac{2.53 \times 10 \times 1000}{1 \times 100} = 253\text{ g}$$

43. $m = \frac{k_b \times w \times 1000}{\Delta T_b \times W} = \frac{2.16 \times 0.15 \times 1000}{0.216 \times 15} = 100$

44. $\Delta T_f = 1.86 \times \frac{342}{342} = 1.86°\text{ C}$

$$\therefore\ T_f = T - \Delta T_f = 0 - 1.86 = -1.86°\text{ C}$$

45. From depression in freezing point expression,

$$M = \frac{1000 \times k_f \times w}{\Delta T \times W}$$

$$62 = \frac{1000 \times 1.86 \times 50}{9.3 \times W}$$

$$W = 161.3 \text{ g}$$

Total water = 200 g

Hence, ice separated = (200 − 161.3) g = 38.7 g

46.

$$i = 1 + \alpha$$

$$= \frac{\text{cal. mol. weight}}{\text{exp. mol. wt}} = \frac{58.5}{30} = 1.95$$

$$\therefore \quad 1 + \alpha = 1.95$$

$$\alpha = 0.95$$

48. In the figure water will move from side (*B*) to side (*A*) if a pressure greater than osmotic pressure is applied on piston (*B*). Thus, (b) is the correct option.

49. An unripe mango placed in a concentrated salt solution to prepare pickle, shivels because it loses water due to osmosis.

51. The solutions having the same osmotic pressure are called isotonic solution. They may have different weight concentrations.

52. Mass of polymer (W_B) = 1.0 g

Molar mass of polymer (M_B) = 185000 g mol^{-1}

Volume of solution (V) = 450 mL = 0.450 L

Temperature (T) = 37 + 273 = 310 K

Solution constant (R) = 8.314×10^3 Pa L K^{-1} mol^{-1}

Osmotic pressure (π) = CRT

$$= \frac{W_B \times R \times T}{M_B \times V}$$

$$\therefore \quad \pi = \frac{(1.0 \text{ g}) \times (8.314 \times 10^3 \text{ Pa L K}^{-1} \text{ mol}^{-1}) \times (310 \text{ K})}{(185000 \text{ g mol}^{-1}) \times (0.450 \text{ L})}$$

= 30.96 Pa

53. $p = \frac{w}{mV} RT$, since, wRT/V are constant thus, $p \propto \frac{1}{m}$

$$\therefore \quad p_2 > p_1 > p_3$$

54. Molarity of urea = $\dfrac{\frac{6}{60}}{\frac{100}{1000}} = 1\text{M}$

Hence, 1 M solution of glucose is isotonic with 6% urea solution.

55. $C = \frac{5}{342} \times \frac{1}{100} \times 1000 = \frac{50}{342}$ mol / L

$$\pi = \frac{50}{342} \times 0.082 \times 423 = 5.07 \text{ atm}$$

56. For isotonic solution

$$\frac{w_1}{m_1} = \frac{w_2}{m_2} \Rightarrow \frac{5}{342} = \frac{1}{m_2} \Rightarrow m_2 = \frac{342}{5} = 68.4$$

57. $\pi = CRT = \frac{W_B \times R \times T}{M_B \times V}$

For both the solutions, R, T and V are constants.

For I solution

$$(4.98 \text{ bar}) = \frac{(36 \text{ g}) \times R \times T}{(180 \text{ g mol}^{-1}) \times V} \quad \text{...(i)}$$

For II solution

$$(1.52 \text{ bar}) = \frac{W_B \times R \times T}{M_B \times V} \quad \text{... (ii)}$$

On dividing Eq. (ii) by Eq. (i), we get

$$\frac{(1.52 \text{ bar})}{(4.98 \text{ bar})} = \frac{W_B \times R \times T}{M_B \times V} \times \frac{180 \times V}{36 \times R \times T}$$

$$\frac{W_B}{M_B} = \frac{1.52}{4.98 \times 5} = 0.0610 \text{ mol L}^{-1}$$

58. Mole fraction units is useful in relating concentration of solution with its vapour pressure.

60. $BaCl_2$ gives maximum ion hence, it shows lowest vapour pressure.

61. Elevation in bp = $ik_b \cdot m$

If k_b and m are same,

Elevation in boiling point $\propto i$

$$NaOH \longrightarrow \underbrace{Na^+ + OH^-}_{\text{2 ions}}$$

$$Na_2SO_4 \longrightarrow \underbrace{2Na^+ + SO_4^{2-}}_{\text{3 ions}}$$

$$NH_4NO_3 \longrightarrow \underbrace{NH_4^+ + NO_3^-}_{\text{2 ions}}$$

$$KNO_3 \longrightarrow \underbrace{K^+ + NO_3^-}_{\text{2 ions}}$$

62. Osmotic pressure is a colligative property.

Osmotic pressure $\propto$ no. of particles

$$NaCl \longrightarrow Na^+ + Cl^-$$

Concentration of particles = 2 × 2M = 4M

Glucose does not dissociate

∴ Concentration of particles = 1 × 1M = 1 M

Urea does not dissociate,

∴ Concentration of urea = 1 × 2 M = 2 M

∴ Glucose solution will have minimum osmotic pressure.

63. KNO_3 dissociates completely while CH_3COOH dissociates to a small extent hence, $p_1 > p_2$.

64. Actual molecular weight of naphthoic acid ($C_{11}H_8O_2$) = 172

Molecular mass (calculated) = $\dfrac{1000 \times k_f \times w}{W \times \Delta T_f}$

$$= \frac{1000 \times 1.72 \times 20}{50 \times 2} = 344$$

$$\text{van't Hoff factor } (i) = \frac{\text{actual mol. wt.}}{\text{calculated mol. wt.}} = \frac{172}{344} = 0.5$$

65.
$$\Delta T_f = i \times k_f \times m$$
$$7.10 \times 10^{-3} = i \times 1.86 \times 0.001$$
$$i = 3.817$$
$$\alpha = \frac{i-1}{n-1}$$
$$1 = \frac{3.817-1}{(x+1)-1}$$
$$x = 2.817 \approx 3$$

∴ Molecular formula of the compound is $K_3[Fe(CN)_6]$.

66.
$$\begin{array}{llll} CuCl_2 & \rightleftharpoons Cu^{2+} & + 2Cl^- & \\ 1\text{ mol} & 0 & 0 & \text{before ionisation} \\ (1-\alpha) & \alpha & 2\alpha & \text{after ionisation} \end{array}$$

Thus, number of particles after ionisation
$$= 1 - \alpha + \alpha + 2\alpha = 1 + 2\alpha$$
$$\therefore \text{ vant' Hoff factor } (i) = \frac{1+2\alpha}{1} \text{ (On 100\% ionisation, } \alpha = 1)$$
$$i = \frac{1 + 2 \times 1}{1} = 3$$

The elevation of boiling point,
$$\Delta T_b = 3 \times k_b \times m$$

Molality of $CuCl_2$ solution
$$(m) = \frac{\text{wt. of } CuCl_2 \text{ in g / mol wt. of } CuCl_2}{\text{wt. of water in kg}}$$
$$= \frac{\frac{13.44}{134.4}}{1} = 0.1 \text{ m}$$

Thus, $\Delta T_b = 3 \times 0.52 \times 0.1 = 0.156° \text{ C} \approx 0.16° \text{ C}$

67.
$$\begin{array}{ccc} HBr & \rightleftharpoons H^+ & + Br^- \\ (1-\alpha) & \alpha & \alpha \end{array}$$
$$i_{\text{total}} = (1-\alpha) + \alpha + \alpha = (1+\alpha)$$
$$i = 1 + 0.9 = 1.9$$
$$\Delta T_f = ik_f m = 1.9 \times 1.86 \times \frac{8.1}{81} \times \frac{1000}{100} = 3.53° \text{ C}$$
$$T_f = T - \Delta T_f = 0 - 3.53° \text{ C} = -3.53° \text{ C}$$

68. According to van't Hoff equation

$$\text{Osmotic pressure } (\pi) = i\,CRT = \frac{in_B RT}{V}$$
$$i = 2.47; \quad V = 2.5 \text{ L}; \quad R = 0.0821 \text{ L atm K}^{-1}\text{mol}^{-1}$$
$$T = 27 + 273 = 300 \text{ K}; \quad \pi = 0.75 \text{ atm}$$
$$n_B = \frac{\pi V}{iRT} = \frac{(0.75 \text{ atm}) \times (2.5 \text{ L})}{(2.47) \times (0.0821 \text{ L atm K}^{-1}\text{mol}^{-1}) \times (300 \text{ K})}$$
$$= 0.0308 \text{ mol}$$

Amount of $CaCl_2$ dissolved $= n_B \times M_B$
$$= (0.0308 \text{ mol}) \times (111 \text{ g mol}^{-1})$$
$$= 3.42 \text{ g}$$

69. Amount of K_2SO_4 dissolved = 25 mg = 0.025 g

Volume of solution = 2 L
$$T = 25° \text{ C} = 25 + 273 \text{ K} = 298 \text{ K}$$

Molar mass of
$$K_2SO_4 = (2 \times 39) + (32) + (4 \times 16) = 174 \text{ g mol}^{-1}$$

Since, K_2SO_4 dissociates completely as
$$K_2SO_4 \xrightarrow{aq} 2\,K^+ + SO_4^{2-}$$

Total ions produced after dissociation (per mol) = 3

$$\text{So, } i = 3, \quad \pi = iCRT = i \times \frac{n}{V} RT = \frac{i \times W \times R \times T}{M \times V}$$
$$= \frac{3 \times (0.025 \text{ g}) \times (0.0821 \text{ L atm K}^{-1}\text{mol}^{-1}) \times (298 \text{ K})}{(174 \text{ g mol}^{-1}) \times (2 \text{ L})}$$
$$= 5.27 \times 10^{-3} \text{ atm}$$

70. ***Step I*** **Calculation of van't Hoff factor of acid**
$$\Delta T_f = 1^\circ\text{C} = 1\text{K}; \; k_f = 1.86 \text{ K kg mol}^{-1}$$
$$\Delta T_f = i\,k_f\,m$$
$$\text{or} \qquad i = \frac{\Delta T_f}{k_f\,m} \qquad \text{...(i)}$$
$$m = \frac{W_B}{M_B \times W_A}$$
$$= \frac{(19.5 \text{ g})}{(78 \text{ g mol}^{-1}) \times (0.5 \text{ kg})}$$
$$= 0.5 \text{ mol kg}^{-1} \qquad \text{... (ii)}$$

Placing the values in Eq. (i), we find the value of van't Hoff factor (i)
$$i = \frac{1}{(1.86 \text{ K kg mol}^{-1}) \times (0.5 \text{ mol kg}^{-1})}$$
$$= 1.0753$$

Step II **Calculation of degree of dissociation of the acid**

Suppose degree of dissociation at the given concentration is α.

$$\begin{array}{llll} & CH_2FCOOH & \overset{aq}{\rightleftharpoons} CH_2FCOO^- & + H^+ \\ \text{Initial conc. } C \text{ mol kg}^{-1} & & 0 & 0 \\ \text{At equilibrium} & C\,(1-\alpha) & C\alpha & C\alpha \end{array}$$
$$\text{Total} = C(1+\alpha)$$
$$\therefore \qquad i = \frac{C\,(1+\alpha)}{C} = 1 + \alpha$$
$$\alpha = i - 1 = 1.0753 - 1 = 0.0753$$

Step III **Calculation of dissociation constant for the acid**
$$\text{(Molal) } C = 0.5 \text{ m} \qquad \text{(From Eq. (ii))}$$
$$K_a = \frac{[CH_2FCOO^-]\,[H^+]}{[CH_2FCOOH]} = \frac{C\alpha \cdot C\alpha}{C\,(1-\alpha)} = \frac{C\alpha^2}{(1-\alpha)}$$
$$K_a = \frac{(0.5)\,(0.0753)^2}{(1-0.0753)} = \frac{(0.5) \times (0.0753)^2}{(0.9247)} = 3.07 \times 10^{-3}$$

Round II

1. ***Step I* Calculation of partial pressure of oxygen and nitrogen**

Partial pressure of O_2

$$(p_{O_2}) = (10\text{ atm}) \times \frac{20}{100} = 2\text{ atm} = 2 \times 760\text{ mm}$$

$$\text{Partial pressure of } N_2\ (p_{N_2}) = (10\text{ atm}) \times \frac{79}{100} = 7.9\text{ atm}$$

$$= 7.9 \times 760\text{ mm}$$

***Step II* Composition of O_2 and N_2 dissolved in water**

The amount of gases dissolved in water is calculated in terms of their mole fractions.

$$\chi_{O_2} = \frac{p_{O_2}}{K_H} = \frac{(2 \times 760\text{ mm})}{(3.30 \times 10^7\text{ mm})}$$

$$= 4.6 \times 10^{-5}$$

$$\chi_{N_2} = \frac{p_{N_2}}{K_H} = \frac{(7.9 \times 760\text{ mm})}{(6.51 \times 10^7\text{ mm})}$$

$$= 9.22 \times 10^{-5}$$

2. ***Step I* Calculation of number of moles of CO_2**

According to Henry's law,

$$\text{Mole fraction of } CO_2\ (\chi_{CO_2}) = \frac{\text{partial pressure of } CO_2}{K_H \text{ for } CO_2}$$

$$K_H = 1.67 \times 10^8\text{ Pa} = \frac{(1\text{ atm})}{(101325\text{ Pa})} \times (1.67 \times 10^8\text{ Pa})$$

$$= 1.648 \times 10^3\text{ atm}$$

$$\chi_{CO_2} = \frac{2.5\text{ atm}}{(1.648 \times 10^3\text{ Pa})} = 1.52 \times 10^{-3}$$

$$n_{H_2O} = \frac{(500\text{ g})}{(18\text{ g mol}^{-1})} = 27.78\text{ mol}$$

$$\chi_{CO_2} = \frac{n_{CO_2}}{n_{CO_2} + n_{H_2O}} = \frac{n_{CO_2}}{n_{H_2O}} = \frac{n_{CO_2}}{(27.78\text{ mol})}$$

$$n_{CO_2} = \chi_{CO_2} \times (27.78\text{ mol})$$

$$= (1.52 \times 10^{-3}) \times (27.78\text{ mol})$$

$$= 0.0422\text{ mol}$$

Note n_{CO_2} is considered negligible due to its little solubility in water.

***Step II* Calculation of mass of dissolved CO_2 in water**

$$\text{Mass of } CO_2 = \text{no}\cdot\text{ of moles of } CO_2 \times \text{molar mass of } CO_2$$

$$= (0.0422\text{ mol}) \times (44\text{ g mol}^{-1})$$

$$= 1.857\text{ g}$$

3. $m = 1.5 \times 10^{-3}$ m or 1.5×10^{-3} mol kg^{-1}

Mass of solute $= 1.5 \times 10^{-3}$ g or 1.5 mg

Mass of solvent = ?

Molar mass of solute

$$(C_{19}H_{21}NO_3) = (12 \times 19) + (1 \times 21) + (14) + (16 \times 3)$$

$$= 311\text{ g mol}^{-1}$$

$$\text{Number of moles of solute} = \frac{\text{mass}}{\text{molar mass}}$$

$$= \frac{(1.5 \times 10^{-3}\text{ g})}{(311\text{ g mol}^{-1})}$$

$$\text{Molality } (m) = \frac{\text{number of moles}}{\text{mass of solvent in kg}}$$

$$\text{Mass of solvent} = \frac{\text{number of moles}}{\text{molality}}$$

$$= \frac{(1.5 \times 10^{-3}\text{ g})}{(311\text{ g mol}^{-1})} \times \frac{1}{(1.5 \times 10^{-3}\text{ mol kg})}$$

$$= \frac{1}{311} = 0.0032\text{ kg or } 3.2\text{ g}$$

4. $\text{Mass of solute in I solution} = \frac{25}{100} \times 300\text{ g} = 75\text{ g}$

$\text{Mass of solute in II solution} = \frac{40}{100} \times 400\text{ g} = 160\text{ g}$

After mixing both solutions,

$$\text{Total mass of solute} = (75 + 160)\text{ g} = 235\text{ g}$$

$$\text{Total mass of solution} = (300 + 400)\text{ g} = 700\text{ g}$$

$$\text{Mass \% of solute in final solution} = \frac{(235\text{ g})}{(700\text{ g})} \times 100 = 33.57\%$$

5. $\text{Molarity of pure water} = \frac{100}{18} = 55.6\text{ M}$

6. When A — A and B—B interactions are nearly same as A—B type interaction, ideal solution is obtained which follows Raoult's law in all conditions of temperature and pressure. Thus, A follows Raoult's law.

When A — A or B — B interactions are stronger than A — B interaction, a solution showing positive deviation from Raoult's law in obtained. Thus, B exhibits positive deviation from Raoult's law.

When A — A or B — B interaction are weaker than A — B interaction a solution showing negative deviation from Raoult's law is obtained. Thus, C exhibits negative deviation from Raoult's law.

7. HgI_2 although insoluble in water but shows complex formation with KI and therefore, freezing point decreases.

8. (ii) 0.1 M glucose,

$$\pi = CRT = 0.1RT$$

(iii) 0.6 g urea in 100 mL solution

$$\pi = \frac{n}{V}RT = \frac{w/m}{V}RT = \frac{0.6/60 \times 1000}{100} \times RT = 0.1RT$$

(iv) 1.0 g of non electrolyte solute (X) is 50 mL solution

$$\pi = \frac{1.0/200}{50} \times 1000RT = 0.1\,RT$$

Hence, option (ii), (iii), (iv) have some osmotic pressure, osmotic pressure of 0.1 M NaCl is higher than (ii), (iii), (iv) because it dissociates to give maximum number or particles.

9. $m = \frac{\Delta T_b}{k_b} = \frac{-0.060}{-1.86} = 3.2\times 10^{-2} = 0.032$

i.e., 0.032 = total particles

∴ The number of $H^+ = (0.032 - 0.025)\,m = 0.007\,MH^+$

$$HA \rightleftharpoons H^+ + A^-$$

$$[H^+] = [A^-] = 0.007\,M$$

$$\therefore \quad HA = 0.018$$

$$K_a = \frac{(0.007)^2}{0.018} = 3\times 10^{-3}$$

$$pK_a = -\log K_a = -\log(3\times 10^{-3}) = 2.5$$

10. Boiling point $(T_b) = 100 + \Delta T_b = 100 + k_b m$

Freezing point $(T_f) = 0 - \Delta T_f = -k_f m$

$$T_b - T_f = (100 + k_b m) - (-k_f m)$$

$$105 = 100 + 0.51m + 1.86\,m$$

$$2.37m = 5 \quad \text{or} \quad m = \frac{5}{2.37} = 2.11$$

∴ Weight of sucrose to be dissolved in 100 g water

$$= \frac{2.11\times 342}{1000}\times 100 = 72\text{ g}$$

11. Molality of solution is 1m. It means that one mole of solute is dissolved in 1000 g of water.

Number of moles of solute $(n_B) = 1$ mol

Number of moles of water

$$(n_A) = \frac{\text{mass of water}}{\text{molar mass}} = \frac{(1000\text{ g})}{(18\text{ g mol}^{-1})}$$

$$= 55.55\text{ mol}$$

Mole fraction of solute

$$(\chi_B) = \frac{n_B}{n_A + n_B} = \frac{(1\text{ mol})}{(55.55 + 1.0)\text{ mol}} = \frac{1}{56.55}$$

$$= 0.0177$$

Mole fraction water $(\chi_A) = 1 - 0.0177 = 0.9823$

Vapour pressure of solution

$$(p_A) = p_A^\circ\,\chi_A = (12.3\text{ kPa})\times 0.9823 = 12.08\text{ kPa}$$

12. For cane sugar solution

W_b (sugar) = 5 g; W_A (water) = 100 − 5 = 95 g

M_B (sugar) = 342 g mol^{-1}; $\Delta T_f = (273.15 - 271.00)$ K

$$= 2.15\text{ K}$$

$$\Delta T_f = \frac{k_f\times W_B}{M_B\times W_A}$$

$$(2.15\text{ K}) = \frac{k_f\times(5\text{ g})}{(342\text{ g mol}^{-1})\times(95\text{ g})} \qquad \text{....(i)}$$

For glucose solution

W_B (glucose) = 5 g; W_A (water) = 100 − 5 = 95 g

M_B (glucose) = 180 g mol^{-1}; ΔT_f = ?

$$\Delta T_f = \frac{k_f\times(5\text{ g})}{(180\text{ g mol}^{-1})\times(95\text{ g})} \qquad \text{...(ii)}$$

On dividing Eq. (ii) by Eq. (i)

$$\frac{\Delta T_f}{(2.15\text{ K})} = \frac{k_f\times(5\text{ g})}{(180\text{ g mol}^{-1})\times(95\text{ g})}\times\frac{(342\text{ g mol}^{-1})\times(95\text{ g})}{(k_f)\times(5\text{ g})}$$

$$\Delta T_f = \frac{342\times 2.15}{180}\text{ K} = 4.085\text{ K}$$

Freezing point for 5% glucose solution

$$= (273.15 - 4.085)\text{ K} = 269.07\text{ K}$$

13. For ideal solution, Raoult's law is $p_T = p_A^\circ\,\chi_A + p_B^\circ\,\chi_B$ and vapour pressure in vapour phase $= \frac{p_A^\circ\,\chi_A}{p_T}$

Thus, the required quantities are χ_A, χ_B and p_T as we know p_A° and p_B°.

Molar mass of benzene (C_6H_6) = 78 g mol^{-1}

Molar mass of naphthalene $(C_{10}H_8)$ = 128 g mol^{-1}

$n_{C_6H_6}$ (Number of moles of benzene)

$$= \frac{80\text{ g}}{(78\text{ g mol}^{-1})} = 1.026\text{ mol}$$

$n_{C_{10}H_8}$ (Number of moles of naphthalene)

$$= \frac{(100\text{ g})}{(128\text{ g mol}^{-1})} = 0.781\text{ mol}$$

Mole fraction of benzene

$$(\chi_{C_6H_6}) = \frac{(1.026\text{ mol})}{(1.026 + 0.781)\text{ mol}} = 0.568$$

Mole fraction of naphthalene $(\chi_{C_{10}H_8}) = 1 - 0.568 = 0.432$

Applying Raoult's law

Partial vapour pressure of benzene in solution $(p_{C_6H_6})$

$$= p^\circ_{C_6H_6}\times\chi_{C_6H_6}$$

$$= (50.71\text{ mm})\times(0.568)$$

$$= 28.80\text{ mm}$$

Partial vapour pressure of naphthalene in solution

$$(p_{C_{10}H_8}) = p^\circ_{(C_{10}H_8)}\times\chi_{C_{10}H_8}$$

$$= (32.06\text{ mm})\times(0.432)$$

$$= 13.85\text{ mm}$$

Total vapour pressure of solution (p) = (28.80 + 13.85) mm

$$= 42.65\text{ mm}$$

Mole fraction of benzene in vapour phase

$$= \frac{\chi_{C_6H_6}\times p^\circ{}_{C_6H_6}}{p_{\text{total}}}$$

$$= \frac{0.568\times(50.71\text{ mm})}{(42.65\text{ mm})} = 0.675$$

14. Degree of association,

$$\alpha = \frac{1-i}{1-\frac{1}{n}}$$

$$0.8 = \frac{1-i}{1-\frac{1}{4}}$$

$$i = 0.4$$

$$\because \quad \Delta T = i \times k_f \times m$$

$$0.3 = 0.4 \times 1.86 \times \frac{w_B \times 1000}{m_B \times w_A}$$

$$0.3 = 0.4 \times 1.86 \times \frac{2.5 \times 1000}{m_B \times 100}$$

$$m_B = \frac{0.4 \times 1.86 \times 2.5 \times 1000}{0.3 \times 100} = 62 \text{ g mol}^{-1}$$

15.

$$\pi_1 V_1 + \pi_2 V_2 = \pi_R (V_1 + V_2)$$

$$1 \times 1 + 3.5V = 2.5(1 + V)$$

$$1 + 3.5V = 2.5 + 2.5V$$

or $$V = 1.5 \text{ L}$$

16. Steps involved to solve the problem are

- (i) In the equation of Raoult's law $(p_A = p^\circ_A \chi_A)$, mole fraction is required, so first find the moles of solute and solvent and then mole fraction in case first.
- (ii) Now put the value of mole fraction in the equation of Raoult's law.
- (iii) Make an another equation in the similar way as mentioned above, when 18 g water is added (so the mass of water will become $= 18 + 19 = 108$ g).
- (iv) Solve two equation to find molar mass.
- (v) Put the value of molar mass in any of the two equations to find vapour pressure.

Step I **Calculation of molar mass of the solute**

Case I Number of mole of solute

$$(n_B) = \frac{\text{mass}}{\text{molar mass}} = \frac{(30 \text{ g})}{(M \text{ g mol}^{-1})} = \frac{30}{M} \text{ mol}$$

Number of moles of water

$$(n_A) = \frac{\text{mass}}{\text{molar mass}} = \frac{(90 \text{ g})}{(18 \text{ g mol}^{-1})} = 5 \text{ mol}$$

Mole fraction of water

$$(\chi_A) = \frac{n_A}{n_A + n_B} = \frac{(5 \text{ mol})}{\left(5 \text{ mol} + \frac{30}{M} \text{ mol}\right)} = \frac{M}{(6 + M)}$$

Vapour pressure of first solution (p_A) = 2.8 kPa

According to Raoult's law, $p_A = p^\circ_A \chi_A$

$$(2.8 \text{ kPa}) = p^\circ_A \text{ x } \frac{M}{(6 + M)} \qquad \text{...(i)}$$

Case II Number of moles of solute $(n_B) = \frac{30}{M}$ mol

Number of moles of water

$$(n_A) = \frac{\text{mass}}{\text{molar mass}} = \frac{(108 \text{ g})}{(18 \text{ g mol}^{-1})} = 6 \text{ mol}$$

Mole fraction of water $(\chi_A) = \frac{n_A}{n_A + n_B}$

$$= \frac{(6 \text{ mol})}{\left(6 \text{ mol} + \frac{30}{M} \text{ mol}\right)}$$

$$= \frac{M}{(5 + M)}$$

Vapour pressure of solution (p_A) = 2.9 kPa

According to Raoult's law, $p_A = p^\circ_A \chi_A$

$$(2.9 \text{ kPa}) = p^\circ_A \times \frac{M}{(5 + M)} \qquad \text{... (ii)}$$

Dividing Eq. (i) by Eq. (ii)

$$\frac{(2.8 \text{ kPa})}{(2.9 \text{ kPa})} = \frac{(5 + M)}{(6 + M)}$$

$$0.9655 = \frac{(5 + M)}{(6 + M)}$$

$$(0.9655 \times 6) + 0.9655 \text{ M} = 5 + M$$

$$0.0345 \text{ M} = 0.793$$

$$M = \frac{0.793}{0.0345} = 23 \text{ g mol}^{-1}$$

Step II **Calculation of vapour pressure of water**

According to Raoult's law, $p_A = p^\circ_A \chi_A$

or $$(2.8 \text{ kPa}) = p^\circ_A = \frac{M}{(6 + M)} \qquad \text{...(iii)}$$

Placing the value of M in Eq. (i)

$$2.8 \text{ kPa} = p^\circ_A \frac{(23 \text{ g mol}^{-1})}{(6 + 23) \text{ g mol}^{-1}}$$

$$p^\circ_A = \frac{2.8 \times 29}{23}$$

$$= \frac{81.2}{23} = 3.53 \text{ kPa}$$

17. ***Step I*** **Calculation of molecular masses of compounds *AB_2* and *AB_4***

For compound *AB_2*

$$W_B(AB_2) = 1 \text{ g};\ W_A(C_6H_6) = 20 \text{ g};\ \Delta T_f = 2.3 \text{ K}$$

$$k_f = 5.1 \text{ K kg mol}^{-1} = 5.1 \times 1000 \text{ K g mol}^{-1}$$

$$M_B = \frac{k_f \times W_B}{\Delta T_f \times W_A} = \frac{(5.1 \times 1000 \text{ K g mol}^{-1}) \times (1 \text{ g})}{(2.3 \text{ K}) \times (20 \text{ g})}$$

$$= 110.87 \text{ g mol}^{-1}$$

For compound *AB_4*

$$W_B(AB_4) = 1 \text{ g};\ W_A(C_6H_6) = 20 \text{ g};\ \Delta T_f = 1.3 \text{ K}$$

$$k_f = 5.1 \text{ K kg mol}^{-1}$$

$$M_B = \frac{(5.1 \text{ K kg mol}^{-1}) \times 1000 \times (1 \text{ g})}{(1.3 \text{ K}) \times (20 \text{ g})}$$

$$= 196.15 \text{ g mol}^{-1}$$

Step II **Calculation of the atomic masses of elements *A* and *B***

Let the atomic mass of element $A = a$

Let the atomic mass of element $B = b$

$$\text{Molecular mass of } AB_2 = a + 2b$$
$$\text{Molecular mass of } AB_4 = a + 4b$$

According to the available data

$$a + 2b = 110.87 \quad \ldots \text{(i)}$$
$$a + 4b = 196.15 \quad \ldots \text{(ii)}$$

Substract Eq. (i) from Eq. (ii)

$$a + 4b - a - 2b = 196.15 - 110.87$$
$$2b = 85.28;\ b = \frac{85.28}{2} = 42.64$$

Substituting the value of b in Eq. (i)

$$a + 2 \times 42.64 = 110.87$$
$$a + 85.28 = 110.87;\ a = 110.87 - 85.28 = 25.59$$

This, atomic mass of element $A = 25.59$

Atomic mass of element $B = 42.64$

18. ***Step I*** **Calculation of degree of dissociation**

Mass of solute $= 10$ g

Molar mass of solute

$$(CH_3CH_2CHClCOOH) = (12 \times 4) + (1 \times 7) + (35.5) + (16 \times 2)$$
$$= 48 + 7 + 35.5 + 32$$
$$= 122.5 \text{ g mol}^{-1}$$

Molal concentration of solution

$$= \frac{\text{mass / molar mass}}{\text{mass of solvent (kg)}}$$
$$= \frac{(10 \text{ g})}{(122.5 \text{ g mol}^{-1}) \times (0.25 \text{ kg})}$$
$$= 0.326 \text{ m}$$

If α is the degree of dissociation of $CH_3CH_2CHCl\ COOH$, then

$$CH_3CH_2CHClCOOH \rightleftharpoons CH_3CHClCOO^- + H^+$$

Initial conc. C mol^{-1} kg		0	0
At equilibrium	$C\ (1-\alpha)$	$C\alpha$	$C\alpha$

$$\therefore \quad K_a = \frac{C\alpha \times C\alpha}{C\ (1-\alpha)} = C\alpha^2$$

[Considering $(1-\alpha) = 1$ for dilute solutions]

$$\alpha^2 = \frac{K_a}{C} \quad \text{or} \quad \alpha = \sqrt{\frac{K_a}{C}}$$

$$\text{So,} \quad \alpha = \sqrt{\frac{1.4 \times 10^{-3}}{0.326}} = \sqrt{42.9 \times 10^{-4}}$$
$$= 6.55 \times 10^{-2} = 0.065$$

Step II **Calculation of van't Hoff factor** (i)

$$CH_3CH_2CHClCOOH \rightleftharpoons CH_3CH_2CHCl\ COO^- + H^+$$

Initial no. of moles	1	0	0
Moles at equilibrium	$1-\alpha$	α	α

Total number of moles after dissociation

$$= (1-\alpha) + (\alpha) + (\alpha) = (1+\alpha)$$

van't Hoff factor

$$(i) = \frac{\text{Total number of moles after dissocation}}{\text{Number of moles before dissocation}}$$
$$i = \frac{(1+\alpha)}{1} = (1+\alpha)$$
$$= 1 + 0.065 = 1.065$$

Step III **Calculation of depression in freezing point** (ΔT_f)

$$\Delta T_f = i\, k_f\, m = (1.065) \times (1.86 \text{ K kg mol}^{-1}) \times (0.326 \text{ mol kg}^{-1})$$
$$\Delta T_f = 0.65 \text{ K}$$

19. Solubility is affected by nature of solute and pressure at constant T and nature of solute and temperature at constant p.

20. Molality and mole fraction are not affected by temperature because they involve masses of the solute and the solvent which do not change with temperature.

21. Isotonic solutions must have the same density and elevation in boiling point.

22. In the graph, when $\chi_A = 1$ and $\chi_B = 0$, then $p = p_A^\circ$ and when $\chi_B = 1$ and $\chi_A = 0$ thus $p = p_B^\circ$

23. Molarity $= \frac{6}{60} = 0.1$. In case of urea, molarity and normality are the same.

24. Molarity depends upon volume which changes with change in temperature. That's why molarity changes with change in temperature.

25. An ideal solution of the components *A* and *B* is defined as the solution in which the intermolecular interactions between *A* and *B* are of the same magnitude as between the pure components or it is a solution there is no volume change or enthalpy change on mixing.

26. When sodium chloride (NaCl) is added to water, depression in freezing point is observed because the vapour pressure reduces.

27. One molar aqueous solution has 1 mole in less than 1000 g of water. Hence, 1000 g of water will be associated with more than 1 mole while 1 molal has 1 mole in 1000 g of water.

28. Extent of dissociation increases steadily with increasing dilution.

29. Isotonic solution have same molarity.

$$\text{Molarity of 18 g glucose} = \frac{18}{180} \Big/ \frac{1000}{1000} = 0.1$$
$$\text{Molarity of 34.2 g sucrose} = \frac{34.2}{342} \Big/ \frac{1000}{1000} = 0.1$$

The concentration of 18 g L^{-1} glucose is same to 34.2 gL^{-1} sucrose.

30. For solutions 1 and 2 the concentration in compartment *B* is higher than in *A*.

31. In hypertonic solution osmotic pressure is higher, therefore, volume rise is higher in *B*.

32. L represents $\Delta T_b = k_b \cdot m$

33. For equimolar solutions $\chi_B = \chi_T = 0.5$

$$p_B = \chi_B \times p_B^\circ = 0.5 \times 160 = 80 \text{ mm}$$

$$p_T = \chi_T \times p_T^\circ = 0.5 \times 60 = 30 \text{ mm}$$

$$p_{\text{Total}} = 80 + 30 = 110 \text{ mm}$$

Mole fraction of toluene in vapour phase $= \dfrac{30}{110} = 0.27$

34. $\Delta T_b = k_b \times m = 0.513 \times 0.69 = 0.354$

$$T_b = T + \Delta T_b = 99.725 + 0.354 = 100.079^\circ \text{ C}$$

35. Total mass of solution $= 1000$ g water $+ 120$ g urea

$$= 1120 \text{ g}$$

Density of solution $= 1.15$ g/mL

Thus, volume of solution $= \dfrac{\text{mass}}{\text{density}} = \dfrac{1120 \text{ g}}{1.15 \text{ g/mL}}$

$$= 973.91 \text{mL}$$

$$= 0.974 \text{ L}$$

$$\text{Moles of solute} = \frac{120}{60} = 2$$

$$\text{Molarity} = \frac{\text{Moles of solute}}{\text{Volume (L) of solution}}$$

$$= \frac{2}{0.974} = 2.05 \text{ mol L}^{-1}$$

36. Coolant is glycol ($C_2H_6O_2$) and is non-electrolyte

$$\Delta T_f = 2.8^\circ$$

$$\Delta T_f = \frac{1000 k_f w_1}{m_1 w_2}$$

$$2.8 = \frac{1000 \times 1.86 \times w_1}{62 \times 1000}$$

$$\therefore \quad w_1 = 93.33 \text{ g}$$

37. $\text{Molality} = \dfrac{\text{moles of solute}}{\text{kg of solvent}}$

$$= \frac{5.2 \text{ mol CH}_3\text{OH}}{1 \text{ kg } (= 1000 \text{ g}) \text{ H}_2\text{O}}$$

$$n_1(\text{CH}_3\text{OH}) = 5.2$$

$$n_2(\text{H}_2\text{O}) = \frac{1000}{18} = 55.56$$

$$\therefore \quad n_1 + n_2 = 5.20 + 55.56 = 60.76 \text{ mol}$$

$$\therefore \quad X_{\text{CH}_3\text{OH}} = \text{Mole fraction of CH}_3\text{OH}$$

$$= \frac{n_1}{n_1 + n_2}$$

$$= \frac{5.2}{60.76} = 0.086$$

38. ΔT_f = Freezing point of H_2O − freezing point of ethylene glycol solution $= 0 - (-6^\circ) = 6^\circ$

$k_f = 1.86^\circ \text{ kg mol}^{-1}$

w_1 = Mass of ethylene glycol in gram

w_2 = Mass of solvent (H_2O) in grams = 4000 g

m_1 = Molar mass of ethylene glycol
$= 62 \text{ g mol}^{-1}$

i = van't Hoff factor = 1

(ethylene glycol being non-electrolyte)

$$\Delta T_f = \frac{1000 \, k_f \, w_1(i)}{m_1 \, w_2}$$

$$\therefore \quad 6 = \frac{1000 \times 1.86 \times w_1 \times 1}{62 \times 4000}$$

$$w_1 = 800 \text{ g}$$

39.

$$\begin{array}{lccc} & A_xB_y & \rightleftharpoons & xA^{y+} + yB^{x-} \\ \text{After dissociation} & (1-\alpha) & & x\alpha \qquad y\alpha \end{array}$$

$$i = n(A_xB_y) + n(A^{y+}) + n(B^{x-})$$

$$= 1 - \alpha + x\alpha + y\alpha$$

$$= 1 + \alpha(x + y - 1)$$

$$\therefore \quad \alpha = \frac{i - 1}{(x + y - 1)}$$

40. Two solutions are isotonic if their osmotic pressures are equal.

$$\pi_1 = \pi_2$$

$$M_1ST_1 = M_2ST_2$$

(M_1 and M_2 are molarities)

At a given temperature,

$$M_1 = M_2$$

$$\frac{1000w_1}{m_1V_1} = \frac{1000w_2}{m_2V_2} \qquad (V_1 = V_2 = 100 \text{ mL})$$

Cane sugar   Unknown

$$\therefore \quad \frac{w_1}{m_1} = \frac{w_2}{m_2}$$

$$\frac{5}{342} = \frac{1}{m_2}$$

$$m_2 = \frac{342}{5} = 68.4 \text{ g mol}^{-1}$$

41. $\text{Na}_2\text{SO}_4 \longrightarrow 2\text{Na}^+ + \text{SO}_4^{2-}$

van't Hoff factor for $\text{Na}_2\text{SO}_4 = 3$

$$\Delta T_f = i \times k_f \times m$$

$$= 3 \times 1.86 \times 0.01 \qquad \left[\because m = \frac{0.01}{1} = 0.01\right]$$

$$= 0.0558 \text{ K}$$

42. $p_T = X_H \cdot p_H^\circ + X_O \cdot p_O^\circ$

$$X_H = \frac{\dfrac{25}{100}}{\dfrac{25}{100} + \dfrac{35}{114}} = 0.45 \text{ and}$$

$$\therefore \quad X_O = 0.55$$

$$p_T = 0.45 \times 105 + 0.55 \times 45$$

$$= 72 \text{ kPa}$$

43. $$p_T = p_A^\circ X_A + p_B^\circ X_B$$

$$550 = p_A^\circ \times \frac{1}{4} + p_B^\circ \times \frac{3}{4}$$

Thus, $p_A^\circ + 3p_B^\circ = 2200$ ...(i)

When, 1 mol of Y is further added to the solution

$$560 = p_A^\circ + \frac{1}{5} + p_B^\circ \times \frac{4}{5}$$

Thus, $p_A^\circ + 4p_B^\circ = 2800$ ...(ii)

On subtraction, II – I

$$p_B^\circ = 2800 - 2200$$

$$p_B^\circ = 600$$

Putting the value of p_B° in Eq. (i)

$$p_A^\circ + 3 \times 600 = 2200$$

$$p_A^\circ = 2200 - 1800 = 400.$$

44. *n*-heptane and ethanol forms non-ideal solution, as resultant *n*-heptane-either molecular interaction is very poor in comparison to ethanol-ethanol or *n*-heptane so gives positive deviation.

45. $p_T = p_A^\circ \chi_A + p_B^\circ \chi_B$

Mixture solution boils at 1 atm = 760 mm = total pressure.

$$760 = 520\chi_A + 1000\,(1 - \chi_A)$$

$$\chi_A = 0.5, \text{mol \% of } A = 50\%$$

46. Moles of glucose $= \frac{18}{180} = 0.1$

Moles of $H_2O = \frac{178.2}{18} = 9.9$

According to Raoult's law

$$\frac{p^\circ - p_s}{p^\circ} = X_{\text{solute}}$$

$$\frac{17.5 - p_s}{17.5} = \frac{0.1}{10}$$

So, $p_s = 17.325$ mm Hg

47. According to Raoult's law :

$$p = p^\circ{}_A\,\chi_A + p^\circ{}_B\,\chi_B$$

$$290 = 200 \times 0.4 + p^\circ{}_B \times 0.6$$

$$p^\circ{}_B = 350$$

48. Solution is isotonic.

$$C_1RT = C_2RT$$

$$C_1 = C_2$$

Density of both the solutions are assumed to be equal to $1.0 \text{ g cm}^{-3} \Rightarrow$ molality = molarity 5.25%

In 100 g 5.25 g of substance, so in 1000 g 52.5 g of substance

Hence, $\frac{52.5}{M} = \frac{15}{60}$,

M = molecular mass of the substance

$$M = \frac{52.5 \times 60}{15} = 210$$

49. Molality $(m) = \frac{M}{1000\,d - MM_1} \times 100$

M = molarity

M_1 = molecular mass

d = density

$$= \frac{2.05}{(1000 \times 1.02) - (2.05 \times 60)} \times 1000$$

$$= 2.28 \text{ mol kg}^{-1}$$

50. Total molarity $= \frac{M_1V_1 + M_2V_2}{V_1 + V_2}$

$$= \frac{1.5 \times 480 + 1.2 \times 520}{480 + 520}$$

$$= 1.34 \text{ M}$$

51. Mixture contains 78 g benzene = 1 mol benzene and 46 g toluene = 0.5 mole toluene

Total moles of benzene and toluene = 1.5 mol

Mole fraction of benzene in mixture $= \frac{1}{1.5} = \frac{2}{3}$

Vapour pressure of benzene $p_b^\circ = 75$ Torr

$\therefore$ Partial vapour pressure of benzene $= p^\circ{}_b\,\chi_b$

$$= 75 \times \frac{2}{3} = 50 \text{ Torr}$$

52. H_3PO_3 is a dibasic acid (*i.e.*, contains two ionisable protons attached directly to O).

$$H_3PO_3 \rightleftharpoons 2H^+ + HPO_4^{2-}$$

$\therefore$ $0.1 \text{ M } H_3PO_3 = 0.2 \text{ N } H_3PO_3$

and $0.1 \text{ M KOH} = 0.1 \text{ N KOH}$

$$\underset{(KOH)}{N_1V_1} = \underset{(H_3PO_3)}{N_2V_2}$$

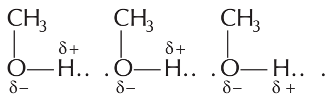
$$0.1V_1 = 0.2 \times 20$$

$$V_1 = 40 \text{ mL}$$

53. Water and hydrochloric acid; and water and nitric acid form miscible solutions. They show negative deviation.

In case of CH_3COCH_3 and $CHCl_3$, there is interaction between them, thus force of attraction between $CH_3COCH_3 \ldots. CHCl_3$ is larger than between $CHCl_3 \ldots. CHCl_3$ or $CH_3COCH_3 \ldots. CH_3COCH_3$ and thus, vapour pressure is less than expected—a negative deviation.

In case of CH_3OH, there is association by intermolecular H-bonding. When benzene is added to CH_3OH, H-bonding breaks and thus, force of attraction between CH_3OH and benzene molecule is smaller than between CH_3OH or benzene molecules (in pure state). Vapour pressure of mixture is greater than expected—a positive deviation.



$$\underset{\delta-}{\overset{\overset{CH_3}{|}}{O}}-\overset{\delta+}{H}\ldots\underset{\delta-}{\overset{\overset{CH_3}{|}}{O}}-\overset{\delta+}{H}\ldots\underset{\delta-}{\overset{\overset{CH_3}{|}}{O}}-\underset{\delta+}{H}\ldots$$

54. (a) $p_A = \chi_A p_A^\circ$ true

(b) $\pi = iMRT = MRT$ true (if van't Hoff factor, $i = 1$)

(c) $i = [1 + (y - 1)\alpha]$

where, y = number of ions

α = degree of ionisation

$i = 3$ for $BaCl_2$, $\alpha = 1$ (strong electrolyte)

$i = 2$ for KCl, $\alpha = 1$ (strong electrolyte)

$i = (1 + \alpha)$ for CH_3COOH $\alpha << 1$ (weak)

$i = 1$ for sucrose (non-electrolyte)

i (for $BaCl_2$) > KCl > CH_3COOH > sucrose

Thus, (c) is also true.

(d) $\Delta T_f = k_f m$.

k_f is dependent on solvent.

Thus, freezing points = [T (solvent) $- \Delta T_f$] are different.

Thus, (d) is false.

55. Let molarity of $Ba(OH)_2 = M_1$

$\therefore$ Normality $= 2\,M_1$

Molarity of HCl = 0.1 M = 0.1 N

$$N_1V_1 = N_2V_2$$

$$2M_1 \times 25 = 0.1 \times 35$$

$$M_1 = 0.07\ \text{M}$$

56. Higher pressure inside the cooker increases boiling point, thus, heat consistently given is used up by food material instead in boiling and constant boiling evaporation.

57. $HX \rightleftharpoons H^+ + X^{-1}$

$$\alpha = 0.3$$

$$i = 1 + \alpha = 1.3$$

$$\Delta T_f = \text{molality} \times k_f \times i$$

$$= 0.2 \times 1.85 \times 1.3 = 0.481^\circ$$

$\therefore$ Freezing point $= -\ 0.481^\circ$ C

58. Negative deviation means lower vapour pressure, it suggests high boiling point, thus resultant intermolecular force should be stronger than individual one.

JEE Main MILESTONE

- Electrolytic and Metallic Conduction
- Conductance in Electrolytic Solutions
- Electrochemical Cells
- Daniell Cell
- Electrodes and Their Types
- Electrode Potential
- Electrochemical Series
- Battery
- Fuel Cells

3.1 Electrolytic and Metallic Conduction

The substances which allow the passage of electric current through them are called **conductors,** *e.g.,* metals such as Cu, Ag, Sn etc. On the other hand, the substances which do not allow such passage through them are called **insulators**, *e.g.,* rubber, wood, sand etc.

The conductors are of two types on the basis of their physical state

Electrochemistry is the branch of chemistry which deals with inter-conversion of chemical energies and electrical energies. The chemical changes involving flow of electric current are referred as electrochemical changes.

(a) Metallic Conductors

These are the metallic substances which allow electricity to pass through them without undergoing any chemical change. Most of them are solids. Free electrons and holes (positive charges) are responsible for the conduction of such conductors. The conduction due to metallic conductors is called **electronic conductivity.** *It depends upon*

(i) nature and structure of metal
(ii) number of valence electrons per atom
(iii) density of metal
(iv) temperature (inverse relation)

Cs, Hg and Ga are metallic conductors but are liquids at room temperature.

(b) Electrolytes or Electrolytic Conductors

These are the substances which allow the electricity to pass through them in their molten states or in the form of their aqueous solutions. These undergo chemical decomposition when electricity pass through them. In real sense an electrolyte can be defined as '*a substance which dissociate into its ions when dissolved in a polar solvent like water*'**.**

The conduction of electricity because of ions is called **electrolytic conduction.** The conductivity of electrolytic solutions depends upon,

(i) nature of electrolyte
(ii) size of ions produced and their solvation (hydration)
(iii) nature of solvent and its viscosity
(iv) concentration of the electrolytes
(v) temperature (direct relation)

Acids, bases and their salts all are the examples of electrolytes. An electrolyte can be **strong** or **weak.** The strength of electrolyte depends upon its ability to dissociate. **Strong electrolytes** (*e.g.,* NaCl, HCl, KCl, NaOH, HNO_3, H_2SO_4 etc.) have the ability to dissociate completely or almost completely while **weak electrolytes** (*e.g.,* H_2CO_3, CH_3COOH, $ZnCl_2$, $HgCl_2$ etc.) on the other hand are very less dissociated as compared to former one.

Table 3.1 **Distinction between Metallic and Electrolytic Conduction**

S.N.	Metallic conduction	Electrolytic conduction
1.	Electric current flows by the movement of electrons.	Electric current flows by the movement of ions.
2.	No chemical change takes place.	Oxidation or reduction of ion occurs at the electrodes.
3.	If does not involve the transfer of any matter.	It involves transfer of matter in the form of ions.
4.	Resistance increases with increase of temperature.	Resistance decreases with increase of temperature.
5.	Faraday law is not followed.	Faraday law is followed.

3.2 Conductance in Electrolytic Solutions

The power of an electrolyte to conduct electric current is called **conductance** or **conductivity.** Just like metallic conductors, electrolytic solutions also obey Ohm's law, which states, "The current flowing through a conductor is directly proportional to the potential difference across it." *i.e.,*

$$I \propto V$$

where, I = current in ampere
V = potential difference in volt

or $$I = \frac{V}{R} \text{ or } V = IR$$

where, R = proportionality constant, called **resistance** of the conductor. Actually, resistance is the obstruction in the flow of current through a conductor and is expressed in ohm (Ω).

The **conductance** and **resistance** have reciprocal relationship *i.e.,*

$$C \propto \frac{1}{R}$$

Thus, the unit of conductance is **ohm^{-1}** or **mho** and is denoted by Ω^{-1}. In SI system, its unit is **siemen** (S).

The resistance of a conductor, is directly proportional to the length (l) and inversely proportional to the area of cross-section (a) of that conductor *i.e.,*

$$R \propto l \text{ and } R \propto \frac{1}{a}$$

i.e., $$R \propto \frac{l}{a}$$

or $$R = \rho \cdot \frac{l}{a}$$

where, ρ is again a proportionality constant, called **specific resistance** or **resistivity.**

If $l = 1$ cm and $a = 1\text{ cm}^2$, then $R = \rho$.

Hence, specific resistance is defined as *the resistance of a conductor of* 1 *cm length and having a cross-sectional area of* 1 *cm*^{2}. The unit of specific resistance is *ohm-cm*.

The factor, $\frac{l}{a}$ is known as **cell constant** and is expressed in cm^{-1}.

The reciprocal of specific resistance is called *specific conductance*, *i.e., the conductance of a solution of* 1 *cm length and having* 1 *cm*^{2} *area of cross-section. It is denoted by* κ *(Kappa).*

$$\kappa = \frac{1}{R} \times \frac{l}{a}$$

or $$\kappa = C \times \frac{l}{a}$$

where, C and R are conductance and resistance respectively.

Units of specific conductance are **ohm^{-1} cm^{-1}** or **mho cm^{-1}** or **siemens m^{-1}** (in SI system). (IUPAC has recommended the use of term conductivity over specific conductance.)

The measurement of resistance of an electrolytic solution may be done with the help of a **conductivity cell** in a Wheatstone bridge.

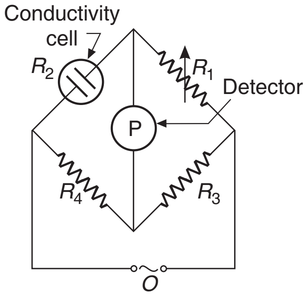

Fig. 3.1 Arrangement for measurement of resistance of a solution of an electrolyte

When null point is obtained, $\frac{R_1}{R_2} = \frac{R_3}{R_4}$

$$\text{Unknown resistance, } R_2 = \frac{R_1 R_4}{R_3}$$

Knowing the values of R_1, R_3 and R_4, R_2 can be calculated. Nowadays, inexpensive conductivity meters are available which can directly read the conductance or resistance of the solution in the conductivity cell.

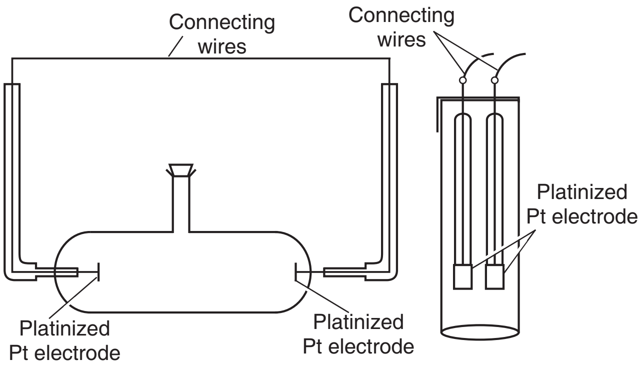

Fig. 3.2 Two different types of conductivity cells

Conductivity cell contains platinum electrodes of area of cross-section a and separated from each other by a distance l. The formula, $\kappa = C \times l/a$ for a conductivity cell is

$$\kappa = C \times C^*$$

where, C^* = cell constant = $\frac{l}{a}$

For a cell it is determined by measuring the resistance of the cell containing a solution whose conductivity is already known. *The Wheatstone bridge here is fed by an AC source and, not by the DC source which may changes the composition of solution taken.*

Caution Point *For accurate results, the solutions should be prepared in a specially purified water, conductance of which is very small. This water is called conductivity water.*

Sample Problem 1 *The resistance of a conductivity cell containing* 0.001 *M* KCl *solution at* 298 *K is* $1500\ \Omega$. *What is the cell constant if conductivity of* 0.001 M KCl *solution at* 298 *K is* 0.146×10^{-3} *S* cm^{-1}? **[NCERT]**

(*a*) $0.219\ cm^{-1}$
(*b*) $0.187\ cm^{-1}$
(*c*) $0.325\ cm^{-1}$
(*d*) $0.018\ cm^{-1}$

Interpret (*a*) $R = 1500\ \Omega;\ \kappa = 0.146 \times 10^{-3}\ \text{S cm}^{-1}$

$$\begin{aligned}\text{Cell constant} &= R \times \kappa \\ &= (1500\ \Omega) \times (0.146 \times 10^{-3}\ \text{S cm}^{-1}) = 0.219\ \text{cm}^{-1}\end{aligned}$$

Sample Problem 2 *When a certain conductivity cell was filled with* 0.020 *M* KCl *which has a specific conductivity* $0.2768\ \Omega^{-1}\ m^{-1}$, *it had a resistance of* $82.40\ \Omega$ *at* 25°C. *With* 0.0025 *M* K_2SO_4, *it has a resistance of* $326.0\ \Omega$. *The conductivity of* K_2SO_4 *solution is*

(*a*) 2.28
(*b*) 0.07
(*c*) 0.54
(*d*) 0.005

Interpret (*b*) $\kappa = \frac{\text{cell constant}}{R}$

$$\begin{aligned}\therefore \quad \text{Cell constant} &= \kappa \times R \\ &= 0.2768 \times 82.4 \\ &= 22.81\ \text{m}^{-1}\end{aligned}$$

$$\therefore \ \text{Specific conductance of } K_2SO_4, \kappa_{K_2SO_4} = \frac{22.81}{326} = 0.07\ \Omega^{-1}\ \text{m}^{-1}$$

Molar Conductivity

The conducting power of all the ions produced by dissolving 1 g-mole of an electrolyte in solution is called **molar conductivity** of that solution. It is denoted by λ_m or μ and is related to specific conductance (κ) as :

$$\lambda_m \text{ or } \mu = \frac{\kappa \times 1000}{M}$$

where, M = concentration in mol/L, *i.e.,* molarity of the solution

Its units are $\mathbf{ohm^{-1}\ cm^2\ mol^{-1}}$ or $\mathbf{mho\ cm^2\ mol^{-1}}$ or $\mathbf{S\ cm^2\ mol^{-1}}$.

Sample Problem 3 *The conductivity of* 0.20 *M solution of* KCl *at* 298 *K is* 0.0248 *S* cm^{-1}. *Its molar conductivity is* **[NCERT]**

(*a*) $1.24\ \Omega^{-1}\ mol^{-1}\ cm^2$
(*b*) $124\ S\ mol^{-1}\ cm^2$
(*c*) $12.4\ \Omega^{-1}\ mol^{-1}\ cm^2$
(*d*) $0.124\ S\ mol^{-1}\ cm^2$

Interpret (*b*) $\mu = \frac{\kappa \times 1000}{m} = \frac{0.0248 \times 1000}{0.20}$

$$= 124\ \text{S mol}^{-1}\ \text{cm}^2$$

Sample Problem 4 *The electrical resistance of a column of* 0.05 M NaOH *solution of diameter* 1 cm *and length* 50 cm *is* 5.55×10^3 *ohm. Calculate its molar conductivity.* **[NCERT]**

(a) 114.8 $S\ cm^2\ mol^{-1}$ (b) 229.6 $S\ cm^2\ mol^{-1}$
(c) 346.9 $S\ cm^2\ mol^{-1}$ (d) 175.3 $S\ cm^2\ mol^{-1}$

Interpret (b) Area (a) $= \pi r^2 = 3.14 \times \left(\frac{1\text{ cm}}{2}\right)^2$

$$= 0.785\text{ cm}^2$$

$$l = 50\text{ cm}$$

$$R = \frac{\rho l}{a} \quad \text{or} \quad \rho = \frac{Ra}{l} = \frac{5.55 \times 10^3\text{ ohm} \times 0.785\text{ cm}^2}{50\text{ cm}}$$

$$= 87.135\text{ ohm cm}$$

$$\text{Conductivity } (\kappa) = \frac{1}{\rho} = \left(\frac{1}{87.135}\right)\text{ S cm}^{-1}$$

$$= 0.01148\text{ S cm}^{-1}$$

$$\text{Molar conductivity } (\lambda_m) = \frac{\kappa \times 100}{M}\text{ cm}^2\text{ L}^{-1}$$

$$= \frac{0.01148\text{ S cm}^{-1} \times 1000\text{ cm}^3\text{ L}^{-1}}{0.05\text{ mol L}^{-1}}$$

$$= 229.6\text{ S cm}^2\text{ mol}^{-1}$$

Equivalent Conductivity

The conducting power of all the ions produced by dissolving 1 g-equivalent of an electrolyte in solution is called its **equivalent conductivity.** It is denoted by λ_{eq} or Λ.

It is related to specific conductance as,

$$\lambda_{eq} \text{ or } \Lambda = \frac{\kappa \times 1000}{C_{eq}\,(N)}$$

where, C_{eq} = concentration of solution in equivalent per litre (*i.e.,* normality)

Its units are **ohm $^{-1}$ cm ^{2}** (equiv^{-1}) or **mho cm ^{2}** (equiv^{-1}). or **S cm ^{2}** (g- equiv^{-1}).

Sample Problem 5 *The resistance of a decinormal solution of a salt occupying a volume between two platinum electrodes* 1.80 cm *apart and* 5.4 cm^2 *in area was found to be* 50 *ohm. The equivalent conductance of the solution is*

(a) 6.66 (b) 66.7
(c) 0.667 (d) 57.8

Interpret (b) Given, $C = \frac{1}{\text{resistance}} = \frac{1}{50}\text{ ohm}^{-1} = 0.02\text{ S}$

$$\text{Cell constant} = \frac{l}{a} = \frac{\text{distance}}{\text{area}} = \frac{1.80}{5.40} = \frac{1}{3}\text{ cm}^{-1}$$

Normality = 0.1 N

$$\therefore \quad \Lambda_{eq} = \frac{1000 \times \text{conductance} \times \text{cell constant}}{\text{concentration (normality)}}$$

$$= \frac{1000 \times 0.02}{0.1} \times \frac{1}{3}$$

$$= 66.66\text{ S cm}^2\text{ equivalent}^{-1}$$

Effect of Nature of Electrolyte over Conductivity

The conductivity of an electrolyte depends upon the **nature of electrolyte** as the conductivity of strong electrolytes is higher in comparison to weak electrolytes. The reason for such a difference is difference in availability of ions present in their solutions. Strong electrolytes dissociate completely, hence more ions are present in their solutions resulting to higher conductivity. Weak electrolytes, on the other hand, dissociate less, hence less ions are present in their solutions resulting to lesser conductivity.

Variation of Conductivity with Dilution (or Concentration)

For both weak and strong electrolytes, the electrolytic conductance as well as the equivalent conductivity (Λ_{eq}) and molar conductivity (Λ_m) increase with dilution. This is because the total volume V of a solution containing 1 g equivalent or 1 mole of electrolyte also increases. It may be noted that decrease in κ on dilution of a solution is more than that compensated by increase in its volume.

Conductivity (or specific conductivity, κ) always decreases with dilution, both for weak and strong electrolytes.

This is due to the fact that the total number of ions in the solution increases on dilution but the number of ions per unit volume that carry the current in the solution decreases on dilution.

(a) For Strong Electrolytes

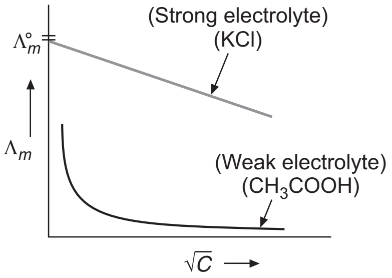
The Λ_{eq} or Λ_m of strong electrolyte increases slowly with dilution and can be represented by **Debye Huckel-Onsager equation**

$$\Lambda^c_{eq} = \Lambda^\circ_{eq} - b\sqrt{c} \quad \text{or} \quad \Lambda^c_{eq} = \Lambda^\infty_{eq} - b\sqrt{c}$$

$$\Lambda^c_m = \Lambda^\circ_m - b\sqrt{c} \quad \text{or} \quad \Lambda^c_m = \Lambda^\infty_m - b\sqrt{c}$$

If a plot of Λ_{eq} or Λ_M against $\sqrt{c}$ is plotted (as shown in figure), a straight line with intercept equal to Λ°_{eq} or Λ°_m and a slope equal to $-b$ is obtained at lower concentration, but it is not linear for higher concentration. The value of the constant b for a given solvent and temperature depends on the type of electrolytes, *i.e.,* the charges on the cation and anion produced during the dissociation of the electrolyte in the solution.

Therefore, electrolytes of a particular type have the same value of *b*. *e.g.,* $CaSO_4$ and $MgSO_4$ (2–2 type) have the same value of *b*.



Moreover, the curve obtained for a strong electrolyte shows that there is a small increase in Λ_{eq}, or Λ_m with dilution. This is because a strong electrolyte is completely ionized in solution and so the number of ions remains almost constant.

At higher concentration, the greater inter-ionic interaction decreases the movement of the ions and therefore, conductance decreases with increasing concentration.

On dilution, the ions are far apart, and therefore inter-ionic attraction decreases and hence, conductance increases and approaches a maximum limiting value at infinite dilution.

It is also observed that the plot for a strong electrolyte becomes linear near high dilution and can be extrapolated to zero concentration to get the value of Λ_m° or Λ_{eq}°. (Conductivity at infinite dilution).

(b) For Weak Electrolytes

The conductance of weak electrolytes is less than that of strong electrolytes at the same concentration since weak electrolytes are not completely ionized. Moreover, the curve for weak electrolytes shows that there is a very large increase in the conductance with dilution near the infinite dilution since on dilution the degree of ionization increases. Thus, an increase in conductance with dilution is due to the increase in the number of ions in the solution. However, it does not reach a limiting value.

For a weak electrolyte, Λ_m or Λ_{eq} increases sharply near high dilution. Hence, an extrapolation at infinite dilution is not possible. Experimentally, it is also not possible to determine the Λ_{eq}° or Λ_m° value for a weak electrolyte because although the ionization is complete but the number of ions per unit volume is so low that the conductivity cannot be measured accurately.

This problem was solved by Kohlrausch who gave a law known as Kohlrausch law of independent migration of ions.

Hot Spot 1

KOHLRAUSCH's Law

It is a very important topic for JEE Main examination. The questions based on this topic are generally numerical type and their level vary from easy to difficult.

According to **Kohlrausch law,** the molar conductivity of an electrolyte at infinite dilution is the sum of molar conductivity of ions produced by the electrolyte at infinite dilution. In other words, we can say that the **sum of molar conductivity of cation and anion at infinite dilution is called molar conductivity of electrolyte,** *e.g.*, if μ_c^∞ and μ_a^∞ are the molar conductivities of cations and anions at infinite dilution then

$$\mu_\infty = n^+ \times \mu_c^\infty + n^- \times \mu_a^\infty$$

where, n^+ and n^- are the number of cations and anions respectively.

(The multiplication of number of ions with molar conductivity of a particular ion is called **molar ionic conductance** of that particular ion.)

In terms of equivalent conductivities, Kohlrausch's law is defined as, **the equivalent conductivity of an electrolyte at infinite dilution is the sum of two values one depending upon the cation and other on anion,** *i.e.,*

$$\Lambda_{eq}^\circ = \lambda_c^\circ + \lambda_a^\circ$$

here, λ_c° and λ_a° are limiting equivalent or ionic conductivities of cation and anion respectively.

Some important applications of Kohlrausch's law are as follows

(a) Calculation of Λ_m° or Λ_{eq}°

This law is helpful in calculation of molar conductance at infinite dilution for weak electrolytes. Suppose, we have to calculate the limiting conductance for CH_3COOH.

Then, according to Kohlrausch's law

$$\mu^\infty_{(CH_3COOH)} = \mu^\infty_{(CH_3COO^-)} + \mu^\infty_{(H^+)} \qquad \text{...(i)}$$

This equation can be obtained by the knowledge of molar conductance at infinite dilution for some strong electrolytes, *i.e.*,

$$\mu^\infty_{(CH_3COO^-Na^+)} = \mu^\infty_{(CH_3COO^-)} + \mu^\infty_{(Na^+)} \qquad \text{...(ii)}$$

$$\mu^\infty_{(HCl)} = \mu^\infty_{(H^+)} + \mu^\infty_{(Cl^-)} \qquad \text{...(iii)}$$

$$\mu^\infty_{(NaCl)} = \mu^\infty_{(Na^+)} + \mu^\infty_{(Cl^-)} \qquad \text{...(iv)}$$

The above Eq. (i) can be obtained by adding Eqs. (ii) and (iii) and subtracting Eq. (iv) from them, *i.e.*,

$$\mu^\infty_{(CH_3COOH)} = \mu^\infty_{(CH_3COONa)} + \mu^\infty_{(HCl)} - \mu^\infty_{(NaCl)}$$

Sample **Problem 6** *Λ_m° for* NaCl, HCl, *and* NaAc *are* 126.4, 425.9, *and* 91.0 *S* cm^2 *mol*$^{-1}$, *respectively. Calculate* Λ° (*S* cm^2 *mol*$^{-1}$) *for* HAc. **[NCERT]**

(*a*) 390.5 (*b*) 180.3 (*c*) 420.2 (*d*) 350.5

Interpret (*a*) $\Lambda^\circ_{m(HAc)} = \Lambda^\circ_{m(HCl)} + \Lambda^\circ_{m(NaAc)} - \Lambda^\circ_{m(NaCl)}$

$$= (425.9 + 91.0 - 126.4)\ \text{S cm}^2\ \text{mol}^{-1}$$

$$= 390.5\ \text{S cm}^2\ \text{mol}^{-1}$$

Sample **Problem 7** 0.1 *M* H_2SO_4 *is diluted to* 0.01 *M* H_2SO_4. *Hence, its molar conductance will be*

(*a*) 10 *times* (*b*) $\frac{1}{10}$ *th*

(*c*) 100 *times* (*d*) 10000 *times*

Interpret (*a*)

$$\lambda_m = \frac{\kappa \times 1000}{M}$$

$$\frac{(\lambda_m)_i}{(\Lambda_m)_f} = \frac{M_f}{M_i}$$

$$\frac{(\Lambda_m)_i}{(\Lambda_m)_f} = \frac{0.01}{0.1}$$

$$(\lambda_m)_i = 0.1 \times (\Lambda_m)_f$$

$$\therefore \quad (\Lambda_m)_f = 10 \times (\Lambda_m)_i$$

(b) Calculation of α

For calculating degree of dissociation, α of weak electrolyte, the formula used is

$$\alpha = \frac{\mu^c}{\mu^\infty}$$

where, α = degree of dissociation

μ^c = molar conductance at any concentration

μ^∞ = molar conductance at infinite dilution

(c) Calculation of K_a

It is helpful in determination of the ionisation constant of a weak electrolyte, as we can calculate α from it.

Sample **Problem 8** *The molar conductivity of* 0.025 *mol* L^{-1} *methanoic acid is* 46.1 *S* cm^2 *mol*$^{-1}$. *Its dissociation constant is* [*Given,* $\lambda^\circ(H^+) = 349.6$ *S* cm^2 *mol*$^{-1}$ *and* $\lambda^\circ(HCOO^-) = 54.6$ *S* cm^2 *mol*$^{-1}$] **[NCERT]**

(*a*) 2.89×10^{-4} (*b*) 1.87×10^{-3}

(*c*) 3.67×10^{-4} (*d*) 4.28×10^{-3}

Interpret (*c*) ***Step I*** **Calculation of degree of dissociation (α) of HCOOH**

$$\Lambda_m^c = 46.1\ \text{S cm}^2\ \text{mol}^{-1}$$

$$\Lambda^\circ_{m(\text{HCOOH})} = \lambda^\circ_{m(\text{HCOO}^-)} + \lambda^\circ_{m(\text{H}^+)}$$

$$= (54.6 + 349.6)\ \text{S cm}^2\ \text{mol}^{-1}$$

$$= 404.2\ \text{S cm}^2\ \text{mol}^{-1}$$

$$\alpha = \frac{\Lambda^c_m}{\Lambda^\circ_m} = \frac{(46.1)\ \text{S cm}^2\ \text{mol}^{-1}}{(404.2)\ \text{S cm}^2\ \text{mol}^{-1}} = 0.1140$$

Step II **Calculation of dissociation constant**

$$\text{HCOOH}(aq) \overset{\text{Water}}{\rightleftharpoons} \text{HCOO}^-(aq) + \text{H}^+(aq)$$

	HCOOH	HCOO⁻	H⁺
Initial conc.	C	0	0
Equilibrium conc.	$C(1-\alpha)$	$C\alpha$	$C\alpha$

$$\text{Dissociation constant, } K_a = \frac{[\text{HCOO}^-][\text{H}^+]}{[\text{HCOOH}]} = \frac{C\alpha \times C\alpha}{C(1-\alpha)} = \frac{C\alpha^2}{(1-\alpha)}$$

$$\text{Placing values } K_a = \frac{(0.025\ \text{mol L}^{-1}) \times (0.114)^2}{(1-0.114)}$$

$$= \frac{(3.249 \times 10^{-4}\ \text{mol L}^{-1})}{(0.886)}$$

$$= 3.67 \times 10^{-4}\ \text{mol L}^{-1}$$

(d) Determination of the Solubility of a Sparingly Soluble Salt

If a salt is very less soluble in the given solvent, its molar or equivalent conductivity at some concentration is taken as its molar or equivalent conductivity at infinite dilution.

$$\text{Thus,}\quad \lim_{c \to 0} \Lambda^c_m = \Lambda^\circ_m \quad \text{and} \lim_{c \to 0} \Lambda^\circ_{\text{eq}} = \Lambda^\circ_{\text{eq}}$$

$$\text{Thus,}\quad \lim_{c \to 0} \Lambda^c_m = \Lambda^\circ_m = \frac{\kappa \times 100}{M} \quad \text{or} \quad \frac{\kappa \times 1000}{S}$$

(S = solubility in mol L^{-1})

$$\lim_{c \to 0} \Lambda^c_{\text{eq}} = \Lambda^\circ_{\text{eq}} = \frac{\kappa \times 1000}{N} \quad \text{or} \quad \frac{\kappa \times 1000}{S}$$

(S = solubility in eq L^{-1})

Λ°_m or $\Lambda^\circ_{\text{eq}}$ can be computed using Kohlrausch's law.

Thus, S can be computed and can be used to calculate the solubility product. For example, for A_xB_y if S mol L^{-1} is the solubility, then

$$K_{\text{sp}} = x^x y^y S^{x+y}$$

Sample **Problem 9** *For a saturated solution of* AgCl *at* $25°$,*C specific conductance is* 3.41×10^{-6} *ohm*$^{-1}$ *cm*$^{-1}$ *and that of water used for preparing the solution was* 1.60×10^{-6} *ohm*$^{-1}$ *cm*$^{-1}$. *The solubility product of* AgCl *is* [$\Lambda^\infty_{\text{eq}}$ (AgCl) = 138.3 *ohm*$^{-1}$ *cm*$^{-1}$ *equiv*$^{-1}$]

(a) 1.31×10^{-5} (b) 1.74×10^{-8}
(c) 1.72×10^{-10} (d) 3.61×10^{-3}

Interpret (c) For AgCl, molarity = normality

Actual specific conductance = (specific conductance of AgCl − specific conductance of water)

$$= (3.41 - 1.60) \times 10^{-6}$$

$$= 1.81 \times 10^{-6}\ \text{ohm}^{-1}\ \text{cm}^{-1}$$

For saturated solution of sparingly soluble salt,

$$\Lambda_{\text{eq}} = \Lambda^\infty_{\text{eq}}, \text{ and solubility = concentration}$$

$$\Lambda^\infty_{\text{eq}} = \frac{1000 \times \text{specific conductance}}{\text{solubility}}$$

$$\therefore \quad 138.3 = \frac{1000 \times 1.81 \times 10^{-6}}{S}$$

$$S\ (\text{mol L}^{-1}) = \frac{1000 \times 1.81 \times 10^{-6}}{138.3}$$

$$= 1.31 \times 10^{-5}\ \text{mol L}^{-1}$$

$$\text{AgCl}(s) \rightleftharpoons \text{Ag}^+(aq) + \text{Cl}^-(aq)$$

$$\therefore \quad K_{\text{sp}} = [\text{Ag}^+][\text{Cl}^-] = S^2$$

$$= (1.31 \times 10^{-5})^2$$

$$= 1.72 \times 10^{-10}\ \text{mol}^2\ \text{L}^{-2}$$

Sample **Problem 10** *Equivalent conductance of* BaCl_2, H_2SO_4 *and* HCl *are* x_1, x_2 *and* x_3 *S cm*^{2} *equiv*$^{-1}$ *at infinite dilution. If specific conductance of saturated* BaSO_4 *solution is* y *S cm*$^{-1}$ *then* K_{sp} *of* BaSO_4 *is*

(a) $\dfrac{10^3 y}{2(x_1 + x_2 - 2x_3)}$ (b) $\dfrac{10^6\, y^2}{(x_1 + x_2 - 2x_3)^2}$

(c) $\dfrac{10^6 y^2}{4(x_1 + x_2 - 2x_3)^2}$ (d) $\dfrac{x_1 + x_2 - 2x_3}{10^6\, y^2}$

Interpret (c) $\Lambda_{\text{BaSO}_4} = \Lambda_{\text{BaCl}_2} + \Lambda_{\text{H}_2\text{SO}_4} - 2 \times \Lambda_{\text{HCl}}$

$$= x_1 + x_2 - 2x_3$$

$$\Lambda_{\text{BaSO}_4} = \frac{1000 \times \kappa}{\text{normality}}$$

$$\therefore \quad \text{Normality} = \frac{10^3 \times y}{x_1 + x_2 - 2x_3}$$

$$\text{Molarity} = \frac{10^3 \times y}{2(x_1 + x_2 - 2x_3)}$$

$$\text{For BaSO}_4, \quad K_{\text{sp}} = (s)^2 = \left[\frac{10^3 \times y}{2(x_1 + x_2 - 2x_3)}\right]^2$$

$$= \frac{10^6 y^2}{4(x_1 + x_2 - 2x_3)^2}$$

Transport Number

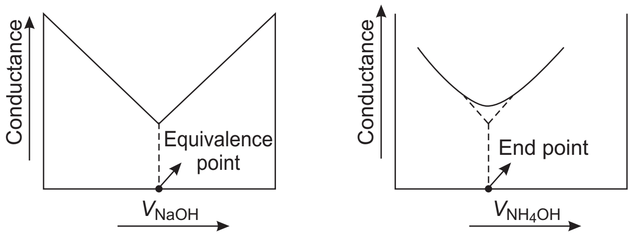
Transport number or transference number is defined as the fraction of the current carried by an ion.

$$\text{Transport number} = \frac{\text{current carried by ion}}{\text{total current carried}}$$

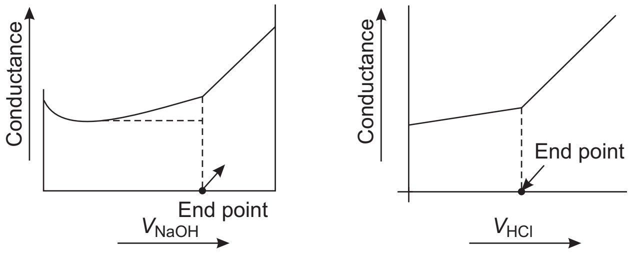
Transport no. of cation + Transport no. of anion = 1

Conductometric Titration

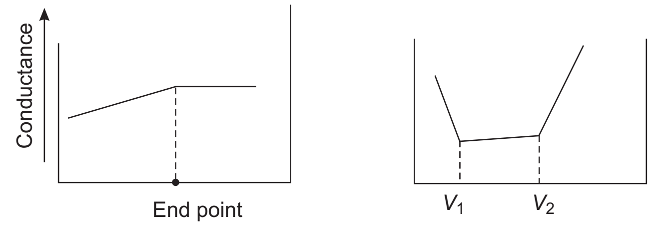
The measurement of conductance of resulting solution from an acid and base titration is used to calculate equivalence point if there is a regular change in the conductance and sharp change at equivalence point. For various titrations, conductometric curves are as follows



(a) For strong acid *vs* strong base (b) For strong acid *vs* weak base



(c) For weak acid *vs* strong base (d) For strong acid *vs* weak base



(e) For weak acid *vs* weak base (f) For a mixture of weak and strong acids *vs* strong base

Fig. 3.3 Titration curves

Check Point 1

1. Solid NaCl does not conduct electricity but an aqueous solution of NaCl or molten NaCl conducts electricity. Explain.
2. At infinite dilution, every ion makes an independent contribution to the total conductivity of solution, why? [**Hints** because of no interionic attraction]
3. Specific conductivity decreases while equivalent conductivity increases with dilution. Explain.
4. Why is it necessary to use AC current for the measurement of the conductivity of the solution?
5. At infinite dilution, the conductance of weak as well as strong electrolytes are same, why?
6. At 50°C, the conductivity of a weak electrolyte is *x* and at 100°C, the conductivity of the same electrolyte is *y*. Find the correct relation between *x* and *y* and also give the appropriate reason.
7. For weak electrolytes, dilution increases equivalence conductance very slowly in higher concentration range but steep rise is observed as concentration approaches to zero-why?

3.3 Electrochemical Cells

Electrochemical cells are the devices in which inter-conversion of electrical energy and chemical energy takes place. *Electrochemical cells are of two basic types*

(i) Electrolytic cell (ii) Galvanic cell

Electrolytic Cell

In an electrolytic cell a chemical reaction is carried out with the help of an external source of electric current. Therefore, in an electrolytic cell, electrical energy is converted into chemical energy. Here a non-spontaneous redox reaction is forces to take place with the help of external current. Like galvanic cell, here also, anode is the site of oxidation and cathode is the site of reduction. An example of non-spontaneous redox reaction which is carried out in an electrolytic cell is

Electrolysis of Molten NaCl

$$\text{NaCl(molten)} \longrightarrow \text{Na}^+ + \text{Cl}^-$$

At anode

$$2\text{Cl}^- + 2\,e^- \longrightarrow \text{Cl}_2\uparrow$$

At cathode

$$2\text{Na}^+ + 2\,e^- \longrightarrow 2\text{Na}(l)$$

Thus, Cl_2 and Na are the products of electrolysis of molten NaCl.

Preferential Discharge Theory

According to this theory if more than one type of ions are attracted towards a particular electrode then the one discharged is the ion which requires least energy. The potential at which the ion is discharged or deposited on the appropriate electrode is termed as the discharge or deposition potential. The values of discharge potential are different for different ions. For example, the discharge potential of H^+ ions is lower than Na^+ ions when platinum or most of the other metals are used as cathodes. Similarly, discharge potential of Cl^- ions is lower than that of OH^- ions. *This can be explained by some examples given below.*

Electrolysis of Aqueous NaCl

In case of aqueous NaCl, H_2O is also present along with Na^+ and Cl^- ions. On passing electricity, the following reactions takes place

At anode

$$2\text{Cl}^-(aq) \longrightarrow \text{Cl}_2(g) + 2\,e^-; \qquad E^\circ = -1.36\text{ V}$$
$$2\text{H}_2\text{O}(l) \longrightarrow \text{O}_2(g) + 4\text{H}^+(aq) + 4\,e^-; \quad E^\circ = -1.23\text{ V}$$

If the solution of NaCl is concentrated, Cl_2 is the main product. However, if it is quite dilute, the product is O_2 instead of Cl_2. This is because of overvoltage.

(From experiments, it was found that the applied voltage required is always higher than that calculated from the standard oxidation and reduction potentials. The additional voltage required is called the overvoltage).

At cathode

$$2Na^+ + 2e^- \longrightarrow 2Na \qquad E^\circ = -2.71\text{ V}$$
$$2H_2O + 2e^- \longrightarrow H_2 + 2OH^- \quad E^\circ = -0.83\text{ V}$$

Similar to above, in case of dilute NaCl solution, here also, the product is H_2 instead of Na due to overvoltage.

However, if cathode is made up of mercury, Na-Hg is the main product as Na is soluble in Hg and the overpotential of hydrogen is higher on mercury. In such case, on hydrolysis NaOH is obtained as main product.

$$2\text{Na-Hg} + 2H_2O \longrightarrow 2NaOH + 2Hg + H_2$$

Caution Point *When* Hg *is used as a cathode,* Na^+ *ions have lower discharge potential than* H^+ *ions.*

Electrolysis of Aqueous $CuSO_4$ Solution

(i) **With inert electrodes like Pt**

At anode

$$2SO_4^{2-}(aq) \longrightarrow S_2O_8^{2-}(aq) + 2e^-; \quad E^\circ = 1.96\text{ V}$$
$$2H_2O(l) \longrightarrow O_2(g) + 4H^+ + 4e^-; E^\circ = -1.23\text{ V}$$

At cathode

$$2H_2O(l) + 2e^- \longrightarrow H_2 + 2OH^-; \quad E^\circ = -0.83\text{ V}$$
$$2Cu^{2+}(aq) + 4e^- \longrightarrow 2Cu(s); \quad E^\circ = +0.337\text{ V}$$

Thus, the main products of electrolysis of aqueous (dilute) solution of $CuSO_4$ are Cu and O_2.

This reaction follows the principle of electrolysis and due to electrolysis, the blue colour of the $CuSO_4$ solution gradually fades.

(b) **With copper electrodes**

At anode

$$Cu(s) \longrightarrow Cu^{2+}(aq) + 2e^-; \quad E^\circ = -0.337\text{ V}$$

At cathode

$$Cu^{2+}(aq) + 2e^- \longrightarrow Cu(s); \qquad E^\circ = +0.337\text{ V}$$

For this process only a very slight voltage is required. The concentration of the solution remains unchanged. This makes the basis of purification of metals, called electrorefining.

Infact, this whole process involves the transference of copper from anode to cathode.

Sample **Problem 11** *A dilute aqueous solution of* H_2SO_4 *is electrolysed using* Pt *electrodes. The products at the anode and cathode are*

(a) O_2, H_2 (b) $S_2O_8^{2-}$, Na (c) O_2, Na (d) $S_2O_8^{2-}$, H_2

Interpret (a) When dilute aqueous solution of H_2SO_4 is subjected to electrolysis following reactions take place at cathode and anode

At anode

$$2H_2O \longrightarrow O_2 + 4H^+ + 4e^-$$
$$2SO_4^{2-} \longrightarrow S_2O_8^{2-} + 2e^-$$

At cathode

$$2H^+ + 2e^- \longrightarrow H_2$$

Thus, O_2 and H_2 are the main products.

Caution Point *When an aqueous solution of a salt is electrolysed if metal has –ve reduction potential less than –0.83 V,* H_2O *is reduced at cathode liberating* $H_2(g)$, *leaving behind metal ion intact in the solution. On the other hand, if anion is nitrate or sulphate,* H_2O *is oxidized at anode liberating* $O_2(g)$.

Faraday's Laws of Electrolysis

Faraday was the first scientist who described the quantitative aspect of electrolysis. He gave two laws of electrolysis, which in their modern combined version may be stated as *"The amount of electricity* (or charge) *required for oxidation or reduction depends upon stoichiometry of the electrode reaction".* However, their previous forms was as follows

Faraday's first law states, "mass of any substance deposited or liberated at any electrode is directly proportional to the quantity of electricity passed" *i.e.,*

$$w = Zit$$

where, w = substance deposited (in gram)
$i \times t$ = electricity passed per unit time
Z = proportionality constant, also called electrochemical equivalent

This electrochemical equivalent is defined as the mass of substance deposited when 1 C electricity is passed through a solution. It can be calculated as

$$Z = \frac{\text{equivalent weight of substance}}{96500}$$

Here, 96500 is called *Faraday's constant.* It is basically the charge on 1 mole of electrons. Its exact value is 96487 and with approximation we take it 96500.

Sample **Problem 12** *If a current of* 0.5 *A flows through a metallic wire for 2 h, then how many electrons would flow through the wire?* **[NCERT]**

(a) 6.022×10^{23} (b) 1.202×10^{22}
(c) 2.246×10^{22} (d) 3.02×10^{24}

Interpret (c)

$$\text{Quantity of charge } (Q) \text{ passed} = \text{Current (C)} \times \text{Time } (t)$$
$$= (0.5\text{A}) \times (2 \times 60 \times 60\text{ s})$$
$$= (3600)\text{ A-s} = 3600\text{ C}$$

Number of electrons flowing through the wire on passing charge of one Faraday (96500 C) $= 6.022 \times 10^{23}$

Number of electrons flowing through the wire on passing a charge of 3600 C

$$= \frac{6.022 \times 10^{23} \times (3600\ \text{C})}{(96500\ \text{C})}$$

$$= 2.246 \times 10^{22}$$

Number of electrons $= 2.246 \times 10^{22}$

Sample Problem 13 10800 *C of electricity on passing through the electrolyte solution deposited* 2.977 g *of metal with atomic mass* 106.4 g mol^{-1}. *The charge on the metal cation is*

(a) +2 (b) +3 (c) +4 (d) +1

Interpret (c) $E = \frac{w \times 96500}{i \times t} = \frac{2.977 \times 96500}{10800}$

$$= 26.6\ \text{g equi}^{-1}$$

$$\therefore \quad \text{Valency} = \frac{\text{at. wt.}}{\text{eq. wt.}} = \frac{106.4}{26.6} = 4$$

Faraday's second law states, "When same quantity of electricity is passed through solutions of different electrolytes connected in series, the weight of substance produced at the electrodes is directly proportional to their equivalent weights" *i.e.,*

$$\frac{\text{Wt. of Cu deposited}}{\text{Wt. of Ag deposited}} = \frac{\text{Eq. wt. of Cu}}{\text{Eq. wt. of Ag}}$$

The above formula can be given when $CuSO_4$ and $AgNO_3$ solutions are connected in series and same quantity of electricity is passed through them.

Now suppose for electrode reactions,

$$Mg^{2+}(l) + 2e^- \longrightarrow Mg(s)$$

$$Al^{3+}(l) + 3e^- \longrightarrow Al(s)$$

the requirement of electrons is 2 moles and 3 moles respectively for completion, *i.e.,* 2 Faraday and 3 Faraday. Similarly for the electrode reaction,

$$Ag^+(aq) + e^- \longrightarrow Ag(s)$$

only 1 mole (1F) of electricity is required for completion. Thus, the requirements of electricity (or charge) is electrode reaction oriented and varies with the change in electrode reactions.

Sample Problem 14 *In an aqueous solution* $AgNO_3$ *and* $CuSO_4$ *are connected in series. If* Ag *deposited at cathode is* 1.08 g *then* Cu *deposited is*

(a) 0.5326 g (b) 0.818 g (c) 0.264 g (d) 0.317 g

Interpret (d) Eq. of Ag = Eq. of Cu

$$\frac{1.08}{108} = \frac{w_{Cu}}{63.5/2}$$

$$W_{Cu} = \frac{63.5 \times 1.08}{2 \times 108} = 0.3175\ \text{g}$$

Current Efficiency

Sometimes the ammeter shows false current due to mechanical fault. In this case,

$$\%\ \text{Current efficiency} = \frac{\text{Actual current}}{\text{Ammeter current}} \times 100$$

Thickness of Coated Layer

Let the dimensions of metal sheet to be coated $= (a\ \text{cm} \times b\ \text{cm})$.

Thickness of coated layer $= c$ cm

Volume of coated layer $= (a \times b \times c)\ \text{cm}^3$

Mass of the deposited substance = volume × density

$$= (a \times b \times c) \times d\ \text{g}$$

$$\therefore \quad (a \times b \times c) \times d = \frac{I \times t \times E}{96500}$$

Using above relation we may calcualte the thickness of coated layer.

Galvanic (Voltaic) Cell

In a galvanic cell, some spontaneous redox reaction takes place producing electric current. Therefore, in galvanic cell, chemical energy is converted into electrical energy. An example of galvanic cell is Daniell cell. *In this cell,*

At cathode $Cu^{2+}(aq) + 2e^- \longrightarrow Cu$ (Reduction)

At anode $Zn(s) \longrightarrow Zn^{2+}(aq) + 2e^-$ (Oxidation)

Overall $Cu^{2+} + Zn(s) \longrightarrow Cu + Zn^{2+}(aq)$

The change of chemical energy to electrical energy causes lowering of free energy, which appears as electrical energy and measured in terms of emf.

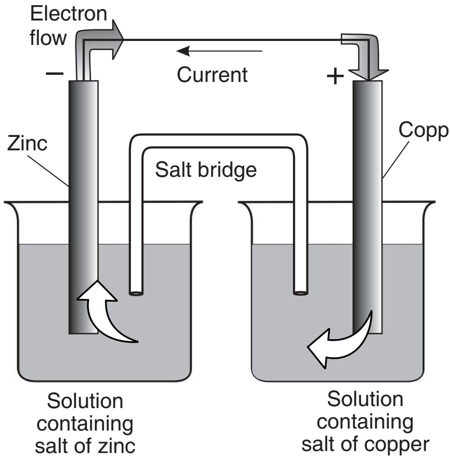


Fig. 3.4 Daniell cell having electrodes of Zn and Cu dipping in the solutions of their respective salts

In galvanic cell, chemical reactions takes place in two compartments, each of which is called a **half-cell** and contains a suitable electrolyte and electrodes.

The solution in two compartments is connected through an inverted U shaped tube containing a mixture of agar-agar jelly and an electrolyte like KCN or KNO_3 or NH_4NO_3 (inert electrolyte) etc. This U tube connecting the two compartments is called **salt bridge.**

The significance of salt bridge includes

1. It connects the solution of two half-cells, thus completes the cell circuit.
2. It prevents transference or diffusion of the solutions from one half-cell to other.
3. It helps in keeping the solution in two half-cells electrically neutral, *i.e.,* it provides negative ions to anodic half-cell, thus preventing the accumulation of extra positive charge in the solution and around anode which normally hinders the flow of electrons from anode. Similarly, in cathodic half-cell, it provides positive ions to prevent the accumulation of extra negative ions in this half.
4. It prevents **liquid-liquid junction potential,** *i.e.,* the potential difference which arises between two solutions when these are in contact with each other due to different movement of ions.

Characteristics of electrolyte used as salt bridge are

1. The electrolyte should be inert and should not react chemically with the electrolyte of either of the two half cells.
2. The cation as well as anion of the electrolyte should have same ionic mobility and almost same transport number, *viz.*, KCl, KNO_3, NH_4NO_3, etc.

The salt bridge can be replaced by a porous partition like a paper strip, clay porous pot, unglazed porcelain or asbestos fibre which allows the migration of ions without allowing the solutions to intermix.

The electrochemical cells may be **reversible** or **irreversible.** A cell is considered as reversible if

(i) The chemical reaction of cell stops when an exactly equal opposing emf is applied.

(ii) The chemical reaction of the cell is reversed and current flows in opposite direction when opposing emf is slightly greater than that of the cell.

Any other cell which does not obey above two conditions is called **irreversible cell,** *e.g.,* a cell consisting of Zn and Cu electrodes dipped in H_2SO_4 is irreversible.

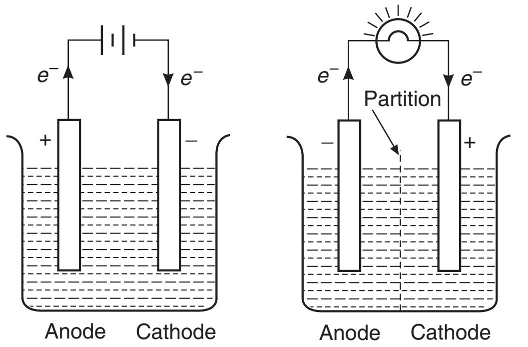
Difference between Electrolytic and Electrochemical Cells

The main points of difference between these two cells are

1. The device in which electrolysis (chemical reaction involving oxidation and reduction) is carried out by using electricity or in which conversion of electrical energy into chemical energy is done is called electrolytic cell while **galvanic** or **voltaic** cell is a device in which **redox** reaction is used to convert chemical energy to electrical energy.
2. In 'electrolytic cell', anode is positive electrode, while cathode is negative electrode. On the other hand, in 'galvanic cell' anode is negative electrode and cathode is positive electrode.

Caution Point *In both the cells anode is always the site of oxidation and cathode is of reduction.*

3. In electrolytic cell, ions are discharged at both the electrodes, while in galvanic cell ions are discharged only at cathode.
4. In electrolytic cell, both the electrodes are fitted in same compartment, while in galvanic cell both the electrodes are fitted in different compartments.



(a) Electrolytic cell (emf is applied to cell)

(b) Voltaic or galvanic cell (emf is generated by cell)

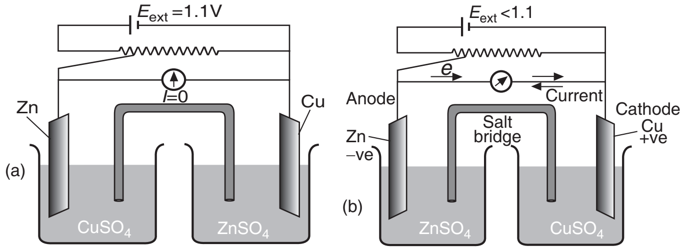
Fig. 19.5

5. Besides salt bridge in both the cells, both the electrodes are connected externally with the help of a wire connected through a voltmeter. Flow of current and electrons occur through this wire.

3.4 Daniell Cell

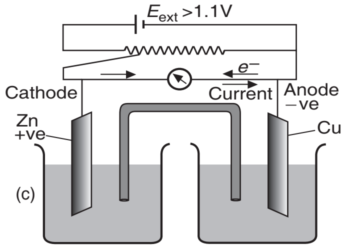
Among the galvanic cells when cell is designed in such a manner to make the use of spontaneous reaction between Zn and Cu ions to produce an electric current, the cell is called **Daniell cell.**

In **Daniell cell,** the anode is made up of Zn rod and dipped in a solution of $ZnSO_4$ (electrolyte). Similarly, the cathode is made up of Cu rod and dipped in the solution of $CuSO_4$.



When E_{ext} =1.1V
(i) No flow of electrons or current
(ii) No chemical reaction.

When E_{ext}<1.1V
(i) Electrons flow from Zn rod to Cu rod, hence current flows from Cu to Zn
(ii) Zn dissolves at anode and copper deposits at cathode.



When E_{ext} >1.1V
(i) Electrons flow from Cu to Zn and current flows from Zn to Cu
(ii) Zinc is deposited at the zinc electrode and copper dissolves at copper electrode.

Fig. 3.6 Functioning of Daniell cell when external voltage (E_{ext}) opposing the cell potential is applied

When the Zn and Cu electrodes are joined by a wire, the following observations are noted :

1. There is a flow of electric current in the external circuit from Cu electrode to Zn electrode *i.e.,* (+)ve electrode to (−)ve electrode.
2. The Zn rod loses its mass, while Cu rod gains its mass.
3. The concentration of $ZnSO_4$ solution increases while that of $CuSO_4$ solution decreases.
4. The solutions in both the compartments remain electrically neutral.

Actually Zn metal is oxidised at Zn electrode and the electrons released travel through the external circuit to Cu electrode where they are used in the reduction of Cu^{2+} ions into metallic Cu which is deposited on the electrode. Thus, the overall redox reaction is,

$$Zn(s) + Cu^{2+}(aq) \longrightarrow Zn^{2+}(aq) + Cu(s)$$

As you know that voltaic or galvanic cell consists of two halves as half-cells. The half-cell in which oxidation occurs is called **oxidation half-cell,** while in which reduction occurs is called **reduction half-cell.**

$$Zn \longrightarrow Zn^{2+} + 2\,e^- \quad \text{(oxidation half-cell)}$$

$$Cu^{2+} + 2\,e^- \longrightarrow Cu \quad \text{(reduction half-cell)}$$

Representation of a Galvanic Cell

The following conventions are used in representing an electrochemical or Galvanic cell

1. The cell representation contains anodic half on the left hand side and cathodic half on the right hand side.
2. The anodic side of the cell is represented by writing metal or solid phase first and then the electrolyte (infact cation of electrolyte).
3. The cathodic side, on the other hand, is represented by writing the electrolyte first (anion) and then the metal or solid phase.
4. Metal and cation are separated by a semicolon (;) or by a vertical line (l).
5. The concentration of electrolyte is also written within brackets after the cation.
6. Salt bridge which separates two half-cells is represented by two vertical lines.

Thus, a complete cell can be represented as,

$$Zn \mid Zn^{2+}\,(1\text{ M}) \,||\, Cu^{2+}\,(1\text{ M}) \mid Cu$$

Caution Point *Here, it may also be noted that a cell can be written by arranging each of the pair i.e., left-right, anode-cathode, oxidation-reduction, negative-positive in an alphabetical order.*

Sample Problem 15 *The cell reaction of galvanic cell*

$Cu(s) \mid Cu^{2+}(aq) \,||\, Hg^{2+}(aq) \mid Hg(l)$ is

(*a*) $Hg + Cu^{2+} \longrightarrow Hg^{2+} + Cu$
(*b*) $Hg + Cu^{2+} \longrightarrow Cu^{+} + Hg^{+}$
(*c*) $Cu + Hg \longrightarrow CuHg$
(*d*) $Cu + Hg^{2+} \longrightarrow Cu^{2+} + Hg$

Interpret (*d*) From the cell, it is clear that

Anode half-reaction is

$$Cu \longrightarrow Cu^{2+} + 2e^-$$

Cathode half-reaction is

$$Hg^{2+} + 2e^- \longrightarrow Hg(l)$$

On adding Eq. (i) and (ii), we get

$$Cu + Hg^{2+} \longrightarrow Cu^{2+} + Hg$$

This is the cell reaction for galvanic cell.

3.5 Electrodes and Their Types

Electrode is the material which conducts electricity in the cell due to movement of electrons. It may be taken in any form like wire, rod, sheet, etc.

Electrodes may be classified further as

1. Inert and Attackable Electrode

The electrode which only conducts electricity is called inert electrode and the electrode which participates in the reaction also, is called attackable electrode.

2. Anode and Cathode

Anode is the electrode at which oxidation occurs and cathode is the electrode at which reduction takes place.

3. Positive and Negative Electrode

In galvanic cells, the electrode at which reduction occurs (cathode) is positive electrode, while the electrode at which oxidation occurs (anode) is negative electrode. However, in the electrolytic cell, the electrode at which cation discharges (cathode) is negative electrode while the electrode at which anions discharges (anode) is positive electrode.

4. Reversible and Irreversible Electrodes

The electrode at which reduction as well as oxidation may take place is called reversible electrode while in irreversible electrodes, reaction occurs only in one direction. *Some of the example of reversible electrodes are as follows*

(a) Metal-metal Salt Electrode

When any metal is immersed in its salt solution, metal atoms have tendency to move in the solution as metal ion (direction of increase in entropy) while the metal ions from solution have tendency to get deposited at the metal surface (direction of decrease in enthalpy).

$$M(s) \rightleftharpoons M^{n+}(aq) + ne^-$$

(b) Metal Insoluble Metal Salt Electrode

In such electrode, normally the metal surface is coated with some of its insoluble salt and the system is immersed in the aqueous solution of some salt having common anion. *e.g.,*

Ag, AgCl | Cl-electrode $Ag(s) + Cl^-(aq) \rightleftharpoons AgCl(s) + e^-$

Calomel electrode $2Hg(l) + 2Cl^-(aq) \rightleftharpoons Hg_2Cl_2(s) + 2e^-$

(c) Gas Electrodes

Any gas in contact with the solution of its corresponding ion also serves as electrode. In this case, Pt-wire is normally used to conduct electricity. *e.g.,*

Hydrogen electrode $H_2(g) \rightleftharpoons 2H^+(aq) + 2e^-$

Oxgen electrode $4OH^-(aq) \rightleftharpoons O_2(g) + 2H_2O(l) + 4e^-$

(d) Redox Electrode

These are the electrodes in which the electrolytic solution contains the same element in two different oxidation states and current is conducted by immersing Pt-wire in the solution. *e.g.,*

$$Fe^{2+}(aq) \rightleftharpoons Fe^{3+}(aq) + e^-$$

$$Sn^{2+}(aq) \rightleftharpoons Sn^{4+}(aq) + 2e^-$$

3.6 Electrode Potential

When a metallic electrode is dipped in its salt solution, a potential difference is developed between the electrode and its salt solution. The reason for the development of such a potential difference is exchange of electrons between the atoms of electrode and cations in its salt solution. Such a potential difference is called *electrode potential. Thus, we can say that the electrode potential is the measure of the tendency of an electrolyte to gain or lose electrons in a half-cell.*

The electrode potential can be of two types

(a) **Oxidation potential** The tendency of an electrode to lose electrons or to get oxidised is called its oxidation potential, (E_{oxi}) *e.g.,*

$$M(s) \rightleftharpoons M^{n+}(aq) + ne^-$$

$$Zn(s) \rightleftharpoons Zn^{2+} + 2e^-$$

$$H_2(g) \rightleftharpoons 2H^+ + 2e^-$$

$$Na(s) \rightleftharpoons Na^+ + e^-$$

Such an electrode is negatively charged with respect to its salt solution.

(b) **Reduction potential** The tendency of an electrode to gain electrons, *i.e.,* to get reduced is called reduction potential (E_{red}), *e.g.,*

$$M^{n+}(aq) + ne^- \rightleftharpoons M(s)$$

$$Cu^{2+} + 2e^- \rightleftharpoons Cu(s)$$

Such an electrode is positively charged with respect to its salt solution.

$$E_{oxi} = -E_{red}$$

The half-cell reactions are always written as reduction half reactions and their potential are represented as *reduction potential.*

The electrode potential depends upon

(i) Nature of metal and its ions,
(ii) Concentration of ions in the solution,
(iii) Temperature.

Standard Electrode Potential

The potential difference developed between metal electrode and solution of its ions of unit molarity (1 M) at 1 atm pressure and 25°C (298 K) is called standard electrode potential. The standard electrode potential is denoted by $E°$. *e.g.,* The potential of the galvanic cell,

$$(Pt)\ H_2\ (g\ 1\ atm) \mid H^+(1\ mol\ L^{-1}) \parallel Zn^{2+}(1\ mol\ L^{-1}) \mid Zn(s)$$

at 298 K, is called the standard electrode potential of zinc electrode. This is denoted by $E°_{Zn^{2+}/Zn}$.

$$E°_{Zn^{2+}/Zn} = -0.76\ V$$

Thus, the standard electrode potential of an electrode describes the electrons accepting tendency of the electrode relative to that of a standard hydrogen electrode, under standard conditions, *viz* 298 K, 1 atm pressure and 1 mol L^{-1} concentration.

Measurement of Electrode Potential

The measurement of absolute value of electrode potential is not possible for a single electrode. Only the difference of potentials between two electrodes can be measured experimentally. It is due to the reason that oxidation or reduction cannot occur alone (*i.e.,* oxidation and reduction occur simultaneously). For indirect measurement of potential of an electrode, we couple the electrode with another electrode whose potential is known. This electrode is called **reference electrode.** The emf of resulting cell is measured experimentally. Now, as we know the emf as well as the potential of reference electrode, the potential of other electrode is determined. *Some important reference electrode are as follows*

Normal Hydrogen Electrode (NHE)

Hydrogen electrode is the primary reference electrode as it is used normally to know the electrode potential of a half-cell of galvanic cell. The reason for such a usage is that it can act as a cathode as well as an anode with respect to other electrode, due to following reactions

$$H_2(g) \longrightarrow 2H^+ + 2e^-$$

$$2H^+ \xrightarrow{+2e^-} H_2$$

The electrode potential of NHE is taken as zero. It is represented as

$$\text{Pt} \mid H_2\ (\text{atm}) \mid H^+\ (1\ \text{M})$$

The hydrogen electrode is constructed by bubbling H_2 gas at a certain pressure over platinised platinum sheet immersed in 1 M HCl solution.

Standard Hydrogen Electrode (SHE)

A hydrogen electrode in which the pressure of H_2 gas is maintained at 1 atm and the concentration of H^+ ions in the solution is 1 M, is called standard hydrogen electrode. The emf of SHE is taken as 0.00 V at all temperatures.

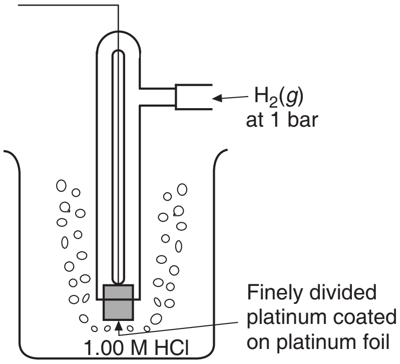


Fig. 3.7 Standard Hydrogen Electrode (SHE)

Caution Point *The use of NHE is not convenient because it is difficult to maintain the* H^+ *ion concentration as 1 M and the pressure of the gas as 1 atm. Hence, it is common to use calomel electrode as the reference electrode.*

Calomel Electrode

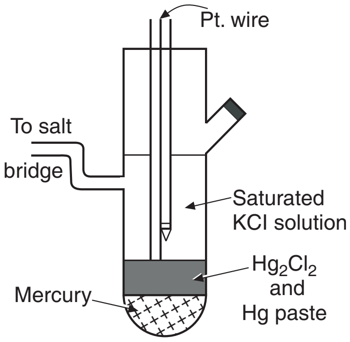

Fig. 3.8 Calomel electrode

It is an another generally used reference electrode but it comes in the category of **secondary reference electrode** (primary reference electrode is standard hydrogen electrode but it is difficult to prepare and maintain it). The electrode consists of Hg at the bottom over which a paste of mercury and mercurous chloride is placed in a tube. The tube is filled with KCl solution over the paste and a glass sealed platinum wire is used for electrical contact. The potential of electrode depends upon KCl solution.

On the basis of concentration of KCl, the calomel electrode is named differently, *e.g.,* If KCl solution is saturated, electrode is called SCE (saturated calomel electrode).

Similarly, if KCl solution is 1 N, the electrode is called NCE (normal calomel electrode) and DNCE (decinormal calomel electrode) for 0.1 N solution of KCl.

The reduction potentials of calomel electrodes on hydrogen scale at 298 K are

for saturated KCl – 0.2415 V
for 1.0 N KCl – 0.2800 V
for 0.1 N KCl – 0.3338 V

Silver-silver Chloride Electrode

Besides hydrogen and calomel electrodes silver-silver chloride electrode is another widely used secondary reference electrode.

Caution Point *A reading on the voltmeter will be obtained only if the negative terminal of the voltmeter is connected to the negative electrode, i.e., where oxidation occurs and the positive terminal to the positive electrode, i.e., where reduction occurs.*

Various Types of Half-Cells

Various type of half-cells have been used, some as reference half-cells, to make complete cell with spontaneous reaction in forward direction. These half-cells along with half-cell reactions have been summarised in Table 3.2.

Table 3.2 **Various Types of Half-Cells**

S. No.	Type	Example	Half-cell reaction	$Q =$	Reversible to
1.	Gas-ion half-cell	$Pt(H_2) \mid H^+(aq)$	$\frac{1}{2}H_2(g) \longrightarrow H^+(aq) + e^-$	$[H^+]$	H^+ ion
		$Pt(Cl_2) \mid Cl^-(aq)$	$Cl^-(aq) \longrightarrow \frac{1}{2}Cl_2(g) + e^-$	$\frac{1}{[Cl^-]}$	Cl^- ion
2.	Metal-metal ion half-cell	$Ag \mid Ag^+(aq)$	$Ag(s) \longrightarrow Ag^+(aq) + e^-$	$[Ag^+]$	Ag^+ ion
3.	Metal-insoluble salt anion half-cell	$Ag, AgCl \mid Cl^-(aq)$	$Ag(s) + Cl^-(aq) \longrightarrow AgCl(s) + e^-$	$\frac{1}{[Cl^-]}$	Cl^- ion
4.	Calomel electrode	$Hg, Hg_2Cl_2 \mid Cl^-(aq)$	$2Hg(l) + 2Cl^-(aq) \longrightarrow Hg_2Cl_2(s) + 2e^-$	$\frac{1}{[Cl^-]^2}$	Cl^- ion
5.	Metal-metal oxide hydroxide half-cell	$Hg, HgO \mid OH^-(aq)$	$Hg(l) + 2OH^-(aq) \longrightarrow HgO(s) + H_2O(l) + 2e^-$	$\frac{1}{[OH^-]^2}$	OH^- ion
6.	Oxidation-reduction half-cell	$Pt \mid Fe^{2+}(aq), Fe^{3+}(aq)$	$Fe^{2+}(aq) \longrightarrow Fe^{3+}(aq) + e^-$	$\frac{[Fe^{3+}]}{[Fe^{2+}]}$	Fe^{2+}, Fe^{3+} ions
7.	Mercury-mercury sulphate half-cell	$Hg, HgSO_4 \mid SO_4^{2-}(aq)$	$SO_4^{2-}(aq) + Hg(l) \longrightarrow HgSO_4(s) + 2e^-$	$\frac{1}{[SO_4^{2-}]}$	SO_4^{2-}
8.	Quinhydrone half-cell	$Pt \mid Quinhydrone \mid H^+(aq)$	 $+ 2H^+ + 2e^-$	$[H^+]^2$	H^+

Hot Spot 2

EMF of Cell

It is an important topic for JEE Main examination point of view. The level of question is easy and a small practice make you able to solve problems of this topic.

In electrochemical cell, the electrodes in different half-cells have different reduction potential. As a result of this, different flow of electrons is seen from the electrode with higher tendency to lose electrons to other electrode. This difference in electrode potential of electrodes is called **electromotive force** or **cell potential** of a cell. This is the driving force for all cell reactions.

We know that reduction occurs at cathode and oxidation occurs at anode, therefore,

EMF = reduction potential of cathode − reduction potential of anode

or, EMF = oxidation potential of anode + reduction potential of cathode

Thus, emf of a cell may also be defined as the potential difference between two electrodes when either no or negligible current is allowed to flow in the circuit.

If the two half cells are selected arbitrarily for the purpose of constructing a galvanic cell, then compare the reduction potentials of two electrodes. The electrode whose reduction potential has greater positive value is made cathode and other electrode is made anode. Alternatively, compare the oxidation potentials of two electrodes. The electrode whose oxidation potential has greater positive value is made anode and the other electrode is made cathode.

Constructing the cell in this manner will always give a positive EMF otherwise sometimes if electrode is choosen wrongly the EMF will be negative. In such cases, if the EMF of the cell is positive, the cell is said to be spontaneous or feasible or exergonic ($\Delta G < 0$). If the EMF of the cell is negative, the cell is said to be non-spontaneous or non-feasible or endergonic ($\Delta G > 0$). Reduction potential is taken as standard potential, *i.e.,* if electrode potential is given (and nothing is mentioned whether it is oxidation or reduction), it is taken as the reduction potential, by default.

Sample Problem 16 *For the given reaction,*

$$2Ce^{4+} + Co \longrightarrow 2Ce^{3+} + Co^{2+}$$

E°_{cell} is 1.89 V. If $E_{Co^{2+}/Co}$ is –0.28 V, what is the value of $E^\circ_{Ce^{4+}/Ce^{3+}}$?

(*a*) 3.78 *V* (*b*) 1.61 *V*
(*c*) 0.94 *V* (*d*) –3.78 *V*

Interpret (*b*) $E^\circ_{cell} = E^\circ_{oxi} + E^\circ_{red}$

$$= E^\circ_{Co/Co^{2+}} + E^\circ_{Ce^{4+}/Ce^{3+}}$$

or $$E^\circ_{cell} = -E^\circ_{Co^{2+}/Co} \,|\, E^\circ_{Ce^{4+}/Ce^{3+}}$$

$$1.89 = -(-0.28) + E^\circ_{Ce^{4+}/Ce^{3+}}$$

$\therefore$ $$E^\circ_{Ce^{4+}/Ce^{3+}} = 1.89 - 0.28 = 1.61 \text{ V}$$

Table 3.3 **Difference between Potential Difference and EMF**

S.N.	Potential difference	EMF
1.	It is the difference between the electrode potentials of the two electrode under any condition.	It is the potential difference between the two electrodes of the cell when no current is flowing in the circuit (*i.e.*, in an open circuit).
2.	It is less than the maximum voltage obtainable from the cell (*i.e.,* EMF of the cell).	It is the maximum voltage obtainable from the cell.
3.	It is measured by a simple voltmeter.	It is measured by potentiometeric method only so that the EMF sent by the potentiometric source is equal and opposite to that of the cell and there is no net current flowing in the circuit. It cannot be measured by voltmeter which draws current.
4.	It is not responsible for the flow of steady current in the circuit.	It is responsible for the flow of steady current in the circuit.

Check Point 2

1. How will the pH of brine (aq. NaCl solution) be affected when it is electrolysed? **[NCERT Exemplar]**
2. Metallic sodium cannot be obtained by electrolysing an aqueous solution of NaCl. Why?
3. Dilute aqueous solution of NaOH, H_2SO_4 and Na_2SO_4 liberate the same products at the electrodes during electrolysis. Explain.
4. The cell potential of a spontaneous reaction is always positive. Explain with appropriate reason.
5. A galvanic cell has electrical potential of 1.1 V. If an opposing potential of 1.1 V is applied to this cell, what will happen to the cell reaction and current flowing through the cell? **[NCERT Exemplar]**

3.7 Electrochemical Series

The arrangement of metals in decreasing order of tendency to lose electrons is called **electrochemical series** or it is the series in which the elements are arranged on the basis of the values of their standard reduction potentials.

Table 3.4 **Standard Electrode Potentials at 25°C "The Electrochemical Series"**

Element	Electrode reaction (reduction)	Standard electrode reduction potential E°, (volt)
Li	$Li^+ + e^- \longrightarrow Li$	– 3.05
K	$K^+ + e^- \longrightarrow K$	– 2.925
Ca	$Ca^{2+} + 2e^- \longrightarrow Ca$	– 2.87
Na	$Na^+ + e^- \longrightarrow Na$	– 2.714
Mg	$Mg^{2+} + 2e^- \longrightarrow Mg$	– 2.37
Al	$Al^{3+} + 3e^- \longrightarrow Al$	– 1.66
Zn	$Zn^{2+} + 2e^- \longrightarrow Zn$	– 0.7628
Cr	$Cr^{3+} + 3e^- \longrightarrow Cr$	– 0.74
Fe	$Fe^{2+} + 2e^- \longrightarrow Fe$	– 0.44
Cd	$Cd^{2+} + 2e^- \longrightarrow Cd$	– 0.403
Ni	$Ni^{2+} + 2e^- \longrightarrow Ni$	– 0.25
Sn	$Sn^{2+} + 2e^- \longrightarrow Sn$	– 0.14
H_2	$2H^+ + 2e^- \longrightarrow H_2$	0.00
Cu	$Cu^{2+} + 2e^- \longrightarrow Cu$	+ 0.337
I_2	$I_2 + 2e^- \longrightarrow 2I^-$	+ 0.535
Ag	$Ag^+ + e^- \longrightarrow Ag$	+ 0.799
Hg	$Hg^{2+} + 2e^- \longrightarrow Hg$	+ 0.885
Br_2	$Br_2 + 2e^- \longrightarrow 2Br^-$	+ 1.08
Cl_2	$Cl_2 + 2e^- \longrightarrow 2Cl^-$	+ 1.36
Au	$Au^{3+} + 3e^- \longrightarrow Au$	+ 1.50
F_2	$F_2 + 2e^- \longrightarrow 2F^-$	+ 2.87

Increasing tendency for reduction
Increasing tendency to accept e^-
Increasing strength as oxidising agent ↓

↑ Increasing strength as reducing agent
Increasing tendency to lose electrons
Increasing tendency for oxidation

In other words we can say that the arrangement of elements in increasing order of their reduction electrode potentials is called **electrochemical series.**

Characteristics of Electrochemical Series

Following characteristics of electrochemical series can be noted.

1. The negative sign of SRP (standard reduction potential) indicates that the electrode when joined with SHE

(standard hydrogen electrode) behaves as anode, *i.e.,* oxidation occurs at that electrode. Similarly, positive sign of SRP suggests behaviour of electrode as cathode when joined with SHE.

2. The above findings suggest that elements which are better reducing agents than hydrogen get their place above hydrogen in this series (such elements have negative value of SRP) while elements which are better oxidising agents than hydrogen get their place below the hydrogen in this series (such elements have (+) ve value of their SRP).
3. Elements which get oxidised easily are good reducing agents (metals) and elements which get reduced easily are good oxidising agents (non-metals).
4. A metal with lower SRP can have the ability to displace metal with higher SRP from their solutions. *Secondly, the reactivity of metals decrease from top to bottom in electrochemical series, i.e.,* metals higher in the series are more active than metals lying lower in the series.

   The elements which are placed above hydrogen in electrochemical series, have the ability to displace hydrogen from any protic solution (any solution containing H^+) .

Hot Spot 3

NERNST Equation

It is the most important topic of the chapter for JEE Main examination. The questions asked were generally numerically type. The level of question is easy to average.

A relationship between electrode potential and concentration of solution is called **Nernst equation.** For a general reduction half reaction, *i.e.,*

$$M^{n+}(aq) + ne^- \longrightarrow M(s)$$

This equation can be given as,

$$E_{(M^{n+}\mid M)} = E^\circ_{(M^{n+}\mid M)} - \frac{RT}{nF}\ln\frac{[M(s)]}{[M^{n+}(aq)]}$$

or

$$E_{(M^{n+}\mid M)} = E^\circ_{(M^{n+}\mid M)} - \frac{2.303RT}{nF}\log\frac{[M(s)]}{[M^{n+}(aq)]}$$

$$(\text{as } \log_e 10 = 2.303 \log 10)$$

where, $E_{(M^{n+}\mid M)}$ = electrode potential, *i.e.*, E

$E^\circ_{(M^{n+}/M)}$ = standard electrode potential, *i.e.*, E°

R = gas constant

T = temperature

F = Faraday constant

n = number of electrons gained during electrode reaction

$[M^{n+}(aq)]$ = concentration of ions

$[M(s)]$ = concentration of metal

Since, the concentration of solid phase is taken as unity, the Nernst equation will become

$$E_{(M^{n+}/M)} = E^\circ_{(M^{n+}/M)} - \frac{2.303RT}{nF}\log\frac{1}{[M^{n+}(aq)]}$$

For a hypothetical redox reaction,

$$M' + M^{n+} \longrightarrow M'^{n+} + M$$

the electrode potentials for two half-cells are given as,

$$E_{(M'^{n+}/M')} = E^\circ_{M'^{n+}/M'} + \frac{2.303RT}{nF}\log\frac{1}{[M'^{n+}(aq)]}$$

$$E_{(M^{n+}/M)} = E^\circ_{(M^{n+}/M)} - \frac{2.303RT}{nF}\log\frac{1}{[M^{n+}(aq)]}$$

In oxidation half-cell reaction,

(i) If $[M^{n+}]$ increases, E_{oxi} decreases.

(ii) If temperature increases at constant $[M^{n+}]$, E_{oxi} decreases.

In reduction half-cell reaction,

(i) If $[M^{n+}]$ increases, E_{red} increases.

(ii) If temperature increases at constant $[M^{n+}]$, E_{red} increases.

We know that, the cell potential,

$$E_{\text{cell}} = E_{(M^{n+}/M)} - E_{(M'^{n+}/M')} \quad [\because\ E_{\text{cell}} = E_{\text{cathode}} - E_{\text{anode}}]$$

$$= E^\circ_{(M^{n+}/M)} - \frac{2.303RT}{nF}\log\frac{1}{[M^{n+}(aq)]} - [E^\circ_{[M'^{n+}/M']} + \frac{2.303RT}{nF}\log\frac{1}{[M'^{n+}]}]$$

$$= E^\circ_{(M^{n+}/M)} - E^\circ_{(M'^{n+}/M')} - \frac{2.303RT}{nF}\log\frac{1}{[M^{n+}(aq)]} - \log\frac{1}{[M'^{n+}(aq)]}$$

$$E_{\text{cell}} = E^\circ_{\text{cell}} - \frac{2.303RT}{nF}\log\frac{[M'^{n+}(aq)]}{[M^{n+}(aq)]} \qquad \text{...(i)}$$

If in both the half-cells, the number of electrons are not same,

$$E_{\text{cell}} = E^\circ_{\text{cell}} - \frac{2.303RT}{nF}\log\frac{[M'^{n+}(aq)]^x}{[M^{n+}(aq)]^y}$$

where, x and y = stoichiometric coefficients of M' and M in balanced equation.

Now, if the values of R, T and F, *i.e.*, 8.314 $\text{JK}^{-1}\ \text{mol}^{-1}$ for R, 298 K for T and 96500 for F, are substituted in Nernst equation we get,

$$E_{\text{cell}} = E^{\circ}_{\text{cell}} - \frac{0.0591}{n}\log\frac{[M'^{n+}(aq)]^{x}}{[M^{n+}(aq)]^{y}}$$

Sample **Problem 17** *Calculate the emf of the cell in which the following reaction takes place*

$$\text{Ni}(s) + 2\ \text{Ag}^{+}(0.002\ \text{M}) \longrightarrow \text{Ni}^{2+}\ (0.160\ \text{M}) + 2\text{Ag}(s)$$

Given that $E^{\circ}_{\text{cell}} = 1.05\,V$ **[NCERT]**

(*a*) 0.61 *V* (*b*) 0.91 *V*
(*c*) 0.82 *V* (*d*) 0.023 *V*

Interpret (*b*) From the given cell reaction and Nernst equation,

$$E_{\text{cell}} = E^{\circ}_{\text{cell}} - \frac{0.0591}{n}\log\frac{[\text{Ni}^{2+}]}{[\text{Ag}^{+}]^{2}}$$

$$= 1.05\text{V} - \frac{0.0591}{2}\log\frac{[0.160]}{[0.002]^{2}}$$

$$= 1.05 - \frac{0.0591}{2}\log(4\times 10^{4})$$

$$= 1.05 - \frac{0.0591}{2}(4.6021)$$

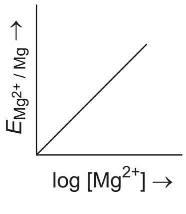
$$= 1.05 - 0.14 = 0.91\text{V}$$

$$E_{\text{cell}} = 0.91\text{V}$$

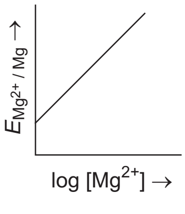
Sample **Problem 18** *Electrode potential for* Mg *electrode varies according to the equation* **[NCERT Exemplar]**

$E_{\text{Mg}^{2+}/\text{Mg}} = E^{\circ}_{\text{Mg}^{2+}/\text{Mg}} - \dfrac{0.059}{2}\log\dfrac{1}{[\text{Mg}^{2+}]}$. *The graph of* $E_{\text{Mg}^{2+}/\text{Mg}}$ *vs* $\log[\text{Mg}^{2+}]$ *is*

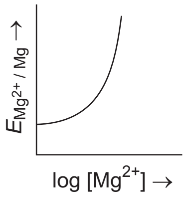
(a)



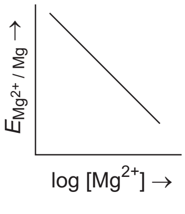
(*b*)



(*c*)



(*d*)



Interpret (*b*) The given equation is of $y = mx + c$ type which is equation of straight line. So, graph of $E_{\text{Mg}^{2+}\mid\text{Mg}}(y)$ *vs* $\log[\text{Mg}^{2+}](x)$ is a straight line with slope $\dfrac{0.059}{2}$ and intercept $E^{\circ}_{\text{Mg}^{2+}\mid\text{Mg}}$.

Determination of the pH of a Solution

Using a suitable reference half-cell, pH of the unknown solution can be determined.

$$\text{Pt}(\text{H}_2)\ |\ \text{H}^{+}\ (\text{pH} = x)\ ||\ \text{Cl}^{-}(1\ \text{M})\ |\ \underset{\text{Calomel}}{\text{Hg}_2\text{Cl}_2}, \text{Hg}$$

LHS half-cell $\quad \text{H}_2(g) \longrightarrow 2\text{H}^{+}(aq) + 2e^{-} \qquad E^{\circ}_{\text{ox}} = 0.00\ \text{V}$

RHS half-cell

$$\text{Hg}_2\text{Cl}_2(s) + 2e^{-} \longrightarrow 2\text{Hg}(l) + 2\text{Cl}^{-}(aq);\quad E^{\circ}_{\text{red}} = 0.2676\ \text{V}$$

Net : $\quad \text{H}_2(g) + \text{Hg}_2\text{Cl}_2(s) \longrightarrow 2\text{H}^{+}(aq) + 2\text{Hg}(l) + 2\text{Cl}^{-}(aq);$

$$E^{\circ}_{\text{cell}} = 0.2676\ \text{V}$$

$$Q = [\text{Cl}^{-}]^{2}[\text{H}^{+}]^{2}$$

$$= [\text{H}^{+}]^{2} \qquad (\text{since } [\text{Cl}^{-}] = 1\ \text{M})$$

$$E_{\text{cell}} = E^{\circ}_{\text{cell}} - \frac{0.0591}{2}\log[\text{H}^{+}]^{2} = E^{\circ}_{\text{cell}} + 0.0591\ \text{pH}$$

$$\therefore \qquad \text{pH} = \frac{E_{\text{cell}} - E^{\circ}_{\text{cell}}}{0.0591}$$

In general, $\quad \text{pH} = \dfrac{E_{\text{cell}} - [E^{\circ}_{\text{reference}} + E^{\circ}_{\text{SHE}}]}{0.0591}$

$$\text{pH} = \frac{E_{\text{cell}} - E^{\circ}_{\text{reference}}}{0.0591}$$

In this case reference half-cell is calomel electrode.

Sample **Problem 19** *Calculate the potential of hydrogen electrode in contact with a solution whose* pH *is* 10. **[NCERT]**

(*a*) 0.0591 V (*b*) – 0.0591 V
(*c*) 0.591 V (*d*) – 0.591 V

Interpret (*d*) For hydrogen electrode, $\text{H}^{+} + e^{-} \longrightarrow \frac{1}{2}\text{H}_2$

Applying Nernst equation,

$$E_{(\text{H}^{+}/1/2\text{H}_2)} = E^{\circ}_{(\text{H}^{+}/1/2\text{H}_2)} - \frac{0.0591}{n}\log\frac{1}{[\text{H}^{+}]}$$

$$= 0 - \frac{0.0591}{1}\log\frac{1}{(10^{-10})}$$

$$[\text{pH} = 10\ ; [\text{H}^{+}] = 10^{-10}\text{M}]$$

$$= 0 - \frac{0.0591}{1}\times(10\log 10) = -\ 0.591\ \text{V}$$

$$E_{(\text{H}^{+}/1/2\text{H}_2)} = -0.591\text{V}$$

Nernst Equation for Concentration Cells

The cells in which both the electrodes are of the same type but the electrolytic solution have different concentration, are called concentration cells.

(a) When Electrode is Reversible with Respect to Cation

e.g., $\quad \text{Zn}\ |\ \text{Zn}^{2+}\ (C_1)\ ||\ \text{Zn}^{2+}(C_2)\ |\ \text{Zn}$

$$\begin{array}{llll} \text{At anode} & Zn \longrightarrow Zn^{2+}(C_1) + 2e^- & & E^\circ = 0.76\ V \\ \text{At cathode} & Zn^{2+}(C_2) + 2e^- \longrightarrow Zn & & E^\circ = -0.76\ V \\ \hline & Zn^{2+}(C_2) \longrightarrow Zn^{2+}(C_1) & & E^\circ = 0.00\ V \\ \hline \end{array}$$

$$E_{cell} = E^\circ_{cell} - \frac{0.0591}{2} \log \frac{C_1}{C_2}$$

or
$$E_{cell} = 0 - \frac{0.0591}{2} \log \frac{C_1}{C_2}$$

or
$$E_{cell} = \frac{0.0591}{2} \log \frac{C_2}{C_1}$$

Thus, for this reaction to be spontaneous, $C_2 > C_1$.

(b) When Electrode is Reversible with Respect to Anion

$$\underset{1\text{ atm}}{Pt(Cl_2)} \mid Cl^-(C_1) \parallel Cl^-(C_2) \mid \underset{1\text{ atm}}{Pt(Cl_2)}$$

$$E_{cell} = \frac{0.0591}{1} \log \frac{C_1}{C_2}$$

For such cases, cell reaction is spontaneous in forward reaction, if $C_1 > C_2$.

(c) When Electrodes at Different Concentration are Dipped into Same Electrolytes

$$\underset{\text{at } p_1}{Pt(H_2)} \mid \underset{1\text{ M}}{HCl} \mid \underset{\text{at } p_2}{Pt(H_2)}$$

Two half-cells are joined by two salt-bridges since they have common electrolyte.

$$\begin{array}{lll} \text{At anode} & H_2(p_1) \longrightarrow \underset{1\text{ M}}{2H^+} + 2e^- & \\ \text{At cathode} & \underset{1\text{ M}}{2H^+} + 2e^- \longrightarrow H_2(p_2) & \\ \text{Net reaction} & \overline{\underline{H_2(p_1) \longrightarrow H_2(p_2)}} & E^\circ_{cell} = 0.00 \end{array}$$

$$E_{cell} = E^\circ_{cell} - \frac{0.0591}{n} \log \frac{p_2}{p_1} = \frac{0.0591}{2} \log \frac{p_1}{p_2}$$

Cell reaction is spontaneous in forward direction, if p_1 (LHS) $> p_2$(RHS).

Sample **Problem 20** *The emf of the following cell is 0.086 V.*

Ag | $AgNO_3$ (0.0093 *M*) || $AgNO_3$ (*xM*) | Ag. *The value of x will be*

(a) 0.295 (b) 0.642

(c) 0.359 (d) 0.266

Interpret (d)
$$E = \frac{0.0591}{n} \log \frac{C_2}{C_1}$$

$$0.086 = \frac{0.0591}{1} \log \frac{x}{0.0093}$$

$$\frac{0.086}{0.059} = \log \frac{x}{0.0093}$$

$$\frac{x}{0.0093} = 28.7$$

$$\therefore \quad x = 0.266\ M$$

Equilibrium Constant from Nernst Equation

For a general electrochemical reaction,

$$aA + bB \longrightarrow cC + dD$$

the Nernst equation can be written as,

$$E_{cell} = E^\circ{}_{cell} - \frac{RT}{nF} \ln \frac{[C]^c[D]^d}{[A]^a[B]^b}$$

or
$$E_{cell} = E^\circ{}_{cell} + \frac{RT}{nF} \ln \frac{[A]^a[B]^b}{[C]^c[D]^d}$$

At equilibrium, $E_{cell} = 0$

and
$$\frac{[C]^c[D]^d}{[A]^a[B]^b} = K_c$$

Thus, Nernst equation may also be used to calculate the equilibrium constant for a cell reaction through the formula

$$E^\circ{}_{cell} = \frac{0.0591}{n} \log K_c$$

where, K_c = equilibrium constant

Sample **Problem 21** *Calculate the equilibrium constant of the reaction :* **[NCERT]**

$$Cu(s) + 2Ag^{\oplus}(aq) \longrightarrow Cu^{2+}(aq) + 2Ag(s) \qquad E^\ominus_{cell} = 0.46\ V$$

(a) 4×10^{15} (b) 3×10^{16}

(c) 2×10^{13} (d) 1.56×10^{16}

Interpret (a)
$$E^\ominus_{cell} = \frac{0.059\ V}{2} \log K_c$$

$$0.46\ V = \frac{0.059\ V}{2} \log K_c$$

$$\therefore \quad \log K_c = \frac{0.46\ V \times 2}{0.059\ V} = 15.6$$

$$K_c = \text{Antilog } (15.6) = 3.98 \times 10^{15}$$

Sample **Problem 22** *Consider the following half-cells.*

$Cl^-(1M) \mid Hg_2Cl_2(s) \mid Hg(l)$; $E^\circ = 0.270$ V

Cl^-(saturated) | $Hg_2Cl_2(s) \mid Hg(l)$, $E = 0.244$ V

What is the concentration of Cl^- *in saturated solution?*

(a) 10.25 *M* (b) 3.84 *M* (c) 2.75 *M* (d) 4.24 *M*

Interpret (c) Half-cell reaction is

$$Hg_2Cl_2 + 2e^- \longrightarrow 2Hg + 2Cl^- \text{ (saturated)}$$

$$K_c = [Cl^-]^2$$

For saturated Cl^- solution, $E = 0.244$ V and for saturated 'half cell, $E^\circ = 0.270$ V

$$\therefore \quad E = E^\circ - \frac{0.0591}{2} \log [Cl^-]^2$$

$$0.244 = 0.270 - 0.0591 \log [Cl^-]$$

$$\log [Cl^-] = \frac{0.026}{0.0591} = 0.4399$$

$$[Cl^-] = 2.754\ M$$

Relationship between Cell Potential and Gibbs Energy Change (ΔG)

In an electrochemical cell, maximum work done (ΔG) is given by

$$\Delta G = nF \times E_{\text{cell}}$$

where, $F =$ Faraday's constant

$n =$ number of moles of electrons transferred.

A galvanic cell does electrical work by transferring electrical charge through an external circuit. When small amount of current is drawn from the cell then

$$-\Delta G = W_{\text{elec.}}$$

(i) If ΔG of the system is positive then the process would be possible only if the surrounding do electrical work on the system (as in electrolysis).

(ii) If ΔG of the system is negative then the system does electric work on the surroundings (as in galvanic cells). For a voltaic cell, the work is done on the surroundings, thus given a negative sign. Hence,

$$\Delta G = W_{\max} = -\,nFE_{\text{cell}}$$

and the standard free energy (ΔG°) is given by,

$$\Delta G^\circ = -\,nFE^\circ_{\text{cell}}$$

Sample Problem 23 *The standard electrode potential for Daniell cell is* 1.1 *V. Calculate the standard Gibbs energy for the reaction.* **[NCERT]**

$$\text{Zn}(s) + \text{Cu}^{2+}(aq) \longrightarrow \text{Zn}^{2+}(aq) + \text{Cu}(s)$$

(a) 2.12 *kJ mol*$^{-1}$ (b) 21.2 *kJ mol*$^{-1}$

(c) 212.2 *kJ mol*$^{-1}$ (d) 2122 *kJ mol*$^{-1}$

Interpret (c) $\Delta_r G^\ominus = -\,nFE^\ominus_{\text{cell}}$

n in the above equation is, $F = 96487\ \text{C mol}^{-1}$ and $E^\ominus_{\text{cell}} = 1.1\ \text{V}$,

$$\therefore \quad \Delta_r G^\ominus = -2 \times 96487\ \text{C mol}^{-1} \times 1.1\ \text{V}$$

$$= -212271\ \text{J mol}^{-1}$$

$$= -212.27\ \text{kJ mol}^{-1}$$

Relation Between Cell Potential (E°_{cell}), Free Energy (ΔG°) and K

The relation between cell potential (E°_{cell}), free energy (ΔG°) and equilibrium constant (K_c) is given by,

$$\Delta G^\circ = -\,2.303RT \log K_c$$

as $\Delta G^\circ = nFE^\circ_{\text{cell}}$ and $E^\circ_{\text{cell}} = \dfrac{2.303\,RT}{nF} \log K_c$

where, n is the number of moles of electrons transferred in the balanced equation for the process to which you apply the Nernst equation.

Relation Between Standard Potentials of Half-cells Containing a Metal in different Oxidation State

If two half-reactions having potentials E_1° and E_2° are combined to give a third half-reaction having a potential E_3°, then

$$\Delta G_3^\circ = \Delta G_1^\circ + \Delta G_2^\circ$$

or
$$-\,n_3FE_3^\circ = -\,n_1FE_1^\circ - n_2FE_2^\circ$$

or
$$n_3E_3^\circ = n_1E_1^\circ + n_2E_2^\circ$$

or
$$E_3^\circ = \frac{n_1E_1^\circ + n_2E_2^\circ}{n_3}$$

Sample Problem 24 *If for the half-cell reactions, E° values are given,*

$$\text{Cu}^{2+} + e^- \longrightarrow \text{Cu}^+; \quad E^\circ = 0.15\ V$$

$$\text{Cu}^{2+} + 2e^- \longrightarrow \text{Cu}; \quad E^\circ = 0.34\ V$$

Calculate E° of the half-cell reaction,

$$\text{Cu}^+ + e^- \longrightarrow \text{Cu}$$

(a) +0.53 *V* (b) −0.53 *V*

(c) − 0.80 *V* (d) −0.28 *V*

Interpret (a) $\text{Cu}^{2+} + e^- \longrightarrow \text{Cu}^+, \quad E^\circ = 0.15\ \text{V}$

(i) $\text{Cu}^+ \longrightarrow \text{Cu}^{2+} + e^- \quad E_1^\circ = -0.15\ \text{V}, n_1 = 1$

(ii) $\text{Cu}^{2+} + 2e^- \longrightarrow \text{Cu}, \quad E_2^\circ = 0.34\ \text{V}, n_2 = 2$

From Eqs. (i) and (ii)

$$\text{Cu}^+ + e^- \longrightarrow \text{Cu} \quad E_3^\circ = ?, n_3 = 1$$

$$\therefore \quad \Delta G_3^\circ = \Delta G_1^\circ + \Delta G_2^\circ$$

$$-n_3E_3^\circ = -n_1E_1^\circ - n_2E_2^\circ$$

$$E_3^\circ = \frac{1 \times (-0.15) + 2 \times (0.34)}{1}$$

$$= +\ 0.53\ \text{V}$$

Variation of EMF (E_{cell}) with Temperature

Using Gibbs Helmholtz equation, the temperature coefficient of the EMF of the cell is written as :

$$\Delta G = \Delta H + T\left[\frac{d(\Delta G)}{dT}\right]_p \quad \text{(at constant pressure)} \qquad \text{...(i)}$$

(since $\Delta G = -\,nFE_{\text{cell}}$)

$$\Rightarrow \quad -nFE_{\text{cell}} = \Delta H + T\left[\frac{d(-nFE_{\text{cell}})}{dT}\right]_p$$

$$= \Delta H - nFT\left(\frac{dE_{\text{cell}}}{dT}\right)_p$$

$$\Rightarrow \quad \left(\frac{dE_{\text{cell}}}{dT}\right)_p = \frac{\Delta H}{nFT} + \frac{E_{\text{cell}}}{T} \qquad \text{...(ii)}$$

Enthalpy change from Eq. (i)

$$\Delta H = -nFE_{\text{cell}} + nFT\left(\frac{dE_{\text{cell}}}{dT}\right)_p$$

$$= -nF\left[E_{\text{cell}} - T\left(\frac{dE_{\text{cell}}}{dT}\right)_p\right]$$

Enthalpy change can be determined by comparing Eq. (i) with $\Delta G = \Delta H - T\Delta S$.

$$\Delta S = -\left(\frac{d(\Delta G)}{dT}\right)_p$$

$$= -\left[\frac{d}{dT}(-nFE_{\text{cell}})_p\right]$$

$$= nF\left(\frac{dE_{\text{cell}}}{dT}\right)_p$$

3.8 Battery

A cell or a **battery** (arrangement of 1 or more cells connected in series) is basically a galvanic cell and used where the chemical energy of redox reaction is converted into electrical energy.

An electrochemical cell to be used as a commercial cell must fulfil the following two requirements

1. It should have the compactness, lightness, and ruggedness for portability.
2. Its voltage should not drop much during use, *i.e.,* drop in voltage should be negligible over the small interval of time during which it is being put to use.

Different applications require batteries with different properties. The battery required to start a car, for example, must be capable of delivering a large electrical currrent for a short time period. The battery that powers a heart pacemaker, on the other hand, must be very small and capable of delivering a small but steady current over an extended time period.

The batteries are of two types basically

Primary Batteries

The primary batteries are those in which the cell reaction occurs only once and the battery becomes dead after use over a period of time and cannot be reused again, *e.g.,* dry cells like Leclanche cell, mercury cell etc.

(a) Leclanche Cell

The electrode reaction for Leclanche cell is

Anode $\mathrm{Zn}(s) \longrightarrow \mathrm{Zn}^{2+} + 2e^-$

Cathode $\mathrm{MnO_2 + NH_4^+ + e^- \longrightarrow MnO(OH) + NH_3}$

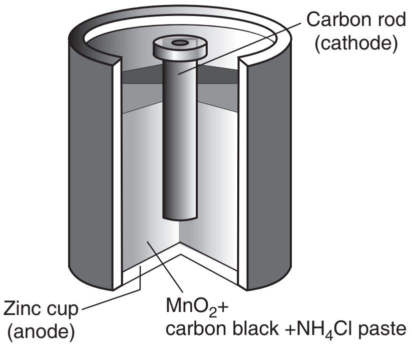


Fig. 3.9 (Leclanche cell) A commercial dry cell containing a graphite (carbon) cathode in a zinc container; the latter acts as the anode

NH_3 formed in the reaction at cathode combines with Zn^{2+} to form the complex like $[\mathrm{Zn(NH_3)_4}]^{2+}$. The cell has a potential of nearly 1.5 V.

(b) Mercury Cell

It shows following electrode reactions :

Anode $\mathrm{Zn(Hg) + 2OH^- \longrightarrow ZnO}(s) + \mathrm{H_2O} + 2e^-$

Cathode $\mathrm{HgO + H_2O} + 2e^- \longrightarrow \mathrm{Hg}(l) + 2\mathrm{OH}^-$

With the overall reaction,

$$\mathrm{Zn(Hg) + HgO}(s) \longrightarrow \mathrm{ZnO}(s) + \mathrm{Hg}(l)$$

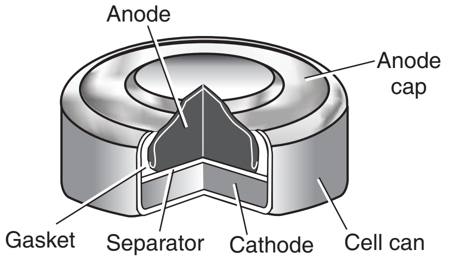

Fig. 3.10 Mercury cell. Here, the reducing agent is zinc and the oxidising agent is mercury (II) oxide

The cell potential is approximately 1.35 V and remains constant throughout its life since overall reaction does not involve any ion, the concentration of which can change during its life-time.

Secondary Batteries

A secondary battery can be recharged by passing current through it in opposite direction, so that it can be used again.

(a) Lead Storage Battery

The most important secondary cell is lead storage battery, commonly used in **automobiles** and **invertors.** A 12 V lead storage battery or lead accumulator generally consists of six cells each producing 2 V. Here 38% solution of H_2SO_4 is used as electrolyte.

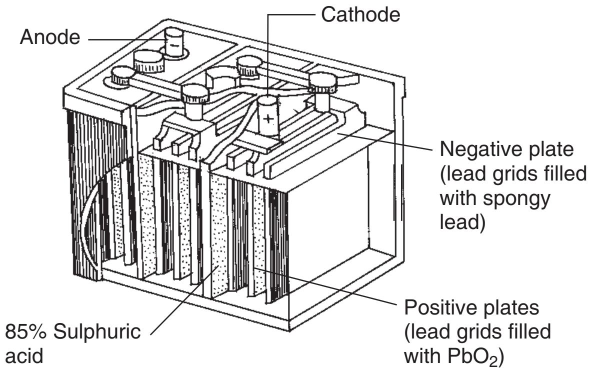

Fig. 3.11 Lead storage battery

The overall reaction for lead stroage battery during discharging (*i.e.*, when cell is in the use) is,

$$Pb(s) + PbO_2(s) + 2H_2SO_4(aq) \longrightarrow 2PbSO_4(s) + 2H_2O(l)$$

Reverse reaction occurs when cell is charged.

$$\begin{array}{l} PbSO_4 + 2e^- \longrightarrow Pb(s) + SO_4^{2-}(aq) \\ PbSO_4(s) + 2H_2O \longrightarrow PbO_2(s) + SO_4^{2-}(aq) + 4H^+(aq) + 2e^- \\ \hline PbSO_4(s) + 2H_2O \longrightarrow Pb(s) + PbO_2(s) + 2H_2SO_4(aq) \\ \hline \end{array}$$

(b) Nickel Cadmium Battery

Another important secondary battery is Ni-Cd battery with longer life but more expensive.

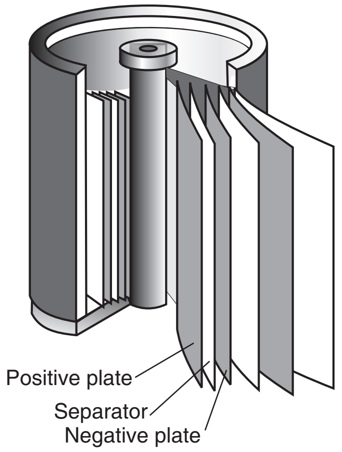

Fig. 3.12 A nickel cadmium battery in a jelly roll arrangement and separated by a layer soaked in moist sodium or potassium hydroxide

The overall reaction for Ni-Cd battery is,

$$Cd(s) + 2Ni(OH)_3(s) \longrightarrow CdO(s) + 2Ni(OH)_2(s) + H_2O(l)$$

3.9 Fuel Cells

Galvanic cells which use energy of combustion of fuels like H_2, CH_4, CH_3OH, etc., as the source to produce electrical energy are called **fuel cells.** One of the most successful fuel cells use reaction of H_2 and O_2 in gaseous state to form water.

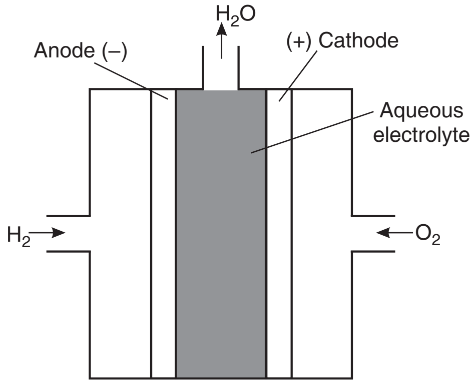

Fig. 3.14 H_2-O_2 Fuel cell

The electrode reactions for the cell are

Cathode $O_2(g) + 2H_2O(l) + 4e^- \longrightarrow 4HO^-(aq)$

Anode $2H_2(g) + 4OH^-(aq) \longrightarrow 4H_2O(l) + 4e^-$

With overall reaction being

$$2H_2(g) + O_2(g) \longrightarrow 2H_2O(l)$$

Advantages of Fuel Cell

1. Due to continuous supply of gases, such cell never becomes dead.
2. Usually operated at 70–140°C.
3. High efficiency than other power plants. (≈ 70%)
4. Pollution free.

Caution Point *Theoretically thermodynamics efficiency* (η)

$$h = \frac{\Delta G}{\Delta H} - \frac{-nEF}{\Delta H}$$

Disadvantages of Fuel Cell

1. Electrolyte causes corrosion.
2. Difficult to make contact between gaseous fuel, the liquid electrolyte and the solid catalyst.
3. High cost of catalyst.
4. Gaseous fuels are difficult to handle at low temperature and high pressure.

Check Point 3

1. The solution of $AgNO_3$ turns blue when a copper rod is immersed in it. Explain, why?
2. HgO on heating decomposes while ZnO does not decompose. Explain
3. Why does a cell stop working after sometime?
4. Unlike dry cell, the mercury cell has a constant cell potential throughout its life, why? **[NCERT Exemplar]**

WORKED OUT Examples

Example 1 *The equivalent conductance of silver nitrate solution at 250°C for an infinite dilution was found to be* $133.3\ ohm^{-1}\ cm^2\ equiv^{-1}$. *The transport number of* Ag^+ *ions in very dilute solution of* $AgNO_3$ *is 0.464. Calculate the equivalent conductance of* NO_3^- *(in* $\Omega^{-1}\ cm^2\ equiv^{-1}$*) at infinite dilution.*

(*a*) 61.9
(*b*) 195.2
(*c*) 133.3
(*d*) 71.4

Solution (*d*) $\lambda^\infty(Ag^+) = \text{transport number of } Ag^+ \times \Lambda^\infty\ (AgNO_3)$

$$\lambda^\infty\ (Ag^+) = n_{Ag^+} \times \Lambda^\infty\ (AgNO_3)$$
$$= 0.464 \times 133.3$$
$$= 61.9\ \text{ohm}^{-1}\ \text{cm}^2\ \text{equiv}^{-1}$$

By Kohlrausch's law,

$$\Lambda^\infty(AgNO_3) = \lambda^\infty(Ag^+) + \lambda^\infty(NO_3^-)$$
$$\therefore \quad \lambda^\infty(NO_3^-) = \Lambda^\infty(AgNO_3) - \lambda^\infty(Ag^+)$$
$$= 133.3 - 61.9$$
$$= 71.4\ \text{ohm}^{-1}\ \text{cm}^2\ \text{equiv}^{-1}$$

Example 2 *EMF of the cell,*
$Ag\,|\,AgNO_3\ (0.1M)\,||\,KBr\ (1N), AgBr(s)\,|\,Ag$ *is* $-0.6\ V$ *at* $298\ K$. $AgNO_3$ *is 80% and* KBr *is 60% dissociated.* K_{sp} *of AgBr at 298 K is*

(*a*) $7 \times 10^{-7}\ M$
(*b*) $6.82 \times 10^{-6}\ M$
(*c*) $4.8 \times 10^{-7}\ M$
(*d*) $1.23 \times 10^{-8}\ M$

Solution (*a*) The above cell is a concentration cell.

$$\therefore \quad E^\ominus_{\text{cell}} = 0.0\ \text{V}$$

The half cell reactions are

Anode reaction

$$Ag\ (\text{anode}) \rightleftharpoons Ag^\oplus(0.1M) + e^-$$

Cathode reaction

$$Ag^\oplus(\text{cathode}) + e^- \rightleftharpoons Ag(s)(\text{cathode})$$

Cell reaction

$$Ag^\oplus(\text{cathode}) \rightleftharpoons Ag^\oplus(0.1M)_{\text{anode}}$$

Since, $AgNO_3$ is 80% ionized.

$$\therefore \quad [Ag^\oplus]_a = 0.1 \times \frac{80}{100} = 0.08\ \text{M}$$

$$\therefore \quad E_{\text{cell}} = E^\ominus_{\text{cell}} - \frac{0.06}{1} \log \frac{[Ag^\oplus]_a}{[Ag^\oplus]_c} \qquad (\text{Take } 0.059 \approx 0.06)$$

$$-0.6\ \text{V} = 0 - 0.06 \log \frac{0.08}{[Ag^\oplus]_c}$$

$$\log\ [Ag^\oplus]_c = \log 0.08 - 10 = (\log 2^3 - \log 100) - 10$$
$$= 0.9 - 2 - 10 = -11.1$$

$$\therefore \quad [Ag^\oplus]_c = \text{Antilog}\ (-11.1) = \text{Antilog}\ (\overline{12}.9) = 0.79 \times 10^{-12}$$
$$\approx 0.8 \times 10^{-12}\ \text{M}$$

Since, KBr is 60% dissociated,

$$\therefore \quad [Br^\ominus] = 1 \times \frac{60}{100} = 0.6\ \text{M}$$

$$\therefore \quad K_{sp} = [Ag^\oplus][Br^\ominus]$$
$$= 0.8 \times 10^{-12} \times 0.6 = 0.48 \times 10^{-12}\ \text{M}^2$$

$$\text{Solubility } (S) = \sqrt{K_{sp}} = \sqrt{0.48} \times 10^{-6}\ \text{M}$$
$$= 0.6928 \times 10^{-6}\ \text{M}$$
$$\approx 0.7 \times 10^{-6}\ \text{M} = 7 \times 10^{-7}\ \text{M}$$

Example 3 *How many electrons per second do pass through a cross-section of a copper wire carrying* $10^{-16}\ A$*?*

(*a*) $555\ e^-/s$
(*b*) $624\ e^-/s$
(*c*) $725\ e^-/s$
(*d*) $433\ e^-/s$

Solution (*b*) $10^{-16}\ \text{A} = 10^{-16}\ \text{C/s}$

Charge on one electron $= 1.603 \times 10^{-19}\ \text{C}/e^-$

$$\therefore \quad \text{Rate} = \frac{10^{-16}}{1.603 \times 10^{-19}}$$
$$= 624\ e^-/s$$

Example 4 *Arrange the following oxidising agents in order of increasing strength under standard state conditions*

Given,

$$Cr_2O_7^{2-} + 14H^+ + 6e^- \longrightarrow 6Cr^{3+} + 7H_2O; \qquad E_1^\circ = 1.33\ V$$
$$Br_2(l) + 2e^- \longrightarrow 2Br^-(aq); \qquad E_2^\circ = 1.06\ V$$
$$Fe^{3+}(aq) + e^- \longrightarrow Fe^{2+}(aq); \qquad E_3^\circ = 0.77\ V$$

(*a*) $Fe^{3+} < Br_2 < Cr_2O_7^{2-}$
(*b*) $Br_2 < Fe^{3+} < Cr_2O_7^{2-}$
(*c*) $Fe^{3+} < Cr_2O_7^{2-} < Br_2$
(*d*) $Cr_2O_7^{2-} < Br_2 < Fe^{3+}$

Solution (*a*) Since, the order of standard reduction potential is

$$E_1^\circ > E_2^\circ > E_3^\circ$$

Higher the value of standard reduction potential, higher is the ease to get reduced. The species which readily gets reduced, is a better oxidising agent. Thus, the order of strength of oxidising agent is

$$Fe^{3+} < Br_2 < Cr_2O_7^{2-}$$

Example 5 *A certain current liberates 0.500 g of* H_2 *in 2.00 hr. How many gram of oxygen can be liberated by the same current in the same time?*

(*a*) 0.500 *g* (*b*) 8.00 *g* (*c*) 4.00 *g* (*d*) 16.00 *g*

Solution (*c*) According to Faraday's first law,

$$w = Z \cdot it$$

Given, *it* is same for H_2 and O_2.

$$\frac{w_{H_2}}{w_{O_2}} = \frac{Z_{H_2}}{Z_{O_2}}$$

$$\frac{w_{H_2}}{w_{O_2}} = \frac{E_{H_2}}{E_{O_2}}$$

$$\frac{0.500}{w_{O_2}} = \frac{2}{16}$$

$$w_{O_2} = 4.00 \text{ g}$$

Example 6 *The reversible reduction potential of pure water is* –0.413 *V under* 1.00 *atm* H_2 *pressure. If the reduction is considered to be* $2H^+ + 2e^- \longrightarrow H_2$, *calculate the pH of pure water.*

(*a*) 4 (*b*) 5 (*c*) 6 (*d*) 7

Solution (*d*) $2H^+ + 2e^- \longrightarrow H_2 \qquad Q = \dfrac{1}{[H^+]^2}$

$$E = E^\circ_{SHE} - \frac{0.0591}{2}\log\frac{1}{[H^+]^2}$$

$$-0.413 = 0 + \frac{0.0591}{2}\log[H^+]^2$$

$$0.413 = -0.0591 \log[H^+]$$

$$= 0.0591 \text{ pH} \qquad [\because -\log[H^+] = \text{pH}]$$

$$\text{pH} = \frac{0.413}{0.0591} = 7$$

Example 7 *The value of the reaction quotient, Q, for the cell,* $Ni(s)\,|\,Ni^{2+}(0.19\,M)\,||\,Cl^-(0.40\,M)\,|\,Cl_2$ (g 0.10 *atm*), Pt(*s*), *is*

(*a*) 3.0×10^{-2} (*b*) 3.0×10^{-3}

(*c*) 3.0×10^{-1} (*d*) 2.5×10^{-2}

Solution (*c*) The half-cell reactions and overall reaction are

$$Ni \longrightarrow Ni^{2+} + 2e^-$$

$$Cl_2 + 2e^- \longrightarrow 2Cl^-$$

$$Ni + Cl_2 \longrightarrow Ni^{2+} + 2Cl^-$$

$$\therefore \qquad Q = \frac{[Ni^{2+}][Cl^-]^2}{[p_{Cl_2}]} = \frac{0.19 \times (0.4)^2}{0.1} = 0.30$$

Example 8 *Calculate* E_{cell} *of the following cell*

$$\underset{\ominus}{Pt}\,|\,Fe^{2+}(0.10\,M), Fe^{3+}(0.20\,M)\,||\,Ag^+(1.0\,M)\,|\,\underset{\oplus}{Ag}.$$

Given, $E^\circ_{Fe^{3+}, Fe^{2+}/Pt} = 0.770$ *V and* $E^\circ_{Ag^+/Ag} = 0.800$ *V.*

(*a*) 0.0254 *V* (*b*) 0.0186 *V*

(*c*) 0.1460 *V* (*d*) 0.0122 *V*

Solution (*d*) At anode,

$$Fe^{2+}(aq) \longrightarrow Fe^{3+}(aq) + e^- \qquad E^\circ_{oxi} = -0.77 \text{ V}$$

At cathode $\quad Ag^+ + e^- \longrightarrow Ag(s) \qquad E^\circ_{red} = 0.80$ V

Overall cell reaction,

$$Fe^{2+}(aq) + Ag^+(aq) \longrightarrow Fe^{3+}(aq) + Ag(s)$$

$$E^\circ_{cell} = E^\circ_{oxi} + E^\circ_{red} = -0.77 + 0.80 = 0.03 \text{ V}$$

$$K_c = \frac{[Fe^{3+}][Ag]}{[Fe^{2+}][Ag^+]} = \frac{[Fe^{3+}]}{[Fe^{2+}][Ag^+]} = \frac{0.20}{(0.10)(1)} = 2$$

Using Nernst equation,

$$E_{cell} = E^\circ_{cell} - \frac{0.0591}{n}\log K_c$$

$$E_{cell} = 0.03 - \frac{0.0591}{1}\log 2$$

$$= 0.0122 \text{ V.}$$

Example 9 *The EMF of the cell,*

$$Cd\,|\,CdCl_2 \text{ (solution) (1 atm)}\,|\,AgCl(s)\,|\,Ag$$

is 0.675 *at* 25°C. *The temperature coefficient of the cell is* -6.5×10^{-4} *V degree*$^{-1}$. *Find the change in heat content* (*kJ mol*$^{-1}$) *and entropy* (*V deg*$^{-1}$) *for the electrochemical reaction that occurs when* 1 *F of electricity is drawn for it.*

(*a*) 78.34, 83.83 (*b*) + 62.73, – 83.83

(*c*) –62.73, –83.83 (*d*) –78.34, +83.83

Solution (*c*) $E_{cell} = 0.675$ V

Cell reaction is

Anode reaction

$$\frac{1}{2}Cd(s) \longrightarrow \frac{1}{2}Cd^{2+}(aq) + e^-$$

Cathode reaction

$$AgCl(s) + e^- \longrightarrow Ag(s) + Cl^{\ominus}(aq)$$

Cell reaction

$$\frac{1}{2}Cd(s) + AgCl \rightleftharpoons Ag(s) + \frac{1}{2}Cd^{2+}(aq) + Cl^{\ominus}(aq)$$

Temperature coefficient of the cell, *i.e.*,

$$\left(\frac{\partial E}{\partial T}\right)_P = -6.5 \times 10^{-4} \text{ V deg}^{-1}$$

$$\Delta S = nF\left(\frac{\partial E}{\partial T}\right)_p \qquad (n_{cell} = 1)$$

$$= 1 \times 96500 \times (-6.5 \times 10^{-4})$$

$$= -62.73 \text{ V deg}^{-1}$$

$$E = -\frac{\Delta H}{nF} + T\left(\frac{\partial E}{\partial T}\right)_p$$

$$0.675\ \text{V} = \frac{-\Delta H}{1\times 96500} + 298\,(-6.5\times 10^{-4})$$

$$\Delta H = -83829.55\ \text{J} \approx -83.83\ \text{kJ mol}^{-1}$$

Example 10 *At 25°C, the free energy of formation of* $H_2O(l)$ *is –56,700 cal mol*$^{-1}$. *The free energy of ionization of water to* $H^{\oplus}$ *and* $\overset{\ominus}{O}H$ *is 19050 cal mol*$^{-1}$. *What is the reversible EMF of the following cell at 25°C ?*

$$H_2(g)\ (1\ atm)\,|\,H^{\oplus}\,|\,\overset{\ominus}{O}H,\ O_2(g),\ 1\ atm$$

(*a*) 0.625 *V* (*b*) 0.305 *V*

(*c*) 0.534 *V* (*d*) 0.405 *V*

Solution (*d*) Given;

$$H_2(g) + \frac{1}{2}O_2(g) \rightleftharpoons H_2O(l) \qquad \text{...(i)}$$

$$H_2O \rightleftharpoons H^{\oplus} + \overset{\ominus}{O}H \qquad \text{...(ii)}$$

$\Delta G_1 = -56700\ \text{cal mol}^{-1}, \Delta G_2 = 19050\ \text{cal mol}^{-1}$

Cell reaction

$$H_2 \rightleftharpoons 2H^{\oplus} + 2e^-$$

$$\frac{1}{2}O_2 + H_2O + 2e^- \rightleftharpoons 2\overset{\ominus}{O}H$$

$$H_2 + \frac{1}{2}O_2 + H_2O \rightleftharpoons 2H^{\oplus} + 2\overset{\ominus}{O}H$$

Multiply Eq. (ii) by 2 and adding Eq. (i), we get

$$H_2 + \frac{1}{2}O_2 + H_2O \rightleftharpoons 2H^{\oplus} + 2\overset{\ominus}{O}H$$

$$\begin{aligned}\therefore \quad \Delta G &= \Delta G_1 + 2\Delta G_2\\ &= -56700 + 2\times 19050\\ &= -18600\ \text{cal mol}^{-1}\\ &= -18600\times 4.2\ \text{J mol}^{-1}\end{aligned}$$

(1 cal = 4.184 J ≈ 4.2 J)

$$= -078120\ \text{J mol}^{-1}$$

$$\Delta G = -nFF_{\text{cell}}$$

$$-78120\ \text{J mol}^{-1} = -2\times 96500\ \text{C}\times E_{\text{cell}}$$

$$\therefore \quad E_{\text{cell}} = 0.405\ \text{V}.$$

Example 11 *The EMF of the cell,* $\text{Pt}\,|\,\text{Ce}^{4+}(90\%),\ \text{Ce}^{3+}(10\%)\,|$ *Normal calomel electrode is 1.464 V at 25°C. Find the value of equilibrium constant of the reaction :*

$$2Ce^{3+} + 2H^{\oplus} \longrightarrow 2Ce^{4+} + H_2$$

The electrode potential of the normal calomel electrode is + 0.28 V.

(*a*) 2.38×10^{38} (*b*) 1.08×10^{42}

(*c*) 1.67×10^{39} (*d*) 3.24×10^{44}

Solution (*b*) $E_{\text{cell}} = E_c - E_a = 1.464\ \text{V}$

$$E_{Ce^{4+}\,|\,Ce^{3+}} = E^{\ominus}_{Ce^{4+}\,|\,Ce^{3+}} - \frac{0.059}{1}\log\frac{[Ce^{3+}]}{[Ce^{4+}]}$$

$$= E^{\ominus}_{Ce^{4+}\,|\,Ce^{3+}} - \frac{0.059}{1}\log\frac{10}{90}$$

$$E_{\text{cell}} = E_{\text{calo}} - E_{Ce^{4+}\,|\,Ce^{3+}}$$

$$1.464 = E_{\text{calo}} - \left[\left(E^{\ominus}_{Ce^{4+}\,|\,Ce^{3+}} - 0.059\log\frac{1}{8}\right)\right]$$

$$1.464 = 0.28 - \left(E^{\ominus}_{Ce^{4+}\,|\,Ce^{3+}} - 0.059\log\frac{1}{8}\right)$$

$$E^{\ominus}_{Ce^{4+}\,|\,Ce^{3+}} = -1.24\ \text{V}$$

Now, $2Ce^{3+} + 2H^{\oplus} \rightleftharpoons 2Ce^{4+} + H_2$

At Eq. $E_{\text{cell}} = 0$.

$$\therefore \quad E^{\ominus} = \frac{0.059}{2}\log K$$

At anode $2Ce^{3+} \longrightarrow 2Ce^{4+} + 2e^-$ (Oxidation)

At cathode $2H^{\oplus} + 2e^- \longrightarrow H_2$ (Reduction)

Cell reaction $2Ce^{3+} + 2H^{\oplus} \longrightarrow 2Ce^{4+} + H_2$

$$\begin{aligned}E^{\ominus}_{\text{cell}} &= E^{\ominus}_{\text{red (cathode)}} - E^{\ominus}_{\text{red (anode)}}\\ &= E^{\ominus}_{\text{red}\,(H_2)} - E^{\ominus}_{\text{red}\,(Ce^{4+}\,|\,Ce^{3+})}\\ &= 0 - (-1.24) = 1.24\end{aligned}$$

$$\therefore \quad E^{\ominus} = \frac{0.059}{2}\log K$$

$$1.24 = \frac{0.059}{2}\log K$$

$$\log K = 42.03 \Rightarrow K = 1.08\times 10^{42}$$

Start Practice for JEE Main

Round I (Topically Divided Problems)

Conduction and Electrolytic Conductance

1. Electrolytes when dissolved in water dissociates into ions because
(a) they are unstable
(b) the water dissolves it
(c) the force of repulsion increases
(d) the force of electrostatic attraction are broken down by water

2. The conductivity of strong electrolyte
(a) increases on dilution slightly
(b) decreases on dilution
(c) does not change with dilution
(d) depends upon density of electrolyte itself

3. Which of the statements about solutions of electrolytes is not correct? **[NCERT Exemplar]**
(a) Conductivity of solution depends upon size of ions
(b) Conductivity depends upon viscosity of solution
(c) Conductivity does not depend upon solvation of ions present in solution
(d) Conductivity of solution increases with temperature

4. The conductivity of a 0.01 N solution is found to be $0.005\ \text{ohm}^{-1}\ \text{cm}^{-1}$. The equivalent conductivity of the solution will be
(a) $5\times 10^{-2}\ \text{ohm}^{-1}\ \text{cm}^2\ \text{equiv}^{-1}$
(b) $5.00\times 10^{-3}\ \text{ohm}^{-1}\ \text{cm}^2$
(c) $500\ \text{ohm}^{-1}\ \text{cm}^2\ \text{equiv}^{-1}$
(d) $0.5\ \text{ohm}^{-1}\ \text{cm}^2\ \text{equiv}^{-1}$

5. The equivalent conductivity of a solution containing 2.54 g of $CuSO_4$ per L is $91.0\,\Omega^{-1}\ \text{cm}^2\ \text{eq}^{-1}$. Its conductivity would be
(a) $2.9\times 10^{-3}\ \Omega^{-1}\ \text{cm}^{-1}$
(b) $1.8\times 10^{-2}\ \Omega^{-1}\ \text{cm}^{-1}$
(c) $2.4\times 10^{-4}\ \Omega^{-1}\ \text{cm}^{-1}$
(d) $3.6\times 10^{-3}\ \Omega^{-1}\ \text{cm}^{-1}$

6. Conductivity (unit Siemen) is directly proportional to the area of vessel and the concentration of the solution in it and is inversely proportional to the length of the vessel. Then, the units of the constant of proportionality is
(a) $S^2\ m^2\ mol$
(b) $S^2\ m^2\ mol^{-2}$
(c) $S\ m^2\ mol^{-1}$
(d) $S\ m\ mol^{-1}$

7. The cell constant of a conductivity cell …… . **[NCERT Exemplar]**
(a) changes with change of electrolyte
(b) changes with change of concentration of electrolyte
(c) changes with temperature of electrolyte
(d) remains constant for a cell

8. The specific conductance of 0.1 N KCl solution at 23°C is $0.012\ \text{ohm}^{-1}\ \text{cm}^{-1}$. The resistance of cell containing the solution at the same temperature was found to be 55 ohm. The cell constant will be
(a) $0.66\ \text{cm}^{-1}$
(b) $1.12\ \text{cm}^{-1}$
(c) $0.918\ \text{cm}^{-1}$
(d) $1.66\ \text{cm}^{-1}$

9. $\Lambda^0_{m\,[NH_4OH]}$ is equal to …… . **[NCERT Exemplar]**
(a) $\Lambda^0_{m(NH_4OH)} + \Lambda^0_{m(NH_4Cl)} - \Lambda^0_{m(HCl)}$
(b) $\Lambda^0_{m(NH_4Cl)} + \Lambda^0_{m(NaOH)} - \Lambda^0_{m(NaCl)}$
(c) $\Lambda^0_{m(NH_4Cl)} + \Lambda^0_{m(NaCl)} - \Lambda^0_{(NaOH)}$
(d) $\Lambda^0_{m(NaOH)} + \Lambda^0_{m(NaCl)} - \Lambda^0_{m(NH_4Cl)}$

10. Given the limiting molar conductivity as

$$\Lambda^\infty_m(\text{HCl}) = 425.9\ \Omega^{-1}\ \text{cm}^2\ \text{mol}^{-1}$$
$$\Lambda^\infty_m(\text{NaCl}) = 126.4\ \Omega^{-1}\ \text{cm}^2\ \text{mol}^{-1}$$
$$\Lambda^\infty_m\ (\text{CH}_3\text{COONa}) = 91\ \Omega^{-1}\ \text{cm}^2\ \text{mol}^{-1}$$

The molar conductivity, at infinite dilution, of acetic acid (in $\Omega^{-1}\ \text{cm}^2\ \text{mol}^{-1}$) will be
(a) 481.5
(b) 390.5
(c) 299.5
(d) 516.9

11. The limiting molar conductivities Λ° for NaCl, KBr and KCl are 126, 152 and 150 S cm^2 mol^{-1} respectively. The Λ° for NaBr is

(a) 128 S cm^2 mol^{-1}
(b) 248 S cm^2 mol^{-1}
(c) 328 S cm^2 mol^{-1}
(d) 348 S cm^2 mol^{-1}

12. The resistance of a conductivity cell filled with 0.1 M KCl solution is 100 Ω. If R of the same cell when filled with 0.02 M KCl solution is 520 Ω, calculate the molar conductivity of 0.02 M KCl solution. The conductivity of 0.1 M KCl solution is 1.29 S m^{-1}. **[NCERT]**

(a) 124 S m^2 mol^{-1}
(b) 124×10^{-2} S m^2 mol^{-1}
(c) 124×10^{-4} S m^2 mol^{-1}
(d) 124×10^{-3} S m^2 mol^{-1}

13. Conductivity of 0.00241 M acetic acid is 7.896×10^{-5} S cm^{-1}. If Λ_m° for acetic acid is 390.5 S cm^2 mol^{-1}, what is its dissociation constant? **[NCERT]**

(a) 1.85×10^{-5} mol L^{-1}
(b) 2.68×10^{-5} mol L^{-1}
(c) 8.4×10^{-4} mol L^{-1}
(d) 3.98×10^{-4} mol L^{-1}

Electrolysis

14. During electrolysis, the species discharged at cathode are

(a) anion
(b) cation
(c) ions
(d) All of these

15. Electrolysis involves oxidation and reduction respectively at

(a) anode and cathode
(b) cathode and anode
(c) at both the electrodes
(d) None of these

16. In the electrolysis of aqueous sodium chloride solution which of the half cell reaction will occur at anode? **[NCERT Exemplar]**

(a) $Na^+(aq) + e^- \longrightarrow Na(s);\quad E^\ominus_{cell} = -2.71\,V$
(b) $2H_2O(l) \longrightarrow O_2(g) + 4H^+(aq) + 4e^-;\quad E^\ominus_{cell} = 1.23\,V$
(c) $H^+(aq) + e^- \longrightarrow \frac{1}{2}H_2(g);\quad E^\ominus_{cell} = 0.00\,V$
(d) $Cl^-(aq) \longrightarrow \frac{1}{2}Cl_2(g) + e^-;\quad E^\ominus_{cell} = 1.36\,V$

17. During the electrolysis of fused NaCl, which reaction occurs at anode?

(a) Chloride ions are oxidised
(b) Sodium ions are oxidised
(c) Chloride ions are reduced
(d) Sodium ions are reduced

18. Use of electrolysis is

(a) electrorefining
(b) electroplating
(c) Both (a) and (b)
(d) None of these

19. For which of the following highest charge is required? **[NCERT]**

(a) 1 mole of Al^{3+} to Al
(b) 1 mole of Cu^{2+} to Cu
(c) 1 mole of MnO_4^- to Mn^{2+}
(d) Same for all

20. The quantity of charge required to obtain one mole of aluminium from Al_2O_3 is **[NCERT Exemplar]**

(a) 1 F
(b) 6 F
(c) 3 F
(d) 2 F

21. The number of Faraday's needed to reduce 4 g-equivalents of Cu^{2+} to Cu metal will be

(a) 1
(b) 2
(c) 4
(d) 8

22. During the electrolysis of an electrolyte, the number of ions produced is directly proportional to the

(a) time consumed
(b) mass of electrons
(c) quantity of electricity passed
(d) electrochemical equivalent of electrolytes

23. The number of coulombs required to reduce 12.3 g of nitrobenzene to aniline, is

(a) 96500 C
(b) 5790 C
(c) 95700 C
(d) 57900 C

24. On passing 3 A of electricity for 50 min, 1.8 g metal deposits. The equivalent mass of metal is

(a) 9.3
(b) 19.3
(c) 38.3
(d) 39.9

25. A solution of $Ni(NO_3)_2$ is electrolysed between platinum electrodes using a current of 5 A for 20 min. What mass of Ni is deposited at the cathode? (Atomic mass of Ni = 58.7) **[NCERT]**

(a) 5.87 g
(b) 1.82 g
(c) 3.97 g
(d) 2.22 g

26. When 9.65 C of electricity is passed through a solution of silver nitrate (atomic weight of Ag = 107.87 taking as 108), the amount of silver deposited is

(a) 5.8 mg
(b) 10.8 mg
(c) 15.8 mg
(d) 20.8 mg

27. An electric current is passed through silver nitrate solution using silver electrodes. 10.79 g of silver was found to be deposited on the cathode. If the same amount of electricity is passed through copper sulphate solution using copper electrodes, the weight of copper deposited on the cathode is

(a) 1.6 g
(b) 2.3 g
(c) 3.2 g
(d) 6.4 g

Galvanic Cell and the Nernst's Equation

28. Which of the following statements is correct? Galvanic cell converts
(a) chemical energy into electrical energy
(b) electrical energy into chemical energy
(c) metal from its elemental state to the combined state
(d) electrolyte into individual ions

29. In a galvanic cell, the electrons flow from
(a) anode to cathode through the external circuit
(b) anode to cathode through the solution
(c) cathode to anode through the external circuit
(d) cathode to anode through the solution

30. What flows in the internal circuit of a galvanic cell?
(a) Ions (b) Electrons
(c) Electricity (d) Atoms

31. Which cell will measure standard electrode potential of copper electrode? **[NCERT Exemplar]**
(a) $\mathrm{Pt}(s)\,|\,\mathrm{H_2}(g, 0.1\text{ bar})\,|\,\mathrm{H^+}(aq, 1\text{ M})\,||\,\mathrm{Cu^{2+}}(aq, 1\text{ M})\,|\,\mathrm{Cu}$
(b) $\mathrm{Pt(s)}\,|\,\mathrm{H_2}(g, 1\text{ bar})\,|\,\mathrm{H^+}(aq, 1\text{ M})\,||\,\mathrm{Cu^{2+}}(aq, 2\text{ M})\,|\,\mathrm{Cu}$
(c) $\mathrm{Pt(s)}\,|\,\mathrm{H_2}(g, 1\text{ bar})\,|\,\mathrm{H^+}(aq, 1\text{ M})\,||\,\mathrm{Cu^{2+}}\,(aq, 1\text{ M})\,|\,\mathrm{Cu}$
(d) $\mathrm{Pt}(s)\,|\,\mathrm{H_2}(g, 1\text{ bar})\,|\,\mathrm{H^+}(aq, 0.1\text{ M})\,||\,\mathrm{Cu^{2+}}(aq, 1\text{ M})||\,\mathrm{Cu}$

32. The standard potential at 25°C for the following half-reactions are given against them

$$\mathrm{Zn^{2+}} + 2e^- \longrightarrow \mathrm{Zn}; \quad E^\circ = -\,0.762\text{ V}$$
$$\mathrm{Mg^{2+}} + 2e^- \longrightarrow \mathrm{Mg}; \quad E^\circ = -\,2.37\text{ V}$$

When zinc dust is added to the solution of $\mathrm{MgCl_2}$,
(a) $\mathrm{ZnCl_2}$ is formed
(b) Mg is precipitated
(c) Zn dissolves in the solution
(d) No reaction takes place

33. Arrange the following metals in the order in which they displace each other from the solution of their salts. Al, Cu, Fe, Mg and Zn. **[NCERT]**
(a) Mg > Zn > Al > Fe > Cu (b) Mg > Fe > Al > Zn > Cu
(c) Mg > Al > Zn > Fe > Cu (d) Mg > Al > Fe > Zn > Cu

34. If a salt bridge is removed from the two half cells, the voltage
(a) drops to zero
(b) does not change
(c) increase gradually
(d) increases rapidly

35. An electrochemical cell can behave like an electrolytic cell when …… . **[NCERT Exemplar]**
(a) $E_{\text{cell}} = 0$ (b) $E_{\text{cell}} > E_{\text{ext}}$
(c) $E_{\text{ext}} > E_{\text{cell}}$ (d) $E_{\text{cell}} = E_{\text{ext}}$

36. Using the data given below find out the correct order of reducing tendency **[NCERT Exemplar]**

$$E^{\ominus}_{\mathrm{Cr_2O_7^{2-}/Cr^{3+}}} = 1.33\text{ V};\; E^{\ominus}_{\mathrm{Cl_2/Cl^-}} = 1.36\text{ V}$$
$$E^{\ominus}_{\mathrm{MnO_4^-/Mn^{2+}}} = 1.51\text{ V};\; E^{\ominus}_{\mathrm{Cr^{3+}/Cr}} = -0.74\text{ V}$$

(a) $\mathrm{Cr^{3+} < Cl^- < Mn^{2+} < Cr}$
(b) $\mathrm{Mn^{2+} < Cl^- < Cr^{3+} < Cr}$
(c) $\mathrm{Cr^{3+} < Cl^- < Cr_2O_7^{2-} < MnO_4^-}$
(d) $\mathrm{Mn^{2+} < Cr^{3+} < Cl^- < Cr}$

37. Use the data given in Q. 36 and find out which of the following is the strongest oxidising agent? **[NCERT Exemplar]**
(a) $\mathrm{Cl^-}$ (b) $\mathrm{Mn^{2+}}$
(c) $\mathrm{MnO_4^-}$ (d) $\mathrm{Cr^{3+}}$

38. The platinum electrodes were immersed in a solution of cupric sulphate and electric current was passed through the solution. After sometime, it was found that colour of copper sulphate disappeared with evolution of gas at the electrode. The colourless solution contains
(a) copper sulphate (b) copper hydroxide
(c) platinum sulphate (d) sulphuric acid

39. Saturated solution of $\mathrm{KNO_3}$ is used to make 'salt-bridge' because
(a) velocities of both $\mathrm{K^+}$ and $\mathrm{NO_3^-}$ are nearly the same
(b) velocity of $\mathrm{K^+}$ is greater than that of $\mathrm{NO_3^-}$
(c) velocity of $\mathrm{NO_3^-}$ is greater than that of $\mathrm{K^+}$
(d) $\mathrm{KNO_3}$ is highly soluble in water

40. Standard electrode potential of NHE at 298 K is
(a) 0.05 V (b) 0.10 V
(c) 0.50 V (d) 0.00 V

41. Which of the following statement is not correct about an inert electrode in a cell? **[NCERT Exemplar]**
(a) It does not participate in the cell reaction
(b) It provides surface either for oxidation or for reduction reaction
(c) It provides surface for conduction of electrons
(d) It provides surface for redox reaction

42. For a cell reaction involving a two electron change, the standard emf of the cell is found to be 0.295 V at 25°C. The equilibrium constant of the reaction, at 25°C, will be
(a) 10 (b) 1×10^{10}
(c) 1×10^{-10} (d) 10×10^{-2}

43. A cell constructed by coupling a standard copper electrode and a standard magnesium electrode has emf of 2.7 V. If the standard reduction potential of copper electrode is +0.34 V then that of the magnesium electrode is

(a) + 2.36 V (b) – 2.36 V
(c) + 3.26 V (d) – 3.26 V

44. $MnO_4^- + 8H^+ + 5e^- \longrightarrow Mn^{2+} + 4H_2O;\ E° = 1.51\ V$
$MnO_2 + 4H^+ + 2e^- \longrightarrow Mn^{2+} + 2H_2O;\ E° = 1.23\ V$

$E°_{MnO_4^- \mid MnO_2}$ is

(a) 1.70 V (b) 0.91 V
(c) 1.37 V (d) 0.548 V

45. The standard reduction potential for Fe^{2+}/Fe and Sn^{2+}/Sn electrodes are -0.44 and -0.14 V respectively. For the given cell reaction, $Fe^{2+} + Sn \longrightarrow Fe + Sn^{2+}$, the standard emf is

(a) 0.42 V (b) – 0.42 V
(c) – 0.30 V (d) – 1.10 V

46. For the electrochemical cell,

$H_2(g)$ 1 atm | H^+(1 M) || Cu^{2+} (1 M) | Cu(s)

which one of the following statements is true?

(a) H_2 is anode, Cu is cathode
(b) Cu is anode, H_2 is cathode
(c) Oxidation occurs at Cu electrode
(d) Reduction occurs at H_2 electrode

47. Standard electrode potential of cell $H_2\ |H^+\ ||\ Ag^+\ |Ag$ is (Given, $E°_{Ag^+/Ag} = 0.80$ V)

(a) 0.4 V (b) 0.8 V
(c) 1.4 V (d) 1.8 V

48. The hydrogen electrode is dipped in a solution of pH = 3 at 25°C. The potential of the cell would be (the value of $\frac{2.303RT}{T}$ is 0.059 V)

(a) 0.059 V (b) 0.088 V
(c) 0.178 V (d) –0.177 V

49. $I_2(s)$ | I^-(0.1 M) half-cell is connected to a $H^+(aq)$ | H_2 (1 bar) | Pt half-cell and emf is found to be 0.7714 V. If $E°_{I_2/I^-} = 0.535$ V, find the pH of H^+/H_2 half-cell.

(a) 1 (b) 2
(c) 3 (d) 5

50. If the standard electrode potential of Cu^{2+}/Cu electrode is 0.34 V, what is the electrode potential at 0.01 M concentration of Cu^{2+}? ($T = 298$ K)

(a) 0.399 V (b) 0.281 V
(c) 0.222 V (d) 0.176 V

51. The standard reduction potential, $E°$ for the half-reactions are as

$$Zn \rightleftharpoons Zn^{2+} + 2e^-, \qquad E° = +0.76\ V$$
$$Fe \rightleftharpoons Fe^{2+} + 2e^-, \qquad E° = +0.41\ V$$

The $E°_{cell}$ for the cell formed by these two electrodes is

(a) – 0.35 V (b) – 1.17 V
(c) + 0.35 V (d) + 1.17 V

52. Which of the following statements is correct?
[NCERT Exemplar]

(a) E_{cell} and $\Delta_r G$ of cell reaction both are extensive properties
(b) E_{cell} and $\Delta_r G$ of cell reaction both are intensive properties
(c) E_{cell} is an intensive property while $\Delta_r G$ of cell reaction is an extensive property
(d) E_{cell} is an extensive property while $\Delta_r G$ of cell reaction is an intensive property

53. If the ΔG of a cell reaction $AgCl + e^- \longrightarrow Ag + Cl^-$ is –21.20 kJ, the standard emf of cell is

(a) 0.239 V (b) 0.220 V
(c) –0.320 V (d) – 0.110 V

54. What will be the emf for the given cell Pt | $H_2(p_1)$ | $H^+(aq)$ || $H_2(p_2)$ | Pt?

(a) $\frac{RT}{2F}\log_e\frac{p_1}{p_2}$ (b) $\frac{RT}{F}\log_e\frac{p_1}{p_2}$
(c) $\frac{RT}{F}\log_e\frac{p_2}{p_1}$ (d) None of these

Batteries

55. When a lead storage battery is charged, it acts as

(a) a primary cell
(b) a galvanic cell
(c) a concentration cell
(d) an electrolytic cell

56. While charging the lead stroage battery
[NCERT Exemplar]

(a) $PbSO_4$ anode is reduced to Pb
(b) $PbSO_4$ cathode is reduced to Pb
(c) $PbSO_4$ cathode is oxidised to Pb
(d) $PbSO_4$ anode is oxidised to PbO_3

57. On the basis of electrochemical theory of aqueous corrosion, the reaction occurring at the cathode is

(a) $O_2(g) + 4H^+(aq) + 4e^- \longrightarrow 2H_2O(l)$
(b) $H_2(g) + 2OH^-(aq) \longrightarrow 2H_2O(l) + 2e^-$
(c) $Fe(s) \longrightarrow Fe^{2+}(aq) + 2e^-$
(d) $Fe^{2+}(aq) \longrightarrow Fe^{3+}(aq) + e^-$

58. Which of the following statements is true for fuel cells?
(a) They are more efficient
(b) They are free from pollution
(c) They run till reactants are active
(d) All of the above

59. Which of the following reactions is used to make a fuel cell?
(a) $2H_2(g) + O_2(g) \longrightarrow 2H_2O(l)$
(b) $2Fe(s) + O_2(g) + 4H^+(aq) \longrightarrow 2Fe^{2+}(aq) + 2H_2O(l)$
(c) $Pb(s) + PbO_2(s) + 2H_2SO_4(aq) \longrightarrow 2PbSO_4(s) + H_2O(l)$
(d) $Cd(s) + 2Ni(OH)_3(s) \longrightarrow CdO(s) + 2Ni(OH)_2 + 2H_2O(l)$

60. When an acid cell is charged, then
(a) voltage of cell increases
(b) resistance of cell increases
(c) electrolyte of cell dilutes
(d) None of the above

Round II (Mixed Bag)

1. Λ_{eq} of 0.10 N solution of CaI_2 is 100.0 S cm^2 eq^{-1} at 298 K. G^* of the cell $= 0.25\ cm^{-1}$. How much current will flow when the potential difference between the electrode is 5 V?
(a) 0.2 A
(b) 0.1 A
(c) 0.4 A
(d) 0.8 A

2. The resistance of a solution A is $50\,\Omega$ and that of solution B is $100\,\Omega$. Both the solutions are taken in same conductivity cell. If equal volumes of solution A and B are mixed, what is the resistance of the mixture using the same cell? (Assume there is no change or increase in the α of A and B on mixing.)
(a) $33.4\,\Omega$
(b) $66.7\,\Omega$
(c) $14.7\,\Omega$
(d) $77.8\,\Omega$

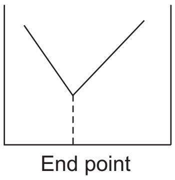
3. Conductivity of a saturated solution of $Co_2[Fe(CN)_6]$ is 2.0×10^{-6} S cm^{-1}. The conductivity water used to prepare the solution has conductivity 8.0×10^{-7} S cm^{-1}. If the ionic molar conductivities of Co^{2+} and $[Fe(CN)_6]^{4-}$ are 80.0 and 440.0 S cm^2 mol^{-1}, respectively, calculate the solubility product (K_{sp}) of $Co_2[Fe(CN)_6]$, assuming 100% ionization of the complex.
(a) 8×10^{-16}
(b) 3.2×10^{-16}
(c) 32×10^{-18}
(d) 3.2×10^{-18}

4. The electrical conductivity of a solution serves as a means of determining the end point in a chemical reaction, involved in the titration of acids, bases, or precipitation. Which of the following conductometric titrations represent the curve of HCl *vs* NH_4OH?

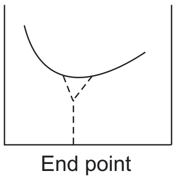
x-axis ⇒ Volume of alkali added

y-axis ⇒ Conductivity

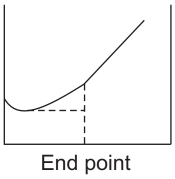
(a)



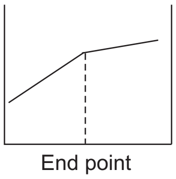
(b)



(c)



(d)



5. A solution of sodium sulphate in water is electrolysed using inert electrodes. The products at the cathode and anode are respectively
(a) H_2, O_2
(b) O_2, H_2
(c) O_2, Na
(d) O_2, SO_2

6. When 1 F of electricity is passed through acidulated water, O_2 evolved is
(a) 1.0 dm^3
(b) 5.6 dm^3
(c) 11.2 dm^3
(d) 22.4 dm^3

7. The reaction,

$$\frac{1}{2}H_2(g) + AgCl(s) \longrightarrow H^+(aq) + Cl^-(aq) + Ag(s)$$

occurs in the galvanic cell
(a) $Pt/H_2(g)$ KCl(sol) || $AgCl(s)$ | Ag
(b) $Pt/H_2(g)$ HCl(sol) || $AgNO_3$(sol) | Ag
(c) $Pt/H_2(g)$ HCl(sol) || $AgCl(s)$ | Ag
(d) Ag/$AgCl(s)$ KCl(sol) || $AgNO_3$ | Ag

8. A gas X at 1 atm is bubbled through a solution containing a mixture of 1 M y^- and 1 M z^- at 25°C. If the order of reduction potential is $z > y > x$ then
(a) y will oxidise x and not z
(b) y will oxidise x and z
(c) y will oxidise z and not x
(d) y will reduce both x and z

9. A solution containing one mole per litre of each $Cu(NO_3)_2$, $AgNO_3$, $Hg_2(NO_3)_2$ and $Mg(NO_3)_2$ is being electrolysed by using inert electrodes. The values of standard electrode potentials in volts (reducing potentials) are $Ag / Ag^+ = +0.80$, $2Hg / Hg^{2+} = +0.79$, $Cu / Cu^{2+} = +0.34$, $Mg / Mg^{2+} = -2.37$. With increasing voltage, the sequence of deposition of metals on the cathode will be

(a) Ag, Hg, Cu
(b) Cu, Hg, Ag
(c) Ag, Hg, Cu, Mg
(d) Mg, Cu, Hg, Ag

10. An electrochemical cell is set up as follows

$Pt(H_2, 1\text{ atm}) \mid 0.1\text{ M HCl} \parallel 0.1\text{ M}$ acetic acid $\mid (H_2, 1\text{ atm})Pt$

Emf of this cell will not be zero because

(a) the pH of 0.1 M HCl and 0.1 M acetic acid is not the same
(b) acids used in two compartments are different
(c) emf of a cell depends on the molarities of acids used
(d) the temperature is constant

11. On passing 1 F of electricity through the electrolytic cells containing Ag^+, Ni^{2+} and Cr^{3+} ions solution, the deposited Ag (at. wt. = 108), Ni (at. wt. = 59) and Cr (at. wt. = 52) is

	Ag	Ni	Cr
(a)	108 g	29.5 g	17.3 g
(b)	108 g	59.5 g	52.0 g
(c)	108 g	108 g	108 g
(d)	108 g	117.5 g	166 g

12. Which of the following will form a cell with the highest voltage?

(a) 0.1 M Ag^+, 2 M Co^{2+}
(b) 2 M Ag^+, 2 M Co^{2+}
(c) 1 M Ag^+, 1 M Co^{2+}
(d) 2 M Ag^+, 0.1 M Co^{2+}

13. The Edison storage cell is represented as

$$Fe(s), FeO(s) \mid KOH(aq) \mid Ni_2O_3(s) \mid NiO(s)$$

The half reactions are

$$Ni_2O_3(s) + H_2O(l) + 2e^- \longrightarrow 2NiO(s) + 2OH^-; \quad E^\circ = +0.40\text{ V}$$

$$FeO(s) + H_2O(l) + 2e^- \longrightarrow Fe(s) + 2OH^-; \quad E^\circ = -0.87\text{ V}$$

Choose the incorrect statement.

(a) E_{anode} increases with increase in concentration of OH^-
(b) $E_{cathode}$ decreases with increase in concentration of OH^-
(c) $E^\circ_{cell} = 1.27$ V
(d) E_{cell} increases with increase in concentration of FeO

14. 1.05 g of lead ore containing impurity of Ag was dissolved in HNO_3 and the volume was made 350 mL. An Ag electrode was dipped in the solution.

$$Pt(H_2) \mid H^+ (1\text{ M}) \parallel Ag^+ \mid Ag$$

The E_{cell} is 0.503 V at 298 K. The per cent of Ag in the ore is ($E^\circ_{Ag^+Ag} = 0.80$ V)

(a) 0.033%
(b) 0.050%
(c) 0.066%
(d) 0.13%

15. Given, standard electrode potentials

$$Fe^{2+} + 2e^- \longrightarrow Fe, \quad E^\circ = -0.440\text{ V}$$

$$Fe^{3+} + 3e^- \longrightarrow Fe, \quad E^\circ = -0.036\text{ V}$$

The standard electrode potential (E°) for

$$Fe^{3+} + e^- \longrightarrow Fe^{2+} \text{ is}$$

(a) + 0.771 V
(b) – 0.771 V
(c) + 0.417 V
(d) – 0.417 V

16. The emf of the cell, $Zn \mid Zn^{2+}\ (0.01\text{ M}) \parallel Fe^{2+}(0.001\text{ M}) \mid Fe$ at 298 K is 0.2905. The value of equilibrium constant for the cell reaction is

(a) $10^{\frac{0.32}{0.0295}}$
(b) $e^{\frac{0.32}{0.0295}}$
(c) $10^{\frac{0.32}{0.0591}}$
(d) $10^{\frac{0.26}{0.0295}}$

17. Consider the following disproportionation reaction,

$$2ClO_3^- \rightleftharpoons ClO_2^- + ClO_4^-$$

If the initial concentration of perchlorate ion is 0.1 M what it would be at equilibrium at 298 K?

($E^\circ_{ClO_4^-/ClO_3^-} = 0.36$ V and $E^\circ_{ClO_3^-/ClO_2^-} = 0.33$ V)

(a) 0.1 M
(b) 0.06 M
(c) 0.07 M
(d) 0.19 M

18. The standard emf for the given cell reaction, $Zn + Cu^{2+} \longrightarrow Cu + Zn^{2+}$ is 1.10 V at 25°C. The emf for the cell reaction, when 0.1 M Cu^{2+} and 0.1 M Zn^{2+} solutions are used, at 25°C, is

(a) 1.10 V
(b) – 1.10 V
(c) 2.20 V
(d) – 2.20 V

19. By how much is the oxidising power of $Cr_2O_7^{2-}/Cr^{3+}$ couple decreased if the H^+ concentration is decreased from 1 M to 10^{-3} M at 25°C?

(a) 0.207 V
(b) 0.414 V
(c) 0.001 V
(d) 0.287 V

20. The emf of a Daniell cell at 298 K is E_1, $Zn \mid \underset{(0.01\text{ M})}{ZnSO_4} \parallel \underset{(1.0\text{ M})}{CuSO_4} \mid Cu$. When the concentration of $ZnSO_4$ is 1.0 M and that of $CuSO_4$ is 0.01 M, the emf changed to E_2. What is the relationship between E_1 and E_2?

(a) $E_1 = E_2$
(b) $E_1 > E_2$
(c) $E_1 < E_2$
(d) $E_2 = 0 \neq E_1$

21. Cu^+ ion is not stable in aqueous solution because of disproportionation reaction. E° value for disproportionation of Cu^+ is

(given, $E^\circ_{Cu^{2+}/Cu^+} = 0.15, E^\circ_{Cu^{2+}/Cu} = 0.34$ V)

(a) + 0.38 V (b) − 0.38 V

(c) + 0.49 V (d) − 0.49 V

22. Consider the following reaction :

$$2Ag^+ + C_6H_{12}O_6 + H_2O \longrightarrow 2Ag(s) + C_6H_{12}O_7 + 2H^+$$

When ammonia is added to the solution, pH is raised to 11. Which half-cell reaction is affected by pH and by how much?

$$Ag^+ + e^- \longrightarrow Ag; \qquad E^\circ_{red} = 0.8 \text{ V}$$

$$C_6H_{12}O_6 + H_2O \longrightarrow C_6H_{12}O_7 + 2H^+ + 2e^-; \quad E^\circ_{red} = -0.05 \text{ V}$$

$$Ag(NH_3)_2^+ + e^- \longrightarrow Ag(s) + 2NH_3; \; E^\circ_{red} = 0.337 \text{ V}$$

(a) $E^\circ_{oxid.}$ will increase by a factor of 0.65 from $E^\circ_{oxid.}$

(b) $E^\circ_{oxid.}$ will decrease by a factor of 0.65 from $E^\circ_{oxid.}$

(c) $E^\circ_{red.}$ will increase by a factor of 0.65 from $E^\circ_{red.}$

(d) $E^\circ_{red.}$ will decrease by a factor of 0.65 from $E^\circ_{red.}$

23. EMF of which of the following cells at 298 K is highest? **[NCERT]**

Given,

$$E^\circ_{(Mg^{2+}/Mg)} = -2.37\text{V};$$

$$E^\circ_{(Cu^{2+}/Cu)} = +0.34\text{V};$$

$$E^\circ_{(Fe^{2+}/Fe)} = -0.44\text{V};$$

$$E^\circ_{(Sn^{2+}/Sn)} = -0.14\text{V};$$

$$E^\circ_{(1/2Br_2/Br^-)} = +1.08\text{V}.$$

(a) $Mg(s)|Mg^{2+}(0.001M)||\,Cu^{2+}(0.0001M)|Cu(s)$

(b) $Fe(s)|Fe^{2+}(0.001M)||H^+(1M)|H_2(g)$ (1 bar)$|Pt(s)$

(c) $Sn(s)|Sn^{2+}(0.050\text{ M})\;||H^+(0.020\text{ M})\;|H_2(g)$ (1 bar)$|Pt(s)$

(d) $Pt(s)|Br_2(l)|Br^-(0.010\text{ M})\;||\;H^+(0.030M)|H_2(g)$ (1bar) $|Pt(s)$

24. Using the following data, for the electrode potentials calculate ΔG°, in kJ, for the indicated reaction.

$$5Ce^{4+}(aq) + Mn^{2+}(aq) + 4H_2O(l) \longrightarrow 5Ce^{3+}(aq) + MnO_4^-(aq) + 8H^+(aq)$$

$$MnO_4^-(aq) + 8H^+(aq) + 5e^- \longrightarrow Mn^{2+}(aq) + 4H_2O(l) \quad E^\circ = +1.51 \text{ V}$$

$$Ce^{4+}(aq) + e^- \longrightarrow Ce^{3+}(aq); E^\circ = +\,1.61 \text{ V}$$

(a) −36.24 (b) − 48.25

(c) −31.54 (d) −19.65

25. The value of K_w can be determined from emf data. If the standard half-reaction potentials are 0.00 V for $H^+(1\,M)\,|\,Pt(H_2)$ and −0.8277 V for the half reaction

$$2H_2O + 2e^- \longrightarrow H_2 + 2OH^-$$

K_w is

(a) 1.01×10^{-14} (b) 1.01×10^{-7}

(c) 2.36×10^{-8} (d) 5.55×10^{-7}

26. $E^\circ_{Cu^{2+}/Cu} = 0.34$ V. Calculate reduction potential at pH = 14 for the Cu^{2+}/Cu couples. K_{sp} of $Cu(OH)_2 = 1.0 \times 10^{-19}$.

(a) 0.22 V (b) − 0.22 V

(c) 0.44 V (d) − 0.44 V

27. The reversible reduction potential of pure water is − 0.413 V under 1.00 atm H_2 pressure. If the reduction is cosidered to be $2H^+ + 2e^- \longrightarrow H_2$, pH of pure water is

(a) 3 (b) 7

(c) 8 (d) 6.85

More than One Correct Option

28. Molar conductivity of ionic solution depends on …… **[NCERT Exemplar]**

(a) temperature

(b) distance between electrodes

(c) concentration of electrolytes in solution

(d) surface area of electrodes

29. What will happen during the electrolysis of aqueous solution of $CuSO_4$ in the presence of Cu electrodes? **[NCERT Exemplar]**

(a) Copper will deposit at cathode

(b) Copper will dissolve at anode

(c) Oxygen will be released at anode

(d) Copper will deposit at anode

30. $E^\ominus_{cell} = 1.1$ V for Daniell cell. Which of the following expressions are correct description of state of equilibrium in this cell? **[NCERT Exemplar]**

(a) $1.1 = K_c$ (b) $\dfrac{2.303RT}{2F} \log K_c = 1.1$

(c) $\log K_c = \dfrac{2.2}{0.059}$ (d) $\log K_c = 1.1$

31. How can the oxidation potential of a hydrogen electrode be decreased?

(a) Increasing the p_{H_2}

(b) Increasing the $[H^+]$

(c) Decreasing the p_{H_2}

(d) Decreasing the pOH of the solution

32. Which of the following conditions will increase the voltage of the cell represented by the following equation?

$$Zn(s) + Cu^{2+}(aq) \longrightarrow Zn^{2+}(aq) + Cu(s)$$

(a) Decrease in temperature
(b) Increase in pressure
(c) Decrease in the concentration of $Zn^{2+}(aq)$ ions
(d) Increase in the concentration of $Cu^{2+}(aq)$ ions

Assertion and Reason

Directions (Q. Nos. 33 to 37) *Each of these questions contains two statements : Statement* I (*Assertion*) *and Statement* II (*Reason*). *Each of these questions also has four alternative choices, only one of which is the correct answer. You have to select one of the codes* (*a*), (*b*), (*c*), (*d*) *given below :*

(a) Statement I is true, Statement II is true; Statement II is a correct explanation for Statement I.
(b) Statement I is true, Statement II is true; Statement II is not a correct explanation for Statement I.
(c) Statement I is true; Statement II is false.
(d) Statement I is false; Statement II is true.

33. **Statement I** Mercury cell does not give steady potential.

Statement II In the cell reaction, ions are not involved in solution. **[NCERT Exemplar]**

34. **Statement I** On increasing dilution, the specific conductance keep on increasing.

Statement II On increasing dilution, degree of ionisation of weak electrolyte increases and molality of ions also increases.

35. **Statement I** $E_{Ag^+/Ag}$ increases with increase in concentration of Ag^+ ions.

Statement II $E_{Ag^+/Ag}$ has a positive value. **[NCERT Exemplar]**

36. **Statement I** If an aqueous solution of NaCl is electrolysed using inert electrodes, chlorine gas is produced at the anode, and H_2 gas is produced at the cathode.

Statement II Electrolysis of aqueous solutions containing metal ion that is a weaker oxidising agent than $H^+(aq)$, will produce H_2 gas at cathode.

37. **Statement I** E_{cell} should have a positive value for the cell to function.

Statement II $E_{cathode} < E_{anode}$ **[NCERT Exemplar]**

Comprehension Based Questions

Directions (Q. Nos. 38 and 39) The concentration of potassium ions inside a biological cell is at least 20 times higher than outside. The resulting potential difference across the cell is important in several processes such as transmission of nerve impulses and maintaining the ion balance. A simple model for a concentration cell involving a metal M is

$$M(s) \mid M^{\oplus}(aq; 0.05\,\text{molar}) \mid\mid M^{\oplus}(aq; 1\,\text{molar}) \mid M(s)$$

For the above electrolytic cell, the magnitude of the cell potential is $|E_{cell}| = 70$ mV.

38. For the above cell

(a) $E_{cell} < 0; \Delta G > 0$	(b) $E_{cell} > 0; \Delta G < 0$
(c) $E_{cell} > 0; \Delta G > 0$	(d) $E_{cell} < 0; \Delta G < 0$

39. If the 0.05 molar solution of $M^{\oplus}$ is replaced by a 0.0025 molar $M^{\oplus}$ solution then the magnitude of the cell potential would be

(a) 35 mV	(b) 70 mV
(c) 140 mV	(d) 700 mV

Directions (Q. Nos. 40 to 42) A fuel cell is continuously supplied with an oxidant and a reductant so that it can deliver a current indefinitely. Fuel cell offer the possibility of achieving high thermodynamic efficiency in the conversion of Gibbs energy into mechanical work. Internal combustion engines at best convert only the fraction $\frac{(T_2 - T_1)}{T_2}$ of the heat of combustion into mechanical work. While the thermodynamic efficiency of the fuel cell is given by $\eta = \frac{\Delta G}{\Delta H}$, where ΔG is the Gibbs energy change for the cell reaction and ΔH is the enthalpy change of the cell reaction,

$$H_2(g) + \frac{1}{2}O_2(g) \longrightarrow H_2O(l) \quad E^\circ = 1.2288\text{ V}$$

40. For a hydrogen-oxygen fuel cell if $\Delta H_f^\circ(H_2O, l) = -285$ kJ/mol then what will be its thermodynamic efficiency under standard conditions?

(a) 0.64	(b) 0.46
(c) 0.83	(d) 0.59

41. If 560 mL of H_2 gas at STP is fed into and is consumed by the fuel cell in 10 min then what is the current output of the fuel cell?

(a) 2	(b) 4
(c) 12	(d) 8

42. The advantage of using fuel cell in a motor car could be

(a) low initial cost	(b) emissionless operation
(c) light weight	(d) freedom from refueling

Previous Years' Questions

43. The standard reduction potentials for Zn^{2+}/Zn, Ni^{2+}/Ni and Fe^{2+}/Fe are – 0.76, – 0.23 and – 0.44 V respectively. The reaction $X + Y^{2+} \longrightarrow X^{2+} + Y$ will be spontaneous when **[AIEEE 2013]**

(a) $X = Ni, Y = Fe$ (b) $X = Ni, Y = Zn$
(c) $X = Fe, Y = Zn$ (d) $X = Zn, Y = Ni$

44. The reduction potential of hydrogen half-cell will be negative if **[AIEEE 2011]**

(a) $p(H_2) = 1$ atm and $[H^+] = 2.0$ M
(b) $p(H_2) = 1$ atm and $[H^+] = 1.0$ M
(c) $p(H_2) = 2$ atm and $[H^+] = 1.0$ M
(d) $p(H_2) = 2$ atm and $[H^+] = 2.0$ M

45. Resistance of 0.2 M solution of an electrolyte is 50 Ω. The specific conductance of the solution is 1.3 S m^{-1}. If resistance of the 0.4M solution of the same electrolyte is 260 Ω, its molar conductivity is **[AIEEE 2011]**

(a) $6250 \text{ S m}^2 \text{ mol}^{-1}$
(b) $6.25 \times 10^{-4} \text{ S m}^2 \text{ mol}^{-1}$
(c) $625 \times 10^{-4} \text{ S m}^2 \text{ mol}^{-1}$
(d) $62.5 \text{ S m}^2 \text{ mol}^{-1}$

46. The Gibbs energy for the decomposition of Al_2O_3 at 500°C is as follows

$$\frac{2}{3} Al_2O_3 \longrightarrow \frac{4}{3} Al + O_2; \ \Delta_r G = +966 \text{ kJ mol}^{-1}$$

The potential difference needed for electrolytic reduction of Al_2O_3 at 500°C is at least **[AIEEE 2010]**

(a) 4.5 V (b) 3.0 V
(c) 2.5 V (d) 5.0 V

47. Given, $E^\circ_{Cr^{3+}/Cr} = -0.72 \text{ V}, E^\circ_{Fe^{2+}/Fe} = -0.42 \text{ V}.$

The potential for the cell $Cr \mid Cr^{3+} (0.1M) \parallel Fe^{2+} (0.01M) \mid Fe$ is **[AIEEE 2008]**

(a) 0.26 V (b) 0.399 V
(c) – 0.339 V (d) – 0.26 V

48. The equivalent conductances of two strong electrolytes at infinite dilution in H_2O (where ions move freely through a solution) at 25°C are given below

$$\Lambda^\circ_{CH_3COONa} = 91.0 \text{ S cm}^2 / \text{equiv}$$
$$\Lambda^\circ_{HCl} = 426.2 \text{ S cm}^2 / \text{equiv}$$

What additional information/quantity one needs to calculate Λ° of an aqueous solution of acetic acid ? **[AIEEE 2007]**

(a) Λ° of NaCl
(b) Λ° of CH_3COOK
(c) The limiting equivalent conductance of H^+ ($\lambda^\circ_{H^+}$)
(d) Λ° of chloroacetic acid ($ClCH_2COOH$)

49. The cell, $Zn \mid Zn^{2+} (1 \text{ M}) \parallel Cu^{2+} (1 \text{ M}) \mid Cu$ ($E^\circ_{cell} = 1.10$ V), was allowed to be completely discharged at 298 K. The relative concentration of Zn^{2+} to Cu^{2+} $\left(\frac{[Zn^{2+}]}{[Cu^{2+}]}\right)$ is **[AIEEE 2007]**

(a) antilog (24.08) (b) 37.3
(c) $10^{37.3}$ (d) 9.65×10^4

50. The molar conductivities Λ°_{NaOAc} and Λ°_{HCl} at infinite dilution in water at 25°C are 91.0 and 426.2 S cm²/mol respectively. To calculate Λ°_{HOAc}, the additional value required is **[AIEEE 2006]**

(a) $\Lambda^\circ_{H_2O}$ (b) Λ°_{KCl}
(c) Λ°_{NaOH} (d) Λ°_{NaCl}

51. Given the data at 25°C,

$$Ag + I^- \longrightarrow AgI + e^-; \quad E^\circ = 0.152 \text{ V}$$
$$Ag \longrightarrow Ag^+ + e^-; \quad E^\circ = -0.800 \text{ V}$$

What is the value of $\log K_{sp}$ for AgI ?

$\left(2.303 \frac{RT}{F} = 0.059 \text{ V}\right)$ **[AIEEE 2006]**

(a) – 8.12 (b) + 8.612
(c) – 37.83 (d) – 16.13

52.

Electrolyte	KCl	KNO_3	HCl	NaOAC	NaCl
Λ^∞ (S cm² mol⁻¹)	149.9	145.0	426.2	91.0	126.5

Calculate Λ^∞_{HOAc} using appropriate molar conductances of the electrolytes listed above at infinite dilution in H_2O at 25°C. **[AIEEE 2005]**

(a) 217.5 (b) 390.7
(c) 552.7 (d) 517.2

53. Aluminium oxide may be electrolysed at 1000°C to furnish aluminium metal (atomic mass = 27 u; 1 Faraday = 96500 C). The cathode reaction is

$$Al^{3+} + 3e^- \longrightarrow Al^0$$

To prepare 5.12 kg of aluminium metal by this method would require **[AIEEE 2005]**

(a) 5.49×10^1 C of electricity
(b) 5.49×10^4 C of electricity
(c) 1.83×10^7 C of electricity
(d) 5.49×10^7 C of electricity

54. In a hydrogen-oxygen fuel cell, combustion of hydrogen occurs to **[AIEEE 2004]**

(a) generate heat
(b) create potential difference between the two electrodes
(c) produce high purity water
(d) remove adsorbed oxygen from electrode surfaces

55. The $E^\circ_{M^{3+}/M^{2+}}$ values for Cr, Mn, Fe and Co are –0.41, + 1.57, + 0.77 and + 1.97 V respectively. For which one of these metals the change in oxidation state from + 2 to + 3 is easiest ? **[AIEEE 2004]**

(a) Cr (b) Mn
(c) Fe (d) Co

56. In a cell that utilises the reaction

$$Zn(s) + 2H^+(aq) \longrightarrow Zn^{2+}(aq) + H_2(g)$$

addition of H_2SO_4 to cathode compartment will **[AIEEE 2004]**

(a) lower the E and shift equilibrium to the left
(b) lower the E and shift the equilibrium to the right
(c) increase the E and shift the equilibrium to the right
(d) increase the E and shift the equilibrium to the left

57. Standard reduction electrode potentials of three metals A, B and C are + 0.5 V, – 3.0 V and – 1.2 V respectively. The reducing power of these metals are **[AIEEE 2003]**

(a) $B > C > A$ (b) $A > B > C$
(c) $C > B > A$ (d) $A > C > B$

the Guidance

Round I

3. Conductivity also depends upon the solvation of ions.

4. $$\Lambda^\circ_{eq} = \kappa \times \frac{1000}{\text{normality}}$$

$$= \frac{0.005 \times 1000}{0.01} = 500 \text{ ohm}^{-1} \text{ cm}^2 \text{ equiv}^{-1}$$

5. $$\kappa = \Lambda_{eq} \cdot C$$

$$= (91 \Omega^{-1} \text{ cm}^2 \text{ eq}^{-1}) \left(\frac{2.54}{159/2 \times 1000} \text{ eq} \cdot \text{cm}^{-3} \right)$$

$$= 2.9 \times 10^{-3} \ \Omega^{-1} \text{ cm}^{-1}$$

8. $$\kappa = \frac{1}{R} \times \text{cell constant}$$

$$\therefore \ \text{Cell constant} = \kappa \times R = 0.012 \times 55 = 0.66 \text{ cm}^{-1}$$

9. From Kohlrausch's law,

$$\Lambda^0_{m(NH_4OH)} = \Lambda^0_{m(NH_4Cl)} + \Lambda^0_{m(NaOH)} - \Lambda^0_{(NaCl)}$$

10. Sum of molar conductivity of reactants = sum of molar conductivity of producs

Therefore, for the reaction

$$CH_3COOH + NaCl \longrightarrow CH_3COONa + HCl$$

$$\Lambda_m^0\ \mathrm{CH_3COOH} = \Lambda_m^0\mathrm{CH_3COONa} + \Lambda_m^0\mathrm{HCl} - \Lambda_m^0\mathrm{NaCl}$$
$$= 91 + 425.9 - 126.4$$
$$= 390.5\ \Omega^{-1}\ \mathrm{cm^2\ mol^{-1}}$$

11. $(126\ \mathrm{S\ cm^2\ mol^{-1}})\Lambda^\infty_{\mathrm{NaCl}} = \Lambda^\infty_{\mathrm{Na^+}} + \Lambda^\infty_{\mathrm{Cl^-}}$ ...(i)

$(152\ \mathrm{S\ cm^2\ mol^{-1}})\ \Lambda^\infty_{\mathrm{KBr}} = \Lambda^\infty_{\mathrm{K^+}} + \Lambda^\infty_{\mathrm{Br^-}}$ ...(ii)

$(150\ \mathrm{S\ cm^2\ mol^{-1}})\ \Lambda^\infty_{\mathrm{KCl}} = \Lambda^\infty_{\mathrm{K^+}} + \Lambda^\infty_{\mathrm{Cl^-}}$ ...(iii)

By Eqs. (i) + (ii) – (iii)

$$\because \quad \Lambda^\infty_{\mathrm{NaBr}} = \Lambda^\infty_{\mathrm{Na^+}} + \Lambda^\infty_{\mathrm{Br^-}}$$
$$= 126 + 152 - 150$$
$$= 128\ \mathrm{S\ cm^2\ mol^{-1}}$$

12. Cell constant, $G^* =$ Conductivity × Resistance

$$= 1.29\ \mathrm{S\ m^{-1}} \times 100\ \Omega$$
$$= 129\ \mathrm{m^{-1}} = 1.29\ \mathrm{cm^{-1}}$$

Conductivity (κ) of 0.02 M KCl solution $= \dfrac{G^*}{R}$

$$= \frac{129\ \mathrm{m^{-1}}}{520\ \Omega} = 0.248\ \mathrm{m^{-1}}$$

Concentration $= 0.02\ \mathrm{M} = 1000 \times 0.02\ \mathrm{mol\ m^{-3}}$

$$= 20\ \mathrm{mol\ m^{-3}}$$

Molar conductivity $(\Lambda_m) = \dfrac{\kappa}{c} = \dfrac{0.248\ \mathrm{S\ m^{-1}}}{20\ \mathrm{mol\ m^{-3}}}$

$$= 124 \times 10^{-4}\ \mathrm{S\ m^2\ mol^{-1}}$$

13. Calculation of molar conductivity (Λ^c_m)

$$\kappa = 7.896 \times 10^{-5}\ \mathrm{S\ cm^{-1}};$$
$$C = 0.00241 \mathrm{mol\ L^{-1}} = \frac{0.00241}{10^3}\ \mathrm{mol\ cm^{-3}}$$
$$= 241 \times 10^{-8} \mathrm{mol\ cm^{-3}}$$
$$\Lambda^c_m = \frac{\kappa}{C} = \frac{(7.896 \times 10^{-5}\ \mathrm{S\ cm^{-1}})}{(241 \times 10^{-8}\ \mathrm{mol\ cm^{-3}})}$$
$$= 32.76\ \mathrm{S\ cm^2\ mol^{-1}}$$

Calculation of degree of dissociation of $\mathrm{CH_3COOH}$ (α)

$$\alpha = \frac{\Lambda^c_m}{\Lambda^\circ_m} = \frac{(32.76\ \mathrm{S\ cm^2\ mol^{-1}})}{(390.5\ \mathrm{S\ cm^2\ mol^{-1}})}$$
$$= 0.084 = 8.4 \times 10^{-2}$$

Calculation of dissociation constant (K_a)

$$K_a = \frac{[\mathrm{CH_3COO^-}]\ [\mathrm{H^+}]}{[\mathrm{CH_3COOH}]} = \frac{C\alpha \times C\alpha}{C(1-\alpha)} = \frac{C\alpha^2}{(1-\alpha)}$$
$$= \frac{(0.00241\ \mathrm{mol\ L^{-1}}) \times (0.084)^2}{(1 - 0.084)}$$
$$= 0.0000185\ \mathrm{mol\ L^{-1}}$$
$$= 1.85 \times 10^{-5}\ \mathrm{mol\ L^{-1}}$$

16. Anode is always the site of oxidation. Thus, the reaction where oxidation occurs, *i.e.*, electron releases occurs at anode. Moreover H_2O is oxidised more readily as compared to $\mathrm{Cl^-}$.

17. During the electrolysis of fused NaCl, chloride ions are oxidised at anode and this process is called oxidation.

19. (i) **1 mol of $\mathbf{Al^{3+}}$ to Al**

electrode reaction : $\underset{1\,\mathrm{mol}}{\mathrm{Al^{3+}}(aq)} + \underset{3\,\mathrm{mol}}{3e^-} \longrightarrow \mathrm{Al}(s)$

Quantity of charge required for reduction of 1 mole of $\mathrm{Al^{3+}} = 3$ Faraday $= 3 \times 96500\ \mathrm{C} = 289500\ \mathrm{C}$

$$= 2.896 \times 10^5\ \mathrm{C}$$

(ii) **1 mol $\mathbf{Cu^{2+}}$ to Cu**

Electrode reaction : $\underset{1\mathrm{mol}}{\mathrm{Cu^{2+}}(aq)} + \underset{2\mathrm{mol}}{2\,e^-} \longrightarrow \mathrm{Cu}(s)$

Quantity of charge required for reducing 1 mole $\mathrm{Cu^{2+}}$ to Cu = 2 F = 2 × 96500 C = 193000 C = 1.93×10^5C

(iii) **1 mol $\mathbf{MnO_4^-}$ to $\mathbf{Mn^{2+}}$**

Electrode reaction : $\underset{\substack{(\text{ox.no.}\\ \text{of Mn} = 7)\\ 1\ \text{mol}}}{\mathrm{MnO_4^-}} + \underset{5\text{mol}}{5e^-} \longrightarrow \underset{\substack{(\text{ox.no.of}\\ \text{Mn} = 2)}}{\mathrm{Mn^{2+}}}$

Quantity of charge required for reducing 1 mole $\mathrm{MnO_4^-}$ to $\mathrm{Mn^{2+}}$ = 5 F = 5 × 96500 = 482500 C = 4.825×10^5C

21. Number of g-equivalent = number of faraday pass

$$4\ \mathrm{g} = 4\,\mathrm{F}$$

22. According to Faraday law, number of ions produced ∝ quantity of electricity passed.

23. $\mathrm{C_6H_5NO_2} + 6\mathrm{H^+} + 6e^- \longrightarrow \mathrm{C_6H_5NH_2} + 2\mathrm{H_2O}$

1 mol (= 123 g) nitrobenzene requires 6 moles of electrons

$$= 6 \times 96500\ \mathrm{C\ charge}$$

∴ 12.3 g nitrobenzene will require charge

$$= \frac{6 \times 96500 \times 12.3}{123}$$
$$= 6 \times 9650 = 57900\mathrm{C}$$

24. $w_{\text{metal}} = \dfrac{E \times i \times t}{96500} = \dfrac{E \times 3 \times 50 \times 60}{96500}$

$$\therefore \quad E = \frac{96500 \times w}{3 \times 50 \times 60} = \frac{96500 \times 1.8}{3 \times 50 \times 60} = 19.3$$

25. Quantity of electricity used = current in amperes × time in second

$$= 5\mathrm{A} \times (20 \times 60)\ \mathrm{s} = 6000\ \mathrm{C}$$

Chemical equation for the reaction during electrolysis :

$$\mathrm{Ni(NO_3)_2}(aq) + 2\mathrm{H^+} + \underset{2\mathrm{F}}{2e^-} \longrightarrow \underset{58.7\mathrm{g\ mol^{-1}}}{\mathrm{Ni}} + 2\mathrm{HNO_3}$$

Charge Q on n moles of electrons is given by : $Q = nF$

Charge required to deposit 1 mole nickel

$$= 2\,F = 2 \times 96500\ \text{C} = 1.93 \times 10^5\ \text{C}$$

Molar mass of nickel = 58.7g mol^{-1}

1.93×10^5 C of charge produces nickel = 58.7g

$$6000\ \text{C of charge produces nickel} = \frac{(58.7\text{g}) \times (6000\ \text{C})}{(1.93 \times 10^5\text{C})}$$

$$= 1.825\ \text{g}$$

26. $w_{\text{Ag}} = \dfrac{E_{\text{Ag}} \times Q}{96500} = \dfrac{108 \times 9.65}{96500} = 1.08 \times 10^{-2}\ \text{g} = 10.8\ \text{mg}$

27. Number of equivalents of silver formed

= number of equivalents of copper formed

In $AgNO_3$, Ag is in +1 oxidation state.

In $CuSO_4$, Cu is in +2 oxidation state.

$$\text{Equivalent weight of Ag} = \frac{108}{1} = 108\ \text{g equi}^{-1}$$

$$\text{Equivalent weight of Cu} = \frac{63.6}{2} = 31.8\ \text{g equi}^{-1}$$

$$\frac{w_1}{w_2} = \frac{E_1}{E_2}$$

$$\therefore \qquad \frac{10.79}{w_{\text{Cu}}} = \frac{108}{31.8}$$

$$\text{or} \qquad w_{\text{Cu}} = \frac{10.79 \times 31.8}{108} = 3.2\ \text{g}$$

31. $\text{Pt}(s)\,|\,H_2(g, 1\text{bar})\,|\,H^+(aq, 1\text{M})\,||\,Cu^{2+}(aq, 1\text{M})\,|\,Cu$

will be use to measure standard electrode potential of copper electrode.

32. $Zn + MgCl_2 \longrightarrow$ no reaction

This type of reaction does not occur because

$Mg^{2+} E^\circ = -\,2.37$ V, while $Zn^{2+} E^\circ = -\,0.76$ V

33. $Mg > Al > Zn > Fe > Cu$

It means that every metal on the left side can displace the next one (s) from its salt solution.

34. When the salt bridge is removed, potential drops to zero.

35. When $E_{\text{ext}} > E_{\text{cell}}$, the cell behaves like an electrolytic cell.

36. More negative or less positive is the value of reduction potential, stronger is the reducing agent.

Thus, the order of reducing tendency is

$$\underset{(1.51)}{Mn^{2+}} < \underset{(1.36)}{Cl^-} < \underset{(1.33)}{Cr^{3+}} < \underset{(-0.74)}{Cr}$$

37. Higher the value of reduction potential, stronger is the oxidising agent. Thus, MnO_4^- is the strongest oxidising agent.

38. During electrolysis of $CuSO_4$, Cu^{2+} gets discharged at cathode and OH^- at anode. Thus, solution becomes acidic due to excess of H^+ and SO_4^{2-} or H_2SO_4 (sulphuric acid).

39. Velocities of both K^+ and NO_3^- are nearly the same in KNO_3, so it is used to make salt-bridge.

40. Standard electrode potential of NHE is taken as 0.00 V at 298 K.

42. We know that, $\Delta G^\circ = -\,nFE^\circ$

$$\Delta G^\circ = -\,2.303\,RT \log K_c$$

$$\therefore \qquad nFE^\circ = 2.303\,RT \log K_c$$

$$\log K_c = \frac{nFE^\circ}{2.303\,RT}$$

$$= \frac{2 \times 96500 \times 0.295}{2.303 \times 8.314 \times 298}$$

$$\log K_c = 9.97$$

$$\therefore \qquad K_c = 1 \times 10^{10}$$

43. Mg lies above Cu in electrochemical series and hence, Cu electrode acts as cathode.

$$E^\circ_{\text{cell}} = E^\circ_{Cu^{2+}/Cu} - E^\circ_{Mg^{2+}/Mg}$$

$$\therefore \qquad 2.70\ \text{V} = 0.34 - E^\circ_{Mg^{2+}/Mg}$$

$$\therefore \qquad E^\circ_{Mg^{2+}/Mg} = -2.36\ \text{V}$$

44. For the reaction,

$$MnO_4^- + 4H^+ + 3e^- \longrightarrow MnO_2 + 2H_2O$$

$$-E_3 = \frac{-1.51 \times 5 + 2 \times 1.23}{3}$$

$$\therefore \qquad E_3 = 1.70\ \text{V}$$

45. For the cell reaction, Fe acts as cathode and Sn as anode. Hence,

$$E^\circ_{\text{cell}} = E^\circ_{\text{cathode}} - E^\circ_{\text{anode}}$$

$$= -\,0.44 - (-\,0.14) = -\,0.30\ \text{V}$$

The negative emf suggests that the reaction goes spontaneously in reversed direction.

46. H_2 is anode because oxidation takes place. Cu is cathode because reduction takes place.

47. $\frac{1}{2}H_2\ |\ H^+\,||\,Ag^+\,|\ Ag$

$$E^\circ_{\text{cell}} = E^\circ_{\text{cathode}} - E^\circ_{\text{anode}}$$

$$= E^\circ_{Ag^+/Ag} - E^\circ_{H^+/\frac{1}{2}H_2}$$

$$= (0.80) - (0.0) = 0.80\ \text{V}$$

48. Reduction potential of hydrogen electrode,

$$E_H = -\,\frac{2.303RT}{F} \log \frac{1}{[H^+]}$$

$$= -\,0.059\ \text{pH} = -\,0.059 \times 3$$

$$= -\,0.177\ \text{V}$$

49. The cell reaction is

$$H_2(g) + I_2(s) \rightleftharpoons 2H^+(aq) + 2I^-(aq)$$

$$0.7714 = 0.535 - \frac{0.0591}{2} \log \frac{[H^+]^2[I^-]^2}{p_{H_2}}$$

$$\therefore \qquad pH = 3$$

50. $Cu^{2+} + 2e^- \longrightarrow Cu$

$$E = E° - \frac{0.0591}{2} \log \frac{1}{[Cu^{2+}]}$$

$$= 0.34 - \frac{0.0591}{2} \log 100$$

$$= 0.34 - 0.0591 = 0.281 \text{ V}$$

51. In this reaction,

$$\underbrace{Fe^{2+} + \underbrace{Zn \longrightarrow Zn^{2+}}_{\text{Oxidation}} + Fe}_{\text{Reduction}}$$

$$\text{EMF} = E_{\text{cathode}} - E_{\text{anode}}$$

$$= -0.41 - (-0.76) = +0.35 \text{ V}$$

52. E_{cell} is an intensive property whereas $\Delta_r G$ for a cell reaction is an extensive property.

53. We know that, $\Delta G° = -nFE°$

$$-21.2 \times 10^3 = -1 \times 96500 \times E$$

$$E = \frac{21.2 \times 10^3}{96500} = 0.220 \text{ V}$$

54. Anode reaction $H_2(p_1) \longrightarrow 2H^+$

Cathode reaction $2H^+ \longrightarrow H_2(p_2)$

$$E_{\text{cathode}} = -\frac{RT}{2F} \ln \frac{p_2}{[H^+]^2}$$

$$E_{\text{anode}} = -\frac{RT}{2F} \ln \frac{[H^+]^2}{p_1}$$

$$E_{\text{cell}} = E_{\text{anode}} + E_{\text{cathode}}$$

$$= -\frac{RT}{2F} \ln \frac{[H^+]^2}{p_1} - \frac{RT}{2F} \ln \frac{p_2}{[H^+]^2}$$

$$= -\frac{RT}{2F} \ln \frac{p_2}{p_1}$$

$$= \frac{RT}{2F} \ln \frac{p_1}{p_2}$$

56. During charging of lead storage battery the reaction occurring is

$$2PbSO_4(s) + 2H_2O \longrightarrow Pb(s) + PbO_2(s) + 2H_2SO_4(aq)$$

57. At cathode $2H^+(aq) + 2e^- \longrightarrow 2H$

$$2H + \frac{1}{2}O_2 \longrightarrow H_2O$$

$$\overline{\underline{2H^+ + \frac{1}{2}O_2 + 2e^- \longrightarrow H_2O}}$$

Round II

1. $\Lambda_{eq} = \dfrac{\kappa \times 1000}{N}$, $\kappa = \dfrac{\Lambda_{eq} \times N}{1000} = \dfrac{100 \times 0.1}{1000} = 0.01 \text{ S cm}^{-1}$

$$G(\text{conductance}) = \frac{\kappa}{G^*(\text{cell constant})}$$

$$= \frac{0.01}{0.25} = 0.04\ \Omega^{-1} \text{ or S}$$

$$R = \frac{1}{G} = \frac{1}{0.04} = 25\ \Omega$$

$$\text{Current in ampere} = \frac{\text{potential difference (by Ohms's law)}}{\text{resistance (ohm)}}$$

$$= \frac{5}{25} = 0.2 \text{ A}$$

2. For solution A,

$$\text{Conductivity } (\kappa_A) = G(\text{Conductance}) \times G^*(\text{cell constant})$$

$$= \frac{1}{50} \times G^* \qquad \ldots(i)$$

For solution B,

$$\text{Conductivity } (\kappa_B) = \frac{1}{100} \times G^* \qquad \ldots(ii) \qquad \left(\begin{array}{l} \because G^* \text{ is same} \\ \text{for } A \text{ and } B \end{array}\right)$$

When equal volumes of A and B are mixed, dilution becomes doubled in both the solutions. Hence, their individual contribution towards the conductivity of the mixture will be $\kappa_A/2$ and $\kappa_B/2$, respectively, and conductivity of the mixture will be $\left(\dfrac{\kappa_A + \kappa_B}{2}\right)$.

$$\text{For the mixture : } \left(\frac{\kappa_A + \kappa_B}{2}\right) = \frac{1}{R} \times G^* \qquad \ldots(iii)$$

From Eqs. (i), (ii) and (iii), we get

$$R = 66.67\ \Omega$$

3. $\Lambda^{\circ}_{m\,(\text{complex solution})} = 2\lambda^{\circ}_{Co^{2+}} + \lambda^{\circ}_{[Fe(CN)_6]^{4-}}$

$$= 2 \times 80 + 440$$

$$= 600 \text{ S cm}^2 \text{ mol}^{-1}$$

$$\kappa_{\text{complex}} = \kappa_{\text{solution}} - \kappa_{H_2O}$$

$$= 2 \times 10^{-6} - 8 \times 10^{-7}$$

$$= 2 \times 10^{-6} - 0.8 \times 10^{-6}$$

$$= 1.2 \times 10^{-6} \text{ S cm}^{-1}$$

If S mol L^{-1} is the solubility of complex, then,

$$\Lambda_m^\circ = \Lambda_m = \frac{\kappa \times 1000}{S}$$

$$600 \text{ S cm}^2 \text{ mol}^{-1} = \frac{1.2 \times 10^{-6} \text{ S cm}^{-1} \times 1000 \text{ cm}^3}{S \text{ mol L}^{-1}}$$

$$\therefore \quad S = \frac{1.2 \times 10^{-6} \times 1000 \text{ cm}^3}{600} = 2 \times 10^{-6} \text{ mol L}^{-1}$$

$$\underset{}{Co_2[Fe(CN)_6] + aq} \rightleftharpoons \underset{2S}{2Co^{2+}} + \underset{S}{[Fe(CN)_6]^{4-}}$$

$$\therefore \quad K_{sp} = [Co^{2+}]^2[Fe(CN)_6^{4-}]$$

$$= (2S)^2 \times S = 4S^3$$

$$= 4 \times (2 \times 10^{-6})^3$$

$$= 3.2 \times 10^{-17} \text{ M}^3$$

4. Curve (b) is the conductimetric curve for strong acid and weak base.

5. **At cathode** $2\,H^+ + 2\,e^- \longrightarrow H_2$

At anode $2OH^- \longrightarrow H_2O + \frac{1}{2}O_2 + 2\,e^-$

6. Reaction for electrolysis of water is

$$2H_2O \rightleftharpoons 4H^+ + 2O^{2-}$$

$$2O^{2-} \longrightarrow O_2 + 4e^-$$

$$4e^- + 4H^+ \longrightarrow 2H_2$$

$\because$ $n = 4$,

So, 4 F charge liberates = 1 mol = 22.4 dm^3 oxygen.

$\therefore$ 1 F charge will liberate $= \frac{22.4}{4} = 5.6$ dm^3 oxygen

7. H_2 undergoes oxidation and $AgCl(Ag^+)$ undergoes reduction.

Hence, the cell is representing as

$$Pt\,|\,H_2(g), HCl(sol)\,||\,AgCl(s)\,|\,Ag$$

8. Since the order of reduction poential is

$$z > y > x$$

so z can oxidise x as well as y.

y can oxidise x but not z

x can reduce z as well as y.

9. A cation having highest reduction potential will be reduced first and so on. However, Mg^{2+} in aqueous solution will not be reduced ($E^\circ_{Mg^{2+}/Mg} < E_{H_2O/\frac{1}{2}H_2 + OH^-}$). Instead water would be reduced in preference.

Thus, the sequence of deposition of metals on the cathode is Ag, Hg, Cu.

10. The pH of 0.1 M HCl and 0.1 M acetic acid is not the same, because HCl is a strong acid, so its pH is less and CH_3COOH is a weak acid, so its pH is most.

11. Weight of Ag deposited = eq. wt. of Ag = 108 g

Weight of Ni deposited = eq. wt. of Ni = 29.5 g

Weight of Cr deposited = eq. wt. of Cr = 17.3 g

12. Cobalt is anode, *i.e.*, oxidation takes place on cobalt electrode *i.e.*, cell reaction is

$$Co + 2Ag^+ \longrightarrow Co^{2+} + 2Ag$$

$$E_{cell} = E^\circ_{cell} - \frac{RT}{nF}\ln\frac{[Co^{2+}]}{[Ag^+]^2}$$

Thus, less is the factor $\frac{[Co^{2+}]}{[Ag^{3+}]}$, greater is the E_{cell}.

13. $E^\circ_{cell} = 0.87 + 0.40 = 1.27$ V

Cell reaction : $Fe + Ni_2O_3 \longrightarrow FeO + 2NiO$

E_{cell} remains unaffected from the concentration of FeO.

14. Cell reaction : $\frac{1}{2}H_2(g) + Ag^+(x) \rightleftharpoons Ag(x) + H^+(1M)$

$$E = E^\circ - \frac{0.0591}{n}\log\frac{[H^+]}{[Ag^+]}$$

$$0.503 = 0.80 - \frac{0.0591}{1}\log\frac{1}{x}$$

$$x = 9.43 \times 10^{-6} \text{ M}$$

Number of moles of Ag^+ in 350 mL

$$= \frac{9.43 \times 10^{-6} \times 350}{1000} = 3.3 \times 10^{-6}$$

Mass of Ag $= 3.3 \times 10^{-6} \times 108 = 3.56 \times 10^{-4}$ g

Percentage of Ag in the ore $= \frac{3.56 \times 10^{-4}}{1.05} \times 100$

$$= 0.0339\%$$

15. We know that,

$$\Delta G^\circ = -\,nFE^\circ$$

$$Fe^{2+} + 2\,e^- \longrightarrow Fe$$

$$\Delta G^\circ = -\,2 \times F \times (-\,0.440 \text{ V}) = 0.880 \text{ F} \qquad \text{...(i)}$$

$$Fe^{3+} + 3\,e^- \longrightarrow Fe$$

$$\Delta G^\circ = -\,3 \times F \times (-\,0.036) = 0.108 \text{ F} \qquad \text{...(ii)}$$

On subtracting Eqs. (i) from (ii), we get

$$Fe^{3+} + e^- \longrightarrow Fe^{2+}$$

$$\Delta G^\circ = 0.108 \text{ F} - 0.880 \text{ F} = -\,0.772 \text{ F}$$

E° for the reaction $= -\frac{\Delta G^\circ}{nF} = -\frac{(-\,0.772 \text{ F})}{1 \times \text{F}} = +\,0.772$ V

16. For the given cell, reaction is

$$Zn + Fe^{2+} \longrightarrow Zn^{2+} + Fe$$

$$E = E^\circ - \frac{0.0591}{n}\log\frac{C_1}{C_2}$$

or, $$E^\circ = E + \frac{0.0591}{n}\log\frac{C_1}{C_2}$$

$$= 0.2905 + \frac{0.0591}{2}\log\frac{10^{-2}}{10^{-3}} = 0.32\text{ V}$$

$$E^\circ = \frac{0.0591}{2}\log K_c$$

$$\therefore \quad \log K_c = \frac{0.32 \times 2}{0.0591} = \frac{0.32}{0.0295}$$

$$K_c = 10^{\frac{0.32}{0.0295}}$$

17. Oxidation half-cell

$$\text{ClO}_3^- \longrightarrow \text{ClO}_4^- + 2e^-; \qquad E^\circ_{\text{cell}} = -0.36\text{ V}$$

Reduction half-cell

$$\text{ClO}_3^- + 2e^- \longrightarrow \text{ClO}_2^-; \qquad E^\circ_{\text{cell}} = 0.33\text{ V}$$

$$E^\circ_{\text{cell}} = 0.33 - 0.36 = -0.03 = \frac{RT}{2F}\ln K$$

or $$-0.03 = \frac{0.059}{2}\log K \quad \text{or} \quad K = 0.1$$

$$\underset{0.1-2x}{2\text{ClO}_3^-} \rightleftharpoons \underset{x}{\text{ClO}_4^-} + \underset{x}{\text{ClO}_2^-}$$

$$\frac{x^2}{(0.1-2x)^2} = 0.1$$

or $$x = 1.94 \times 10^{-2}$$

$$C = 0.1 - 2 \times 1.94 \times 10^{-2}$$

$$= 0.06$$

18. $$E_{\text{cell}} = E^\circ_{\text{cell}} - \frac{0.059}{n}\log\frac{[\text{Zn}^{2+}]}{[\text{Cu}^{2+}]}$$

$$= 1.10 - \frac{0.059}{2}\log\frac{0.1}{0.1}$$

$$= 1.10\text{ V}$$

19. Half-cell reaction is

$$\text{Cr}_2\text{O}_7^{2-} + 14\text{H}^+ + 6e^- \longrightarrow 2\text{Cr}^{3+} + 7\text{H}_2\text{O}$$

$$E_{\text{Cr}_2\text{O}_7^{2-}/\text{Cr}^{3+}} - E^\circ_{\text{Cr}_2\text{O}_7^{2-}/\text{Cr}^{3+}}$$

$$= -\frac{0.0591}{n}\log\frac{[\text{Cr}^{3+}]^2}{[\text{Cr}_2\text{O}_7^{2-}][\text{H}^+]^{14}}$$

$$= \frac{0.0591}{6}\log[10^{-3}]^{14} = -0.414\text{ V}$$

20. $$E_1 = E_0 - \frac{0.0591}{2}\log\frac{0.01}{1} = E_0 + \frac{0.0591}{2} \times 2$$

$$E_2 = E_0 - \frac{0.0591}{2}\log\frac{1}{0.01}$$

$$= E_0 - \frac{0.0591}{2} \times 2$$

$$\therefore \quad E_1 > E_2$$

21. The required reaction ($\text{Cu}^{2+} + \text{Cu} \longrightarrow 2\text{Cu}^+$) can be obtained by using the following reactions

$$\text{Cu}^{2+} + e^- \longrightarrow \text{Cu}^+, \quad E^\circ_{\text{Cu}^{2+}/\text{Cu}^+} = 0.15\text{ V} \qquad \text{...(i)}$$

$$\text{Cu}^{2+} + 2e^- \longrightarrow \text{Cu}, \quad E^\circ_{\text{Cu}^{2+}/\text{Cu}} = 0.34\text{ V} \qquad \text{...(ii)}$$

Multiplying Eq. (i) by 2, we get

$$2\text{Cu}^{2+} + 2e^- \longrightarrow 2\text{Cu}^+,$$

$$\Delta G_1 = -nFE = -2 \times F \times 0.15 \qquad \text{...(iii)}$$

$$\text{Cu}^{2+} + 2e^- \longrightarrow \text{Cu}$$

$$\Delta G_2 = -nFE = -2 \times F \times 0.34 \qquad \text{...(iv)}$$

Subtract the Eq. (iv) from Eq. (iii)

$$\text{Cu}^{2+} + \text{Cu} \longrightarrow 2\text{Cu}^+$$

$$\Delta G_3 = -nFE = -1 \times F \times E^\circ$$

Also, $$\Delta G_3 = \Delta G_1 - \Delta G_2$$

$$\therefore \quad -1FE^\circ = (-2F \times 0.15) - (-2F \times 0.34)$$

$$E^\circ = -0.38$$

This is the value for the reaction

$$\text{Cu}^{2+} + \text{Cu} \longrightarrow 2\text{Cu}^+$$

But the given reaction is just reverse of it.

$\therefore$ E_{cell} for given reaction $= +\ 0.38$ V

22. As ammonia is added the concentration of H^+ decreases thus oxidation potential increases by 0.65.

23. (i) Cell equation : $\text{Mg}(s) + \text{Cu}^{2+}(aq) \longrightarrow \text{Mg}^{2+}(aq) + \text{Cu}(s)$ $(n = 2)$

$$\text{Nernst equation : } E_{\text{cell}} = E^\circ_{\text{cell}} - \frac{0.0591}{2}\log\frac{[\text{Mg}^{2+}]}{[\text{Cu}^{2+}]}$$

$$\text{EMF of the cell, } E_{\text{cell}} = [0.34 - (-2.37)] - \frac{0.0591}{2}\log\frac{[10^{-3}]}{[10^{-4}]}$$

$$= 2.71 - 0.02955 = 2.68\text{V}$$

$$\text{EMF} = 2.68\text{V}$$

(ii) Cell equation : $\text{Fe}(s) + 2\text{H}^+(aq) \longrightarrow \text{Fe}^{2+}(aq) + \text{H}_2(g)$ $(n = 2)$

$$\text{Nernst equation : } E_{\text{cell}} = E^\circ_{\text{cell}} - \frac{0.0591}{2}\log\frac{[\text{Fe}^{2+}]}{[\text{H}^+]^2}$$

$$\text{EMF of the cell, } E_{\text{cell}} = [0 - (-0.44)] - \frac{0.0591}{2}\log\frac{[10^{-3}]}{[1]^2}$$

$$= 0.44 - \frac{0.591}{2} \times (-3)$$

$$= 0.44 + 0.0887$$

$$= 0.5287\text{ V} \approx 0.53\text{ V}$$

$$\text{EMF} = 0.53\text{V}$$

(iii) Cell equation : $\text{Sn}(s) + 2\text{H}^+(aq) \longrightarrow \text{Sn}^{2+}(aq) + \text{H}_2(g)$ $(n = 2)$

$$\text{Nernst equation : } E_{\text{cell}} = E^\circ_{\text{cell}} - \frac{0.0591}{2}\log\frac{[\text{Sn}^{2+}]}{[\text{H}^+]^2}$$

EMF of the cell,

$$E_{\text{cell}} = [0 - (-0.14)] - \frac{0.0591}{2}\log\frac{[0.05]}{[0.02]^2}$$

$$= 0.14 - \frac{0.0591}{2} \times (2.097)$$

$$= 0.14 - 0.0620 \approx 0.08 \text{ V}$$

$$\text{EMF} = 0.08 \text{ V}$$

(iv) Cell equation : $2Br^-(l) + 2H^+(aq) \longrightarrow Br_2(l) + H_2(g)$ $(n = 2)$

Nernst equation : $E_{cell} = E^\circ_{cell} - \frac{0.0591}{2} \log \frac{1}{[Br^-]^2[H^+]^2}$

EMF of the cell,

$$E_{cell} = [0 - 1.08] - \frac{0.0591}{2} \log \frac{1}{(0.01)^2 \times (0.03)^2}$$

$$= -1.08 - \frac{0.0591}{2} \log(1.111 \times 10^7)$$

$$= -1.08 - \frac{0.0591}{2} (7.0457)$$

$$= -1.08 - 0.208 = -1.288 \text{ V}$$

$$\text{EMF} = -1.288 \text{ V}$$

(∴ Oxidation will occur at hydrogen electrode and reduction at Br_2 electrode.)

Thus, emf is highest for Mg-Cu cell.

24. $E^\circ_{cell} = E^\circ_{(RHS)} - E^\circ_{(LHS)} = 1.61 - 1.51 = 0.10$ V

$$\Delta G^\circ = -nFE^\circ$$

$$= -5 \times 96500 \times 0.10 \text{ J}$$

$$\Delta G^\circ = -48.25 \text{ kJ}$$

25. We can write cell reaction to make H^+ and OH^- on RHS

$$H_2(g) \longrightarrow 2H^+(aq) + 2e^- \qquad E^\circ = 0.00 \text{ V}$$

$$2H_2O + 2e^- \longrightarrow H_2(g) + 2OH^-(aq) \qquad E^\circ = -0.8277 \text{ V}$$

$$2H_2O \longrightarrow 2H^+ + 2OH^-, n = 2 \quad E^\circ_{cell} = -0.8277 \text{ V}$$

$$\therefore \qquad Q = [H^+]^2[OH^-]^2 = K_w^2$$

or $\qquad H_2O \longrightarrow H^+ + OH^-,$

$$Q = [H^+][OH^-] = K_w \text{ for } n = 1$$

$$\therefore \qquad E_{cell} = 0.00 \text{ V (at equilibrium)}$$

$$\therefore \qquad E^\circ_{cell} = \frac{0.0591}{n} \log Q$$

$$-0.8277 = \frac{0.0591}{1} \log K_w \qquad \text{(if we use } n = 1)$$

$$-0.8277 = \frac{0.0591}{2} \log K_w^2 \qquad \text{(if we use } n = 2)$$

$$\log K_w = -14.0051$$

$$K_w = 1.012 \times 10^{-14}$$

26. $pH = 14 \quad \therefore \quad pOH = 0, [OH^-] = 1M$

$$\therefore \qquad [Cu^{2+}][OH^-]^2 = K_{sp} = 1.0 \times 10^{-19}$$

$$\therefore \qquad [Cu^{2+}] = 1 \times 10^{-19} \text{ M}$$

$$Cu^{2+} + 2e^- \longrightarrow Cu$$

$$\therefore \qquad E_{Cu^{2+}/Cu} = E^\circ_{Cu^{2+}/Cu} - \frac{0.0591}{2} \log \frac{1}{[Cu^{2+}]}$$

$$= 0.34 - \frac{0.0591}{2} \log 10^{19}$$

$$= 0.34 - \frac{0.0591 \times 19}{2}$$

$$= 0.34 - 0.56 = -0.22 \text{ V}$$

27. $2H^+ + 2e^- \longrightarrow H_2 \qquad Q = \frac{1}{[H^+]^2}$

$$E = E^\circ_{SHE} - \frac{0.0591}{2} \log \frac{1}{[H^+]^2}$$

$$-0.413 = 0 + \frac{0.0591}{2} \log [H^+]^2$$

$$0.413 = -0.0591 \log [H^+], \quad [\text{since}, -\log [H^+] = pH]$$

$$= 0.0591 pH$$

$$\therefore \qquad pH = \frac{0.413}{0.0591} = 7$$

28. Molar conductivity depends upon the concentration of electrolyte solution and temperature.

29. When aqueous solution of $CuSO_4$ is electrolysed by using copper electrodes, copper will dissolve from anode and gets deposited at cathode.

30. Nernst equation is

$$E = E^\circ - \frac{2.303RT}{nF} \log Q_c$$

At equilibrium,

$$E = 0 \quad \text{and} \quad Q_c = K_c$$

$$\therefore \qquad E^\circ = \frac{2.303\, RT}{nF} \log K_c$$

$$1.1 = \frac{2.303RT}{2F} \log K_c$$

or $\qquad 1.1 = \frac{0.059}{2} \log K_c$

$$\frac{2.2}{0.059} = \log K_c$$

$$K_c \text{ or } \log K_c \neq 1.1$$

31. In the given case,

$$E_{oxi} = -\frac{0.059}{1} \log \frac{[H^+]}{\sqrt{p_{H_2}}}$$

∴ Increase $[H^+]$ or decrease p_{H_2}, to decrease E_{oxi}

32. $E_{cell} = E^\circ_{cell} - \frac{RT}{nF} \ln \frac{[Zn^{2+}]}{[Cu^{2+}]}$. Decrease in $[Zn^{2+}]$ or increase in $[Cu^{2+}]$ will increase E_{cell}.

33. Since, ions are not involved in solution in case of mercury cell, its potential is steady.

34. The specific conductivity decreases while equivalent and molar conductivities increase with dilution.

35. $E_{Ag^+/Ag}$ has positive value.

For $E_{Ag^+/Ag}$

$$E = E° - \frac{0.0591}{1}\log\frac{1}{[Ag^+]}$$

$$= E° + 0.051 \log [Ag^+]$$

Thus, $E_{Ag^+/Ag}$ increases with increase in the concentration of Ag^+ ions.

36. Na metal is not produced at the cathode (instead H_2 is formed) because water contains H_3O^+ ions or H^+ ions which are stronger oxidising agent than Na^+, and are therefore more easily reduced.

37. For a cell to function, $E_{cell} = +\text{ ve}$

$$E_{cell} = E_{cathode} - E_{anode}$$

So, $\quad E_{cathode} > E_{anode}$

38. $M(s) + M^{\oplus}(1 M) \longrightarrow M^{\oplus}(0.5 M) + M(s)$

$$E^{\ominus}_{cell} = 0 \qquad \text{(for concentration cell)}$$

$$E_{cell} = E^{\ominus}_{cell} - \frac{2.303RT}{F}\log\frac{[M^{\oplus}]_{(0.05\,M)}}{[M^{\oplus}]_{(1\,M)}}$$

$$= 0 - \frac{2.303RT}{F}\log(5 \times 10^{-2}) \qquad \text{...(i)}$$

$$= +\text{ ve}$$

Hence, $|E_{cell}| = E_{cell} = 70$ mV and $\Delta G < 0$ for the feasibility of the reaction.

39. Substituting the value of $E_{cell} = 70$ mV in Eq. (i) in Q. 38, we get the value of $\frac{2.303RT}{F} = 0.0538$.

So, $$E_{cell} = E^{\ominus}_{cell} - \frac{0.0538}{1}\log(0.0025)$$

$$= 0 - \frac{0.0538}{1}(\log 5^2 + \log 10^{-4})[\log 5 \approx 0.7]$$

$$= -0.0538\,(2 \times 0.7 - 4)$$

$$= -0.0538 \times -2.6$$

$$= 0.1398 \text{ V} \approx 0.140 \text{ V} \approx 140 \text{ mV}$$

40. $$\Delta G° = -nE°_{cell}F$$

$$= -2 \times 96500 \times 1.2288$$

$$= -237.1584 \text{ kJ / mol}$$

So, thermodynamic efficiency $= \frac{237.1584}{285} = 0.83$

41. 560 mL of H_2 gas $= \frac{560}{11200}$ mol H_2 gas

$$= 0.05 \text{ mol}$$

$$= 0.05 \times 96500 \text{ C}$$

$$= 4825 \text{ C}$$

So, electric current $= \frac{4825}{600} = 8.04$ A

42. For the emissionless operation, the fuel cell is used in the motor car.

43. A cell reaction is spontaneous if $\Delta G° < 0$.

Since, $\quad \Delta G° = -nFE°_{cell}$

Thus, $\quad E°_{cell} > 0$

$$E°_{cell} = E°_{ox} + E°_{red}$$

$$\overbrace{X + Y^{2+} \longrightarrow X^{2+} + Y}^{\text{red}}$$
$$\underbrace{X + Y^{2+} \longrightarrow X^{2+}}_{\text{ox}}$$

(a) $\quad X = \text{Ni}, \; Y = \text{Fe}$

$$\text{Ni} + \text{Fe}^{2+} \longrightarrow \text{Ni}^{2+} + \text{Fe}$$

$$E°_{Ni/Ni^{2+}} = +0.23 \text{ V}$$

$$E°_{Fe^{2+}/Fe} = -0.44 \text{ V}$$

Thus, $\quad E°_{cell} = E°_{Ni/Ni^{2+}} + E°_{Fe^{2+}/Fe}$

$$= -0.21 \text{ V}$$

$$E°_{cell} < 0$$

(b) $\quad X = \text{Ni}, \; Y = \text{Zn}$

$$\text{Ni} + \text{Zn}^{2+} \longrightarrow \text{Ni}^{2+} + \text{Zn}$$

$$E°_{Ni/Ni^{2+}} = 0.23 \text{ V}$$

$$E°_{Zn^{2+}/Zn} = -0.76 \text{ V}$$

$\therefore \quad E°_{cell} = -0.53 \text{ V}$

$$E°_{cell} < 0$$

(c) $\quad X = \text{Fe}, \; Y = \text{Zn}$

$$\text{Fe} + \text{Zn}^{2+} \longrightarrow \text{Fe}^{2+} + \text{Zn}$$

$$E°_{cell} = E°_{Fe/Fe^{2+}} + E°_{Zn^{2+}/Zn}$$

$$= 0.44 - 0.76 = -0.32 \text{ V}$$

$$E°_{cell} < 0$$

(d) $\quad X = \text{Zn}, \; Y = \text{Ni}$

$$\text{Zn} + \text{Ni}^{2+} \longrightarrow \text{Zn}^{2+} + \text{Ni}$$

$$E°_{cell} = E°_{Zn/Zn^{2+}} + E°_{Ni^{2+}/Ni}$$

$$= 0.76 - 0.23$$

$$= 0.53 \text{ V}$$

$$E°_{cell} > 0$$

Thus, this reaction (d) is spontaneous.

44. Reduction hydrogen half-cell is

$$H^+\ (xM)\ \underset{+\ \text{Pressure}\ p_{H_2}}{|}\quad Pt(H_2)$$

Half-cell reaction is

$$2H^+\ (aq) + 2e^- \longrightarrow H_2(g)$$

Reaction quotient, $Q = p_{H_2}/[H^+]^2$, $n = 2$

$$E_{\text{red}} = E^\circ_{\text{red}} - \frac{0.0591}{n}\log Q$$

$$= 0 - \frac{0.0591}{2}\log Q$$

	p_{H_2}	$[H^+]$	Q	E_{red}
(a)	1 atm	2.0 M	0.25	+ve
(b)	1 atm	1.0 M	1.0	0
(c)	2 atm	1.0 M	2.0	–ve
(d)	2 atm	2.0 M	0.50	+ ve

[$E^\circ_{\text{red}} = 0.00$ V for standard hydrogen electrode]

If $Q > 1$, then $E_{\text{red}} = -$ ve.

45. Specific conductance = conductance × cell constant

$$1.3\ \text{Sm}^{-1} = \frac{1}{50}\ \text{S} \times \text{cell constant}$$

$$\therefore\ \text{Cell constant} = 1.3 \times 50\ \text{m}^{-1}$$

$$= 65\ \text{m}^{-1}$$

$$= (65/100)\ \text{cm}^{-1}$$

Molar conductivity

$$= \frac{1000 \times \text{conductance} \times \text{cell constant}}{\text{molarity}}$$

$$= \frac{1000}{0.4} \times \frac{1}{260} \times \frac{65}{100}$$

$$= 6.25\ \text{S cm}^2\ \text{mol}^{-1}$$

$$= 6.25 \times 10^{-4}\ \text{S m}^2\ \text{mol}^{-1}$$

46. $\frac{2}{3}\ Al_2O_3 \longrightarrow \frac{4}{3}\ Al + O_2$

$$\Delta G = +966\ \text{kJ mol}^{-1} = 966 \times 10^3\ \text{J mol}^{-1}$$

$$\Delta G = -nFE_{\text{cell}}$$

$$966 \times 10^3 = -4 \times 96500 \times E_{\text{cell}}$$

$$E_{\text{cell}} = 2.5\ \text{V}$$

47. Cr | Cr^{3+} (0.1 M) || Fe^{2+} (0.01 M) | Fe

Oxidation half cell

$$Cr \longrightarrow Cr^{3+} + 3e^-] \times 2$$

Reduction half cell

$$Fe^{2+} + 2e^- \longrightarrow Fe] \times 3$$

Net cell reaction

$$2Cr + 3Fe^{2+} \longrightarrow 2Cr^{3+} + 3Fe;\ n = 6$$

$$E^\circ_{\text{cell}} = E^\circ_{\text{oxid}} + E^\circ_{\text{red}}$$

$$= 0.72 - 0.42 = 0.30\text{V}$$

$$E_{\text{cell}} = E^\circ_{\text{cell}} - \frac{0.0591}{n}\log\frac{[Cr^{3+}]^2}{[Fe^{2+}]^3}$$

$$= 0.30 - \frac{0.0591}{6}\log\frac{(0.1)^2}{(0.01)^3}$$

$$= 0.30 - \frac{0.0591}{6}\log\frac{10^{-2}}{10^{-6}}$$

$$= 0.30 - \frac{0.0591}{6}\log 10^4$$

$$E_{\text{cell}} = 0.2606\ \text{V}$$

48. We know from Kohlrausch's law

$$\Lambda^\circ_{CH_3COOH} = \Lambda^\circ_{CH_3COONa} + \Lambda^\circ_{HCl} - \Lambda^\circ_{NaCl}$$

49. Cell is completely discharged, it means equilibrium gets established, $E_{\text{cell}} = 0$

$$Zn \mid Zn^{2+}\ (1\ M)\ \|\ Cu^{2+}\ (1\ M) \mid Cu$$

Cell reaction : $Zn + Cu^{2+} \rightleftharpoons Zn^{2+} + Cu$

$$K_{eq} = \frac{[Zn^{2+}]}{[Cu^{2+}]}$$

We know,

$$E_{\text{cell}} = E^\circ_{\text{cell}} - \frac{0.0591}{n}\log K_{eq}$$

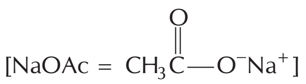
$$E^\circ_{\text{cell}} = \frac{0.0591}{n}\log K_{eq}$$

or $$1.10 = \frac{0.0591}{2}\log K_{eq}$$

$$K_{eq} = \frac{[Zn^{2+}]}{[Cu^{2+}]} = \text{antilog}\frac{2.20}{0.0591}$$

$$= \text{antilog } 37.3$$

50. According to Kohlrausch's law



$$[\text{NaOAc} = CH_3\overset{\overset{\displaystyle O}{\|}}{C}-O^-Na^+]$$

$$\Lambda^\circ_{CH_3COOH} = \lambda^\circ_{CH_3COO^-} + \lambda^\circ_{H^+} \qquad \text{...(i)}$$

$$\Lambda^\circ_{HCl} = \lambda^\circ_{H^+} + \lambda^\circ_{Cl^-} \qquad \text{...(ii)}$$

$$\Lambda^\circ_{CH_3COONa} = \lambda^\circ_{CH_3COO^-} + \lambda^\circ_{Na^+} \qquad \text{....(iii)}$$

Thus, on adding Eqs (ii) and (iii) if $\lambda^\circ_{Na^+}$ and $\lambda^\circ_{Cl^-}$ are subtracted we can obtained the value of Λ°_{HOAc}. Thus, additional value required is Λ°_{NaCl}.

51. $AgI(s) + e^- \rightleftharpoons Ag\ (s) + I^-$; $E^\circ = -\ 0.152$ N

$$\underline{Ag(s) \longrightarrow Ag^+ + e^- \quad ; \quad E^\circ = -\ 0.8\ \text{V}}$$

$$AgI(s) \longrightarrow Ag^+ + I^- \quad ; \quad E^\circ = -\ 0.952$$

$$E^\circ_{\text{cell}} = \frac{0.059}{n}\log K_{sp}$$

$$-0.952 = \frac{0.059}{1}\log K_{sp}$$

$$\log K_{sp} = \frac{-0.952}{0.059} = -16.135$$

52. $\Lambda^{\infty}_{AcOH} = \Lambda^{\infty}_{AcONa} + \Lambda^{\infty}_{HCl} - \Lambda^{\infty}_{NaCl}$

$$= 91.0 + 426.2 - 126.5 = 390.7$$

53. $Al^{3+} + 3e^{-} \rightarrow Al$

$$w = zQ$$

where, w = amount of metal

$$= 5.12 \text{ kg} = 5.12 \times 10^{3} \text{ g}$$

z = electrochemical equivalent

$$= \frac{\text{equivalent weight}}{96500}$$

$$= \frac{\text{atomic mass}}{\text{electrons} \times 96500}$$

$$= \frac{27}{3 \times 96500}$$

$$5.12 \times 10^{3} = \frac{27}{3 \times 96500} \times Q$$

$$Q = \frac{5.12 \times 10^{3} \times 3 \times 96500}{27} \text{ C}$$

$$= 5.49 \times 10^{7} \text{ C}$$

54. Any cell (like fuel cell), works when potential difference is developed.

55.

$$E^{\circ}_{Cr^{3+}/Cr^{2+}} = -0.41 \text{ V}$$

$$E^{\circ}_{Mn^{3+}/Mn^{2+}} = +1.57 \text{ V}$$

$$E^{\circ}_{Fe^{3+}/Fe^{2+}} = +0.77 \text{ V}$$

$$E^{\circ}_{Co^{3+}/Co^{2+}} = +1.97 \text{ V}$$

More negative value of E°_{red} indicates better reducing agent, thus easily oxidised. Thus, oxidation of Cr^{2+} to Cr^{3+} is the easiest.

56. $Zn(s) + 2H^{+} \longrightarrow Zn^{2+}(aq) + H_2(g)$

Reaction quotient, $Q = \dfrac{[Zn^{2+}]}{[H^{+}]^{2}}$

Corresponding cell is

$$\underset{\text{anode}}{\overset{-}{Zn}} \mid Zn^{2+}(C_1) \parallel H^{+}(aq) \mid \underset{\text{cathode}}{\overset{+}{Pt(H_2)}}$$

and $E_{cell} = E^{\circ}_{cell} - \dfrac{0.0591}{2}\log K$

$$= E^{\circ}_{cell} - \frac{0.0591}{2}\log\frac{[Zn^{2+}]}{[H^{+}]^{2}}$$

$$= E^{\circ}_{cell} + \frac{0.0591}{2}\log\frac{[H^{+}]^{2}}{[Zn^{2+}]}$$

If H_2SO_4 is added to cathodic compartment, (towards reactant side), then Q decrease (due to increase in H^{+}).

Hence, equilibrium is displaced towards right and E_{cell} increases.

57. More negative value of E° means higher reducing power. Thus, the correct order is

$$B > C > A$$

4 Chemical Kinetics

JEE Main MILESTONE

- Chemical Reactions
- Elementary and Complex Reactions
- Rate of a Chemical Reaction
- Rate Law and Rate Constant
- Molecularity of Reaction
- Order of Reaction
- Differential and Integral Forms of Different Order Reactions
- Methods of Determination of Order of Reaction
- Effect of Temperature on Rate of Reaction
- Theories of Rate of Reaction

4.1 Chemical Reactions

When one or more substance(s) undergoes such a change which result in the formation of a new product that differ from the original one in composition and properties, the change is called chemical reactions.

Chemical reactions involve breaking and formation of bonds. Therefore, different bonds require different amount of energy for breaking and different amount of energy is evolved during bond formation. Thus, the rates of different reactions are different.

Chemical kinetics is that branch of science which deals with the speeds or the rate of chemical reactions, the factors affecting the rate of reactions and the mechanism by which reactions proceed.

Types of Chemical Reactions

Depending upon their rates or speeds, chemical reactions can be classified as

(a) Instantaneous or Fast Reactions

These are infact very fast reactions and it is practically impossible to measure the speed of such reactions. Typical examples of such reactions include

(i) ionic reactions

(ii) organic substitution reactions

(iii) explosive reactions of oxygen with hydrogen and hydrocarbons.

(b) Extremely Slow Reactions

Such reactions proceed at very slow speed and here the speed is so slow that again it is not possible to measure the speed of such reactions, *e.g.,* rusting of iron.

(c) Moderately Slow Reactions

Reactions belonging to third category, *i.e.,* **with moderate speed** are utilised in the study of chemical kinetics. Inversion of cane sugar and hydrolysis of starch are common examples of this type of reactions.

4.2 Elementary and Complex Reactions

Elementary or Simple Reactions

The reactions taking place in one step are called elementary reactions.

Complex Reactions

The reactions which do not take place in one step are called complex reactions. These are the reactions in which all the atoms, ions, or molecules as represented in the balanced chemical reaction may not come together to collide simultaneously. *e.g.*,

$$5Br^{\ominus}(aq) + BrO_3^{\ominus}(aq) + 6H^+(aq) \longrightarrow 3Br_2(aq) + 3H_2O(l)$$

It is impossible for all the 12 ions of the reactant to come together simultaneously to collide. Such reactions are called complex reactions. Such reactions take place in a sequence of a number of steps. Each of these step reactions is called an elementary reaction. Molecularity is defined only for an elementary reaction, not for the complex reactions.

Caution Point *Different steps of complex reaction are also elementary reactions.*

4.3 Rate of a Chemical Reaction

The rate or speed or velocity of a reaction is the rate of change of concentration of reactants or products in unit time. When a reaction occurs, the concentration of reactants starts decreasing while the concentration of products starts increasing.

Therefore,

Rate of a reaction

$$= \frac{\text{decrease in the concentration of reactants}}{\text{time interval}}$$

or Rate of reaction

$$= \frac{\text{increase in the concentration of product}}{\text{time interval}}$$

e.g., in the reaction

$$A + B \longrightarrow C + D$$

$$\text{Rate of reaction} = -\frac{\Delta[A]}{\Delta t} \text{ or } -\frac{\Delta[B]}{\Delta t}$$
$$= +\frac{\Delta[C]}{\Delta t} \text{ or } +\frac{\Delta[D]}{\Delta t}$$

In general for a reaction,

$$n_1A + n_2B \longrightarrow m_1C + m_2D$$

The rate expression may be expressed as

$$\text{Rate of reaction} = -\frac{1}{n_1}\frac{\Delta[A]}{\Delta t} = -\frac{1}{n_2}\frac{\Delta[B]}{\Delta t}$$
$$= +\frac{1}{m_1}\frac{\Delta[C]}{\Delta t} = +\frac{1}{m_2}\frac{\Delta[D]}{\Delta t}$$

Caution Point *The negative sign indicates that the concentration of reactants decreases with time whereas the positive sign indicates that the concentration of products increases with time.*

Types of Rate of Reactions

The rate of a reaction can be categorised into

(a) Average Rate of Reaction

Average rate of a reaction is defined as the rate of change of concentration per unit time. It is calculated by dividing the total change in concentration of any one of the reactant or product by the total time taken to do so. For the reaction,

$$PCl_5 \longrightarrow Cl_2 + PCl_3$$

$$\text{Average rate} = \frac{\text{decrease in conc. of } PCl_5}{\text{time taken}}$$

It can also be expressed in terms of increase in concentration of PCl_3 and Cl_2 as

$$\text{Rate} = -\frac{\Delta[PCl_5]}{\Delta t} = +\frac{\Delta[Cl_2]}{\Delta t} = +\frac{\Delta[PCl_3]}{\Delta t}$$

Sample **Problem 1** *For the reaction, $R \longrightarrow P$, the concentration of a reactant changes from 0.03 M to 0.02 M in 25 min. Calculate the average rate of reaction using units of time in seconds.* **[NCERT]**

(a) 6.66×10^{-5} (b) 6.6×10^{-6}

(c) 5.67×10^{-5} (d) 7.26×10^{-6}

Interpret (*b*) For the reaction $R \longrightarrow P$

Average rate of reaction

$$= \frac{\text{change in concentration of reactant/product}}{\text{time taken}}$$
$$= \frac{-\Delta[R]}{\Delta t} = -\frac{[R_2]-[R_1]}{t_2 - t_1} = -\frac{(0.02 - 0.03)\text{ M}}{(25 \times 60)\text{ s}}$$
$$= -\frac{(-0.01)\text{ M}}{(1500)\text{ s}} = 6.66 \times 10^{-6}\text{ Ms}^{-1}$$
$$= 6.66 \times 10^{-6}\text{ mol L}^{-1}\text{ s}^{-1}$$

(b) Instantaneous Rate of Reaction

The rate of reaction at any particular instant of time is known as **instantaneous rate** of reaction. It is equal to the small change in concentration (dx) in small interval of time (dt).

$$\text{Rate} = \frac{dx}{dt}$$

In general, for a reaction,

$$n_1A + n_2B \longrightarrow m_1C + m_2D$$

The rate expression may be expressed as

$$-\frac{1}{n_1}\frac{\Delta[A]}{\Delta t} = -\frac{1}{n_2}\frac{\Delta[B]}{\Delta t}$$

$$= \frac{1}{m_1}\frac{\Delta[C]}{\Delta t} = \frac{1}{m_2}\frac{\Delta[D]}{\Delta t}$$

Thus, for the reaction,

$$2NO(g) + O_2(g) \longrightarrow 2NO_2(g)$$

stoichiometric coefficient of NO, O_2, and NO_2 are 2, 1, and 2, respectively, and hence, the rate is given by

$$\text{Rate} = \frac{-d[NO]}{2\,dt} = \frac{-d[O_2]}{dt} = \frac{-d[NO_2]}{2\,dt}$$

Caution Point *In aqueous solution, the rate of reaction is not expressed in terms of change of concentration of water because there is a negligible change, e.g., from* 55.5 *M to* 55.49 *M.*

Sample **Problem 2** *The decomposition of* NH_3 *on platinum surface is zero order reaction. What are the rates of production of* N_2 *and* H_2 *if* $k = 2.5 \times 10^{-4}$ mol^{-1} L s^{-1}? **[NCERT]**

(a) 3.75×10^{-4} *and* 1.25×10^{-4} *respectively*

(b) 1.25×10^{-4} *and* 3.75×10^{-4} *respectively*

(c) 3.75×10^{-3} *and* 2.45×10^{-3} *respectively*

(d) 1.25×10^{-3} *and* 3.25×10^{-3} *respectively*

Interpret (*b*) $2NH_3 \longrightarrow N_2 + 3H_2$

By dividing the equation by 2

$$NH_3 \longrightarrow \frac{1}{2}N_2 + \frac{3}{2}H_2$$

$$\text{Rate} = -\frac{d[NH_3]}{dt} = +\frac{2d[N_2]}{dt} = \frac{2}{3}\frac{d[H_2]}{dt}$$

For zero order reaction, rate $= k$

So, $$\frac{-d[NH_3]}{dt} = \frac{2d[N_2]}{dt} = \frac{2}{3}\frac{d[H_2]}{dt}$$

$$= 2.5 \times 10^{-4}\ \text{mol L}^{-1}\text{s}^{-1}$$

$\therefore$ Rate of production of $N_2 = \frac{d[N_2]}{dt}$

$$= \frac{(2.5 \times 10^{-4}\ \text{mol L}^{-1}\text{s}^{-1})}{2}$$

$$= 1.25 \times 10^{-4}\text{mol L}^{-1}\text{s}^{-1}$$

$\therefore$ Rate of production of

$$H_2 = \frac{d[H_2]}{dt} = \frac{3}{2} \times (2.5 \times 10^{-4}\ \text{mol L}^{-1}\text{s}^{-1})$$

$$= 3.75 \times 10^{-4}\ \text{mol L}^{-1}\text{s}^{-1}$$

Note For zero order reaction rate $= k$. You will read about this in further chapter.

Calculation of Rates by Graphical Method

To calculate rate, a graph is plotted between the concentration and time.

Then, rate is calculated as

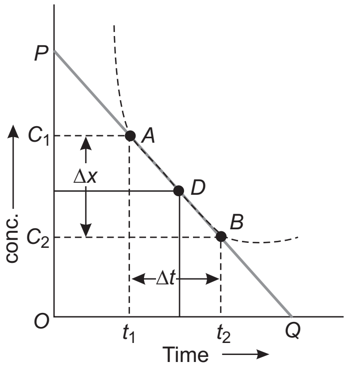

Fig. 4.1 Graph of concentration *vs* time

$$\text{Average rate} = \frac{\Delta x}{\Delta t} = \frac{C_2 - C_1}{t_2 - t_1}$$

$$\text{Instantaneous rate} = \frac{OP}{OQ}$$

Units of Rate of Reaction

Rate of reaction has the units of concentration or molarity divided by time. Therefore, the units of rate of reaction may be expressed as mol L^{-1} s^{-1} or mol L^{-1} min^{-1} etc.

In case of gaseous reactions, pressure is used in place of molar concentration and as pressure is expressed in atmosphere, therefore, the units of rate of reaction becomes atmosphere/sec or atmosphere/min etc.

Factors Affecting Rate of Reaction

The factors which affect the rate of reaction are as follows

(a) Concentration of Reactants

An increase in concentration of reactants increases the reaction rate.

(b) Nature of Reactants

The nature of bonds in a molecule influences the rate of reaction at which it changes into products.

(c) Temperature

Reaction rates are normally favoured by increase of temperature. The temperature effect is expressed in terms of temperature coefficient which is the ratio of the velocity constant of a reaction at two temperature differing by 10°C.

$$\text{Temperature coefficient} = \frac{k_{(t+10)°\text{C}}}{k_{t°\text{C}}}$$

For most of the reactions, the rate is doubled for every 10°C *rise in temperature.*

Sample **Problem 3** *The velocity constant of a reaction at 290 K was found to be* 3.2×10^{-3}. *At 300 K, it will be*

(a) 9.6×10^{-3}
(b) 3.2×10^{-4}
(c) 6.4×10^{-3}
(d) 1.25×10^{-2}

Interpret (c) As we know that the velocity constant become double by increasing the temperature by 10°C. So at 290 K, velocity constant $= 3.2 \times 10^{-3}$ then at 300 K,

velocity constant $= 2(k_{290}) = 2 \times 3.2 \times 10^{-3} = 6.4 \times 10^{-3}$

(d) Presence of Catalyst

A catalyst is a substance which alters the reaction rate but itself remains unchanged in amount and chemical composition at the end of the reaction. Actually the reactants in a reaction have to cross an energy barrier to form the product. The higher the energy barrier, the slower is the reaction rate.

A catalyst provides a new reaction path with a lower energy barrier. So that more and more reactant molecules can form the product. The same can be seen through the graph given below.

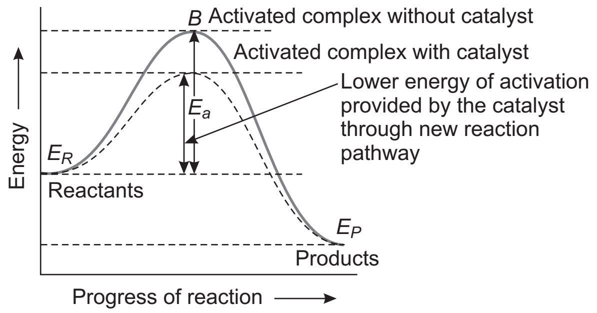

Fig. 4.2 Energy profile diagram in the absence and presence of catalyst

(e) Surface Area of Reactants

The rate of reaction increases as the surface area of the reactant increases.

(f) Presence of Light

Reaction rate normally becomes faster in the presence of light. Light gives the necessary activation energy for starting the reaction.

Check Point 1

1. What is the significance of writing negative and positive signs before the expression for rate of reaction?
2. Why is the use of instantaneous rate of reaction preferred over average rate of reaction?
3. Explain, why powdered sugar dissolves faster than crystalline sugar?
4. The rate of reaction, on increasing the temperature of the reaction system by 10°C becomes almost double. Explain it.

4.4 Rate Law and Rate Constant

The mathematical relation between the rate of reaction and the concentration of the reactants is termed as the Rate Equation or Rate Law Expression.

The rate law for a given reaction has to be established by experimental study of the rate over a wide range of concentration of the reactants. The rate law thus established is also called **differential rate equation** or **rate expression.**

If we consider the reaction,

$$A + B \longrightarrow \text{products}$$

Now if $[A]^\alpha$ and $[B]^\beta$ are the molar concentrations of A and B respectively then

$$\text{Rate} \propto [A]^\alpha [B]^\beta \quad \text{or} \quad \text{Rate} = k[A]^\alpha [B]^\beta$$

here, $k =$ velocity constant or rate constant

Now, if all concentrations are taken as unity, *i.e.,*

$$[A] = [B] = 1 \text{ mol/L}$$

then $\text{Rate} = k$

Thus, *rate constant is defined as the rate of the reaction when the concentration of each reactant is taken as unity.* It is also known as *specific reaction rate.*

Different Characteristics of rate constant are given below

1. It is the measure of the rate of reaction. Greater is the value of rate constant, faster is the reaction.
2. Each reaction has a particular value of rate constant at a particular temperature.
3. The value of rate constant for the same reaction changes with temperature.
4. The value of rate constant for a reaction does not depend upon the concentration of the reactants.

Unit of Rate Constant

Since the dimensions of rate are concentration/time and the SI units for concentration are mol m^{-3}, mol dm^{-3}, or mol L^{-1} and second for time but other units are used depending on how fast or slow is the reaction. For very slow reactions, time may be chosen in years and for very fast reactions it may be chosen in nano (10^{-9}) or pico (10^{-12}) second.

For the nth order of a reaction.

$$nA \longrightarrow \text{Product}$$

$$\text{Rate} = k[A]^n.$$

$$\therefore \qquad k = \frac{\text{Rate}}{[A]^n}$$

Thus, the dimensions of k are equal to

$$\frac{\text{Concentration / Time}}{[\text{Concentration}]^n} = [\text{Concentration}]^{1-n}[\text{Time}]^{-1}$$

$$= (\text{mol})^{1-n}\ \text{L}^{n-1}\ \text{s}^{-1}$$

where, n = order of reaction.

Units of Rate Constants for Gaseous Reactions

In case of gaseous reactions, concentrations are expressed in terms of pressure in the units of atmosphere. Thus, the rate has the units of atm per second. New the unit of different rate constants would be listed in the following table.

Table 4.1 **Units of Rate Constant**

	Reaction	Order	Unit of rate constant	Units of k for gaseous reactions
(a)	Zero order reaction	0	$\frac{(\text{mol L}^{-1})}{\text{s}} \times \frac{1}{(\text{mol L}^{-1})^0}$ $= \text{mol L}^{-1}\text{s}^{-1}$	atm s^{-1}
(b)	First order reaction	1	$\frac{(\text{mol L}^{-1})}{\text{s}} \times \frac{1}{(\text{mol L}^{-1})} = \text{s}^{-1}$	s^{-1}
(c)	Second order reaction	2	$\frac{(\text{mol L}^{-1})}{\text{s}} \times \frac{1}{(\text{mol L}^{-1})^2}$ $= \text{mol}^{-1}\text{ L s}^{-1}$	atm^{-1} s^{-1}
(d)	nth order reaction	n	$\frac{(\text{mol L}^{-1})}{s} \times \frac{1}{(\text{mol L}^{-1})^n}$ $= (\text{mol/L})^{1-n}\text{s}^{-1}$ $= \text{mol}^{1-n}\ \text{L}^{n-1}\text{s}^{-1}$	atm^{1-n} s^{-1}

Sample **Problem 4** *The decomposition of dimethyl ether leads to the formation of* CH_4, H_2 *and* CO *and the reaction rate is given by :*

Rate $= k[CH_3OCH_3]^{3/2}$. *The rate of reaction is followed by increase in pressure in a closed vessel, so the rate can be expressed in terms of the partial pressure of dimethyl ether i.e,* Rate $= k\,(p_{CH_3OCH_3})^{3/2}$. *If the pressure is measured in bar and time in minutes, then the units of rate and rate constants are respectively?* **[NCERT]**

(a) *bar* min^{-1}, *bar* min^{-1}
(b) min^{-1} bar^{-1}, *bar* min^{-1}
(c) *bar* min^{-1}, $bar^{-1/2}$, min^{-1}
(d) *bar* min^{-1}, $bar^{-3/2}$ min^{-1}

Interpret (c) Unit of rate = bar min^{-1}

$$\text{Unit of } k = \frac{\text{Rate}}{[(p_{CH_3OCH_3}]^{3/2}}$$

$$= \frac{\text{bar min}^{-1}}{(\text{bar})^{3/2}} = \text{bar}^{-1/2}\ \text{min}^{-1}$$

4.5 Molecularity of Reaction

It can be defined as "*The number of atoms or molecules which collide together at the same time for the reaction to occur*". Reactions are classified in terms of molecularity as unimolecular, bimolecular, termolecular depending upon the number of molecules involved in the reaction. Example of these reactions are as follows

Unimolecular reaction

$$PCl_5 \rightleftharpoons PCl_3 + Cl_2$$

Bimolecular reaction

$$CH_3COOC_2H_5 + NaOH \rightleftharpoons CH_3COONa + C_2H_5OH$$

Termolecular reaction

$$2FeCl_3 + SnCl_2 \longrightarrow 2FeCl_2 + SnCl_4$$

Caution Point *Only a few termolecular reactions are known while no reaction having molecularities more than three is known because more than three molecules may not mutually collide with each other.*

Determination of Molecularity

In case of simple reactions (elementary reactions), the molecularity is simply the sum of the molecules of different reactants as represented by the balanced chemical equation, *e.g.*,

$$O_2F_2 \longrightarrow O_2 + F_2 \qquad \text{(Unimolecular)}$$

$$2HI \longrightarrow H_2 + I_2 \qquad \text{(Bimolecular)}$$

$$2NO + O_2 \longrightarrow 2NO_2 \qquad \text{(Termolecular)}$$

In case of complex reactions (multistep reactions) the atoms, molecules or ions participating in rate determining step decide the molecularity. Among many steps, the **slowest step is the rate determining step.** So atoms, molecules or ions participating in this rate determining step, determine the molecularity of the reaction.

e.g., consider the reaction

$$HBrO_3 + 6HI \longrightarrow HBr + 3H_2O + 3I_2$$

The reaction takes place through following steps

$$HBrO_3 + HI \xrightarrow{\text{Slow}} HBrO_2 + HIO$$

$$HBrO_2 + 4HI \xrightarrow{\text{Fast}} HBr + 2H_2O + 2I_2$$

$$HIO + HI \xrightarrow{\text{Fast}} H_2O + I_2$$

Here, 2 molecules participate in the slowest step, thus reaction is of bimolecular type.

Characteristics of Molecularity

1. Molecularity of a reaction is always a whole number. It can never be fractional or zero.
2. It does not provide any idea about the rate or mechanism of the reaction.

4.6 Order of Reaction

In chemical kinetics the reactions are generally classified in terms of their order. The order of a reaction is defined as "*The sum of the concentration terms on which the rate of a reaction actually depends as observed experimentally*".

OR

"*The order of reaction is given as the sum of the exponents (powers) to which the concentration terms in the rate law equation are raised to express the observed rate of the reaction.*"

In the reaction rate expression,

$$\text{Rate} = k[A]^{\alpha}\,[B]^{\beta}$$

the sum $\alpha + \beta =$ **order of reaction**

Order of reaction is purely experimental quantity. It may be whole number, zero or in fractions. Depending upon whether $\alpha + \beta$ is equal to zero, 1, 2 or 3, the reactions are said to be of zero order, first order, second order or third order respectively.

Caution Points

(*i*) *Order of a reaction can change with change in conditions such as temperature, pressure etc.*

(*ii*) *When one of the reactants is present in large excess, the second order rate expression becomes a first order rate expression because the value of change in concentration for other reactant is taken as negligible.*

Sample **Problem 5** *A reaction is second order with respect to a reactant. How is the rate of reaction affected if the concentration of the reaction is*

(*i*) *doubled*
(*ii*) *reduced to half?* **[NCERT]**

(*a*) *Becomes 4 times and $\frac{1}{4}$ times respectively*
(*b*) *Becomes $\frac{1}{4}$ times and $\frac{1}{2}$ times respectively*
(*c*) *Becomes 2 times and 4 times respectively*
(*d*) *Becomes 4 times and 2 times respectively*

Interpret (*a*) (For II order reaction), rate $= k[A]^2$. Find the rate expression when concentration is doubled or reduced to half and compare it with the normal rate. e.g.,

For a reaction, $A \longrightarrow$ Products

$$\text{Rate} = k[A]^2 = ka^2$$

(i) When concentration of A is doubled

i.e., $[A] = 2a$

$$\text{Rate} = k(2a)^2 = 4ka^2$$

Rate of reaction becomes 4 times

(ii) When concentration of A is reduced to $\frac{1}{2}$

i.e., $[A] = \frac{1}{2}a$

$$\text{Rate} = k\left(\frac{a}{2}\right)^2 = \frac{1}{4}ka^2$$

Rate of reaction becomes $\frac{1}{4}$ times *i.e.,* reduced to one fourth.

The main differences between molecularity and order of reaction are tabulated below.

Table 4.2 **Difference between Order and Molecularity**

S.N.	Molecularity	Order of reaction
1.	It is the total number of reacting species (molecules, atoms or ions) which bring the chemical change.	It is the sum of powers of molar concentrations of the reacting species in the rate equation of the reaction.
2.	It is a theoretical concept.	It is experimentally determined.
3.	It is always a whole number.	It may be a whole number, zero, fractional, positive or negative.
4.	It is meaningful only for simple reactions or individual steps of a complex reaction.	It is meant for the reaction and not for its individual steps.

4.7 Differential and Integral Forms of Different Order Reactions

For a general reaction :

$$aA + bB \longrightarrow cC + dD$$

$$\text{Rate} = \frac{-d[R]}{dt} = k[A]^{\alpha}[B]^{\beta}$$

This form of the equation is called differential rate equation. It relates the rate of change of concentration with time or instantaneous rate. It is not always convenient to determine the instantaneous rate as it is measured by the determination of the slope of the tangent at point *t* in the concentration *versus* time curve. This makes it difficult to determine the rate law and hence, the determination of the order of the reaction. In order to avoid this difficulty, we can integrate the rate equation and obtain integrated rate equation that gives a relation between directly measured experimental quantities, *i.e.,* concentrations at different times. The integrated rate equations are different for reactions of different orders.

Zero Order Reactions

Reactions in which the concentration of reactants do not change with time and the concentration rates remain constant throughout are said to be zero order reactions.

For the reaction,

$$A \longrightarrow \text{products to be zero order,}$$

$$\text{Rate} = \frac{-d[A]}{dt} = k[A]^0 = k$$

or $$d[A] = -k\,dt$$

Integrating both sides, we get

$$[A] = -kt + I \qquad \text{...(i),}$$

where, *I* is a constant of integration

At $t = 0$, $[A] = [A]_0$

$\therefore$ $[A]_0 = I$

Substituting this value of *I* in Eq. (i), we get

$$[A] = -kt + [A]_0 \qquad \text{...(ii)}$$

or $$kt = [A]_0 - [A]$$

or $$k = \frac{1}{t}\{[A]_0 - [A]\} \qquad \text{...(iii)}$$

This is the expression for the rate constant for reactions of zero order.

Characteristics of Zero Order Reactions

1. Any reaction of zero order must obey Eq. (ii)

$$[A] = [A]_0 - kt$$

This shows that the plot of concentration of reactants against time will be a straight line passing through the origin.

2. Also, as the rate is independent of concentration, the plot of rate *versus* concentration will be a straight line parallel to the concentration axis.

Caution Point *The rate of reaction remains constant throughout the course of the reaction.*

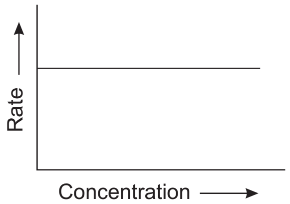

Fig 4.3 Plot of rate *versus* concentrations for the reaction of zero order

3. The units of rate constant for zero order reaction is mol L^{-1} time^{-1}.
4. The time required to reduce the initial concentration of the reactant to half of its initial value is called **half life time** or **half life period** and is denoted by $t_{1/2}$. When $[A] = [A]_0/2$, $t = t_{1/2}$, substituting these values in Eq. (iii), we get

$$t_{1/2} = \frac{1}{k}\{[A]_0 - [A]/2\} = \frac{[A]_0}{2k}$$

i.e., $$t_{1/2} = \frac{[A]_0}{2k}$$

or $$t_{1/2} \propto [A]_0.$$

Thus, the half-life period of zero order reaction is directly proportional to initial concentration, *i.e.,* $t_{1/2} \propto [A]_0$.

Caution Point *In zero order reaction, it is the amount of reactant that changes and not the concentration.*

Some Examples of Zero Order Reactions

(i) Photochemical synthesis of HCl, *i.e.,*

$$H_2(g) + Cl_2(g) \xrightarrow{h\nu} 2HCl$$

(ii) Decomposition of ammonia in the presence of a catalyst, *i.e.,*

$$2NH_3 \xrightarrow{\text{Mo or W}} N_2 + 3H_2$$

Hot Spot 1

FIRST ORDER Reactions

It is an important topic for JEE Main examination. The nature of question is generally numerical type. The level of question very from moderate to typical.

The **first order reaction** is defined as "The reaction in which the reaction rate is determined by the change of one concentration term of the reactant only", *e.g.,* In the reaction

$$\begin{array}{cccl} A & \longrightarrow & B + C & \\ a & & 0 \quad 0 & \text{(concentration initially)} \\ (a-x) & & x \quad x & \text{(concentration after time } t\text{)} \end{array}$$

The rate of reaction after time t is given by the expression.

$$\frac{dx}{dt} = k(a-x) \qquad \text{...(i)}$$

or $$\frac{dx}{(a-x)} = k\,dt$$

Upon integration of above equation,

$$\int \frac{dx}{(a-x)} = k \int dt$$

or $$-\log(a-x) = kt + c \qquad \text{...(ii)}$$

where c is the integration constant.

When $t = 0, x = 0$

$$c = -\log a$$

Putting the value of c in Eq. (ii), we get

$$-\log(a-x) = kt - \log a$$

or $$\log a - \log(a-x) = kt$$

or $$\log \frac{a}{(a-x)} = kt$$

or $$k = \frac{2.303}{t} \log \frac{a}{(a-x)}$$

or $$k = \frac{2.303}{t} \log \frac{[A]_0}{[A]} \qquad \text{...(iii)}$$

This is known as the **kinetic equation for a reaction of the first order.**

Eq. (iii) can be written in the exponential form as

$$\frac{[A]_0}{[A]} = e^{kt}$$

or $$\frac{[A]}{[A]_0} = e^{-kt}$$

or $$[A] = [A]_0 e^{-kt} \qquad \text{...(iv)}$$

Characteristics of First Order Reactions

1. Any reaction of the first order must obey Eq. (iii) which can also be written as

$$\log[A] = \frac{-kt}{2.303} + \log[A]_0 \qquad \text{...(v)}$$

This is the equation of a straight line ($y = mx + c$)

Thus, if log $[A]$ or log $(a-x)$ values are plotted against time t, the graph obtained should be a straight line. The intercept on y-axis would be log $[A]_0$ and the slope of the line would be equal to $\left(\frac{-k}{2.303}\right)$, *i.e.,* slope $= \frac{-k}{2.303}$

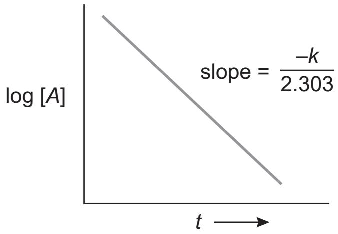

Fig. 4.4 Plot of log $[A]$ *vs* time (t)

Thus, if we plot log $\frac{[A]_0}{[A]}$ *versus t,* a staight line graph will be obtained with slope $= \frac{k}{2.303}$ as shown belown

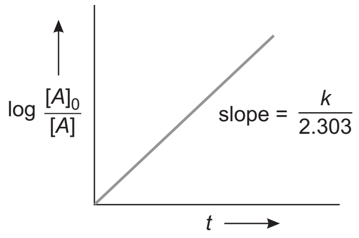

Fig. 4.5 Plot of log ($[A_0]/[A]$) *vs* time (t)

2. The time taken for the completion of same fraction of change *i.e.,* half life is independent of initial concentration. *e.g.*, for half change,

$$x = 0.5a \text{ and } t = t_{1/2}$$

so, $$k = \frac{2.303}{t_{1/2}} \log \frac{a}{0.5a} = \frac{2.303}{t_{1/2}} \log 2 = \frac{0.693}{t_{1/2}}$$

or $$t_{1/2} = \frac{0.693}{k}$$

Thus, $t_{1/2}$ is independent of initial concentration a.

3. Since the rate is independent of concentration and depends inversely on the time, the unit of k will be time^{-1}, *i.e.,* s^{-1} or h^{-1}.

4. Average life $(\lambda) = \frac{1}{k} = \frac{t_{1/2}}{0.693} = 1.443\,t_{1/2}$

5. Relation between $t_{1/2}$ and $t_{x\%}$ (amount decomposed):

$$t_{x\%\,\text{decomposes}} = \frac{2.3}{k}\log\left(\frac{100}{100-x}\right) \quad \text{...(vi)}$$

$$t_{1/2} = \frac{0.69}{k} = \frac{0.3 \times 2.3}{k} \quad \text{...(vii)}$$

Divide Eq. (vii) by (vi)

$$\frac{t_{1/2}}{t_{x\%}} = \frac{0.3}{\log\left(\dfrac{100}{100-x}\right)}$$

Sample Problem 6 *The half-life for radioactive decay of ^{14}C is 5730 yr. An archaeological artifact containing wood had only 80% of the ^{14}C found in a living tree. Estimate the age of the sample.* **[NCERT]**

(a) 1400 *yr* (b) 1500 *yr*
(c) 1850 *yr* (d) 1100 *yr*

Interpret (c) Decay constant $(k) = \frac{0.693}{t_{1/2}} = \frac{0.693}{5730}\text{ yr}^{-1}$

All radioactive decay follow first order kinetics

$$t = \frac{2.303}{k}\log\frac{[A]_0}{[A]}$$

Given, $[A] = 80\%$ It means that $[A]_0 = 100\%$

$$t = \frac{2.303 \times 5730}{0.693}\text{yr} \times \log\frac{100}{80}$$

$$= \frac{2.303 \times 5730 \times 0.0969}{0.693}$$

$$= 1845 \text{ yr}$$

Estimated age = 1845 yr

Sample Problem 7 *For a first order reaction, show how time required for 99% completion is related to the time required for the completion of 90% of reaction.* **[NCERT]**

(a) $t_{90\%} = 2 \times t_{99\%}$ (b) $t_{90\%} = 4 \times t_{99\%}$
(c) $t_{99\%} = \frac{1}{2} \times t_{90\%}$ (d) $t_{99\%} = 2 \times t_{90\%}$

Interpret (d) To solve out such problem follow the following steps.

Step I If $a = 100$; $(a - x) = (100 - 99) = 1$

For 99% completion of the reaction

$$t_{99\%} = \frac{2.303}{k}\log\frac{100}{1} = \frac{2.303}{k}\log 10^2$$

$$= \frac{2.303 \times 2}{k}$$

$$t_{99\%} = \frac{4.606}{k} \quad \text{...(i)}$$

Step II If $a = 100$; $(a - x) = (100 - 90) = 10$

For 90% completion of the reaction

$$t_{90\%} = \frac{2.303}{k}\log\frac{100}{10}$$

$$= \frac{2.303}{k}\log 10 = \frac{2.303}{k} \quad \text{...(ii)}$$

Step III On dividing Eq. (i) by Eq. (ii), we get

$$\frac{t_{99\%}}{t_{90\%}} = \frac{4.603}{k} \times \frac{k}{2.303} = 2$$

It means that time required for 99% completion of the reaction is twice the time required to complete 90% of the reaction.

Sample Problem 8 *The experimental data for decomposition of N_2O_5 $[2\,N_2O_5 \longrightarrow 4NO_2 + O_2]$ in gas phase at 318 K are given below :*

t/s	0	400	800	1200	1600	2000	2400	2800	3200
$10^{-2} \times [N_2O_5]$/ mol L^{-1}	1.63	1.36	1.14	0.93	0.78	0.64	0.53	0.43	0.35

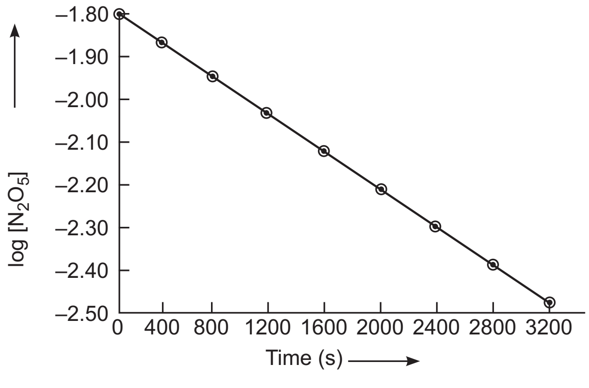
Calculate the rate constant and the half-life period. **[NCERT]**

(a) $4.8 \times 10^{-4}\ s^{-1}$, 1400 *s* (b) $3.92 \times 10^{-4}\ s^{-1}$, 1445 *s*
(c) $2.72 \times 10^{-4}\ s^{-1}$, 1200 *s* (d) $8.29 \times 10^{-4}\ s^{-1}$, 1575 *s*

Interpret (a) In order to solve such problem first we have to plot a graph between log $[A]$ and t and then obtain k from the slope and $t_{1/2}$ from K.

For graph between log $[N_2O_5]$ and time, we first find the values of log$[N_2O_5]$.

Time (s)	0	400	800	1200	1600	2000	2400	2800	3200
$[N_2O_5] \times 10^{-2}$ mol L^{-1}	1.63	1.36	1.14	0.93	0.78	0.64	0.53	0.43	0.35
log $[N_2O_5]$	–1.79	–1.87	–1.94	–2.03	–2.11	–2.19	–2.28	–2.37	–2.46



Since, the graph between log$[N_2O_5]$ and time is a straight line, the reaction is of first order.

The rate law : Rate = $k\,[N_2O_5]$

$$\text{Slope of the line} = -\frac{k}{2.303} = \frac{-2.46-(-1.79)}{3200-0} = \frac{-0.67}{3200}$$

$$\frac{-k}{2.303} = \frac{-0.67}{3200}$$

$$k = \frac{0.67 \times 2.303}{3200}$$

or $$k = 4.82 \times 10^{-4}\ \text{s}^{-1}$$

$$\text{Half-life period } (t_{1/2}) = \frac{0.693}{k}$$
$$= \frac{0.693}{4.82 \times 10^{-4}\ \text{s}^{-1}}$$
$$= 1438\ \text{s}$$

Typical First Order Gas Phase Reactions

Consider a typical first order gas phase reaction:

$$A(g) \longrightarrow B(g) + C(g)$$

Let p_0 be the initial pressure of A and p_t is the total pressure at time t. The integrated rate equation for such a reaction can be derived as :

Total pressure $(p_t) = p_A + p_B + p_C$ (pressure units), where p_A, p_B, and p_C are the partial pressures of A, B and C, respectively.

If x atmosphere be the decrease in the pressure of A at time t and one mole each of B and C is being formed, then increase in the pressure of B and C will also be x atm each.

	$A(g)$	$\longrightarrow$	$B(g)$	+	$C(g)$
At $t = 0$	p_0 atm		0 atm		0 atm
At time t	$(p_0 - x)$ atm		x atm		x atm

where p_0 is the initial pressure at time $t = 0$.

$$p_t = (p_0 - x) + x + x = p_0 + x$$
$$x = (p_t - p_0)$$

where, $$p_A = p_0 - x = p_0 - (p_t - p_0)$$
$$= 2p_0 - p_t$$
$$k = \left(\frac{2.303}{t}\right)\left(\log \frac{p_0}{p_A}\right)$$
$$= \frac{2.303}{t} \log \frac{p_0}{(2p_0 - p_t)} \qquad \text{...(i)}$$

Sample **Problem 9** *The following data were obtained during the first order thermal decomposition of* $N_2O_5(g)$ *at constant volume.*

$$2N_2O_5(g) \longrightarrow 2N_2O_4(g) + O_2(g)$$

S.N.	Time (s)	Total pressure (atm)
(i)	0	0.5
(ii)	100	0.512

Calculate the rate constant. **[NCERT Exemplar]**

(a) $3.39 \times 10^{-4}\ s^{-1}$

(b) $1.39 \times 10^{-5}\ s^{-1}$

(c) $5.45 \times 10^{-4}\ s^{-1}$

(d) $4.98 \times 10^{-4}\ s^{-1}$

Interpret (*d*) Let the pressure of $N_2O_5(g)$ decreases by $2x$ atm. As 2 moles of N_2O_5 decompose to give 2 moles of $N_2O_4(g)$ and 1 mole of $O_2(g)$, the pressure of $N_2O_4(g)$ increases by $2x$ atm and that of $O_2(g)$ increases by x atm.

	$2N_2O_5(g)$	$\longrightarrow$	$2N_2O_4(g)$	+	$O_2(g)$
When $t = 0$	0.5 atm		0 atm		0 atm
At time t	$(0.5 - 2x)$ atm		$2x$ atm		x atm

$$\text{Total pressure } (p_t) = p_{(N_2O_5)} + p_{(N_2O_4)} + p_{(O_2)}$$
$$= (0.5 - 2x) + 2x + x$$
$$= 0.5 + x$$
$$\therefore \qquad x = p_t - 0.5$$
$$p_{N_2O_5} = 0.5 - 2x$$
$$= 0.5 - 2(p_t - 0.5)$$
$$= 1.5 - 2p_t$$

At $t = 100$ s; $p_t = 0.512$ atm

$$p_{(N_2O_5)} = 1.5 - 2 \times 0.512 = 0.476\ \text{atm}$$
$$\therefore \qquad k = \frac{2.303}{t} \log \left(\frac{p_0\ (N_2O_5)}{p_A\ (N_2O_5)}\right)$$
$$= \frac{2.303}{100\ \text{s}} \log \left(\frac{0.5\ \text{atm}}{0.476\ \text{atm}}\right)$$
$$= \frac{2.303}{100\ \text{s}} \times 0.02136$$
$$= 4.92 \times 10^{-4}\ \text{s}^{-1}$$

Direct or Indirect Estimation of Reactants

Sometimes volumes of reagents are given in volumetric analysis (when one of the reactant is estimated directly or indirectly, *i.e.*, when V_∞ is not given). Let us take an example of decomposition of hydrogen peroxide (H_2O_2).

$$2H_2O_2(l) \longrightarrow 2H_2O(l) + O_2(g)$$

The rate of this first order reaction is measured by titrating a fixed volume of H_2O_2 (undecomposed) against a standard solution of $KMnO_4$. Here $KMnO_4$ acts as oxidizing agent and H_2O_2. acts as reducing agent. The volumes of $KMnO_4$ used for H_2O_2 after regular intervals of time are as follows.

Time instants	$t = 0$	t_1	t_2	t_3	t_4	t_5
Volume of $KMnO_4$	V_0	V_1	V_2	V_3	V_4	V_5

Volume of $KMnO_4$ at $t = 0$ corresponds to volume of H_2O_2 initially present.

$$\Rightarrow \qquad c_0 \propto V_0$$

Volume of $KMnO_4$ at time instant $t_1, t_2, t_3, \ldots$ corresponds to volume of H_2O_2 remaining after $t_1, t_2, t_3, \ldots$

$$\Rightarrow \qquad c_1 \propto V_t$$

Now, it being a first order reaction, follows first order kinetics, so

$$k = \frac{2.303}{t} \log \frac{V_0}{V_t}$$

Now, using the above expression, if we calculate the values of k for different intervals $t_1, t_2, \ldots$ (for actual numerical data), the values of k should be same if the reaction follows first order kinetics.

Sample **Problem 10** *In the dehydration of oxalic acid by conc.* H_2SO_4

$$(COOH)_2 \longrightarrow CO + CO_2 + H_2O$$

2 mL of the solution was withdrawn at different times and titrated against 0.1 *N* $KMnO_4$ *solution. Find the order of reaction.*

Time (mins)	0	300	450	600
Vol of $KMnO_4$ used (mL)	22.0	17.0	15.0	13.4

(*a*) 0 (*b*) 1 (*c*) 2 (*d*) 3

Interpret (*b*) $(COOH)_2 \longrightarrow CO + CO_2 + H_2O$

$$k = \frac{2.303}{t}\log\frac{V_0}{V_t}$$

(i) $$k = \frac{2.303}{300}\log\frac{22}{17} = \frac{2.303 \times 0.119}{300} = 0.00085\ \text{min}^{-1}$$

(ii) $$k = \frac{2.303}{450}\log\frac{22}{15} = 0.00085\ \text{min}^{-1}$$

(iii) $$k = \frac{2.303}{600}\log\frac{22}{13.4} = 0.00085\ \text{min}^{-1}$$

The value of k is constant. Hence, the reaction is of first order.

Direct or Indirect Estimation of Products

Consider a condition when one of the product is estimated directly or indirectly, *i.e.,* when V_0 is not given. *e.g.,* in the decomposition of NH_4NO_2, the volume of N_2 is directly measured at different intervals of time.

The volume of nitrogen (N_2) collected after a regular interval of times are as follows

Time instants	$t = 0$	t_1	t_2	t_3	t_4	t_∞
Volume of N_2	V_0	V_1	V_2	V_3	V_4	V_∞

At $t = 0$, clearly the volume of $N_2 = 0$.

Time instant $t = \infty$ means the end of a reaction, *i.e.,* when whole of NH_4NO_2 is decomposed.

At $t = \infty, V_\infty$ corresponds to the initial volume of NH_4NO_2.

Always keep in mind that the ratio of stoichiometric coefficient for both $N_2 : NH_4NO_2$ is 1 : 1

$$c_0 \propto V_t$$

At $t = t_1, t_2, t_3, \ldots$ the volume of N_2 corresponds to the concentration of product formed, *i.e.,* equal to x.

$$x \propto V_t$$
$$c_0 - x \propto V_\infty - V_t$$

Hence, from first order kinetic,

$$k = \frac{2.303}{t}\log\frac{V_\infty}{V_\infty - V_t}$$

Sample **Problem 11** *The following data were reported for the decomposition of* N_2O_5 *in* CCl_4 *at 303 K*

Time (min)	120	160	200	240	∞
Volume of O_2 (mL)	37.70	45.85	52.67	58.34	84.35

Calculate the rate constant.

(*a*) 0.089 min^{-1} (*b*) 0.0049 min^{-1}
(*c*) 0.0025 min^{-1} (*d*) 0.0035 min^{-1}

Interpret (*b*) $2N_2O_5 \longrightarrow 4NO_2 + O_2$

$$k = \frac{2.303}{t}\log\frac{V_\infty}{V_\infty - V_t}$$

(i) $$k = \frac{2.303}{120}\log\frac{84.35}{84.35 - 37.70} = \frac{2.303}{120}\log\frac{84.35}{46.65}$$

$$= \frac{2.303}{120} \times 0.2572 = 0.0049\ \text{min}^{-1}$$

(ii) $$k = \frac{2.303}{160}\log\frac{84.35}{84.35 - 45.85} = 0.0049\ \text{min}^{-1}$$

(iii) $$k = \frac{2.303}{200}\log\frac{84.35}{84.35 - 52.67} = 0.0049\ \text{min}^{-1}$$

(iv) $$k = \frac{2.303}{240}\log\frac{84.35}{84.35 - 58.34} = 0.0049\ \text{min}^{-1}$$

Since, the value of k is constant, the reaction is of first order. (Remember, here it is necessary to find out the value of k from all the values as if they are not same, the reaction is not of first order and does not follow this equation.)

Hydrolysis of Ester (CH_3COOR') in Acidic Medium

$$CH_3COOR'\ (\text{Ester}) + H_2O + HCl(H^{\oplus}) \longrightarrow CH_3COOH + R'OH$$

The reaction rate is measured by titrating the acid (CH_3COOH) produced against a standard alkali solution. Note that when a test sample is prepared from the reacting mixture, there are two acids : one is mineral acid $H^{\oplus}$ (HCl or any other) and second is CH_3COOH produced. So the volume of alkali used gives the titration value for both acids. The data is collected in the following manner.

Time instants	$t = 0$	t_1	t_2	t_3	t_4	t_∞
Volume of NaOH	V_0	V_1	V_2	V_3	V_4	V_∞

(i) When V_0 is given

At $t = 0, V_0$ is the volume NaOH used to neutralize the mineral acid present ($H^{\oplus}$) being used as catalyst (At $t = 0$, no CH_3COOH is yet produced)

At $t = \infty$ (*i.e.,* at the end of hydrolysis), V_∞ is the volume of NaOH used to neutralize whole of CH_3COOH plus the volume of HCl present. At $t = \infty$, the volume of CH_3COOH corresponds to the volume of ester taken initially.

$\Rightarrow$ $c_0 \propto V_\infty - V_0$ (as $V_0 \equiv$ volume of HCl)

At $t = t_1, t_2, t_3, \ldots, V_1, V_2, V_3, \ldots$ correspond to the volume of HCl plus the volume of CH_3COOH being produced.

$$\Rightarrow \quad x \propto V_t - V_0$$
$$\Rightarrow \quad c_0 - x \propto (V_\infty - V_0) - (V_t - V_0)$$
$$\Rightarrow \quad c_0 - x \propto V_\infty - V_t$$

Hence, from the first order kinetics, it follows :

$$k = \frac{2.303}{t} \log \frac{V_\infty - V_0}{V_\infty - V_t}$$

(ii) When V_0 is not given

Let $[V_\infty - V_0 = c_0$ and $V_\infty - V_t = c_t]$

When $t = t_1$, then

$$k = \frac{2.303}{t_1} \log \frac{c_0}{c_{t_1}} \qquad \text{...(i)}$$

Similarly, when $t = t_2$

$$k = \frac{2.303}{t_2} \log \frac{c_0}{c_{t_2}} \qquad \text{...(ii)}$$

Operating Eq. (i) – Eq. (ii), we get

$$k(t_1 - t_2) = 2.303 \log \frac{c_{t_2}}{c_{t_1}}$$

or
$$k = \frac{2.303}{(t_1 - t_2)} \log \frac{c_{t_2}}{c_{t_1}} \qquad \text{...(iii)}$$

Similarly, when $t = t_3$ and so on, we get

$$k = \frac{2.303}{(t_1 - t_3)} \log \frac{c_{t_3}}{c_{t_1}} \qquad \text{...(iv)}$$

Sample **Problem 12** *Methyl acetate is hydrolysed with* 0.1 *N* HCl *at* 25°*C. 5 mL of the reacting mixture is withdrawn at various time intervals and is quickly titrated with* 1.0 *N* NaOH. *The volumes of* NaOH *consumed are as follows :*

Time (s)	339	1242	2745	4546	∞
Volume of NaOH (mL)	26.34	27.80	29.70	31.81	39.81

Find the average rate constant (*k*).

(*a*) $4.29 \times 10^{-4}\ s^{-1}$ (*b*) $3.29 \times 10^{-4}\ s^{-1}$

(*c*) $8.68 \times 10^{-4}\ s^{-1}$ (*d*) $1.23 \times 10^{-4}\ s^{-1}$

Interpret (*d*) For ester hydrolysis, equation

$$k = \frac{2.303}{t} \log \frac{V_\infty - V_0}{V_\infty - V_t}$$

Since, V_0 is not given

or
$$k = \frac{2.303}{(t_1 - t_2)} \log \frac{c_{t_2}}{c_{t_1}} \qquad \text{...(iii)}$$

Now, find c_t.

t	339 s	1242 s	2745 s	4546 s
$c_t = V_\infty - V_t$	39.81 – 26.34 = 13.47 mL	39.81 – 27.80 ≈ 12.0 mL	39.81 – 29.70 = 10.11 mL	39.81 – 31.81 = 8.0 mL

and
$$t_1 - t_2 = 339 - 1242 = -903 \text{ s}$$
$$t_1 - t_3 = 339 - 2745 = -2406 \text{ s}$$
$$t_1 - t_4 = 339 - 4546 = -4207 \text{ s}$$

Using relation given in Eq. (iii),

$$\therefore \quad k_1 = \frac{2.303}{-903} \log \frac{12.0}{13.47} = -0.0025 \times \log (0.89)$$
$$= -0.0025 \times -0.0506 = 1.27 \times 10^{-4} \text{ s}^{-1}$$
$$k_2 = \frac{2.303}{-2406} \log \frac{10.11}{13.47} = -0.0095 \times \log (0.75)$$
$$= -0.00095 \times -0.1249 = 1.19 \times 10^{-4} \text{ s}^{-1}$$
$$k_3 = \frac{2.303}{-4207} \log \frac{8.0}{13.47} = -0.00054 \times \log (0.59)$$
$$= -0.00054 \times -0.2291 = 1.23 \times 10^{-4} \text{ s}^{-1}$$
$$k_{\text{average}} = 1.23 \times 10^{-4} \text{ s}^{-1}$$

Examples of First Order Reactions

(i) Decomposition of H_2O_2,

$$H_2O_2 \longrightarrow H_2O + \frac{1}{2} O_2$$

(ii) Dissociation of N_2O_5,

$$2N_2O_5 \longrightarrow 4NO_2 + O_2$$

(iii) Decomposition of ammonium nitrite,

$$NH_4NO_2 \longrightarrow N_2 + 2H_2O$$

(iv) Decomposition of SO_2Cl_2,

$$SO_2Cl_2 \longrightarrow SO_2 + Cl_2$$

(v) Inversion of cane sugar,

$$\underset{\text{sucrose}}{C_{12}H_{22}O_{11}} \xrightarrow{H_2O/H^+} \underset{\text{glucose}}{C_6H_{12}O_6} + \underset{\text{fructose}}{C_6H_{12}O_6}$$

(vi) Hydrolysis of methyl acetate,

$$CH_3COOCH_3 + H_2O \rightleftharpoons CH_3COOH + CH_3OH$$

Second Order Reactions

The reaction is said to be of **second order** if its reaction rate is determined by the variation of two concentration terms of reactants. It can be represented as

$$-\frac{\Delta R}{\Delta t} \text{ or } \frac{\Delta p}{\Delta t} = k[A]^2 \qquad (\text{For } 2A \longrightarrow \text{ product})$$

or
$$-\frac{\Delta R}{\Delta t} \text{ or } \frac{\Delta p}{\Delta t} = k[A][B] \quad (\text{For } A + B \longrightarrow \text{ product})$$

e.g., In the reactions where the concentrations of both the reactants are equal.

$$\begin{array}{cccccl} A & + & B & \longrightarrow & \text{Product} & \\ a & & a & & 0 & \text{(initially)} \\ (a-x) & & (a-x) & & x & \text{(after time t)} \end{array}$$

The rate constant, k for the reaction is given by

$$k = \frac{1}{t} \times \frac{x}{a(a-x)}$$

In cases where the concentration of reactants are not equal

$$\begin{array}{cccccl} A & + & B & \longrightarrow & \text{Product} & \\ a & & b & & 0 & \text{(initially)} \\ (a-x) & & (b-x) & & x & \text{(after time } t\text{)} \end{array}$$

The rate constant, k for the reaction is given by

$$k = \frac{2.303}{t(a-b)} \log_{10} \frac{b(a-x)}{a(b-x)}$$

The units of k are given as L mol^{-1} time^{-1}. The time required to complete a certain fraction of the reaction is inversely proportional to the initial concentration of reactants in the case of second order reactions.

Some examples of second order reactions are

(i) Dissociation of HI,

$$2HI \longrightarrow H_2 + I_2$$

(ii) Saponification of ethyl acetate,

$$CH_3COOC_2H_5 + NaOH \longrightarrow CH_3COO^-Na^+ + C_2H_5OH$$

(iii) Reaction between NO and O_3,

$$NO + O_3 \longrightarrow NO_2 + O_2$$

(iv) Reaction between potassium persulphate and potassium iodide,

$$K_2S_2O_8 + 2KI \longrightarrow 2K_2SO_4 + I_2$$

Third Order Reactions

A reaction is said to be of third order if its rate is determined by the variation of three concentration terms.

$$-\frac{\Delta R}{\Delta t} \text{ or } \frac{\Delta P}{\Delta t} = k[A]^3 \qquad \text{(For } 3P \rightarrow \text{product)}$$

or $$-\frac{\Delta R}{\Delta t} \text{ or } \frac{\Delta P}{\Delta t} = k[A][B][C] \qquad \text{(For } A + B + C \rightarrow \text{product)}$$

When the concentration of all the three reactants is same or three molecules of the same reactant are involved, the rate expression is given as

$$\begin{array}{cccccccl} A & + & B & + & C & \longrightarrow & \text{Product} & \\ a & & a & & a & & 0 & \text{(initially)} \\ (a-x) & & (a-x) & & (a-x) & & x & \text{(after time } t\text{)} \end{array}$$

The rate constant, k for the reaction is given by

$$k = \frac{1}{t} \cdot \frac{x(2a-x)}{2a^2(a-x)^2}$$

The units of rate constant for third order reaction are L^2 mol^{-2} time^{-1}

Reactions of **third** and **higher orders** are rare, but some examples of 3rd order reactions are definitely seen. This is due to the fact that the chances of three molecules of coming to a single point simultaneously, *i.e.*, probability of trimolecular collisions is much less as compared to unimolecular or bimolecular collisions.

Examples of third order reactions are

(i) $2NO + O_2 \longrightarrow 2NO_2$

(ii) $2NO + Cl_2 \longrightarrow 2NOCl$

(iii) $2NO + Br_2 \longrightarrow 2NOBr$

(iv) Reaction between silver acetate and sodium formate *i.e.*,

$$2CH_3COOAg + HCOONa \longrightarrow 2Ag + CO_2 + CH_3COOH + CH_3COO^-Na^+$$

Reactions Involving Order in Fraction

There are some reactions, rate of which is expressed by fractions of concentration terms. For example

(i) $$CO + Cl_2 \longrightarrow COCl_2$$
$$\text{Rate} = k[CO]^2[Cl_2]^{1/2}$$
Order = 2.5

(ii) $$COCl_2 \longrightarrow Cl_2 + CO$$
$$\text{Rate} = k[COCl_2]^{3/2}$$
Order = 1.5

(iii) $$CH_3CHO \longrightarrow CH_4 + CO$$
$$\text{Rate} = [CH_4CHO]^{3/2}$$
Order = 1.5

(iv) $$H_2 + Br_2 \longrightarrow 2HBr$$
$$\text{Rate} = k[H_2][Br_2]^{1/2}$$
Order = 1.5

(v) Reaction between H_2 and D_2
$$\text{Rate} = k_pH_2\,(p_{D_2})^{1/2}$$

The conversion of parahydrogen to orthohydrogen at high temperature; Rate = $k(p_{H_2})^{1.5}$.

The non-integer values are generally due to complex nature of reaction which involves more than one elementary step. The overall rate law is obtained by combining rates of individual elementary steps.

Negative Order Reactions

Sometimes the rate of reaction decreases as the concentration of one of the constituent is increased, *e.g.*, transformation of ozone into oxygen, *i.e.*, $2O_3 \longrightarrow 3O_2$

$$\text{rate} = -\frac{1}{2}\frac{d}{dt}[O_3] = K\frac{[O_3]^2}{[O_2]} = K[O_3]^2[O_2]^{-1}$$

Because the reaction involves two steps as

$$O_2 + O \xrightarrow{\text{Fast}} O_3 \qquad \text{...(i)}$$

$$O_3 + O \xrightarrow{\text{Slow}} 2O_2 \qquad \text{...(ii)}$$

Reaction (ii) gives the rate law as it is the slow step.

$$\text{Rate} = k[O_3][O] \qquad \text{...(iii)}$$

Since [O] is an intermediate species and takes part in the fast reaction, so

$$K' = \frac{[O_3]}{[O_2][O]} \text{ or } [O] = \frac{O_3}{K'[O_2]}$$

On putting the value of [O] in rate law, we get,

$$\text{Rate} = \frac{k[O_3][O_3]}{k'[O_2]} = k_1[O_3]^2[O_2]^{-1} \qquad [\text{where, } k_1 = k \cdot K']$$

Consecutive or Sequential Reactions

A reactant (A) decomposes to (B), which in turn decomposes to (C), *i.e.,*

$$A \xrightarrow[\text{Step 1}]{k_1} B \xrightarrow[\text{Step 2}]{k_2} C$$

$$\therefore \qquad \frac{-d[A]}{dt} = k_1[A], \ \frac{-d[B]}{dt} = k_1[A] - k_2[B],$$

$$\frac{-d[C]}{dt} = k_2[B]$$

If $t = 0$, $[B] = 0$, and $k_1 < k_2$, then at $t = t$.

$$[B]_t = \frac{k_1[A]_0}{k_2 - k_1}[e^{-k_1 t} - e^{-k_2 t}]$$

(where, $[A]_0$ = initial concentration of (A))

Also maximum concentration of $[B]$ at time t is given by

$$t_{\max} = \frac{2.303}{k_2 - k_1} \log\left[\frac{k_2}{k_1}\right]$$

Side or Parallel or Concurrent Elementary Reactions

A single reactant gives two products B and C simultaneously with different decay constants. For first order reaction:

$$A \begin{cases} \xrightarrow{k_1} B \ (90\%) \ (\text{Main reaction}) \\ \xrightarrow{k_2} C \ (10\%) \ (\text{Side reaction}) \end{cases}$$

$$\text{Rate} = -\frac{d[A]}{dt} = k_1[A] + k_2[A] = (k_1 + k_2)[A] = k_{av}[A]$$

If after a time interval say $x\,M$ of B are formed and $y\,M$ of C are formed, then if reaction is carried out with A, when $t = 0$, $[B] = [C] = 0$.

$$\therefore \qquad \frac{x}{y} = \frac{k_1}{k_2}$$

$$\text{Also} \qquad \frac{\frac{d[B]}{dt}}{\frac{d[C]}{dt}} = \frac{k_1}{k_2}$$

$$k_1 = (\% \text{ yield of } B) \times k_{av}$$

$$\Rightarrow \qquad \% \text{ yield of } B = \frac{k_1}{k_{av}} = \frac{k_1}{k_1 + k_2}$$

$$k_2 = (\% \text{ yield of } C) \times k_{av}$$

$$\Rightarrow \qquad \% \text{ yield of } C = \frac{k_2}{k_{av}} = \frac{k_2}{k_1 + k_2}$$

Some examples

(i) Phenol $\xrightarrow[\text{Nitration}]{}$ o-nitrophenol + p-nitrophenol

(ii) $$C_2H_5Br + KOH \begin{cases} \longrightarrow H_2C{=}CH_2 + KBr + H_2O \\ \longrightarrow C_2H_5OH + KBr \end{cases}$$

Opposed or Reversible Elementary Reactions

(i) $$H_2 + I_2 \underset{k_2}{\overset{k_1}{\rightleftharpoons}} 2HI$$

$$\text{Rate} = \frac{1}{2}\frac{d[HI]}{dt} = k_1[H_2][I_2] - k_2[HI]^2$$

(ii) $$2NO_2 \underset{k_2}{\overset{k_1}{\rightleftharpoons}} N_2O_4$$

$$-\frac{d[NO_2]}{dt} = 2k_1[NO_2]^2 - 2k_2[N_2O_4]$$

Case I First order-opposed by first order

$$A \underset{k_2}{\overset{k_1}{\rightleftharpoons}} B$$

$$\begin{array}{lcc} [t = 0] & a & 0 \\ [t = t] & a - x & x \end{array}$$

$$t = \frac{2.303}{(k_1 + k_2)} \log \frac{X_{eq}}{X_{eq} - x}$$

($X_{eq} = [B]$ formed at equilibrium)

Case II First order-opposed by first order

$$A \underset{k_2}{\overset{k_1}{\rightleftharpoons}} B.$$

$$\begin{array}{lcc} [t = 0] & a & b \\ [t = t] & a - x & b + x \end{array}$$

$$t = \frac{2.303}{(k_1 + k_2)} \log \frac{X_{eq}}{X_{eq} - x}$$

($X_{eq} = [B]$ formed a equilibrium)

Pseudomolecular Reactions

There are several reactions which are considered as unimolecular, although in reality they are bi-or tri-molecular, *e.g.,* consider the hydrolysis of methyl acetate in the presence of acid

$$CH_3COOCH_3 + H_2O \xrightarrow{\text{acid}} CH_3COOH + CH_3OH$$

According to the law of mass action, this reaction seems to follow bimolecular process with the rate dependent on concentration of both ester and water. However, it is found that the rate is independent of water, it depends only on concentration of ester. Hence, reactions showing such a behaviour are called **pseudounimolecular reactions.**

The pseudounimolecular nature of above written reaction can be explained on the basis of the fact that here water is present in such excess that its concentration remains practically constant during the course of reaction. The pseudounimolecular reactions are also called **pseudo first order reactions.**

4.8 Methods of Determination of Order of Reaction

Several methods are used to determine order of a reaction, like initial rate method, integration method, half-life method, Ostwald isolation method, etc.

1. Integration Method

The **integration method** is also called **hit and trial method.** In this method a, x and t are determined and substituted in kinetic equations of various orders. The equation which gives the most constant value of rate constant for a series of time intervals is the one to which the order of reaction corresponds.

In this method the kinetic equation used for same molar concentration are

$$k = \frac{2.303}{t} \log_{10} \frac{a}{a-x} \text{ for first order reactions}$$

$$k = \frac{1}{t}\left[\frac{1}{a-x} - \frac{1}{a}\right] \text{ for second order reactions}$$

$$k = \frac{1}{2t}\left[\frac{1}{(a-x)^2} - \frac{1}{a^2}\right] \text{ for third order reactions}$$

In general for the reactions of n order, given as below,

$$nA \longrightarrow \text{Products}$$

the rate equation of the form given below is obtained.

$$k_n = \frac{1}{t(n-1)}\left[\frac{1}{(a-x)^{n-1}} - \frac{1}{a^{n-1}}\right]$$

This equation is applicable for all orders except first order.

2. Half-life Method

The half-life method is also called **fractional change method.** The half-life period (time required to reduce the initial concentration to half of its value) depends differently on the initial concentrations of reactants for different orders of reactions, *i.e.,*

For zero order reaction

$$t_{1/2} \propto [A]_i$$

For first order reaction, $t_{1/2}$ is independent of initial concentration. For first order reaction half-life period depends upon the rate constant as

$$t_{1/2} = \frac{0.693}{k}$$

For n order reaction

$$t_{1/2} \propto \frac{1}{[A]_i^{n-1}}$$

Now suppose initial concentration of A is a, then

$$t_{1/2} \propto \frac{1}{a^{(n-1)}}$$

Starting with two independent reactions having initial concentrations a_1 and a_2 at corresponding half-lives $(t_{1/2})_1$ and $(t_{1/2})_2$ we have

$$(t_{1/2})_1 \propto \frac{1}{a_1^{(n-1)}}$$

$$(t_{1/2})_2 \propto \frac{1}{a_2^{(n-1)}}$$

or

$$\frac{(t_{1/2})_1}{(t_{1/2})_2} = \left(\frac{a_2}{a_1}\right)^{n-1}$$

Taking log on both the sides we obtain

$$\log \frac{(t_{1/2})_1}{(t_{1/2})_2} = (n-1) \log \left(\frac{a_2}{a_1}\right)$$

$$n = 1 + \frac{\log [(t_{1/2})_1/(t_{1/2})_2]}{\log (a_2/a_1)}$$

Hence, from this equation, n, the order of reaction is calculated.

For gaseous equations, the initial pressure (p) is taken instead of initial concentration a, thus, for them the above formula is changed to

$$n = 1 + \frac{\log [(t_{1/2})_1/(t_{1/2})_2]}{\log (p_2/p_1)}$$

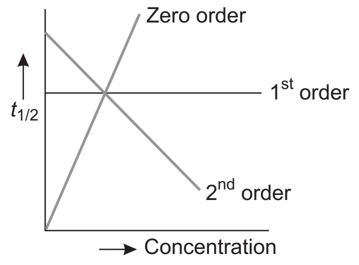


Fig. 4.6 Plots between half-life period and concentration

Average life is reciprocal of the rate constant

$$t_{av} = \frac{1}{k}$$

and for first order reaction,

$$t_{av} = 1.44 t_{1/2}$$

3. Ostwald Isolation Method

This method is employed in determining the order of complicated reactions by isolating one of the reactants so far as its influence on the reaction rate is concerned. Suppose the reaction under consideration is

$$n_1A + n_2B + n_3C \longrightarrow \text{products}$$

In this reaction for the determination of any of the reactants say A, rest of the reactants *i.e.*, B and C are taken in large excess, so that there is no change practically in their concentrations.

The order of the reaction for A is then determined by using any of the methods written before. The procedure is likewise for B and C also. *e.g.*, It is observed as follows

(i) Keeping the concentrations of B and C constant, if concentration of A is doubled, the rate of reaction becomes 4 times. This means that

$$\text{Rate} \propto [A]^2$$

i.e., order of reaction with respect to A is 2.

(ii) Keeping the concentrations of A and C constant, if concentration of B is doubled, the rate of reaction becomes 2 times. This means that

$$\text{Rate} \propto [B]$$

i.e., order of reaction with respect to B is 1.

(iii) Keeping the concentrations of A and B constant, if the concentration of C is doubled, the rate of the reaction remains unaffected. This means that rate is independent of concentration of C, *i.e.*, order of reaction with respect to C is zero.

Hence, the overall rate law expression will be

$$\text{Rate} = k\,[A]^2\,[B]\,[C]^0$$

Thus, order of reaction = 2 + 1 + 0 = 3

Hot Spot 2

INITIAL Rate Method

It is also an important topic of the chapter for JEE Main examination. The questions are generally numerical type and level of question is average generally.

In this method, the order of a reaction is determined by varying the concentration of one of the reactants while others are kept constant (The initial rate, r_1 is determined either numerically or from the slope of the curve of concentration *versus* time at time, $t = 0$)

Thus, for the reaction

$$aA + bB + cC \longrightarrow \text{product}$$
$$r_i = k\,[A_i]^a[B_i]^b[C_i]^c$$

Now if $[B]$ and $[C]$ remain constant,

$$r_i = k_i[A_i]^a \quad \text{where,} \quad k_i = k[B_i]^b[C_i]^c$$

Here the value of a can be determined by inspecting the rate at different values of $[A]$ as

If we know the initial rates at different concentration of A we have

$$[r_i]_1 = k_i[A_i]_1^a,\ [r_i]_2 = k_i[A_i]_2^a$$

where, $[r_i]_1$ and $[r_i]_2$ are the initial rates of reaction and $[A_i]_1$, and $[A_i]_2$ are initial concentrations of A. On dividing both the equations, we get

$$\frac{[r_i]_1}{[r_i]_2} = \left[\frac{[A_i]_1}{[A_i]_2}\right]^a$$

Taking log on both the sides, we obtain

$$\log\frac{[r_i]_1}{[r_i]_2} = a\log\frac{[A_i]_1}{[A_i]_2},$$

$$a = \frac{\log\,[(r_i)_1/(r_i)_2]}{\log\,[(A_i)_1/(A_i)_2]}$$

In this way, the order of reaction with respect to a is determined. Similarly, it can also be determined for other reactants also, The overall order of reaction is the sum of all such orders, *i.e.*,

$$n = a + b + c\ \ldots$$

Sample Problem 13 *In a reaction between A and B the initial rate of reaction (r_0) was measured for different initial concentrations of A and B as given below.*

A / mol L^{-1}	0.20	0.20	0.40
B / mol L^{-1}	0.30	0.10	0.05
r_0 / mol L^{-1}s^{-1}	5.07×10^{-5}	5.07×10^{-5}	1.43×10^{-5}

What is the rate law? **[NCERT]**

(a) $r = k[A]^2[B]$
(b) $r = k[A]^{1.5}[B]$
(c) $r = k[A][B]^2$
(d) $r = k[A]^{1.5}$

Interpret (*d*) Let the order of reaction with respect to A and B are respectively x and y, so rate law can be written as

$$\text{Rate} = k\,[A]^x\,[B]^y$$

On putting values,

$$(\text{Rate})_1 = k\,[0.20]^x\,[0.30]^y = 5.07 \times 10^{-5} \quad \ldots\text{(i)}$$
$$(\text{Rate})_2 = k\,[0.20]^x\,[0.10]^y = 5.07 \times 10^{-5} \quad \ldots\text{(ii)}$$
$$(\text{Rate})_3 = k\,[0.40]^x\,[0.05]^y = 1.43 \times 10^{-4} \quad \ldots\text{(iii)}$$

Dividing Eq. (i) by Eq. (ii)

$$\frac{(\text{Rate})_1}{(\text{Rate})_2}=\frac{k\,[0.20]^x\,[0.30]^y}{k\,[0.20]^x\,[0.10]^y}=\frac{5.07\times10^{-5}}{5.07\times10^{-5}}=1$$

$$[3]^y=[3]^0=1;\ y=0$$

Now dividing Eq. (ii) by Eq. (iii)

$$\frac{(\text{Rate})_2}{(\text{Rate})_3}=\frac{k\,[0.20]^x\,[0.10]^0}{k\,[0.40]^x\,[0.05]^0}=\frac{5.07\times10^{-5}}{1.43\times10^{-4}}$$

$$\left[\frac{1}{2}\right]^x=\frac{1}{2.82}$$

$$2^x=2.82$$

$$x\log 2=\log 2.82$$

$$\therefore\quad x=1.4957\simeq 1.5$$

Order with respect to $A=1.5$

Order with respect to $B=0$

$$r=k[A]^{1.5}[B]^0$$

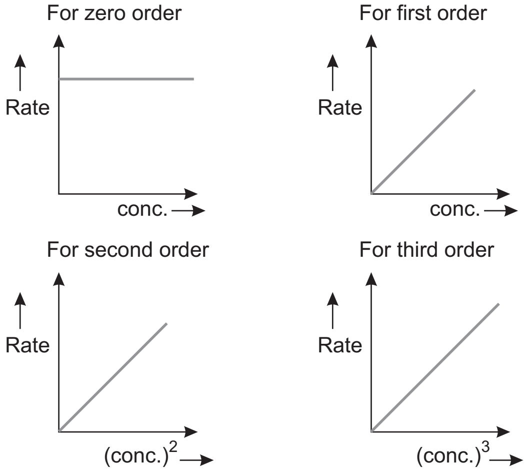
---

4. Graphical Method

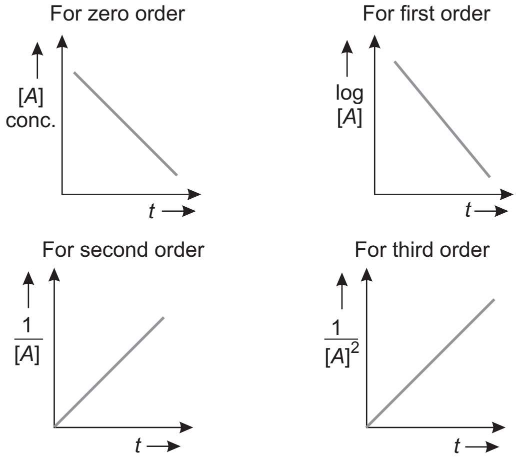
In this method, the values of $\Delta x/\Delta t$ at different intervals of time is determined by plotting a curve between x (the amount of substance decomposed) and time t. The value of $\Delta x/\Delta t$ at a particular time corresponding to a particular value of $(a-x)$ is given by the slope of the curve at that curve.

Linear Plots for Different Order Reactions are as

(a) Plots of Rate *vs* Concentration



(b) Plots From Integrated Rate Equations



Hence, in graphical method

1. If the plot of $\log(a-x)$ *versus* t is a straight line, the reaction follows first order.
2. If the plot of $\frac{1}{(a-x)}$ *versus* t is a straight line, the reaction follows second order.
3. If the plot of $\frac{1}{(a-x)^2}$ *versus* t is a straight line, the reaction follows third order.
4. If graphs are plotted between $\log\left(\frac{dx}{dt}\right)$ and $\log(a-x)$, the slope of the line gives the order of reaction.

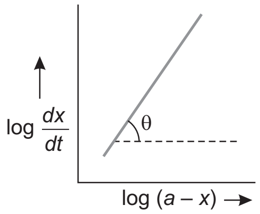


Fig. 4.7 Plot of $\log\left(\frac{dx}{dt}\right)$ *vs* $\log(a-x)$

$$\because\quad \frac{dx}{dt}=k(a-x)^n$$

$$\therefore\quad \log\left(\frac{dx}{dt}\right)=\log k+n\log(a-x)$$

Thus, slope $n=\tan\theta$

4.9 Effect of Temperature on Rate of Reaction

Rate constants and, therefore rate of a chemical reaction depends strongly on temperature. Typically rates of all reactions increase with increase in temperature. A rough rule, valid for many reactions in solution, is that near room temperature, rate constant (k) doubles or triples for each 10°C rise in temperature.

Arrhenius Equation

In year 1889, Arrhenius noted that $k(T)$ data for many reactions fit the equation.

$$k = Ae^{-E_a/RT}$$

here, A = a constant called frequency factor (because it gives the frequency of binary collisions of the reacting molecules per second per litre). It is also called **collision number** or **pre-exponential factor**

R = gas constant, T = absolute temperature

E_a = energy of activation

The factor $e^{-E_a/RT}$ is referred as Boltzmann factor and gives the fraction of molecules having energy equal to or greater than activation energy.

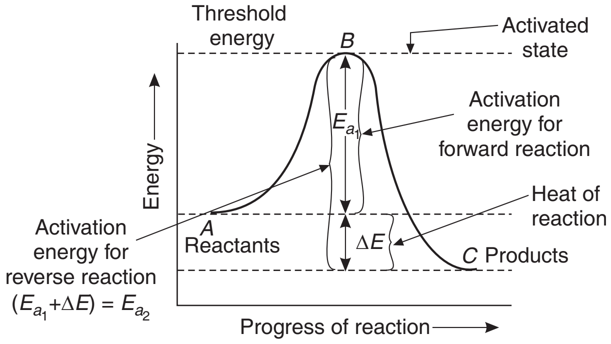
Hot Spot 3

ACTIVATION Energy

It is an another topic of the chapter from which questions have frequently seen in JEE Main examination. The question is generally numerical type and its level is easy to moderate.

The activation energy can also be defined as "The energy that activates passive or non-active molecules after its adsorption or minimum energy in excess to normal energy of molecules, which molecules must possess in order to form product on collision.

The concept of activation energy gives us an idea whether a given reaction is slow or fast at a given temperature. A reaction which has lower activation energy proceed at a faster rate at a given temperature or *vice-versa*. The differences in activation energy are mainly responsible for observed difference in rates of reactions. The concept of activation energy as applied to chemical reaction can be explained by plotting energy against the progress of reaction as shown in the figure below.



$$E_a = E_{th} - E_R$$

where, E_{th} = threshold energy (the minimum energy required over and above the energy possessed by the reactants in order to cross the energy barrier).

E_R = energy possessed by the reactant.

Calculation of Activation Energy

Activation energy can be calculated by knowing the rate constants at two different temperatures, assuming that E_a and A remains constant.

Taking log of both the sides in Arrhenius equation, we get

$$\ln k = \ln A - \frac{E_a}{RT}$$

Now, if the values of rate constant at temperatures T_1 and T_2 are k_1 and k_2 respectively then

$$\ln k_1 = \ln A - \frac{E_a}{RT_1} \qquad \text{...(i)}$$

$$\ln k_2 = \ln A - \frac{E_a}{RT_2} \qquad \text{...(ii)}$$

Subtracting the Eq. (i) from (ii), we get

$$\ln k_2 - \ln k_1 = -\frac{E_a}{RT_2} - \left(-\frac{E_a}{RT_1}\right)$$

$$= \frac{E_a}{RT_1} - \frac{E_a}{RT_2}$$

$$\ln \frac{k_2}{k_1} = \frac{E_a}{R}\left[\frac{1}{T_1} - \frac{1}{T_2}\right]$$

$$= \frac{E_a}{R}\left[\frac{T_2 - T_1}{T_1T_2}\right]$$

$$\log \frac{k_2}{k_1} = \frac{E_a}{2.303R}\left(\frac{T_2 - T_1}{T_1T_2}\right) \qquad \text{[Here, } T_2 > T_1\text{]}$$

This relation is used when rate constants at two different temperatures are given.

This reaction is also written as

$$\frac{d \log k}{dT} = \frac{E}{RT^2}$$

Arrhenius equation is purely an empirical equation that gives a reasonably good representation of temperature dependence of the rate constant.

When $\log k$ is plotted against $1/T$, we get a straight line which is represented by Arrhenius equation as

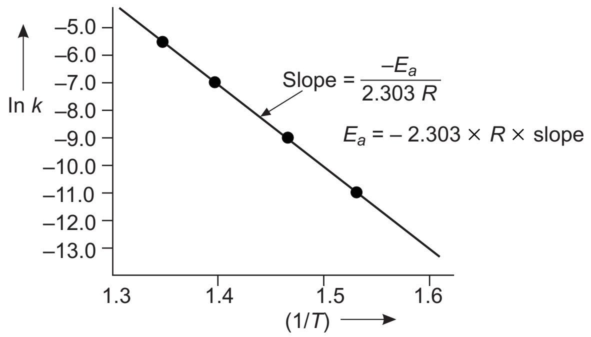
$$k = Ae^{-E_a/RT}$$

$$\ln k = \ln A - E_a/RT$$

$$\log k = \log A - \frac{E_a}{2.303\,RT}$$

The intercept of this line is equal to $\log A$ and slope is equal to $-\frac{E_a}{2.303\,R}$.

Therefore, $E_a = -2.303\,R \times \text{slope}$



Caution Points

(*i*) *Different reactions have different rates because their activation energies are different. Lesser the activation energy, faster is the reaction rate.*

(*ii*) *Activation energy can never be zero. If $E_a = 0$, then according to Arrhenius equation, $k = A$, i.e., every collision between molecules leads to a chemical reaction. This can never be true.*

Sample **Problem 14** *The rate constant for the first order decomposition of H_2O_2 is given by the following equation, $\log k = 14.34 - 1.25 \times 10^4\ \text{K}/\text{T}$. Calculate E_a for this reaction and at what temperature will its half-life period be 256 min?* **[NCERT]**

(a) 239.3 *kJ and* 669 *K*

(*b*) 846 *kJ and* 700 *K*

(c) 134.2 *kJ and* 492 *K*

(*d*) 239.3 *kJ and* 339 *K*

Interpret (*a*) **Calculation of activation energy E_a**

According to Arrhenius equation; $k = Ae^{-E_a/RT}$

$$\log k = \log A - \frac{E_a}{2.303\ RT} \quad \text{...(i)}$$

$$\log k = 14.34 - \frac{1.25 \times 10^4\ \text{K}}{T} \quad \text{...(ii)}$$

On comparing both equations.

$$\frac{E_a}{2.303RT} = \frac{1.25 \times 10^4\ \text{K}}{T}$$

$$E_a = 1.25 \times 10^4\ \text{K} \times 2.303 \times 8.314\ (\text{JK}^{-1}\ \text{mol}^{-1})$$

$$= 23.93 \times 10^4\ \text{J mol}^{-1}$$

$$= 239.3\ \text{kJ mol}^{-1}$$

Calculation of required temperature If $t_{1/2} = 256$ min.

For first order reaction ;

$$k = \frac{0.693}{t_{1/2}} = \frac{0.693}{(256\ \text{min})} = \frac{0.693}{256 \times 60\ \text{s}}$$

$$= 4.51 \times 10^{-5}\ \text{s}^{-1}$$

According to Arrhenius theory,

$$\log k = 14.34 - \frac{1.25 \times 10^4\ \text{K}}{T}$$

$$\log (4.51 \times 10^{-5}) = 14.34 - \frac{1.25 \times 10^4\ \text{K}}{T}$$

$$-4.35 = 14.34 - \frac{1.25 \times 10^4\ \text{K}}{T}$$

$$\frac{1.25 \times 10^4}{T} = 14.34 + 4.35 = 18.69$$

$$T = \frac{1.25 \times 10^4}{18.69} = 669\ \text{K}$$

Sample **Problem 15** *The first order rate constant for the decomposition of C_2H_5I by the reaction,*

$$C_2H_5I(g) \longrightarrow C_2H_4(g) + HI(g)$$

at 600 K is $1.60 \times 10^{-5}\ s^{-1}$. Its energy of activation is 209 kJ mol^{-1}. Calculate the rate constant at 700 K. **[NCERT Exemplar]**

(a) $4.87 \times 10^{-4}\ s^{-1}$

(*b*) $6.36 \times 10^{-3}\ s^{-1}$

(c) $1.98 \times 10^{-4}\ s^{-1}$

(*d*) $2.68 \times 10^{-3}\ s^{-1}$

Interpret (*b*) We know that

$$\log k_2 - \log k_1 = \frac{E_a}{2.303\ R}\left[\frac{T_2 - T_1}{T_1 T_2}\right]$$

$$\log k_2 = \log k_1 + \frac{E_a}{2.303R}\left[\frac{T_2 - T_1}{T_1 T_2}\right]$$

$$= \log (1.60 \times 10^{-5}) + \frac{209 \times 10^3\ \text{J mol}^{-1}}{2.303 \times 8.314\ \text{J mol}^{-1}\ \text{K}^{-1}} \times \left[\frac{10}{600 \times 700}\right]\text{K}$$

$$\log k_2 = -4.796 + 2.599 = 2.197$$

$$k_2 = \text{Antilog}\ (-2.197)$$

$$= \text{Antilog}\ (\bar{3}.803)$$

$$= 6.36 \times 10^{-3}\ \text{s}^{-1}$$

Sample **Problem 16** *How faster would a reaction proceed at 25°C than at 0°C if the activation energy is 65 kJ?*

(a) 11 *times* (b) 9 *times*
(c) 6 *times* (d) 2 *times*

Interpret (a) $2.303 \log \frac{k_2}{k_1} = \frac{E_a}{R}\left[\frac{T_2 - T_1}{T_1 T_2}\right]$

$$\therefore \qquad 2.303 \log \frac{k_2}{k_1} = \frac{65 \times 10^3}{8.314}\left[\frac{25}{298 \times 273}\right]$$

$$\therefore \qquad k_2/k_1 = 11.05$$

Sample **Problem 17** *Milk turns sour at 40°C three times faster as at 0°C. The energy of activation for souring of milk is*

(a) 5.683 *kcal* (b) 2.532 *kcal*
(c) 4.693 *kcal* (d) 4.246 *kcal*

Interpret (c) $2.303 \log \frac{k_2}{k_1} = \frac{E_a}{R} \frac{[T_2 - T_1]}{T_1 T_2}$

$$\therefore \qquad 2.303 \log 3 = \frac{E_a}{2} \frac{[313 - 273]}{313 \times 273}$$

$$E_a = 4.693 \text{ kcal}$$

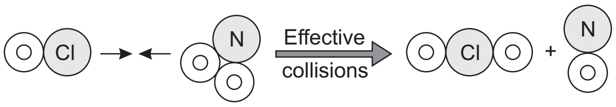
4.10 Theories of Rate of Reaction

Following theories are given to explain the rate of a reaction.

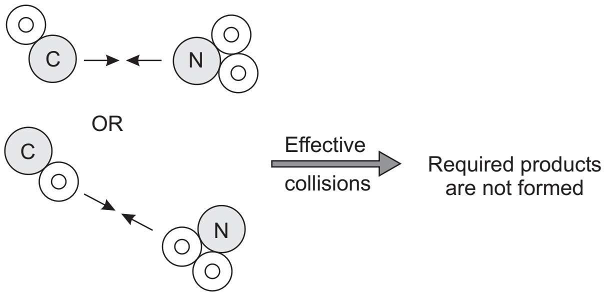
Collision Theory of Bimolecular Reactions

The collision theory states that

1. If two molecules are to react together, they must collide with each other.
2. The collision between all molecules do not lead to chemical reaction.
3. The collisions in which the molecules acquire energy greater than the activation energy, results in chemical reaction.



Properly oriented collisions to form products



Collisions are not properly oriented

Fig. 4.8 Orientation of reactants

4. The colloiding molecules must posses certain minimum energy (**threshold energy**) to make the collision effective.
5. The additional energy required by the molecule to attain threshold energy is called **activation energy.** During the collisions, this energy is acquired by the molecules as a result of interchange of energies. Thus,

Activation energy = threshold energy − energy of colliding molecules

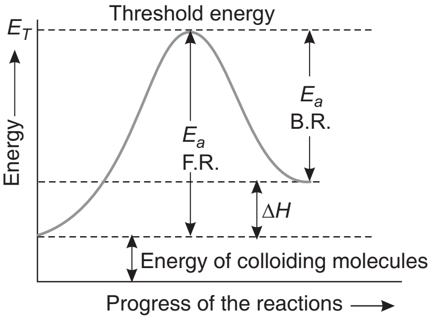


Fig. 4.9 Energy profile diagram

If we assume that the rate of reaction is equal to the rate of collisions per unit volume per unit time multiplied by the fraction of collisions (that have sufficient relative kinetic energy to overcome the energy barrier E^*) then the rate constant is given by the expression

$$k = Z_{AB} \cdot e^{-E^*/KT} \qquad \text{...(i)}$$

here, Z_{AB} = **collision frequency factor,** *i.e.*, the number of collisions between reactant molecules A and B per unit volume per unit time divided by N_A and N_B, the number of molecules per unit volume of A and B respectively.

It can be shown by kinetic theory of gases that

$$Z_{AB} = (8KT/\pi\mu)^{1/2}\pi d^2$$

here, $\mu = \frac{m_A \times m_B}{m_A + m_B}$ *i.e.*, reduced mass of colliding reactant molecules

$d = r_A + r_B$ *i.e.*, the sum of radii of two reactant molecules. Now, putting the value of Z_{AB} in Eq. (i), we get

$$k = \left(\frac{8KT}{\pi\mu}\right)^{1/2} \times \pi d^2 \times e^{-E^*/KT}$$

If we assume that energy required for Avogadro number of effective collisions, $E_a = N_A E^*$ then

$$k = \left(\frac{8KT}{\pi \mu}\right)^{1/2} \times \pi d^2 \times e^{-E_a/RT}$$

$$k = Z_{AB} \times e^{-E_a/RT}$$

For a successful collision, however it is also important that the molecules must be oriented properly in space alongwith their energy requirements. Thus, if P is the **orientation factor** (also called steric factor) then above rate equation can be changed as

$$K = PZ_{AB}\, e^{-E_a/RT}$$

Now, if we compare above equation, with Arrhenius equation we get

$$A = PZ_{AB}$$

where, $A =$ Arrhenius collision factor

Transition State Theory

This theory is also known as **absolute reaction rate theory** or **activated complex theory.** This theory is based on the idea that bond breaking and bond making involved in a chemical reaction must occur continuously or simultaneously. According to this theory

1. The reactant molecules must come together to form an activated complex, whose energy is higher than the reactant molecules.
2. The activated complex is supposed to be in equilibrium with the reactant molecules and has all the attributes of normal molecule except that one of the vibrational degree of freedom is converted into translational degree of freedom.
3. This complex though unstable, has a transient existence and its potential energy is maximum. Finally it decomposes into products.
4. The energy of activation according to this theory is the additional energy which the reacting molecules must acquire to form the activated complex.

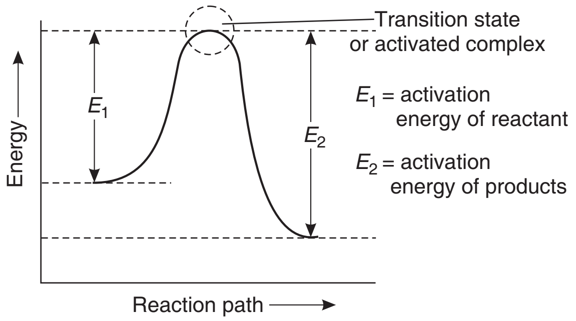

Fig. 4.10 Energy profile diagram of an exothermic reaction

Mathematical Expression of Transition State Theory

Consider the following reaction

$$A + B \longrightarrow X^* \longrightarrow \text{products}$$

The equilibrium constant, K^* for the activated complex is,

$$K^* = \frac{[X^*]}{[A][B]}$$

or $$[X^*] = K^*[A][B] \qquad \text{...(i)}$$

Now, according to transition state theory, the rate of reaction is the number of activated complexes which pass over the potential barrier per unit time, which in turn is equal to the concentration of activated complexes multiplied by the frequency at which the complex would decompose into products. Mathematically

$$\text{Rate of reaction} = \frac{d\,[\text{product}]}{dt}$$

$$\frac{\Delta x}{\Delta t} = [X^*] \times \text{ rate of dissociation of activated complex}$$

Now, putting the value of $[X^*]$ from the above Eq. (i) we get

$$\frac{\Delta x}{\Delta t} = K^*[A][B] \times \text{rate of dissociation of activated complex} \qquad \text{... (ii)}$$

The activated complex would decompose only if the enough vibrational energy is supplied to the system *i.e.,* vibration degree of freedom will be converted into translational degree of freedom. Due to this vibrational energy, the atoms vibrate with certain critical frequency leading to the bond rupture. This frequency of bond rupture is equal to the frequency with which the activated complex decomposes into products.

Therefore,

frequency for the dissociation of activated complex $= E_{\text{vib}}/h$

where, $E_{\text{vib}} =$ average vibrational energy at temperature T

Vibrational energy is also equal to kT or $\frac{RT}{N}$.

where R = universal gas constant
N = Avogadro number.
and $h =$ Planck's constant
Thus, frequency $= RT/Nh$

Now putting this value into Eq. (ii), we get

$$\frac{\Delta x}{\Delta t} = K^*[A][B] \times \frac{RT}{Nh} \qquad \text{...(iii)}$$

We also know that for a bimolecular conversion of reactants into products,

$$\frac{\Delta x}{\Delta t} = k\,[A][B] \qquad \text{...(iv)}$$

Putting this value into Eq. (iii) we get

$$k[A][B] = k^*[A][B] \times \frac{RT}{Nh}$$

$$\therefore \qquad k = k^* \times \frac{RT}{Nh} \qquad \text{... (v)}$$

This is called mathematical statement of transition state theory.

Relation Between K^* and ΔG^*

K^* can be correlated with ΔG^* as

$$\Delta G^* = -RT \ln K^*$$

where $\Delta G^* =$ [free energy of activated complex – free energy of reactants] and called **standard free energy change.**

So $\qquad \Delta G^* = \Delta H^* - T\Delta S^*$

or $\qquad -RT \ln k^* = \Delta H^* - T\Delta S^*$

or $\qquad \ln k^* = \dfrac{-(\Delta H^* - T\Delta S^*)}{RT}$

or $\qquad k^* = e^{-(\Delta H^* - T\Delta S^*)/RT} \qquad$ ...(vi)

Putting this value into the mathematical statement of transition state theory, we get

$$k = e^{-(\Delta H^* - T\Delta S^*)/RT} \times \frac{RT}{Nh}$$

also $\qquad k = \dfrac{RT}{Nh} \times e^{-\Delta H^*/RT} \cdot e^{\Delta S^*/R}$

here, $\Delta H^* =$ standard enthalpy change, *i.e.,* standard heat of activation

$\Delta S^* =$ standard entropy change, *i.e.,* standard entropy of activation

The activation energy for the forward reaction (E_a^f) and the activation energy for the reverse reaction (E_a^r) are related to the enthalpy (ΔH) of the reaction by the equation

$$\Delta H = E_a^f - E_a^r$$

For endothermic reaction,

$$\Delta H > 0 \Rightarrow E_a^r < E_a^f$$

For exothermic reaction,

$$\Delta H < 0 \Rightarrow E_a^r > E_a^f$$

Check Point 3

1. Molecularity of reaction is not found more than three. Why?
2. Can a reaction has zero activation energy?
3. Explain, why hydrogen and oxygen do not react at room temperature?
4. Differentiate between the chemical reactions having high and low activation energy.

WORKED OUT
Examples

Example 1 *The rate law for a reaction between the substances A and B is given by rate $= k[A]^a [B]^b$. On doubling the concentration of A and halving the concentration of B, the ratio of the new rate to the earlier rate of the reaction will be as*

(a) $2^{\frac{1}{a+b}}$ (b) $a+b$ (c) $a-b$ (d) $2^{(a-b)}$

Solution (d)

$$r_1 = k[A]^a [B]^b$$

$$r_2 = k[2A]^a \left[\frac{B}{2}\right]^b = k[A]^a [B]^b \, 2^{(a-b)}$$

$$\therefore \quad \frac{r_2}{r_1} = 2^{(a-b)}$$

Example 2 *The rate constant k, for the reaction*

$N_2O_5(g) \longrightarrow 2NO_2(g) + \frac{1}{2}O_2(g)$ *is* $2.3 \times 10^{-2} s^{-1}$. *Which equation given below describe the change of* $[N_2O_5]$ *with time?* $[N_2O_5]_0$ *and* $[N_2O_5]_t$ *correspond to concentration of* N_2O_5 *initially and at time* t.

(a) $[N_2O_5]_t = [N_2O_5]_0 + kt$

(b) $[N_2O_5]_t = [N_2O_5]_0 \, e^{kt}$

(c) $\ln \frac{[N_2O_5]_0}{[N_2O_5]_t} = kt$

(d) $\log_{10}[N_2O_5]_t = \log_{10}[N_2O_5]_0 - kt$

Solution (c) $N_2O_5(g) \longrightarrow 2NO_2(g) + \frac{1}{2}O_2(g)$

$$\text{Rate constant} = 2.3 \times 10^{-2} \text{ s}^{-1}$$

The unit of rate constant (*i.e.*, s^{-1}), shows that reaction is of first order.

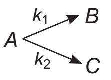
For first order reaction,

$$k = \frac{1}{t}\ln\frac{a}{a-x} \quad \Rightarrow \quad k = \frac{1}{t}\ln\frac{[N_2O_5]_0}{[N_2O_5]_t}$$

or

$$\ln\frac{[N_2O_5]_0}{[N_2O_5]_t} = kt$$

Example 3 *A substance undergoes first order decomposition. The decomposition follows the parallel first order reactions as*



$k_1 = 1.26 \times 10^{-4} \text{ s}^{-1}$

$k_2 = 3.8 \times 10^{-5} \text{ s}^{-1}$

The percentage distribution of B and C are

(a) 76.83, 23.17 (b) 24.9, 75.1

(c) 60, 40 (d) 50, 50

Solution (a) % distribution of $B = \frac{k_1}{k_1 + k_2} \times 100$

$$= \frac{1.26 \times 10^{-4}}{1.26 \times 10^{-4} + 3.8 \times 10^{-5}} \times 100$$

$$= 76.83\%$$

and, % distribution of $C = \frac{k_2}{k_1 + k_2} \times 100$

$$= \frac{3.8 \times 10^{-5}}{1.26 \times 10^{-4} + 3.8 \times 10^{-5}} \times 100$$

$$= 23.17\%$$

Example 4 *For a chemical reaction,* $A \to B$, *the rate of reaction increases by a factor of 1.837 when the concentration of A is increased by 1.5 times. The order of reaction with respect to A is*

(a) 0 (b) 1 (c) 1.5 (d) 2

Solution (c)

$$r_1 = k[A]^n$$

$$r_2 = 1.837\, r_1 = k[1.5 \text{ A}]^n$$

$$\therefore \quad \frac{r_2}{r_1} = 1.837 = (1.5)^n$$

$\Rightarrow \quad n = \frac{3}{2} = 1.5$ (On solving by logarithmic method)

Example 5 *For a reaction* $A + B \longrightarrow C + D$, *if the concentration of A is doubled without altering the concentration of B, the rate gets doubled. If the concentration of B is increased by nine times without altering the concentration of A, the rate gets tripled. The order of the reaction is*

(a) 1 (b) 1.5 (c) 2 (d) –1

Solution (b) For reaction, $A + B \longrightarrow C + D$

$$r_1 = k[A]^a [B]^b \qquad \text{...(i)}$$

$$r_2 = 2r_1 = k[2A]^a [B]^b \qquad \text{...(ii)}$$

and

$$r_3 = 3r_1 = k[A]^a [9B]^b \qquad \text{...(iii)}$$

From (i) and (ii) $a = 1$

Form (i) and (iii), $b = \frac{1}{2}$

$$\therefore \quad \text{Order} = a + b$$

$$= 1 + \frac{1}{2} = \frac{3}{2} = 1.5$$

Example 6 *The time of completion of 90% of the first order reaction is approximately*

(a) $4.4t_{1/2}$ (b) $3.3t_{1/2}$ (c) $2.2t_{1/2}$ (d) $1.1t_{1/2}$

Solution (b) For first order reaction

$$k = \frac{2.303}{t}\log_{10}\frac{a}{(a-x)}$$

or

$$t = \frac{2.303}{k}\log_{10}\frac{100}{(100-90)}$$

$$= \frac{2.303 \times t_{1/2}}{0.693} \times \log 10 \qquad \left[\because k = \frac{t_{1/2}}{0.693}\right]$$

$$= 3.3 \times t_{1/2}$$

Example 7 *The half-time of a first order decomposition of nitramide is* 2.1 *h at* 15°*C.*

$$NH_2NO_2(aq) \longrightarrow N_2O(g) + H_2O(l)$$

If 6.2 *g of nitramide is allowed to decompose then time taken for it to decompose* 99% *will be*

(a) 2.1 *h* (b) 12 *h* (c) 13.96 *h* (d) 33 *h*

Solution (c) For first order reaction,

$$k = \frac{0.693}{t_{1/2}} = \frac{0.693}{2.1} = 0.33\ \text{h}^{-1}$$

and

$$k = \frac{2.303}{t}\log_{10}\frac{a}{(a-x)}$$

or

$$t = \frac{2.303}{k}\log_{10}\frac{100}{(100-99)}$$

$$= \frac{2.303}{0.33} \times \log_{10} 100$$

$$= \frac{2.303}{0.33} \times 2 = 13.96\ \text{h}$$

Example 8 *The chemical reaction between mercuric chloride and potassium oxalate proceeds as under :*

$$2HgCl_2 + K_2C_2O_4 \longrightarrow 2KCl + 2CO_2 + Hg_2Cl_2$$

The mass of Hg_2Cl_2 *precipitated from different solutions in a given time, at* 100°*C was as follows*

Exp. no.	**$HgCl_2$** (mol L^{-1})	**$K_2C_2O_4$** (mol L^{-1})	**Time** (min)	**Hg_2Cl_2 precipitated** (mol)
(i)	0.0836	0.404	65	0.0068
(ii)	0.0836	0.202	120	0.0031
(iii)	0.0418	0.404	60	0.0032

The order of reaction will be

(a) 1 (b) 2 (c) 3 (d) 0

Solution (c) rate $= k[HgCl_2]^{\alpha}\,[K_2Cr_2O_4]^{\beta}$

$$\frac{0.0068}{65} = k(0.0836)^{\alpha}\,(0.404)^{\beta} \qquad \text{...(i)}$$

$$\frac{0.0031}{120} = k(0.0836)^{\alpha}\,(0.202)^{\beta} \qquad \text{...(ii)}$$

$$\frac{0.0032}{60} = k(0.0418)^{\alpha}\,(0.404)^{\beta} \qquad \text{...(iii)}$$

From (i) and (ii), $4 = 2^{\beta} \Rightarrow \beta = 2$

From (i) and (iii), $2 = 2^{\alpha} \Rightarrow \alpha = 1$

$\therefore$ Order of reaction $= \alpha + \beta = 1 + 2 = 3$

Example 9 *A first order reaction is* 50% *completed in* 30 *min at* 27°*C and in* 10 *min at* 47°*C. Calculate the activation energy of the reaction.*

(a) 43.8 *kJ* mol^{-1} (b) 4.38 *kJ* mol^{-1}

(c) 0.438 *kJ* mol^{-1} (d) 438 *kJ* mol^{-1}

Solution (a) At 27°C, $t_{1/2} = 30$ min

$$k_1 = \frac{0.693}{30} = 0.0231$$

and at 47°C, $t_{1/2} = 10$ min

$$k_2 = \frac{0.693}{10} = 0.0693$$

From,

$$\log\frac{k_2}{k_1} = \frac{E_a}{2.303R}\left[\frac{1}{T_1} - \frac{1}{T_2}\right]$$

$\Rightarrow$

$$\log\frac{0.0693}{0.0231} = \frac{E_a}{2.303 \times 8.314}\left[\frac{1}{300} - \frac{1}{320}\right]$$

or

$$\log 3 = \frac{E_a}{2.303 \times 8.314}\left[\frac{20}{300 \times 320}\right]$$

or

$$0.4771 = \frac{E_a \times 20}{2.303 \times 8.314 \times 300 \times 320}$$

or

$$E_a = 43848\ \text{J mol}^{-1} = 43.8\ \text{kJ mol}^{-1}$$

Example 10 *The rate constant, the activation energy and the Arrhenius parameter of a chemical reaction at* 25°*C are* $3.0 \times 10^{-4}\ s^{-1}$, 104.4 *kJ* mol^{-1} *and* $6.0 \times 10^{14}\ s^{-1}$ *respectively. The value of the rate constant at* $T \to \infty$ *is*

(a) $2.0 \times 10^{18}\ s^{-1}$ (b) $6.0 \times 10^{14}\ s^{-1}$

(c) $3.6 \times 10^{30}\ s^{-1}$ (d) *infinity*

Solution (b) Given, $T_1 = 25°\text{C} = 298$ K, $T_2 = T$ (say)

$$E_a = 104.4\ \text{kJ mol}^{-1} = 104.4 \times 10^3\ \text{J mol}^{-1}$$

$$k_1 = 3 \times 10^{-4}\ \text{s}^{-1}, k_2 = ?$$

From,

$$\log\frac{k_2}{k_1} = \frac{E_a}{2.303R}\left[\frac{1}{T_1} - \frac{1}{T_2}\right]$$

$$\log\frac{k_2}{3 \times 10^{-4}} = \frac{104.4 \times 10^3}{2.303 \times 8.314}\left[\frac{1}{298} - \frac{1}{T}\right]$$

or

$$\log\frac{k_2}{3 \times 10^{-4}} = \frac{104.4 \times 10^3}{2.303 \times 8.314} \times \frac{1}{298} \quad \left[\text{as } T \to \infty, \frac{1}{T} \to 0\right]$$

or

$$\log\frac{k_2}{3 \times 10^{-4}} = 18.297$$

or

$$\frac{k_2}{3 \times 10^{-4}} = 1.98 \times 10^{18}$$

or

$$k_2 = 1.98 \times 10^{18} \times 3 \times 10^{-4}$$

$$= 5.94 \times 10^{14} \approx 6 \times 10^{14}\ \text{s}^{-1}$$

Start **Practice** *for* JEE Main

Round I (Topically Divided Problems)

Rate of Reaction and Factors Affecting it

1. Which of the following statements is correct? **[NCERT Exemplar]**

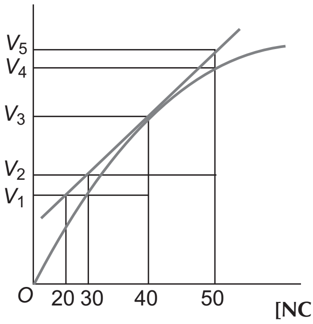
(a) The rate of a reaction decreases with passage of time as the concentration of reactants decreases

(b) The rate of a reaction is same at any time during the reaction

(c) The rate of a reaction is independent of temperature change

(d) The rate of a reaction decreases with increase in concentration of reactant(s)

2. A graph of volume of hydrogen released *vs* time for the reaction between zinc and dil.HCl is given in figure. On the basis of this mark the correct option.



[NCERT Exemplar]

(a) Average rate upto 40s is $\frac{V_3 - V_2}{40}$

(b) Average rate upto 40 seconds is $\frac{V_3 - V_2}{40 - 30}$

(c) Average rate upto 40 seconds is $\frac{V_3}{40}$

(d) Average rate upto 40 seconds is $\frac{V_3 - V_1}{40 - 20}$

3. Consider the graph given in Q. 2. Which of the following options does not show instantaneous rate of reaction at 40th second? **[NCERT Exemplar]**

(a) $\frac{V_5 - V_2}{50 - 30}$ (b) $\frac{V_4 - V_2}{50 - 30}$

(c) $\frac{V_3 - V_2}{40 - 30}$ (d) $\frac{V_3 - V_1}{40 - 20}$

4. In a reaction, $2A \longrightarrow$ products, the concentration of A decreases from 0.5 mol L^{-1} to 0.4 mol L^{-1} in 10 min. The rate during this interval is **[NCERT]**

(a) 0.05 mol L^{-1} min^{-1} (b) 0.42 mol L^{-1} min^{-1}

(c) 0.005 mol L^{-1} min^{-1} (d) 0.5 mol L^{-1} min^{-1}

5. Which of the following expression is correct for the rate of reaction given below? **[NCERT Exemplar]**

$$5Br^-(aq) + BrO_3^-(aq) + 6H^+(aq) \longrightarrow 3Br_2(aq) + 3H_2O(l)$$

(a) $\frac{\Delta[Br^-]}{\Delta t} = 5\frac{\Delta[H^+]}{\Delta t}$ (b) $\frac{\Delta[Br^-]}{\Delta t} = \frac{6}{5}\frac{\Delta[H^+]}{\Delta t}$

(c) $\frac{\Delta[Br^-]}{\Delta t} = \frac{5}{6}\frac{\Delta[H^+]}{\Delta t}$ (d) $\frac{\Delta[Br^-]}{\Delta t} = 6\frac{\Delta[H^+]}{\Delta t}$

6. For a gaseous reaction, the units of rate of reaction are

(a) L atm s^{-1} (b) atm s^{-1}

(c) atm mol^{-1} s^{-1} (d) mol s^{-1}

7. Pieces of wood burn faster than a log of wood of the same mass because

(a) surface area of log of wood is larger and needs more time to burn

(b) pieces of wood have large surface area

(c) all pieces of wood catch fire at the same time

(d) block of wood has higher density than pieces of the same wood

8. The rate constant for the reaction,

$$2N_2O_5 \longrightarrow 4NO_2 + O_2$$

is 3.0×10^{-5} s^{-1}. If the rate is 2.40×10^{-5} then the concentration of N_2O_5 (in mol/L) is

(a) 1.4 (b) 1.2 (c) 0.04 (d) 0.8

9. For a chemical reaction $2X + Y \longrightarrow Z$, the rate of appearance of Z is 0.05 mol L^{-1} min^{-1}. The rate of disappearance of X will be

(a) 0.05 mol L^{-1} h^{-1} (b) 0.05 mol L^{-1} min^{-1}

(c) 0.1 mol L^{-1} min^{-1} (d) 0.25 mol L^{-1} min^{-1}

10. In the reversible reaction

$$2NO_2 \underset{k_2}{\overset{k_1}{\rightleftharpoons}} N_2O_4$$

the rate of disappearance of NO_2 is equal to

(a) $\frac{2k_1}{k_2}[NO_2]^2$ (b) $2k_1[NO_2]^2 - 2k_2[N_2O_4]$

(c) $2k_2[NO_2]^2 - k_2[N_2O_4]$ (d) $(2k_1 - k_2)[NO_2]$

Molecularity and Rate Law Expression

11. For which type of reaction order and molecularity have the same value? **[NCERT** Exemplar**]**

(a) first order reaction

(b) bimolecular reaction

(c) termolecular reaction

(d) elementary reaction

12. For a single step reaction,

$A + 2B \longrightarrow$ Products, the molecularity is

(a) 0 (b) 1

(c) 2 (d) 3

13. Rate law for the reaction $A + 2B \longrightarrow C$ is found to be

$$\text{Rate} = k[A][B]$$

Concentration of reactant 'B' is doubled, keeping the concentration of 'A' constant, the value of rate constant will be **[NCERT** Exemplar**]**

(a) the same (b) doubled

(c) quadrupled (d) halved

14. The conversion of molecules x to y follows second order kinetics. If concentration of x is increased to three times, the rate of formation of y will **[NCERT]**

(a) increase by three times

(b) decrease by three times

(c) increase by nine times

(d) decrease by nine times

15. The rate of a gaseous reaction is equal to $k[A][B]$. The volume of the reaction vessel containing these gases is reduced by one-fourth of the initial volume. The rate of the reaction would be

(a) $\frac{1}{16}$ (b) $\frac{16}{1}$

(c) $\frac{1}{8}$ (d) $\frac{8}{1}$

16. The hydrolysis of ethyl acetate was carried out separately with 0.05 M HCl and 0.05 M H_2SO_4. The rate constants were found to be (k_1) and (k_2) respectively then

(a) $k_1 < k_2$ (b) $k_1 > k_2$

(c) $k_1 = k_2$ (d) $k_2 = 2k_1$

17. Units of rate constant of first and zero order reactions in terms of molarity M unit are respectively

(a) s^{-1}, M s^{-1} (b) s^{-1}, M

(c) M s^{-1}, s^{-1} (d) M, s^{-1}

18. In the sequence of reaction,

$$A \xrightarrow{k_1} B \xrightarrow{k_2} C \xrightarrow{k_3} D$$

$k_3 > k_2 > k_1$ then the rate determining step of the reaction is

(a) $A \longrightarrow B$ (b) $B \longrightarrow C$

(c) $C \longrightarrow D$ (d) $A \longrightarrow D$

19. Given the hypothetical reaction mechanism

$$A \xrightarrow{\text{I}} B \xrightarrow{\text{II}} C \xrightarrow{\text{III}} D \xrightarrow{\text{IV}} E$$

and the data as,

Species formed	Rate of its formation
B	0.002 mol/h, per mole of A
C	0.030 mol/h, per mole of B
D	0.011 mol/h, per mole of C
E	0.042 mol/h, per mole of D

The rate determining step is

(a) step I (b) step II

(c) step III (d) step IV

20. The rate of the reaction,

$$CCl_3CHO + NO \longrightarrow CHCl_3 + NO + CO$$

is equal to rate $k[CCl_3CHO][NO]$. If concentration is expressed in mol/L, the unit of k is

(a) L mol^{-1} s^{-1} (b) mol L^{-1} s^{-1}

(c) L^2 mol^{-2} s^{-1} (d) s^{-1}

Order of Reaction

21. For the reaction $A \longrightarrow B$, the rate expression is $r = k[A]^n$. When the concentration of A is doubled, the rate of reaction is quadrupled. The value of n is

(a) 1 (b) zero

(c) 3 (d) 2

22. Which of the following statements is not correct about order of a reaction? **[NCERT** Exemplar**]**

(a) The order of a reaction can be a fractional number.

(b) Order of a reaction is experimentally determined quantity.

(c) The order of a reaction is always equal to the sum of the stoichiometric coefficients of reactants in the balanced chemical equation for a reaction.
(d) The order of a reaction is the sum of the powers of molar concentration of the reactants in the rate law expression.

23. For a reaction, $A + B \longrightarrow$ product; the rate law is given by, $r = k[A]^{1/2}[B]^2$. What is the order of the reaction? **[NCERT]**
(a) $\frac{2}{3}$ (b) $\frac{5}{2}$
(c) $\frac{1}{2}$ (d) $\frac{3}{2}$

24. If a certain reaction is first order with respect to A, second order with respect to B and zero order with respect to C then what is the order of reaction?
(a) First (b) Second
(c) Third (d) Zero

25. The unit and value of rate constant and that of rate of reaction are same for
(a) zero order (b) first order
(c) second order (d) third order

26. In the reaction $A + B \longrightarrow$ products, if B is taken in excess, then it is an example of
(a) second order reaction
(b) zero order reaction
(c) pseudounimolecular reaction
(d) first order reaction

27. The rate constant for a chemical reaction has unit L mol^{-1} s^{-1}, order of the reaction will be
(a) 0 (b) 1
(c) 2 (d) 3

28. The rate constant of a zero order reaction is 0.2 mol dm^{-3} h^{-1}. If the concentration of the reactant after 30 min is 0.05 mol dm^{-3}, then its initial concentration would be
(a) 0.01 mol dm^{-3} (b) 0.15 mol dm^{-3}
(c) 0.25 mol dm^{-3} (d) 4.00 mol dm^{-3}

29. What is the two third life of a first order reaction having $k = 5.48 \times 10^{-14}$ s^{-1}?
(a) 2.01×10^{13} s (b) 2.01×10^{12} s
(c) 4.02×10^{13} s (d) 4.02×10^{26} s

30. Half-life of a reaction is found to be inversely proportional to the cube of initial concentration. The order of reaction is
(a) 4 (b) 3
(c) 5 (d) 2

31. Radioactive decay is a
(a) first order reaction
(b) zero order reaction
(c) second order reaction
(d) third order reaction

32. The inversion of cane sugar into glucose and fructose according to the equation

$$C_{12}H_{22}O_{11} + H_2O \longrightarrow C_6H_{12}O_6 + C_6H_{12}O_6$$

is an example of
(a) first order reaction (b) third order reaction
(c) second order reaction (d) zero order reaction

33. The reaction $L \longrightarrow M$ is started with 10.0 g of L. After 30 and 90 min, 5.0 g and 1.25 g of L respectively are left. The order of the reaction is
(a) 0 (b) 1
(c) 2 (d) 3

34. The rate law for the reaction

RCl + NaOH $\longrightarrow$ ROH + NaCl is given by

Rate = k [RCl]. The rate of this reaction
(a) is doubled by doubling the concentration of NaOH
(b) is halved by reducing the concentration of RCl by one half
(c) is increased by increasing the temperature of the reaction
(d) in unaffected by change in temperature

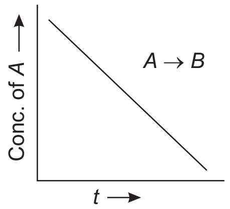
35. Sucrose decomposes in acid solution into glucose and fructose according to the first order rate law, with $t_{1/2} = 3.00$ h. What fraction of sample of sucrose remains after 8 h? **[NCERT]**
(a) 1.023 M (b) 0.8725 M
(c) 0.023 M (d) 0.1576 M

36. The rate constant for a first order reaction is 60 s^{-1}. How much time will it take to reduce the initial concentration of the reactant to its 1/16th value? **[NCERT]**
(a) 0.046 s (b) 0.025 s
(c) 0.098 s (d) 0.060 s

37. The half-life of two samples are 0.1 and 0.8 s. Their respective concentration are 400 and 50 respectively. The order of the reaction is
(a) 0 (b) 2
(c) 1 (d) 4

38. In a second order reaction when the concentrations of both the reactants are equal, the reaction is completed in 500 s. How long will it take for the reaction to go to 60% completion?
(a) 1000 s (b) 300 s
(c) 3000 s (d) 2000 s

39. For a general reaction, $A \longrightarrow B$, plot of concentration of A *vs* time is given in figure.
What are the units of rate constant?



[NCERT Exemplar]

(a) mol L^{-1} s^{-1} (b) mol^{-1} L s^{-1}
(c) s^{-1} (d) mol^{-2} L^2 s^{-1}

40. 1 g of $_{79}Au^{198}$ ($t_{1/2} = 65$ h) gives stable mercury by β-emission. What amount of mercury will left after 260 h?
(a) 0.9375 g (b) 0.3758 g
(c) 0.7586 g (d) 0.9000 g

41. Compounds 'A' and 'B' react according to the following chemical equation.

$$A(g) + 2B(g) \longrightarrow 2C(g)$$

Concentration of either 'A' or 'B' were changed keeping the concentrations of one of the reactants constant and rates were measured as a function of initial concentration. Following results were obtained.

Experiment	Initial concentration of [A]/mol L^{-1}	Initial concentration of [B]/mol L^{-1}	Initial rate of formation of [C]/mol L^{-1} s^{-1}
1.	0.30	0.30	0.10
2.	0.30	0.60	0.40
3.	0.60	0.30	0.20

Choose the correct option for the rate equations for this reaction. **[NCERT Exemplar]**
(a) Rate = $k[A]^2[B]$ (b) Rate = $k[A][B]^2$
(c) Rate = $k[A][B]$ (d) Rate = $k[A]^2[B]^0$

42. A first order reaction is 50% completed in 1.26×10^{14} s. How much time would it take for 100% completion? **[NCERT Exemplar]**
(a) 1.26×10^{15} s (b) 2.52×10^{14} s
(c) 2.52×10^{28} s (d) Infinite

Effect of Temperature on Rate of Reaction

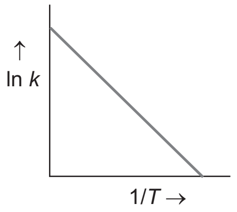
43. Consider the Arrhenius equation given below and mark the correct option. **[NCERT Exemplar]**

$$k = Ae^{-E_a/RT}$$

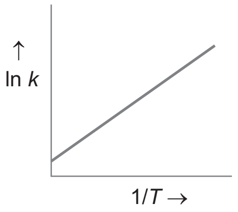
(a) Rate constant increases exponentially with increasing activation energy and decreasing temperature
(b) Rate constant decreases exponentially with increasing activation energy and decreasing temperature
(c) Rate constant increases exponentially with decreasing activation energy and decreasing temperature
(d) Rate constant increases exponentially with decreasing activation energy and increasing temperature

44. According to Arrhenius equation rate constant k is equal to $Ae^{-E_a/RT}$. Which of the following options represents the graph of ln k *vs* $\frac{1}{T}$? **[NCERT Exemplar]**

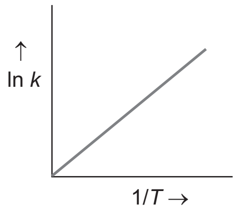
(a)



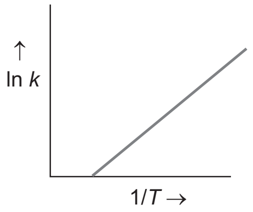
(b)



(c)

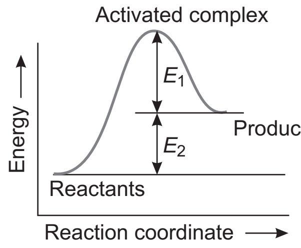


(d)



45. When a graph is plotted between ln k and $1/T$ for a first order reaction, a straight line is obtained. The slope of the line is equal to
(a) $-\frac{E_a}{2.303}$ (b) $-\frac{E_a}{2.303R}$
(c) $-\frac{2.303}{E_aR}$ (d) $-\frac{E_a}{R}$

46. Consider figure and mark the correct option.



[NCERT Exemplar]

(a) Activation energy of forward reaction is $E_1 + E_2$ and product is less stable than reactant.

(b) Activation energy of forward reaction is $E_1 + E_2$ and product is more stable than reactant

(c) Activation energy of both forward and backward reaction is $E_1 + E_2$ and reactant is more stable than product.

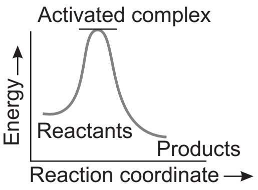
(d) Activation energy of backward reaction is E_1 and product is more stable than reactant

47. An endothermic reaction $A \longrightarrow B$ has an activation energy of 15 kcal/mol and the energy of reaction is 5 kcal/mol. The activation energy for the reaction $B \longrightarrow A$ is

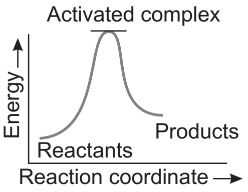
(a) 20 kcal/mol (b) 15 kcal/mol
(c) 10 kcal/mol (d) zero

48. Which of the following graphs represents exothermic reaction?

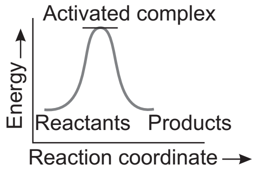
(i)



(ii)



(iii)



(a) (i) only (b) (ii) only
(c) (iii) only (d) (i) and (ii)

49. Arrhenius equation may not be represented as

(a) $\ln \frac{A}{k} = \frac{E_a}{RT}$

(b) $\frac{d \ln k}{dT} = \frac{E}{RT^2}$

(c) $\log A = \log k + \frac{E_a}{2.303\, RT}$

(d) $\log \left[-\frac{E_a}{RT} \right] = \frac{k}{A}$

50. The rate constant (k') of one of the reaction is found to be double that of the rate constant (k'') of another reaction. Then the relationship between the corresponding activation energies of the two reactions $(E_a'$ and $E_a'')$ can be represented as

(a) $E_a' > E_a''$ (b) $E_a' = 4E''$
(c) $E_1' = E_a''$ (d) $E_a' < E_a''$

51. Which of the following statements is incorrect about the collision theory of chemical reaction?

[NCERT Exemplar]

(a) It considers reacting molecules or atoms to be hard spheres and ignores their structural features

(b) Number of effective collisions determines the rate of reaction

(c) Collision of atoms or molecules possessing sufficient threshold energy results into the product formation

(d) Molecules should collide with sufficient threshold energy and proper orientation for the collision to be effective

52. For the decomposition of N_2O_5 at a particular temperature, according to the equations

$$2N_2O_5 \longrightarrow 4NO_2 + O_2$$
$$N_2O_5 \longrightarrow 2NO_2 + \frac{1}{2} O_2$$

The activation energies are E_1 and E_2 respectively then

(a) $E_1 > E_2$ (b) $E_1 < E_2$
(c) $E_1 = 2E_2$ (d) $E_1 = E_2$

53. If the reaction rate at a given temperature becomes slower then

(a) the free energy of activation is higher

(b) the free energy of activation is lower

(c) the entropy changes

(d) the initial concentration of the reactants remains constant

54. In Arrhenius equation, $k = Ae^{-E_a/RT}$; A may be called the rate constant at

(a) very low temperature

(b) zero activation energy

(c) the boiling temperature of reaction mixture

(d) All of the above

55. The rate of a reaction quadruples when the temperature changes from 293 K to 313 K. Calculate the energy of activation of the reaction assuming that it does not change with temperature. **[NCERT]**

(a) 48.625 kJ mol^{-1} (b) 654.35 kJ mol^{-1}
(c) 354.20 kJ mol^{-1} (d) 52.863 kJ mol^{-1}

56. The decomposition of A into product has values of k as $4.5 \times 10^3\ s^{-1}$ at 10°C and energy of activation 60 kJ mol^{-1}. At what temperature would k be $1.5 \times 10^4\ s^{-1}$. **[NCERT]**

(a) 273.15 K (b) 24.19°C
(c) 280.39 K (d) 45.29°C

57. The rate constant of the chemical reaction doubled for an increase of 10 K in absolute temperature from 295 K. Calculate E_a. **[NCERT]**

(a) 51.8 kJ mol^{-1} (b) 82.1 kJ mol^{-1}
(c) 23.8 kJ mol^{-1} (d) 62.1 kJ mol^{-1}

58. The activation energy for the given reaction $2HI(g) \longrightarrow H_2(g) + I_2(g)$ is $209.5 \text{ kJ mol}^{-1}$ at 581 K. Calculate the fraction of molecules of reactants having energy equal to or greater than activation energy. **[NCERT]**

(a) 1.82×10^{-18}

(b) 1.47×10^{-19}

(c) 2.67×10^{-16}

(d) 3.89×10^{-19}

59. The rate constant of a reaction increases by 5% when its temperature is raised from 27°C to 28°C. The activation energy of the reaction is

(a) 36.6 kJ/mol (b) 16.6 kJ/mol

(c) 46.6 kJ/mol (d) 26.6 kJ/mol

60. The activation energy of a reaction is 9 kcal/mol. The increase in the rate constant when its temperature is raised from 295 to 300 K is approximately

(a) 10% (b) 50%

(c) 100% (d) 28%

Round II (Mixed Bag)

Only One Correct Option

1. The rate of a reaction is expressed in different ways as follows

$$+\frac{1}{2}\frac{d[C]}{dt} = -\frac{1}{5}\frac{d[D]}{dt} = +\frac{1}{3}\frac{d[A]}{dt} = -\frac{d[B]}{dt}$$

The reaction is

(a) $4A + B \longrightarrow 2C + 3D$

(b) $B + 5D \longrightarrow 3A + 2C$

(c) $4A + 2B \longrightarrow 2C + 3D$

(d) $B + \frac{1}{2}D \longrightarrow 4A + 2C$

2. Which of the following statements are incorrect?

(a) Rate of the reaction involving conversion of *ortho* hydrogen to *para* hydrogen $= -\frac{d[H_2]}{dt} = k[H_2]^{3/2}$

(b) Rate of the reaction involving the thermal decomposition of acetaldehyde $= k[CH_3CHO]^{1/2}$

(c) In the formation of phosgene from CO and Cl_2, the rate of the reaction $= k[CO][Cl_2]^{1/2}$

(d) In the decomposition of H_2O_2, the rate of reaction $= k[H_2O_2]$

3. In a first order reaction the concentration of reactant decreases from 800 mol/dm^3 to 50 mol/dm^3 in 2×10^4 s. The rate constant of the reaction in s^{-1} is

(a) 2×10^4 (b) 3.45×10^{-5}

(c) 1.386×10^{-4} (d) 2×10^{-4}

4. The chemical reaction $2O_3 \longrightarrow 3O_2$ proceeds as follows

$$O_3 \rightleftharpoons O_2 + O \text{ (fast)}$$
$$O + O_3 \longrightarrow 2O_2 \text{ (slow)}$$

The rate law expression should be

(a) $r = k[O_3]^2$ (b) $r = k[O_3]^2[O_2]^{-1}$

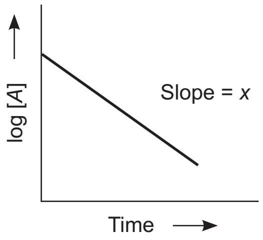
(c) $r = k[O_3][O_2]$ (d) unpredictable

5. The rate of a chemical reaction doubles for every 10°C rise in temperature. If the temperature is increased by 60°C, the rate of reaction increases by

(a) 20 times (d) 32 times

(c) 64 times (d) 128 times

6. For a first order reaction, the graph $\log[A]$ *vs* t is given below



x is equal to

(a) $\frac{0.693}{k}$ (b) $\frac{k}{2.303}$

(c) $-\frac{k}{2.303}$ (d) $\log[A]_0$

7. Two first order reactions have half-lives in the ratio 8 : 1. Calculate the ratio of time intervals $t_1 : t_2$. The time t_1 and t_2 are the time period for (1/4)th and (3/4)th completion.

(a) 1 : 0.602 (b) 2 : 301

(c) 0.256 : 0.603 (d) 0.2 : 0.301

8. The time required for 10% completion of a first order reaction at 298 K is equal to that required for its 25% completion at 308 K. If the value of A is $4 \times 10^{10} \text{ s}^{-1}$. Calculate k at 318 K. **[NCERT]**

(a) $2.89 \times 10^{-2} \text{ s}^{-1}$

(b) $3.26 \times 10^{-2} \text{ s}^{-1}$

(c) $1.03 \times 10^{-2} \text{ s}^{-1}$

(d) $0.03 \times 10^{-2} \text{ s}^{-1}$

9. The following data were obtained during the first order thermal decomposition of SO_2Cl_2 at a constant volume.

$$SO_2Cl_2(g) \longrightarrow SO_2(g) + Cl_2(g)$$

Experiment	Time/s^{-1}	Total pressure/atm
1	0	0.5
2	100	0.6

Calculate the rate of the reaction when total pressure is 0.65 atm. **[NCERT Exemplar]**

(a) 2.84×10^{-7} atm s^{-1} (b) 7.80×10^{-4} atm s^{-1}

(c) 4.42×10^{-7} atm s^{-1} (d) 5.62×10^{-4} atm s^{-1}

10. During nuclear explosion one of the products is ^{90}Sr with half-life of 28.1 yr. If 1 μ g of ^{90}Sr was absorbed in the bones of a newly born baby instead of calcium, how much of it will remain after 60 yr if it is not lost metabolically? **[NCERT]**

(a) 0.184 μg (b) 0.025 μg

(c) 0.262 μg (d) 0.228 μg

11. For the decomposition of azoisopropane to hexane and nitrogen at 543 K, the following data are obtained. Calculate the rate constant. **[NCERT]**

t (s)	p (mm of Hg)
0	35.0
360	54.0
720	63.0

(a) 2.21×10^{-3} s^{-1} (b) 3.48×10^{-3} s^{-1}

(c) 1.26×10^{-3} s^{-1} (d) 8.46×10^{-3} s^{-1}

12. The rate constant of a reaction is given by $k = 2.1\times10^{10}\exp(-2700RT)$.

It means that

(a) $\log k$ *vs* $1/T$ will be a curved line with slope $= -\dfrac{2700}{2.303R}$

(b) $\log k$ vs $1/T$ will be a straight line with intercept on $\log k$ axis $= \log 2.1\times10^{10}$

(c) the number of effective collisions are 2.1×10^{10} cm^{-3} s^{-1}

(d) half-life of the reaction increases with increase of temperature

13. Which of the following statements are correct?

1. Order of a reaction can be known from experimental result and not from the stoichiometry of reaction.
2. Overall molecularity of a reaction may be determined in a manner similar to overall order of reaction.
3. Overall order of reaction,
   $A^m + B^n \longrightarrow AB_x$ is $(m+n)$
4. Molecularity of a reaction refers to
   (i) molecularity of each of the elementary steps (slow steps) in a multistep reaction.
   (ii) molecularity of that particular step in a single step reaction.

Select the correct answer by using the codes given below.

(a) 1, 3 and 4 (b) 1, 2 and 3

(c) 2, 3 and 4 (d) 1, 2 and 4

14. An exothermic chemical reaction occurs in two steps as follows

(I) $A + B \longrightarrow X$ (fast)

(II) $X \longrightarrow AB$ (slow)

The progress of the reaction can be best represented by

(a) 
(b) 
(c) 
(d) All are correct

15. The decomposition of hydrocarbon follows the equation $k = (4.5\times10^{11}\ s^{-1})\,e^{-28000}$ K/T. Calculate the activation energy E_a. **[NCERT]**

(a) 232.79 kJ mol^{-1} (b) 425.25 kJ mol^{-1}

(c) 300 kJ mol^{-1} (d) 885.2 kJ mol^{-1}

More than One Correct Option

16. In any unimolecular reaction **[NCERT Exemplar]**

(a) only one reacting species is involved in the rate determining step.

(b) the order and the molecularity of slowest step are equal to one.

(c) the molecularity of the reaction is one and order is zero.

(d) both molecularity and order of the reaction are one.

17. Rate law cannot be determined from balanced chemical equation if **[NCERT Exemplar]**

(a) reverse reaction is involved.

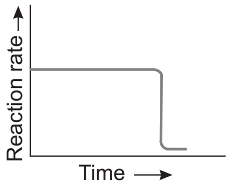
(b) it is an elementary reaction.

(c) it is a sequence of elementary reactions.

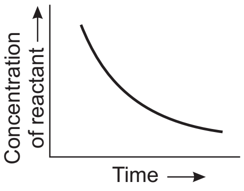
(d) any of the reactants is in excess.

18. Which of the following graphs is correct for a zero order reaction?

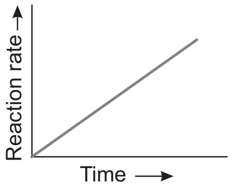
(a)



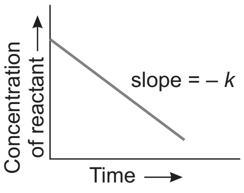
(b)



(c)



(d)



19. For a reaction $2A + B \longrightarrow C$ with the rate law $\frac{d[C]}{dt} = k[A][B]^{-1}$ and started with A and B in stoichiometric proportion which is/are true?

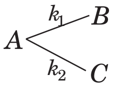
(a) $[C] = 2\,kt$

(b) $[C] = kt$

(c) unit of k is mol L^{-1} s^{-1}

(d) $[A][B]$ and $[C]$ all will be linear funtions of time

20. Consider the following case of completing first order reactions



After the start of the reaction at $t = 0$ with only A, the $[B]$ is equal to the $[C]$ at all times. The time in which all three concentrations will be equal is given by

(a) $t = \frac{1}{3k_1}\ln 2$ (b) $t = \frac{1}{2k_1}\ln 3$

(c) $t = \frac{1}{3k_2}\ln 2$ (d) $t = \frac{1}{2k_2}\ln 3$

Assertion and Reason

Directions (Q. Nos. 21 to 25) *Each of these questions contains two statements : Statement* I (*Assertion*) *and Statement* II (*Reason*). *Each of these questions also has four alternative choices, only one of which is the correct answer. You have to select one of the codes* (*a*), (*b*), (*c*), (*d*) *given below :*

(a) Statement I is true, Statement II is true; Statement II is a correct explanation for Statement I.

(b) Statement I is true, Statement II is true; Statement II is not a correct explanation for Statement I.

(c) Statement I is true; Statement II is false.

(d) Statement I is false; Statement II is true.

21. Statement I Order and molecularity are same.

Statement II Order is determined experimentally and molecularity is the sum of the stoichiometric coefficient of rate determining elementary step. **[NCERT Exemplar]**

22. Statement I Rate constants determined from Arrhenius equation are fairly accurate for simple as well as complex molecules.

Statement II Reactant molecules undergo chemical change irrespective of their orientation during collision. **[NCERT Exemplar]**

23. Statement I The numerical value of specific rate constant is independent of the concentration of any species present in the reaction mixture.

Statement II When a reaction is carried out in aqueous solution and some alcohol is added to the reaction mixture, the rate of reaction will not change.

24. Statement I In the reaction $I_2 + 2S_2O_3^{2-} \longrightarrow S_4O_6^{2-} + 2I^-$, the two $S_2O_3^{2-}$ ions are used for every I_2.

Statement II The rate of disappearance of I_2 is one half the rate of disappearance of $S_2O_3^{2-}$.

25. Statement I Lower the activation energy, faster is the reaction.

Statement II If the activation energy of reaction is zero, temperature will have no effect on the rate constant.

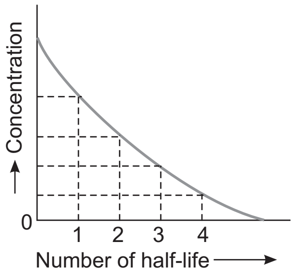
Comprehension Based Questions

Directions (Q. Nos. 26 to 28) $t_{1/2}$ of reaction is the time required for the concentration of reactant to decrease by half, *i.e.*,

$$[A]_t = \frac{1}{2}[A].$$

$$t_{1/2} = 0.693 / k$$

that is $t_{1/2}$ is independent of initial concentration. Figure shows that typical variation of concentration of reactant exhibiting first order kinetics. It may be noted that though the major portion of the first order kinetics may be over in a finite time, but the reaction will never cease as the concentration of reactant will be zero only at infinite time.



26. 75% of a reaction of the first order was completed in 32 min. When was it half completed?

(a) 8 min (b) 16 min
(c) 64 min (d) 48 min

27. The half-life period for a first order reaction is 693 s. The rate constant of this reaction would be

(a) $1 \times 10^{-2}\ s^{-1}$ (b) $1 \times 10^{-3}\ s^{-1}$
(c) $0.1\ s^{-1}$ (d) $-1 \times 10^{-4}\ s^{-1}$

28. The rate of a first order reaction is 1.5×10^{-2} mol L^{-1} min^{-1} at 0.5 M concentration of the reactant. The half-life of the reaction is

(a) 13.6 min (b) 42.5 min
(c) 23.1 min (d) 32.5 min

Directions (Q. Nos. 29 to 31) Note all chemical reactions proceed to a stage at which the concentrations of the reactants become vanishingly small. Here we consider the kinetics of such reactions. Let a reaction be represented in general terms by the scheme

$$A \underset{k_2}{\overset{k_1}{\rightleftharpoons}} B$$

where k_1 and k_2 represent the rate constants for the forwards and reverse reactions respectively. The equilibrium constant for this reaction may be written as

$$k = [B]_\infty / [A]_\infty = k_1 / k_2$$

The initial concentration of species A is $[A]_0$ and that of B is $[B]_0$. After a time t, let the concentration of species A be $[A]_t$ and that of B be $[B]_t$. The total rate of change of $[A]_t$ is given by

$$d[A]_{t/dt} = -k_1[A]_t + k_2[B]_t$$

$$d[A]_{t/dt} = -k_1[A]_t + k_2([A]_0 - [A]_t)$$

$$d[A]_{t/dt} = -(k_1 + k_2)\left([A]_t - \frac{k_2}{k_1 + k_2}[A]_0\right)$$

29. What is the k_c of the reaction $2C \rightleftharpoons 2A$ if $[C] = 0.4$ and $[A] = 0.6$?

(a) 9/4 (b) 2/3
(c) 4/3 (d) 5/2

30. At what time is the rate of change of concentration of A equal to rate of change of concentration of C in magnitude?

(a) $t = 10$ only (b) $t = 0$ only
(c) $t \geq t_{\text{equilibrium}}$ (d) All times

31. Which of the following relation is correct for k_f and k_b in an equilibrium process that contains equal moles of reactants and products?

(a) $k_f < k_b$ (b) $k_f > k_b$
(c) $k_f = k_b$ (d) Not predictable

Previous Years' Questions

32. The rate of a chemical reaction doubles for every 10°C rise of temperature. If the temperature is raised by 50°C, the rate of the reaction increases by about **[AIEEE 2011]**

(a) 10 times (b) 24 times
(c) 32 times (d) 64 times

33. A reactant (A) forms two products

$$A \xrightarrow{k_1} B, \text{Activation energy } E_{a_1}$$

$$A \xrightarrow{k_2} C, \text{ Activation energy } E_{a_2}$$

If $E_{a_2} = 2\,E_{a_1}$, then k_1 and k_2 are related as **[AIEEE 2011]**

(a) $k_1 = 2k_2e^{E_{a2}/RT}$ (b) $k_1 = k_2e^{E_{a1}/RT}$
(c) $k_2 = k_1e^{E_{a2}/RT}$ (d) $k_1 = A\,k_2e^{E_{a1}/RT}$

34. The time for half-life period of a certain reaction, $A \rightarrow$ products is 1 h. When the initial concentration of the reactant 'A' is 2.0 mol L^{-1}, how much time does it take for its concentration to come from 0.50 to 0.25 mol L^{-1}, if it is a zero order reaction? **[AIEEE 2010]**

(a) 4 h (b) 0.5 h
(c) 0.25 h (d) 1 h

35. Consider the reaction,

$$Cl_2(aq) + H_2S(aq) \longrightarrow S(s) + 2H^+(aq) + 2Cl^-(aq)$$

The rate equation for this reaction is,

$$\text{rate} = k[Cl_2][H_2S]$$

Which of these mechanisms is/are consistent with this rate equation? **[AIEEE 2010]**

(A) $Cl_2 + H_2S \longrightarrow H^+ + Cl^- + Cl^+ + HS^-$ (slow)
$Cl^+ + HS^- \longrightarrow H^+ + Cl^- + S$ (fast)
(B) $H_2S \rightleftharpoons H^+ + HS^-$ (fast equilibrium)
$Cl_2 + HS^- \longrightarrow 2\ Cl^- + H^+ + S$ (slow)

(a) (B) only (b) Both A and B
(c) Neither A nor B (d) A only

36. The half-life period of a first order chemical reaction is 6.93 min. The time required for the completion of 99% of the chemical reaction will be (log 2 = 0.301)

(a) 230.3 min (b) 23.03 min
(c) 46.06 min (d) 460.6 min

37. For a reaction $\frac{1}{2}A \longrightarrow 2B$, rate of disappearance of 'A' is related to the rate of appearance of 'B' by the expression **[AIEEE 2008]**

(a) $-\frac{d[A]}{dt}=\frac{1}{2}\frac{d[B]}{dt}$ (b) $-\frac{d[A]}{dt}=\frac{1}{4}\frac{d[B]}{dt}$

(c) $-\frac{d[A]}{dt}=\frac{d[B]}{dt}$ (d) $-\frac{d[A]}{dt}=4\frac{d[B]}{dt}$

38. Consider the reaction, $2A + B \rightarrow$ products. When concentration of B alone was doubled, the half-life did not change. When the concentration of A alone was doubled, the rate increased by two times. The unit of rate constant for this reaction is **[AIEEE 2007]**

(a) L mol^{-1} s^{-1} (b) no unit

(c) mol L^{-1} s^{-1} (d) s^{-1}

39. The energies of activation for forward and reverse reactions for $A_2 + B_2 \rightleftharpoons 2AB$ are 180 kJ mol^{-1} and 200 kJ mol^{-1} respectively. The presence of a catalyst lowers the activation energy of both (forward and reverse) reactions by 100 kJ mol^{-1}. The enthalpy change of the reaction $(A_2 + B_2 \rightarrow 2AB)$ in the presence of catalyst will be (in kJ mol^{-1}) **[AIEEE 2007]**

(a) 300 (b) 120

(c) 280 (d) 20

40. The following mechanism has been proposed for the reaction of NO with Br_2 to form NOBr

$$NO(g) + Br_2(g) \rightleftharpoons NOBr_2(g)$$
$$NOBr_2(g) + NO(g) \longrightarrow 2NOBr(g)$$

If the second step is the rate determining step, the order of the reaction with respect to NO (g) is **[AIEEE 2006]**

(a) 1 (b) 0

(c) 3 (d) 2

41. Rate of a reaction can be expressed by Arrhenius equation as

$$k = Ae^{-E/RT}$$

In this equation, E represents **[AIEEE 2006]**

(a) the energy above which all the colliding molecules will react

(b) the energy below which colliding molecules will not react

(c) the total energy of the reacting molecules at a temperature, T

(d) the fraction of molecules with energy greater than the activation energy of the reaction

42. A reaction involving two different reactants can never be **[AIEEE 2005]**

(a) bimolecular reaction

(b) second order reaction

(c) first order reaction

(d) unimolecular reaction

43. Consider an endothermic reaction $X \rightarrow Y$ with the activation energies E_b and E_f for the backward and forward reactions respectively. In general **[AIEEE 2005]**

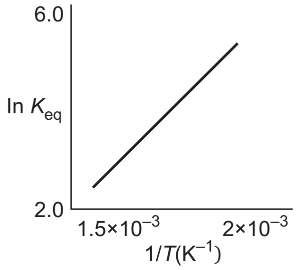
(a) there is no definite relation between E_b and E_f

(b) $E_b = E_f$

(c) $E_b > E_f$

(d) $E_b < E_f$

44. A schematic plot of $\ln K_{eq}$ *versus* inverse of temperature for a reaction is shown below



The reaction must be **[AIEEE 2005]**

(a) highly spontaneous at ordinary temperature

(b) one with negligible enthalpy change

(c) endothermic

(d) exothermic

45. The rate equation for the reaction $2A + B \rightarrow C$ is found to be rate $= k[A][B]$

The correct statement in relation to this reaction is that the **[AIEEE 2004]**

(a) unit of k must be s^{-1}

(b) $t_{1/2}$ is a constant

(c) rate of formation of C is twice the rate of disappearance of A

(d) value of k is independent of the initial concentrations of A and B

46. In a first order reaction, the concentration of the reactant, decreases from 0.8 M to 0.4 M in 15 min. The time taken for the concentration to change from 0.1 M to 0.025 M is **[AIEEE 2004]**

(a) 30 min (b) 15 min

(c) 7.5 min (d) 60 min

47. For the reaction system :

$$2NO(g) + O_2(g) \longrightarrow 2NO_2(g)$$

volume is suddenly reduced to half its value by increasing the pressure on it. If the reaction is of first order with respect to O_2 and second order with respect to NO; the rate of reaction will **[AIEEE 2003]**

(a) diminish to one-fourth of its initial value

(b) diminish to one-eight of its initial value

(c) increase to eight times of its initial value

(d) increase to four times of its initial value

48. For the reaction : $H_2 + I_2 \longrightarrow 2HI$, the differential rate law is **[AIEEE 2002]**

(a) $-\frac{d[H_2]}{dt} = -\frac{d[I_2]}{dt} = 2\frac{d[HI]}{dt}$

(b) $-2\frac{d[H_2]}{dt} = -2\frac{d[I_2]}{dt} = \frac{d[HI]}{dt}$

(c) $-\frac{d[H_2]}{dt} = -\frac{d[I_2]}{dt} = \frac{d[HI]}{dt}$

(d) $-\frac{d[H_2]}{2dt} = -\frac{d[I_2]}{2dt} = \frac{d[HI]}{dt}$

49. Rate constant, k of the first order reaction when initial concentration (C_0) and concentration at time t, (C_t) is given by the equation

$$kt = \log C_0 - \log C_t$$

Graph is a straight line if we plot **[AIEEE 2002]**

(a) t *vs* $\log C_0$

(b) t *vs* $\log C_t$

(c) t^{-1} *vs* $\log C_t$

(d) $\log C_0$ *vs* $\log C_t$

the Guidance

Round I

1. Rate of reaction $= \frac{-\Delta[R]}{\Delta t}$

Where negative sign shows that rate of reaction decreases as concentration of reactants decreases.

2. Average rate $= \frac{\Delta R}{\Delta t} = \frac{V_3}{40}$

3. Instantaneous speed $= \frac{x_2 - x_1}{t_2 - t_1}$

$\therefore$ Instantaneous speed $= \frac{V_5 - V_2}{50 - 30}$

$$= \frac{V_3 - V_2}{40 - 30}$$

$$= \frac{V_3 - V_1}{40 - 20}$$

$$= \frac{V_4 - V_2}{45 - 30}$$

4. Rate of reaction = Rate of disappearance of A

$$= -\frac{1}{2}\frac{\Delta[A]}{\Delta t} = -\frac{1}{2}\frac{(0.4 - 0.5)\ \text{mol L}^{-1}}{10\ \text{min}}$$

$$= 0.005\ \text{mol L}^{-1}\ \text{min}^{-1}$$

5.
$$\text{Rate} = -\frac{1}{5}\frac{\Delta[Br^-]}{\Delta t} = -\frac{1}{6}\frac{\Delta[H^+]}{\Delta t}$$

or
$$\frac{\Delta[Br^-]}{\Delta t} = +\frac{5}{6}\frac{\Delta[H^+]}{\Delta t}$$

8. For a first order reaction,

$$\text{rate} = k[\text{reactant}]$$

$$[\text{reactant}] = \frac{\text{rate}}{k}$$

$$= \frac{2.40 \times 10^{-5}}{3.0 \times 10^{-5}} = 0.8$$

9. For the reaction,

$$2X + Y \longrightarrow Z$$

$$\text{Rate} = -\frac{1}{2}\frac{d[X]}{dt} = \frac{d[Z]}{dt}$$

$$= 0.05 \text{ mol L}^{-1} \text{ min}^{-1}$$

$$-\frac{1}{2}\frac{d[X]}{dt} = 0.05$$

$$-\frac{d[X]}{dt} = 2 \times 0.05$$

$$= 0.1 \text{ mol L}^{-1} \text{ min}^{-1}$$

10.

$$2NO_2 \underset{k_2}{\overset{k_1}{\rightleftharpoons}} N_2O_4$$

$$\text{Rate} = -\frac{1}{2}\frac{d[NO_2]}{dt}$$

$$= k_1[NO_2]^2 - k_2[N_2O_4]$$

$\therefore$ Rate of disappearance of NO_2

i.e., $$-\frac{d[NO_2]}{dt} = 2k_1[NO_2]^2 - 2k_2[N_2O_4]$$

11. If the reaction is an elementary reaction,

order = molecularity.

13. Value of rate constant remains unaffected from change in concentration.

14. For second order kinetics, rate $= k\,[\text{reactant}]^2$, So make two equation first by taking initial rate and concentration, second by taking tripled concentration and unknown rate (r'). Compare them to find a relation between r and r'.

For the reaction $x \longrightarrow y$

$$\text{Reaction rate } (r) = k\,[x]^2 \qquad \ldots\text{(i)}$$

If the concentration of x is increased three times, then

$$\text{Reaction rate } (r') = k[3x]^2 = k \times [9x^2] \qquad \ldots\text{(ii)}$$

Dividing Eq. (ii) by Eq. (i);

$$\frac{r'}{r} = \frac{k \times [9x^2]}{k \times [x^2]} = 9$$

It means that the rate of formation of y will increase by **nine times**.

15. Rate $(r) = k[A][B] = kab$

When volume is reduced by one fourth then concentration becomes 4 times.

Hence, $$r' = k(4a)(4b)$$

$$= 16kab$$

$\therefore$ $$r' = 16r$$

16. In the presence of acid, hydrolysis of ethyl acetate is a pseudo-unimolecular reaction but the actual value of k depends upon the concentration of H^+ ion. As H_2SO_4 is stronger acid than HCl and moreover H^+ ions produced from 0.05 M H_2SO_4 is double than 0.05 M HCl therefore, $k_1 < k_2$.

17. For nth order reaction

$$k = (\text{mol L}^{-1})^{1-n} \text{ s}^{-1}$$

For first order reaction

Unit of $k = \text{s}^{-1}$

For zero order reaction

Unit of $k = \text{mol L}^{-1} \text{ s}^{-1} = \text{M s}^{-1}$

18. $A \xrightarrow{k_1} B \xrightarrow{k_2} C \xrightarrow{k_3} D$

$\because$ $$k_3 > k_2 > k_1$$

As k_1 is slowest hence $A \longrightarrow B$ is the rate determining step of the reaction.

19. The slowest step is the rate determining step. Formation of B (*i.e.,* step I) is the slowest step, therefore, step I is the rate determining step.

20. For the reaction:,

$$CCl_3CHO + NO \longrightarrow CHCl_3 + NO + CO$$

$$\text{Rate} = \frac{dx}{dt} = k[CCl_3CHO][NO]$$

$$k = \frac{dx}{dt \times [CCl_3CHO][NO]}$$

$$= \frac{\text{mol / L}}{\text{s} \times \text{mol / L} \times \text{mol / L}}$$

$$k = \text{L mol}^{-1} \text{ s}^{-1}$$

21. Let $$r = k[A]^n \qquad \ldots\text{(i)}$$

When concentration is doubled then

$$4r = k(2A)^n \qquad \ldots\text{(ii)}$$

Divide Eq. (ii) by (i)

$$4 = 2^n$$

$\therefore$ $$n = 2$$

22. Order of reaction may or may not equal to the sum of stoichiometric coefficient of reactants in a balanced chemical equation.

23. Order = Sum of powers of the concentration of reactants.

$$\text{Order of reaction} = \frac{1}{2} + 2 = \frac{5}{2}$$

$$\text{Order} = \frac{5}{2}$$

24. Rate law $\frac{dx}{dt} = k[A]^1[B]^2[C]^0 = k[A]^1[B]^2$

Hence, order of reaction $= 1 + 2 = 3$

25. For zero order reaction, for example,

$$A \longrightarrow B$$

$$\frac{-d\,[A]}{dt} = k[A]^0$$

$$\frac{-d\,[A]}{dt} = k$$

27. Unit of rate constant $= \dfrac{\text{time}^{-1}}{\text{concentration}^{(n-1)}}$

where, n = order of reaction

Given, unit of rate constant $=$ L mol^{-1}s^{-1}

$$\therefore \quad \text{L mol}^{-1}\text{s}^{-1} = \frac{(\text{s})^{-1}}{(\text{L mol}^{-1})^{n-1}} = \frac{(\text{s})^{-1}}{(\text{L mol}^{-1})^{1-n}}$$

$$= \text{s}^{-1}(\text{L mol}^{-1})^{n-1}$$

$$\text{or} \qquad 1 = n - 1 \quad \text{or} \quad n = 2$$

$\therefore$ Order of reaction $= 2$

28. For zero order reaction,

$$x = kt$$

$$= 0.2 \text{ mol dm}^{-3}\text{ h}^{-1} \times \frac{30}{60}\text{ h}$$

$$= 0.1 \text{ mol dm}^{-3}$$

Now, concentration $=$ 0.05 mol dm^{-3}

Hence, initial concentration $=$ 0.1 $+$ 0.05 $=$ 0.15 mol dm^{-3}

29. For 2/3 of a reaction

$$[A]_0 = a, \qquad [A] = a - \frac{2}{3}a = \frac{a}{3}$$

$$\because \qquad t_{2/3} = \frac{2.303}{k}\log\frac{[A]_0}{[A]}$$

$$= \frac{2.303}{5.48 \times 10^{-14}}\log\frac{a}{a/3}$$

$$= \frac{2.303}{5.48 \times 10^{-14}}\log 3$$

$$t_{2/3} = 2.01 \times 10^{13}\text{ s}$$

30.
$$t_{1/2} \propto \frac{1}{a^{n-1}}$$

When $\qquad n = 4$

$$t_{1/2} \propto \frac{1}{a^3}$$

Hence, order of reaction $= 4$

34. $R\text{Cl} + \text{NaOH} \longrightarrow R\text{OH} + \text{NaCl}$

$$\text{Rate} = k[R\text{Cl}]$$

For this reaction, rate of reaction depends upon the concentration of RCl.

It means, the rate of reaction is halved by reducing the concentration of RCl by one half.

35. For first order reactions,

$$k = \frac{0.693}{t_{1/2}} = \frac{0.693}{(3.0\text{ h})}$$

$$t = \frac{2.303}{k}\log\frac{[A]_0}{[A]}$$

$$\text{or} \qquad \log\frac{[A]_0}{[A]} = \frac{k \times t}{2.303}$$

$$\log\frac{[A]_0}{[A]} = \frac{0.693}{3\text{ h}} \times \frac{(8\text{ h})}{2.303} = 0.8024$$

$$\frac{[A]_0}{[A]} = \text{Antilog}\, 0.8024 = 6.345$$

$$[A]_0 = 1\text{M};\ [A] = \frac{[A]_0}{6.345} = \frac{1\text{M}}{6.345}$$

$$= 0.1576\text{ M}$$

After 8 h sucrose left $=$ 0.1576 M

36. For first order reaction

$$t = \frac{2.303}{k}\log\frac{a}{(a-x)} \qquad \text{...(i)}$$

Given, $(a - x) = \dfrac{a}{16}$; $k = 60\text{ s}^{-1}$

Placing the values in Eq. (i)

$$t = \frac{2.303}{60\text{ s}^{-1}}\log\frac{a \times 16}{a} = \frac{2.303}{60\text{ s}^{-1}}\log 16 = \frac{2.303}{60\text{ s}^{-1}}\log 2^4$$

$$= \frac{2.303}{60\text{ s}^{-1}} \times 4\log 2 = \frac{2.303}{60\text{ s}^{-1}} \times 4 \times 0.3010$$

$$= 4.62 \times 10^{-2}\text{ s}$$

$$\text{Time} = 4.62 \times 10^{-2}\text{ s}$$

37. We know that

$$\frac{(t_{1/2})_1}{(t_{1/2})_2} = \left[\frac{a_2}{a_1}\right]^{n-1}$$

where, n = order of the reaction

Given, $(t_{1/2}) = 0.1\text{ s}$, $a_1 = 400$

$(t_{1/2})_2 = 0.8\text{ s}$, $a_2 = 50$

On substituting the values,

$$\frac{0.1}{0.8} = \left[\frac{50}{400}\right]^{n-1}$$

On taking log both sides

$$\log\frac{0.1}{0.8} = (n-1)\log\frac{50}{400}$$

$$\log\frac{1}{8} = (n-1)\log\frac{1}{8}$$

$$0.90 = (n-1)\,0.90$$

$$n - 1 = 1$$

$$n = 2$$

38.
$$k = \frac{1}{t}\left[\frac{x}{a(a-x)}\right]$$

$$k = \frac{1}{500}\left[\frac{0.2a}{a(a-0.2a)}\right]$$

$$k = \frac{1}{2000\,a}$$

$$\frac{1}{2000\,a} = \frac{1}{t}\left[\frac{0.6a}{a(a-0.6a)}\right]$$

$$t = 3000\text{ s.}$$

39. From the graph it is clear that the reaction is of zero order and hence, the units of rate constant = mol L^{-1} s^{-1}

40.
$$ {}_{79}Au^{198} \xrightarrow{-\beta} {}_{80}Hg^{198} $$
$$ k = \frac{0.693}{t_{1/2}} = \frac{0.693}{65} $$

After 260 hr,
$$ k = \frac{2.303}{260} \log \frac{a}{a-x} $$
$$ \frac{0.693}{65} = \frac{2.303}{260} \log \frac{a}{a-x} $$
$$ \frac{a}{a-x} = 16 $$
$$ \frac{1}{1-x} = 16 $$
$$ x = \frac{15}{16}\text{ g} = 0.9375\text{ g} $$

41. Let the order of reaction with respect to A is x and B is y.

$\therefore$ rate law, $r = k[A]^x[B]^y$ ...(iv)

On putting values, we get
$$ 0.10 = k[0.30]^x[0.30]^y \quad \text{...(i)} $$
$$ 0.40 = k[0.30]^x[0.60]^y \quad \text{...(ii)} $$
$$ 0.20 = k[0.60]^x[0.30]^y \quad \text{...(iii)} $$

From Eq. (i) and (ii) we get
$$ \frac{0.1}{0.4} = \left(\frac{0.30}{0.30}\right)^x \left(\frac{0.30}{0.60}\right)^y $$
$$ \frac{1}{4} = \left(\frac{1}{2}\right)^y $$

or $$ 4 = 2^y $$
$$ (2)^2 = 2^y \quad \text{or} \quad y = 2 $$

From Eq. (ii) and (iii), we get
$$ \frac{0.40}{0.20} = \left(\frac{0.30}{0.60}\right)^x \left(\frac{0.60}{0.30}\right)^y $$
$$ 2 = \left(\frac{1}{2}\right)^x (2)^y $$

On putting the values of y, we get
$$ 2 = \left(\frac{1}{2}\right)^x (2)^2 $$
$$ \frac{2}{4} = \left(\frac{1}{2}\right)^x $$
$$ \left(\frac{1}{2}\right)^1 = \left(\frac{1}{2}\right)^x $$

or $$ x = 1 $$

On putting the values of x and y in Eq. (iv), we get
$$ r = k[A]^1[B]^2 = k[A][B]^2 $$

42. Since the reaction is 50% completed in 1.26×10^{14} s.
$$ \therefore \quad t_{1/2} = 1.26 \times 10^{14}\text{ s} $$
$$ k = \frac{0.693}{t_{12}} = \frac{0.693}{1.26 \times 10^{14}} $$

For 100% completion,
$$ t = \frac{2.303}{k} \log \frac{a}{a-x} $$
$$ t = \frac{2.303 \times 1.26 \times 10^{14}}{0.693} \log \frac{100}{0} = \infty $$

43. The given equation clearly shown that the rate constant k increases exponentially with decreasing activation energy and increasing temperature.

44. $k = Ae^{-E_a/RT}$

On taking log, we get
$$ \log k = \log A - \frac{E_a}{2.203RT} $$

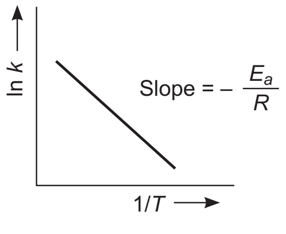
or $$ \ln k = \ln A - \frac{E_a}{RT} $$

$\therefore$ A graph between $\ln k$ *vs* $1/T$ is a straight line (according to equation of straight line *viz.* $y = mx + c$) with $-\frac{E_a}{k}$ slope (negative slope) and $\ln A$ intercept.

$\therefore$ Correct graph is graph (a).

In all other graphs slope is positive.

45. Arrhenius equation is
$$ k = Ae^{-E_a/RT} $$
$$ \ln k = \ln A - \frac{E_a}{RT} $$
$$ \ln k = \ln A - \frac{E_a}{RT} $$
$$ \text{Slope} = -\frac{E_a}{R} $$



46. Activation energy of backward reaction $= E_1$

$\therefore$ Activation energy of forward reaction $= E_1 + E_2$

Since the energy of product > energy of reactants

and $$ \text{energy} \propto \frac{1}{\text{stability}} $$

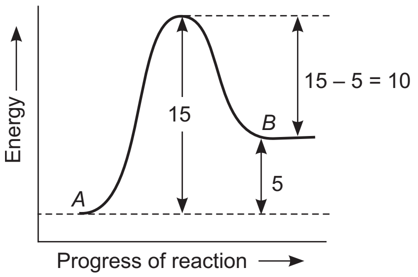
$\therefore$ Products are less stable than reactants.

47. For endothermic reaction $A \longrightarrow B$

Activation energy = 15 kcal/mol

Energy of reaction = 5 kcal/mol

Hence, activation energy for the reaction $B \longrightarrow A$ is $15 - 5 = 10$ kcal/mol



48. For exothermic reaction,
Energy of reactants > energy of product, which is the case given in (i).

50. $\because$ Rate constant (k') > rate constant (k'')
Greater the rate constant lesser will be the activation energy.

$$\therefore \qquad E_a' < E_a''$$

51. According to collision theory, the two main conditions for the formation of products are sufficient threshold energy and proper orientation.

52. Activation energy of a reaction is constant at constant temperature hence, $E_1 = E_2$.

53. Slow reaction rate indicates higher free energy of activation.

55. According to Arrhenius equation

$$\log \frac{k_2}{k_1} = \frac{E_a}{2.303\,R}\left[\frac{1}{T_1} - \frac{1}{T_2}\right];$$

$$[\because T_1 = 293\,\text{K}; T_2 = 313\,\text{K}; T_2 - T_1 = 20\,\text{K}]$$

$$\log \frac{4}{1} = \frac{E_a}{2.303 \times (8.314\ \text{J mol}^{-1}\ \text{K}^{-1})} \times \frac{20}{293 \times 313}$$

$$0.6021 = \frac{E_a}{2.303 \times (8.314\ \text{J mol}^{-1})} \times \frac{20}{293 \times 313}$$

$$E_a = \frac{0.6021 \times 2.303 \times 8.314 \times 293 \times 313}{20}\ \text{J mol}^{-1}$$

$$= 52863\ \text{J mol}^{-1}$$

$$E_a = 52.863\ \text{kJ mol}^{-1}$$

56. According to Arrhenius equation

$$\log \frac{k_2}{k_1} = \frac{E_a}{2.303\,R} \times \frac{T_2 - T_1}{T_1\,T_2}$$

$$k_1 = 4.5 \times 10^3\,\text{s}^{-1}; k_2 = 1.5 \times 10^4\,\text{s}^{-1}\ ;\ T_1 = 10°\text{C} = 283\ \text{K}$$

$$\log \frac{1.5 \times 10^4}{4.5 \times 10^3} = \frac{(60000\ \text{J mol}^{-1})}{2.303 \times (8.314\ \text{J mol}^{-1})}\left(\frac{T_2 - 283}{283\,T_2}\right)$$

$$\log 3.333 = 3133.62\left(\frac{T_2 - 283}{283\,T_2}\right)$$

$$\frac{0.5228}{3133.62} = \frac{T_2 - 283}{283 T_2}$$

$$\frac{0.5288 \times 283}{3133.62} = \frac{T_2 - 283}{T_2}$$

$$1 - \frac{283}{T_2} = 0.04776$$

or $$T_2 = \frac{283}{1 - 0.04776} = \frac{283}{0.95224}$$

$$T_2 = 297.19\ \text{K}$$

$$= (297.19 - 273.0) = 24.19°\,\text{C}$$

Temperature = 24.19° C

57. According to Arrhenius equation.

$$\log \frac{k_2}{k_1} = \frac{E_a}{2.303 R}\left[\frac{1}{T_1} - \frac{1}{T_2}\right]$$

$$\frac{k_2}{k_1} = 2;\ T_1 = 295\ \text{K};\ T_2 = 305\ \text{K};\ R = 8.314\ \text{JK}^{-1}\ \text{mol}^{-1}$$

$$\therefore \qquad \log 2 = \frac{E_a}{2.303 \times (8.314\ \text{JK}^{-1}\ \text{mol}^{-1})}\left[\frac{1}{295\,\text{K}} - \frac{1}{305\,\text{K}}\right]$$

or $$0.3010 = \frac{E_a}{2.303 \times (8.314\ \text{J mol}^{-1})} \times \frac{(10)}{295 \times 305}$$

$$E_a = \frac{0.3010 \times 2.303 \times 8.314 \times 295 \times 305}{10}\ (\text{J mol}^{-1})$$

$$= 51855\ \text{J mol}^{-1}$$

or $$= 51.855\ \text{kJ mol}^{-1}$$

Activation energy for the reaction = 51.855 kJ mol^{-1}

58. Fraction of molecules (x) having energy equal to or more than activation energy may be calculated as follows

$$x = n/N = e^{-E_a/RT}$$

$$\ln x = \frac{-E_a}{RT} \quad \text{or} \quad \log x = -\frac{E_a}{2.303\,RT}$$

or $$\log x = -\frac{209.5 \times 10^3\ \text{J mol}^{-1}}{2.303 \times (8.314\ \text{JK}^{-1}\ \text{mol}^{-1}) \times 581\ \text{K}}$$

$$= -\ 18.8323$$

$$x = \text{Antilog}\,(-\ 18.8324) = \text{Antilog}\,\overline{19}.1677$$

$$= 1.471 \times 10^{-19}$$

$$\text{Fraction of molecules} = 1.471 \times 10^{-19}$$

59. $$\log \frac{k_2}{k_1} = \frac{E_a}{2.303\ R} \times \frac{T_2 - T_1}{T_1 \cdot T_2}$$

$$\log \frac{105}{100} = \frac{E_a}{2.303 \times 8.314} \times \frac{1}{300 \times 301}$$

$$E_a = 36.65\ \text{kJ}$$

60. $$\log \frac{k_2}{k_1} = \frac{E_a}{2.303R}\left(\frac{T_2 - T_1}{T_1 T_2}\right)$$

$$\log \frac{k_2}{k_1} = \frac{9000}{2.303 \times 2}\left(\frac{5}{295 \times 300}\right)$$

$$\log \frac{k_2}{k_1} = 0.1103$$

$$\frac{k_2}{k_1} = 1.288, \quad k_2 = 1.288\,k$$

i.e., increase by 28.8%

Round II

1. $B + 5D \longrightarrow 3A + 2C$

$$-\frac{d[B]}{dt} = -\frac{1}{5}\frac{d[D]}{dt} = +\frac{1}{3}\frac{d[A]}{dt} = +\frac{1}{2}\frac{d[C]}{dt}$$

2. Thermal decomposition,

$$CH_3CHO \xrightarrow{\Delta} CH_4 + CO$$

$$\frac{dx}{dt} = k[CH_3CHO]^{3/2}$$

3. $$C_n = \frac{C_0}{2^n}$$

or $$50 = \frac{800}{2^n}$$

$$2^n = \frac{800}{50} = 16 = 2^4$$

$\therefore$ $$n = 4$$

$$T = n \times t_{1/2}$$

$$t_{1/2} = \frac{2 \times 10^4}{4} = 0.5 \times 10^4 \text{ s}$$

$$k = \frac{0.693}{0.5 \times 10^4} = 1.386 \times 10^{-4}$$

4. Rate depends upon the slowest step. Hence, from equation

$$O + O_3 \longrightarrow 2O_2$$

$$r = k[O_3][O]$$

and from equation $O_3 \rightleftharpoons O_2 + O$

$$K_{eq} = \frac{[O_2][O]}{[O_3]}$$

$$[O] = \frac{K_{eq}[O_3]}{[O_2]}$$

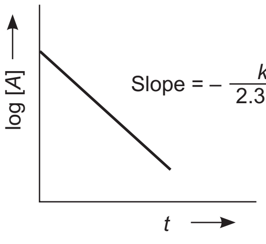
$\therefore$ $$r = k[O_3]\frac{K_{eq}[O_3]}{[O_2]}$$

$$= k'[O_3]^2[O_2]^{-1}$$

5. If the temperature is increased by 60°C then 10° increase has been made 6 times and therefore, rate will increase by $2^6 = 64$ times.

6. For first order reaction

$$\log[A] = -\frac{kt}{2.303} + \log[A]_0$$



7. $$t_1 = \frac{2.303\,(t_{1/2})_1}{0.693}\log\left(\frac{1}{1-(1/4)}\right)$$

and $$t_2 = \frac{2.303\,(t_{1/2})_2}{0.693}\log\left(\frac{1}{1-(3/4)}\right)$$

$$\frac{t_1}{t_2} = \frac{8}{1} \times \frac{\log(4/3)}{\log 4}$$

$$= \frac{8 \times 0.125}{0.602} = 1 : 0.602$$

8. For first order reaction : $k = \frac{2.303}{t}\log\frac{[A]_0}{[A]}$

At 298 K; $$k_1 = \frac{2.303}{t}\log\frac{100}{90} \quad \text{...(i)}$$

At 308 K; $$k_2 = \frac{2.303}{t}\log\frac{100}{75} \quad \text{...(ii)}$$

Dividing eq. (ii) by (i);

$$\frac{k_2}{k_1} = \frac{\log\frac{100}{75}}{\log\frac{100}{90}} = \frac{0.1249}{0.0458} = 2.73$$

According to Arrhenius theory;

$$\log\frac{k_2}{k_1} = \frac{E_a}{2.303\,R} \times \frac{T_2 - T_1}{T_1 T_2}$$

$$\log 2.73 = \frac{E_a}{2.303\,R}\left[\frac{308 - 298}{298 \times 308}\right]$$

$$E_a = \frac{0.4361 \times 2.303 \times (8.314 \text{ J mol}^{-1}) \times 298 \times 308}{10}$$

$$E_a = 76640 \text{ Jmol}^{-1} = 76.640 \text{ kJ mol}^{-1}$$

Now, according to Arrhenius equation

$$\log k = \log A \frac{-E_a}{2.303\,RT}$$

$$\log k = \log(4 \times 10^{10}) - \frac{76640 \text{ J mol}^{-1}}{2.303 \times (8.314 \text{ J mol}^{-1}\text{K}^{-1}) \times (318 \text{ K})}$$

$$\log k = 10.6021 - 12.5870 = -1.9849$$

$$k = \text{Antilog}(-1.9849)$$

$$= \text{Antilog}(\bar{2}.0151) = 1.035 \times 10^{-2} \text{ s}^{-1}$$

9. $$\begin{array}{lccc} & SO_2Cl_2(g) & \longrightarrow SO_2(g) & + \; Cl_2(g) \\ \text{Initially} & p_i & 0 & 0 \\ \text{After time } t & p_i - p & p & p \end{array}$$

Total pressure after time t *i.e.,*

$$p_t = p_i - p + p + p = p_i + p$$

So, $$a = p_i$$

$$a - x = p_i - (p_t - p_i)$$

$$= p_i - p_t + p_i = 2p_i - p_t$$

Substitutions of the value of *a* and (*a* − *x*) gives

$$k = \frac{2.303}{t}\log\frac{p_i}{(2p_i - p_t)}$$

(a) Calculation of rate constant *k*

Given, $p_i = 0.5$ atm ; $p_t = 0.6$ atm,

$$k = \frac{2.303}{t}\log\frac{p_i}{(2p_i - p_t)}$$

$$= \frac{2.303}{(100\text{ s})}\log\frac{0.5\text{ atm}}{0.4\text{ atm}}$$

$$= \frac{2.303}{(100\text{ s})}\log 1.25 = \frac{2.303}{(100\text{ s})}\times 0.0969$$

$$= 2.23\times10^{-3}\text{ s}^{-1}$$

(b) Calculation of reaction rate when total pressure is 0.65 atm

$$p_{SO_2Cl_2} = 0.5 - (0.65 - 0.50)$$

$$= (1 - 0.65) = 0.35\text{ atm}$$

$$k = 2.23\times10^{-3}\text{ s}^{-1}$$

$$\text{Rate} = k\times p_{SO_2Cl_2} = (2.23\times10^{-3}\text{ s}^{-1})\times(0.35\text{ atm})$$

$$\text{Rate} = 7.8\times10^{-4}\text{ atm s}^{-1}$$

10. $t_{1/2} = 28.1\text{ yr}\ ;\ k = \frac{0.693}{t_{1/2}} = \frac{0.693}{28.1}\text{ yr}^{-1}$

For first order reaction

$$t = \frac{2.303}{k}\log\frac{a}{(a-x)}$$

$$a = 1\mu,\ t = 60\text{ yr}\ ;\ k = \frac{0.693}{28.1}\text{ yr}^{-1}$$

$$60\text{ yr} = \frac{2.303}{0.693/28.1}\times\log\frac{a}{(a-x)}$$

$$\log\frac{a}{(a-x)} = \frac{(60\text{ yr})\times 0.693/28.1\text{ yr}^{-1})}{2.303} = 0.642$$

$$\frac{a}{(a-x)} = \text{Antilog}\,0.642 = 4.385$$

$$(a-x) = \frac{a}{4.385} = \frac{(1\ \mu\text{g})}{4.385} = 0.2280\ \mu\text{g}$$

Amount left after 60 yr = 0.2280 μg

11. $(CH_3)_2CHN{=}NCH\,(CH_3)_2(g) \longrightarrow N_2(g) + C_6H_{14}\,(g)$

	$(CH_3)_2CHN{=}NCH(CH_3)_2$	N_2	C_6H_{14}
Initial pressure	p_i	0	0
After time *t*	$p_i - p$	p	p

Total pressure after time *t*,

i.e., $(p_t) = (p_i - p) + p + p = p_i + p$

or $p = p_t - p_i$

$a = p_i$; $(a - x) = p_i - p$ on substituting the values of p ;

$(a - x) = p_i - (p_t - p_i)$, *i.e.*, $(a - x) = 2p_i - p_t$

The decomposition reaction is of gaseous nature and the rate constant *k* can be calculated as

$$k = \frac{2.303}{t}\log\frac{a}{a-x}$$

Substitution of value of *a* and (*a* − *x*) gives

$$k = \frac{2.303}{t}\log\left(\frac{p_i}{2p_i - p_t}\right)$$

(i) Rate constant after 360 s = k_1

$$k_1 = \frac{2.303}{(360\text{ s})}\log\frac{(35\text{ atm})}{(70 - 54)\text{ atm}}$$

$$= \frac{2.303}{(360\text{ s})}\log\frac{35}{16} = \frac{2.303}{(360\text{ s})}\log 2.1875$$

$$= \frac{2.303\times 0.33995}{(360\text{ s})} = 2.17\times10^{-3}\text{ s}^{-1}$$

(ii) Rate constant after 720 s = k_2

$$k_2 = \frac{2.303}{(720\text{ s})}\log\frac{(35\text{ atm})}{(70 - 63)\text{ atm}}$$

$$= \frac{2.303}{(720\text{ s})}\log 5 = \frac{2.303\times 0.6990}{(720\text{ s})}$$

$$= 2.24\times10^{-3}\text{ s}^{-1}$$

$$\text{Average rate constant } k = \frac{(2.17 + 2.24)\times10^{-3}\text{ s}^{-1}}{2}$$

$$k = 2.21\times10^{-3}\text{ s}^{-1}$$

12. $k = 2.1\times10^{10}\exp(-2700/RT)$

i.e., $\log k$ *vs* $1/T$ will be straight line

intercept of $\log k$ axis = $\log 2.1\times10^{10}$

13. $A^m + B^n \longrightarrow ABx$

In this case,

overall order of reaction may or may not be = $m + n$

Hence, code 3 is wrong.

14. The reaction occurring in two steps has two activation energy peaks. The first step, being fast needs less activation energy. The second step being slow, needs more activation energy. Therefore, second peak will be higher than the first.

15. According to Arrhenius equation

$$k = Ae^{-E_a/RT} \qquad \text{...(i)}$$

According to the available data

$$k = (4.5\times10^{11}\text{s}^{-1})\,e^{-28000}\text{ K/T} \qquad \text{...(ii)}$$

On comparing both equations;

$$-\frac{E_a}{RT} = \frac{-28000\text{ K}}{T}$$

$$E_a = (28000\text{ K})\times R = (28000\text{ K})\times(8.314\ \text{K}^{-1}\text{J mol}^{-1})$$

$$= 232792\text{ kJ mol}^{-1}$$

$$E_a = 232.792\text{ kJ mol}^{-1}$$

16. Slowest step of a reaction is called the rate determining step. If in this step only one reactant is involved, the reaction is called unimolecular. For such reactions, the order and molecularity of slowest step are equal to one.

17. Only in case of elementary reaction, rate law is determined from the balanced chemical equation.

18. For zero order reaction,

$$\text{rate} = -\frac{d[A]}{dt} = k \quad \text{or} \quad \frac{d[A]}{dt} = -k$$

On integrating, we get

$$\int \frac{d[A]}{dt} = -\int k\,dt$$

$$[A] = -kt + c \qquad \ldots\text{(i)}$$

When, $t = 0$ $\quad [A] = [A]_0$

$\therefore$ $\quad C = [A]_0$

On putting the value of c in Eq. (i)

$$[A] = -kt + [A]_0$$

$\therefore$ A graph of $[A]$ *vs* t is a straight line with slope $= -k$. Here, $[A] =$ concentration of reactant.

Thus, graph (a) and (d) are correct.

19. Reaction is zero order so rate of formation of product or rate of decomposition of reactant is constant so concentration will be linear function.

For zero order reaction, $k = \frac{a}{2t_{1/2}}$

So unit of k is mol L^{-1} s^{-1}

$$\frac{dx}{dt} = k(2a-2x)\times(a-x)^{-1} = 2\text{K}$$

$$x = [C] = 2kt$$

20. $k_1 = k_2 = \frac{2}{3}$rd of A has reacted for $[A] = [B] = [C]$

$$\therefore \quad k_1 + k_2 = \frac{1}{t}\ln\frac{[A]_0}{\frac{1}{3}[A]_0}$$

or $$t = \frac{1}{k_1+k_2}\ln 3 = \frac{1}{2k_1}\ln 3 = \frac{1}{2k_2}\ln 3$$

21. Order and molecularity of a reaction may or may not be same. *e.g.,* pseudounimolecular reactions where molecularity is 2 and order is 1.

Order is determined experimentally whereas molecularity is the sum of stoichiometric coefficients of reactants in elementary step.

22. Only those reactant molecules undergo chemical change which have proper orientation and sufficient kinetic energy for the formation of products.

Rate constants determined from Arrhenius equation are fairly accurate for simple as well as complex molecules.

23. For reactions carried out in solution, changing the solvent will generally change the rate of a reaction. The rate of reaction will change, when some alcohol is added.

24. The change in the concentrations of all the reactants and products can be expressed as

$$\frac{-d[I_2]}{dt} = -\frac{1}{2}\frac{d[S_2O_3^{2-}]}{dt}$$

$$= \frac{d[S_4O_6^{2-}]}{dt} = \frac{1}{2}\frac{d[I^-]}{dt}$$

25. According to Arrhenius equation

$$k = Ae^{-E_a/RT}$$

when $E_a = 0, k = A$

26. $$k = \frac{2.303}{t}\log_{10}\frac{a}{(a-x)}$$

$$\frac{0.693}{t_{1/2}} = \frac{2.303}{t}\log\frac{100}{100-75}$$

$\therefore$ $\quad t_{1/2} = 16$ min

27. $$k = \frac{0.693}{t_{1/2}} = \frac{0.693}{693}\ s^{-1}$$

$$= 1\times10^{-3}\ s^{-1}$$

28. For a first order reaction

$$\text{Rate} = k\,(\text{concentration})$$

$$\therefore \quad k = \frac{\text{Rate}}{\text{concentration}} = \frac{1.5\times10^{-2}\ \text{mol L}^{-1}\ \text{min}^{-1}}{0.5\ \text{mol L}^{-1}}$$

$$= 3\times10^{-2}\,\text{min}^{-1}$$

$$t_{1/2} = \frac{0.693}{k} = \frac{0.693}{3\times10^{-2}}\text{min}$$

$$= \frac{69.3}{3}\text{min or } 23.1 \text{ min}$$

29. $$A \underset{k_b}{\overset{k_f}{\rightleftharpoons}} C$$

$$k_c = \frac{k_f}{k_b} = \frac{[C]}{[A]} = \frac{0.4}{0.6} = \frac{2}{3}$$

For $\quad 2C \rightleftharpoons 2A$

$$k_c = \left(\frac{1}{k_c}\right)^2 = \left(\frac{1}{2/3}\right)^2 = \frac{9}{4}$$

30. $$-\frac{dA}{dt} = k_f[A] - k_b[C]$$

and $d[C]/dt = k_f[A] - k_b[C]$ at any time

and slope between conc. and time is known as rate and they are always equal at any time.

31. $k_c = k_f/k_b$

$$= \frac{\text{Conc. of products as per rate law}}{\text{Conc. of reactants as per rate law}}$$

Stoichiometry of reaction is required.

32. For every 10°C rise of temperature, rate is doubled. Thus, temperature coefficient of the reaction = 2

When temperature is increased by 50°, rate becomes

$$= 2^{(50/10)} = 2^5 \text{ times}$$

$$= 32 \text{ times}$$

33. $A \xrightarrow{k_1} B, A \xrightarrow{k_2} C,$

By Arrhenius equation,

$$k_1 = A' \, e^{-E_{a_1}/RT}$$

and $$k_2 = A' \, e^{-E_{a2}/RT}.$$

(A' is Arrhenius constant.)

$$(\text{Since, } E_{a_2} = 2E_{a_1})$$

$\therefore$ $$k_2 = A' \, e^{-2E_a/RT}$$

$$\frac{k_1}{k_2} = \frac{A' \, e^{-E_{a_1}/RT}}{A' \, e^{-2E_{a_1}/RT}} = e^{E_{a_1}/RT}$$

$\therefore$ $$k_1 = k_2 e^{E_{a\,1}/RT}$$

34. For a zero order reaction,

$$k_0 = \frac{[A]_0}{2t_{1/2}}$$

Since, $[A]_0 = 2 \text{ M}, t_{1/2} = 1 \text{h}$

So, $k_0 = 1$

and $$k_0 = \frac{\Delta x}{t}$$

or $$t = \frac{0.50 - 0.25}{1} = 0.25 \text{ h}$$

35. Slowest step is the rate determining step. Thus, in case (A), rate law is given as rate $= k[Cl_2][H_2S]$

While for the reaction given in case (*B*), rate law is given as

$$\text{rate} = k[H_2S][Cl_2][H^+]^{-1}.$$

Hence, only mechanism (A) is consistent with the given rate law.

36. Half-life $= 6.93$ min $\quad k_1 = \dfrac{0.693}{6.93} = 0.1$

We know, k_1 for per cent completion

$$k_1 = \frac{2.303}{t} \log\left(\frac{100}{100 - x}\right)$$

$$0.1 = \frac{2.303}{t} \times \log \frac{100}{1}$$

$$0.1 = \frac{2.303}{t} \log 10^2$$

$$t = \frac{2.303 \times 2}{0.1}$$

$$= 46.06 \text{ min}$$

37. $$\frac{1}{2} A \longrightarrow 2B$$

For the given reaction

$$-\frac{2d\,[A]}{dt} = \frac{1}{2}\frac{d\,[B]}{dt} = \text{Rate of reaction}$$

Rate of disappearance of *A*

$$= -\frac{d\,[A]}{dt} = \frac{1}{2 \times 2}\frac{d[B]}{dt} = \frac{1}{4}\frac{d\,[B]}{dt}$$

38. $$2A + B \longrightarrow \text{products}$$

[*B*] is doubled, half-life didn't change, *i.e.*, half-life is independent of change in conc of reactant *i.e.*, first order. First order *wrt* to *B*

When [*A*] is doubled, rate increased by two times

$\Rightarrow$ First order *wrt A*

Hence, net order of reaction $= 1 + 1 = 2$

Unit for the rate constant $= \text{conc}^{(1-n)}\, t^{-1}$

$$= (\text{mol L}^{-1})^{-1} \cdot \text{s}^{-1}$$

$$= \text{L} \cdot \text{mol}^{-1} \text{ s}^{-1}$$

39. $A_2 + B_2 \rightleftharpoons 2AB$

$$E_a \text{ (forward)} = 180 \text{ kJ mol}^{-1}$$

$$E_a \text{ (backward)} = 200 \text{ kJ mol}^{-1}$$

In the presence of catalyst :

$$E_a \text{ (forward)} = 180 - 100 = 80 \text{ kJ mol}^{-1}$$

$$E_a \text{ (backward)} = 200 - 100 = 100 \text{ kJ mol}^{-1}$$

$$\Delta H = E_a \text{ (forward)} - E_a \text{ (backward)}$$

$$= 80 - 100 = -20 \text{ kJ mol}^{-1}$$

40. $$\text{Rate} = k\,[NOBr_2]\,[NO] \qquad \text{...(i)}$$

But $NOBr_2$ is in equilibrium

$$K_{eq} = \frac{[NOBr_2]}{[NO]\,[Br_2]}$$

$$[NOBr_2] = K_{eq}\,[NO]\,[Br_2] \qquad \text{...(ii)}$$

Putting the value of $[NOBr_2]$ in Eq (i)

$$\text{Rate} = k \cdot K_{eq}\,[NO]\,[Br_2]\,[NO]$$

Hence, $$\text{Rate} = k \cdot K_{eq}\,[NO]^2\,[Br_2]$$

$$\text{Rate} = k'\,[NO]^2\,[Br_2]$$

where $$k' = k \cdot K_{eq}$$

41. $k = Ae^{-E/RT}$

E is activation energy. It is that energy, which molecule must have to give the product.

42. There are two different reactants (say *A* and *B*).

$$A + B \longrightarrow \text{product}$$

Thus, it is a bimolecular reaction.

If $$\frac{dx}{dt} = k\,[A]\,[B]$$

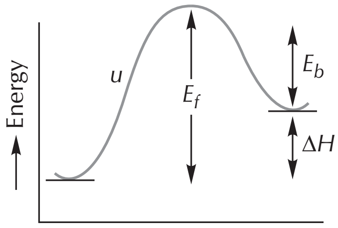
it is second order reaction

If $$\left(\frac{dx}{dt}\right) = k\,[A] \quad \text{or} \quad = k\,[B]$$

it is first order reaction.

Molecularity is independent of rate, but is the sum of the reacting substances, thus it cannot be unimolecular reaction.

43. $X \rightarrow Y$ is an endothermic reaction, $\Delta H = +$ ve



E_b = energy of activation of backward reaction

E_f = energy of activation of forward reaction

ΔH = heat of reaction

Thus, $\quad E_f = E_b + \Delta H$

Thus, $\quad E_f > E_b$

44. Variation of K_{eq} with temperature T is given by van't Hoff equation.

$$\log K_{eq} = -\underset{A}{\frac{\Delta H^\circ}{2.303\,RT}} + \underset{B}{\frac{\Delta S^\circ}{R}}$$

Slope of the given line is positive indicating that term A is positive, thus ΔH° is negative.

Thus, reaction is exothermic.

45. $2A + B \longrightarrow C$

$$\text{Rate} = k\,[A]\,[B]$$

It represents second order reaction.

Thus, unit of k is $M^{-1}\ s^{-1}$

$t_{1/2}$ is dependent of concentration but not constant.

and $\quad -\frac{1}{2}\frac{d\,[A]}{dt} = \frac{d\,[C]}{dt}$

46. Order = 1

Concentration changes from 0.8 M to 0.4 M in (50%) 15 min, thus half-life = 15 min = T_{50}

A change from 0.1 M to 0.025 M is 75% and for first order reaction

$$T_{75} = 2 \times T_{50} = 2 \times 15 = 30 \text{ min}$$

or $\quad T_{50} = 15$ min

$$k = \frac{2.303 \log 2}{T_{50}} = \frac{2.303 \log 2}{15}$$

$$a = 0.1 \text{ M}$$

$$(a - x) = 0.025 \text{ M}$$

For first order :

$$k = \frac{2.303}{t} \log \left(\frac{a}{a - x}\right)$$

$$\frac{2.303 \log 2}{15} = \frac{2.303}{t} \log \frac{0.1}{0.025}$$

$$= \frac{2.303}{t} \log 4$$

$$\therefore \quad \frac{2.303 \log 2}{15} = \frac{2 \times 2.303 \log 2}{t}$$

$$\therefore \quad t = 30 \text{ min}$$

47.

$$\left(\frac{dx}{dt}\right) = k\,[\text{NO}]^2\,[O_2]$$

$$= k\left(\frac{n_{\text{NO}}}{V}\right)^2\left(\frac{n_{O_2}}{V}\right)$$

$$\left(\frac{dx}{dt}\right) = \frac{k}{V^3}\,(n_{\text{NO}})^2\,(n_{O_2})$$

$$\left(\frac{dx}{dt}\right) = \frac{k\,(n_{\text{NO}})^2\,(n_{O_2})}{\left(\frac{V}{2}\right)^3} = 8\left(\frac{dx}{dt}\right)$$

48. $H_2 + I_2 \longrightarrow 2HI$

$$\text{Rate of reaction} = \frac{-d\,[H_2]}{dt} = \frac{-d\,[I_2]}{dt} = \frac{1}{2}\frac{d\,[HI]}{dt}$$

or $\quad \frac{-2d\,[H_2]}{dt} = \frac{-2d\,[I_2]}{dt} = \frac{d\,[HI]}{dt}$

49. $kt = -\log_e C_t + \log_e C_0$

$$t = -\frac{1}{k}\log_e C_t + \log_e C_0$$

$y = mx + c$, straight line, negative slope.

- Applications of Colloids

5.1 Adsorption

When a solid surface is exposed to a gas or a liquid, molecules from the gas or the liquid accumulate at the surface. The phenomenon of concentration of molecules of a gas or a liquid at a solid surface rather than in its bulk is called adsorption. The substance that concentrates at the surface is called **adsorbate** and the solid at the surface of which the concentration occurs, is called **adsorbent.**

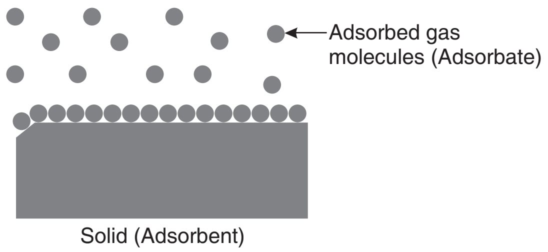

Fig. 5.1 Adsorption of gas molecules over solid surface

Surface chemistry deals with the phenomenon that occurs at the surface or interfaces. There are several properties of substances, particularly of solids and liquids and solids and gases, which depend upon the nature of the surface of interface.

Some examples of adsorption are

(i) Finely divided charcoal if stirred into a dilute solution of methylene blue, the dye molecules are adsorbed by the charcoal particles and the depth of colour of the solution decreases appreciably.

(ii) If a gas (SO_2, Cl_2, NH_3) is treated with powdered charcoal in a closed vessel, the gas molecules adsorb on charcoal surface and the gas pressure is reduced.

The common adsorbents are **charcoal** (vegetable and animal), **silica gel** (prepared by heating a mixture of sodium silicate and 10% HCl at 50°C), **metals** such as Ni, Cu, Ag, Au, Pt and colloids.

Distinction between Adsorption and Absorption

1. Adsorption implies concentration at the surface only while absorption implies penetration into the body of the solid.
2. Absorption is a rapid process and equilibrium is maintained in a short time. While in adsorption, the equilibrium is reached slowly.
3. Both adsorption and absorption often take place side by side and it is difficult to distinguish between two processes.
4. Mc Bain introduced the general term **sorption,** which includes both the processes.

Characteristics of Adsorption

Important characteristics of adsorption are as follows

(a) Specificity and Selectivity

Adsorption is specific and selective phenomenon, which strictly refers to the existence of a higher concentration of any particular component at the surface of a liquid or a solid phase.

(b) Exothermic Process

Adsorption is accompanied with decrease in free energy of the system. In adsorption, there is a decrease in entropy of the system.

As, $\Delta G < 0$

and $\Delta S < 0$,

Therefore, $\Delta H < 0$ $(\Delta H = \Delta G + T\Delta S)$

Hence, the adsorption is associated with decrease in enthalpy of the system. Thus, *adsorption is always an exothermic process.*

(c) Residual Valency Bonds

The atoms or molecules of a solid surface have unbalanced or residual attractive forces on the surface, which can hold adsorbate particles together. Thus, the adsorbed atoms or molecule can be held on the surface of a metal by physical van der Waals' forces or chemical forces due to residual valence bonds.

Molecular adsorption

Atomic adsorption

(d) Extent of Adsorption

All solids adsorb gases to some extent. Adsorption is not very pronounced unless an adsorbent possesses a large surface area for a given mass. Various types of charcoals, silica gels, metal, etc., are used as adsorbents. Appreciable adsorption also takes place on some smooth surfaces, such as those of platinum and glass. Charcoal and other solids gain increased power of adsorption on heating at low pressure with various gases or in air or vacuum at temperature varying from 350–1000°C. Such treated charcoal is called **activated charcoal** and the process is called **activation**. On activation

1. the hydrocarbons and other impurities are removed from charcoal.
2. the surface area may increase due to chemical interaction with the oxidising agent which is used as **activator.**
3. the degree of unsaturation of the surface atoms may be increased.

Different Types of Adsorption

Adsorption may be classified into the following two types

On the basis of Concentration

On the basis of concentration of adsorbates adsorption can be of following two types

(a) Positive Adsorption

If the concentration of adsorbate is more on the surface as compared to its concentration in the bulk phase then it is called positive adsorption. *e.g.*, when a concentrated solution of KCl is shaken with blood charcoal, it shows positive adsorption.

(b) Negative Adsorption

If the concentration of the adsorbate is less than its concentration in the bulk then it is called negative adsorption. *e.g.,* when a dilute solution of KCl is shaken with blood charcoal, it shows negative adsorption.

Hot Spot 1

PHYSICAL and Chemical Adsorption

It is an important topic of the chapter for JEE Main examination. The questions, if asked, from this chapter may be from this topic. The level of questions is easy to average and its nature is generally theoretical.

On the basis of nature of force existing between adsorbate and adsorbent adsorption again of the following two types

(a) Physical Adsorption or van der Waals' Adsorption

If the physical or van der Waals' forces of attraction hold the adsorbate molecules to the surface of adsorbent, it is termed as physical adsorption (physisorption). Since physical forces involves, van der Waals' forces, it is

1. Reversible
2. Involves physical forces
3. Appreciable only at low temperature below the boiling point of adsorbate
4. Not very specific
5. Cause multilayer adsorption
6. Generally has heat of adsorption less than 10 kcal/mol

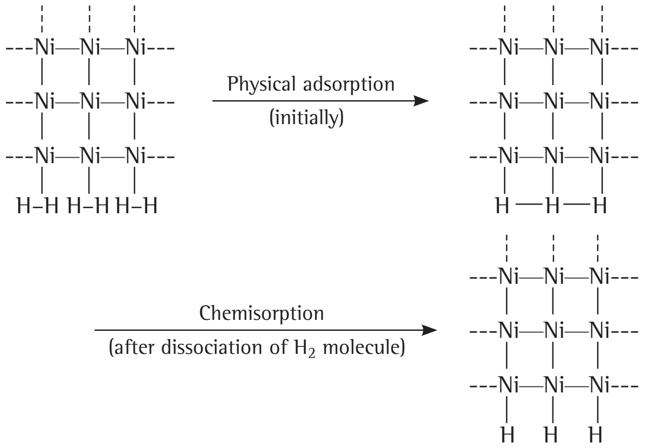
Due to the formation of multilayers, physical adsorption decreases after sometimes.

(b) Chemical Adsorption or Activated Adsorption

If the chemical forces hold the gas molecules to the surface of the adsorbent, the adsorption is termed as chemical adsorption (chemisorption). Since activated chemisorbent involves a high degree of specificity like chemical forces, thus chemisorption is

1. Irreversible
2. Involves transfer of electrons between gas and solid
3. Appreciable at high temperatures
4. May be rapid as well as slow
5. May involve activation energy in the adsorption process
6. Highly specific
7. Leads almost to a monolayer
8. Generally has heat of adsorption greater than about 20 kcal/mol

Often adsorption is a combination of both the two types of adsorptions. *e.g.,* hydrogen molecules are first adsorbed by van der Waals' forces on a nickel surface and then dissociate. The hydrogen atoms are thus adsorbed on nickel as



Comparison between physical and chemical adsorption is tabulated below

Table 5.1 **Comparison between Physisorption and Chemisorption**

S.N.	Physisorption	Chemisorption
1.	It is caused by intermolecular van der Waals' forces	It is caused by chemical bond formation
2.	It is not specific	It is highly specific
3.	It is reversible	It is irreversible
4.	It depends on the nature of gas. More easily liquefiable gases get adsorbed readily	It depends on the nature of gas. Gases which form compounds with the adsorbent exhibit it
5.	Heat of adsorption is low. (about 5 kcal mol^{-1})	Heat of adsorption is high (20 to 100 kcal mol^{-1})
6.	Low temperature is favourable. It decreases with increase of temperature	High temperature is favourable. It increases with increase of temperature
7.	No appreciable activation energy is involved	High activation energy is involved
8.	High pressure is favourable. Decrease of pressure causes desorption	High pressure is favourable. Decrease of pressure does not cause desorption
9.	It depends on the surface area. It increases with increase of surface area	It also depends on the surface area. It increases with increase of surface area

Factors Affecting the Extent of Adsorption

The extent of adsorption is affected by following factors

(a) Nature of Adsorbent

A gas is adsorbed in different amounts on different adsorbents. *e.g.,* hydrogen is strongly adsorbed on nickel surface, while it is weakly adsorbed on alumina surface under identical conditions.

(b) Surface Area

Increase in the surface area of the adsorbent, increases the total amount of the gas adsorbed because number of adsorbing sites increases. Thus, finely divided metals (Pt, Ni) and porous substance (charcoal, silica gel) are best solid adsorbents.

(c) Nature of the Gas

In general, the more liquifiable a gas is, the more readily will it be adsorbed. Thus, the amount of adsorption of gas on same mass of charcoal follows the following order

$$SO_2(T_c = 157°C) > CH_4(T_c = -83°C) > H_2(T_c = -120°C).$$

Easily liquifiable gases, such as NH_3, HCl, Cl_2, SO_2, CO_2 etc., are readily adsorbed than the permanent gases, such as O_2, N_2, H_2 etc. *The higher the critical temperature of the gas, the greater the extent of adsorption.*

Caution Point *Nature of adsorption of nitrogen on the surface of iron depends on the temperature. AT 83 K, nitrogen is physisorbed on iron surface as N_2 molecules. The degree of adsorption decreases rapidly as the temperature increases. At room temperature, there is no adsorption of N_2 on iron. When temperature is further increased up to 773 K and above, then nitrogen is chemisorbed on the iron surface as nitrogen atom.*

(d) Exothermic Nature

The energy liberated when 1 g mol of a gas is adsorbed on a solid surface is defined as **heat of adsorption.**

(e) Pressure

At the surface of adsorbent, a fix number of adsorption sites are available where only gaseous molecules can be adsorbed. Initially as pressure is increased, the number of molecules which strike the unit area of the surface increases in proportion to the increase of pressure and hence adsorption increases almost linearly with pressure. Since a fixed number of adsorption sites are available, eventually at some high pressure, a stage would be reached where all the sites are occupied and hence further increase in pressure would not cause any further adsorption to occur, *i.e.,* extent of adsorption becomes independent of pressure after a certain high pressure. In the intermediate range of pressure, the increase in adsorption is not as fast as in the beginning. This can be understood on the basis that the phenomenon of adsorption and desorption proceed simultaneously due to its reversible nature.

Adsorption Isotherms

The amount of gas adsorbed depends on equilibrium pressure and temperature. The relationship between the equilibrium pressure (p) of a gas and its amount adsorbed on the solid adsorbent at any constant temperature is called an adsorption isotherm.

Two such isotherms are given below.

(a) Freundlich Adsorption Isotherm

Freundlich gave the relationship between the gas adsorbed by solid adsorbent surface and pressure of the gas at a particular temperature. He proposed the following empirical equation

$$\frac{x}{m} = kp^{1/n} \quad \text{...(i)}$$

where, x is the mass of gas adsorbed on a mass m of adsorbent at a pressure p. k and n are constant, which depend upon the nature of the gas and the adsorbent and upon temperature. From the relationship curves,

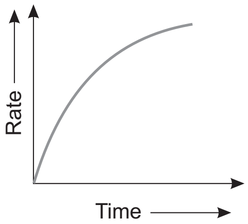


Fig. 5.2 Rate *vs T* graph

When $n = 1, \frac{x}{m} = kp$ or $\frac{x}{m} \propto p$ (at low pressure)

When $n > 1,$ $\frac{x}{m} = k$ (independent of pressure)

It is observed that at high pressure when saturation point is reached, logarithmic form of Eq. (i) is

$$\log \frac{x}{m} = \log k + \frac{1}{n} \log p$$

Graph between $\log \frac{x}{m}$ and $\log p$ is a straight line with slope $\frac{1}{n}$ and intercept $\log k$.

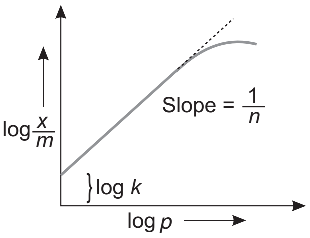

Fig. 5.3 Graph between log *x/m* and log *p*

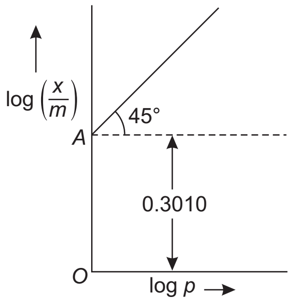
The limitations of Freundlich isotherm are as

1. Concept of Freundlich adsorption is purely empirical.
2. It is not applicable at high pressure.
3. It does not consider the role of surface area of adsorbent in the process of adsorption.

Sample Problem 1 *Graph between* $\log\left(\frac{x}{m}\right)$ *and* $\log p$ *is a straight line at angle 45° with intercept as shown in the figure. Hence,* $\left(\frac{x}{m}\right)$ *at a pressure of 0.2 atm is*



(a) 0.2 (b) 0.4
(c) 0.6 (d) 0.8

Interpret (b) $\log\left(\frac{x}{m}\right) = \log k + \frac{1}{x}\log p$

Here, $\frac{1}{n} = \tan 45° = 1 \Rightarrow n = 1$

and $\log k = 0.3010 \Rightarrow k = 2$

Again, since, $\left(\frac{x}{m}\right) = kp^{1/n}$

therefore, $\left(\frac{x}{m}\right) = 2(0.2)^1 = 0.4$

(b) Langmuir Adsorption Isotherm

Langmuir developed adsorption isotherm on the basis of the following assumptions

1. The layer of gas adsorbed on the solid adsorbent is one molecule thick.
2. The adsorbed layer is uniform all over the adsorbent.
3. There is no interaction between the adjacent adsorbed molecules.

If 'θ' is the fraction of surface covered by the adsorbed molecules, the fraction of naked area is $(1-\theta)$.

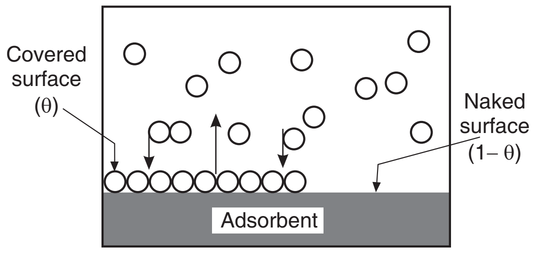


Fig. 5.4 Unimolecular adsorption on solid surface

Rate of desorption,

$$R_d \propto \theta$$

$$\Rightarrow \quad R_d = k_d\,\theta$$

Rate of adsorption,

$$R_a \propto (1-\theta) \Rightarrow R_a = k_a(1-\theta)p$$

where, k_d and k_a are the rate constants for desorption and adsorption processes respectively.

At equilibrium, $R_a = R_d$, giving

$$k_d\theta = k_a(1-\theta)p$$

or

$$\theta = \frac{k_a\,p}{k_d + k_a\,p}$$

$$= \frac{k_a/k_d p}{1 + k_a/k_d p} = \frac{Kp}{1+Kp}$$

where, $K = \frac{k_a}{k_d}$ is the equilibrium constant referred to as **adsorption coefficient.**

According to Langmuir, the degree of adsorption is directly proportional to the θ, *i.e.*, the fraction of surface area occupied,

i.e., $$\frac{x}{m} \propto \theta = k\theta$$

$$\frac{x}{m} = \frac{kKp}{1+Kp}$$

$$\frac{x}{m} = \frac{K'p}{1+kp} \qquad \text{...(i)}$$

where, $K' = kK$ = constant

This relationship is called Langmuir adsorption isotherm.

Eq. (i) may be written as

$$\frac{p}{(x/m)} = \frac{1}{K'} + \left(\frac{k}{K'}\right)p$$

$$\frac{p}{(x/m)} = \frac{1}{K'} + \frac{p}{K''}$$

where, $K'' = k/K'$ = constant

It is of the form $(y = c + mx)$, *i.e.*, equation of straight line but not passing through origin.

Thus, if $\frac{p}{(x/m)}$ is plotted against p, it will result in a straight line.

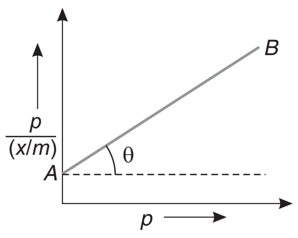

Fig. 5.5 Plot of $\frac{p}{x/m}$ vs p

Slope of the line $AB = \frac{k}{K'} = \tan\theta$

Interpretation of Langmuir Adsorption Isotherm Let us consider the mathematical relation

$$\frac{x}{m}=\frac{K'p}{1+kp}$$

Case I When pressure is very high

then $1+Kp=Kp$

$$\therefore \qquad \frac{x}{m}=\frac{K'p}{Kp}=\text{constant}$$

Thus, at high pressure, the degree of adsorption approaches to a limiting value.

Case II When pressure is low then $1+Kp=1$

$$\therefore \qquad \frac{x}{m}=K'p \quad \text{or} \quad \frac{x}{m}\propto p$$

Thus, degree of adsorption is directly proportional to pressure.

Case III When pressure is moderate then expression is of the form $\frac{x}{m}=Kp^{1/n}$;

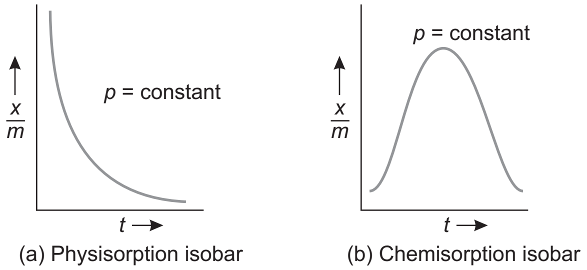
where $\frac{1}{n}$ lies between 0 and 1.

The limitations of Langmuir isotherm is that (i) this isotherm holds good at low pressure but fails at high pressure.

Caution Point *The Langmuir adsorption isotherm is restricted to the formation of unimolecular layer of gas molecules on the surface of solids. However, it was suggested that there is possibility of multimolecular layer of gas molecules on the surface of the solids rather than single layer. On this basis Brunauer, Emmelt and Teller proposed a new theory known as BET theory.*

Adsorption Isobars

A graph drawn between extent of adsorption $\left(\frac{x}{m}\right)$ and temperature '*t*' at a constant pressure of adsorbate gas is known as adsorption isobar.



(a) Physisorption isobar (b) Chemisorption isobar

Fig. 5.6 Adsorption isobars

Adsorption isobars of physical and chemical adsorption show an important difference and this difference is helpful in distinguishing these two types of adsorption.

Adsorption Isostere

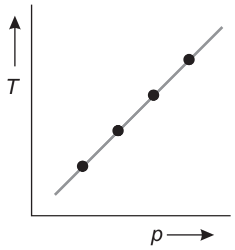


Fig 5.7 Adsorption isostere

Degree of adsorption depends on temperature as well as on pressure. When temperature increases, the extent of adsorption decreases. A linear relationship should exist between temperature and pressure with a certain amount of adsorption. The plot of temperature *versus* pressure for a given amount of adsorption is called adsorption isostere.

Adsorption From Solution

Solids can adsorb solutes from solution also. The following observations have been made in the case of adsorption from solution phase

(i) The extent of adsorption decreases with the increase of temperature.

(ii) The extent of adsorption increases with the increase of surface area of the adsorbent.

(iii) The extent of adsorption depends on the concentration of the solute in solution.

(iv) The extent of adsorption depends on the nature of the adsorption and the adsorbate.

The precise mechanism of adsorption from solution is not known. Freundlich's equation approximately describes the behaviour of adsorption from solution with the difference that instead of pressure, concentration of the solution is taken into account, *i.e.,*

$$\frac{x}{m}=kC^{1/n}$$

(C is the equilibrium concentration, *i.e.,* when adsorption is complete.)

On taking logarithm we get

$$\log\frac{x}{m}=\log k+\frac{1}{n}\log C$$

Plotting $\log x/m$ against $\log C$ gives a straight line which shows the validity of Freundlich isotherm.

This can be tested experimentally by taking solutions of different concentration of acetic acid. Equal volumes of solutions are added to equal amounts of charcoal in different flasks. The final concentration is determined in each flask after adsorption.

The difference in the initial concentration and final concentration gives the value of x. Using the above equation, validity of Freundlich isotherm can be established.

Sample **Problem 2** *The mass x of a solute adsorbed per gram of a solid adsorbent is given by Freundlich isotherm* $x = kC^n$ *where* $(k = 0.160$ *and* $n = 0.431)$. *Calculate the amount of the acetic acid that 1 kg charcoal would adsorb from a 0.837 M acetic acid solution.*

(a) 2.47 (b) 3.25 (c) 4.28 (d) 5.24

Interpret (a) $x = kC^n$

$$= 0.160(0.837)^{0.431}$$

$$= 0.1482 \text{ g acetic acid per gram charcoal}$$

$$-148.2 \text{ g acetic acid per kg charcoal}$$

$$= \frac{148.2}{60} \text{ mol acetic acid per kg charcoal}$$

$$= 2.47 \text{ mol acetic acid per kg charcoal.}$$

Ion-Exchange Adsorption

The specialised specific application of adsorption is seen in the cases of ion-exchangers where ion-exchange adsorption play its role. e.g., synthetic resin are utilised as ion-exchangers. The resin has one ion adsorbed on them, which afterwards releases this ion and adsorbs another like ion. This process is called ion-exchange adsorption.

There may be two types of ionic exchanges

(a) Cationic Exchange

The resin which exchanges cations is called cationic exchanger. These are high polymers containing acidic groups (*e.g.*, sulphonic acid group, SO_3H). The resulting macroanion has adsorbed H^+ ions, which are exchanged when solution of another cation is allowed to flow over it.

$$R^-H^+ + Na^+ \rightleftharpoons R^-Na^+ + H^+$$

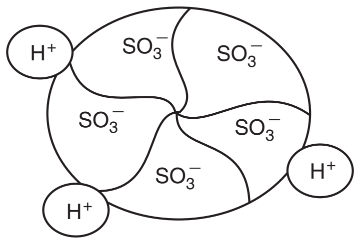

Fig. 5.8 Cationic exchange

(b) Anionic Exchange

The resin which exchanges anions is called anionic exchanger. It contains a basic group (*e.g.,* quaternary ammonium hydroxides, $—N^+R_3OH$). The macrocation has adsorbed OH^- ions, which are exchanged by another anion.

$$R^+OH^- + Cl^- \rightleftharpoons R^+Cl^- + OH^-$$

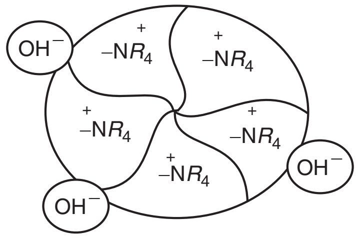

Fig. 5.9 Anionic exchange

The ionic exchangers are reversible and the original exchange resin can be regenerated by the treatment of the exchange resin with suitable acid or base.

Applications of Ion-exchange Adsorption

Ion-exchange adsorption is widely used as

(a) Water Softening

Hard water is softened by passing through a column packed with sodium cation exchanger resin, R^-Na^+.

$$2R^-Na^+ + Ca^{2+} \longrightarrow R_2^-Ca^{2+} + Na^+$$

(b) Deionisation of Water

Using a cation and an anion-exchanger resins, all dissolved ions in water can be removed. Such water is referred to as **deionised** or **demineralised water.**

(c) Medical Uses

Excess sodium salts can be removed from the body fluids by giving the patient a suitable ion-exchanger to eat. Weakly basic anion-exchangers are used to remove excess acid or **acidity** in stomach.

Applications of Adsorption

Adsorption is utilised in several processes, some important of which are as follows :

(a) Production of High Vacuum

A partially evacuated vessel is connected to a container of activated charcoal cooled with liquid air, which adsorbs all the gas molecules in the vessel resulting in a very high vacuum.

(b) Gas Masks

All gas masks contain an adsorbent (finely divided charcoal or activated charcoal) or a series of adsorbents, which remove poisonous gases by adsorption.

(c) Heterogeneous Catalysis

The reactant molecules are expected to be adsorbed on the catalyst surface and decompose later on to yield product molecules.

(d) Removal of Colouring Matter from Solutions

Animal charcoal removes colours of solutions by adsorbing coloured impurities.

(e) In Froth Floatation Process

The low-grade sulphide ores (PbS, ZnS, Cu_2S) are made free from silica and other earthly matters by froth floatation process. Finely divided ore particles mixed with oil are adsorbed on air bubbles created in water with detergent and rise to the surface.

(f) Chromatographic Analysis

Chromatography involves the principal of selective adsorption.

(g) Removal of Impurities

Colloidal silica is used to adsorb impurities from petroleum oils, motor sprits and waxes. Fuller's earth is also used for the same purpose.

(h) Miscellaneous Uses

Ferric hydroxide is used as an antidote adsorbent in case of arsenic poisoning. Many drugs are selectively adsorbed. Various adsorbents are used in industry to recover solvent vapour from air or particular solvents from a mixture.

Silica gel and alumina are used as good drying agents.

Check Point 1

1. Which will absorb more, a lump of charcoal or charcoal powder and why?
2. Why are all adsorption processes exothermic?
3. What is the sign of ΔH and ΔS when a gas gets adsorbed on a solid?
4. Why physisorption is multimolecular whereas chemisorption is unimolecular?
5. Activated charcoal is used in gas masks, why?

5.2 Catalysis

A substance that alters the rate of a reaction without being consumed in the reaction is called **catalyst** and the phenomenon is known as catalysis. As these are not consumed in a reaction that means these are required in very small quantities in the reaction. The term catalyst was given by Berzelius.

Types of Catalysis

Catalysis may be classified into the following classes

(a) Homogeneous Catalysis

If the catalyst is present in the same phase as reactants, it is called **homogeneous catalyst** and the phenomenon is known as homogeneous catalysis. *e.g.,*

(i) Hydrolysis of ester in the presence of mineral acid, *i.e.,*

$$RCOOR'(l) + H_2O(l) \xrightleftharpoons{H_2SO_4(s)} RCOOH + R'OH$$

(ii) Catalytic decomposition of ozone by chlorine atoms in gaseous phase, *i.e.,*

$$O_3(g) + O(g) \xrightarrow{Cl(g)} 2O_2$$

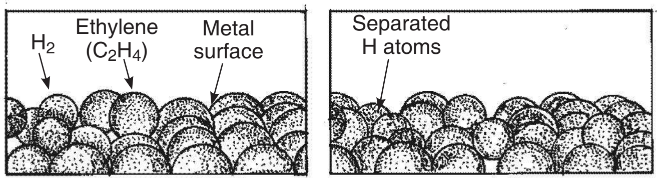
(iii) Oxidation of CO by O_2 in the presence of NO as a catalyst,

i.e., $$2CO(g) + O_2(g) \xrightarrow{NO(g)} 2CO_2(g)$$

(b) Heterogeneous Catalysis

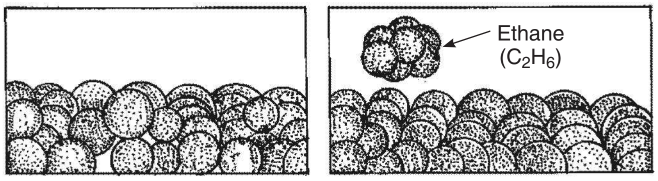
In **heterogeneous catalysis,** the catalyst is present in a different phase from that of reactants. Here, the catalyst is generally a solid (sometimes liquid) and the reactants are generally gaseous. *e.g.,*

(i) Hydrogenation of unsaturated hydrocarbons in the presence of metals like Ni, Pt or Pd at 250°C near about. The process can be seen as



1. H_2 and C_2H_4 approach and adsorb to metal surface

2. Rate-limiting step is H-H bond breakage



3. One H atom bonds to adsorbed C_2H_4

4. Another C-H bond forms and C_2H_6 leaves the surface

Fig. 5.10 Procedure of heterogeneous catalysis

(ii) NH_3 is manufactured from N_2 and H_2 (Haber's process) using Fe as catalyst.

$$N_2(g) + 3H_2(g) \xrightarrow{Fe(s)} 2NH_3(g)$$

(iii) Methyl alcohol synthesis from water gas and H_2 using CuO, ZnO and Cr_2O_3 as catalyst.

$$\underbrace{CO(g) + H_2(g)}_{\text{water gas}} + H_2(g) \xrightarrow{Cu/ZnO-Cr_2O_3(s)} CH_3OH(l)$$

Sample **Problem 3** *Which reaction represents homogeneous catalysis?*

(*a*) $2SO_2(g) + O_2(g) \xrightarrow{NO(g)} 2SO_3(g)$

(*b*) $N_2(g) + 3H_2(g) \xrightarrow{Fe(s)} 2NH_3(g)$

(*c*) $4NH_3(g) + 5O_2(g) \xrightarrow{Pt(s)} 4NO(g) + 6H_2O(g)$

(*d*) $4HCl(g) + O_2(g) \xrightarrow{Cu_2Cl_2(s)} 2H_2O(g) + 2Cl_2(g)$

Interpret (*a*) In reaction given in option (a), the state of reactants SO_2, O_2 and catalyst NO are same, so this is an example of homogeneous catalysis.

In other given reactions, the state of reactants and catalyst used are not same, so these are examples of heterogeneous catalysis.

(c) Positive Catalysis

When the rate of reaction is accelerated by the foreign substance, it is said to be a *positive catalyst* and the phenomenon is known as *positive catalysis. e.g.,*

(i) Oxidation of ammonia in the presence of platinum gauze.

$$4NH_3(g) + 5O_2(g) \xrightarrow[300°C]{Pt(s)} 4NO(g) + 6H_2O(g)$$

(ii) Decomposition of H_2O_2 in the presence of colloidal platinum.

$$2H_2O_2(l) \xrightarrow{Pt} 2H_2O(l) + O_2(g)$$

(iii) Synthesis of ammonia by Haber's process in the presence of a mixture of iron and molybdenum.

$$N_2(g) + 3H_2(g) \xrightarrow[450-500°C]{Fe(s),\ MO} 2NH_3(g)$$

(iv) Oxidation of hydrochloric acid into chlorine by Deacon's process in the presence of $CuCl_2$.

$$4HCl(g) + O_2(g) \xrightarrow[450°C]{CuCl_2(s)} 2Cl_2(g) + 2H_2O(g)$$

(d) Negative Catalysis

When the rate of reaction is retarded by the foreign substance, it is said to be a **negative catalyst** and the phenomenon is called negative catalysis. *e.g.,*

(i) The oxidation of chloroform by air is retarded if some alcohol is added to it.

$$2CHCl_3(l) + O_2(g) \xrightarrow{Alcohol(l)} 2COCl_2(g) + 2HCl(g)$$

(ii) The decomposition of hydrogen peroxide decreases in the presence of glycerine.

$$2H_2O_2(l) \xrightarrow{Glycerine\ (l)} 2H_2O(l) + O_2(g)$$

(iii) The oxidation of sodium sulphite by air is retarded by alcohol.

$$2Na_2SO_3(s) + O_2(g) \xrightarrow{Alcohol(l)} 2Na_2SO_4(s)$$

(iv) The oxidation of benzaldehyde is retarded if some diphenyl amine is added.

$$2C_6H_5CHO(l) + O_2(g) \xrightarrow{Diphenyl\ amine(l)} 2C_6H_5COOH(l)$$

(e) Auto Catalysis

In certain reactions, one of the product acts as catalyst. This type of phenomenon in which one of the products itself acts as a catalyst is known as auto catalysis. *e.g.,*

During hydrolysis of ethyl acetate, acetic acid and ethyl alcohol are formed. The reaction is initially very slow but gradually its rate increases. This is due to the formation of acetic acid which acts as an auto catalyst in this reaction.

$$CH_3COOC_2H_5 + H_2O \longrightarrow CH_3COOH + C_2H_5OH$$

In the case of homogeneous auto catalytic reaction, rate increases with passage of time because in such cases rate of reaction is directly proportional to concentration of catalyst, *e.g.,*

$$CH_3COOC_2H_5 + H_2O \longrightarrow CH_3COOH + C_2H_5OH$$

$$\text{Rate} = k\underbrace{[CH_3COOC_2H_5]}_{\text{reactant}}\underbrace{[CH_3COOH]}_{\text{catalyst}}$$

(f) Induced Catalysis

When one reaction does not occur under ordinary conditions, but influenced by other reaction, the phenomeonon is termed as induced catalysis. *e.g.,*

Sodium arsenite solution is not oxidised by air. If, however air is passed through a mixture of the solution of sodium arsenite and sodium sulphite, both of them undergo simultaneous oxidation. The oxidation of sodium sulphite, thus, induces the oxidation of sodium arsenite.

Catalytic Promoters or Activators

It has been observed in a number of cases that the activity of a catalyst is considerably increased by the addition of a second substance which by itself has no catalytic property. Such a substance, which (though not a catalyst by itself) promotes the activity of a catalyst, is called a **promoter.** *e.g.,* Molybdenum (Mo) promotes the catalytic activity of iron in the **Haber process** for the manufacture of ammonia.

$$N_2 + 3H_2 \xrightarrow[Mo]{Fe} 2NH_3$$

Oxides of aluminium, thorium also have the same role in this process.

Catalytic Poisons

When the activity of a catalyst is decreased by the addition of a second substance which by itself has no catalytic property, such a substance is called catalytic poison. *e.g.,* The activity of iron catalyst is decreased (even stop) by the presence of H_2S or CO in the synthesis of ammonia by Haber's process.

$$N_2 + 3H_2 \xrightarrow[H_2S]{Fe} 2NH_3$$

Characteristics of Catalysts

Some important characteristics of catalysts are discussed below

1. They become temporarily involved in a reaction, providing an alternative reaction path of lower activation energy than that for the uncatalysed reaction.
2. They catalyse both forward and backward reactions to the same extent in a reversible reaction and thus have no effect on the equilibrium constant.
3. The catalyst remains unchanged in amount and chemical composition at the end of the reaction. It may undergo some physical change.
4. Only a small quantity of the catalyst is generally needed. One mole of colloidal platinum in 10^8 L can catalyse decomposition of H_2O_2.
5. In certain reactions, the rate of the reaction is dependent on the concentration of the catalyst. *e.g.,* Rate of inversion of cane sugar is dependent on the concentration of H^+ used as catalyst.
6. Rate of the reaction in certain heterogeneous reaction varies with surface area of the catalyst. Hence, finely divided metals are preferred in the form of catalyst.
7. The catalyst does not initiate the reaction and are specific in their action. *e.g.,* starting from H_2 and CO, 3 different products are possible using different catalysts as

   (i) $CO(g) + 3H_2(g) \xrightarrow{Ni} CH_4(g) + H_2O(g)$

   (ii) $CO(g) + 2H_2(g) \xrightarrow{Cu/ZnO—Cr_2O_3} CH_3OH(g)$

   (iii) $CO(g) + H_2(g) \xrightarrow[250°C]{Cu} HCHO$

   The catalyst cannot alter the nature of the products of the reaction.

Activity and Selectivity of Catalyst

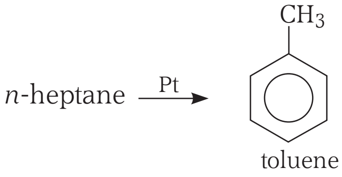
Catalysts possess unique property of activity and selectivity which are discussed below

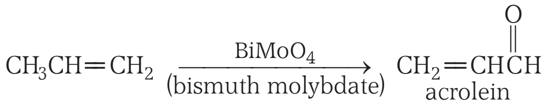
(a) Activity

Activity is the ability of catalysts to accelerate chemical reactions. The degree of acceleration can be as high as 10^{10} times in certain reactions. *e.g.,* Reaction between H_2 and O_2 to form H_2O in the presence of platinum as catalyst takes place with explosive violence. In the absence of catalyst, H_2 and O_2 can be stored indefinitely without any reaction.

(b) Selectivity

It is the ability of catalysts to direct reaction to yield particular products (excluding other). *e.g.,*





$$CH_3CH{=}CH_2 \xrightarrow[\text{(bismuth molybdate)}]{BiMoO_4} \underset{\text{acrolein}}{CH_2{=}CH\overset{\overset{\Large O}{\|}}{C}H}$$

Similarly, acetylene on hydrogenation in the presence of Pt or Ni or Pd catalyst gives ethane.

$$H—C{\equiv}C—H + 2H_2(g) \xrightarrow{Pt/Pd/Ni} \underset{\text{ethane}}{CH_3—CH_3}$$

Hydrogenation of acetylene in the presence of Lindlar's catalyst gives ethylene.

$$H—C{\equiv}C—H + H_2 \xrightarrow[\substack{\text{Sulphur or}\\ \text{quinoline}}]{Pd\text{-}BaSO_4} \underset{\text{ethylene}}{CH_2{=}CH_2}$$

Zeolite : Shape Selective Catalysts

Zeolites are alumino-silicates of the general formula

$$M_{x/n}[(AlO_2)_x \cdot (SiO_2)_y] \cdot mH_2O$$

where, M may be simple cation like Na^+, K^+ or Ca^{2+},

n is the charge on the simple cation.

m is the number of molecules of water of crystallisation.

Some well known zeolites are

Erionite : $Na_2K_2CaMg(AlO_2)_2(SiO_2)_2 \cdot 6H_2O$
Gemelinite : $Na_2Ca(AlO_2)_2(SiO_2)_4 \cdot 6H_2O$
Fauzasite (natural) : $Na_{56}[(Al_2O)_{56}(SiO_2)_{136}] \cdot 250H_2O$
ZSM–5 :$H_x[(AlO_2)_x \cdot (SiO_2)_{96-x}] \cdot 16H_2O$

The characteristic feature of zeolites is the openness of the structure, which permits cavities of different sizes. The open structure is provided by silica in which aluminium occupies $x/(x+y)$ fraction of the tetrahedral sites.

The negative charge of the alumino silicate framework is neutralised by the replaceable cations. The void space forms more than 50% of the total volume, which is occupied by water molecules. The reaction selectivity of zeolites depends upon the size of cavities (cages), pores (apertures) and the distribution of pores in the structure. The pore size in zeolites generally varies from 260 pm to 740 pm.

There is a new class of highly siliceous zeolites with an optimal pore diameter of 550 pm. ZSM-5 is one such zeolite. This converts alcohol to gasoline (petrol) by dehydrating the alcohol and producing a mixture of wide variety of hydrocarbons. The product distribution depends on the ability of the pores to accommodate linear, branched, *iso*-alkanes as well as benzene derivatives.

Theories of Catalysis

The theories explaining the mechanism of catalysis are discussed below

(a) Intermediate Compound Formation Theory

According to this theory, the catalyst first forms an intermediate compound with one of the reactants. The intermediate compound is formed with less energy consumption than needed for the actual reaction. The intermediate compound being unstable combines with other reactant to form the desired product and the catalyst is regenerated.

e.g., a reaction of the type

$$A + B \xrightarrow{K} AB$$

which occurs in the presence of a catalyst *K,* may takes place as

$$\underset{\text{}}{A} + \underset{\text{catalyst}}{K} \longrightarrow \underset{\text{intermediate compound}}{AK} \quad \text{(Slow reaction)}$$

$$AK + B \longrightarrow \underset{\text{product}}{AB} + \underset{\text{catalyst}}{K} \quad \text{(Fast reaction)}$$

Many catalytic reactions can be explained on the basis of this theory. The catalytic oxidation of sulphur dioxide to sulphur trioxide in the lead chamber process probably takes place as

$$\underset{\text{catalyst}}{2NO} + O_2 \longrightarrow \underset{\text{intermediate product}}{2NO_2}$$

$$NO_2 + SO_2 \longrightarrow \underset{\text{product}}{SO_3} + \underset{\text{catalyst}}{NO}$$

This theory explains why the catalyst remains unchanged in mass and chemical composition at the end of the reaction and is effective even in small quantities.

Limitations of this theory are

1. Intermediate compound is formed only in case of homogeneous catalysis only.
2. It cannot explain the action of catalytic promotors, poisions and finely divided catalysts.

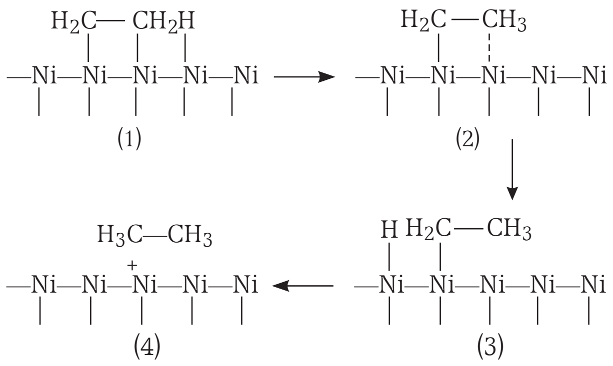
(b) Adsorption Theory

According to this theory, the catalytic activity is localised on the surface of the catalyst. *This theory proposed following steps of mechanism.*

1. Firstly reactants on the solid surface are adsorbed (chemisorption). The adsorption step is thought to involve chemical bonding of reactants to the highly reactive metal atoms on the surface which accompanying breaking or at least weakening of bonds in the reactants.
2. Diffusion of reactants along the surface.
3. Reaction at an active site to form adsorbed product called the **activated surface complex.**
4. Desorption of the product and the catalyst surface is regenerated.

   e.g., hydrogenation of ethene at nickel surface at 400 K takes place in the following stages (1) to (4)

$$CH_2{=}CH_2(g) + H_2(g) \xrightarrow{Ni(s)} CH_3{-}CH_3(g)$$



Applications of Catalysis

Some of the important catalytic processes are listed below

Table 5.2 **Catalysts in Industry**

S.N.	Industrial process	Catalyst used
1.	Acetic acid from acetaldehyde by oxidation with air	V_2O_5
2.	Bosch process for the manufacture of H_2	$Fe_2O_3 + Cr_2O_3$
3.	Contact process for the manufacture of H_2SO_4	V_2O_5, Pt
4.	Dacon's process for the manufacture of Cl_2	$CuCl_2$
5.	Dehydrogenation of alcohol to aldehyde	Cu
6.	Haber's process for the synthesis of NH_3	Fe_2O_3 or Fe + Mo
7.	Lead chamber process for the manufacture of H_2SO_4	NO
8.	Manufacture of vegetable ghee	Ni
9.	Methanol from water gas and H_2	ZnO, Cr_2O_3
10.	Ostwald's process for the manufacture of HNO_3	Pt gauze
11.	Polymerisation of alkenes	H_3PO_4 on Kieselguhr
12.	Preparation of O_2 from $KClO_3$	MnO_2
13.	Synthetic petrol from coal (Bergius process)	Iron oxalate

5.3 Enzyme Catalysis

Enzymes are complex nitrogenous substances secreted by low forms of vegetable and animal organisms. Either the organisms in bulk (like yeast) or the chemicals synthesised by and extracted from them (like yeast extract) may be used for catalysing certain reactions.

Table 5.3 **Examples of Enzyme Catalysts**

S.N.	Reaction	Catalyst used
1.	$\underset{\text{glucose}}{C_6H_{12}O_6} \longrightarrow \underset{\text{ethanol}}{2C_2H_5OH} + 2CO_2$	Zymase
2.	$\underset{\text{sucrose}}{C_{12}H_{22}O_{11}} + H_2O \longrightarrow \underset{\text{glucose}}{C_6H_{12}O_6} + \underset{\text{fructose}}{C_6H_{12}O_6}$	Invertase
3.	$\underset{\text{maltose}}{C_{12}H_{22}O_{11}} + H_2O \longrightarrow \underset{\text{glucose}}{2C_6H_{12}O_6}$	Maltase
4.	$\underset{\text{starch}}{(C_6H_{10}O_5)_n} + nH_2O \longrightarrow \underset{\text{maltose}}{C_{12}H_{22}O_{11}}$	Diastase
5.	$\underset{\text{urea}}{NH_2CONH_2} + H_2O \longrightarrow 2NH_3 + CO_2$	Urease
6.	$N_2\text{(atmospheric)} \longrightarrow NH_3$	Nitrogenase
7.	$CO_2(aq) + H_2O(l) \rightleftharpoons H^+(aq) + HCO_3^-(aq)$	Carbonic anhydrase (in human body)

Characteristics of Enzyme Catalysis

Some important characteristics of enzyme catalysis are listed below

1. In the case of enzyme catalysis, the rate of the reaction is much more dependent on the amount of the catalyst (enzyme) than it is in the case of the other types of catalysis.
2. The enzyme reactions are sensitive to temperature, optimum temperature for maximum enzyme activity varies between 15°C to 25°C.
3. The activators or promoters for enzyme reactions are called **co-enzymes** and for every enzyme there is a co-enzyme. If co-enzyme is separated from the enzyme, the activity of the enzyme is paralysed.
4. The addition of electrolyte deactivates enzyme. It is due to coagulation of enzymes.

Mechanism of Enzyme Catalysis

Enzymes are highly specific in their function because of the presence of active site on their surface such as $—NH_2$, —COOH, —SH, —OH, etc. These are actually the active centers on the surface of enzyme particles; when the reactant molecules, called the substance of the reaction,bind at the active site, a chemical change is initiated and an activated complex is formed which then decomposes to yield the products. In most cases, the substrate binds to the active site through intermolecular forces: H-bonds, dipole forces, and other weak attractions.

Two models of enzyme action have been proposed. These are

(a) Lock and key model
(b) Induced fit model

(a) **Lock and Key Model**

According to this model, every lock (active site) has a particular shape and when a particular key (subtrate), which has complementary shape, fits into a lock, the chemical change begins, which finally results into a product (Fig. 5.11)

$$E + S \rightleftharpoons [E - S] \longrightarrow E + P$$

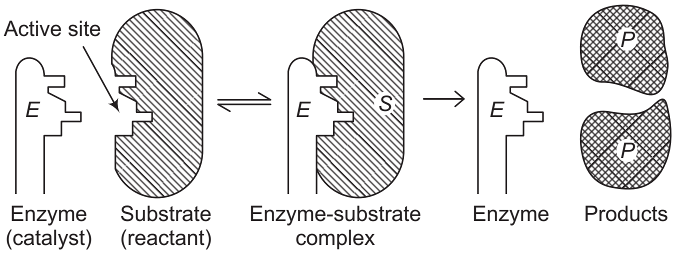


Fig. 5.11 Mechanism of enzyme-catalyzed reaction

(b) Induced Fit Model

Modern X-ray crystallographic and spectroscopic methods have shown that in many cases, unlike an ordinary lock, the protein molecules (enzyme) slightly change the shape when a substrate lands at the active site. The ability of an enzyme to undergo the correct distortion also determines whether the key will fit or not. This refinement of the original lock and key model is known as induced fit model. According to which, a substrate induces the active site to adopt a perfect fit rather than a rigidly shaped lock and key. Therefore, we can picture this model as *hand in a glove,* in which the glove (active site) does not attain its functional shape until the hand (substrate) moves into place.

Check Point 2

1. Explain why rough surface of a catalyst is more effective than smooth surface?
2. Chloroform, an anaesthetic, is kept in dark-coloured bottles and mixed with ethyl alcohol. Explain, why?
3. What is the role of a catalyst in establishing equilibrium?
4. Why is it necessary to remove CO when ammonia is obtained by Haber's process?
5. Why is ester hydrolysis slow in the beginning and becomes faster after sometime?
6. How does BF_3 act as a catalyst in industrial process?
   (Hint because of Lewis acidity)

5.4 Colloidal State

Thomas Graham observed that crystalline substances, such as sugar, urea, sodium chloride etc., could diffuse very readily in solution and could pass through animal and vegetable membranes, while others like glue, gelatin, gum, starch, proteins, etc., did not. He named the former **crystalloids** and the latter **colloids.** According to Graham, the inability of the colloids towards diffusion is due to their high molecular weights (big particle size, thus low osmotic pressure).

However, the term colloid does not apply to a particular class of substances. It is a state and any substance, regardless of its nature, could be converted into a colloid by subdividing it into particles of colloidal size.

Classification of Solution

On the basis of size of particles of dispersed phase (internal phase or discontinuous phase) and dispersion medium (external phase or continuous phase), a solution may be divided into following classes

(a) True Solution

In a true solution (*e.g.,* sugar or salt in water), the dispersed particles are as single molecules or ions. Thus, the diameter of the dispersed particles ranges from 1Å to 10Å (0.1 – 1 mμ).

(b) Suspension

In a suspension (*e.g.,* sand stirred into water), the dispersed particles are aggregates of millions of molecules. The diameter of these particles is of the order of 2000Å (0.2 μ).

(c) Colloidal Solutions

The colloidal solutions are intermediate between true solutions and suspensions.

Thus, the diameter of dispersed particles range from 10 Å to 2000 Å (1 mμ – 0.2 μ).

In fact, the upper limit of colloidal range is fixed as the lower limit of microscopic visibility. *It is not possible to see any particle whose diameter is less than half of the wavelength of light used.*

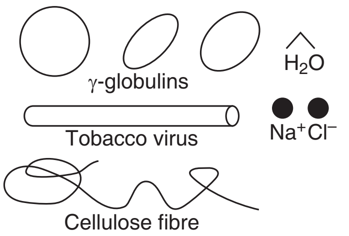

Fig. 5.12 Substances of different diameter

The lowest wavelength of visible light = 4000Å = 0.4 μ (approx.) and thus,

The upper limit of colloidal particles = 2000 Å = 0.2 μ.

The colloidal particles are not necessarily corpuscular in shape, but may be rod-like, disc-like, thin films or long filaments.Thus, *at least one of the dimensions has to be in colloidal range so that the system may be classified as a colloidal one.*

A colloidal system is made of two phases. The substance distributed as the colloidal particles is called the *dispersed phase, discontinuous phase* or *internal phase.* The second phase in which the colloidal particles are scattered is called the *dispersion medium, continuous phase* or *external phase. e.g.,* for a colloidal solution of copper in water, copper particles form dispersed phase and water is dispersion medium.

Sample Problem 4 *Select the correct statement.* **[NCERT]**

(*a*) *colloid is a substance*
(*b*) *colloid is a state of substance*
(*c*) *colloid is state as well as substance*
(*d*) *None of the above*

Interpret (*b*) Colloid is not a substance but a state of substance is a true statement. Because there are some substances which are crystalloid under certain conditions but colloid under the other. *e.g.*, NaCl is such substance which is called a crystalloid and behaves as a crystalloid in aqueous medium. But when mixed with benzene, it behaves as colloid. So, the above statement is correct.

Moreover, the diameter of colloidal particles ranges from 1 to1000 nm.

If particle diameter is lesser than 1 nm, the solution is true solution and if it is more than 1000 nm, the solution is a suspension.

The colloidal state is an intermediate state between these two.

Table 5.4 **Distinction among True, Colloids and Suspensions Solutions**

S.N.	Property	True solutions	Colloids	Suspensions
1.	Particle size	$< 10^{-7}$ cm or 10 Å or 1 mμ	10^{-7} cm to 10^{-5} cm or 10 Å to 10^3 Å or 1 m μ to 100 mμ	$> 10^{-5}$ cm or 10^3 Å or 100 mμ
2.	Visibility	Not visible with any of the optical means	Visible with ultra microscope	Visible with naked eye
3.	Separtion			
	(i) with filter paper	Not possible	Not possible	Possible
	(ii) with membranes	Not possible	Possible	Possible
4.	Diffusion	Diffuses rapidly	Diffuses very slowly	Does not diffuse
5.	Settling	Does not settle	Does not settle but it may settle under centrifuge	Settles under gravity
6.	Nature	Homogeneous	Heterogeneous	Heterogeneous
7.	Appearance	Clear	Generally clear	Opaque

5.5 Classification of Colloids

Colloids are classified on several basis which are given below

On the Basis of Physical States of the Dispersed Phase and Dispersion Medium

On the above basis, colloidal solutions are of following eight types (colloidal dispersion of one gas in another is not possible). These are as tabulated below

Table 5.5 **Different Types of Colloidal Systems**

S.N.	Type name	Dispersed phase	Dispersion medium	Examples
1.	Foam	Gas	Liquid	Whipped cream, shaving cream, soda-water froth
2.	Solid foam	Gas	Solid	Cork, pumice stone, foam rubber.
3.	Aerosol	Liquid	Gas	Fog, mist and clouds.
4.	Emulsion	Liquid	Liquid	Milk, hair cream
5.	Solid emulsion (Gel)	Liquid	Solid	Butter, cheese
6.	Smoke	Solid	Gas	Dust in air
7.	Sol	Solid	Liquid	Paint, ink, colloidal gold, protein, starch ruby glass (gold dispersed in glass), alloys, rock salt
8.	Solid sol	Solid	Solid	Salt

The colloidal solutions in water are termed as **hydrosols** or **aquasols.**

When the dispersion medium in alcohol or benzene, the sols are termed as **alcosols** and **benzosols,** respectively.

Caution Point *A colloidal system of gas in gas is not possible as gases are completely miscible and always form homogeneous true solution.*

On the Basis of Nature of Interaction Between Dispersed Phase and Dispersion Medium

On this basis, colloidal solutions are of the following types

(a) Lyophilic Colloids

Lyophilic colloides are those in which the dispersed phase exhibits a difinite affinity for the medium or the solvent. These are also known as **emulsoids.** Such colloids are more stable and may be taken as reversible colloids. *e.g.*, Dispersion of starch, gum rubber and protein in water form lyophilic colloids.

(b) Lyophobic Colloids

Lyophobic colloids are those in which the dispersed phase has no attraction for the medium or the solvent. These are also known as **suspensoids.** These are generally less stable and regarded as irreversible colloids. *e.g.*, Dispersion of gold, silver, AgCl, $Fe(OH)_3$ and sulphur in water form lyophobic colloids.

Most inorganic colloids are hydrophobic (or lyophobic), while most organic colloids are lyophilic.

The affinity of the sol particles for the medium, in a lyophilic sol, is due to hydrogen bonding in water.

Table 5.6 **Difference between Lyophilic and Lyophobic Colloids**

Property	Lyophilic colloids	Lyophobic colloids
Preparation	Prepared by direct mixing with dispersion medium.	Cannot be prepared by direct mixing with the medium
Charge on particles	Particles carry little or no charge	Particles carry characteristic positive or negative charges
Solvation	Particles are generally solvated	No solvation of particles
Viscosity	Viscosity higher than the dispersion medium as the particles size increases due to solvation. Warm solutions of the dispersed phase on cooling set to a gel	Viscosity is almost same as of medium and do not set to a gel
Surface tension	Surface tension is usually low.	Surface tension is almost the same as that of the solvent
Precipitation	Precipitated by high concentration of electrolytes, when the sol particle's are desolvated. Hence, coagulation is difficult	Precipitated by low concentration of electrolytes. These are easily coagulated
Reversibility	Reversible	Irreversible
Tyndall effect	Do not exhibit Tyndall effect, as they do not scatter light due to relatively small particles size	Exhibit Tyndall effect
Migration in electric field	Particles migrate to anode or cathode, or not at all	Particles migrate to either anode or cathode
Stability	Are more stable	Are less stable

On the Basis of Types of Particles of Dispersed Phase

On the above basis colloidal solutions are of the following types

(a) Multimolecular Colloids

When on dissolution, atoms of smaller molecules of substances (having diameter less than 1 nm) aggregate together to form particles of colloidal dimensions, the particles thus formed are **multimolecular colloids.** These atoms or molecules are held together by van der Waals' forces. They show generally lyophilic character. *e.g.,*

(i) Gold sol contains particles of various sizes having several atoms of gold.

(ii) Sulphur sol consists of particles containing about a thousand of S_8 molecules.

(b) Macromolecular Colloids

In macromolecular type of colloids, the particles are themselves large molecules (usually polymers) which on dissolution form size in the colloidal range. They show generally lyophobic character. *e.g.,*

(i) Starch, cellulose, proteins, enzymes geletin etc., are the examples of naturally occurring macromolecules.

(ii) Nylon, polythene, plastics, polystyrene etc., are examples of synthetic macromolecules.

(c) Associated Colloids

Substance whose molecules aggregate spontaneously in a given solvent to form particles of colloidal dimensions are called **associated colloids**. Such colloids occur in case of soap or detergents, whose molecules are smaller than colloidal size but they aggregate in concentrated solution to colloid size. The colloidal aggregates of soap or detergent molecules formed in the solvent are referred to as **micelles.**

Their molecules contain both lyophilic and lyophobic behaviour. These are the cluster or aggregated particles formed by association of colloids in solution. Micelles may contain 100 or more molecules. These are capable of forming ions. *e.g.,* Soap (sodium stearate, $C_{17}H_{35}COONa$) is a typical example of micelles. When soap is dissolved in water, it gives Na^+ and $C_{17}H_{35}COO^-$ ions.

$$\underset{\text{(sodium stearate)}}{C_{17}H_{35}COONa} \rightleftharpoons \underset{\text{stearate ion}}{C_{17}H_{35}COO^-} + Na^+$$

The stearate ions associated to form **ionic micelles** of colloidal size. It has long hydrocarbon part of $C_{17}H_{35}$ radical which is **lyophobic** and COO^- part which is **lyophilic.** In the figure, the chain corresponds to stearate ion, ($C_{17}H_{35}COO^-$). When the concentration of the solution is below from its CMC (10^{-3} mol L^{-1}), it behaves as **normal electrolyte.** But above this concentration, it aggregates to behave as **micelles.**

The main function of a soap is to reduce oily and greasy dirt to colloidal particles (as emulsion). Soap therefore, are known is **emulsifying agent.**

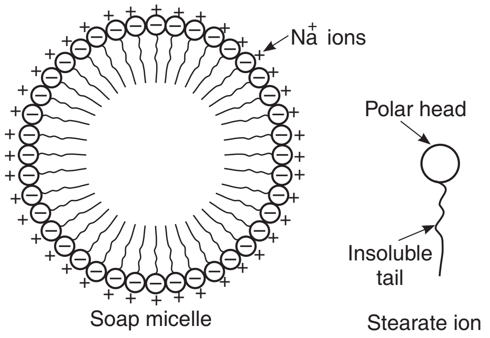

Fig. 5.13 Micelle formation

The cleaning action of soap may be due to

(i) **Solubilisation of grease into the micelle** The grease stain is absorbed into the interior of the micelle, which behaves like liquid hydrocarbon. As the stain is detached from the fabric, the dirt particles sticking to the stain are also removed.

(ii) **Emulsification of grease** When soap solution is added to a fabric, the tails of the soap anions are pegged into the grease stain. The polar heads protrude from the grease surface and form a charged layer around it. Thus, by mutual repulsion, the grease droplets are suspended in water. This emulsified greases stains are washed away.

Some other examples of micelles are sodium palmitate ($C_{15}H_{31}COONa$), sodium lauryl sulphate $[CH_3(CH_2)_{11}SO_3O^-Na^+]$, cetyl trimethyl ammonium bromide $[CH_3(CH_2)_{15}(CH_2)_3N^+Br^-]$ etc.

Critical micelle concentration (CMC)

It is the lowest concentration at which micelle formation apears. It increases with the total surfactant concentration. At concentration higher than CMC, they form extended parallel sheets, known as **lamellar micelles** which resemble biological membranes with two molecular thick. The individual molecule is perpendicular to the sheets such that hydrophilic groups are towards outside in aqueous solution and towards inside in non-polar medium.

Increasing the hydrophobic part of the surfactant molecules favours micelle formation. Micelle formation is opposed by thermal agitation and CMC would thus be expected to increase with increasing temperature.

With ionic micelles, the addition of simple electrolyte reduces the repulsion between the charged groups at the surface of the micelle by the screening action of the added ions. The CMC is, therefore lowered.

Kraft point The temperature above which a surfactant forms micelle is called kraft point.

5.6 Preparation of Colloids

Lyophilic colloids may be prepared by simply warming the solid with the liquid dispersion medium. On the other hand, lyophobic colloids have to be prepared by special methods.

There are in general two methods for the preparation of lyophobic colloids. These are

Dispersion Methods

In these methods the larger particles are broken down to the particles of colloidal size.

Some dispersion methods are discussed below

(a) Mechanical Dispersion

Here **colloidal mill** is used to prepare colloidal sol. In this, the solid along with the liquid dispersion medium is fed into a colloid mill. Colloidal graphite (a lubricant) and printing inks are prepared by this method.

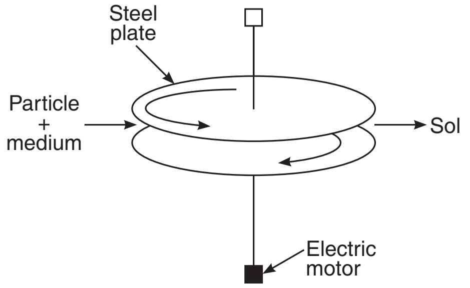

Fig. 5.14 Mechanical dispersion

(b) Bredig's Arc Method [Electro-dispersion]

It is used to prepare hydrosols of metals, *e.g.*, silver, gold, platinum. An arc is struck between the two metal electrodes held close together beneath deionised water. The intense heat of the spark vaporises some of the metal and the vapour condenses under water. Traces of KOH are added to water as stabilising agent.

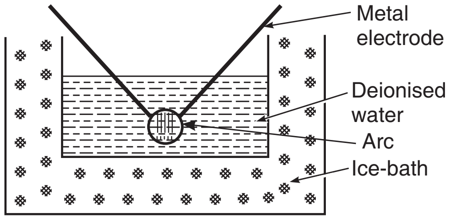

Fig. 5.15 Bredig's arc method

(c) Peptisation

In peptisation, some freshly precipitated ionic solids are dispersed into colloidal solution in water by the addition of small quantities of electrolytes, particularly containing a common ion. The precipitate adsorbs the common ions and electrically charged particles then split from the precipitate as colloidal particles.

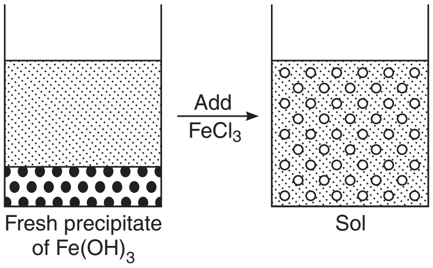

Fig. 5.16 Procedure of peptisation

The dispersal of a precipitated material into colloidal solution by the action of an electrolyte in solution is termed as **peptisation** and the electrolyte is called a **peptising agent.** *e.g.,*

(i) AgCl can be converted into a sol by adding HCl.

(ii) $Fe(OH)_3$ yields a sol by adding $FeCl_3$.

Aggregation Methods

In these methods, colloidal size particles (or molecules) are built up by aggregating ions or smaller particles.

Some important aggregation methods are as follows

(a) Double Decomposition

e.g., the arsenic sulphide sol is prepared by passing a slow stream of H_2S gas through a cold solution of arsenious oxide.

$$As_2O_3 + 3H_2S \longrightarrow \underset{\text{(yellow)}}{As_2S_3\text{(sol)}} + 3H_2O$$

Excess of H_2S is removed by passing in a stream of hydrogen.

(b) Reduction

e.g., Sols of noble metals (Au, Ag, Pt, Pb) can be obtained by treating dilute solutions of their salts with organic reducing agents like tannic acid, ethanol, formaldehyde or phenyl hydrazine etc.

$$AgNO_3 + \text{tannic acid} \longrightarrow \text{Ag} - \text{sol}$$

$$AuCl_3 + \text{tannic acid} \longrightarrow \text{Au} - \text{sol}$$

$$\underset{\text{chloroauric acid}}{2H[AuCl_4]} + 5K_2CO_3 \longrightarrow \underset{\substack{\text{potassium}\\ \text{aurate}}}{2KAuO_2} + 5CO_2 + 8KCl$$

$$2KAuO_2 + \underset{\text{formaldehyde}}{2HCHO} + K_2CO_3 \xrightarrow{\Delta} 2Au\text{(sol)} + 3HCOOK + KHCO_3$$

$KAuO_2$ acts as the stabiliser of the red gold sol obtained represented as

$$m[\text{Au}]\ n\text{auO}_2^-\ (n-x)\ \text{K}^+]\ x\text{K}^+$$

(c) Oxidation

e.g., A sol of sulphur is produced by passing H_2S into a solution of sulphur dioxide.

$$2H_2S + SO_2 \longrightarrow 2H_2O + S\downarrow$$

(d) Hydrolysis

e.g., Sols of the hydroxides of iron, chromium and aluminium are readily prepared by the hydrolysis of salts of respective metals.

$$FeCl_3 + 3H_2O \longrightarrow \underset{\text{(red sol)}}{Fe(OH)_3} + 3HCl$$

(e) Change of Solvent

e.g., When a solution of sulphur or resin in ethanol is added to an excess of water, the sulphur or resin sol is formed owing to decrease in solubility.

(f) Change of Physical State

e.g., Colloidal solutions of certain elements such as mercury and sulphur are obtained by passing their vapour through cold water containing a stabilizer.

Caution Point *The colloidal sol of ice in an organic solvent (as $CHCl_3$ or ether) can be obtained by freezing a solution of water in the solvent. The molecules of water which can no longer be held in solution separately combine to form particles of colloidal size. (Excessive cooling).*

Purification of Colloidal Solution

(a) Dialysis

The process of removing ions (or molecules) from a sol by diffusion through a permeable membrane is called **dialysis.**

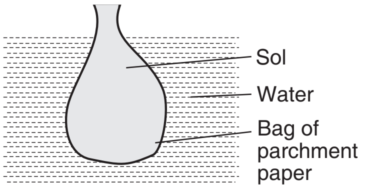

Fig. 5.17 Dialysis

In this process a sol containing dissolved ions or molecules is placed in a bag of permeable membrane (animal bladder, parchment paper and cellophone sheet), dipping in water, the ions diffuse through the membrane. By using a continuous flow of water, the concentration of electrolyte outside the membrane is made zero. *e.g.,* A ferric hydroxide sol can be purified by this method.

(b) Electrodialysis

In this process, dialysis is carried under the influence of electric field. Potential is applied between the metal screen supporting the membranes. This speeds up the migration of ions to the opposite electrodes. Hence, dialysis is greatly accelerated.

This method is not suitable for non-electrolyte impurities like urea etc.

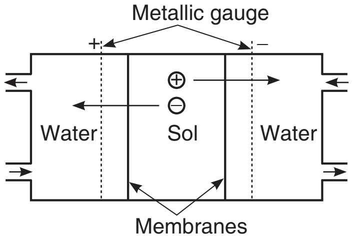

Fig. 5.18 Electrodialysis

(c) Ultrafiltration

If filter paper is impregnated with colloidion (a 4% solution of nitrocellulose in a mixture of alcohol and ether is usually applied) or regenerated cellulose such as cellophone, the pores size is much reduced. Such a modified filter paper is called an **ultrafilter.** The separation of the sol particles from the liquid medium and electrolytes by filtration through an ultra-filter is called **ultrafiltration.**

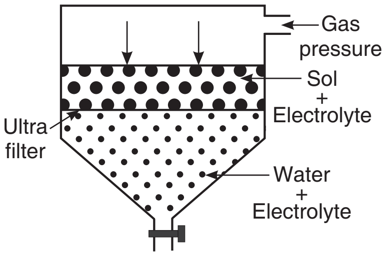

Fig. 5.19 Ultrafiltration of colloidal sol

Ultrafiltration is a slow process. Gas pressure has to be applied to speed it up. The colloidal particles left on the ultra-filter (in form of slime) is stirred onto fresh medium to get back the pure solution.

(d) Electrodecantation

It is used for purification as well as for concentration of the sol. When the **electrodialysis** is carried without stirring, the bottom layer gradually become settled while the top layer, containing pure and concentrated colloid, may be siphoned off.

5.7 Properties of Colloids

The important characteristics exhibited by colloids are as follows

1. General Properties

Some of the general characteristics of colloids are as follows

(a) Heterogeneity

Colloidal system is a heterogeneous system and consist of two phases *viz.* dispersed phase and dispersion medium.

(b) Filtrability

Colloids particles cannot be filtered by ordinary filter papers but can be filtered by ultra-filters.

(c) Diffusibility

Colloidal suspensions, unlike true solutions do not diffuse readily through membranes.

(d) Surface Area

The total surface area of the particles in a colloidal system is enormous, compared with an equal mass of the matter in the usual coarse-grained size. Due to large surface area, colloidal system show extensive adsorption of foreign materials.

(e) Concentration and Density of Sols

The concentration of most of the colloids is small. Most metal sols usually contain 0.1–0.5% metal. Sols of hydroxides and sulphides contains 1–5% of the solid. Concentration of fibrous molecule colloids is also small and usually lies between 0.2–1%.

(f) Colligative Properties

Like true solution, colloidal solution also exhibits colligative properties, but the effects observed are much smaller and except the osmotic pressure, the effects are practically negligible. This is because of their bigger size.

(g) Colour

The colour of a colloidal solution depends on the wavelength of the light scattered by the dispersed particles, which in turn depends on the size and the nature of the particles. *e.g.,* gold sol may be either red or a mixture of red and blue depending upon the size of the particles. Sulphur sol may be colourless, faint yellow or dark yellow in reflected light, while reddish in transmitted light. Dilute milk gives a bluish tinge in reflected light and reddish tinge in transmitted light.

2. Optical Properties (Tyndall effect)

When a strong beam of light is passed through a sol and viewed at right angles, the path of light shows up as a hazy beam or cone. This is due to the fact that sol particles absorb light energy and then emit light in all directions in space (scattering of light). This illuminates the path of the beam in the colloidal dispersion. The phenomenon of the scattering of light by the particles is called Tyndall effect. The illuminated beam or cone formed by the scattering of light by the sol particles is reffered as **Tyndall beam** or **Tyndall cone.**

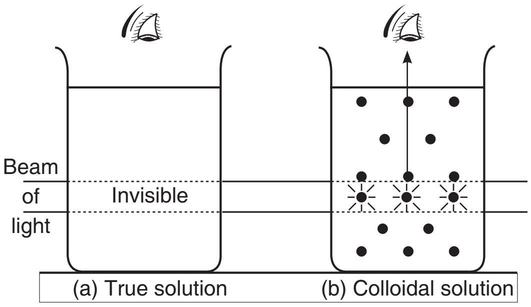

Fig. 5.20 Tyndall effect

True solutions do not exhibit Tyndall effect due to too small size of the ions or absolute molecules.

In order that a system would show Tyndall effect

(i) The refractive index of the dispersed phase and dispersion medium must differ considerably.

(ii) The diameter of the particles of the dispersed phase must not be much smaller than the wavelength of light used.

Examples of Tyndall effects are blue appearance of sky and sea water, visibility of tails of comets, twinkling of stars.

In lyophilic sols, the particles are largely solvated, and so the difference in refractive index is very small, hence Tyndall effect is weak.

3. Electrical Properties of Sols

Stern showed that the double layer is a bit different and made up of

(i) A **compact layer** of positive and negative charges fixed firmly on the particle's surface.

(ii) A **diffused layer** of counter ions diffused into the medium.

The combination of the compact and diffused layers is referred to as **stern double layer.** The diffused layer is only loosely attached to the particle surface.

Because of the distribution of charge around the particles, there is a potential difference between the compact layer and the bulk of solution across the diffuse layer. This is called **electrokinetic** or **zeta potential.** The presence of double layer accounts for the electric properties like **cataphoresis** and **electro-osmosis.**

(a) Electrophoresis or Cataphoresis

The movement of sol particles under an applied potential is called electrophoresis. By noting the direction of movements of the sol particle, it can be determined whether they carry a positive or negative charge.

(b) Electro-osmosis

Electro-osmosis is the movement of the dispersion medium under the influence of applied potential. When the applied potential exceeds the zeta potential, the diffused layer moves and causes electro-osmosis.

4. Kinetic Properties of Sols
(Brownian Motion)

Brownian motion the continuous rapid *zig-zag* movement executed by a colloidal particle in the dispersion medium.

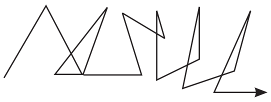

Fig. 5.21 Brownian motion

Suspensions and true solutions do not exhibit Brownian motion. Brownian motion is independent of the nature of colloid but depends on the size of the particles and the viscosity of solution. Smaller the size and lesser the viscosity, faster is the motion.

The Brownian movement is due to the unbalanced bombardment of the particles by the molecules of the dispersion medium. The Brownian movement has a stirring effect which does not permit the particles to settle and thus, is responsible for the stability of sols.

The motion becomes intense at high temperature. The distance between two points decreases at elevated temperature.

5. Charge on Colloidal Particles

The sol particles carry an electric charge *i.e.*, acquire positive or negative charge by preferrential adsorption of positive or negative ions from dispersion medium. *e.g.*,

(i) $Fe(OH)_3$ sol prepared by the hydrolysis of $FeCl_3$ solution adsorbs Fe^{3+} and thus is positively charged.

$$FeCl_3 + 3H_2O \rightleftharpoons Fe(OH)_3 + 3HCl$$

$$Fe(OH)_3 + FeCl_3 \longrightarrow \underset{\text{fixed part}}{[Fe(OH)_3]Fe^{3+}} : \underset{\text{diffused part}}{3Cl^-}$$

Positive charge on colloidal sol is due to adsorption of Fe^{3+} ion [common between $Fe(OH)_3$ and $FeCl_3$].

(ii) As_2S_3 colloidal sol is obtained when As_2O_3 is saturated with H_2S.

$$As_2O_3 + 3H_2S \longrightarrow As_2S_3 + 3H_2O$$

As_2S_3 adsorbs S^{2-} ion (common between $H_2S$and As_2S_3) and thus is negatively charged.

$$As_2S_3 + H_2S \longrightarrow \underset{\text{fixed part}}{[As_2S_3]S^2} : \underset{\text{diffused part}}{2H^+}$$

(iii) AgI in contact with $AgNO_3$ forms positively charged colloidal sol due to adsorption of Ag^+ ion.

$$\underset{\text{fixed part}}{AgI + AgNO_3 \longrightarrow [AgI]Ag^+} : \underset{\text{duffused part}}{NO_3^-}$$

(iv) AgI in contact with KI forms negatively charged colloidal sol due to adsorption of I^- ion.

$$\underset{\text{fixed part}}{AgI + KI \longrightarrow [AgI]I^-} : \underset{\text{diffused part}}{K^+}$$

(v) SnO_2 is acidic medium forms positively charged colloidal sol due to adsorption of Sn^{4+} formed.

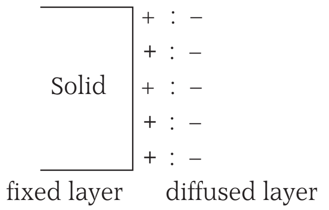
$$SnO_2 + 4H^+ \longrightarrow Sn^{4+} + 2H_2O$$
$$SnO_2 + Sn^{4+} \longrightarrow [SnO_2]Sn^{4+}$$

SnO_2 in alkaline medium forms negatively charged colloidal sol due to adsorption of SnO_3^{2-} formed.

$$SnO_2 + 2OH^- \longrightarrow SnO_3^{2-} + H_2O$$
$$SnO_2 + SnO_3^{2-} \longrightarrow [SnO_2]SnO_3^{2-}$$

There is formation of an **electrical double layer** of opposite charges on the surface of colloidal particles.

$$[AgI]I^- : K^+$$
$$[AgI]Ag^+ : NO_3^-$$
$$[Fe(OH)_3]Fe^{3+} : 3Cl^-$$



The combination of the two layers of positive and negative charges around the sol particles is called **Helmholtz electrical double layer.**

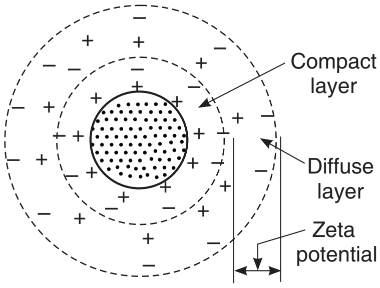


Fig. 5.22 Formation of electrical double layer

Potential difference of this electrical double layer is called **zeta potential** or **electrokinetic potential,** Z, given by

$$Z = \frac{4\pi\eta u}{D}$$

where η is called the coefficient of viscosity, D is the dielectric constant of the medium and u is the velocity of the colloidal particles when an electric field is applied.

Using water as the dispersion medium, the charges on some common sols are as

Negatively charged → Metals, *e.g.,* Au, Ag, Pt; arsenic sulphide, starch, clay

Positively charged → Ferric hydroxide; aluminium hydroxide, basic dyes, haemoglobin.

Sample **Problem 5** *Which of the following process is not responsible for the presence of electric charge on the sol particles?* **[NCERT Exemplar]**

(*a*) *Electron capture by sol particles.*
(*b*) *Adsorption of ionic species from solution.*
(*c*) *Formation of Helmholtz electrical double layer.*
(*d*) *Adsorption of ionic species from solution.*

Interpret (*d*) In adsorption, the ionic species is distributed evenly throughout the solution, so no charge is developed at the surface. Hence, it is not responsible for the presence of electric charge on the sol particles.

Hot Spot 2

COAGULATION or Precipitation

It is also an important topic of the chapter for JEE Main examination. The level of questions is generally average.

The colloidal particles contain positive or negative charges. The repulsive forces between them do not allow them to settle. If, some how, the charge is removed, they aggregate (or flocculate) and settle down under the action of gravity. The flocculation and settling down of the discharged sol particles is called **coagulation** or **precipitation.**

The coagulation of given colloid can be brought about in many ways

1. By addition of electrolytes
2. By electrophoresis
3. By boiling
4. By persistent dialysis
5. By mixing two oppositely charged sols, called **mutual coagulation**

The most important method among these is precipitation by adding some suitable electrolyte. The coagulating power of ion is decided by **Hardy-Schulze Rule.** According to Hardy and Schulze, *"the precipitating effect of an ion on dispersed phase of opposite charge increases with the valence of the ions".*

e.g., For precipitating an As_2S_3 sol (–ve), the precipitating power of Al^{3+}, Ba^{2+}, Na^+ ions (+ve) is in the order

$$Al^{3+} > Ba^{2+} > Na^+$$

Similarly, for precipitating $Fe(OH)_3$ sol (+ve), the precipitating power of anions $[Fe(CN)_6]^{3-}$, SO_4^{2-}, Cl^- (–ve) is in the order

$$[Fe(CN)_6]^{3-} > SO_4^{2-} > Cl^-.$$

The minimum concentration of an electrolyte in millimoles per litre required to cause precipitation of a sol is called **flocculation value.** The smaller the flocculating value, the higher will be the coagulating power of an ion.

Sample Problem 6 *In the coagulation of a positive sol, the focculation powers of* Cl^-, SO_4^{2-}, PO_4^{3-} *and* $[Fe(CN)_6]^{4-}$ *are in the order of*

(a) $Cl^- > SO_4^{2-} > [Fe(CN)_6]^{4-} > PO_4^{3-}$
(b) $Cl^- > PO_4^{3-} > SO_4^{2-} > [Fe(CN)_6]^{4-}$
(c) $[Fe(CN)_6]^{4-} > PO_4^{3-} > SO_4^{2-} > Cl^-$
(d) $Cl^- > SO_4^{2-} > PO_4^{3-} > [Fe(CN)_6]^{4-}$

Interpret (c) According to Hardy-Schulze rule, the flocculation power is directly proportional to the charge. Thus, correct order is

$$[Fe(CN)_6]^{4-} > PO_4^{3-} > SO_4^{2-} > Cl^-$$

Sample Problem 7 *Number of moles of* $[NH_4OH]$ *required to coagulate* 1 *mole of* $[Fe(OH)_3]Fe^{3+}$ *are*

(a) 1 (b) 2
(c) 3 (d) 4

Interpret (c) $3NH_4OH + [Fe(OH)_3]Fe^{3+} \longrightarrow Fe(OH)_3 \downarrow$

$\therefore$ Moles of NH_4OH required to coagulate $[Fe(OH)_3]Fe^{3+}$ ion = 3

5.8 Protective Colloids

Lyophobic colloids are readily precipitated by small amounts of electrolytes. However, these colloids are often stabilised by the addition of lyophilic colloids, which form a layer around particles, thus, protect them from electrolytes. The property of lyophilic colloids to prevent the precipitation of lyophobic colloid is called **protection.** The lyophilic colloid used is called protective colloid.

Gold Number

The protective power of lyophilic colloids is measured in terms of gold number. This terms was introduced by **Zsigmondy** and can be defined as : *"the number of milligrams of a hydrophilic colloid that will just prevent the precipitation of* 10 *mL of a gold sol on the addition of* 1 *mL of* 10% *sodium chloride solution".* The smaller the gold number of hydrophilic colloids, the greater is its protective power.

Sample Problem 8 *The gold numbers of three protective colloids x, y and z are* 0.1, 0.01, *and* 0.001 *respectively. The increasing order of their protective power is*

(a) *x, y, z*
(b) *z, y, x*
(c) *x, z, y*
(d) *y, z, x*

Interpret (a) $\because$ Protective power $\propto \dfrac{1}{\text{Gold number}}$

$\therefore$ The increasing order of protective power

$$\underset{(0.1)}{x} < \underset{(0.01)}{y} < \underset{(0.001)}{z}$$

Rubbin Number

It is the mass in milligrams of a colloid per 100 cc of solution which just prevents the colour change of standard sol of dye congo-Rubbin from red to violet when 0.16 g equivalent KCN is added to it.

5.9 Emulsion

An **emulsion** is a dispersion of finely divided droplets in another liquid. Thus, these are liquid-liquid colloidal systems. Generally, one of two liquids is water and the other, which is immiscible with water, is designated as oil.

Types of Emulsions

Two types of emulsions may be formed with two types of liquids.

(a) Oils Dispersed in Water (O/W type)

In this system, water acts as dispersion medium. *e.g.,* milk, in which tiny droplets of liquid fat are dispersed in water.

(b) Water Dispersed in Oil (W/O type)

In this system, oil acts as dispersion medium. *e.g.,* stiff greases, in which water being dispersed in lubricating oil.

Preparation of Emulsion

The dispersion of a liquid in the form of an emulsion is called **emulsification.** This is done by agitating a small proportion of one liquid with the bulk of the other, or by passing a mixture of two liquids through a colloidal mill known as **homogenizer.**

Emulsifying Agent

The emulsions obtained by shaking the two liquids are unstable. A small amount of a third substance is added during the preparation to stabilise the emulsion. These are called **emulsifiers** or emulsifying agents. These may be a soap, synthetic detergent or a hydrophilic colloid, protein, gum and agar. The emulsifier concentrates at the interface and reduces surface tension on the side of one liquid, which rolls into droplets.

Emulsions can be diluted with any amount of the dispersion medium. On the other hand, the dispersed liquid when mixed with it, at once form a separate layer.

Breaking of Emulsions

Emulsions can be broken to get the constituent liquids by heating, freezing, centrifuging or by addition of appreciable amounts of electrolytes. They are also broken by destroying the emulsifying agent.

5.10 Applications of Colloids

Most of the substances, we come across in our daily life, are colloidal in nature. The meal we eat, the clothes we wear, the wooden are largely composed of colloids.

The applications of colloids are limitless. *In general, these can be divided into following two classes*

1. Natural Applications

The natural applications of colloids include.

(a) Blue Colour of The Sky

Colloidal particles scatter blue light. Dust particles along with water suspended in air scatter blue light which reaches our eyes and the sky looks blue to us.

(b) Foods

Many of foods are colloids, *e.g.,* milk, salad deserts, fruit jellies and whipped cream. Bread is a dispersion of air in baked dough.

(c) Soils

Fertile soils are colloidal in nature in which humus acts as a protective colloid.
On account of colloidal nature, soils absorb moisture and nourishing materials.

(d) Formation of Delta

River water is a colloidal solution of clay. Seawater contains a number of electrolytes. When river water meets the seawater, the electrolytes present in seawater coagulate the colloidal solution of clay which gets deposited with the formation of delta.

(e) Artificial Rain

Artificial rain is caused by spraying oppositely charged colloidal dust or sand particles over the clouds by aeroplanes. The colloidal water particles of the clouds are neutralised and coagulate to bigger water drops which cause artificial rain.

(f) Digestion of Fats

Digestion of fats in intestines is aided by emulsification. A little amount of fat forms a sodium soap with alkaline medium of intestine and this soap emulsifies rest of fat. It is easier for digestive enzymes to carry out their function on emulsified fat.

2. Technical Applications

These technical applications of colloids include.

(a) Electrical Precipitation of Smoke

Smoke is a colloidal solution of solid particles such as carbon, arsenic compounds, dust, etc., in air. The smoke, before it comes out from the chimney, is led throughout a chamber containing plates having a charge opposite to that carried by smoke particles. The particles on coming in contact with these plates lost their charge and get precipitated. The particles thus, settle down on the floor of the chamber. The precipitator is called **cottrell precipitator.**

(b) In Disinfectants

Dettol and lysol give oil in water type emulsion with water.

(c) In Metallurgical Operations

Metal ores are concentrated by froth floatation process, which involves the treatment of pulverized ore in emulsion of pine oil.

(d) Rubber Plating

The negatively charged rubber particles from the rubber sol are deposited on wires, handles of different tools, rubber gloves, etc., by electroplating.

(e) Sewage Disposal

Sewage water contains particles of dirt, rubbish etc., which are of colloidal size, carry charge and therefore, do not settle down easily. These particles can be removed by electrophoresis. The deposited matter is used as manure and the water left behind is used for irrigation.

(f) Medicines

Colloidal medicines being finely divided, are more effective and are easily absorbed in our system. Halibut-liver oil and cod-liver oil are emulsions of the respective oils in water. Many ointments are physiologically active components dissolved in oil and made into an emulsion with water. Antibiotics such as penicillin and streptomycin are produced in colloidal form which are suitable for injections.

Following are some commonly used medicines in colloidal forms.

(i) **Aragrol and Protargol** used as eye lotions and are protected silver solution.
(ii) **Colloidal metals** Au, Mn, Ca used in intramuscular injections.
(iii) **Colloidal antimony** curing kalazar.
(iv) **Colloidal sulphur** germ killer in plants.
(v) **Cod liver oil** tonic in nature.

(g) Purification of Municipal Water

Colloidal particles in water are removed by coagulating with aluminium sulphate (alum).

$$Al^{3+} + 3H_2O \longrightarrow Al(OH)_3 + 3H^+$$

$$Al(OH)_3 + 4H_2O + H^+ \longrightarrow Al(OH)_3(H_2O)_4^+$$

(h) Adsorption Indicators

They function by preferential adsorption of ions onto sol particles, *e.g.,* fluorescein used in titration of NaCl against $AgNO_3$ solution.

(i) Photographic Plates and Films

The photographic plates or films are precipitated by coating an emulsion of the light sensitive silver bromide in gelatin over glass plates or celluloid films.

(j) Disinfectants

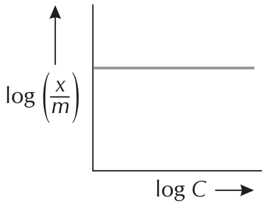
The disinfectants such as dettol and lysol give emulsion of oil in water type when mixed with water.

Check Point 3

1. How can one distinguish colloidal solution from true solution?
2. Colloidal sulphur exhibits Brownian movement while a solution of sulphur in CS_2 does not. Explain it.
3. Explain how is a delta formed?
4. Explain why medicines in colloidal state are more effective?
5. Why does sky appear blue?
6. Tyndall effect is not exhibited by a sugar solution but milk exhibits it. Explain.

WORKED **OUT**
Examples

Example 1 *For the adsorption of solution on a solid surface* $\frac{x}{m} = kC^{1/n}$ *adsorption isotherm of* $\log\left(\frac{x}{m}\right)$ *and* $\log C$ *was found the following type*



This is when

(a) $C = 0$ (b) $C = 2\,M$

(c) C = *constant* (d) $\frac{1}{n} = 0$

Solution (d) Here, $\theta = 0 \Rightarrow \tan\theta = \tan 0 = 0$

$$\because \quad \frac{1}{n} = \tan\theta \quad \therefore \quad \frac{1}{n} = 0$$

Example 2 *It is said that finely divided catalyst has greater catalytic activity than the solid in compact form. For a catalysed reactions, a total surface area of* $6291456\ \text{cm}^2$ *is required for adsorption of gaseous reactants. How many splits should be made of a cube exactly 1 cm in length?*

(a) 10 (b) 15 (c) 20 (d) 30

Solution (c) Total surface area of six faces of a cube $= 6 \times (1 \times 1) = 6\ \text{cm}^2$

now suppose that we divide each side in two equal halves, then there will be total of eight cubes each of side 0.5 cm.

then total surface area $= 8 \times 6 \times \left(\frac{1}{2} \times \frac{1}{2}\right) = 12\ \text{cm}^2$

General formula of surface area on n splits (cube) is

$$= 8^n \times 6 \times \left(\frac{1}{2}\right)^{2n} = 2^n \times 6$$

$$2^n \times 6 = 6291456\ \text{cm}^2$$

On solving $\quad n = 20$

Thus, total of 20 splits are to be made of a cube of 1 cm length.

Example 3 *A sample of charcoal weighing 6.00 g was brought into contact with a gas contained in a vessel of 1 L capacity at 27°C. The pressure of the gas was found to fall from 700 to 400 mm. Calculate the volume of the gas (reduced to STP) that is adsorbed per gram of the adsorbent under the condition of the experiment (density of charcoal sample is* $1.5\ g\ cm^{-3}$*)*

(a) 30 *mL* (b) 60 *mL* (c) 90 *mL* (d) 120 *mL*

Solution (b) The adsorption is taking place in a closed vessel hence as pressure falls, there is correspondingly increase in volume and to keep volume constant, excess of the volume of the gas would be adsorbed.

Using $\quad p_1V_1 = p_2V_2$

$$V_2 = p_1\frac{V_1}{p_2} = 700 \times \frac{1000}{400} = 1750\ \text{mL}$$

Actual volume of the flask $= 1000 -$ volume of charcoal

$$= 1000 - \frac{6.00}{1.50} = 996\ \text{mL}$$

Volume of the gas adsorbed $= 1750 - 996 = 754$ mL

Volume of the gas adsorbed per gram of charcoal

$$= \frac{754}{6} = 125.67\ \text{mL g}^{-1}$$

Volume of the gas adsorbed per gram at STP $\left(\text{Using } \frac{p_1V_1}{T_1} = \frac{p_2V_2}{T_2}\right)$

$$= \frac{125.67 \times 400 \times 273}{300 \times 760} = 60.19\ \text{mL}$$

Example 4 *The density of gold is* $19\ g/cm^3$. *If* 1.9×10^{-4} *g of gold is dispersed in one litre of water to give a sol having spherical gold particles of radius 10 nm, then the number of gold particles per* mm^3 *of the sol will be*

(a) 1.9×10^{12} (b) 6.3×10^{14}

(c) 6.3×10^{10} (d) 2.4×10^{6}

Solution (d) Volume of the gold dispersed in 1 L water

$$= \frac{\text{Mass}}{\text{Density}} = \frac{1.9 \times 10^{-4}}{19} = 1 \times 10^{-5}\ \text{cm}^3$$

Radius of gold sol particle $= 10\ \text{nm} = 10 \times 10^{-9}$ m

$$= 10 \times 10^{-7}\ \text{cm} = 10^{-6}\ \text{cm}$$

Volume of the gold sol particle $= \frac{4}{3}\pi r^3 = \frac{4}{3} \times \frac{22}{7} \times (10^{-6})^3$

$$= 4.19 \times 10^{-18}\ \text{cm}^3$$

No. of gold sol particles in $1 \times 10^{-5}\ \text{cm}^3 = \frac{1 \times 10^{-5}}{4.19 \times 10^{-18}}$

$$= 2.38 \times 10^{12}$$

No. of gold sol particles in one $\text{mm}^3 = \frac{2.38 \times 10^{12}}{10^6} = 2.38 \times 10^6$

Start Practice for JEE Main

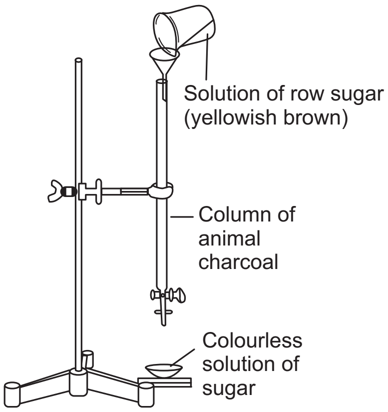
Round I (Topically Divided Problems)

Adsorption

1. Which of the following is an example of absorption? [NCERT Exemplar]

(a) Water on silica gel
(b) Water on calcium chloride
(c) Hydrogen on finely divided nickel
(d) Oxygen on metal surface

2. Which of the following phenomenon is applicable to the process shown in the figure? [NCERT Exemplar]



(a) Absorption (b) Adsorption
(c) Coagulation (d) Emulsification

3. The substance that gets adsorbed on the surface of solid is called

(a) adsorbate (b) adsorbent
(c) micelle (d) absorbent

4. Which of the following is not a favourable condition for physical adsorption? [NCERT Exemplar]

(a) High pressure
(b) Negative ΔH
(c) Higher critical temperature of adsorbate
(d) High temperature

5. Extent of physisorption of a gas increases with [NCERT Exemplar]

(a) increase in temperature
(b) decrease in temperature
(c) decrease in surface area of adsorbent
(d) decrease in strength of van der Waals' forces

6. Which of the following is adsorbed greatly by activated charcoal?

(a) SO_2 (b) CO_2
(c) NO_2 (d) Water vapours

7. Which of the following statements is correct about Langmuir's adsorption isotherm?

(a) It forms monolayer
(b) It is reversible in nature
(c) It occurs at low temperature
(d) None of the above

8. Which of the following is less than zero during adsorption?

(a) ΔG (b) ΔS
(c) ΔH (d) All of these

9. At the equilibrium position in the process of adsorption [NCERT Exemplar]

(a) $\Delta H > 0$ (b) $\Delta H = T\Delta S$
(c) $\Delta H > T\Delta S$ (d) $\Delta H < T\Delta S$

10. Indicate the correct statement

(a) In chemisorption, there is no disruption of bonding in an adsorbed molecule
(b) The rate of decomposition of the substance adsorbed on a surface depends on the surface coverage
(c) In heterogeneous catalytic reaction, no surface reaction occurs
(d) Increase in surface area of catalyst reduces the surface phase reactions

11. Extent of adsorption of adsorbate from solution phase increases with **[NCERT Exemplar]**
(a) increase in amount of adsorbate in solution
(b) decrease in surface area of adsorbent
(c) increase in temperature of solution
(d) decrease in amount of adsorbate in solution

12. Which is correct in the case of van der Waals' adsorption?
(a) High temperature, low pressure
(b) Low temperature, high pressure
(c) Low temperature, low pressure
(d) All of the above

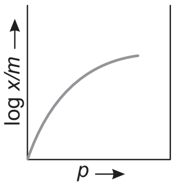
13. Adsorption is accompanied by
(a) ΔS of system is negative
(b) decrease in enthalpy of system
(c) $T\Delta S$ for the process is negative
(d) All of the above

14. Which of the following statements is incorrect?
(a) Physical adsorption occurs at very low temperature and chemisorption occur at all temperature
(b) The magnitude of chemisorption decreases with rise in temperature and physisorption increases with rise in temperature
(c) Chemisorption is irreversible and physisorption is reversible
(d) In physisorption, the activation energy of desorption is very low and in chemisorption, the activation energy of desorption is very high

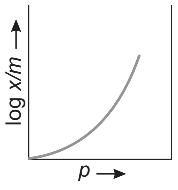
15. What will be the Freundlich adsorption isotherm equation at high pressure ?
(a) $\frac{x}{m} = k$
(b) $\frac{x}{m} = kp^{1/n}$
(c) $\frac{x}{m} = kp$
(d) None of these

16. Which of the following curves is in accordance with Freundlich adsorption isotherm? **[NCERT Exemplar]**

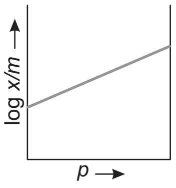
(a)



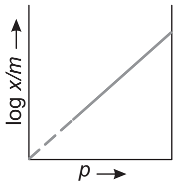
(b)



(c)



(d)



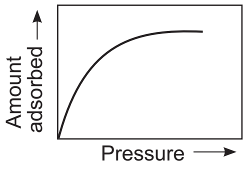
17. Which among the following statements is false?
(a) Adsorption may be monolayered or multilayered
(b) Particle size of adsorbent will not effect the amount of adsorption
(c) Increase of pressure increases the amount of adsorption
(d) Increase of temperature may decrease the amount of adsorption

18. In Langmuir's model of adsorption of a gas on a solid surface,
(a) the rate of dissociation of adsorbed molecules from the surface does not depend on the surface covered
(b) the adsorption at a single site on the surface may involve multiple molecules at the same time
(c) the mass of gas striking a given area of surface is proportional to the pressure of the gas
(d) the mass of gas striking a given area of surface is independent of the pressure of the gas

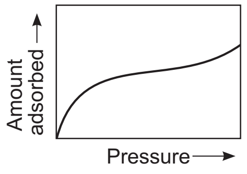
19. According to Freundlich adsorption isotherm, which of the following is correct?
(a) $\frac{x}{m} \propto p^1$
(b) $\frac{x}{m} \propto p^{1/n}$
(c) $\frac{x}{m} \propto p^0$
(d) All of the above are correct for different ranges of pressure

20. Which of the following curves do not correspond to adsorption isotherms?

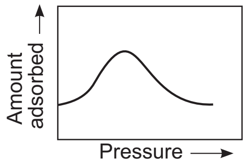
(a)



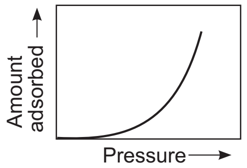
(b)



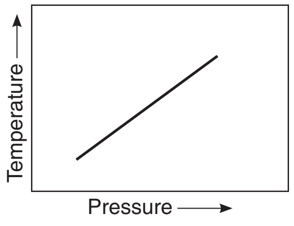
(c)



(d)



21. The curve showing the variation of pressure with temperature for a given amount of adsorption is called



(a) adsorption isobar
(b) adsorption isotherm
(c) adsorption isostere
(d) adsorption isochore

22. What is the role of activated charcoal in gas mask used in coal mines? **[NCERT Exemplar]**
(a) Absorption of poisonous gases
(b) Adsorption of poisonous gases
(c) Neutralisation of gases
(d) None of the above

23. On the basis of data given below predict which of the following gases shows least adsorption on a definite amount of charcoal? **[NCERT Exemplar]**

Gas	CO_2	SO_2	CH_4	H_2
Critical temp/K	304	630	190	33

(a) CO_2 (b) SO_2 (c) CH_4 (d) H_2

Catalysis (Including Enzyme Catalysis)

24. Term catalyst was given by
(a) Rutherford (b) Berzilius
(c) Wohler (d) Kolbe

25. Catalysis is a phenomenon in which
(a) a substance alters the speed of the chemical reaction
(b) heat is evolved in a chemical reaction
(c) the reaction is induced by light
(d) None of the above

26. In chemical reaction, catalyst
(a) alters the amount of the products
(b) lowers the activation energy
(c) decreases the ΔH of forward reaction
(d) increases the ΔH of forward reaction

27. A catalyst in finely divided state is more efficient because in this state
(a) it has larger activation energy
(b) it can react with one of the reactants more efficiently
(c) it has large surface area
(d) All of the above

28. Which of the following reactions is an example of negative catalysis?
(a) $2H_2O_2 \xrightarrow{Pt} 2H_2O + O_2$
(b) $N_2 + 3H_2 \xrightarrow{Fe} 2NH_3$
(c) $2KClO_3 \xrightarrow{MnO_2} 2KCl + 3O_2$
(d) $4CHCl_3 + 3O_2 \xrightarrow{C_2H_5OH} 4COCl_2 + 2Cl_2 + 2H_2O$

29. Which of the following is a heterogeneous catalysis?
(a) $2C_2H_5OH \xrightarrow{\text{Conc } H_2SO_4} C_2H_5OC_2H_5 + H_2O$
(b) $2CO + O_2 \xrightarrow{NO} CO_2$
(c) $SO_2 + \frac{1}{2} O_2 \xrightarrow{NO_2} SO_3$
(d) $SO_2 + \frac{1}{2} O_2 \xrightarrow{V_2O_5} SO_3$

30. By dividing the catalyst into fine powder there will be increase in
(a) surface area
(b) free valancies
(c) active centres
(d) All of these

31. Which of the following process does not occur at the interface of phases? **[NCERT Exemplar]**
(a) Crystallisation
(b) Heterogenous catalysis
(c) Homogeneous catalysis
(d) Corrosion

32. Which of the following acts as a catalyst?
(a) Metals with variable valency
(b) Metals with non-variable valency
(c) Non-metals with fixed valency
(d) Inert gases

33. According to the adsorption theory of catalysis, the speed of the reaction increases because
(a) the concentration of reactant molecules at the active centres of the catalyst becomes high due to adsorption
(b) in the process of adsorption, the activation energy of the molecules becomes large
(c) adsorption produces heat which increases the speed of the reaction
(d) adsorption lowers the activation energy of the reaction

34. Shape selective catalysts are so called because of
(a) the shape of the catalyst
(b) the specificity of the catalyst
(c) the size of the pores of catalyst which can trap selective molecules only
(d) their use for only some selected reaction

35. Catalyst used in Haber's process is
(a) nickel powder
(b) iron and molybdenum powder
(c) black lead
(d) iodine

36. In contact process of manufacture of H_2SO_4, the catalyst used is
(a) iron
(b) V_2O_5
(c) chromium
(d) oxides of nitrogen

37. A biological catalyst is
(a) an amino acid
(b) a carbohydrate
(c) a nitrogen molecule
(d) an enzyme

Colloids and their Applications

38. Point out the false statement.
(a) The size range of colloidal particles is 10–2000Å
(b) Colloidal solutions are homogeneous systems
(c) Colloids carry charge
(d) Colloids show Tyndall effect

39. A colloidal system having a solid substance as a dispersed phase and a liquid as a dispersion medium is classified as **[NCERT Exemplar]**
(a) solid sol (b) gel
(c) emulsion (d) sol

40. Which of the following is mismatched?

	Dispersed phase	Dispersed medium	Specific name
(a)	liquid	liquid	emulsion
(b)	solid	solid	solid sol
(c)	liquid	gas	aerosol
(d)	gas	solid	foam

41. Fog is a colloidal solution of
(a) liquid particles dispersed in a gas
(b) gaseous particles dispersed in a liquid
(c) solid particles dispersed in a liquid
(d) solid particles dispersed in a gas

42. Which will not form colloidal solution?

(Where DP = Dispersed phase and DM = Dispersion medium)
(a) DP–gas, DM–liquid (b) DP–liquid DM–solid
(c) DP–gas, DM–gas (d) DP–solid, DM–solid

43. Multimolecular colloids are present in
(a) soap solution (b) sol of proteins
(c) sol of gold (d) All of these

44. Which of the following is not the property of hydrophilic sol?
(a) Coagulation is reversible
(b) Viscosity and surface tension are equal to that of water
(c) Charge on the particle depends upon pH of the medium. It may be positive, negative or zero
(d) Dispersed phase acquires higher concentration easily

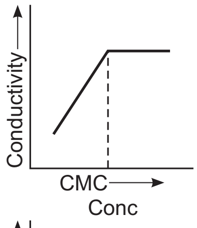
45. Micelles have
(a) same colligative property as that of common colloidal solution
(b) lower colligative property as that of common colloidal solution
(c) higher colligative property as that of common colloidal solution
(d) None of the above

46. At high concentration of soap in water, soap behaves as **[NCERT Exemplar]**
(a) molecular colloid (b) associated colloid
(c) macromolecular colloid (d) lyophilic colloid

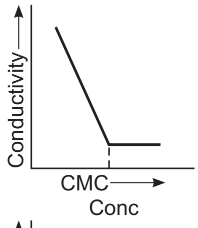
47. Choose macromolecular colloids among the following
(a) soap (b) detergent
(c) starch and cellulose (d) All of these

48. Which graph is correct for critical micelle concentration (CMC)?

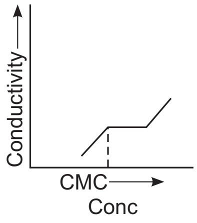
(a)



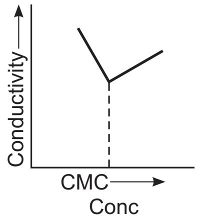
(b)



(c)



(d)



49. Match Column I with Column II and select the correct match.

	Column I		Column II
A.	Rain cloud	1.	Sol
B.	Milk of magnesia	2.	Foam
C.	Whipped cream	3.	Micelles
D.	Soap in water	4.	Aerosol

Codes

	A	B	C	D		A	B	C	D
(a)	1	2	3	4	(b)	4	1	2	3
(c)	4	2	3	1	(d)	3	1	2	4

50. Purple of cassius is
(a) colloidal solution of Au
(b) colloidal solution of Pt
(c) colloidal solution of Ag
(d) colloidal solution of As

51. Choose the intrinsic colloids among the following
(a) sulphur (b) arsenic sulphide
(c) egg albumen (d) ferric hydroxide

52. Surfactant molecules or ions cluster together as micelles
(a) due to their hydrophilic tails tend to congregate
(b) due to their hydrophobic heads provide protection
(c) which are colloid sized clusters of molecules
(d) None of the above

53. Freshly prepared precipitate sometimes gets converted to colloidal solution by **[NCERT Exemplar]**

(a) coagulation (b) electrolysis
(c) diffusion (d) peptisation

54. Which of the following reactions lead to the formation of colloidal solution?

(a) $Cu + HgCl_2 \longrightarrow CuCl_2 + Hg$
(b) $2HNO_3 + 3H_2S \longrightarrow 3S + H_2O + 2NO$
(c) $2Mg + CO_2 \longrightarrow 2MgO + C$
(d) $Cu + CuCl_2 \longrightarrow 2CuCl$

55. Peptisation involves

(a) precipitation of colloidal particles
(b) disintegration of colloidal aggregates
(c) evaporation of dispersion medium
(d) impact of molecules of the dispersion medium on the colloidal particles

56. Blood may be purified by

(a) dialysis (b) electroosmosis
(c) coagulation (d) filtration

57. The values of colligative properties of colloidal solution are of small order in comparison to those shown by true solutions of same concentration because of colloidal particles **[NCERT Exemplar]**

(a) exhibit enormous surface area
(b) remain suspended in the dispersion medium
(c) form lyophilic colloids
(d) are comparatively less in number

58. The Brownian movement is due to

(a) enthalpy change during the formation of colloids
(b) attractive forces between the colloidal particles and the molecules of dispersion medium
(c) the impact of molecules of the dispersion medium on the colloidal particles
(d) the movement of positively charged colloidal particle to negatively charged particle

59. Sedimentation potential is the reverse of

(a) electrosmosis
(b) electrophoresis
(c) electrokinetic potential
(d) dorn potential

60. Which of the following is incorrect for electrophoresis?

(a) In electrophoresis, solution migrates either to anode or to the cathode depending upon the positively or negatively charged solution
(b) Electrophoresis is a useful method for finding the charge of a solution
(c) Electrophoresis with a high potential is helpful in destroying an emulsion
(d) Colloids are uncharged particles and do not migrate towards the electrodes when electric field is applied

61. Which of the following statements is correct for Tyndall effect ?

(a) Scattering and polarising of light by small suspended particles is called Tyndall effect
(b) Tyndall effect of colloidal particles is due to dispersion of light
(c) Tyndall effect is due to refraction of light
(d) *Zig-zag* motion of suspended particles

62. Method by which lyophobic sol can be protected, is. **[NCERT Exemplar]**

(a) by addition of oppositely charged sol
(b) by addition of an electrolyte
(c) by addition of lyophilic sol
(d) by boiling

63. Hardy-Schulze law states that

(a) higher the charge of the coagulating ions, greater its coagulating power, having opposite sign of solution
(b) solution must have zero gold number
(c) disperse phase and dispersion medium must be of the same sign
(d) micelles coagulate in the presence of surfactants

64. Which of the following is the most effective in the coagulation of gold sol?

(a) $NaNO_3$ (b) $MgCl_2$
(c) Na_3PO_4 (d) $K_4[Fe(CN)_6]$

65. Colloidal gold is given by injection to act as

(a) disinfectant
(b) anticancer agent
(c) germ killer
(d) tonic to raise vitality of human systems

66. Which of the following process is responsible for the formation of delta at a place where rivers meet the sea? **[NCERT Exemplar]**

(a) Emulsification
(b) Colloid formation
(c) Coagulation
(d) Peptisation

67. Ferric chloride is applied to stop bleeding because

(a) Fe^{3+} ions coagulate negatively charged blood solution
(b) Fe^{3+} ions coagulate positively charged blood solution
(c) Cl^- ions coagulate positively charged blood solution
(d) Cl^- ions coagulate negatively charged blood solution

68. The leather get hardened after tanning because of **[NCERT Exemplar]**

(a) coagulation (b) peptisation
(c) oxidation (d) reduction

69. How does it become possible to cause artificial rain by spraying silver iodide on the clouds? [**NCERT** Exemplar]

(a) Due to coagulation
(b) Due to peptisation
(c) Due to development of charge
(d) Both (a) and (c)

70. Gelatin which is peptide is added to ice creams. What can be its role? [**NCERT** Exemplar]

(a) As coagulating agent
(b) As pepting agent
(c) As emulsifying agent
(d) As floculating agent

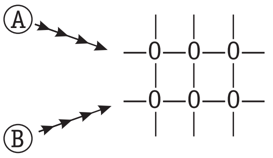
Round II (Mixed Bag)

Single Option Correct

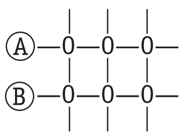
1. In physisorption, adsorbent does not show specificity for any particular gas because .... [**NCERT** Exemplar]

(a) involved van der Waals' forces are universal
(b) gases involved behave like ideal gases
(c) enthalpy of adsorption is low
(d) it is a reversible process

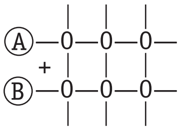
2. Arrange the following diagrams in correct sequence of steps involved in the mechanism of catalysis, in accordance with modern adsorption theory. [**NCERT** Exemplar]



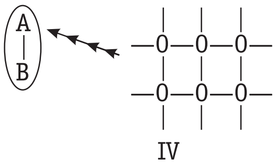
I



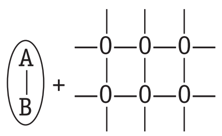
II



III



IV



V

(a) I $\longrightarrow$ II $\longrightarrow$ III $\longrightarrow$ IV $\longrightarrow$ V
(b) I $\longrightarrow$ III $\longrightarrow$ II $\longrightarrow$ IV $\longrightarrow$ V
(c) I $\longrightarrow$ III $\longrightarrow$ II $\longrightarrow$ V $\longrightarrow$ IV
(d) I $\longrightarrow$ II $\longrightarrow$ III $\longrightarrow$ V $\longrightarrow$ IV

3. Which one of the following is not applicable to the phenomenon of adsorption? [**NCERT** Exemplar]

(a) $\Delta H > 0$ (b) $\Delta G < 0$
(c) $\Delta S < 0$ (d) $\Delta H < 0$

4. Identify the gas which is readily adsorbed by activated charcoal

(a) H_2 (b) N_2 (c) SO_2 (d) O_2

5. For adsorption of a gas on a solid, the plot of $\log \frac{x}{m}$ *vs* $\log p$ is linear with slope equal to (n being whole number)

(a) K (b) $\log k$
(c) n (d) $\frac{1}{n}$

6. Plot of $\log \frac{x}{m}$ against $\log p$ is a straight line inclined at an angle of 45°. When the pressure is 0.5 atm and Freundlich parameter, k is 10, the amount of solute adsorbed per gram of adsorbent will be ($\log 5 = 0.6990$)

(a) 1 g (b) 2 g
(c) 3 g (d) 5 g

7. 50 mL of 1 M oxalic acid is shaken with 0.5g wood charcoal. The final concentration of the solution after adsorption is 0.5 M. What is the amount of oxalic acid absorbed per gram of carbon ?

(a) 3.15 g (b) 3.45 g
(c) 6.30 g (d) None of these

8. Pd can adsorb in the space between its atoms, 900 times its volume of hydrogen. This process is called

(a) absorption (b) desorption
(c) adsorption (d) chemisorption

9. Which of the following processes does not involve a catalyst?

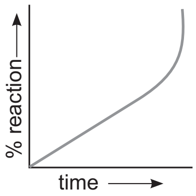
(a) Ostwald process (b) Contact process
(c) Thermite process (d) None of these

10. In Haber's process for the manufacture of ammonia, the reaction is usually carried at about 500°C. If a temperature of about 250°C was used then

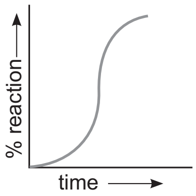
(a) a catalyst would be of no use at all at this temperature
(b) the rate of formation of ammonia would be too slow
(c) no ammonia would be formed at all
(d) the percentage of ammonia in the equilibrium mixture would be too low

11. Which graph represents auto catalysis?

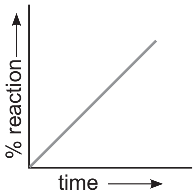
(a)



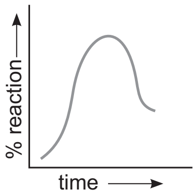
(b)



(c)



(d)



12. In which of the following reactions heterogeneous catalysis is involved? **[NCERT Exemplar]**

I. $2SO_2(g) + O_2(g) \xrightarrow{NO(g)} 2SO_3(g)$

II. $2SO_2(g) \xrightarrow{Pt(s)} 2SO_3(g)$

III. $N_2(g) + 3H_2(g) \xrightarrow{Fe(s)} 2NH_3(g)$

IV. $CH_3COOCH_3(l) + H_2O(l) \xrightarrow{HCl(l)} CH_3COOH(aq) + CH_3OH(aq)$

(a) II, III (b) II, III, IV (c) I, II, III (d) IV

13. Choose the incorrect statement.

(a) If the mutual affinity between the dispersed phase and the dispersion medium is small, the system will be lyophobic

(b) If the mutual affinity between the dispersed phase and dispersion medium is great, the system will be lyophilic

(c) In a system, when water is the dispersion medium, the system may be hydrophobic or hydrophilic

(d) Ionic surfactant molecules cluster together in clumps

14. Match the statement given in Column I with the phenomenon given in Column II.

	Column I		Column II
A.	Dispersion medium moves in an electric field	1.	Osmosis
B.	Solvent molecules pass through semi permeable membrane towards solvent side.	2.	Electrophoresis
C.	Movement of charged colloidal particles under the influence of applied electric potential towards oppositely charged electrodes	3.	Electroosmosis
D.	Solvent molecules pass through semi permeable membranes towards solution side	4.	Reverse osmosis

Codes

	A	B	C	D
(a)	3	4	2	1
(b)	3	1	2	4
(c)	3	4	1	2
(d)	3	2	1	4

15. Match the following.

	Column I		Column II
A.	Smoke	1.	Aerosol of liquid
B.	Milk	2.	Aerosol of solid
C.	Butter	3.	Emulsion
D.	Fog	4.	Gel

Codes

	A	B	C	D		A	B	C	D
(a)	2	1	3	4	(b)	3	2	4	1
(c)	1	2	3	4	(d)	2	3	4	1

16. Match the following.

	Column I		Column II
A.	Protective colloid	1.	$FeCl_3$ + NaOH
B.	Liquid-liquid colloid	2.	Lyophilic colloids
C.	Positively charged colloid	3.	Emulsion
D.	Negatively charged colloid	4.	$FeCl_3$ + hot water

Codes

	A	B	C	D
(a)	1	2	3	4
(b)	2	3	1	4
(c)	2	3	4	1
(d)	3	2	1	4

17. Match the following.

	Column I		Column II
A.	Dialysis	1.	Precipitate converts to colloidal solution
B.	Peptisation	2.	Precipitation of colloidal solution
C.	Flocculation	3.	Protective power
D.	Gold number	4.	Purification of colloidal solution

Codes

	A	B	C	D		A	B	C	D
(a)	1	3	2	4	(b)	4	1	2	3
(c)	2	4	3	1	(d)	3	2	4	1

18. In which of the following reactions colloids are not prepared by the double decomposition method?

(a) $2H_3AsO_4 + 3H_2S \longrightarrow As_2S_3 + 6H_2O$

(b) $3K_4[Fe(CN)_6] + 4FeCl_3 \longrightarrow Fe_4[Fe(CN)_6]_3 + 12KCl$

(c) $Mg(CN)_2 + H_2S \longrightarrow HgS + 2HCN$

(d) $Cu + HgCl_2 \longrightarrow CuCl_2 + Hg$

19. Which of the following substances will precipitate the negatively charged emulsions? **[NCERT Exemplar]**

I. KCl II. glucose
III. urea IV. NaCl

The correct answer is

(a) I and II (b) I and III
(c) I and IV (d) II and III

20. An emulsion cannot be broken by …… and …… . **[NCERT Exemplar]**

I. heating
II. adding more amount of dispersion medium
III. freezing
IV. adding emulsifying agent

The correct answer is

(a) I and II (b) II and III
(c) II and IV (d) I, II and III

21. Which of the following will show Tyndall effect? **[NCERT Exemplar]**

(a) Aqueous solution of soap below critical micelle concentration
(b) Aqueous solution of soap above critical micelle concentration
(c) Aqueous solution of sodium chloride
(d) Aqueous solution of sugar

22. Which of the following electrolytes will have maximum coagulating value for AgI/Ag^+ sol? **[NCERT Exemplar]**

(a) Na_2S (b) Na_3PO_4
(c) Na_2SO_4 (d) NaCl

23. The minimum flocculation power of KCl, $MgCl_2$, $CrCl_3$ and $SnCl_4$ for a positively charged sol are in the order of

(a) $KCl < MgCl_2 < CrCl_3 < SnCl_4$
(b) $KCl = MgCl_2 = CrCl_3 = SnCl_4$
(c) $MgCl_2 < KCl < CrCl_3 < SnCl_4$
(d) $SnCl_4 < CrCl_3 < MgCl_2 < KCl$

24. The gold number of gelatin, haemoglobin and sodium acetate are 0.005, 0.05 and 0.7 respectively. The protective actions will be in the order of

(a) Gelatin < haemoglobin < sodium acetate
(b) Gelatin > haemoglobin > sodium acetate
(c) Haemoglobin > gelatin > sodium acetate
(d) Sodium acetate > gelatin > haemoglobin

25. Which of the following forms cationic micelles above certain concentration?

(a) Urea
(b) Sodium dodecyl sulphate
(c) Sodium acetate
(d) Cetyltrimethylammonium bromide

26. The coagulation of 10 cm^3 of gold sol is completely prevented by addition of 0.025 g of starch to it. The gold number of starch is

(a) 0.025 (b) 0.25
(c) 2.55 (d) 25

27. Which one of the following impurities present in colloidal solution cannot be remove by electrodialysis?

(a) Sodium chloride
(b) Potassium sulphate
(c) Urea
(d) Calcium chloride

28. Blue colour of the sky and red colour of the sunsets are due to

(a) scattering of light from the sun
(b) scattering of light from particles of dust in the atmosphere
(c) refraction of blue light by impurities in sea water
(d) scattering of light due to ozone layer

29. The Rubin number which was proposed by Ostwald as an alternative to the gold number in order to measure the protective efficiency of a lyophilic colloid may be defined as the

(a) mass in milligrams of a colloid per 100 cc of solution which just prevents the colour change of standard sol of dye Congo-Rubin from red to violet when 0.16 g aq. KCl is added to it
(b) mass in grams of a colloid per 100 cc of solution which just prevents the colour change of standard sol of dye Congo-Rubin from red to violet when 0.1 M KCl is added to it
(c) mass in grams of a colloid per 100 cc of solution which just prevents the colour change of standard sol of dye Congo-Rubin from red to violet when 0.2 M KCl is added to it
(d) mass in grams of a colloid per 100 cc of solution which just prevents the colour change of standard sol of dye Congo-Rubin from red to violet when 1 M KCl is added to it

More than One Correct Option

30. Which of the following options are correct? **[NCERT Exemplar]**

(a) Micelle formation by soap in aqueous solution is possible at all temperatures
(b) Micelle formation by soap in aqueous solution occurs above a particular concentration
(c) On dilution of soap solution micelles may revert to individual ions
(d) Soap solution behaves as a normal strong electrolyte at all concentrations

31. Which of the following statements are correct about solid catalyst? **[NCERT Exemplar]**

(a) Same reactants may give different product by using different catalysts

(b) Catalyst does not change ΔH of reaction

(c) Catalyst is required in large quantities to catalyse reactions

(d) Catalytic activity of a solid catalyst does not depend upon the strength of chemisorption

32. Which phenomenon occurs when an electric field is applied to a colloidal solution and electrophoresis is prevented? **[NCERT Exemplar]**

(a) Reverse osmosis takes place

(b) Electroosmosis takes place

(c) Dispersion medium begins to move

(d) Dispersion medium becomes stationary

33. Freundlich adsorption isotherm is given by the expression $\frac{x}{m} = kp^{1/n}$ which of the following conclusions can be drawn from this expression? **[NCERT Exemplar]**

(a) When $\frac{1}{n} = 0$, the adsorption is independent of pressure

(b) When $\frac{1}{n} = 0$, the adsorption is directly proportional to pressure

(c) When $n = 0$, $\frac{x}{m}$ *vs* p graph is a line parallel to x-axis

(d) When $n = 0$, plot of $\frac{x}{m}$ *vs* p is a curve

34. Which of the following statements is/are correct about physical adsorption?

(a) It is a selective and specific process

(b) It is a reversible process

(c) An increase in the gaseous adsorbate causes increase in adsorption. However, at higher pressure the adsorption become constant

(d) It is an endothermic process

35. Which is/are correct statement about the role of a catalyst in a reaction?

(a) It is reactant in a rate-determining step and then a product of some subsequent steps

(b) It provides an alternate mechanism with a lower energy of activation

(c) It increases the rate of chemical reaction but does not itself undergo a permanent change during the course of the reaction

(d) It increases quantity of the product

36. H_2 gas is adsorbed on activated charcoal to a very little extent in comparison to easily liquefiable gases due to **[NCERT Exemplar]**

(a) very strong van der Waals' interaction

(b) very weak van der Waals' forces

(c) very low critical temperature

(d) very high critical temperature

37. 1 mole of $[AgI]Ag^+$ sol is coagulated by

(a) 1 mol of KI (b) 500 mL of 1 M K_2SO_4

(c) 1 L of 1 M KI (d) None of these

38. On adding $AgNO_3$ solution into KI solution, a negative charged colloidal sol is obtained when they are in

(a) 100 mL of 0.1 M $AgNO_3$ + 100 mL of 0.1 M KI

(b) 100 mL of 0.1 M $AgNO_3$ + 100 mL of 0.2 M KI

(c) 100 mL of 0.2 M $AgNO_3$ + 100 mL of 0.1 M KI

(d) 100 mL of 0.15 $AgNO_3$ + 100 mL of 0.25 M KI

Assertion and Reason

Directions (Q. Nos. 39 to 43) *Each of these questions contains two statements : Statement* I (*Assertion*) *and Statement* II (*Reason*). *Each of these questions also has four alternative choices, only one of which is the correct answer. You have to select one of the codes* (*a*), (*b*), (*c*), (*d*) *given below.*

(a) Statement I is true, Statement II is true; Statement II is a correct explanation for Statement I.

(b) Statement I is true, Statement II is true; Statement II is not a correct explanation for Statement I.

(c) Statement I is true; Statement II is false.

(d) Statement I is false; Statement II is true.

39. **Statement I** According to Freundlich, $\frac{x}{m} = k \cdot p^{1/n}$.

Statement II The isotherm shows variation of the amount of gas adsorbed by the adsorbent with temperature.

40. **Statement I** Detergents with low CMC are more economical to use. **[NCERT Exemplar]**

Statement II Cleansing action of detergents involves the formation of micelles. These are formed when the concentration of detergents becomes equal to CMC.

41. **Statement I** An ordinary filter paper impregnated with collodion solution stops the flow of colloidal particles. **[NCERT Exemplar]**

Statement II Pore size of the filter paper becomes more than the size of colloidal particle.

42. **Statement I** Coagulation power of Al^{3+} is more than Na^+. **[NCERT Exemplar]**

Statement II Greater the valency of the flocculating ion added, greater is its power to cause precipitation (Hardy Schulze rule).

43. **Statement I** ZSM–5 is used as a catalyst in petrochemical industries.

Statement II Zeolites are three dimensional network silicates in which some silicon atoms are replaced by aluminium atoms.

Comprehension Based Questions

Directions (Q. Nos. 44 to 46) Freundlich adsorption isotherm is obeyed by the adsorptions where the adsorbate forms a multimolecular layer on the surface of adsorbent. In such case, the degree of adsorption varies linearly with pressure but at high pressure, it becomes independent of pressure. It is given as

$$\frac{x}{m} = kp^{1/n}$$

where, k and n are constants.

Langmuir adsorption isotherm is obeyed by the adsorption where the adsorbate forms only a unimolecular adsorbed layer. The mathematical relation of Langmuir adsorption isotherm is

$$\frac{x}{m} = \frac{ap}{1+bp}$$

44. When $\log\left(\frac{x}{m}\right)$ is plotted against $\log p$, we get a straight line with slope

(a) $\frac{1}{n}$ (b) n

(c) x (d) m

45. The degree of adsorption $\left(\frac{x}{m}\right)$ at low pressure will be

(a) $\frac{x}{m} = n$ (b) $\frac{x}{m} = ap$

(c) Both (a) and (b) (d) None of these

46. Freundlich adsorption isotherm is valid for

(a) physisorption (b) chemisorption

(c) Both (a) and (b) (d) None of these

Directions (Q. Nos. 47 to 49) Emulsions are also the colloidal solutions in which disperse phase as well as dispersion medium are liquids. It may be oil in water or water in oil type. Bancroft proposed that the phase in which the emulsifier is more soluble becomes the outer phase of the emulsion. Emulsifiers can be used to stabilise the emulsion. Soaps, detergents, proteins and gum etc, are used as emulsifiers.

47. Addition of lyophilic solution to the emulsion forms

(a) a protective film around the dispersed phase

(b) a protective film around the dispersion medium

(c) an aerosol

(d) true solution

48. Which of the following is homogeneous?

(a) Milk (b) Paint

(c) Shampoo (d) None of these

49. Milk is an emulsion in which

(a) a gas is dispersed in water

(b) a solid is dispersed in water

(c) fat is dispersed in water

(d) lactose is dispersed in water

Previous Years' Questions

50. Which of the following statement is incorrect regarding physisorptions?

(a) It occurs because of van der Waals' forces

(b) More easily liquefiable gases are adsorbed readily

(c) Under high pressure it results into multimolecular layer on adsorbent surface

(d) Enthalpy of adsorption ($\Delta H_{\text{adsorption}}$) is slow and positive

51. Gold numbers of protective colloids A, B, C and D are 0.50, 0.01, 0.10 and 0.005, respectively. The correct order of their protective powers is [AIEEE 2008]

(a) $D < A < C < B$ (b) $C < B < D < A$

(c) $A < C < B < D$ (d) $B < D < A < C$

52. In Langmuir's model of adsorption of a gas on a solid surface, [AIEEE 2006]

(a) the rate of dissociation of adsorbed molecules from the surface does not depend on the surface covered

(b) the adsorption at a single site on the surface may involve multiple molecules at the same time

(c) the mass of gas striking a given area of surface is proportional to the pressure of the gas

(d) the mass of gas striking a given area of surface is independent of the pressure of the gas

53. The disperse phase in colloidal iron (III) hydroxide and colloidal gold is positively and negatively charged respectively. Which of the following statement is not correct? [AIEEE 2005]

(a) Coagulation in both sols can be brought about by electrophoresis

(b) Mixing the sols has no effect

(c) Sodium sulphate solution causes coagulation in both sols

(d) Magnesium chloride solution coagulates the gold sol more readily than the iron (III) hydroxide sol

54. The volume of a colloidal particle, V_C as compared to the volume of a solute particle in a true solution V_S, could be [AIEEE 2005]

(a) $\frac{V_C}{V_S} \approx 10^3$ (b) $\frac{V_C}{V_S} \approx 10^{-3}$

(c) $\frac{V_C}{V_S} \approx 10^{23}$ (d) $\frac{V_C}{V_S} \approx 1$

55. Which one of the following characteristics is not correct for physical adsorption ? **[AIEEE 2003]**

(a) Adsorption on solids is reversible

(b) Adsorption increases with increase in temperature

(c) Adsorption is spontaneous

(d) Both enthalpy and entropy of adsorption are negative

the Guidance

Round I

1. Water on calcium chloride is an example of absorption as water is also distributed in the bulk.

3. The substance that gets adsorbed on the surface of solid is called adsorbate and the solid on which adsorption occurs is called adsorbent.

4. High temperature is not a favourable condition for physical adsorption as it is an exothermic process.

5. Extent physisorption of a gas increase with decrease in temperature because of its exothermic nature.

6. Activated charcoal has great affinity for water vapour as they easily form hydrogen bond among themselves.

7. Langmuir's adsorption is monomolecular, *i.e.,* the gas adsorbed forms unimolecular layer.

8. Adsorption is a process where randomness decreases and energy is released hence ΔS, ΔH and ΔG, all have negative values.

9. At the equilibrium position in the process of adsorption $\Delta H = T\Delta S$

11. Extent of adsorption of adsorbate from solution phase increase with increase an amount of adsorbate in solution.

13. In adsorption, due to forces of attraction, ΔH is negative and as the particles came closer entropy of the system decrease, *i.e.,* ΔS is negative, hence $T\Delta S$ is also negative.

14. For chemisorption, high temperature is favourable. It increases with rise in temperature. On the other hand low temperature is favourable for physisorption so it decreases with rise in temperature.

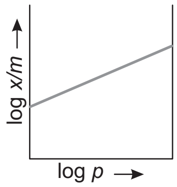
15. Freundlich adsorption isotherm is given as

$$\frac{x}{m} = kp^{1/n} \text{ (at a particular pressure)}$$

When $x = 1, \frac{x}{m} = kp$ (at low pressure)

When $n > 1, \frac{x}{m} = k$ (at high pressure)

16. Curve (c) is in accordance with Freundlich adsorption isotherm as $\frac{x}{m} = kp^{1/n}$ or $\log \frac{x}{m} = \log k + \frac{1}{n} \log p$



18. In Langmuir's adsorption isotherm, the mass of gas striking a given area of surface is proportional to the pressure of the gas as

$$\frac{x}{m} = \frac{k'p}{1+kp}$$

21. The plot of temperature *versus* pressure for a given amount of adsorption is called adsorption isostere.

22. Activated charcoal adsorbs various poisonous gases on its surface present in coal mines, so it is used in gas masks.

23. Extent of adsorption depends upon the liquefication or critical temperature of a gas.

Since H_2 has lower critical temperature than the others, it exhibits least adsorption.

26. A catalyst alters the nature of chemical reaction by lowering the activation energy of the rectants and products.

29. Equation, $SO_2(g) + \frac{1}{2} O_2(g) \xrightarrow{V_2O_5(l)} SO_3(g)$ is only example of heterogeneous catalysis.

31. Homogeneous catalysis does not occur at the interface of phases.

32. Transitional metals, showing variable valency in finely divided state mostly acts as catalyst.

35. In Haber's process, a mixture of iron powder and molybdenum powder is used as catalyst.

$$N_2 + 3H_2 \underset{Mo}{\overset{Fe}{\rightleftharpoons}} 2NH_3$$

36. The reaction in contact process is

$$2SO_2 + O_2 \xrightarrow{V_2O_5} 2SO_3$$

37. Enzymes are biological catalyst, as they catalyse the biological processes.

38. Colloidal solutions are heterogeneous in nature.

39. A colloidal system having a solid substance as a dispersed phase and a liquid as a dispersion medium is classified as sol.

40. When dispersed phase is gas and dispersion medium is solid the colloidal sol obtained is termed as solid foam.

41. Fog is a colloidal solution in which water (liquid, dispersed phase) is dispersed in air (gas, dispersion medium).

42. A colloidal solution cannot form when dispersion medium as well as dispersion medium both are gases.

44. For hydrophilic sol, viscosity is higher than water whereas surface tension is low.

45. Micelles show lower colligative properties as that of common colloidal solution.

46. At high concentration of soap in water, soap behaves as associated colloid.

47. Starch and cellulose are macromolecular particles.

49. Rain cloud is an example of aerosol. Milk of magnesia is a sol. Whipped cream is foam and soap in water is a form of associated colloids, *i.e.,* micelles.

50. Colloidal solution of gold is called purple of cassius.

53. The dispersal of a precipitated material into colloidal solution by the action of an electrolyte in the solution is termed as peptisation and the electrolyte is called a peptising agent. Thus, freshly prepared precipitate sometimes gets converted to colloidal solution by peptisation.

54. $2HNO_3 + 3H_2S \longrightarrow 3S + H_2O + 2NO$

This equation is used for the preparation of sulphur sol.

55. Peptisation is a process in which freshly prepared precipitate disintegrates into colloidal solution.

57. The values of colligative properties of colloidal solution are of small order in comparison to those shown by true solutions of same concentration because colloidal particles because of their large size are comparatively less in number.

58. The continuous rapid *zig-zag* motion by a colloidal particle in the dispersion medium is called Brownian movement.

61. The phenomenon of the scattering of light by the particles is called Tyndall effect.

64. Among Na^+, K^+, Mg^{2+} ions, Mg^{2+} ion has maximum valency, thus it will be the most effective in the coagulation of gold sol.

65. In medical field, colloidal gold is used as tonic to raise vitality of human systems.

66. Coagulation process is responsible for the formation of delta at a place where rivers meet the sea.

68. Animal leather is colloidal in nature and has positively charged particles. When it is soaked in tanin (negatively charged), a colloid, it results in mutual coagulation and gets harden.

69. Clouds are colloidal in nature and carry charge. Spray of silver iodide, an electrolyte, results in coagulation leading to rain.

70. Ice cream (emulsion) is stabilised by emulsifying agents like gelatin.

Round II

1. In physisorption, adsorbent does not show specificity for any particular gas because it involve van der Waals' forces which are universal.

2. In the mechanism of catalysis in accordance with modern adsorption theory the correct sequence of steps involved are $\text{I} \rightarrow \text{III} \rightarrow \text{II} \rightarrow \text{IV} \rightarrow \text{V}$.

3. $\Delta G < 0$, $\Delta S < 0$ and $\Delta H < 0$ are applicable to the phenomenon of adsorption but $\Delta H > 0$ is not applicable to the phenomenon of adsorption.

4. Easily liquefiable gases like SO_2, NH_3, CO_2 are adsorbed to a greater extent than the elemental gases like N_2, O_2, H_2.

5. According to Freundlich adsorption isotherm,

$$\log \frac{x}{m} = \log k + \frac{1}{n} \log p$$

It is clear from the above equation that slope is equal to $\frac{1}{n}$.

6. Freundlich adsorption isotherm equation is

$$\frac{x}{m} = kp^{1/n}$$

On taking log both sides

$$\log \frac{x}{m} = \log k + \frac{1}{n} \log p$$

$$\log \frac{x}{m} = \log 10 + 1 \cdot \log 0.5$$

$$(\because \text{ slope} = \frac{1}{n} = \tan \theta = \tan 45° = 1)$$

$$\log \frac{x}{m} = 1 + \log (5 \times 10^{-1})$$

$$\log \frac{x}{m} = 1 + 0.6990 - 1$$

$$= 0.6990$$

$$\frac{x}{m} = 5.00 = 5 \text{ g}$$

7. 50 mL of 1 M oxalic acid $[(COOH)_2 \cdot 2H_2O] = 50$ millimol

$$= 0.050 \text{ mol}$$

$$= 0.050 \times 126 \text{ g}$$

$$= 6.3 \text{ g}$$

50 mL of 0.5 M oxalic acid = 3.15 g

$\therefore$ Oxalic acid adsorbed on 0.5 g charcoal = 6.3 – 3.15

$$= 3.15 \text{ g}$$

$\therefore$ Amount of oxalic acid adsorbed per gram of charcoal

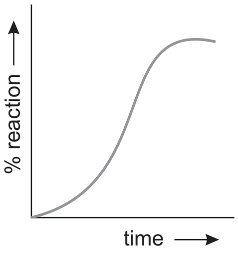
$$= \frac{3.19}{0.5} = 6.3$$

8. Palladium being a transition element, adsorbs the hydrogen gas to a greater extent and the molecules of H_2 are held to the surface of the metal by chemical forces.

9. Catalysis is a process where the rate of a chemical reaction alters due to mere presence of foreign substance. In thermite process, no other substance present except the reacting substances.

10. The optimum temperature for the production of ammonia by Haber's process is 500°C. If the temperature is lowered down then production of ammonia becomes slow down.

11.



12. In the heterogeneous catalysis, the catalyst is present in a different phase from that of reactants. Here the catalyst is generally a solid (sometimes liquid) and the reactants are generally gaseous. Thus, in the reaction II and III, reactants and the catalyst are in different phase, *i.e.,* in these reactions, heterogeneous catalysis is involved.

13. Ionic surfactant molecules are preferentially adsorbed at the interfaces.

14. In electrosmosis, dispersion medium moves in an electric field. When solvent molecules pass through semipermeable membrane towards solvent side, the process is called reverse osmosis.

Electrophoresis is the process of movement of charged colloidal particles under the influence of applied electric potential towards oppositely charged electrodes.

In osmosis, solvent molecule pass through semipermeable membrane towards solution side.

15. Smoke is an aerosol of solid, milk is an emulsion, butter is a gel and fog is an aerosol of liquid.

16. (A) Protective colloids are infact lyophilic colloids which being stable stabilises the lyophobic colloids if added from coagulation.

(B) Liquid-liquid colloids are called emulsion.

$$FeCl_3 + \underset{\text{excess}}{3NaOH} \longrightarrow Fe(OH)_3 + 3NaCl$$

$$Fe(OH)_3 + OH^- \longrightarrow Fe(OH)_3 : OH^-$$

(C) $FeCl_3 + 3H_2O \longrightarrow Fe(OH)_3 + 3HCl$

(D) $Fe(OH)_3 + FeCl_3 \longrightarrow [Fe(OH)_3]Fe^{3+} : 3Cl^-$

17. (A) Dialysis is used for the purification of colloidal solution.

(B) In peptisation, freshly prepared precipitates converted in to colloidal solution.

(C) Flocculation is precipitation of colloidal solution.

(D) Gold number is a scale of protective power.

18. Colloidal solution of $CuCl_2$ is not prepared by double decomposition method.

19. Potassium chloride (KCl) and sodium chloride (NaCl) will precipitate the negatively charged emulsions as they provide positive ions (K^+, Na^+).

20. An emulsion cannot be broken by adding more amount of dispersion medium and adding emulsifying agent.

21. Aqueous solution of soap above critical micelle concentration shows Tyndall effect.

22. Na_3PO_4 electrolytes have the maximum coagulating value for AgI/Ag^+ sol.

23. The order of minimum flocculation power KCl, $MgCl_2$, $CrCl_3$ and $SnCl_4$ for a positively charged sol are

$$KCl = MgCl_2 = CrCl_3 = SnCl_4$$

24. $\because$ Protective power $\propto \dfrac{1}{\text{gold number}}$

$\therefore$ Order of protective power will be

$$\underset{(0.005)}{\text{Gelatin}} > \underset{(0.05)}{\text{haemoglobin}} > \underset{(0.7)}{\text{sodium acetate}}$$

25. $R(NH_3)_3Br \longrightarrow R(NH_3)_3^+ + Br^-$

Alkyl trimethyl ammonium ions aggregates to form cationic micelles.

26. Gold number is the amount of substance in milligram that is required to prevent coagulation of 10 cm^3 of gold sol by addition of 1 mL of 10% NaCl solution.

Convert 0.025 g into milligram = 25

$$0.025 \text{ g starch} = 0.025 \times 1000 = 25 \text{ mg}$$

Thus, the gold number of starch = 25

27. Electrodialysis is the technique by which electrolytic impurities can be removed. Hence, urea, being non-elecrolyte cannot be removed by this method.

28. Blue colour of the sky and red colour of the red sun sets are due to scattering of light from particles of dust in the atmosphere.

29. A new definition for protective power of a lyophobic sol as given by Ostwald and known as Rubin number. It is the mass (in mg) of a colloid per 100 cc of solution which just prevents the colour change of standard sol of dye Congo-Rubin from red to violet when 0.16 g eq. KCl is added to it.

30. The colloidal aggregates of soap or detergent molecules formed in the solvent are referred to as micelles. The formation of micelle by soap in aqueous solution occurs above a particular concentration. And on dilution of soap solution, micelles may revert to individual ions.

31. In solid catalyst same reactants may give different products by using different catalysts. A catalyst does not change ΔH of reaction.

32. Electroosmosis takes place and dispersion medium begins to move when an electric field is applied to a colloidal solution and electrophoresis is prevented.

33. Freundlich adsorption isotherm is given by the expression $\dfrac{x}{m} = kp^{1/n}$

And when $\dfrac{1}{n} = 0$, the adsorption is independent of pressure and when $n = 0$, $\dfrac{x}{m}$ *vs* p graph is a line parallel to x-axis.

34. Adsorption is a selective, specific and reversible process. It increases in the gaseous adsorbate. But it is an exothermic process.

35. A catalyst is reactant in a rate-determining (r/d) step and then a product of some subsequent step. It also provides an alternate mechanism with a lower energy of activation. It alters rate of chemical reaction but cannot change quantity of the product.

36. H_2 gas is adsorbed on activated charcoal to a very little extent in comparison to easily liquefiable gases due to very weak van der Waals' forces and very low critical temperature.

37. One mole of $[AgI]Ag^+$ is coagulated by 1 mole of I^-.

$$[AgI]Ag^+ + I^- \longrightarrow AgI + AgI$$

$$\underset{\substack{2 \text{ mol} \\ 1 \text{ mol}}}{2[AgI]Ag^+} + \underset{\substack{1 \text{ mol} \\ 0.5 \text{ mol}}}{SO_4^{2-}} \longrightarrow 2AgI + Ag_2SO_4$$

$$500 \text{ mL of } 1 \text{ M } K_2SO_4 = 0.5 \text{ mol}$$

Thus, (b) is not true.

$$1 \text{ L of } 1 \text{ M KI} = 1 \text{ mol } I^-$$

Thus, (c) is also true.

38. AgI is precipitated by reaction of equivalent amount of Ag^+ and I^-. I^- is adsorbed (if present in excess) on the surface of AgI forming negatively charged colloidal sol. Thus,

$$Ag^+ + I^- \longrightarrow AgI$$

$$AgI + I^- \longrightarrow [AgI]I^-$$

(a) 100 mL of 0.1 M $AgNO_3$ = 10 millimol Ag^+

100 mL of 0.01 M KI = 10 millimol I^-

AgI is only precipitated.

(b) 20 millimol I^- > 10 millimol Ag^+

Thus, AgI is precipitated and then $[AgI]I^-$ colloidal sol is formed.

(c) 20 millimole of Ag^+ > 10 millimole of I^-

AgI is precipitated and then $[AgI]Ag^+$ colloidal sol is formed.

(d) 25 millimole I^- > 15 millimole of Ag^+

Thus, $[AgI]I^-$ colloidal sol is formed.

39. Freundlich adsorption isotherm gives an empirical relationship between the quantity of gas adsorbed by unit mass of solid adsorbent and pressure at a particular temperature.

40. Detergents with low CMC are more economical to use. Cleansing action of detergent involves the formation of micelles. These are formed when the concentration of detergent becomes equal to CMC.

41. An ordinary filter paper impregnated with colloidion solution stops the flow of colloidal particles because the pore size of the filter paper becomes less than the size of colloidal particles.

42. Coagulation power of Al^{3+} is more than Na^+ because according to Hardy Schulze rule, greater the valency of the flocculating ion added, greater is its power to cause precipitation.

43. ZSM-5 converts alcohols directly into gasoline (petrol) by dehydrating them so that a mixture of hydrocarbons is formed.

44. Freundlich adsorption isotherm is given as

$$\frac{x}{m} = kp^{1/n}$$

or, $$\log\frac{x}{m} = \log k + \frac{1}{n}\log p$$

Thus, when $\log\left(\frac{x}{m}\right)$ is plotted against $\log p$, we have a straight line with slope $\left(\frac{1}{n}\right)$ and intercept $\log k$.

45. From Langmuir adsorption isotherm,

$$\frac{x}{m} = \frac{ap}{1+bp}$$

When pressure is low then $1 + bp \approx 1$

$$\therefore \qquad \frac{x}{m} = ap$$

46. Decrease of pressure does not cause desorption in chemisorption, while it causes desorption in physisorption. In Freundlich adsorption isotherm, the degree of adsorption varies linear with pressure.

Thus, this isotherm is valid only for chemisorption.

47. Addition of lyophilic solution to the emulsion forms a protective film around the dispersed phase.

48. Milk, paint and shampoo are examples of colloidal solutions. A colloidal solution is always a heterogeneous system instead of homogeneous system.

49. In milk, milk fat (dispersed phase) is dispersed in water (dispersion medium).

50. Adsorption is an exothermic process *i.e.,* energy is released against van der Waals' force of attraction (physisorptions).

Hence, ΔH is always negative.

51. Higher the gold number, lesser will be the protective power of colloid. Therefore, the correct order of protective powers of colloids is $A < C < B < D$.

52. The adsorption of a gas is directly proportional to the pressure of the gas.

53. Mixing the soles together can cause coagulation, since the charges are neutralised.

54. Size of colloidal particles $= 1$ to 100 nm

(say 10 nm)

$$V_C = \frac{4}{3}\pi r^3 = \frac{4}{3}\pi(10)^3$$

Size of true solution particles ≈ 1 nm

$$V_S = \frac{4}{3}\pi(1)^3$$

Thus, $$\frac{V_C}{V_S} = 10^3$$

55. As temperature increases desorption increases.

$$\text{Adsorbent} + \text{Adsorbate} \rightleftharpoons \text{Adsorbed state} + \Delta E$$

Adsorption is an exothermic process (forward direction), desorption is endothermic process (backward direction).

According to Le-Chatelier's principle, increase in temperature favours endothermic process.

6

General Principles and Processes of Isolation of Metals

JEE Main MILESTONE

- Modes of Occurrence of Elements in Nature
- Metallurgy
- Steps Involved in the Extraction of Metals
- Principles Involved in the Extraction of Metals
- Extraction Schemes of Some Metals

6.1 Modes of Occurrence of Elements in Nature

Based on their reactivity elements (metals) generally occurs in two forms in nature

(i) In native state

(ii) In combined state

Less reactive metals are found in **native state** (free state) in nature. Such metals are not attacked by O_2, H_2O, CO_2 etc. Examples of such metals include Ag, Au, Pt etc. Sometimes, Cu is also found in free state.

Reactive metals are found in **combined state** in nature. Such metals are attacked by O_2, H_2O, CO_2 etc. Examples of such metals include Na, Ca, Mg, Fe, Cu, Zn, Al etc.

Earth crust is a source of many elements. Oxygen is present in the most abundance in the earth crust. Among metals, Al is the most abundant metal of earth crust and Fe comes second. The percentage of different elements in the earth crust is O–49%; Si–26%; Al–7.5%; Fe–4.2%; Ca–3.2%; Na–2.4%; K–2.3%; Mg–2.3%; H–1%; other elements–2%. Besides earth crust, some soluble salts of metals, such as NaCl, $MgCl_2$, KBr, $CaBr_2$, KI etc., are also found in sea water.

Metals in their pure form are of great importance because of their utilisation for the synthesise of several compounds, for making articles (as alloys) etc. But most of metals due to their high reactivity found in the combined form. So, it is necessary to extract metal from the compound. This chapter deals with the various principles and processes used during extraction process.

Caution Point *In earth crust metals generally not found as their nitrates because of their high solubility in water.*

Minerals, Ores and Matrix

The natural material in the form of which the metal is found in nature is called mineral and those minerals from which a metal can be extracted conveniently, economically and in large quantity are called ores. Thus, we can say that *all the ores are minerals but all the minerals are not ores.*

Common ores/minerals of some important metals are given as follows

Table 6.1 **Ores of Some Metals**

Metal	Ore/mineral	Formula
Li	Spodumene	$LiAlSi_2O_6$
	Lepidolite	$(Li, Na, K)_2Al_2(SiO_2)_3F(OH)$
Na	Common salt	$NaCl$ (rock salt)
	Chile salt petre	$NaNO_3$
	Glauberite	$Na_2SO_4 \cdot 10H_2O$ (Glauber's salt)
	Borax	$Na_2B_4O_7 \cdot 10H_2O$
	Trona	$Na_2CO_3 \cdot NaHCO_3 \cdot 2H_2O$
	Soda ash	Na_2CO_3
	Feldspar	$NaAlSi_3O_8$
K	Sylvine	KCl
	Nitre	KNO_3 (salt petre)
	Schonite	$K_2SO_4 \cdot MgSO_4 \cdot 6H_2O$
Mg	Magnesite	$MgCO_3$
	Dolomite	$MgCO_3 \cdot CaCO_3$
	Carnallite	$KCl \cdot MgCl_2 \cdot 6H_2O$
	Epsom salt	$MgSO_4 \cdot 7H_2O$
	Asbestos	$CaMg_3(SiO_3)_4$
	Talc	$Mg_2(Si_2O_5)_2Mg(OH)_2$
Ca	Gypsum	$CaSO_4 \cdot 2H_2O$
	Limestone	$CaCO_3$
	Phosphorite	$Ca_3(PO_4)_2$
	Fluorspar	CaF_2
Al	Bauxite	$Al_2O_3 \cdot 2H_2O$
	Diaspore	$Al_2O_3 \cdot H_2O$
	Corundum	Al_2O_3
	Cryolite	Na_3AlF_6
	Kaolinite	$Al_2O_3 \cdot 2SiO_2 \cdot 2H_2O$
	Mica	$K_2O \cdot 3Al_2O_3 \cdot 6SiO_2 \cdot 2H_2O$
Sn	Cassiterite	SnO_2 (tin stone)
Pb	Galena	PbS
	Cerussite	$PbCO_3$
	Anglesite	$PbSO_4$
	Lanarkite	$PbO \cdot PbSO_4$
Cu	Chalcopyrite	$CuFeS_2$ (copper pyrites)
	Chalcocite	Cu_2S (copper glance)
	Cuperite	Cu_2O (rubby copper)
	Azurite	$2CuCO_3 \cdot Cu(OH)_2$
	Malachite	$CuCO_3 \cdot Cu(OH)_2$
Ag	Argentite	Ag_2S (silver glance)
	Cerargyrite	$AgCl$ (horn silver)
	Pyrargyrite	$Ag_2S \cdot Sb_2S_3$ (ruby silver)
Fe	Haematite	Fe_2O_3 (red haematite)
	Limonite	$Fe_2O_3 \cdot 3H_2O$ (brown haematite)
	Magnetite (load stone)	Fe_3O_4 (magnetic oxide of iron)
	Siderite	$FeCO_3$
	Iron pyrite	FeS_2
Hg	Cinnabar	HgS
Zn	Zinc blende	ZnS (black zinc or sphalerite)
	Calamine	$ZnCO_3$
	Zincite	ZnO (red zinc)
	Willemite	Zn_2SiO_4
Mn	Pyrolusite	MnO_2
	Manganite	$Mn_2O_3 \cdot H_2O$
Cr	Chromite	$Cr_2O_3 \cdot FeO$

Metallic ores are often found to contain certain non-metallic rocky substances in them, *e.g.,* sand, clay, quartz, feldspar, silicates, mica, etc. These unwanted impurities are called **gangue** or **matrix.** Thus, the waste material present in an ore is called **gangue.**

6.2 Metallurgy

The process of extracting a metal in pure form from its ores is known as metallurgy. Metallurgical processes can be of following three types : hydrometallurgy, pyrometallurgy and electrometallurgy.

In **hydrometallurgy** the concentrated ore is treated with aqueous solution of some reagent, *e.g.,* NaCN or Cl_2 in the presence of water etc. The metal present in ore forms soluble salt and comes in solution which is then recovered from the solution either by electrolysis or through precipitation by adding some suitable more electropositive metal in the solution. It is generally applicable for less reactive metals like AgBr or highly reactive metals like Al.

Pyrometallurgy generally refers to the extraction through heat. Roasting, calcination, smelting etc., processes are included in it. Generally it is applicable for moderately active metals like Cu, Pb, Zn, Fe, etc.

In **electrometallurgy**, metal is generally extracted with the help of electrolysis. It is applicable for highly reactive metals like Na, K, Al, etc.

6.3 Steps Involved in the Extraction of Metals

It is not possible to chalk out a universal scheme for the extraction of all metals since the extraction of each metal is an individual problem and the line of treatment depends upon the nature of the ore, impurities and the metal.

The various metallurgical operations used in the extraction of pure metals from their respective ores are given below.

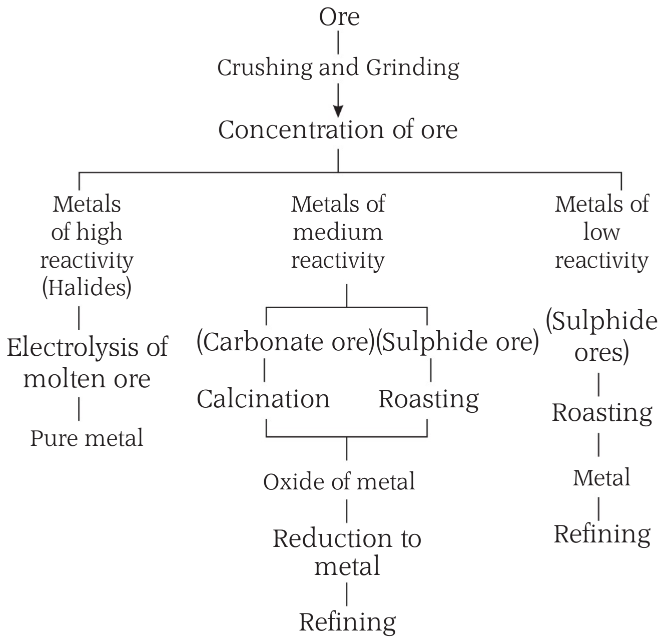


Fig. 6.1 Steps involved in the extraction of metals from ores

Crushing and Grinding of the Ore

Generally, ores occur in nature as huge lumps. They are crushed into small pieces in gyratory crushers. The crushed ore is then grinded with the help of rollers or in the stamp mill to powder form.

Concentration of the Ore

The process of gangue removal or increase in concentration of ore depends upon the nature of ore and the impurities present in it.

Some of the important methods involved are

(a) Gravity Separation or Levigation

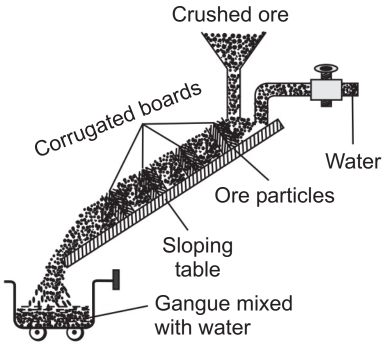

Fig. 6.2 Concentration of ore by levigation

In this method, the ore is powdered and then washed in a running stream of water. The lighter earthy material and gangue are washed away, while the heavy ore particles remain behind. The oxide ores of iron Fe_2O_3 and Fe_3O_4 are concentrated by this method. This method is also called **levigation.**

(b) Froth Floatation Process

In this process, the ore is powdered and then placed in a water tank. Now some **pine oil and potassium ethylxanthate** is added to it. A strong stream of air is passed then in the tank containing water and powdered ore. When the whole mass is agitated, froth is formed. The ore particles are preferentially wetted by the oil and come at the surface along with the froth.

Some compounds are used to stabilize the froth (*e.g.,* cresols and aniline) and are called **froth stabilizers.** The impurities are wetted by water and remain behind in the tank. The substances like pine oil, xanthates and fatty acids are called **collector**, which attach themselves by polar groups to grains of minerals which then become water repellant and thus pass on into the froth.

Activators and depressants are the compounds which activate and depress respectively the floating property of one of the components of the ore and thus, help in the separation of different minerals present in the same ore. Copper sulphate is an example of activator, while sodium and potassium cyanides are the examples of depressants.

The use of these three types of reagents can be illustrated in the separation of galena PbS which is usually associated with sphalerite ZnS and pyrites FeS_2. Floatation is carried out in presence of potassium ethyl xanthate (collector) and sodium cyanide and alkali (depressants). The latter compounds depress the floatation property of ZnS and FeS_2 particles and hence, only PbS particles go into the froth when air is blown in. After the removal of galena, the process is repeated by adding copper sulphate (activator) which activates the floating character of ZnS particles and thus, this time ZnS comes with the froth. The acidification of remaining slurry leads to the floatation of FeS_2.

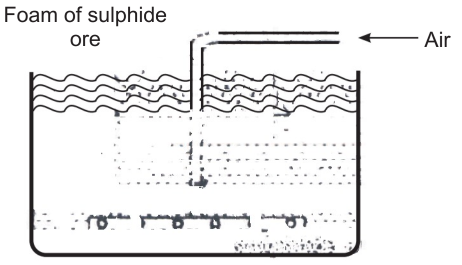

Fig. 6.3 Froth floatation process for the concentration of sulphide ores

The sulphide ores of Cu, Ag, Zn, Pb, etc., are concentrated by this process.

(c) Magnetic Separation

The process of magnetic separation depends upon the magnetic properties of the ore and the gangue. If the ore or the impurity is magnetic then this process is used to separate the magnetic substance from non-magnetic substance.

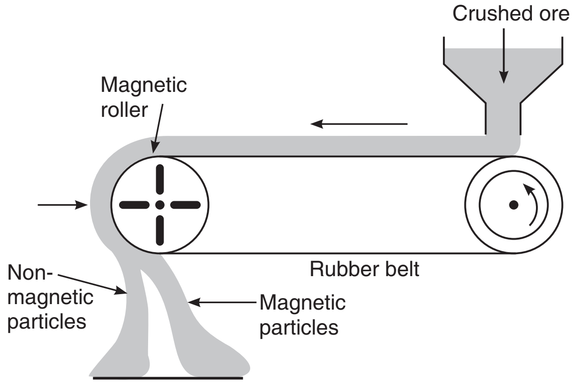

Fig. 6.4 An electromagnetic separator, used to concentrate the ore

The ore is concentrated by a magnetic separator which consists of a leather belt moving over two rollers. One of the roller is magnetic. The method is useful for separating tungsten ore particles from cassiterite (SnO_2). The process may also be employed for separating other transition metal ores like magnetite (Fe_3O_4), chromite ($FeO \cdot Cr_2O_3$) and pyrolusite (MnO_2) from unwanted gangue.

(d) Leaching

It involves the treatment of the ore with a suitable reagent so as to make it soluble while impurities remain insoluble. The ore is recovered from the solution by suitable chemical methods. Some important examples of leaching are

(i) In **Bayer's process** pure aluminium oxide is obtained from the bauxite ore by treating the powdered ore with a concentrated solution of NaOH resulting in dissolution of Al_2O_3, leaving the impurities behind as,

$$Al_2O_3(s) + 2OH^-(aq) + 3H_2O \longrightarrow 2Al(OH)_4^-(aq)$$

(ii) Similarly, the leaching method is also employed in concentrating Ag and Au ores with the help of their dissolution in NaCN or KCN or Cu with the help of H^+ or Fe scraps..

In case of gold, $O_2(g)$ oxidises free metal to Au^+, which complexes with CN^-.

$$4Au(s) + 8CN^- + O_2(g) + 2H_2O \longrightarrow 4[Au(CN)_2]^- + 4OH^-$$

The pure metal is then displaced from the solution by active metal (as Zn).

$$[2Au(CN)_2]^- + Zn \longrightarrow 2Au(s)\downarrow + [Zn(CN)_4]^{2-}$$

Conversion of Concentrated Ore to Oxide

The concentrated ore, if not an oxide, is converted into oxide because oxides can be reduced easily as compared to sulphides and other such compounds.

The concentrated ore is converted into its oxide by following two ways

(a) Roasting

The concentrated ore is heated alone or mixed with some other substance, *below its melting point in the presence of air,* resulting in oxidation of ore and impurities. This type of specialised heating of concentrated ore is called roasting. *Usually the sulphide ores undergo roasting.* In the process of roasting in general, normally the impurities like As and S are oxidised to volatile oxides like SO_2, As_2O_3 etc., and removed.

Some examples of roasting are

(i) In extraction of iron as

$$S + O_2 \longrightarrow SO_2\uparrow$$
$$4As + 3O_2 \longrightarrow 2As_2O_3\uparrow$$
$$4FeO + O_2 \longrightarrow 2Fe_2O_3$$

Here, sulphur and arsenic impurities are removed as volatile oxides due to roasting, while any ferrous oxide present is converted to ferric oxide.

(ii) Zinc blende (ZnS) is roasted to give ZnO in the extraction of Zn as

$$2ZnS + 3O_2 \longrightarrow 2ZnO + 2SO_2$$

(iii) On roasting, the copper ore chalcopyrite ($CuFeS_2$), the impurities S and As present in it are removed as volatile SO_2 and $As_2O_3 \cdot CuFeS_2$ is converted into cuprous sulphide and ferrous sulphide as

$$S + O_2 \longrightarrow SO_2\uparrow$$
$$4As + 3O_2 \longrightarrow 2As_2O_3\uparrow$$
$$2CuFeS_2 + O_2 \longrightarrow Cu_2S + 2FeS + SO_2$$

Some part of cuprous sulphide and ferrous sulphide is converted into Cu_2O and FeO as

$$2FeS + 3O_2 \longrightarrow 2FeO + 2SO_2\uparrow$$
$$2Cu_2S + 3O_2 \longrightarrow 2Cu_2O + 2SO_2\uparrow$$

(iv) For silver ore, chloro roasting is done as

$$Ag_2S + 2NaCl \longrightarrow 2AgCl + Na_2S$$
$$AgCl + 2Hg \longrightarrow Ag-Hg + HgCl$$

(b) Calcination

The hydroxide and carbonate ores after concentration does not undergo roasting, these are subjected to calcination instead. In the process of calcination, the ore is heated below its melting point in the absence of air or in the limited supply of air. Such a heating results in conversion of these hydroxide and carbonate ores to metal oxides.

During calcination, the ore becomes porous, and volatile impurities are removed.

Some examples of calcination are given below

(i) Aluminium hydroxide is converted to alumina as,

$$2Al(OH)_3 \xrightarrow{1500^\circ C} Al_2O_3 + 3H_2O$$

(ii) Limonite (iron ore) gives anhydrous ferric oxide as,

$$Fe_2O_3 \cdot 3H_2O \xrightarrow{\Delta} Fe_2O_3 + 3H_2O$$

(iii) Siderite (iron ore) gives ferrous oxide as,

$$FeCO_3 \xrightarrow{\Delta} FeO + CO_2$$

(iv) Calamine (zinc ore) gives zinc oxide as,

$$ZnCO_3 \xrightarrow{\Delta} ZnO + CO_2$$

(v) $NaHCO_3$ gives Na_2CO_3 and $CaCO_3$ gives CaO as,

$$2NaHCO_3 \xrightarrow{\Delta} Na_2CO_3 + CO_2 + H_2O$$

$$CaCO_3 \xrightarrow{\Delta} CaO + CO_2$$

It must be noted that calcination proceeds only with the expulsion of some small molecules like water, CO_2, SO_2, etc., without any other chemical change while during roasting definite chemical changes like oxidation, chlorination, etc., takes place. Calcination and roasting also make the mass porous so that it can easily be reduced to the metallic state in the next operation.

Calcination and roasting are carried out in various types of furnaces, most important of which is reverberatory furnace. The furnaces used in calcination and roasting employ refractory materials which resist high temperature and do not become soft.

Acidic refractories	: SiO_2 and $SiO_2 + Al_2O_3$
Basic refractories	: CaO and MgO
Neutral refractories	: Graphite, chromites, carborundum (SiC).

Refractory material should not combine with the ore or the metal and must be able to protect the furnace from high temperature.

Reduction of Oxide to Metal

Once an ore has been concentrated, it is reduced to free metals by several methods. The method used depends on the activity of the metal as measured by its standard reduction potential. The most active metals have the most negative standard reduction potential and are most difficult to reduce and the least active metals have the most positive standard reduction potential and are easiest to reduce.

(a) Smelting or Reduction by Carbon or its Oxides

Carbon (as coal, coke, charcoal, CO etc.,) reduces many metal oxides into respective metals, such as

$$\underset{\text{cassiterite}}{SnO_2} + 2C \xrightarrow{1473-1573\text{ K}} Sn + 2CO$$

$$ZnO + CO \xrightarrow{1600\text{ K}} Zn + CO_2$$

$$Fe_2O_3 + CO \xrightarrow{823\text{ K}} 2FeO + CO_2$$

$$FeO + CO \xrightarrow{1123\text{ K}} Fe + CO_2$$

Besides these, oxides of Pb, Cr, Mn, Be, etc., can also be reduced by the same process.

Some of the oxide ores like haematite (Fe_2O_3), tinstone (SnO_2) contain some infusible earthy impurities even after concentration. The impurities may be basic (*i.e.,* metallic oxides like CaO, FeO, MgO etc.) or acidic (*i.e.,* non-metallic oxides like SiO_2, P_2O_5, etc.). In order to remove acidic or basic impurities, the concentrated ore is mixed with coke and another substance, called the **flux.** The mixture is heated in the presence of air at high temperature and this heating is called **smelting.** Reactions taking place in smelting are

(i) Coke or CO reduces oxide ore to free metal, *e.g.,*

$$PbO + C \longrightarrow Pb\,(\text{molten lead}) + CO\uparrow$$

$$PbO + CO \xrightarrow{\text{High temperature}} Pb\,(\text{molten lead}) + CO_2\uparrow$$

$$Fe_2O_3(\text{haematite}) + 3CO \longrightarrow 2Fe(\text{spongy iron}) + 3CO_2\uparrow$$

$$SnO_2(\text{tinstone}) + 2C \longrightarrow Sn\,(\text{molten tin}) + 2CO\uparrow$$

(ii) The flux combines with acidic or basic impurities present in the oxide ore and forms a fusible mass, called **slag.** Thus, the impurity is removed in the form of fusible slag as

$$\text{flux} + \text{impurity} \longrightarrow \text{fusible slag}$$

The slag floats over the molten metal and can be removed from upper exit.

Depending upon the requirement, a flux may be acidic or basic. Basic flux is used to remove acidic impurities and *vice-versa*. The examples of acidic flux are SiO_2, P_2O_5, B_2O_3, etc. The examples of basic flux are CaO, MgO, etc.

In case of tin, the concentrated ore is mixed with one-fifth of its weight of powdered anthracite (carbon) and a little limestone, $CaCO_3$ and heated in a reverberatory furnace at 1200–1300°C. The ore is reduced to metallic state while silica (impurity) is removed as slag.

$$SnO_2 + 2C \longrightarrow Sn + 2CO\uparrow$$

$$CaCO_3 \xrightarrow[-CO_2]{\Delta} CaO \xrightarrow{SiO_2} \underset{\substack{\text{calcium silicate}\\ \text{(slag)}}}{CaSiO_3}$$

Excess of lime must be avoided because it would otherwise react with tin to form calcium stannate.

The molten metal collects on the bottom of the furnace. It contains 99.5% of metallic tin, called the **black tin.**

Caution Points

- (*i*) *Some ores are self-fluxing because they contain some gangue (stony matrix accompanying the ore) which is self fusible and thus, no foreign flux is required.*
- (*ii*) *Blast furnace is used in the reduction of iron oxides while reverberatory furnace is used in the reduction of tin oxide.*

(b) With Hydrogen

Hydrogen being inflammable is used as a reducing agent in very few cases, *e.g.,*

$$MO_3 + 3H_2 \longrightarrow M + 3H_2O \qquad (M = \text{Mo or W})$$

This method is not widely used, because many metals react with H_2 at elevated temperatures forming hydrides. Also there are chances of explosion of H_2 with O_2.

Sample **Problem 1** *Although carbon and hydrogen are better reducing agents but they are not used to reduce metallic oxides at high temperatures because* **[NCERT Exemplar]**

- (a) *they are non-metals*
- (b) *they are less reactive*
- (c) *they become more reactive and from carbide and hydride*
- (d) *they are costly*

Interpret (c) This is because at high temperatures, carbon and hydrogen react with metals to form carbides and hydrides respectively.

(c) Goldschmidt Aluminothermic Process

Chromium and manganese oxides are reduced through aluminothermic reduction processes or Goldschmidt aluminothermic process, *e.g.,*

$$Cr_2O_3 + 2Al \longrightarrow Al_2O_3 + 2Cr$$
$$3Mn_3O_4 + 8Al \longrightarrow 4Al_2O_3 + 9Mn$$

In this process, mixture of the metallic oxide and aluminium powder, commonly known as **thermite,** is taken in a steel crucible placed in a bed of sand. A mixture of aluminium powder and barium peroxide (BaO_2) is placed over the charge in the form of a heap and magnesium wire is embedded in it. The charge is covered by a thick layer of carbon followed by a thin layer of feldspar to avoid loss of heat and to protect the mass from oxidation. The magnesium ribbon which acts as a fuse is lighted. It starts burning and hence, mixture also starts burning. Since the reaction is highly exothermic, once it starts, it goes on till all the oxide is converted into metal.

Sample **Problem 2** *In aluminothermite process, aluminium is used as*

- (a) *reducing agent* (b) *oxidising agent*
- (c) *solder* (d) *flux*

Interpret (a) The reaction occurring in aluminothermic process is

$$\underbrace{\overset{+3}{M}_2O_3 + 2Al \longrightarrow Al_2O_3 + 2\overset{0}{M}}_{\text{Reduction}}$$

Here, metal is reducing from its +2 to 0 oxidation state, so Al acts as a reducing agent.

(d) Reduction by Water Gas

It is applied for nickel oxide.

$$2NiO + CO + H_2 \longrightarrow 2Ni + CO_2 + H_2O$$

(e) With Other Metals

Na and Mg metals are used in certain cases as reducing agents, *e.g.,*

$$TiO_2 + 2Mg \longrightarrow Ti + 2MgO$$
$$TiO_2 + 4Na \longrightarrow Ti + 2Na_2O$$

(f) Auto-reduction

This process is also known as **self reduction.** This is used when no external reducing agent is required. The sulphide ores of less electropositive metals like Hg, Pb, Cu etc., are heated in air to either convert the complete ore or part of the ore into oxide or sulphate which then reacts with the remaining sulphide ore to give the metal and sulphur dioxide, *e.g.,*

(i) Extraction of Cu from copper glance

$$2Cu_2S + 3O_2 \longrightarrow 2Cu_2O + 2SO_2$$
$$Cu_2S + 2Cu_2O \longrightarrow 6Cu + SO_2$$

(ii) Extraction of Hg from cinnabar

$$2HgS + 3O_2 \longrightarrow 2HgO + 2SO_2$$
$$2HgO \xrightarrow{\Delta} 2Hg + O_2$$

(iii) Extraction of Pb from galena

$$2PbS + 3O_2 \longrightarrow 2PbO + 2SO_2$$
$$2PbO + PbS \longrightarrow 3Pb + SO_2$$

Caution Point *Oxides of metals lying below* Hg (*and that of* Hg) *in electrochemical series, i.e., oxides of* Ag, Pd, Pt, Au *decompose on heating giving metal.*

(g) Displacement Method

If the temperature needed for carbon to reduce an oxide is too high for economic or practical purpose, the reduction may be affected by another highly electropositive metal. *e.g.,* Ag and Au are obtained from their complex cyanides (cyanide process) when more reactive Zn metal displaces them as

$$2M(CN)_2^- + Zn \longrightarrow Zn(CN)_4^{2-} + 2M$$

(where, M = Ag, Au)

(h) Electrolytic Method

The oxides of highly electropositive metals of group 1 and 2 cannot be reduced easily with carbon at moderate temperatures. These metals are thus, extracted by the electrolysis of their salts (generally, oxides, hydroxides or chlorides in fused state). The metal is liberated at the cathode. *e.g.,* Sodium is obtained by the electrolysis of fused NaCl or brine.

$$NaCl \rightleftharpoons Na^+ + Cl^-$$

$$Na^+ + e^- \longrightarrow Na \qquad \text{(at cathode)}$$

$$Cl^- \longrightarrow Cl + e^- \qquad \text{(at anode)}$$

$$Cl + Cl \longrightarrow Cl_2$$

In the case of NaCl (brine solution), Hg electrodes are used so that Na metal after deposition at cathode forms amalgam with Hg.

Metals other than those of s-block can also be extracted by electrolysis of fused compounds, *e.g.,* fused Al_2O_3 mixed with Na_3AlF_6 is used for the production of Al.

Caution Point *Electrolysis can be carried out in solvents other than water.* F_2 *reacts violently with* H_2O *hence, it is produced by electrolysis of* KHF_2 *in* HF.

Refining of Crude Metal

Metals extracted through any of the methods described above are usually contain some impurities.

Following methods are used to purify the metals

(a) Distillation Method

This process is used for those metals which are easily volatile. In this method, the impure metal is heated in a retort and its vapours are separately condensed in a receiver. The non-volatile impurities are left behind in the retort. This is used for the purification of Zn, Cd, Hg, etc.

(b) Liquation Method

Low melting metals can be separated by this method. In this method, the impure metal is poured on the sloping hearth of a reverberatory furnance and heated gently to a temperature slightly above the melting point of the metal. The pure molten metal runs out leaving behind the infusable matter (called dross) on the hearth. This is used for the purification of Bi, Sn, Pb, Hg, etc.

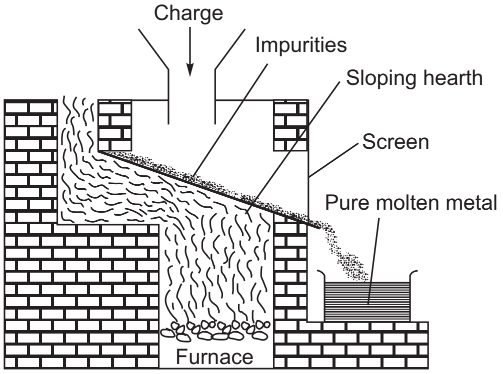

Fig. 6.5 Liquation method

(c) Electrolysis

Many of metals such as Cu, Ag, Au, Al, Pb etc., are purified by this method. Here, the cathode is made up of pure metal and anode is made up of impure metal. The electrolyte used is infact an aqueous solution of salt of the metal. Thus,

$$\text{Anode} \longrightarrow \text{impure metal}$$

$$\text{Cathode} \longrightarrow \text{pure metal}$$

$$\text{Electrolyte} \longrightarrow \text{salt of metal in aqueous solution}$$

On passing electric current, pure metal deposits on cathode. The equivalent mass of anode dissolves in the form of salt and comes in the solution. The impurities either remain dissolved in solution or settled down as anode mud around anode. The applied voltage here is such that more electropositive metals (impurity) remain as ions in the both whereas, the less electropositive metals (also impurities) remain unionised and fall down as anode mud.

(i) Electrorefining of Cu

Anode Blister copper (98%); **Cathode** : Pure copper

Electrolyte Aq. solution of $CuSO_4$ (15%) + 5% dil. H_2SO_4

The function of dil. H_2SO_4 is to check the hydrolysis of $CuSO_4$ and increases and the conductance of the solution.

(ii) Electrorefining of silver (Moebius process)

Anode Impure silver; **Cathode** : Pure silver

Electrolyte Aq. $AgNO_3$ + 1% dil. HNO_3.

(iii) Electrorefining of lead (Bett's process)

Anode Impure lead; **Cathode** : Pure lead

Electrolyte A mixture of $PbSiF_6$ and H_2SiF_6.

(d) Poling

The impure metal containing its oxides as impurity can be purified by this method. The molten impure metal is stirred with green poles of wood. The green poles of wood release the hydrocarbon gases which reduce the oxide impurities. This method is especially used in the purification of copper (old method).

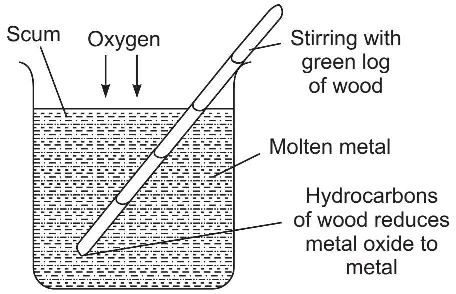

Fig. 6.6 Refining of metal by poling

(e) Zone-Refining Method

This method is employed to get the metals of very high purity. Metals like Ge, Si, B, Ga, In, etc., are purified by this method. The method is based upon the principle that an impure molten metal on gradual cooling will deposit crystals of the pure metal while impurities will be left in remaining part of molten metal. In this process, the impure metal is taken in the form of rod and a circular heater is fitted around this rod which is slowly moved along the length of the rod. As the heater moved, the molten impurities also moved along with the heater while the pure metal recrystallises without leaving its position. Lastly the end of rod where the impurities finally get concentrated is cut off, leaving the rod of comparative more pure metal. The process is repeated a number of times until the desired state of purity is reached. The method is especially useful for producing the semiconductors of very high purity.

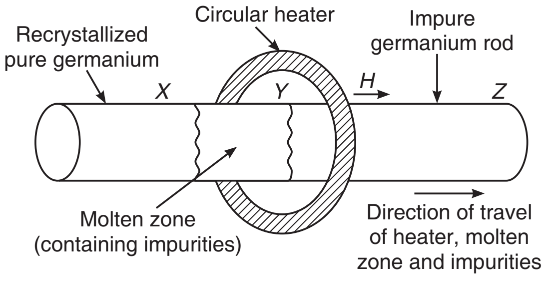

Fig. 6.7 Zone refining of germanium metal

(f) Vapour Phase Refining Method

This method is based upon the principle that the impure metal is converted into suitable volatile compound which on being heated, gets decomposed to give pure metal. Among its examples we can observe,

(i) Mond process (also called carbonyl process)
(ii) van-Arkel de-Boer's process (also called iodine refining process)

The **Mond's process** is used for the purification of Ni. It is the most important process for getting 99.9% pure Ni metal from crude Ni. The process was discovered by German chemist, **Ludvig** in 1893. In the process, the crude Ni is heated in the stream of CO to form volatile nickel carbonyl, $Ni(CO)_4$. This $Ni(CO)_4$ when heated higher, it will decomposed to give pure metal as

$$\underset{\text{impure}}{\text{Ni}} + 4\text{CO} \xrightarrow{330-350\text{ K}} \text{Ni(CO)}_4 \xrightarrow{450-470\text{ K}} \underset{\text{pure}}{\text{Ni}} + 4\text{CO}$$

In the **van-Arkel de-Boer's process,** the impure metal is heated with iodine in a sealed vessel, so that the metal forms volatile metallic iodide and impurities do not react with iodine. The metallic iodide is then decomposed when heated further at higher temperatures. The metals purified through this way are Zr (zirconium), Ti (titanium), V (vanadium), Th (thorium), etc. For example, purification of Ti through this method can be done as

$$\underset{\text{(impure)}}{\text{Ti}} + 2\text{I}_2(g) \xrightarrow{150-250^\circ\text{C}} \text{TiI}_4(g) \xrightarrow[\text{tungsten filament}]{1400^\circ\text{C}} \underset{\text{pure}}{\text{Ti}(s)} + 2\text{I}_2(g)$$

(g) Amalgamation Process

This method is used for the extraction of noble metals like Ag, Au etc., from the native ores. The finely powdered ore is brought in contact with Hg which combines with the particles of the metal present in the ore and form amalgam. The metal is recovered from the amalgam by subjecting it to distillation, where the Hg distills over, leaving behind the metal.

(h) Cupellation

This method is used when impure metal contains impurities of other metals which form volatile oxides, *e.g.,* traces of lead ore removed from silver (as volatile PbO) by this process.

(i) Chromatography

This method is used when the elements are available only in minute quantities and the impurities are not very much different in their chemical behaviour from the element to be purified.

Adsorption chromatography is generally used. In this, the impure metal is dissolved in a suitable solvent and the solution is allowed to run slowly into an adsorbent column packed with alumina (Al_2O_3). The metal and the impurities present are adsorbed at different rates. These are then eluted with suitable eluent (solvent). In this method, weakly adsorbed component is eluted first and the strongly adsorbed component is eluted afterwards.

Check Point 1

1. Impurity of FeO is removed by SiO_2 instead of CaO. Why?
2. Explain, why is chalcocite roasted but not calcined during recovery of copper?
3. Explain, why aluminium metal is frequently used as a reducing agent for the extraction of metals such as Cr, Mn etc?
4. In electrolysis, why graphite is used as anode instead of diamond?

6.4 Principles Involved in the Extraction of Metals

Extraction of metal from its ore depends upon thermodynamic as well as electrochemical principles, *which are described below*

Electrochemical Principles Involved in Extraction

The method employed for the extracting a metal from its ore depends on the nature of the metal and that of the ore and may be related to the position of the metal in the electrochemical series. In general, metals with $E° < -1.5$ V yield compounds which are very difficult to reduce and the help of electricity has usually to be taken for the isolation of such metals. On the other hand, noble metals with $E° > +0.5$ V form easily reducible compounds. In general, a metal higher up in the electrochemical series should be more difficult to reduce to metallic form. However, it must be borne in mind that this is a very general statement and cannot be strictly applied because metals are seldom extracted from aqueous solution.

Hot Spot 1

THERMODYNAMIC Principles Involved in Metallurgy

It is an important topic of the chapter for JEE Main examination. The nature of questions may vary from easy to typical and sometimes is confusing.

The free energy change (ΔG) occurring during the reduction processes help in deciding the suitable method for reduction.

For the spontaneous reduction of an oxide, halide or sulphide by an element, the essential condition is that there is a decrease in the free energy of the system (–ve ΔG).

More the negative value of ΔG, the higher is the reducing power of an element. ΔG can be given as

$$\Delta G = \Delta H - T\Delta S$$

where, ΔH = enthalpy change;

ΔG = Gibbs free energy

T = temperature;

ΔS = entropy change

For the reduction of a metal oxide with a reducing agent, the plot of $\Delta G°$ against temperature is studied, which is called **Ellingham diagram.**

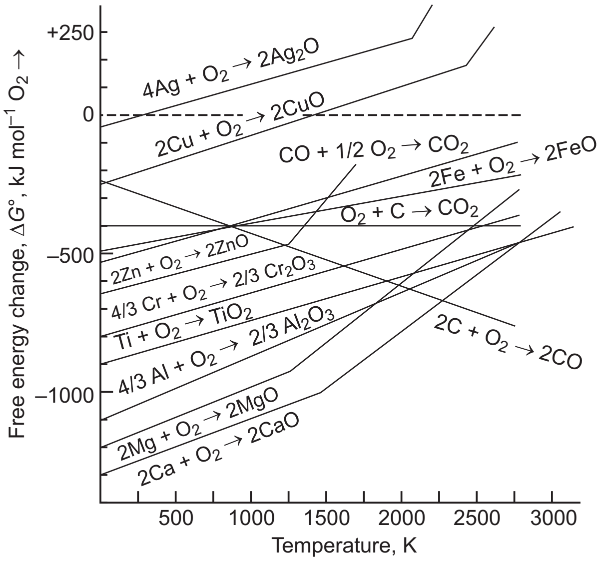

Fig. 6.8 Combined Ellingham diagram for metals and carbon

Characteristics of Ellingham Diagram

1. All the plots slope upwards since $\Delta G°$ becomes more positive when temperature increases, *i.e.,* stability of oxides decreases.
2. A metal will reduce the oxide of other metals which lie above it in Ellingham diagram, *i.e.,* the metals for which the free energy of formation (ΔG_f°) of their oxides is more negative can reduce those metal oxides which has less negative ΔG_f°.
3. The decreasing order of the negative values of ΔG_f° of metal oxides is

   Ca > Mg (below 1773 K) > Al > Ti > Cr> C > Fe > Ni > Hg > Ag

   Thus, Al reduces FeO, CrO and NiO in thermite reduction but it will not reduce MgO at temperature below 1773 K.

   Mg can reduce Al_2O_3 below 162 K but above 1023 K, Al can reduce MgO.
4. CO is more effective reducing agent below 1073 K and above 1073 K, coke is more effective reducing agent, *e.g.,* CO reduces Fe_2O_3 below 1073 K but above it, coke reduces Fe_2O_3. Coke reduces ZnO above 1270 K.

Example

It is interesting to think of the reduction of ZnO with C as involving a competition between Zn and C for O atoms. We consider following values at 1100°C for the oxidation of Zn and C.

(i) $2Zn + O_2 \longrightarrow 2ZnO; \quad \Delta G° = -360 \text{ kJ}$

(ii) $2C + O_2 \longrightarrow 2CO; \quad \Delta G° = -460 \text{ kJ}$

(i) and (ii) gives

$2Zn + 2CO \longrightarrow 2ZnO + 2C; \quad \Delta G° = +100 \text{ kJ}$

or (iii) $Zn + CO \longrightarrow ZnO + C; \quad \Delta G° = +50 \text{ kJ mol}^{-1}$

(iv) $ZnO + C \longrightarrow Zn + CO; \quad \Delta G° = -50 \text{ kJ mol}^{-1}$

For reaction (iii), in which Zn reduces CO, $\Delta G°$ is positive indicating that this reduction is non-spontaneous (in forward direction), but for the reaction (iv) with negative value of $\Delta G°$ in which C reduces ZnO is spontaneous (in forward direction).

Why must we carry out the reduction of ZnO with C at 1100°C? From an energy stand point it would certainly be more economical to carry it out at a lower temperature. The following graphical representation (Ellingham diagram) is useful tool to help answer such questions. The lines ($2C + O_2 \longrightarrow 2CO$) and ($2Zn + O_2 \longrightarrow 2ZnO$) cross at about 950°C. At about this temperature, Zn and C have equal affinities for O atoms. $\Delta G°$ for reaction (iv) is zero. Above this temperature $\Delta G°$ is negative, and below this temperature $\Delta G°$ is positive. To make reaction (iv) go essentially to completion we need a temperature somewhat in excess of 950°C.

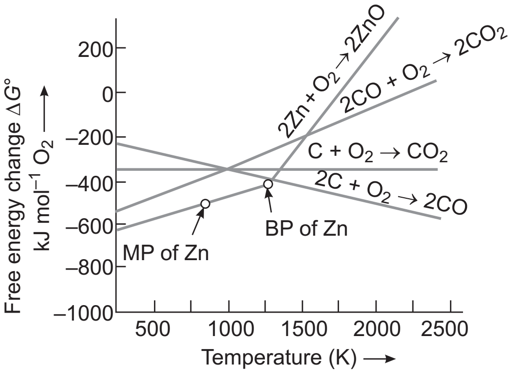

Fig. 6.9 Ellingham diagram for carbon, carbon monoxide and zinc systems

Sample Problem 3 *The value of* $\Delta_f G°$ *for formation of* Cr_2O_3 *is –540 kJ/mol and that of* Al_2O_3 *is –827 kJ/mol. The correct statement from the following is*

(*a*) Cr *have more affinity towards oxygen as compared to* Al
(*b*) Al *have more affinity towards oxygen as compared to* Cr
(*c*) *Affinity towards oxygen depends upon temperature.*
(*d*) *Both (b) and (c)*

Interpret (*b*) The two thermochemical equations may be written as

(i) $\frac{4}{3}\text{Cr}(s) + O_2(g) \longrightarrow \frac{2}{3}Cr_2O_3(s); \quad \Delta_f G° = -540 \text{ kJ}$

(ii) $\frac{4}{3}\text{Al}(s) + O_2(g) \longrightarrow \frac{2}{3}Al_2O_3(s); \quad \Delta_f G° = -827 \text{ kJ}$

Subtracting Eq. (i) from Eq. (ii), we get

$$\frac{2}{3}Cr_2O_3(s) + \frac{4}{3}\text{Al}(s) \longrightarrow \frac{2}{3}Al_2O_3(s) + \frac{4}{3}\text{Cr}(s); \; \Delta_f G° = -287 \text{ kJ}$$

As $\Delta_f G°$ comes out to be negative, the reaction is feasible, *i.e.,* Al can be used for the reduction of Cr_2O_3 or Al have more affinity towards oxygen as compared to Cr.

Sample Problem 4 *The reaction,*

$$Cr_2O_3(s) + 2\text{Al}(s) \longrightarrow Al_2O_3 + 2\text{Cr}; \quad (\Delta G° = -421 \text{kJ})$$

is thermodynamically feasible as is apparent from the Gibbs energy value, but the reaction does not occur at room temperature because **[NCERT]**

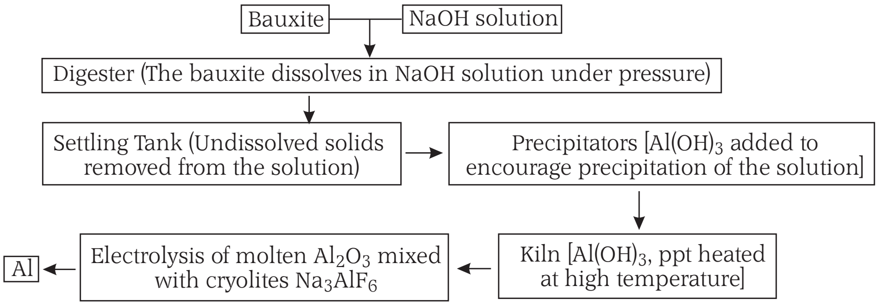
(*a*) *the reaction is reversible at low temperature*
(*b*) *the reactants are solids*
(*c*) *the products are solids*
(*d*) Cr *has more affinity towards oxygen as compared to* Al

Interpret (*b*) The reactants are solids so they cannot react in the present state. When the temperature is elevated, reactants melt and the reaction proceeds. Therefore, a higher temperature than room temperature is required.

6.5 Extraction Schemes of Some Metals

Aluminium

Its chief ore is **bauxite** ($Al_2O_3 \cdot 2H_2O$). *The outline of its extraction from its ore is shown below*



Cryolite improves the electrical conductivity of the cell as Al_2O_3 is poor conductor. This also serves as an added impurity and lower the melting point of the mixture to about 950°C. Al of 99.6 to 99.8% purity is obtained. Probable net reactions are

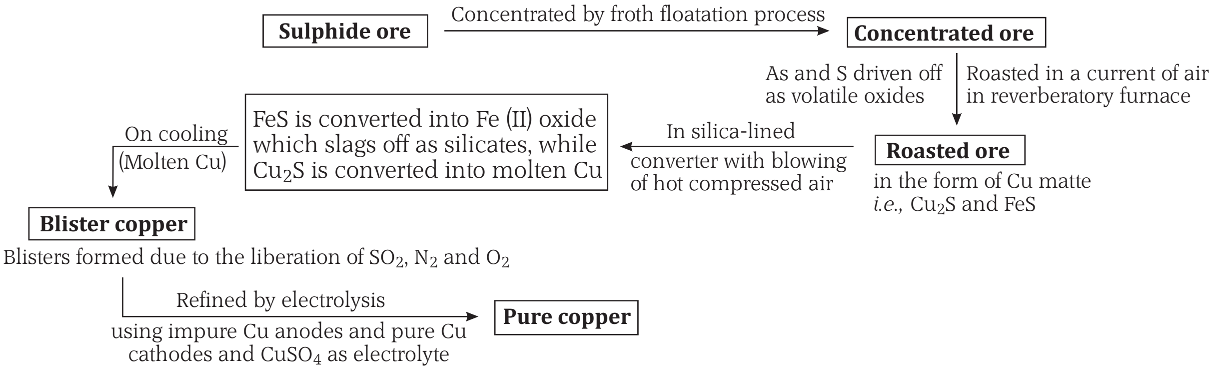
Oxidation at anode $\quad C + 2O^{2-} \longrightarrow CO_2 + 4e^-] \times 3$

Reduction at cathode $\quad Al^{3+} + 3e^- \longrightarrow Al] \times 4$

$$3C + 4Al^{3+} + 6O^{2-} \longrightarrow 4Al + 3CO_2$$

Copper

It does not occur abundantly in nature. Its chief ore are **copper pyrites** ($CuFeS_2$), **malachite** ($CuCO_3 \cdot Cu(OH)_2$), **cuperite** (Cu_2O), **copper glance** (Cu_2S). *The outline of its extraction from its ore looks like*



Low grade copper can be extracted by hydrometallurgical process (wet process) as

Step I Leaching with H_2SO_4 converts salts into sulphates :

$$CuCO_3 + H_2SO_4 \xrightarrow{\Delta} CuSO_4 + H_2O + CO_2$$

$$Cu(OH)_2 + H_2SO_4 \xrightarrow{\Delta} CuSO_4 + 2H_2O$$

$$CuFeS_2 + 2H_2SO_4 \xrightarrow{\Delta} CuSO_4 + FeSO_4 + 2H_2S$$

***Step II* Electrochemical Displacement** Fe is above Cu in electrochemical series hence if Fe scrap is added to $CuSO_4$ solution, Cu is displaced :

$$CuSO_4 + Fe \longrightarrow FeSO_4 + Cu\downarrow$$

Sample **Problem 5** *How is leaching carried out in case of low grade copper ores?* **[NCERT]**

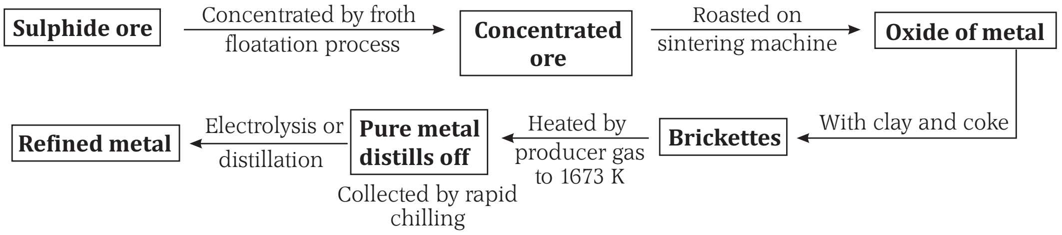
- (a) *By treating copper ore with heat*
- (b) *By treating copper ore with scrap iron*
- (c) *By treating copper ore with* H_2
- (d) *Both* (b) *and* (c)

Interpret (b) In case of low grade ores of copper, hydrometallurgy is used for extraction purposes. Leaching is done by using acid or bacteria. The solution containing Cu^{2+} is treated with scrap iron or H_2.

$$Cu^{2+}(aq) + H_2(g) \longrightarrow Cu(s) + 2H^+(aq)$$

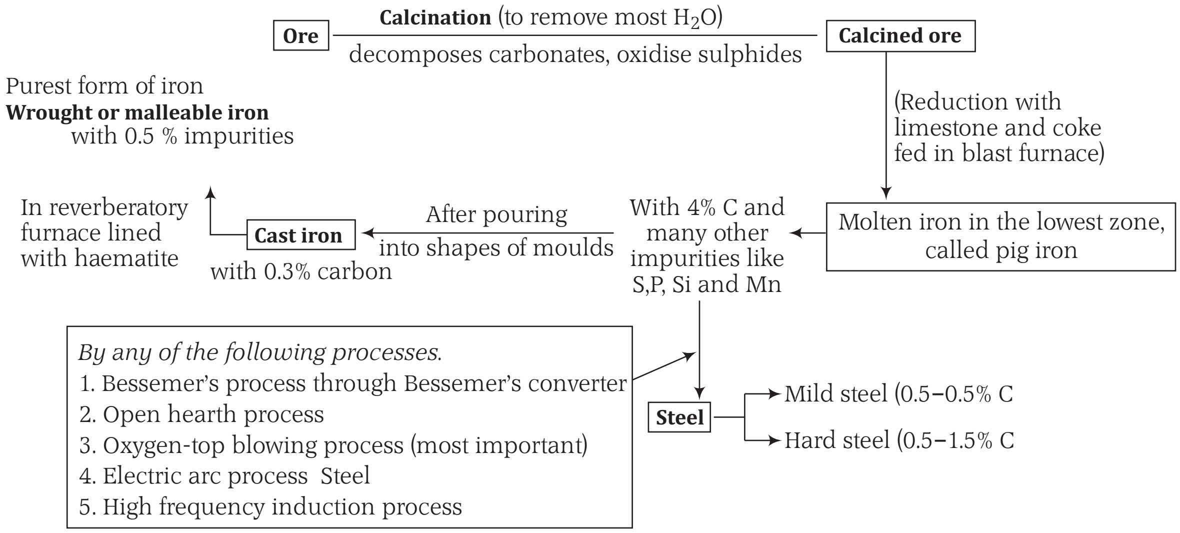
Zinc

Its chief ore is **zinc blende** (ZnS) and other ores are **calamine** ($ZnCO_3$), z**incite** (ZnO), **willemite** (Zn_2SiO_4) etc. *The outline of its extraction looks like*



Iron

Iron is the second most abundant metal after Al in the earth's crust. Its most important ores are **haematite** (Fe_2O_3), **magnetite** (Fe_3O_4), **siderite** ($FeCO_3$) and **iron pyrites** (FeS_2). *The outline of its extraction from its ore looks like*



Reactions Occurring in Blast Furnace

Formation of reducing agents, principally CO(*g*) and H_2(g):

$$2C + O_2 \longrightarrow 2CO \qquad (1700^\circ C)$$

$$C + CO_2 \longrightarrow 2CO \qquad (> 1000^\circ C)$$

$$C + H_2O \longrightarrow CO + H_2 \qquad (> 600^\circ C)$$

Reduction of iron oxide :

$$3CO + Fe_2O_3 \longrightarrow 2Fe + 3CO_2 \qquad (900^\circ C)$$

$$3H_2 + Fe_2O_3 \longrightarrow 2Fe + 3H_2O \qquad (900^\circ C)$$

Slag formation to remove impurities from ore :

$$CaCO_3 \xrightarrow{\Delta} CaO + CO_2 \qquad (800-900^\circ C)$$

$$CaO + SiO_2 \longrightarrow CaSiO_3(l) \qquad (1200^\circ C)$$

$$3CaO + P_2O_5 \longrightarrow Ca_3(PO_4)_2(l) \qquad (1200^\circ C)$$

Impurity formation in iron

$$MnO + C \longrightarrow Mn + CO \qquad (1400^\circ C)$$

$$SiO_2 + 2C \longrightarrow Si + 2CO \qquad (1400^\circ C)$$

$$P_2O_5 + 5C \longrightarrow 2P + 5CO \qquad (1400^\circ C)$$

Iron obtained from a blast furnace is called pig iron. It contains about 95% Fe, 4% C and varying quantities of other impurities. Cast iron can be obtained by pouring pig iron directly into molds of the desired shape. Cast iron is very hard and brittle and can be used where it will not be subjected to mechanical or thermal shock.

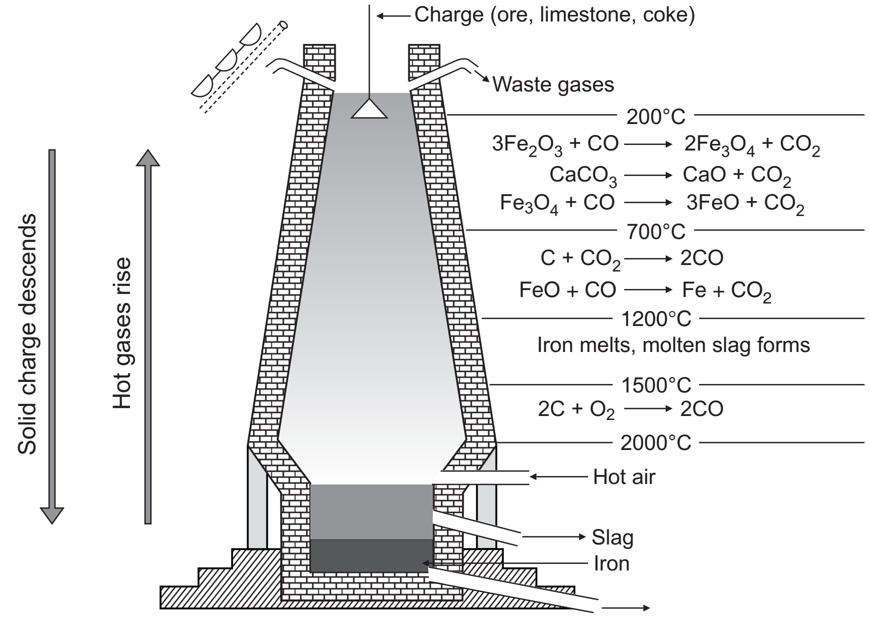


Fig. 6.10 Reduction process of iron oxide in blast furnace

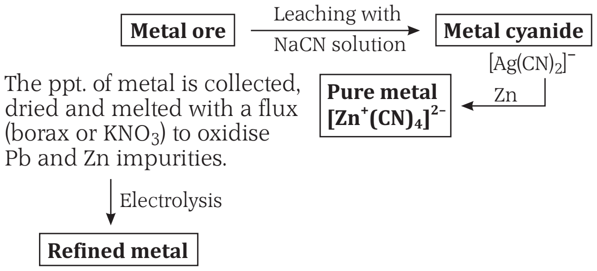
Caution Point *Heating the steel to appropriate temperature for a short time and then cooling it rapidly in order to give it the desired mechanical properties is called tempering. In this way, the ratio of carbon present as graphite and as cementite can be varied within rather wider limits.*

Silver

It occurs as **argentite** or **silver glance** (Ag_2S), **pyrargyrite** or **ruby silver** (Ag_3SbS_3), **proustite** (Ag_3AsS_3) and **horn silver** (AgCl). The most important method of extraction is cyanide process in which



Desilverisation of Lead

When lead-silver alloy is poor in silver (such as argentiferrous lead or galena), desilverisation of lead is affected by **Parke's process.** *It depends upon the fact that:*

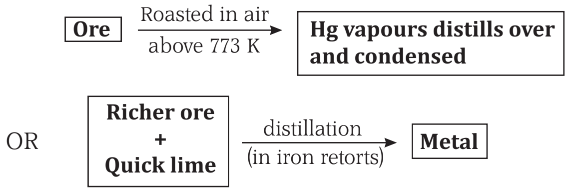
(i) When zinc is added to a melted alloy of silver and lead, zinc takes away silver from the alloy and itself forms an alloy with silver and not with lead.
(ii) Alloy of zinc and silver melts at a higher temperature than lead.
(iii) The alloy of silver and zinc is lighter than lead and forms two separate layers.
(iv) On distillation of silver and zinc alloy, zinc separates.

Pattinson's Process

It depends upon the fact that the alloy of lead and silver containing less than 1.8 per cent of silver, melts at a lower temperature than pure lead. If this type of alloy is melted, and the melted alloy is allowed to cool, lead first separates and repeating the process, one becomes richer in silver. Further recovery is done by cupellation process.

Mercury

It is found as $1 \times 10^{-5}\%$ of earth crust and its most important ore is **cinnabar** (HgS).



It can be purified by dropping slowly through dil. HNO_3. The metallic impurities displace Hg from nitrate and go into the solution. Further purification is carried out by distillation under reduced pressure.

Check Point 2

1. Give an example in which water gas is used in the extraction of metal?
2. In place of copper, zinc is used for the recovery of silver from the complex $[Ag(CN)_2]^-$. Why?
3. In the electrolysis of aluminium, some cryolite is added. Explain, why?
4. Why lime stone is used in blast furnace?

WORKED OUT Examples

Example 1 *Lead is extracted from galena* (PbS), *either by following ways.*

(*I*) $PbS \xrightarrow[-SO_2]{\text{Roasted in air}} PbO \xrightarrow[-CO_2]{\text{Heated with C}} Pb$

(*II*) $PbS \xrightarrow[-SO_2]{\text{Roasted in air}} PbO \xrightarrow{\text{Heated with PbS}} Pb + SO_2$

Auto-reduction process is

(a) *I*	(*b*) *II*
(c) *Both* (a) *and* (*b*)	(*d*) *None of these*

Solution (*b*) In auto-reduction, no external reducing agent is required. In such a reduction reaction, the product formed acts as a reducing agent and reduces the oxide to metal. Thus, only reaction II is called auto-reduction.

$$2PbS + 3O_2 \xrightarrow{\text{Roasted in air}} 2PbO + 2SO_2$$

$$\underset{\substack{\text{product (acts as}\\\text{reducing agent)}}}{2PbO} + PbS \longrightarrow 3Pb + SO_2$$

Example 2 *The chemical process in the production of steel from haematite ore involves*

(a) *reduction*
(*b*) *oxidation*
(*c*) *reduction followed by oxidation*
(*d*) *oxidation followed by reduction*

Solution (*d*) In haematite, some FeO is also present alongwith Fe_2O_3. Thus, first of all this FeO is oxidised to Fe_2O_3 and after that the Fe_2O_3 gets reduced to Fe_3O_4 and then FeO and finally to Fe. Hence, in this process, first oxidation occurs and after that reduction takes place.

Example 3 *Select the incorrect reduction process.*

(a) $2[Ag(CN)_2]^- + Zn \longrightarrow [Zn(CN)_4]^{2-} + 2Ag$

(*b*) $CuO + H_2 \longrightarrow Cu + H_2O$

(*c*) $ZnO + H_2 \longrightarrow Zn + H_2O$

(*d*) $MgO + C \longrightarrow Mg + CO$

Solution (*c*) It is not possible for a less reactive element to reduce a more reactive element. Zn is moderately reactive metal and is more reactive as compared to hydrogen. Thus, hydrogen has no ability to reduce Zn^{2+} to Zn. Cu being less reactive is reduced by hydrogen.

Example 4 *Which of the following process involves smelting?*

(*a*) $Al_2O_3 \cdot 2H_2O \xrightarrow{\Delta} Al_2O_3 + 2H_2O$

(*b*) $Fe_2O_3 + 3C \xrightarrow{\Delta} 2Fe + 3CO$

(*c*) $ZnCO_3 \xrightarrow{\Delta} ZnO + CO_2$

(*d*) $2PbS + 3O_2 \xrightarrow{\Delta} 2PbO + 2SO_2$

Solution (*b*) When concentrated ore is mixed with coke and flux and heated in the presence of air at high temperature, impurities get removed. This process is called smelting. Actually, it is a reduction process, in which oxide is reduced to metal. Therefore, following process will involve smelting.

$$Fe_2O_3 + 3C \xrightarrow{\Delta} 2Fe + 3CO$$

Example 5 *Match the method of concentration of the ore in Column I with the ore in Column II and select the correct alternate.*

Column I	*Column II*
i. *Magnetic separation*	(*A*) $Al_2(SiO_3)_3$
ii. *Gravity separation*	(*B*) Ag_2S
iii. *Froth floatation*	(C) $FeCr_2O_4$

	(i)	(ii)	(iii)
(a)	*A*	*B*	*C*
(*b*)	*C*	*B*	*A*
(*c*)	*B*	*A*	*C*
(*d*)	*C*	*A*	*B*

Solution (*d*) (i) Magnetic separation method is used when either ore or impurity is magnetic in nature, e.g., $FeCr_2O_4$.

(ii) Gravity separation is used when ore is heavy and impurities are lighter e.g., $Al_2(SiO_3)_3$.

(iii) Froth floatation is generally used for sulphide ores e.g., Ag_2S.

Example 6 *Consider* $\Delta G_f^\circ(CuO) = -129.7\ kJ\ mol^{-1}$, $\Delta G_f^\circ(H_2O) = -237.2\ kJ\ mol^{-1}$ *and* $\Delta G_f^\circ(CO) = -137.2\ kJ\ mol^{-1}$. *The better reducing agent for the reduction of* CuO *is*

(*a*) *hydrogen*	(*b*) CO
(*c*) C	(*d*) *All can be used*

Solution (*a*) (I) $CuO + C \longrightarrow Cu + CO$

$$\Delta G^\circ = \Delta G_f^\circ(CO) - \Delta G_f^\circ(CuO)$$
$$= -137.2 + 129.7$$
$$= -7.5 \text{ kJ mol}^{-1}$$

(II) $CuO + H_2 \longrightarrow Cu + H_2O$

$$\Delta G^\circ = \Delta G_f^\circ(H_2O) - \Delta G_f^\circ(CuO)$$
$$= -237.2 + 129.7$$
$$= -107.5 \text{ kJ mol}^{-1}$$

More negative value of ΔG° for reaction (II) indicates that H_2 is better reducing agent.

Example 7 *In which of the following isolations no reducing agent is required?*

(*a*) *Iron from haematite*
(*b*) *Aluminium from bauxite*
(*c*) *Zinc from zinc blende*
(*d*) *Mercury from cinnabar*

Solution (*d*) In case of auto-reduction, no reducing agent is required

(a) $\underset{\text{haematite}}{Fe_2O_3} + \underset{\text{reducing agent}}{3CO} \longrightarrow 2Fe + 3CO_2$

(b) $\underset{\text{bauxite}}{Al_2O_3} + \underset{\text{reducing agent}}{3C} + N_2 \longrightarrow 2AlN + 3CO\uparrow$

$$AlN + 3H_2O \longrightarrow Al(OH)_3 + NH_3$$
$$2Al(OH)_3 \xrightarrow{\Delta} Al_2O_3 + 3H_2O$$
$$\xrightarrow{\text{electrolysis}} Al$$

(c) $\underset{\text{zinc blende}}{2ZnS} + 3O_2 \longrightarrow 2ZnO + 2SO_2$

$ZnO + \underset{\text{reducing agent}}{C} \longrightarrow Zn + CO$

(d) $\underset{\text{cinnabar}}{2HgS} + 3O_2 \longrightarrow 2HgO + 2SO_2$

$$\underset{\text{product}}{2HgO} \xrightarrow{\Delta} 2Hg + O_2$$

Example 8 *Of the following reduction processes*

(*I*) $PbO + C \longrightarrow Pb$
(*II*) $ZnO + C \longrightarrow Zn$
(*III*) $Fe_2O_3 + C \longrightarrow FeO$
(*IV*) $Ca_3(PO_4)_2 + C \longrightarrow P$

correct processes are

(*a*) *I, II*	(*b*) *I, II, IV*
(*c*) *II, III*	(*d*) *All of these*

Solution (*b*) Except III, all the reduction processes are correct. Fe_2O_3 (haematite ore) is reduced into Fe, instead of FeO.

$$Fe_2O_3 + 3CO \longrightarrow 2Fe + 3CO_2$$

Start Practice for JEE Main

Round I (Topically Divided Problems)

Occurrence of Metals

1. Metal occur in the native form because of their
(a) high electronegativity (b) high reactivity
(c) low reactivity (d) low density

2. Which of the following metal is sometimes found native in nature?
(a) Mg (b) Cu
(c) Al (d) Fe

3. All ores are minerals, while all minerals are not ores because
(a) minerals are complex compounds
(b) the minerals are obtained from mines
(c) the metal cannot be extracted economically from all the minerals
(d) All of the above are correct

4. A number of elements are available in earth's crust but most abundant elements are **[NCERT Exemplar]**
(a) Al and Fe (b) Al and Cu
(c) Fe and Cu (d) Cu and Ag

5. Formula of magnetite is
(a) Fe_3O_4 (b) Fe_2O_3
(c) FeS_2 (d) $FeCO_3$

6. Which is not a mineral of aluminium?
(a) Corundum (b) Anhydrite
(c) Diaspore (d) Bauxite

7. An important ore of iron is
(a) pyrites (b) malachite
(c) haematite (d) siderite

8. Which of the following is a carbonate ore?
(a) Pyrolusite (b) Diaspore
(c) Cassiterite (d) Malachite

9. Metal which can be extracted from all the three dolomite, magnesite and carnallite is
(a) Na (b) K
(c) Mg (d) Ca

10. Ore pitch blende is the main source of
(a) Ra (b) Th
(c) Mg (d) Ce

Steps Involved in the Extraction of Metals

11. The ore that can be concentrated by magnetic separation method is **[NCERT]**
(a) magnetite (b) haematite
(c) siderite (d) All of these

12. Froth floatation process for the concentration of the ores is an illustration of the practical application of
(a) adsorption (b) sedimentation
(c) coagulation (d) absorption

13. Which of the following ore is not concentrated by froth floatation process?
(a) Pyrolusite (b) Pentlandite
(c) Zinc blende (d) Copper pyrites

14. How do we separate two sulphide ores by froth floatation method?
(a) by adding pine oil
(b) by adding sodium cyanide
(c) by adding foaming agent
(d) by passing air

15. Copper pyrites is concentrated by
(a) gravity method
(b) froth floatation process
(c) electromagnetic method
(d) All of the above

16. Cassiterite is concentrated by
(a) liquation
(b) floatation
(c) electromagnetic separation
(d) levigation

17. Froth floatation method is successful in separating impurities from ores because
- (a) the pure ore is soluble in water containing additives like pine oil, cresylic acid etc
- (b) the pure ore is lighter than water containing additives like pine oil, cresylic acid, etc
- (c) the impurities are soluble in water containing additives like pine oil, cresylic acid, etc
- (d) the pure ore is not easily wetted by water as by pine oil, cresylic acid, etc

18. The method of concentrating the ore which makes use of the difference in density between ore and impurities is called
- (a) leaching
- (b) liquation
- (c) levigation
- (d) magnetic separation

19. Bauxite ore is concentrated by
- (a) froth floatation
- (b) electromagnetic separation
- (c) chemical separation
- (d) hydraulic separation

20. Extraction of gold and silver involves leaching the metal with CN^- ion. The metal is recovered by …… . **[NCERT** Exemplar**]**
- (a) displacement of metal by some other metal from the complex ion
- (b) roasting of metal complex
- (c) calcination followed by roasting
- (d) thermal decomposition of metal complex

21. The reaction $2ZnS + 3O_2 \longrightarrow 2ZnO + 2SO_2$ in the metallurgical process of zinc is called
- (a) roasting
- (b) smelting
- (c) cupellation
- (d) calcination

22. In blast furnace, iron oxide is reduced by
- (a) silica
- (b) carbon
- (c) limestone
- (d) CO

23. In the metallurgy of iron, when $CaCO_3$ is added to blast furnace, calcium ion appears as
- (a) slag
- (b) gangue
- (c) CaO
- (d) metallic Ca

24. Which statement is correct?
- (a) Slags are carefully choosen to combine with the slag present in the ore to produce easily fusible gangue to carry away the impurities
- (b) Gangues are carefully choosen to combine with the slag present in the ore to produce easily fusible flux to carry away the impurities
- (c) Gangues are carefully choosen to combine with flux present in the ore to produce easily fusible slag to carry away the impurities
- (d) Fluxes are carefully choosen to combine with the gangue present in the ore to produce easily fusible slag to carry away the impurities

25. In metallurgy, flux is a substance used to convert
- (a) soluble impurities to insoluble impurities
- (b) infusible impurities to fusible material
- (c) fusible impurities to infusible impurities
- (d) mineral into silicate

26. In the extraction of copper from its sulphide ore, the metal is formed by the reduction of Cu_2O with **[NCERT** Exemplar**]**
- (a) FeS
- (b) CO
- (c) Cu_2S
- (d) SO_2

27. Which of the following reactions is an example of auto-reduction? **[NCERT** Exemplar**]**
- (a) $Fe_3O_4 + 4CO \longrightarrow 3Fe + 4CO_2$
- (b) $Cu_2O + C \longrightarrow 2Cu + CO$
- (c) $Cu^{2+}(aq) + Fe(s) \longrightarrow Cu(s) + Fe^{2+}(aq)$
- (d) $Cu_2O + \frac{1}{2}Cu_2S \longrightarrow 3Cu + \frac{1}{2}SO_2$

28. When copper ore is mixed with silica in a reverberatory furnace, copper matte is produced. The copper matte contains …… . **[NCERT** Exemplar**]**
- (a) sulphides of copper (III) and iron (II)
- (b) sulphides of copper (II) and iron (III)
- (c) sulphides of copper (I) and iron (II)
- (d) sulphides of copper (I) and iron (III)

29. Why copper matte is put in silica lined converted? **[NCERT]**
- (a) To oxidise it
- (b) To reduce it
- (c) to convert its impurities into fusible mass
- (d) to convert its impurities into infusible mass

30. The slag obtained during the extraction of copper from copper pyrites is composed of
- (a) Cu_2S
- (b) SiO_2
- (c) $CuSiO_3$
- (d) $FeSiO_3$

31. The electrolytic method of reduction is employed for the preparation of metals that
- (a) are strongly electropositive
- (b) are weakly electropositive
- (c) are moderately electropositive
- (d) from oxides

32. Which metal is extracted by electrolytic reduction method?
- (a) Cu
- (b) Al
- (c) Ag
- (d) Fe

33. Electrolytic reduction of alumina to aluminium by Hall-Heroult process is carried out
(a) in the presence of NaCl
(b) in the presence of fluorite
(c) in the presence of cryolite which forms a melt with lower melting point
(d) in the presence of cryolite which forms a melt with high melting point

34. In the metallurgy of aluminium …… . **[NCERT Exemplar]**
(a) Al^{3+} is oxidised to $Al(s)$.
(b) graphite anode is oxidised to carbon monoxide and carbon dioxide.
(c) oxidation state of oxygen changes in the reaction at anode.
(d) oxidation state of oxygen changes in the overall reaction involved in the process.

35. What is the role of graphite rod in the electrometallurgy of aluminium? **[NCERT]**
(a) It acts as anode
(b) It acts as cathode
(c) It acts as oxidising agent
(d) Both (a) and (c)

36. Brine is electrolysed by using inert electrodes. The reaction at anode is …… . **[NCERT Exemplar]**
(a) $Cl^-(aq) \longrightarrow \frac{1}{2}Cl_2(g) + e^-$; $E^\ominus_{cell} = 1.36$ V
(b) $2H_2O(l) \longrightarrow O_2(g) + 4H^+ + 4e^-$; $E^\ominus_{cell} = 1.23$ V
(c) $Na^+(aq) + e^- \longrightarrow Na(s)$; $E^\ominus_{cell} = 2.71$ V
(d) $H^+(aq) + e^- \longrightarrow \frac{1}{2}H_2(g)$; $E^\ominus_{cell} = 0.00$ V

37. Purest form of iron is
(a) pig iron (b) wrought iron
(c) cast iron (d) steel

38. Zone refining is based on the principle that …… . **[NCERT Exemplar]**
(a) impurities of low boiling metals can be separated by distillation.
(b) impurities are more soluble in molten metal than in solid metal.
(c) different components of a mixture are differently adsorbed on an adsorbent.
(d) vapours of volatile compound can be decomposed in pure metal.

39. Electrolytic refining is used to purify which of the following metals? **[NCERT Exemplar]**
(a) Cu and Zn (b) Ge and Si
(c) Zr and Ti (d) Zn and Hg

40. In order to refine blister copper, it is melted in a furnace and is stirred with green logs of wood. The purpose is
(a) to expel the dissolved gases in blister copper
(b) to bring the impurities to surface and oxidize them
(c) to increase the carbon content of copper
(d) to reduce the metallic oxide impurities with hydrocarbon gases liberated from the wood

41. Which method is used to refine Zr and Ti? **[NCERT Exemplar]**
(a) Mond's process (b) Cyanide process
(c) van Arkel method (d) Lavigation

42. What should be the considerations during the extraction of metals by electrochemical method? **[NCERT Exemplar]**
(a) Reactivity of metal obtained
(b) Selectivity of metal obtained
(c) Suitability of electrodes
(d) Both (a) and (c)

43. Mond's process is used for the purification of
(a) Ni (b) Ti
(c) Zr (d) Hg

44. Refractory materials are generally used in furnaces because
(a) they can withstand high temperature
(b) they are chemically inert
(c) they do not require replacement
(d) they possess great structural strength

45. In the modern blast furnaces, the charge consists of a mixture of
(a) iron pyrites + bituminous coal
(b) hydrated iron oxides + dolomite + coke
(c) calcined iron oxides + limestone + coke
(d) calcined iron oxides + lime + anthracite coal

46. In blast furnace, the highest temperature is in
(a) fusion zone (b) reduction zone
(c) combustion zone (d) slag zone

47. In the equation,

$$4M + 8CN^- + 2H_2O + O_2 \longrightarrow 4[M(CN)_2]^- + 4OH^-,$$

identify the metal M.
(a) Au (b) Fe
(c) Zn (d) Cu

Miscellaneous

48. Thermite is a mixture of
(a) Fe powder and Al_2O_3 (b) Al powder and Fe_2O_3
(c) Cu powder and Fe_2O_3 (d) Zn powder and Cr_2O_3

49. Which statement is incorrect?
(a) Galena is an ore of Pb
(b) Electrostatic separation is used for lead sulphide
(c) Ore is heated strongly, above its melting point in roasting
(d) Silica acts as acidic flux

50. Match Column I with Column II and select the correct answer using the codes given below the list.

	Column I		Column II
1.	Ti	A.	Bauxite
2.	Si	B.	Cerussite
3.	Al	C.	van-Arkel method
4.	Pb	D.	Zone refining

Codes
(a) 1–B, 2–A, 3–C, 4–D (b) 1–B, 2–C, 3–A, 4–B
(c) 1–C, 2–A, 3–B, 4–D (d) 1–C, 2–D, 3–A, 4–B

Round II (Mixed Bag)

Only One Correct Option

1. Load stone is an ore of
(a) iron (b) lead
(c) silicon (d) tin

2. One of the following metals forms a volatile compound and this property is taken advantage for its extraction. This metal is
(a) cobalt (b) iron
(c) tungsten (d) nickel

3. Wolframite ore is separated from tin stone ore by the process, called
(a) calcination
(b) electromagnetic separation
(c) roasting
(d) smelting

4. 'Lapis-Lazuli' is a blue coloured precious stone. It is mineral of the class
(a) sodium alumino silicate
(b) basic copper carbonate
(c) zinc cobalt
(d) Prussian blue

5. When a metal is to be extracted from its ore, if the gangue associated with the ore is silica, then
(a) a basic flux is needed
(b) an acidic flux is needed
(c) both basic and acidic flux are needed
(d) neither of them is needed

6. An ore of tin containing $FeCrO_4$ is concentrated by
(a) electrostatic method (b) gravity separation
(c) magnetic separation (d) froth floatation

7. Gallium arsenide is purified by
(a) van-Arkel method (b) zone refining method
(c) electrolytic method (d) liquation

8. Pb and Sn are extracted from their chief ore by
(a) electrolysis and self reduction
(b) self reduction and electrolysis
(c) carbon reduction and self reduction
(d) self reduction and carbon reduction

9. Native silver metal forms a water soluble complex with a dilute aqueous solution of NaCN in the presence of
(a) nitrogen (b) oxygen
(c) carbon dioxide (d) argon

10. Which of the following statement is incorrect?
(a) Silver glance mainly contains silver sulphide
(b) Zinc blende mainly contains zinc chloride
(c) Gold is found in native state
(d) Copper pyrites also contains Fe_2S_3

11. Among the following statements, the incorrect one is
(a) calamine and siderite are carbonates
(b) malachite and azurite are ores of copper
(c) argentite and cuprite are oxides
(d) zinc blende and pyrites are sulphides

12. Bauxite ore is made up of $Al_2O_3 + SiO_2 + TiO_2 + Fe_2O_3$. This ore is treated with conc NaOH solution at 500 K and 35 bar pressure for few hours and filtered when hot. In the filtrate, the species present are
(a) $NaAl(OH)_4$ only
(b) $Na_2Ti(OH)_6$ only
(c) $NaAl(OH)_4$ and Na_2SiO_3 both
(d) Na_2SiO_3 only

13. Among the following groups of oxides, the group containing oxides that cannot be reduced by carbon to give the respective metals is
(a) Cu_2O, K_2O (b) PbO, Fe_3O_4
(c) Fe_2O_3, ZnO (d) CaO, K_2O

14. Match items of Column I with the items of Column II and assign the correct codes.

	Column I		Column II
(A)	Cyanide process	(1)	Ultrapure Ge
(B)	Froth floatation process	(2)	Dressing of ZnS
(C)	Electrolytic reduction	(3)	Extraction of Al
(D)	Zone refining	(4)	Extraction of Au
		(5)	Purification of Ni

Codes

	A	B	C	D
(a)	4	2	3	1
(b)	2	3	1	5
(c)	1	2	3	4
(d)	3	4	5	1

15. Match the items of Column I with the items of Column II and assign the correct code.

	Column I		Column II
(A)	Pendulum	(1)	Chrome steel
(B)	Malachite	(2)	Nickel steel
(C)	Calamine	(3)	Na_3AlF_6
(D)	Cryolite	(4)	$CuCO_3, Cu(OH)_2$
		(5)	$ZnCO_3$

Codes

	A	B	C	D
(a)	1	2	3	4
(b)	2	4	5	3
(c)	2	3	4	5
(d)	4	5	3	2

More than One Correct Option

16. Which of the following statements are correct? **[NCERT Exemplar]**

(a) A depressant prevents certain type of particles to come to the froth

(b) Copper matte contains Cu_2S and ZnS

(c) The solidified copper obtained from reverberatory furnace has blistered appearance due to the evolution of SO_2 during the extraction

(d) Zinc can be extracted by self-reduction

17. Which of the following statements is correct about the role of substances added in the froth floatation process? **[NCERT Exemplar]**

(a) Collectors enhance the non-wettability of the mineral particles

(b) Collectors enhance the wettability of gangue particles

(c) By using depressants in the process two sulphide ores can be separated

(d) Froth stabilisers decrease wettability of gangue

18. In the froth floatation process, zinc sulphide and lead sulphide can be separated by …… . **[NCERT Exemplar]**

(a) using collectors

(b) adjusting the proportion of oil to water

(c) using depressant

(d) using froth stabilisers

19. Which of the following reactions occur during calcination? **[NCERT Exemplar]**

(a) $CaCO_3 \longrightarrow CaO + CO_2$

(b) $2FeS_2 + \frac{11}{2}O_2 \longrightarrow Fe_2O_3 + 4SO_2$

(c) $Al_2O_3 \cdot xH_2O \longrightarrow Al_2O_3 + xH_2O$

(d) $ZnS + \frac{3}{2}O_2 \longrightarrow ZnO + SO_2$

20. Which of the following options are correct? **[NCERT Exemplar]**

(a) Cast iron is obtained by remelting pig iron with scrap iron and coke using hot air blast

(b) In extraction of silver, silver is extracted as cationic complex

(c) Nickel is purified by zone refining

(d) Zr and Ti are purified by van Arkel method

Assertion and Reason

Directions (Q. Nos. 21 to 26) *Each of these questions contains two statements : Statement* I (*Assertion*) *and Statement* II (*Reason*). *Each of these questions also has four alternative choices, only one of which is the correct answer. You have to select one of the codes* (*a*), (*b*), (*c*), (*d*) *given below :*

(a) Statement I is true, Statement II is true; Statement II is a correct explanation for Statement I.

(b) Statement I is true, Statement II is true; Statement II is not a correct explanation for Statement I.

(c) Statement I is true; Statement II is false.

(d) Statement I is false; Statement II is true.

21. **Statement I** In the Hoop's process of purification of aluminium, the fused materials remains in three diffferent layers. These layers remain intact even in electrolytic reduction.

Statement II All the layers have different densities.

22. **Statement I** Sulphide ores are concentrated by froth floatation method.

Statement II Cresols stabilise the froth in froth floatation method. **[NCERT Exemplar]**

23. **Statement I** Hydrometallurgy involves dissolving the ore in a suitable reagent followed by precipitation by a more electropositive metal.

Statement II Copper is extracted by hydrometallurgy.
[NCERT Exemplar]

24. **Statement I** Zirconium can be purified by van Arkel method.

Statement II ZrI_4 is volatile and decomposes at 1800K. **[NCERT Exemplar]**

25. **Statement I** Alkaline earth metals are not easy to produce by chemical reduction.

Statement II Their aqueous solutions cannot be used for displacing one metal by another.

26. **Statement I** The reduction of a metal oxide is easier if the metal formed is in liquid state at the temperature of reduction.

Statement II The value of entropy change of the reduction process is more on positive side when the metal formed is in liquid state.

Comprehension Based Questions

Directions (Q. Nos. 27 to 29) Metallurgy is the process of extraction of metals from the substances in which these are found in nature. It involves a series of processes like ore dressing, conversion of concentrated ore to oxide, reduction and refining of metal.

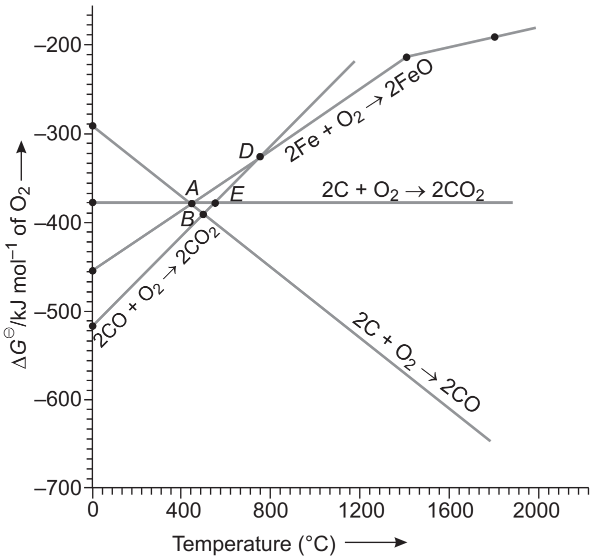
In one of the refining processes, the molten impure metal is stirred with green logs of wood. These wood release some gases by which the impurities are reduced and thus, removed.

27. The metal which is purified by the method discussed above is
- (a) sodium
- (b) copper
- (c) iron
- (d) manganese

28. The gas release during the process to remove the impurities is
- (a) CO
- (b) H_2
- (c) CH_4
- (d) CO_2

29. This process is used for metals which
- (a) are less volatile
- (b) are less fusible
- (c) contains infusible impurities
- (d) contains oxides as impurity

Directions (Q. Nos. 30 to 33)



30. Choose the correct option of temperature at which carbon reduces FeO to iron and produces CO.
[NCERT Exemplar]
- (a) Below temperature at point A.
- (b) Approximately at the temperature corresponding to point A.
- (c) Above temperature at point A but below temperature at point D.
- (d) Above temperature at point A.

31. Below point 'A' FeO can …… .
- (a) be reduced by carbon monoxide only.
- (b) be reduced by both carbon monoxide and carbon.
- (c) be reduced by carbon only.
- (d) not be reduced by both carbon and carbon monoxide.

32. For the reduction of FeO at the temperature corresponding to point D, which of the following statements is correct?
- (a) ΔG value for the overall reduction reaction with carbon monoxide is zero.
- (b) ΔG value for the overall reduction reaction with a mixture of 1 mole carbon and 1 mole oxygen is positive.
- (c) ΔG value for the overall reduction reaction with a mixture of 2 moles carbon and 1 mole oxygen will be positive.
- (d) ΔG value for the overall reduction reaction with carbon monoxide is negative.

33. At the temperature corresponding to which of the points in figure, FeO will be reduced to Fe by coupling the reaction $2FeO \longrightarrow 2Fe + O_2$ with all of the following reactions?

(i) $C + O_2 \longrightarrow CO_2$ (ii) $2C + O_2 \longrightarrow 2CO$ and (iii) $2CO + O_2 \longrightarrow 2CO_2$

(a) Point *A* (b) Point *B*
(c) Point *D* (d) Point *E*

Previous Years' Questions

34. Which of the following factors is of **no significance** for roasting sulphide ores to the oxides and not subjecting the sulphide ores to carbon reduction directly **[AIEEE 2008]**

(a) Metal sulphides are thermodynamically more stable than CS_2
(b) CO_2 is thermodynamically more stable than CS_2
(c) Metal sulphides are less stable than the corresponding oxides
(d) CO_2 is more volatile than CS_2

35. During the process of electrolytic refining of copper, some metals present as impurity settle as 'anode mud'. These are **[AIEEE 2005]**

(a) Fe and Ni (b) Ag and Au
(c) Pb and Zn (d) Se and Ag

36. Which one of the following ores is best concentrated by froth-floatation method ? **[AIEEE 2004]**

(a) Magnetite (b) Cassiterite
(c) Galena (d) Malachite

37. Aluminium is extracted by the electrolysis of **[AIEEE 2002]**

(a) alumina
(b) bauxite
(c) molten cryolite
(d) alumina mixed with molten cryolite

38. Cyanide process is used for the extraction of **[AIEEE 2002]**

(a) barium (b) silver (c) boron (d) zinc

39. Refining of impure copper with zinc impurity is to be done by electrolysis using electrodes as **[AIEEE 2002]**

	Cathode	**Anode**
(a)	pure copper	pure zinc
(b)	pure zinc	pure copper
(c)	pure copper	impure copper
(d)	pure zinc	impure zinc

the Guidance

Round I

1. Less reactive metals are found in native state (free state).

2. Copper is found in native as well as in combined state.

3. Metals cannot be extracted economically from all the minerals that is why all minerals are not ores.

6. Bauxite ($Al_2O_3 \cdot 2H_2O$)
Corundum (Al_2O_3)
Diaspore ($Al_2O_3 \cdot H_2O$)

8. Pyrolusite — MnO_2
Malachite — $CuCO_3 \cdot Cu(OH)_2$
Diaspore — $Al_2O_3 \cdot H_2O$
Cassiterite — SnO_2

9.

Dolomite	$MgCO_3 \cdot CaCO_3$
Magnesite	$MgCO_3$
Carnallite	$KCl \cdot MgCl_2 \cdot 6H_2O$

10. Ore pitch blende is main source of radium.

11. Magnetic ores (iron ores) are generally separated by this method. Magnetite (Fe_3O_4), haematite (Fe_2O_3), siderite ($FeCO_3$) are such ores.

12. The adsorption phenomenon is involved in the froth floatation process.

13. Pyrolusite (MnO_2) is not a sulphide ore, so it is not concentrated by froth floatation process.

14. Two sulphide ores can be separated by adjusting the proportion of oil and water or by using depressants, *e.g.*, If an ore contains ZnS and PbS both, a depressant NaCN is added during froth floatation. It forms a complex with ZnS and prevents it from coming into froth. PbS comes into the froth and thus, separated.

17. In froth floatation method, the pure ore is not easily wetted by water but wetted by pine oil, so it is successfully separated from impurities.

18. Levigation (gravity separation) is based on the difference in the specific gravities of the gangue particles and the ore particles.

19. Bauxite ore is concentrated by chemical separation or leaching. In this, powdered ore is treated with a suitable reagent which can dissolve the ore but not the impurities.

20. Extraction of gold and silver involves leaching the metals with CN^- ion. The metal is recovered by displacement of metal by some other metals from the complex ion.

23. In the metallurgy of iron, when $CaCO_3$ is added to blast furnace, it removes impurities from ore and forms slag.

$$CaCO_3 \longrightarrow CaO + CO_2 \quad (1070\text{–}1170\text{ K})$$
$$CaO + SiO_2 \longrightarrow CaSiO_3 \quad (1470\text{ K})$$
$$3CaO + P_2O_5 \longrightarrow Ca_3(PO_4)_2$$

24. Flux is a substance with combine with gangue that present in the roasted or calcined ore to form fusible product, called slag.

25. Flux is mixed with concentrated ore which is not soluble in molten metal. It converts the infusible impurities to fusible material.

26. In the extraction of copper (Cu) from its sulphide ore, the metal is formed by the reduction of Cu_2O with Cu_2S (cuprous sulphide).

27. Auto-reduction is also known as self reduction. This is used when no external reducing agent is required. The sulphide ores of less electropositive metal like Hg, Pb, Cu etc., are heated in air to convert a part of the ore into oxide or sulphide which then reacts with the remaining sulphide ore to give the metal and sulphur dioxide, *e.g.*,

$$Cu_2O + \frac{1}{2}Cu_2S \longrightarrow 3Cu + \frac{1}{2}SO_2$$

28. Copper matte is produced when copper ore is mixed with silica in reverberatory furnace. The copper matte contains sulphide of copper (I) and iron (II).

29. In copper matte iron sulphide, FeS is present as impurity which in the presence of oxygen converts into iron oxide, a basic impurity. Silica (SiO_2) is an acidic flux.

Copper matte mainly contains Cu_2S and FeS. For removing the gangue FeS, silica present in the lining of the Bessemer's converter acts as a flux and forms slag (iron silicate) on reaction with FeO.

$$\underset{\text{gangue}}{2FeS} + 3O_2 \longrightarrow 2FeO + 2SO_2$$
$$\underset{\text{gangue}}{FeO} + \underset{\text{flux}}{SiO_2} \longrightarrow \underset{\text{slag}}{FeSiO_3}$$

30. The slag obtained during the extraction of copper from copper pyrites is of $FeSiO_3$. It is carried out in smelting.

$$FeO + SiO_2 \longrightarrow \underset{\text{slag}}{FeSiO_3}$$

31. In electrolytic reduction, the oxides of highly electropositive metals are reduced at very high temperature.

32. Metals like, Na, K, Mg, Ca, Al etc., are reduced by electrolytic reduction.

34. In the metallurgy of aluminium (Al) graphite anode is oxidised to carbon monoxide (CO) and carbon dioxide (CO_2).

35. Graphite rods act as anode during the electrolytic reduction of alumina (Hall-Heroult process). At anode, O_2 gas is produced which reacts with the carbon of anode (rods) to produce CO_2 gas, so these graphite rods are consumed slowly and need to be replaced from time to time.

$$Al_2O_3 \rightleftharpoons 2Al^{3+} + 3O^{2-}$$

At cathode $\quad Al^{3+} + 3e^- \longrightarrow Al$

At anode $\quad 3O^{2-} \longrightarrow 3[O] + 6e^-] \times 2$

or $\quad 3[O] + 3[O] \longrightarrow 3O_2$

$\quad C(s) + O_2(g) \longrightarrow CO_2(g)$

36. Brine is electrolysed by using inert electrodes. And at anode the reaction is

$$Cl^-(aq) \longrightarrow \frac{1}{2}Cl_2(g) + e^-; \qquad E^{\ominus}_{cell} = 1.36\text{ V}$$

As anode is always the site of oxidation.

37. Wrought or malleable iron is the purest form of iron.

38. Zone refining method is employed to get the metals of very high purity. Metals like Ge, Si, B, Ga, In etc., are purified by this method. This method is based on the principle that impurities are more soluble in molten metal than in solid metal.

39. Electrolytic refining is used to purify several metals such as Cu, Zn, Ag, Au, Pb, Al, etc.

40. $2Cu_2S + 3O_2 \longrightarrow 2Cu_2O + 2SO_2$

$$3Cu_2O + \underset{\text{from green logs of wood}}{CH_4} \longrightarrow 6Cu + 2H_2O + CO$$

41. Zr and Ti are refined by van Arkel method. It involves 2 steps :

(a) **Formation of iodide**; *e.g.*, zirconium

$$Zr + 2I_2 \longrightarrow ZrI_4$$

(b) **Decomposition of iodide**

$$ZrI_4 \xrightarrow{1800\text{ K}} \underset{\text{pure}}{Zn} + 2I_2$$

42. (1) Reactivity of metal produced.

(2) Suitability of electrodes.

Above two considerations are taken into account during extraction of metals by electrochemical method.

43. Mond's process is used for the purification of Ni.

$$Ni + 4CO \xrightarrow{\text{Heat}} [Ni(CO)_4] \xrightarrow{\text{Decompose}} Ni + 4CO$$

44. Refractory materials are the substances which can withstand very high temperature without melting or becoming salt.

46.

Combustion zone	1800 K
Fusion zone	1600 K
Slag zone	1300 K
Reduction zone	800 K

47. This reaction is used for the extraction of gold from its ores.

$$4Au + 8CN^- + 2H_2O + O_2 \longrightarrow 4[Au(CN)_2]^- + 4OH^-$$

48. Thermite is a mixture of Al and Fe_2O_3 in 1 : 3 ratio.

49. Roasting is the process in which the ore is heated strongly below its melting point in the presence of air.

50. Ti — van Arkel method

Si — Zone refining method

Al — Bauxite (Al_2O_3)

Pb — Cerussite ($PbCO_3$)

Round II

1. Load stone (magnetite, Fe_3O_4) is an ore of iron.

2. Mond's process for refining of Ni is an example of vapour phase refining.

3. Wolframite ore [$FeWO_4$] is present in tin stone as impurities and it has same mass per unit volume as that of tin stone. So, it is separated by electromagnetic separator because wolframite is magnetic in nature, hence it gets attracted by magnet while tin stone does not.

4. Lapis lazuli is the sodium aluminosilicate, present in earth rocks as blue stone.

5. $$\underset{\text{acidic impurity}}{SiO_2} + \underset{\text{basic flux}}{CaO} \longrightarrow \underset{\text{slag}}{CaSiO_3}$$

6. Electromagnetic separation is used when either the ore or the impurities associated with it, are magnetic in nature.

7. Gallium arsenide is purified by zone refining method.

8. PbO and $PbSO_4$ get reduced by PbS itself which is already present in mixture. Because the reduction takes place by mixture itself, hence the process is known as self reduction.

$$2PbO + PbS \xrightarrow{\Delta} 3Pb + SO_2\uparrow$$

$$PbSO_4 + PbS \xrightarrow{\Delta} 2Pb + 2SO_2\uparrow$$

SnO_2 is reduced by C.

9. A water soluble complex of silver with a dilute aqueous solution of NaCN is sodium argentocyanide. In the cyanide process, the native form is crushed and treated with 0.1–0.2% solution of NaCN and aerated.

$$4Ag + 8NaCN + 2H_2O + O_2 \longrightarrow 4Na[Ag(CN)_2] + 4NaOH$$

Argentocyanide is soluble. Further metal is recovered from the complex by reduction with zinc.

10. Zinc blende is ZnS, not $ZnCl_2$.

11. Cuprite (Cu_2O) is oxide but argentite (Ag_2S) is not oxide.

12. In bauxite ore, only Al_2O_3 and SiO_2 react with conc NaOH and forms sodium metaaluminate and silicate respectively. Aluminate further dissolves in water.

$$Al_2O_3 + 2H_2O + 2NaOH \xrightarrow[35\text{ bar}]{500\text{ K}} 2NaAlO_2 + 3H_2O$$

$$NaAlO_2 + 2H_2O \longrightarrow 2NaAl(OH)_4$$

13. CaO, K_2O cannot be reduced by carbon reduction method.

14. Noble metals like Ag and Au are concentrated (or extracted) by cyanide process.

Froth floatation process is used to concentrate sulphide ore like ZnS. Ore concentration is also known as ore dressing.

Electrolytic reduction is applied in case of highly reactive metals like Al, Na, etc.

Ultrapure metals like Ge, Si, etc., are purified by zone refining.

15. Nickel steel is related with pendulum, $CuCO_3 \cdot Cu(OH)_2$ is malachite, $ZnCO_3$ is calamine and Na_3AlF_6 is cryolite.

16. The solidified copper obtained from reverberatory furnace has blistered appearance due to evolution of sulphur dioxide (SO_2) during the extraction. A depressant prevents, certain type of particles to come to the froth.

17. In the froth floatation process collector enhance the non-wettability of the mineral particles. In this process, depressant helps in separating two different sulphide ores.

18. In the froth floatation process, zinc sulphide (ZnS) and lead sulphide (PbS) can be separated by the using depressant and adjusting the proportion of oil to water.

19. Calcination involves heating of the ore below its melting point in the absence of air or in limited supply. Oxygen containing ores like oxide, hydroxides and carbonates are calcined. Thus, the following reactions occurs during calcination.

$$CaCO_3 \xrightarrow{\Delta} CaO + CO_2$$

$$Al_2O_3 \cdot xH_2O \xrightarrow{\Delta} Al_2O_3 + xH_2O$$

20. Zr (zirconium), Ti (titanium), V (vanadium), Th (thorium) etc., are purified by van-Arkel method.

Cast iron is obtained by remelting pig iron with scrap iron and coke using hot air blast.

Nickel is purified by Mond's process and silver is extracted as anionic complex.

21. Upper most layer of pure molten aluminium, middle layer of molten fluorides of Na^+, Ba^{2+} and Al^{3+} and lower layer of molten impure aluminium have different densities.

22. Sulphide ores of Cu, Ag, Zn, Pd, etc. are concentrated by froth floatation method as they form froth with froathing agent. The cresols stabilise the froth in froth floatation method.

23. Hydrometallurgy involves dissolving the ore in a suitable reagent and this process is followed by precipitation by a more electropositive metal. Copper (Cu) is extracted by hydrometallurgy.

24. The van-Arkel method is used for the purification of zirconium (Zr).

ZrI_4 when heated higher, it will decomposed to give pure metal as

$$\underset{\text{(impure)}}{Zr} + 2I_2(g) \xrightarrow{\Delta} ZrI_4 \xrightarrow{1800\text{ K}} \underset{\text{(pure)}}{Zr} + 2I_2(g)$$

25. Alkaline earth metals are strong reducing agents so they can't be produced by reduction method. Aqueous solutions of alkaline earth metals can't be used for displacing one metal by another.

26. Degree of randomness increases on changing the phase from solid to liquid or from liquid to gas.

27. The discussion is about copper metal which is refined by poling, *i.e.,* by stirring impure metal with green logs of wood.

28. During this process, methane, CH_4 gas (hydrocarbon gases) is obtained which reduces copper oxide to copper.

29. This method is applicable for metals having their oxide as impurity.

30. Above temperature at point *A* carbon (C) reduces FeO to iron (Fe) and is also produced carbon monoxide (CO).

31. FeO can be reduced by carbon monoxide only at below point *A*.

32. ΔG value for the overall reduction reaction with carbon monoxide (CO) is zero for the reduction of FeO at the temperature corresponding to point *D*.

33. The temperature at the point *B* and point *E*, reduce FeO to Fe (iron) by coupling the reaction $2FeO \longrightarrow 2Fe + O_2$ with all of the following reactions.

(i) $C + O_2 \longrightarrow CO_2$

(ii) $2C + O_2 \longrightarrow 2CO$

(iii) $2CO + O_2 \longrightarrow 2CO_2$

34. $2MS + C \longrightarrow 2M + CS_2; \quad \Delta G_1 = \text{positive}$

$2MO + C \longrightarrow 2M + CO_2; \quad \Delta G_2 = \text{negative}$

The value of ΔG for the formation of CO_2 is negative, *i.e.*, it is thermodynamically more stable than CS_2. Also metal sulphides are thermodynamically more stable than CS_2. Metal sulphides are more stable than the corresponding oxides, so they are roasted to convert into less stable oxides.

35. During electrolysis, noble metals (inert metals) like Ag, Au and Pt are not affected and separate as anode mud from the impure anode.

36. Froth floatation is used to concentrate sulphide ores [Galena (PbS)].

37. Aluminium is extracted by electrolysis of a fused mixture of alumina (2-8%), synthetic cryolite Na_3AlF_6 (80-85%), AlF_3 and fluorspar. This makes alumina good conductor and lowers the fusion temperature also.

38. Cyanide process or Mac Arthur-Forest cyanide process

$$2Ag_2S + 8NaCN + O_2 + 2H_2O \longrightarrow 4Na[Ag(CN)_2] + 4NaOH + 2S$$

Soluble silver complex is filtered and treated with zinc dust and silver gets precipitated.

$$2Na[Ag(CN)_2] + Zn \longrightarrow Na_2[Zn(CN)_4] + 2Ag\downarrow$$

39. For purification, impure copper gets oxidised (deelectronation) falling into solution with mud, that's why impure at anode.

7 *p*-Block Elements-II

JEE Main MILESTONE

- Group15 Elements
- Nitrogen (N)
- Phosphorus
- Group16 Elements
- Ozone (O_3)
- Sulphur
- Group17 Elements
- Compounds of Elements of Group 17
- Group 18 Elements
- Compounds of Elements of Group 18

VA (15) Group Elements and Their Compounds

7.1 Group15 Elements

Group VA contains 5 elements, namely, **nitrogen** (N), **phosphorus** (P), **arsenic** (As), **antimony** (Sb) and **bismuth** (Bi). These elements are collectively called **pnicogens** (taken from Greek word '*pniomigs*' meaning suffocating) and their compounds are called **pniconides.**

Elements of group 15, 16, 17 *and* 18 *are included in p-block II. These have general configuration* $ns^2 np^{3-6}$*. The similarity among these elements is that most of these are non-metals. All of these elements are of great importance and found use in our daily life.*

Occurrence

Nitrogen constitutes about 78% (by volume) of atmosphere, and is therefore, the most common gas. Phosphorus is the only element that does not occur in free state. It is usually found as phosphate. Nitrogen in combined state, is found as nitrates or in proteins and amino acids. The rest elements occur as sulphides or oxides. P is the eleventh most abundant element in the earth's crust.

General and Physical Properties

Elements of this group exhibit a regular trend in general and physical properties. *These properties along with their trend along the group are described below.*

(a) Electronic Configuration

The electronic configuration of various elements of this family are as

Table 7.1 **Electronic Configuration of VA Group Elements**

S.N.	Element	Atomic number	Electronic configuration
1.	Nitrogen, N	7	[He] $2s^2p^3$
2.	Phosphorus, P	15	[Ne] $3s^2p^3$
3.	Arsenic, As	33	[Ar] $3d^{10}\ 4s^2p^3$
4.	Antimony, Sb	51	[Kr] $4d^{10}\ 5s^2p^3$
5.	Bismuth, Bi	83	[Xe] $4f^{14}5d^{10}6s^2p^3$

It is clear from the electronic configuration that their *p*-orbitals of valence shell are half-filled. This is a stable configuration in accordance with Hund's rule. Thus, these elements, having exactly half-filled orbitals, are fairly stable and not so reactive (*e.g.*, nitrogen behaves as almost inert element).

(b) Atomic Volumes and Radii

Atomic volumes and atomic radii increases down the group, however **arsenic shows exceptionally low value of atomic volume.**

(c) Physical State

A gradual transition in physical state is seen among the elements under ordinary conditions, *i.e.,* nitrogen is a gas which can be converted into a liquid at very low temperature; phosphorus though a solid but can pass readily into vapour state. Arsenic, antimony and bismuth are infact solids of varying boiling and melting points.

(d) Ionisation Energy

The first ionisation energy of N is very high and the values for succeeding elements decreases symmetrically as seen in *s*-block elements.

(e) Metallic Character

It increases down the group as, nitrogen and phosphorus are distinctly **non-metals,** succeeding two members are **amphoteric** in nature *i.e.,* As and Sb have metallic as well as non-metallic character while, the last element, Bi is a **metal.**

(f) Electronegativity

It decreases down the group as we move from N to Bi indicating a gradual change from non-metallic to metallic character. These elements are more electronegative as compared to the elements of 14 group.

(g) Melting and Boiling Points

These elements do not show a regular trend of melting and boiling points. In this group, the melting point first increases from N to As and afterwards decreases. While boiling point increases from N to Sb and then decreases. But Bi has less boiling point as compared to Sb. We can write these order as

$$\text{N} < \text{P} < \text{As} > \text{Sb} > \text{Bi} \quad \text{(melting point)}$$
$$\text{N} < \text{P} < \text{As} < \text{Sb} > \text{Bi} \quad \text{(boiling point)}$$

(h) Oxidation State

The normal oxidation states of these elements are +5 and +3, out of which +3 stabilises on moving down the group due to inert pair effect. Nitrogen show all oxidation states from +5 to −3 as +5 in N_2O_5, +4 in N_2O_4, + 3 in N_2O_3, +2 in NO, +1 in N_2O, 0 in N_2, −1 in NH_2OH, −2 in N_2H_4 and −3 in NH_3. Nitrogen even shows oxidation state of $-\frac{1}{3}$ in hydrazoic acid, N_3H. Phosphorus show three oxidation states +3, +4 and +5 while, rest of the elements show only +5 and +3 oxidation states.

Nitrogen, however, have least tendency to form compounds in + 5 oxidation state due to the fact that it does not have vacant *d*-orbitals.

All the elements in their tripositive state (+3 oxidation state) have the tendency to donate one **electron pair.** Nitrogen shows this tendency to maximum extent. All elements (except N) also show the tendency to accept electron pair. Nitrogen does not show such a property due to absence of vacant *d*-orbital in it.

The above described properties are summarised in the table given below

Table 7.2 **Physical Properties of Group 15 Elements**

Property	Nitrogen	Phosphorus	Arsenic	Antimony	Bismuth
At. no.	7	15	33	51	83
At. mass (amu)	14.007	30.970	74.922	121.750	208.980
Density in solid state (g cm^{-3})	1.03	1.82	5.73	6.62	9.78
Atomic volume (cm^3)	17.3	17.0	13.1	18.4	21.3
Atomic radius (Å)	0.75	1.06	1.19	1.38	1.46
Ionic radius of trivalent ion (Å)	1.71	2.12	2.22	2.45	1.20
IE (kJ mol^{-1})	1402	1012	946	840	703

Property	Nitrogen	Phosphorus	Arsenic	Antimony	Bismuth
Oxidation state	–3, – 2, – 1, 0 +1, +2, +3, +4, +5	–3, + 3, +4, +5	–3, +3, +5	–3, + 3, +5	+3, + 5
Electronegativity	3.0	2.1	2.0	1.8	1.7
MP (°C)	–210	44.1 (white phosphorus)	817 (at 36 atm)	630.5	271.3
BP (°C)	–195.8	280	615 (sublimes)	1587	1564
Heat of fusion (kJ mol^{-1})	0.36	0.63	27.7	19.9	10.9

(i) Nature of Compounds

Since, it is not easy from energy considerations to gain three electrons to achieve stable configuration, the formation of trinegative (A^{3-}) ion is rare. Only N has the capability to form such a type of ion due to its small size. However, covalent compounds of nitrogen are more common. The electronegativities of other elements are so low that they would generally form covalent bonds even with highly electropositive elements. Bi compounds, although covalent, do give ions in polar solvents like water.

(j) Catenation

All the elements of this group show property of catenation *i.e.,* self linkage to a very smaller extent (in comparison with carbon). The catenation in stable nitrogen compounds is restricted generally to two or three nitrogen atoms as, *eg,* in N_2H_4, N_3^- etc. The P atom has maximum tendency to catenate amongst group 15th elements, which can be explained on the basis of P—P bond energy (200.8 kJ/mol) which is more closer to C—C bond energy (353.9 kJ/mol) in comparison to N—N or As—As bond energies (163.1 and 146.1 kJ/mol respectively).

(k) Molecular State

Nitrogen has the tendency to form $p\pi$-$p\pi$ bonds with other atoms of similar type (N) or different type, *e.g.,* carbon. Stable nitrogen compounds contain maximum two or three nitrogen atoms but unstable compounds containing up to 8 nitrogen atoms in a chain have also been synthesized.

Thus, nitrogen usually exists as discrete diatomic gaseous molecule ($N\equiv N$). Other members, however, do not have a tendency of $p\pi$ - $p\pi$ bonding, but have empty d-orbitals, thus, they exist as discrete tetra atomic molecules like P_4, As_4, Sb_4 in which, the atoms are linked together by single bonds.

(l) Allotropy

All the elements of group 15 *(except* Bi*) show allotropy as*

1. N exists in two solid forms namely α-**nitrogen** with cubic crystalline structure and β-**nitrogen** with hexagonal crystalline structure. The transition temperature is −238.5°C. It also has one gaseous allotropic form.
2. Phosphorus exists in a number of allotropic forms, *e.g.,* white phosphorus, red phosphorus, scarlet phosphorus, metallic or α-black phosphorus, β-black phosphorus, violet phosphorus etc.
3. As exists as **grey, yellow** and **black** arsenic.
4. Similarly, Sb exists as **metallic,** α- or **yellow** and **black** or β-**antimony**.

Chemical Properties

Elements of this group form compounds mainly covalent compounds with other elements.

Properties of these compounds are described below.

(a) Hydrides

These elements form AH_3 type hydrides *e.g.,* **ammonia** (NH_3), **phosphine** (PH_3), **arsine** (AsH_3), **stibine** (SbH_3) and **bismuthine** (BiH_3). These hydrides are prepared from binary metal compounds, *e.g.,* Mg_3N_2, Ca_3P_2, Zn_3As_2, Mg_3Sb_2, Mg_3Bi_2 etc., as

$$Mg_3N_2 + 6H_2O \longrightarrow 3Mg(OH)_2 + 2NH_3$$

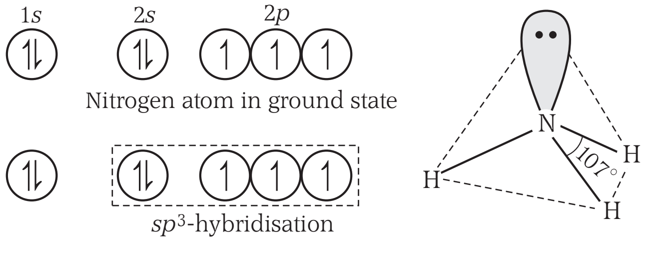
$$Ca_3P_2 + 6H_2O \longrightarrow 3Ca(OH)_2 + 2PH_3$$

$$Zn_3As_2 + 6HCl \longrightarrow 3ZnCl_2 + 2AsH_3$$

These can also be prepared by the reduction of trihalides of these elements with $LiAlH_4$ as

$$MCl_3 + 3LiAlH_4 \longrightarrow MH_3 + 3LiCl + 3AlH_3$$

The hydrides have pyramidal structure with sp^3-hybridisation as shown below



Pyramidal structure of NH_3 molecule formed by sp^3-hybridisation of N orbitals

The physical properties of these hydrides are summarised in the following table

Table 7.3 **Comparative Study of the Properties of Hydrides**

S. No.	Property	NH_3	PH_3	AsH_3	SbH_3	BiH_3
1.	Thermal stability	Highly stable	Not so decomposes at 400°C	Unstable 230°	Unstable at room temperature	Unstable, having half-life 20 min
2.	Reducing character	Not good	Moderate	Good	Strong	Strong
3.	Basic character	Base	Weak base	Neutral	Neutral	Feebly acidic
4.	Reactions (i) with metal salt solutions	Precipitate as hydroxides, *e.g.*, $Fe(OH)_3$	Precipitate as phosphides, *e.g.*, Ag_3P	Precipitate as arsenides, *e.g.*, Ag_3As	Precipitate as antimonides *e.g.*, Ag_3Sb (unstable)	No such reaction
	(ii) complexes	Stable, *e.g.*, $[Cu(NH_3)_4]^{2+}$	No stable complexes	No stable complexes	No stable complexes	No stable complexes
5.	Structure	Pyramidal	Pyramidal	Pyramidal	Pyramidal	
6.	Bond angle	–107.3°	–93.5°	–91.8°	–91.3°	–90°
7.	Melting point	–78°C	–132°C	–119°C	–88°C	—
8.	Boiling point	–34.5°C	–87.5°C	–62.4°C	–18.4°C	+ 16.8°C
9.	Bond length	1.02	1.42	1.52	1.71	—
10.	H–bonding	Present	Not present	Not present	Not present	Not present
11.	Heat of formation	–46.1	–9.6	66.4	145.1	277.8

The above physical properties can be explained as

1. The decrease in thermal stability can also be explained by increase in size of central atom. Due to such increase, the tendency to form stable covalent bond with comparatively small H atom decreases i.e., strength of *M*—H bond decreases resulting to decreased thermal stability.
2. The increase in reducing behaviour can be explained on the basis of decrease in thermal stability. Thus, while NH_3, being stable is not a good reducing agent, other hydrides being less stable are good reducing agents.
3. The variation in bond angles may be explained on the basis of the size and electronegativity of central atom. On moving down the group, the size of central atom increases and electronegativity decreases. So, the location of bond pairs of electrons shifts more and more away from the central atom as we go from NH_3 to SbH_3. Due to such a shifting, the repulsion between bond pair of electrons decreases owing to which bond angle also decreases.
4. The boiling point of these hydrides follows the trend

$$PH_3 < AsH_3 < NH_3 < SbH_3 < BiH_3$$

The abnormally high boiling point of NH_3 is attributed to presence of intermolecular H–bonding in NH_3.

(b) Halides

They form trihalides of AX_3 type and pentahalides of AX_5 type.

The important characteristics of these trihalides are as follows

1. These trihalides are mostly covalent and their ionic character increases down the group *i.e.*, trihalides of Bi are ionic in nature.
2. These halides have **pyramidal structure** and sp^3-hybridisation.
3. The halides particularly the chlorides, are readily hydrolysed but the products of hydrolysis differ in different cases *e.g.*, if trihalides are **completely hydrolysed**

$$\left\{\begin{array}{l} PCl_3 + 3H_2O \longrightarrow H_3PO_3 + 3HCl \\ NCl_3 + 3H_2O \longrightarrow NH_3 + 3HClO \\ 2AsCl_3 + 3H_2O \longrightarrow As_2O_3 + 6HCl \end{array}\right.$$

If partially hydrolysed,

$$\left\{\begin{array}{l} SbCl_3 + H_2O \longrightarrow SbOCl + 2HCl \\ BiCl_3 + H_2O \longrightarrow BiOCl + 2HCl \end{array}\right.$$

The ease of hydrolysis of trihalides (for same halogens) is

$$NCl_3 > PCl_3 > AsCl_3 > SbCl_3 > BiCl_3$$

NF_3 and PF_3 do not undergo hydrolysis.

4. The trihalides of P, As and Sb, especially fluorides and chlorides, are **Lewis acids** *e.g.,*

$$PF_3 + F_2 \longrightarrow PF_5$$
$$SbF_3 + 2F^- \longrightarrow [SbF_5]^{2-}$$
$$SbCl_3 + 2Cl^- \longrightarrow [SbCl_5]^{2-}$$

5. The order of basic character of trihalides of nitrogen is

$$NI_3 > NBr_3 > NCl_3 > NF_3$$

Except NF_3, all other trihalides of nitrogen are unstable and decompose with explosive violence.

6. The P—*X*—P bond angle decreases while acid strength increases as the electronegativity of halogen increases,

i.e., Bond angle $\propto$ electronegativity of halogen.

$$\propto \frac{1}{\text{acid strength}}$$

P, As and Sb have the ability to form pentahalides but Bi and N (due to the absence of vacant *d*-orbital) do not form them. The pentahalides of P (except PCl_5) are not stable due to inert pair effect. PCl_5 itself is not very stable and decomposes to PCl_3 and Cl_2.

The other properties of pentahalides are as follows

1. These pentahalides have sp^3d-hybridisation and **trigonal bipyramidal** structure.
2. They are thermally less stable than the trihalides.
3. PCl_5 is molecular in gaseous phase but exists as, $[PCl_4]^+[PCl_6]^-$ in crystalline state, Similarly, PBr_5 and PI_5 also exist in ionic forms as, $[PBr_4]^+[Br]^-$ and $[PI_4]^+[I]^-$ respectively in solid state.

In addition to trihalides and pentahalides, some other halides are also known, *e.g.,* N_2F_4, N_2F_2, N_3F etc. Besides this, several mixed halides of nitrogen are also known *e.g.,* NCl_2F, $NClF_2$, $NBrF_2$, NF_2H, NF_2H, NCl_2H etc. However, these are unstable and difficult to isolate. P also forms P_2Br_4 and several mixed halides like PCl_4F, $PClF_4$, PCl_2F_3 etc. As and Sb also form mixed halides like AsF_2Cl, $AsFCl_2$, $AsClBr_2$, $AsCl_2Br$, $SbCl_4F$ etc.

(c) Oxides

All elements form oxides of type R_2O_3 and R_2O_5. Besides N, P, Sb and Bi also form dioxides of formula RO_2. N show all oxidation states from +1 to +5 in its oxides as :

Table 7.4 **Different Oxides of V Group Elements**

S. No.	Oxidation state	N	P	As	Sb	Bi
1.	+1	N_2O	—	—	—	—
2.	+2	NO	—	—	—	—
3.	+3	N_2O_3	P_4O_6	As_2O_3	Sb_2O_3	Bi_2O_3
4.	+4	N_2O_4	P_4O_8	—	—	—
5.	+5	N_2O_5	P_4O_{10}	As_2O_5	Sb_2O_5	Bi_2O_5

The trioxides of nitrogen, phosphorus and arsenic are acidic; the trioxide of Sb is **amphoteric** while that of Bi is **basic** in nature.

This is because down the group, metallic character increases, and metal oxides are more basic than the non-metal oxides.

However, the pentoxides are acidic in all the cases but acidic nature decreases down the group. All the penta-oxides (except P_2O_5) can readily loose oxygen to form lower oxides, thus they act as **strong oxidising agents.** The stability of pentaoxides follows the order

$$P_2O_5 > As_2O_5 > Sb_2O_5 > N_2O_5 > Bi_2O_5$$

The ability of nitrogen to form $p\pi$-$p\pi$ bonds depicts in the structure of its oxides.

(d) Oxyacids

All elements (except Bi) of this group form oxyacids.

Anomalous Behaviour of Nitrogen

Nitrogen, because of its small size, high electronegativity, high ionisation energy, non-availability of *d*-orbital and capacity of $p\pi$-$p\pi$ multiple bond formation shows properties that are quite different from the other members of the group.

These properties are as follows

1. Nitrogen is a gas while other members are found in solid state.
2. Nitrogen exists in diatomic form while other elements like phosphorus, arsenic and antimony exist as tetra-atomic molecules (P_4, As_4, Sb_4).
3. Nitrogen forms trinegative ion, *i.e.,* N^{3-} while other members do not form.
4. Nitrogen is chemically inert under ordinary conditions due to high bond dissociation energy, while other members are quite reactive because of the presence of single bond in their molecules.
5. Nitrogen does not show pentacovalency due to non-availability of *d*-orbitals while it is shown by all other elements.

6. The hydride of nitrogen (NH_3) is highly basic in nature while the hydrides of other elements are slightly basic. Moreover, only hydrides of nitrogen shows H-bonding while those of other members do not.
7. Nitrogen forms oxides of five types (*i.e.,* N_2O, NO, N_2O_3, N_2O_4 and N_2O_5) while other members of the family form oxides of only two types (*i.e.*, tri and pentaoxides).
8. Except NF_3, other halides of nitrogen *i.e.,* NCl_3, NBr_3 and NI_3 are unstable while the halides of other elements are fairly stable.
9. Nitrogen does not form complexes due to the non-availability of *d*-orbitals while other members have a tendency of complex formation, *e.g.,* $[PCl_6]^-$, $[AsCl_6]^-$ etc.

Sample **Problem 1** *Which of the following is the strongest reducing agent amongst all the hydrides of group15 elements?*

[**NCERT** Exemplar]

(*a*) NH_3 (*b*) BiH_3 (*c*) PH_3 (*d*) AsH_3

Interpret (*b*) Reducing agents have a tendency to lose hydrogen atom and lesser the bond dissociation enthalpy of *E*—H bond, more is the reducing character of hydrides.

Among the 15 group elements, the size of Bi atom is largest and hence, the Bi—H bond length is largest or Bi—H bond dissociation energy is lowest. That's why Bi—H bond dissociates more readily than the other hydrides of the group, and hence, BiH_3 is the strongest reducing agent.

7.2 Nitrogen (N)

N is fairly widely distributed in nature both in free as well as in combined state. In combined state it occurs only as nitrates *e.g.,* $NaNO_3$ (chile salt petre), KNO_3 (salt petre). Coal containing compounds of nitrogen yield NH_3 on distillation which is an important compound. N is also an essential constituent of all living cells as the protein part which contains about 16% of nitrogen.

Its some compounds are discussed below

Dinitrogen (N_2)

It is the molecular form of elemental nitrogen and chemically inert.

Methods of Preparation

1. In laboratory, dinitrogen is obtained by heating ammonium nitrite or ammonium dichromate.

$$NH_4Cl(aq) + NaNO_2(aq) \longrightarrow N_2(g) + 2H_2O(l) + NaCl(aq)$$

$$(NH_4)_2Cr_2O_7 \xrightarrow{\text{Heat}} N_2 + 4H_2O + Cr_2O_3$$

2. Pure nitrogen in small amounts can be obtained be heating sodium or barium azides.

$$Ba(N_3)_2 \xrightarrow{\Delta} Ba + 3N_2$$

3. On commercial scale, nitrogen is invariably obtained by liquifying air and then carrying out its fractional evaporation. It having a lower boiling point (77.2 K) boils of more readily than less volatile oxygen (boiling point 90.04 K).

Physical Properties

The important physical properties of nitrogen are as

1. Nitrogen is a colourless, tasteless, odourless gas which does not support combustion and is non-poisonous. However, animals die in its atmosphere for want of oxygen.
2. It is sparingly soluble in water.
3. Liquid nitrogen is colourless and boils at 195.8°C.
4. On rapid evaporation, it changes to an ice like solid melting at 209.9°C.
5. Naturally occurring nitrogen consists of two isotopes N^{14} and N^{15}. N^{15} is often used as an isotopic tracer.

Chemical Properties

N_2 is an inert diatomic gas with the structure

$$\ddot{N}\equiv\ddot{N}$$

The heat of dissociation of N_2 is extremely large (945 kJ) that's why even at 3000°C, there is no appreciable dissociation. This speakes for a very strong N≡N bond which is principally responsible for the inactivity of free nitrogen.

However, nitrogen shows the following chemical reactions

1. N_2 combines readily with **highly electropositive metals** (first group elements) even at room temperature and form ionic nitrides with N^{3-} ion. These nitrides are crystalline compounds with high melting points.
2. N_2 combines with less electropositive elements like Mg, Ca, Sr, Ba etc., at red heat; with B and Al at bright red heat and with Si at white heat, to form corresponding nitrides as :

$$3Mg + N_2 \longrightarrow Mg_3N_2$$

$$2Al + N_2 \longrightarrow 2AlN$$

$$3Si + 2N_2 \longrightarrow Si_3N_4$$

Out of these nitrides, the nitrides of group 2nd elements are generally ionic, while those of group 3rd and 4th are covalent in nature.

The nitrides formed with transitional metals like Fe, Mn, Mo, W are true interstitial compounds with N_2 atoms occupying the interstices in the metal structure. These nitrides are extremely hard with high melting point, metallic lustre and metallic conductivity.

3. N_2 combines with H_2 to give NH_3 (Haber's process) as :

$$N_2 + 3H_2 \rightleftharpoons 2NH_3 \qquad (\Delta H = -92 \text{ kJ})$$

The reaction is carried out in the presence of finely divided Fe with a little Mo, at 100-1000 atm pressure and 400-550°C.

4. N_2 combines **with** O_2 to give NO as

$$N_2 + O_2 \rightleftharpoons 2NO \qquad (\Delta H = +180.7 \text{ kJ})$$

The reaction is highly endothermic and takes place at elevated temperatures (about 3000°C), but even at such a high temperature, the yield is 5% maximum.

5. When N_2 combines with $CaCl_2$, the product is calcium cynamide, $CaCN_2$(CaNCN) as

$$CaC_2 + N_2 \longrightarrow CaNCN + C$$

(The reaction takes place at 1000°C in the current of N_2.)

Active Nitrogen

When we pass electric discharge in the atmosphere of nitrogen at low pressure, **active nitrogen** is produced. The process of formation of active nitrogen is accompanied by a yellow glow which persists for several hours and indicates slow release of energy in the process. This nitrogen gets deactivated on collision with the walls of vessels. This process is accompanied with the release of energy and accounts for the yellow glow. As the name implies, it is highly reactive chemically and reacts with liquid Hg, Na vapours, As, P etc, giving their nitrides.

The exact nature of active nitrogen has not been fully understood but it is suggested that it contains some nitrogen in atomic state which is responsible for its high reactivity.

Uses

Nitrogen is used

(i) for filling electric lamps.
(ii) to dilute the action of oxygen in air.
(iii) to provide inert atmosphere in certain metallurgical operations and in the packets of foodstuffs.
(iv) for the manufacture of certain chemicals like NH_3. HNO_3, calcium cyanamide and other nitrogen compound.

Sample **Problem 2** *On heating ammonium dichromate and barium azide separately we get* [**NCERT** Exemplar]

(a) N_2 *in both cases*
(b) N_2 *with ammonium dichromate and* NO *with barium azide*
(c) N_2O *with ammonium dichromate and* N_2 *with barium azide*
(d) N_2O *with ammonium dichromate and* NO_2 *with barium azide*

Interpret (*a*) $\underset{\text{ammonium dichromate}}{(NH_4)_2Cr_2O_7} \xrightarrow{\Delta} Cr_2O_3 \downarrow + N_2 \uparrow + 3H_2O$

$$\underset{\text{barium azide}}{Ba(N_3)_2} \xrightarrow{\Delta} Ba + 3N_2$$

Ammonia

It was first isolated by Priestley (in 1774).

Methods of Preparation

Following methods are employed to prepare NH_3

1. NH_3 is prepared on industrial scale by **Haber's process** which involves the direct combination of N_2 and H_2 according to the equation :

$$N_2 + 3H_2 \rightleftharpoons 2NH_3 \qquad (\Delta H = -92.0 \text{ kJ})$$

The reaction is reversible, exothermic and proceeds with a tremendous decrease in volume. Thus, it requires **low temperature** and **high pressure** for a better yield of ammonia (according to Le-Chatelier's principle) alongwith highly porous finely divided iron containing small amount of promotors (Mo or oxides of K and Al).

2. It can also be prepared by decomposing ammonium salts with caustic alkalies or lime. In laboratory, it is prepared by heating with slaked lime.

$$2NH_4Cl + CaO \longrightarrow CaCl_2 + H_2O + 2NH_3$$

Ammonia obtained, cannot be dried over concentrated sulphuric acid, calcium chloride or phosphorus pentoxide as the gas reacts with these substances. However, quicklime can be used.

3. It is also prepared by the hydrolysis of calcium cyanamide with superheated steam at 450 K.

$$CaCN_2 + 3H_2O \longrightarrow CaCO_3 + 2NH_3$$

Physical Properties

NH_3 is a colourless, pungent smelling gas, lighter than air and highly soluble in water. Because of hydrogen bonding, ammonia has a higher boiling point (−33.4°C) than the expected value. Its high solubility in water is also due to the hydrogen bonding between NH_3 and H_2O. Its aqueous solution is basic in nature.

$$NH_3 + H_2O \rightleftharpoons NH_4OH$$

Chemical Properties

Its important chemical properties are as follows

1. Ammonia burns in oxygen with a greenish-yellow flame as

$$4NH_3 + 3O_2 \longrightarrow 2N_2 + 6H_2O$$

2. When electric spark is passed over a mixture of NH_3 and O_2, it gets exploded and if the temperature is 500°C and Pt guaze is present as catalyst, the following reaction occurs

$$4NH_3 + 5O_2 \xrightarrow[\text{electric spark, Pt gauze}]{500°C} 4NO + 6H_2O$$

3. It acts as reducing agent and reduces metallic oxides like CuO and PbO to metals and itself gets oxidised to N_2, *e.g.,*

$$3CuO + 2NH_3 \longrightarrow 3Cu + 3H_2O + N_2$$

4. With calcium, it forms calcium hydride and nitrogen.
5. It reacts with conc. HCl and produces white fumes of the ammonium chloride.

$$NH_3 + HCl \longrightarrow NH_4Cl$$

6. When heated with alkali metals and barium, amides are obtained.

$$2Na + 2NH_3 \longrightarrow 2NaNH_2 + H_2$$

7. With chlorine, it forms NH_4Cl and nitrogen gas.

$$\underset{\text{excess}}{8NH_3} + 3Cl_2 \longrightarrow N_2 + 6NH_4Cl$$

However, if chlorine is in excess, the following reaction occurs

$$NH_3 + \underset{\text{excess}}{3Cl_2} \longrightarrow \underset{\text{explosive}}{NCl_3} + 3HCl$$

8. Aqueous ammonia contains uncombined ammonia (46.2%), hydrated ammonia ($H_3N...HOH$, 52.4%) and relatively few (1.4%) NH_4^+ and OH^- ions. It precipitate many metallic hydroxides from their salt solutions. In some cases, the precipitated hydroxides dissolve in excess ammonia and form complex amines.

$$CuSO_4 + 2NH_4OH \longrightarrow Cu(OH)_2 \downarrow + (NH_4)_2SO_4$$
$$Cu(OH)_2 + 4NH_3 \longrightarrow [Cu(NH_3)_4](OH)_2$$

9. It gives yellow-brown colour or precipitate with Nessler's reagent (*i.e.,* alkaline K_2HgI_4)

$$\underbrace{2K_2HgI_4 + 3KOH}_{\text{(Nessler's reagent)}} + NH_3 \longrightarrow \underset{\substack{\text{(iodide of Millon's base)}\\ \text{(yellow-brown)}}}{H_2NHgOHgI} + 7KI + 2H_2O$$

10. It gives yellow precipitate of ammonium chloroplatinate with chloro-platinic acid.

$$2NH_4Cl + H_2PtCl_6 \rightleftharpoons (NH_4)_2PtCl_6 + 2HCl$$

Liquid ammonia is an excellent ionising solvent. It ionises as

$$2NH_3 \rightleftharpoons NH_4^+ + NH_2^-$$

In it, alkali metals and to a lesser extent Ca, Sr and Ba dissolve and deep blue solutions are obtained. These deep blue solutions are excellent reducing agents and are electrical conductor due to the presence of solvated electrons.

Uses

Ammonia is used for the following purposes

1. It is used for the manufacture of other reagents like HNO_3 (Ostwald's process), $NaHCO_3$ (Solvay process), $(NH_4)_2SO_4$, etc.
2. It is used as a cleansing agent for removing greese.
3. It is used as a refrigerant.
4. It is also used for the synthesis of urea, an excellent fertilizer.

Structure of Ammonia

Ammonia is covalent molecule, in which three H-atoms are linked to N by single covalent bonds.

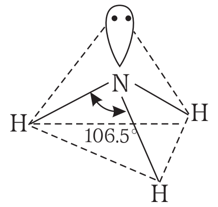


Fig. 7.1 Pyramidal structure of NH_3

Sample Problem 3 *When ammonia reacts with a solution of Cu^{2+}, colour of solution becomes* **[NCERT Exemplar]**

(*a*) *orange red*
(*b*) *deep green*
(*c*) *deep blue*
(*d*) *greenish yellow*

Interpret (*c*) When ammonia (in aqueous solution as ammonium hydroxide) reacts with a solution of Cu^{2+}, a deep blue solution is obtained due to the formation of tetraamine copper (II) ion.

$$Cu^{2+}(aq) + 4NH_4OH(aq) \xrightarrow{\Delta} \underset{\substack{\text{tetraamine copper}\\ \text{(II) ion}\\ \text{(deep blue solution)}}}{[Cu(NH_3)_4]^{2+}} + 4H_2O$$

Nitric Acid, HNO_3

It is the hydrate of N_2O_5.

Methods of Preparation

Following methods can be employed to prepare nitric acid.

1. In the **laboratory,** it is prepared by heating $NaNO_3$ or KNO_3 with conc. H_2SO_4. Reddish brown vapours of HNO_3 so produced, are condensed in a water-cooled receiver.

$$NaNO_3 + H_2SO_4(\text{conc.}) \longrightarrow NaHSO_4 + HNO_3$$

The acid thus produced is yellow in colour due to the presence of NO_2 formed by the decomposition of HNO_3.

$$4HNO_3 \xrightarrow{\Delta} 4NO_2 + 2H_2O + O_2$$

The acid is purified by redistillation and by passing a current of dry air or CO_2 through the warm acid.

2. **On a large scale,** the acid is generally prepared by **Ostwald's process** which consists of the following steps

   ***Step* 1** $NH_3(N = -3)$ obtained by Haber's process is oxidised to NO (N = +2) by atmospheric O_2 (free from dust) in the presence of platinum-guaze catalyst electrically heated at 750 – 900°C

   $$4NH_3 + 5O_2 \longrightarrow 4NO + 6H_2O \ (\Delta H = -90.0 \text{ kJ})$$

   Since, the reaction is exothermic, heat generated in the reaction maintains the temperature for the catalyst.

   ***Step* 2** NO produced as above is oxidised by atmospheric O_2 to NO_2 which is cooled to about 50°C and then absorbed in water (in the presence of air) to give HNO_3.

   $$2NO + O_2 \longrightarrow 2NO_2$$
   $$4NO_2 + O_2 + 2H_2O \longrightarrow 4HNO_3$$

   (The usual concentrated nitric acid contains 98% HNO_3 and its specific gravity = 1.5).

Physical Properties

The important physical properties of HNO_3 *are as*

1. Pure HNO_3 is colourless fuming liquid of specific gravity 1.56 (at 0°C). It boils at 86°C and freezes to a colourless solid having melting point – 41.3°C. It is soluble in water in all proportions.
2. It is highly corrosive in nature and causes painful blisters when it comes in contact with skin.
3. HNO_3 is colourless but often gradually turns yellow. This is because HNO_3, when exposed to light, undergoes decomposition to form NO_2 which gets dissolved in HNO_3 and gives it yellow colour.

   $$4HNO_3 \longrightarrow 4NO_2 + O_2 + 2H_2O$$

   The yellow colour of the acid can be removed by warming it to 60 – 80° C and bubbling dry air through it.

Chemical Properties

HNO_3 is a strong acid and also a very strong oxidising agent. *Its important chemical reactions are as follows*

1. At room temperature, the pure acid undergoes dissociation to give N_2O_4 and O_2.

   $$HNO_3 \longrightarrow N_2O_5 + H_2O$$
   $$N_2O_5 \rightleftharpoons N_2O_4 + \frac{1}{2}O_2$$

   On heating, HNO_3 decomposes to give O_2 and brown fumes of NO_2.

   $$4HNO_3 \longrightarrow 4NO_2 + O_2 + 2H_2O$$

2. HNO_3 being a very strong monobasic acid, reacts with basic oxides, carbonates, bicarbonates, sulphites and hydroxides, forming corresponding nitrates. *e.g.*,

   $$CaO + 2HNO_3 \longrightarrow Ca(NO_3)_2 + H_2O$$
   $$Na_2CO_3 + 2HNO_3 \longrightarrow 2NaNO_3 + H_2O + CO_2$$

3. Being a strong acid, HNO_3 is completely ionised in water as :

   $$HNO_3 \longrightarrow H^+ + NO_3^-$$

4. HNO_3 is a very strong oxidising agent, since it can easily give nascent oxygen both in the conc. and dil. forms.

   $$2HNO_3 \longrightarrow H_2O + 2NO_2 + O$$

   In these reactions, HNO_3 is reduced to NO_2, O_2, NH_4NO_3 (or NH_4^+ ions), N_2O, NO, N_2 or NH_2OH depending on the nature of the substance to be oxidised, concentration of HNO_3 and the temperature employed.

Non-metals and metalloids (*e.g.,* C, Sn, P, As, Pb, S and I) are oxidised to their corresponding highest oxy-acids while, the metals like Mg, Mn, Zn, Fe, Sn, Pb, Cu, Ag and Hg are oxidised to their corresponding nitrates.

Some examples of such type of reactions (*i.e., the reactions in which* HNO_3 *acts as an oxidising agent*) *are given below*

I. **HNO_3 oxidises non-metals and metalloids to their oxyacids as**

(i) P is oxidised to H_3PO_4.

$$P + 5HNO_3 \longrightarrow H_3PO_4 + 5NO_2 + H_2O$$

This reaction takes place through the following steps :

$$2P + \underset{(\text{from } HNO_3)}{5O} \longrightarrow P_2O_5$$
$$P_2O_5 + 3H_2O \longrightarrow 2H_3PO_4$$
$$\overline{\underline{2P + 5O + 3H_2O \longrightarrow 2H_3PO_4}}$$

(ii) Carbon is oxidised to H_2CO_3.

$$C + 4HNO_3 \longrightarrow H_2CO_3 + 4NO_2 + H_2O$$

(iii) Tin is oxidised to metastannic acid, H_2SnO_3 (by conc. HNO_3)

$$Sn + 4HNO_3 \longrightarrow H_2SnO_3 + 4NO_2 + H_2O$$

(iv) P, As and Sb are oxidised to H_3PO_4 (phosphoric acid), H_3AsO_4 (arsenic acid) and H_3SbO_4 (antimonic acid) respectively

$$M + 5HNO_3 \longrightarrow H_3MO_4 + 5NO_2 + H_2O$$
$$(M = \text{P, As, Sb})$$

(v) Sulphur is oxidised to H_2SO_4.

$$S + \underset{(\text{conc. and hot})}{6HNO_3} \longrightarrow H_2SO_4 + 6NO_2 + 2H_2O$$

(vi) Iodine is oxidised to iodic acid, HIO_3.

$$I_2 + 10HNO_3 \longrightarrow 2HIO_3 + 10NO_2 + 4H_2O$$

II. **It converts reactive metals** (present above hydrogen in electrochemical series) to metal nitrates and itself gets reduced to H_2 (in case of Mg and Mn) or to NH_4NO_3, NO_2 , NO and NO_2 (with other metals). Actually in later case following two steps are involved.

***Step* 1** The metal (M) on being treated with HNO_3 is converted into metallic nitrate and nascent hydrogen is produced

$$M + 2HNO_3 \longrightarrow M(NO_3)_2 + 2H$$

***Step* 2** Nascent hydrogen, produced as above, reduces HNO_3 to NH_4NO_3 (or NH_4^+ ion), N_2O, NO or NO_2

$$2HNO_3 + 8H \longrightarrow NH_4NO_3 + 3H_2O$$
$$2HNO_3 + 8H \longrightarrow N_2O + 5H_2O$$
$$HNO_3 + H \longrightarrow NO_2 + H_2O$$
$$HNO_3 + 3H \longrightarrow NO + 2H_2O$$

Some important examples of such reactions are as follows

Zinc

(i) Zn reacts with very dil. HNO_3 (6%) and is oxidised to $Zn(NO_3)_2$. Here, HNO_3 is reduced to NH_4NO_3 as :

$$4Zn + \underset{\text{(very dilute)}}{10HNO_3} \longrightarrow 4Zn(NO_3)_2 + NH_4NO_3 + 3H_2O$$

(ii) Zn reacts with cold and dil. HNO_3 (20%) and is oxidised to $Zn(NO_3)_2$. Here, HNO_3 is reduced to N_2O as

$$4Zn + \underset{\substack{\text{(cold and}\\\text{dilute)}}}{10HNO_3} \longrightarrow 4Zn(NO_3)_2 + N_2O + 5H_2O$$

(iii) Zn reacts with cold and conc. HNO_3 (70%) and is oxidised to $Zn(NO_3)_2$. Here, HNO_3 is reduced to NO_2 as

$$Zn + \underset{\text{(cold and conc.)}}{4HNO_3} \longrightarrow Zn(NO_3)_2 + 2NO_2 + 2H_2O$$

(iv) If Zn reacts with cold and moderately conc HNO_3 (50%), NO is evolved and $Zn(NO_3)_2$ is formed

$$3Zn + 8HNO_3 \longrightarrow 3Zn(NO_3)_2 + 4H_2O + 2NO$$

Iron

(i) Fe reacts with very dil. HNO_3 and is oxidised to $Fe(NO_3)_2$. Here, HNO_3 is reduced to NH_4NO_3 as

$$4Fe + \underset{\text{(very dilute)}}{10HNO_3} \longrightarrow 4Fe(NO_3)_2 + NH_4NO_3 + 3H_2O$$

(ii) Fe is oxidised to $Fe(NO_3)_2$ by dil HNO_3 and HNO_3 is reduced to N_2O as

$$4Fe + \underset{\text{(dilute)}}{10HNO_3} \longrightarrow 4Fe(NO_3)_2 + N_2O + 5H_2O$$

(iii) Fe reacts with cold and conc. HNO_3 and is oxidised to $Fe(NO_3)_3$. Here, HNO_3 is reduced to NO_2 as

$$Fe + \underset{\text{(cold and conc.)}}{6HNO_3} \longrightarrow Fe(NO_3)_3 + 3NO_2 + 3H_2O$$

(iv) With hot and conc. HNO_3, Fe is oxidised to $Fe(NO_3)_3$ and HNO_3 is reduced to NO as

$$Fe + \underset{\text{(hot and conc.)}}{4HNO_3} \longrightarrow Fe(NO_3)_3 + 2H_2O + NO$$

Highly conc. HNO_3 renders iron passive (inert).

III. **HNO_3 also oxidises less reactive metals** (present below hydrogen in the electrochemical series) Examples of such metals are Cu, Ag and Hg. These metals when treated with HNO_3 are oxidised to their corresponding nitrates and HNO_3 is reduced to NO_2, NO, NO_2 or N_2 depending on the nature of the metal, concentration of the acid and temperature employed. Thus,

$$M + 2HNO_3 \longrightarrow M(NO_3)_2 + N_2O, NO, NO_2 \text{ or } N_2 + H_2O$$
(M = Cu, Ag, Hg)

These reactions, infact, involve the following two steps

(i) Since, Cu, Ag and Hg lie below hydrogen in the electrochemical series, they are not able to liberate hydrogen from HNO_3 as Zn, Fe, Sn and Pb can do. In case of these metals HNO_3 acts as an oxidising agent, *i.e.*, HNO_3 gives nascent oxygen and is itself reduced to N_2O, NO, NO_2 or N_2.

$$2HNO_3 \longrightarrow N_2O + H_2O + 4O$$
$$2HNO_3 \longrightarrow 2NO + H_2O + 3O$$
$$2HNO_3 \longrightarrow 2NO_2 + H_2O + O$$
$$2HNO_3 \longrightarrow N_2 + H_2O + 5O$$

(ii) Nascent oxygen obtained as above, oxidises the metal to its oxide which on reaction with HNO_3, gives metallic nitrate.

$$M + O \longrightarrow MO \text{ (metallic oxide)}$$
$$MO + 2HNO_3 \longrightarrow M(NO_3)_2 + H_2O$$

Some important examples of such reactions are

Copper

(i) With cold and dil HNO_3 evolves N_2O as

$$\underset{\text{(cold and dil)}}{10HNO_3} + 4Cu \longrightarrow N_2O + 5H_2O + 4Cu(NO_3)_2$$

(ii) With cold and moderately conc. HNO_3 evolves NO as

$$3Cu + \underset{\substack{\text{(cold and}\\\text{moderately conc)}}}{8HNO_3} \longrightarrow 3Cu(NO_3)_2 + 2NO + 4H_2O$$

(iii) With cold and conc. HNO_3 evolves NO_2 as

$$Cu + 4HNO_3 \longrightarrow Cu(NO_3)_2 + 2NO_2 + 2H_2O$$

(iv) With hot and conc. HNO_3 evolves N_2 as

$$12HNO_3 + 5Cu \longrightarrow N_2 + 6H_2O + 5Cu(NO_3)_2$$

Silver

(i) With dil HNO_3, $AgNO_3$ is obtained and NO is evolved as

$$3Ag + \underset{\text{(dilute)}}{4HNO_3} \longrightarrow 3AgNO_3 + NO + 2H_2O$$

(ii) With conc. HNO_3, NO_2 is evolved as

$$Ag + \underset{\text{(conc.)}}{2HNO_3} \longrightarrow AgNO_3 + NO_2 + H_2O$$

Mercury

(i) With dil HNO_3, $Hg_2(NO_3)_2$ is formed and NO is evolved as

$$6Hg + \underset{\text{(dilute)}}{8HNO_3} \longrightarrow \underset{\text{mercurous nitrate}}{3Hg_2(NO_3)_2} + 2NO + 4H_2O$$

(ii) With conc. HNO_3, mercuric nitrate, $Hg(NO_3)_2$ is obtained and NO_2 is evolved as :

$$Hg + \underset{\text{(conc.)}}{4HNO_3} \longrightarrow Hg(NO_3)_2 + 2NO_2 + 2H_2O$$

IV. **HNO_3** (Both dil. and conc. can also oxidise many compounds) In these reactions, dil. HNO_3 reduced to NO while conc. HNO_3 is reduced to NO_2. When HNO_3 oxidises $SnCl_2$ in presence of HCl, it is reduced to NH_2OH. Thus,

$$\underset{\text{(dil.)}}{2HNO_3} \longrightarrow H_2O + 2NO + 3O$$

$$\underset{\text{(conc.)}}{2HNO_3} \longrightarrow H_2O + 2NO_2 + O$$

$$HNO_3 + 6H \longrightarrow 2H_2O + NH_2OH$$

Some important examples of such reactions with HNO_3 *are as follows.*

(i) **I_2 is liberated from KI solution** ($I^- \longrightarrow I_2^0$)

$$\underset{\text{(dil.)}}{8HNO_3} + 6KI \longrightarrow 2NO + 4H_2O + 6KNO_3 + 3I_2$$

(ii) **CuS is oxidised to sulphur** ($S^{2-} \longrightarrow S$)

$$\underset{\text{(dil.)}}{8HNO_3} + 3CuS \longrightarrow 2NO + 4H_2O + 3S + 3Cu(NO_3)_2$$

(iii) **H_2S is oxidised to sulphur** (by both dil. and conc. HNO_3 ($S^{2-} \longrightarrow S$)

$$\underset{\text{(dil.)}}{2HNO_3} + 3H_2S \longrightarrow 2NO + 4H_2O + 3S$$

$$\underset{\text{(conc.)}}{2HNO_3} + H_2S \longrightarrow 2NO_2 + S + 2H_2O$$

(iv) **FeS is oxidised to $FeSO_4$** ($S^{2-} \longrightarrow SO_4^{2-}$)

$$FeS + \underset{\text{(conc)}}{8HNO_3} \longrightarrow FeSO_4 + 8NO_2 + 4H_2O$$

(v) **SO_2 is oxidised to H_2SO_4** (by both dil. and conc. HNO_3)

($SO_2 \longrightarrow SO_4^{2-}$)

$$SO_2 + \underset{\text{(conc.)}}{2HNO_3} \longrightarrow H_2SO_4 + 2NO_2$$

$$\underset{\text{(dil.)}}{2HNO_3} + 2H_2O + 3SO_2 \longrightarrow 2NO + 3H_2SO_4$$

(vi) **Solution of $FeSO_4$ is oxidised to $Fe_2(SO_4)_3$** (by both dil. and conc. HNO_3) in the presence of H_2SO_4 ($Fe^{2+} \longrightarrow Fe^{3+}$)

$$\underset{\substack{\text{green}\\\text{solution}}}{6FeSO_4} + 3H_2SO_4 + \underset{\text{dil.}}{2HNO_3} \longrightarrow \underset{\substack{\text{yellow}\\\text{solution}}}{3Fe_2(SO_4)_3} + 2NO + 4H_2O$$

$$2FeSO_4 + \underset{\text{conc.}}{2HNO_3} + H_2SO_4 \longrightarrow Fe_2(SO_4)_3 + 2NO_2 + 2H_2O$$

(vii) **HBr and HI are oxidised to Br_2 and I_2 respectively** ($Br^- \longrightarrow Br_2$, $I^- \longrightarrow I_2$)

$$\underset{\text{(dil.)}}{2HNO_3} + 6HX \longrightarrow 2NO + 4H_2O + 3X_2$$

$$\underset{\text{(conc.)}}{2HNO_3} + 2HX \longrightarrow X_2 + 2NO_2 + 2H_2O$$

(viii) **As_2O_3 is oxidised to** H_3AsO_4 ($As^{3+} \longrightarrow AsO_4^{3-}$)

$$2HNO_3 + As_2O_3 + H_2O \longrightarrow 4NO_2 + 2H_3AsO_4$$

(ix) **Cane-sugar** (sucrose), **$C_{12}H_{22}O_{11}$ is oxidised to oxalic acid, $H_2C_2O_4$ by conc. HNO_3**

$$\underset{\text{(conc.)}}{36HNO_3} + C_{12}H_{22}O_{11} \longrightarrow 23H_2O + 36NO_2 + 6H_2C_2O_4$$

(x) **Toluene** ($C_6H_5CH_3$) **is oxidised to benzoic acid** (C_6H_5COOH) **by dil. HNO_3**

$$\underset{\text{(dil)}}{2HNO_3} + C_6H_5CH_3 \longrightarrow 2NO + 2H_2O + C_6H_5COOH$$

(xi) **$SnCl_2$ is oxidised to $SnCl_4$ in presence of HCl** ($Sn^{2+} \longrightarrow Sn^{4+}$)

$$3SnCl_2 + 6HCl + HNO_3 \longrightarrow 2H_2O + 3SnCl_4 + NH_2OH$$

V. Metals like Cr, Ni, Al, Fe become passive (inert) when treated with conc HNO_3, *e.g.*, Fe displaces Cu from $CuSO_4$ solution but this property of Fe is lost when it is dipped in slightly conc HNO_3. This is because, a thin oxide (iron oxide) layer is deposited over the metal surface, when it is treated with conc HNO_3. This layer makes the iron passive or inert.

VI. When 1 part of conc. HNO_3 is mixed with 3 parts of conc. HCl, we get **aqua-regia.** *Aqua-regia produces nascent chlorine* (Cl) *along with nitrosyl chloride* (NOCl) *as*

$$HNO_3 + 3HCl \longrightarrow NOCl + 2H_2O + 2Cl$$

Due to production of nascent chlorine, aqua-regia is very active, *e.g.,* Au and Pt (noble metals) which are not acted upon by HNO_3 get dissolved in aqua-regia due to the formation of soluble complexes namely $H[AuCl_4]$ and $H_2[PtCl_6]$ respectively. *e.g.,*

$$2Au + 3HNO_3 + 11HCl \longrightarrow H[AuCl_4] + 2NOCl + 6H_2O$$

VII. Conc. HNO_3 attacks many aromatic organic compounds (*e.g.*, C_6H_6, $C_6H_5CH_3$, C_6H_5OH etc.) in the presence of conc. H_2SO_4 and substitutes one or more H-atoms in these organic compounds by nitro group, producing nitro compounds (nitration). Here, H_2SO_4 absorbs water liberated in the reaction and also produces nitronium ion (NO_2^+) by reacting with HNO_3. This NO_2^+ ion makes the nitration of aromatic compounds. *e.g.*,

$$HNO_3 + C_6H_6 \xrightarrow{H_2SO_4} \underset{\text{nitrobenzene}}{C_6H_5NO_2} + H_2O$$

VIII. With protein, HNO_3 gives yellow coloured xanthoprotein. The acid produces yellow stain on skin and wood, since the skin and wood both contain protein.

Uses

Nitric acid is used

1. as a laboratory reagent and making aqua-regia.
2. as strong oxidising agent.
3. to clean noble metals such as Au, Ag, Pt.
4. to make explosive materials such as TNT, picric acid, gun cotton etc.
5. in making of colour, perfume, artificial fibre etc.
6. for the manufacture of fertilizers.

Sample **Problem 4** *Which of the following products will be obtained when copper metal is reacted with* HNO_3? [**NCERT**]

(*a*) NO *and* N_2O_5 (*b*) NO_2 *and* N_2O_5
(*c*) NO *and* NO_2 (*d*) HNO_2 *and* N_2

Interpret (*c*) The products of the reaction of copper with HNO_3 depends upon the concentration of HNO_3 used.

(i) Copper metal reacts with dilute HNO_3 to form nitrogen (II) oxide (NO).

$$3Cu + 8HNO_3(\text{dilute}) \longrightarrow 3Cu(NO_3)_2 + 2NO + 4H_2O$$

(ii) Copper metal reacts with conc. HNO_3 to form nitrogen (IV) oxide or nitrogen dioxide (NO_2).

$$Cu + 4HNO_3(\text{conc.}) \longrightarrow Cu(NO_3)_2 + 2NO_2 + 2H_2O$$

Sample **Problem 5** *In the preparation of* HNO_3, *we get* NO *gas by catalytic oxidation of ammonia. The moles of* NO *produced by the oxidation of two moles of* NH_3 *will be* [**NCERT Exemplar**]

(*a*) 2 (*b*) 3 (*c*) 4 (*d*) 6

Interpret (*c*) In the preparation of nitric acid by Ostwald's process, ammonia is oxidised to NO by atmospheric O_2 in the presence of platinum-guaze catalyst.

$$4NH_3 + 5O_2 \longrightarrow 4NO + 6H_2O$$

or
$$2NH_3 + \frac{5}{2}O_2 \longrightarrow 2NO + 3H_2O$$

Oxides of Nitrogen

Nitrogen forms Several Oxides

The preparation and properties of these oxides can be summarised as

Table 7.5 **Preparation and Properties of Various Oxides of Nitrogen**

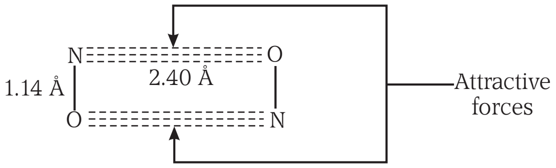
Formula	Name	Preparation	Properties
N_2O	Nitrous oxide or laughing gas	$NH_4NO_3 \rightarrow N_2O + 2H_2O$	Colourless gas, rather unreactive.
NO	Nitrogen monoxide (Nitric oxide)	$3Cu + 8HNO_3 \rightarrow 3Cu(NO_3)_2 + 2NO + 4H_2O$	Colourless gas, reactive, paramagnetic.
NO_2	Nitrogen dioxide	$Pb(NO_3)_2 \rightarrow 2PbO + 4NO_2 + O_2$	Brown gas, reactive, paramagnetic.
N_2O_3	Dinitrogen trioxide or nitrous anhydride	$NO + NO_2 \rightarrow N_2O_3$	Dark blue in the liquid or solid state, unstable in the gas phase.
N_2O_4	Dinitrogen tetroxide (mixed anhydride of N_2O and NO)	$2NO_2 \rightleftharpoons N_2O_4$	Colourless, exists in equilibrium with NO_2 both in the gaseous and liquid state.
N_2O_5	Dinitrogen pentoxide	$2HNO_3 + P_2O_5 \rightarrow 2HPO_3 + N_2O_5$	Unstable as gas; in the solid state exists as $[NO_2]^+[NO_3]^-$.

Some other Properties of Oxides of Nitrogen

1. N_2O (nitrous oxide) is a colourless gas, fairly soluble in cold water but practically insoluble in hot water, easily liquifiable at room temperature by applying pressure (critical temperature 35°C). It has a faint odour. When inhaled in moderate quantities, it produces hysterical laughter (that's why called **laughing gas**). Its higher quantity doses may make a person unconcious. Chemically, it is relatively inert and does not reacts with halogens, alkali metals and even ozone at room temperature. However, it decomposes to N_2 and O_2 at 600°C and form metal azides with molten alkali metals as

$$NaNH_2 + N_2O \xrightarrow{200°C} NaN_3 + H_2O$$

2. **NO** (nitric oxide) is an odd electron molecule, because of the presence of an unpaired electron. It undergoes partial dimerisation in liquid state and exists as a dimer in solid state as



It readily reacts with oxygen to give brown fumes of NO_2 as

$$2NO(g) + O_2(g) \longrightarrow 2NO_2(g)$$

3. **NO_2** (nitrogen dioxide) is also an odd electron molecule and in gaseous phase, exists in equilibrium with dimer N_2O_4 which is colourless *i.e.*,

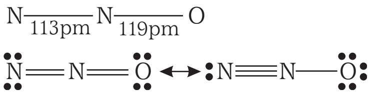
$$\underset{\substack{\text{brown}\\\text{(paramagnetic)}}}{2NO_2(g)} \qquad \underset{\substack{\text{colourless}\\\text{(diamagnetic)}}}{N_2O_4(g)}$$

4. **N_2O_5** (dinitrogen pentaoxides) is the strongest acid among all the pentoxides and a very strong oxidising agent.

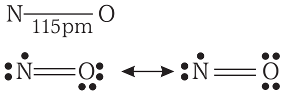
Structure of Oxides of Nitrogen

The molecular and Lewis dot resonance structures of oxides of nitrogen are shown as

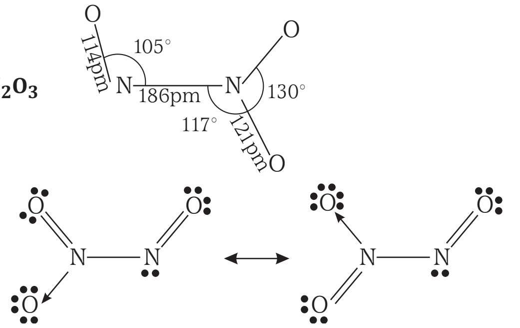
(i) **N_2O**



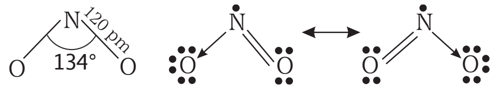
(ii) **NO**



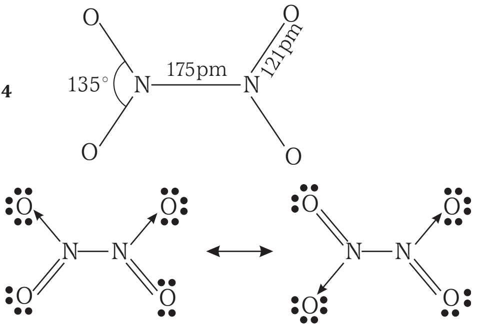
(iii) **N_2O_3**



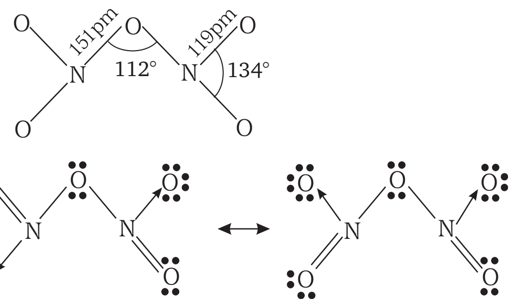
(iv) **NO_2**



(v) **N_2O_4**



(vi) **N_2O_5**



Sample **Problem 6** *Nitric acid forms an oxide of nitrogn on reaction with P_4O_{10}. How many resonating structures of the oxide of nitrogen will be formed?* **[NCERT Exemplar]**

(*a*) 2

(*b*) 3

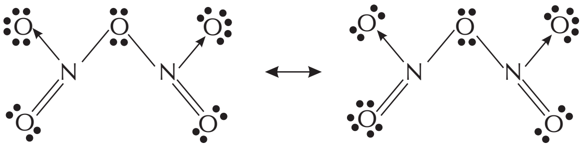
(*c*) 4

(*d*) 5

Interpret (*a*) P_4O_{10} being a dehydrating agent, removes a molecule of water and forms anhydride of HNO_3.

$$4HNO_3 + P_4O_{10} \longrightarrow 4HPO_3 + 2N_2O_5$$

Resonation structures of N_2O_5 are



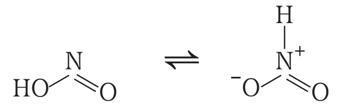
Oxyacids of Nitrogen

Nitrogen forms following oxyacids

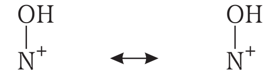
(i) Hyponitrous acid, $H_2N_2O_2$
(ii) Nitrous acid, HNO_2
(iii) Nitric acid, HNO_3
(iv) Pernitrous acid, HOONO
(v) Pernitric acid, $HOONO_2$

Out of these, the most important one is nitric acid.

The structure of some oxyacids of nitrogen are



(nitrous acid)



(nitric acid)

7.3 Phosphorus

It is the most reactive element in this group and found in the combined state as phosphates in the rocks and in the soil. It is an essential constituent of teeth, bones, blood and nervous tissues. its important minerals are phosphorite $[Ca_3(PO_4)_2]$, chlorapatite $[3Ca_3(PO_4)_2 . CaCl_2]$, Fluorapatite or apatite $[3Ca_3(PO_4)_2 . CaF_2]$. Ist yellow form is always kept under water.

MethodS of Preparation

Following methods are employed to prepare phosphorus.

(a) **Retort Process**

$$\underset{\text{phosphorite}}{Ca_3(PO_4)_2} + 3H_2SO_4 \longrightarrow \underset{\text{orthophosphoric acid}}{2H_3PO_4} + 3CaSO_4$$

$$H_3PO_4 \longrightarrow \underset{\text{methaphosphoric acid}}{HPO_3} + H_2O$$

$$4HPO_3 + 10C \longrightarrow P_4 + 10CO + 2H_2O$$

(b) **Electrothermal Process**

Phosphorus is obtained from direct reduction of mineral phosphorite by carbon in presence of silica.

$$2Ca_3(PO_4)_2 + 6SiO_2 + 10C \xrightarrow{1400\text{-}1500°C} 6CaSiO_3 + P_4 + 10CO$$

(c) **From Bone Ash**

It is manufactured by heating bone ash or phosphorite with sand (SiO_2) and coke (C) in an electric furnance as

$$2Ca_3(PO_4)_2 + 6SiO_2 + 10C \longrightarrow 6CaSiO_3 + 10CO + P_4$$

Allotropes of Phosphorus

Phosphorus exists in following allotropic forms, which are inter convertible.

1. **White P** is a waxy transluscent solid, readily soluble in CS_2. Below 800°C, its vapour density corresponds to formula P_4 while above 800°C it dissociates to P_2. It melts at 44.1°C and boils at 280°C. Its ignition temperature is very low. When exposed to air, it undergoes oxidation which gradually raises its temperature and ultimately, it catches fire when temperature exceeds 30°C. That's why, **it is always kept in water.** Being extremely poisonous, it proves fatal if taken internally. P glows in dark on account of its slow oxidation (phosphorescence). It is readily soluble in turpentine oil and ether. Its structure in P_4 form can be seen as

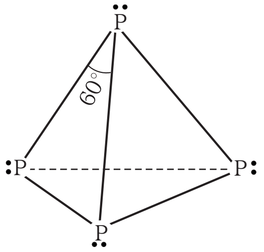


Fig. 7.2 Tetrahedral phosphorus molecule

2. **Red P** is violet red powder consisting of some crystals and some amorphous variety. It differs from white variety as it is more stable under ordinary conditions, does not ignite spontaneously in air

$$\text{Red P} \xrightarrow[\text{heating}]{\text{Sublimes on}} \text{vapours} \xrightarrow{\text{Condensed}} \text{white P}$$

Red P has an iron-grey lusture and does not show phosphorescence. It is insoluble in CS_2 and other organic solvents.

Red P does not melt at a definite temperature, its density is also variable. Because of this reason, it is not regarded as the definite allotrope of phosphorus. It is thought to be a solid solution of scarlet P in metallic (α-black) phosphorus. The exact nature of red P is however, uncertain.

3. **Metallic or α-black P** is a very stable allotrope of P and does not oxidise in air unless heated very strongly. It does not conduct electricity.

4. β-**black P** is the only form of phosphorus whose structure is definitely known. It is crystalline in nature and consists of corrugated sheets. Here, each P atom is covalently bonded to other three neighbouring atoms as shown in figure below

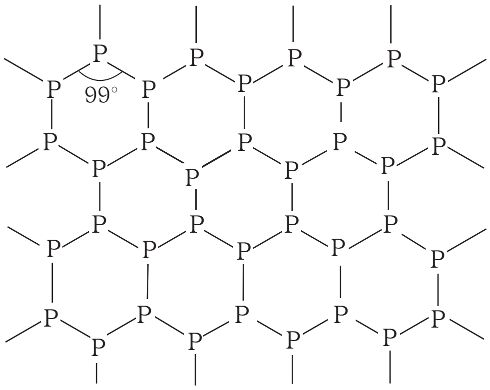

Fig. 7.3 Layer structure of β-black phosphorus

The atoms within a layer are more strongly bound than the atoms in adjacent layers. This gives rise to flaky crystals which resemble those of graphite. Its melting point is 587°C and specific gravity is 2.69. It does not burn in air even up to 400°C. It is good conductor of electricity just like graphite.

5. **Scarlet P** resembles the red variety in its physical properties and white P in its chemical properties. It has the property of only slow oxidation in air.
6. **Violet phosphorus** is crystalline in nature.

Chemical Properties of Phosphorus

White P is more reactive than other varieties and exhibits the following reactions

1. It burns in air forming its trioxide and pentoxide.
2. White P combines with hot solutions of KOH or NaOH giving phosphene.

$$P_4 + 3NaOH + 3H_2O \longrightarrow 3NaH_2PO_2 + PH_3$$

However, red P does not react with dilute alkalies. Thus, this property is helpful in separating red P with white P.

3. P forms trihalides and pentahalides with halogens, white P reacts more vigorously than red P.
4. P combines to S with explosive violence forming a number of sulphides *e.g.*, P_2S_3, P_2S_5, P_4S_3 and P_4S_7 etc.
5. P combines with metals to form phosphides as

$$6Mg + P_4 \longrightarrow 2Mg_3P_2$$
$$6Ca + P_4 \longrightarrow 2Ca_3P_2$$

(Na and K react vigorously with a white flash).

6. Since, white P can be easily oxidised, it acts as strong reducing agent. It reduces HNO_3 to nitrogen dioxide and H_2SO_4 to SO_2. It also reduces solutions of Cu, Ag and Au salts to the corresponding metals *e.g.*,

$$P_4 + 8CuSO_4 + 14H_2O \longrightarrow 8Cu + 8H_2SO_4 + 2H_3PO_4 + 2H_3PO_3$$

Uses

1. Red phosphorus is used in match industry.
2. Radioactive phosphorus is used in the treatment of leukemia and other blood disorders.
3. Yellow phosphhorus and zinc phosphide are used as a rat poison.

Sample Problem 7 *White phosphorus reacts with chlorine and the product hydrolyses in the presence of water. Calculate the mass of* HCl *obtained by the hydrolysis of the product formed by the reaction of 62 g of white phosphorus with chlorine in the presence of water.* [**NCERT** Exemplar]

(*a*) 0.219 g
(*b*) 2.19 g
(*c*) 21.9 g
(*d*) 219.0 g

Interpret (*d*) Equations for the reactions

$$\begin{array}{rcl} P_4 + 6Cl_2 & \longrightarrow & 4PCl_3 \\ PCl_3 + 3H_2O & \longrightarrow & H_3PO_3 + 3HCl \times 4 \\ \hline \underset{1\text{ mol}}{P_4} + 6Cl_2 + 12H_2O & \longrightarrow & 4H_3PO_3 + \underset{12\text{ mol}}{12HCl} \end{array}$$

$31 \times 4 = 124$ g $\qquad 12 \times 36.5 = 438.0$ g

$\because$ 124 g of white phosphorus produces HCl = 438 g

$\therefore$ 62 g of white phosphorus will produces

$$HCl = \frac{438}{124} \times 62 = 219.0 \text{ g HCl}$$

Phosphine (PH_3)

It is discovered by **Gembre** in 1783.

Methods of Preparation

Following methods are used to prepare PH_3 *(phosphine)*

1. PH_3 is generally prepared by boiling white P with a concentrated solution of NaOH in inert atmosphere of CO_2, oil gas or hydrogen as

$$P_4 + 3NaOH + 3H_2O \longrightarrow 3NaH_2PO_2 + PH_3$$

It is necessary to exclude air from the apparatus because, although pure PH_3 will not burn unless ignited, it is often accompanied with P_2H_4 and H_2 which are spontaneously flammable.

$$2P + 2NaOH + 2H_2O \longrightarrow 2NaH_2PO_2 + H_2\uparrow$$
$$6P + NaOH + 4H_2O \longrightarrow 4NaH_2PO_2 + P_2H_4$$

Because of this reaction, phosphine is used in making **Holme's signals.**

(Pure phosphine is obtained by using alcoholic KOH in place of aqueous NaOH solution).

2. It can also be obtained by heating phosphorus acid.

$$4H_3PO_3 \longrightarrow 3H_3PO_4 + PH_3$$

3. Treatment of phosphonium iodide with 30% KOH solution also gives phosphine.

$$PH_4I + KOH \longrightarrow KI + H_2O + PH_3$$

The evolved gas is passed through HCl (which decomposes P_2H_4) and then through NaOH (where HI is absorbed).

4. It is also obtained by the hydrolysis of Ca_3P_2 with water or dilute HCl.

$$Ca_3P_2 + 6H_2O \longrightarrow 3Ca(OH)_2 + 2PH_3$$

Physical Properties

It is colourless, highly reactive and extremely toxic gas with a slight smell of garlic or rotten fish. It liquefies at −89°C and solidifies at −134°C. It is highly poisonous in nature.

Chemical Properties

Important chemical properties exhibited by phosphine are as follows

1. PH_3, unlike NH_3, is not very soluble in water. Its aqueous solution is neutral. It is more soluble in non-polar solvent like CS_2 and other organic solvents.
2. When heated out of contact of air to 440°C or when electric sparks are passed, phosphine decomposes and gives red phosphorus and hydrogen gas as

$$4PH_3 \longrightarrow P_4 + 6H_2$$

A pure sample of phosphine is not spontaneously inflammmable. It burns in air or oxygen when heated at 150°C.

$$2PH_3 + 4O_2 \xrightarrow{\Delta} P_2O_5 + 3H_2O$$

However, white smoke (vortex rings) is formed, if PH_3 comes in contact with air. This is because of the formation of vortex ring of P_2O_5 due to impurity of P_2H_4 (diphosphine).

3. In contact with nitric acid, phosphine begins to burn.

$$2PH_3 + 16HNO_3 \longrightarrow P_2O_5 + 16NO_2 + 11H_2O$$

4. It forms addition compounds with anhydrous $AlCl_3$ and $SnCl_4$.

$$AlCl_3 + 2PH_3 \longrightarrow AlCl_3 \cdot 2PH_3$$
$$SnCl_4 + 2PH_3 \longrightarrow SnCl_4 \cdot 2PH_3$$

5. Phsophine gives a black precipitate of cupric phosphide, when passed through $CuSO_4$ solution.

$$3CuSO_4 + 2PH_3 \longrightarrow Cu_3P_2 + 3H_2SO_4$$

It also gives a similar reaction with silver nitrate solution.

$$3AgNO_3 + PH_3 \longrightarrow Ag_3P + 3HNO_3$$

6. The mixture of PH_3 and N_2O or PH_3 and NO explodes in the presence of electric spark.

$$PH_3 + 4NO_2 \longrightarrow H_3PO_4 + 4N_2$$

7. PH_3 is a better reducing agent than NH_3 and reduces
   (i) Ag^+ to Ag metal as

$$6Ag^+ + PH_3 + 3H_2O \longrightarrow H_3PO_3 + 6Ag\downarrow + 6H^+$$

   (ii) Cu^{2+} to Cu metal as

$$4Cu^{2+} + PH_3 + 4H_2O \longrightarrow H_3PO_4 + 4Cu\downarrow + 8H^+$$

8. In liquid NH_3, phosphine dissolves to give $NH_4^+PH_2^-$.

$$\underset{\text{base}}{NH_3} + \underset{\text{acid}}{PH_3} \longrightarrow NH_4^+PH_2^-$$

Structure of Phosphine

In phosphine, three H atoms are attached with P atom through covalent bonds and P has one lone pair of electrons, thus, its structure is pyramidal like NH_3.

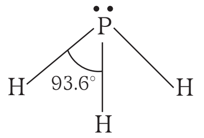

Fig. 7.4 Structure of PH_3

Uses

PH_3 is used

1. For making smoke screens.
2. For making metallic phosphides.
3. For making **Holme's signals.** For this a mixture of calcium carbide, CaC_2 and calcium phosphide, Ca_3P_2 is placed in metallic containers. Two holes are made and the container is thrown into the sea. Water enters in the container and produces acetylene and phosphine. The gaseous mixture catches fire spontaneously because of the presence of P_2H_4. The acetylene gives a bright luminous flame which serves as a signal to the approaching ship.

Sample **Problem 8** *On heating with concentrated* NaOH *solution in an inert atmosphere of* CO_2*, white phosphorus gives a gas. Which of the following statement is incorrect about the gas?* [**NCERT** Exemplar]

(a) *It is highly poisonous and has smell like rotten fish.*
(b) *Its solution in water decomposes in the presence of light.*
(c) *It is more basic than* NH_3.
(d) *It is less basic than* NH_3.

Interpret (c) White phosphorus combines with a concentrated solution of NaOH in inert atmosphere of CO_2, to yield a highly poisonous gas, phosphine. It has rotten fish like smell.

$$P_4 + 3NaOH + 3H_2O \longrightarrow 3NaH_2PO_2 + PH_3\uparrow$$

Its aqueous solution is neutral, so it is not more basic than NH_3.

Phosphorus Trichloride

Its formula is PCl_3.

Method of Preparation

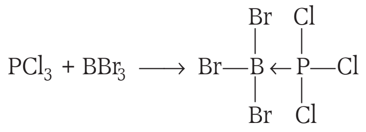
It is obtained when dry Cl_2 is passed over red or white phosphorus heated gently in a retort over a water bath.

$$P_4 + 6Cl_2 \longrightarrow 4PCl_3$$

Physical and Chemical Properties

Important properties of PCl_3 *are as*

1. It is a low boiling liquid (b.p. 74°C) with a pungent odour and fumes in moist air.
2. It violently hydrolysed by water as
$$PCl_3 + 3H_2O \longrightarrow 3HCl + H_3PO_3$$
3. It reacts with chlorine and sulphur chloride as
$$PCl_3 + Cl_2 \longrightarrow PCl_5$$
$$3PCl_3 + SCl_2 \longrightarrow PCl_5 + 2PSCl_3$$
4. It reacts with oxygen and SO_3 as
$$2PCl_3 + O_2 \longrightarrow 2POCl_3$$
$$3PCl_3 + SO_3 \longrightarrow POCl_3 + SO_2$$
5. It gives many substitution reactions as
$$PCl_3 + 3AgCN \longrightarrow P(CN)_3 + 3AgCl$$
$$PCl_3 \xrightarrow{PF_3} PCl_2F + PClF_3$$
6. It forms adduct with BBr_3 as

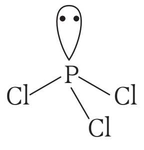


$$PCl_3 + BBr_3 \longrightarrow Br{-}\underset{\displaystyle Br}{\overset{\displaystyle Br}{B}} \leftarrow \underset{\displaystyle Cl}{\overset{\displaystyle Cl}{P}}{-}Cl$$

7. It acts as reducing agent and reduces SO_2Cl_2 and SO_3 to SO_2 and itself gets oxidised to PCl_5 or $POCl_3$. It also reduces $SOCl_2$ and SO_2Cl_2 as :
$$PCl_3 + SO_2Cl_2 \longrightarrow PCl_5 + SO_2$$
$$3PCl_3 + SOCl_2 \longrightarrow POCl_3 + PSCl_3 + PCl_5$$
8. It reacts with finely divided metals when hot as
$$12Ag + 4PCl_3 \longrightarrow 12AgCl + P_4$$
9. It reacts with concentrated H_2SO_4 forming chloro-sulphonic acid as
$$4H_2SO_4 + 2PCl_3 \longrightarrow \underset{\text{chloro-sulphonic acid}}{2HSO_3Cl} + P_2O_5 + 2SO_2 + 4HCl + H_2O$$
10. It reacts with organic compounds containing hydroxyl group.
$$\underset{\text{ethyl alcohol}}{3C_2H_5OH} + PCl_3 \longrightarrow \underset{\text{ethyl chloride}}{3C_2H_5Cl} + H_3PO_3$$
$$\underset{\text{acetic acid}}{3CH_3COOH} + PCl_3 \longrightarrow \underset{\text{acetyl chloride}}{3CH_3COCl} + H_3PO_3$$

Structure of PCl_3

Its structure is similar to ammonia, *i.e.*, it has pyramidal geometry.



Phosphorus Pentachloride

Its formula is PCl_5.

Method of Preparation

It is prepared either by passing dry Cl_2 gas (in excess) over PCl_3 or by the action of SO_2Cl_2 on P_4 or PCl_3..
$$PCl_3 + Cl_2 \longrightarrow PCl_5$$
$$P_4 + 10SO_2Cl_2 \longrightarrow 4PCl_5 + 10SO_2$$

Physical and Chemical Properties

Important properties of PCl_5 *are as follows*

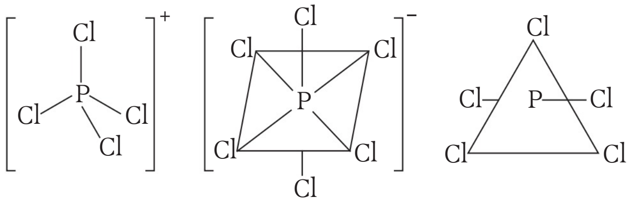
1. It is yellowish white crystalline compound with a sharp odour, m.p. −45°C (under pressure) and sublimation temperature 160°C.
2. It have the ability to dissociate as
$$PCl_5 \rightleftharpoons PCl_3 + Cl_2$$
3. It is violently hydrolysed by water as
$$PCl_5 + H_2O \xrightarrow{\text{Insufficient water}} POCl_3 + 2HCl$$
$$PCl_5 + 4H_2O \xrightarrow{\text{Excess of water}} H_3PO_4 + 5HCl$$
4. It reacts with compounds containing —OH group as
$$CH_3COOH + PCl_5 \longrightarrow CH_3COCl + POCl_3 + HCl$$
$$H_2SO_4 + PCl_5 \longrightarrow \underset{\text{sulphuryl chloride}}{SO_2Cl_2} + 2POCl_3 + HCl$$
5. It reacts with P_4O_{10} as
$$6PCl_5 + P_4O_{10} \longrightarrow 10POCl_3$$
6. It reacts with ammonium chloride as
$$nPCl_5 + nNH_4Cl \xrightarrow{150°C} (NPCl_2)_n + 4nHCl$$
7. It reacts with Cl^- acceptors as
$$PCl_5 + BCl_3 \longrightarrow [PCl_4]^+[BCl_4]^-$$
8. With hydrogen it forms PCl_3 as
$$PCl_5 + H_2 \longrightarrow PCl_3 + 2HCl$$
9. It reacts with KF as
$$PCl_5 + 6KF \longrightarrow KPF_6 + 5KCl$$

Uses

It is used as chlorinating agent in organic chemistry.

Structure of PCl_5

X-ray studies have revealed that solid PCl_5 consists of ionic lattices, *i.e.*, tetrahedral $[PCl_4]^+$ cations and octahedral $[PCl_6]^-$ anions. In vapour state, it has trigonal bipyramidal shape in which P has gone sp^3d hybridisation.



(a) $[PCl_4]^+$ (b) $[PCl_6]^-$ (c) PCl_5 in vapour state

Fig.7.5 Structure of PCl_5 in solid and vapour phase

Sample **Problem 9** *Hydrolytic reaction of* PCl_5 *in heavy water produces.* **[NCERT]**

(a) D_3PO_4 (b) $POCl_3$

(c) *Both* (a) *and* (b) (d) *None of these*

Interpret (a) Here reactions are same as those with water (H_2O). PCl_5 shows following hydrolytic reactions with heavy water (D_2O).

Step I $PCl_5 + D_2O \longrightarrow POCl_3 + 2DCl$

Step II $POCl_3 + 3D_2O \longrightarrow D_3PO_4 + 3DCl$

Overall reaction $PCl_5 + 4D_2O \longrightarrow \underset{\text{deuterio phosphoric acid}}{D_3PO_4} + \underset{\text{deuterium chloride}}{5DCl}$

Oxides of Phosphorus

Phosphorus trioxide exists as a dimer and is formulated as P_4O_6.

Methods of Preparation

When white P is burn in the limited supply of air both P_4O_6 and P_4O_{10} are formed. The vapour of the mixture of oxides are passed through a condensor in which water at 50−60°C is circulated, P_4O_{10} being solid at 60°C separates out easily.

P_4O_{10} is obtained by burning P in a free supply of air or oxygen. The pentoxide formed is purified further by sublimation at 360°C.

Properties and Uses of Oxides of Phosphorus

Among the various pentoxides, P_2O_5 has the strongest affinity for water. It can extract water from several inorganic and organic compounds, thus acts as a strong **dehydrating agent.** It dehydrates H_2SO_4 to SO_3, HNO_3 to N_2O_5, **cellulose** to **carbon** and **amides** to **nitriles.**

Based upon the tetrahedral structure of phosphorus molecule, the tetrahedral structure of P_4O_6 is

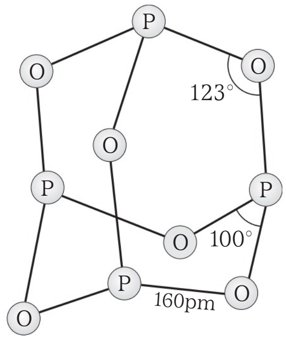


Fig. 7.6 Structure of P_4O_6

This structure has been confirmed by X-ray diffraction data.The oxides As_4O_6, Sb_4O_6 also have tetrahedral structures.

The structure assigned to P_4O_{10} molecule is

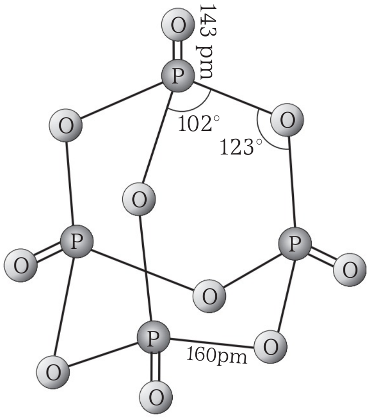

Fig. 7.7 Structure of P_4O_{10}

Hot Spot 1

OXYACIDS of Phosphorus

It is an important topic for JEE Main examination. Questions based upon this topic are generally based upon their basicity and preparation method.

The oxyacids of phosphorus can be grouped into following three series

1. Phosphorous acid series which contains following acids :

- (i) Hypophosphorous acid, H_3PO_2
- (ii) Phosphorous acid, or *ortho*phosphorous acid, H_3PO_3
- (iii) Pyrophosphorous acid, $H_4P_2O_2$
- (iv) *Meta*phosphorous acid, HPO_2

2. Phosphoric acid series, which contains

- (i) Hypophosphoric acid, $H_4P_2O_6$

3. Polyphosphoric acid series with general formula $H_{n-2}\ P_nO_{3n+1}$

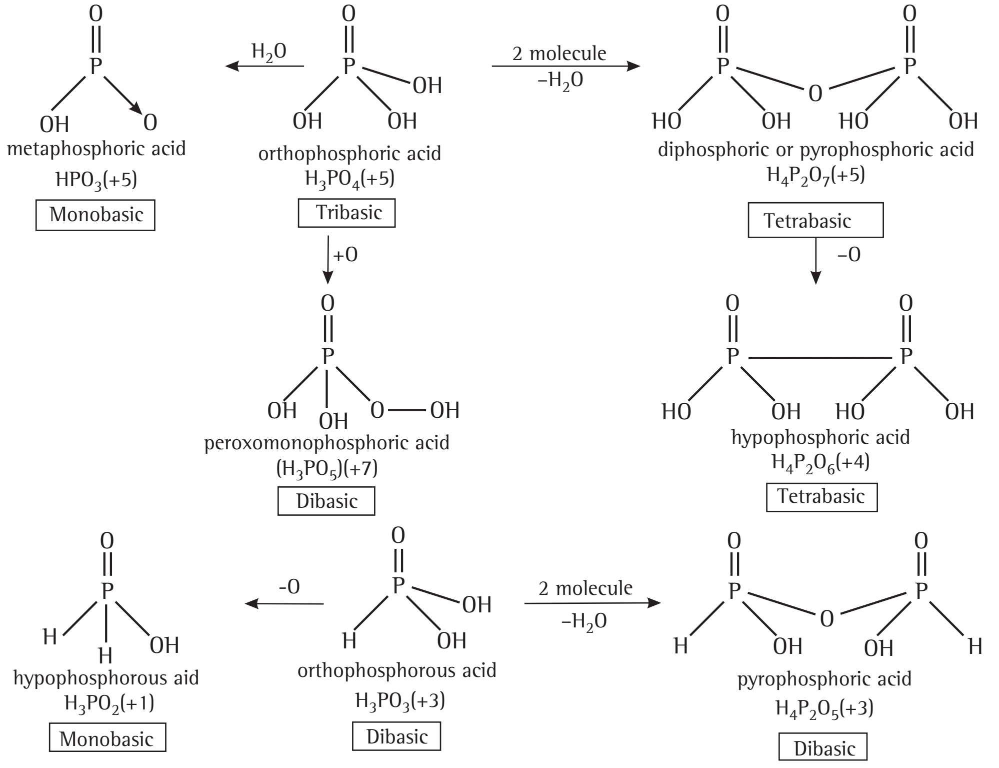
- (i) Diphosphoric acid or pyrophosphoric acid, $H_4P_2O_7$
- (ii) Triphosphoric acid, $H_5P_3O_{10}$
- (iii) Tetraphosphoric acid, $H_6P_4O_{13}$
- (iv) Metaphosphoric acid, HPO_3
- (v) Orthophosphoric acid, H_3PO_4

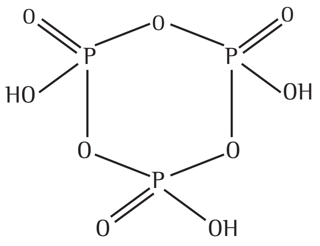
4. Peroxyphosphoric acid series, which contains

- (i) Peroxymonophosphoric acid, H_3PO_5
- (ii) Peroxydiphosphoric acid, $H_4P_2O_8$

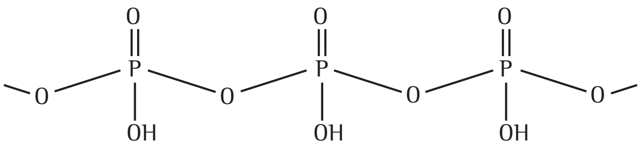
Structure

The structures of some main oxyacids of phosphorus can be summarised as





cyclometaphosphoric acid $(HPO_3)_3$



polymeta phosphoric acid (HPO_3)

The strength and solubility of the oxyacids follow the order,

$$HNO_3 > H_3PO_4 > H_3AsO_4 > H_3SbO_4$$

Some important facts related to oxyacids of phosphorus are

(i) H_3PO_3 is a strong reducing agent but weaker as compared to H_3PO_2.

(ii) $4H_3PO_3 \xrightarrow[-PH_3]{475\text{ K}} 3H_3PO_4 \xrightarrow{520\text{ K}} H_4P_2O_7 \xrightarrow{>520\text{ K}} HPO_3$

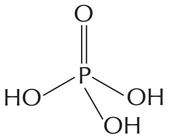
(iii) Aqueous solutions of both pyrophosphoric acid, $H_4P_2O_7$ as well as metaphosphoric acid (HPO_3) on heating give orthophosphoric acid.

Sample Problem 10 *What is the basicity of* H_3PO_4? **[NCERT]**

(a) 1 (b) 2
(c) 3 (d) 4

Interpret (c) Basicity is the number of replaceable H atoms. Only those hydrogen atoms of H_3PO_4 are replaceable which are present as OH, so draw the structure of H_3PO_4 to find the number of P—OH bonds.

The structure of H_3PO_4 is as



From the structure it is clear that it has 3 P—OH bonds which can produce three H^+ ions per molecule of H_3PO_4 in aqueous solution. Hence, basicity is three.

$$\underset{\text{Orthophosphoric acid}}{H_3PO_4} \overset{H_2O}{\rightleftharpoons} 3H^+ + PO_4^{3-}$$

Sample Problem 11 *On reaction with* Cl_2, *phosphorus forms two types of halides 'A' and 'B'. Halide 'A' is yellowish white powder but halide 'B' is colourless oily liquid. Which of the following is/are their hydrolysis products?* **[NCERT Exemplar]**

(I) H_3PO_2 (II) H_3PO_3
(III) H_3PO_4 (IV) H_3PO_4
(a) I *and* II (b) II *and* III (c) III *and* IV (d) I *and* IV

Interpret (a) *'A'* is PCl_5 and *'B'* is PCl_3.

$$P_4 + 10Cl_2 \longrightarrow 4PCl_5$$
$$P_4 + 6Cl_2 \longrightarrow 4PCl_3$$

When *'A'* and *'B'* are hydrolysed

(a) $\underset{\substack{[A]\\ \text{phosphorus}\\ \text{pentachloride}}}{PCl_5} + 4H_2O \longrightarrow \underset{\substack{\text{phosphoric}\\ \text{acid}}}{H_3PO_4} + 5HCl$

(b) $\underset{\substack{[B]\\ \text{phosphorus}\\ \text{trichloride}}}{PCl_5} + 3H_2O \longrightarrow \underset{\substack{\text{phosphrous}\\ \text{acid}}}{H_3PO_3} + 3HCl$

Check Point 1

1. Why does nitrogen not form NCl_5?
2. Why is yellow phosphorus kept under water?
3. Why are vortex rings formed if PH_3 comes in contact with air?
4. While showing oxidising properties, HNO_3 itself gets reduced to different products. Explain.
5. How is orthophosphoric acid related to pyrophosphoric acid?

VIA(16) Group Elements and Their Compounds

7.4 Group 16 Elements

This group contains 5 elements *i.e.*, **oxygen, sulphur, selenium, tellurium** and **polonium** and called **oxygen family**. The first four members are non-metals and collectively known as **chalcogens** (meaning ore forming) as metal ores normally occur in the form of oxides, sulphides etc.

Occurrence

There are three naturally occurring isotopes of oxygen *i.e.*, ${}_8O^{16}$ (99.762%), ${}_8O^{17}$ (0.038%) and ${}_8O^{18}$ (0.200%). Oxygen is most abundant element on earth and constitutes 50% by weight of earth crust. Water contains 88.8% oxygen by weight. Dioxygen (O_2) makes up about 23.2% by weight of atmosphere.

Sulphur occurs in the earth crust to the extent of 0.05% mostly as metal sulphides and sulphates. It also occur (in elemental form) in large underground beds. Se and Te are less abundant than S (0.05 ppm-Se, 0.002 ppm-Te), polonium is radioactive. It occurs in nature in radium minerals such as pitch blend to the extent of 5×10^{-9} %. It is known since, 1898.

General and Physical Properties

Elements of group 16 *shows following trends in their general and physical properties.*

(a) Electronic Configuration

General electronic configuration for the elements of this group is ns^2np^4. (where, $n = 2, 3, 4, 5, \ldots$)

(b) Atomic Volume and Atomic Radii

Both atomic volume and atomic radii increase on moving down the group.

(c) Physical State

Oxygen is a gas while, all other elements exists in solid state.

(d) Ionisation Energy

On moving down the group, the ionisation energy decreases. These elements, however, have lower ionisation energy than the corresponding elements of group 15.

(e) Electronegativity

These elements are more electronegative as compared to the corresponding elements of group 15, and there is seen a steep drop in electronegativity as the atomic size increases. Oxygen is the second most electronegative element of the periodic table and hence, its all compounds (except with fluorine) are called oxides.

(f) Electron Affinity

Electron affinity of these elements also decreases as the atomic size increases. However, electron affinity of O is lesser as compared to S. This is because of the small size and high charge density of O atom.

(g) Nature of Bonding

Oxygen can form ionic as well as covalent compounds but other elements because of their low electronegativity form mainly covalent compounds. Compounds of oxygen with highly electropositive metals like Li, Mg etc., are ionic while with less electropositive metals and non-metals are covalent.

(h) Oxidation State

Oxygen, being highly electronegative, exhibit +2, −2 and −1 oxidation states while other elements show +2, +4 and +6 oxidation states. On moving down the group, the stability of +4 oxidation state increases while that of +6 state decreases due to inert pair effect.

(i) Metallic Character

The first four elements are non-metals but non-metallic character is stronger in oxygen and sulphur. Po is distinctly a metal but it is radioactive and only short lived.

(j) Melting and Boiling Points

On moving down the group, the magnitude of van der Waals' interatomic forces increases and thus, the melting and boiling point increase regularly.

The above physical properties can be summarised in the following table

Table 7.6 **Physical Properties of 16 Group Elements**

Property	Oxygen	Sulphur	Selenium	Tellurium	Polonium
Atomic number	8	16	34	52	84
Atomic mass (amu)	15.999	32.064	78.96	127.60	210
Density in solid state (g cm^{-3})	1.14	2.07	4.79	6.23	9.2
Atomic radius (Å)	0.73	1.09	1.16	1.35	—
Ionic radius (Å) of divalent ion	1.40	1.84	1.98	2.21	—
Atomic volume (cc)	14.0	15.5	16.5	20.5	22.7
Ionisation energy (kJ mol^{-1})	1313.7	999.4	940.9	869.5	813.5
Oxidation states	−2, −1, +2	−2, +2, +4, +6	−2, +2, +4, +6	−2, +2, +4, +6	+2, +4
Electronegativity	3.5	2.5	2.4	2.1	2.0
Melting point (°C)	−218.8	114.0	217.0	449.5	254.0
Boiling point (°C)	−183.0	444.6	685.0	989.8	962
Heat of fusion (kJ mol^{-1})	0.22	1.42	5.3	17.7	11.0
Heat of atomisation (kJ mol^{-1})	250	280	207	197	145

(k) Molecular State

Oxygen exists as O_2 (diatomic gaseous molecule). S and Se occur as S_8 and Se_8 with Puckered ring structure as seen below

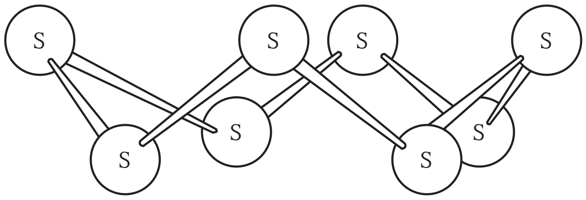


Fig. 7.8 Puckered ring structure of S_8 molecule

The reason for such a difference is the tendency of O–atom to form multiple bonds ($p\pi$ - $p\pi$ bonds) which is missing in the case of sulphur and selenium.

(l) Catenation

Oxygen has some while sulphur has a high tendency to catenate. *e.g.,* H—O—O—H (H_2O_2)., H—S—S—S—S—H (H_2S_4)

(m) Allotropy

Oxygen exist in two allotropic forms-O_2 and O_3. Sulphur exists as–**rhombic** or α**-form, monoclinic** or β**-form, plastic** or γ**-form, colloidal** or δ**-form,** λ**-sulphur** and μ**-sulphur.** Selenium exists in two forms- **red form** and **grey form.** Tellurium exists in two forms- one of which is metallic and other is non-metallic. Polonium exists in two forms namely α and β**-forms** both of which are metallic.

Chemical Properties

Elements of the group form compound with several elements.

The properties of these compounds are described below

(a) Oxides

Among the compounds of group 16 elements the most important ones are oxides. The oxides of metals are basic, that of non-metals are acidic and that of semi-metals are amphoteric in nature. The acidic character of oxides increases across a period from left to right and basic character of oxides increases down a group. The oxides are mainly **monoxides** (AO type)**, dioxides** (AO_2) type and trioxides (AO_3 type). However, sulphur forms heptoxide also with formula S_2O_7. Out of these the oxides of sulphur are most important commercially. The oxides, formed by S, Se, Te and Po are tabulated below.

Table 7.7 **Different Oxides of 16 Group Elements**

S.N.	Type of oxide	S	Se	Te	Po
1.	Monoxide	SO	—	TeO	PoO
2.	Dioxide	SO_2	SeO_2	TeO_2	PoO_2
3.	Trioxide	SO_3	SeO_3	TeO_3	PoO_3
4.	Heptoxide	S_2O_7	—	—	—

Some important facts related to oxides are

(i) All elements except Se forms **monoxides** but all the monoxide are not so stable. Out of these, SO is formed by passing electric discharge through SO_2 while TeO and PoO are formed by heating corresponding trioxides.

(ii) Dioxides are formed by all the members (except oxygen of course). These dioxides differ from each other considerably *e.g.,* SO_2 and SeO_2 are acidic oxides with good solubility in water while TeO_2 and PoO_2 are amphoteric in nature and have poor solubility in water.

(iii) SO_2 has angular structure. SeO_2 in gaseous phase has angular structure but in solid state (white volatile solid) it has polymeric structure comprising of infinite chains as

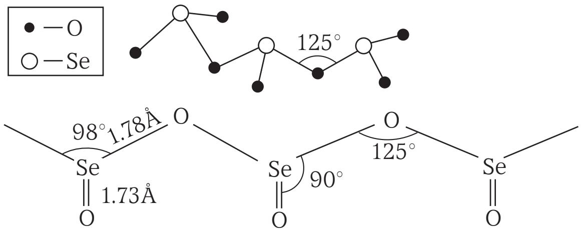

Fig. 7.9 Polymeric structure of SeO_2 in solid state

Dioxides of Te and Po are also non-volatile crystalline ionic solids, out of which TeO_2 has a layer structure consisting of TeO_4 units.

Dioxides show differences in their reaction with water as

(i) SO_2 dissolves in water giving H_2SO_3 (known in solution only).

(ii) SeO_2 gives selenious acid with water which can be isolated in crystalline state.

(iii) TeO_2 is almost insoluble in water. It however dissolves in alkalies (to form tellurites) and in acids (to form basic salts) showing its amphoteric nature.

(iv) PoO_2 shows similar behaviour.

Among trioxides, SO_3 is the most important. They all are acidic in nature, *i.e.,* form acids with water and this nature decreases on moving down the group. SO_3, in gaseous phase exists as planar triangular geometry while in solid state, has linear cyclic trimer or a polymeric chain structure. SeO_3 on the other hand, exists as a cyclic tetramer (Se_4O_{12}) in the solid state as shown below

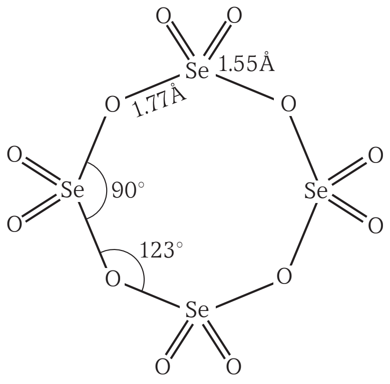

Fig. 7.10 The cycle structure of tetrameric Se_4O_{12}

TeO_2 exists in polymeric form.

(b) **Hydrides**

Group 16 elements form binary hydrides of general formula M_2A (where, A = O, S, Se, Te or Po). The thermal stability of these hydrides decreases from oxygen to polonium. Unlike H_2O, other hydrides are unpleasant foul smelling poisonous gases. The unique behaviour of H_2O is due to extensive intermolecular H–bonding. Hydrides of H_2R_2 type are also known.

Hydrides of S, Se and Te are prepared by the action of metals on metal sulphides, selenides and tellurides respectively. H_2S, H_2Se and H_2Te are weak diprotic acids in aqueous solutions. The acidity increases in the series as $H_2S < H_2Se < H_2Te$. H_2O is neutral in nature. Increase in acidic strength of hydrides can be easily explained on the basis of increase in the size of central atom from oxygen to Te. As the result of such an increase, the length of R–H bond also increases gradually which is always inversely proportional to bond strength. Thus, bond strength decreases.

The other properties of these hydrides are summarised as

Table 7.8 **Properties of Hydrides of Group 16 Elements**

Property	H_2O	H_2S	H_2Se	H_2Te
Melting point (°C)	0	– 85.5	– 65.7	–51.1
Boiling point (°C)	100.0	– 60.75	– 41.5	–1.8
Bond angle H—X—H	104.5°	92.5°	90°	89°
Bond length H—X (Å)	0.95	1.30	1.45	1.72
Dissociation constant as an acid at 25°C	1.0×10^{-14}	1.0×10^{-7}	1.7×10^{-4}	2.3×10^{-3}

As the size of central atom increases, the M—H (M = O to Po) bond becomes weaker and longer. Consequently, the thermal stability decreases. Since, reducing power varies inversely with bond strength, it increases as the bond strength decreases or bond length increases.

First two members of the family also form hydrides of the formula H_2R_2 (*i.e.*, H_2O_2 and H_2S_2). However, these two hydrides differ considerably from each other *e.g.*, H_2O_2 is fairly stable but H_2S_2 is unstable. It decomposes readily to give S and H_2S as

$$H_2S_2 \xrightarrow{OH^-} H_2S + S$$

Similarly, H_2O_2 on account of hydrogen bonding is highly associated while, H_2S_2 forms discrete molecules.

(c) **Halides**

Oxygen forms halides only with fluorine (OF_2 or F_2O-oxygen difluoride) and its compounds with rest of the halogens are called oxides (not halides) as its electronegativity is more than any other halogen. S and other chalcogens form a number of halides.

All the halides of these elements can be tabulated as

Table 7.9 **Halides of Oxygen Family**

	F	Cl	Br	I
O	OF_2, F_2O_2	Cl_2O_6, Cl_2O_7, Cl_2O, ClO_2 etc	Br_2O, BrO_2, BrO_3	I_2O, I_2O_4, I_2O_5
S	S_2F_2, SF_4, SF_6, S_2F_{10}	S_2Cl_2, SCl_2, SCl_4	S_2Br_2	
Se	SeF_2, SeF_4 SeF_6	Se_2Cl_2, $SeCl_4$	Se_2Br_2, $SeBr_4$	
Te	TeF_4, Te_2F_{10}, TeF_6	$TeCl_2$, $TeCl_4$	$TeBr_2$, $TeBr_4$	TeI_4
Po	—	$PoCl_2$, $PoCl_4$	$PoBr_2$, $PoBr_4$	PoI_4

Some important facts related to halides of 16 *group elements are as follows*

(i) The stability of halides decreases in the order F > Cl > Br > I. The highest oxidation state is realised only in fluorides.

(ii) The general preparative routes for chalcogen halides involve the direct reaction of chalcogen with respective halogen *i.e.*,

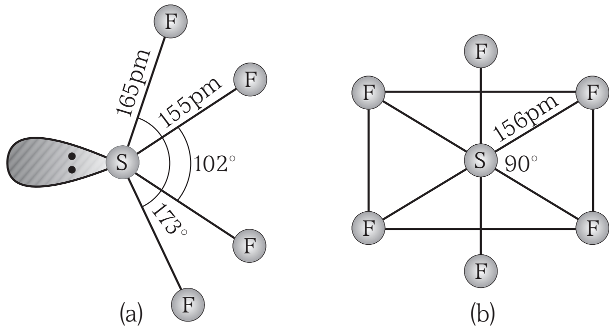
$$\frac{1}{8}S_8(s) + 3F_2(g) \longrightarrow SF_6(g)$$

$$Te\,(s) + 2Cl_2(g) \longrightarrow TeCl_4(s)$$

(iii) Direct fluorination of elemental sulphur yields mainly SF_6 alongwith traces of $SF_4 \cdot SF_4$ is prepared by the fluorination of SCl_2 with NaF in acetonitrile at 350 K as

$$3SCl_2 + 4NaF \xrightarrow{\text{MeCOCN, 350 K}} S_2Cl_2 + SF_4 + 4NaCl$$

(iv) SF_6 is an inert non-toxic gas at room temperature. It is inert due to sterically protected atom. In contrast, less sterically hindered SeF_6 and SF_4 undergo hydrolysis readily.



(a) (b)

Fig. 7.11 The structure of (a) SF_4 (b) SF_6

Compared to sulphur halides, the halides of Se and especially Te adopt oligomeric or polymeric structures in +4 oxidation state, $SeCl_4$, $SeBr_4$, $TeCl_4$, $TeBr_4$ and TeI_4 exist as tetramer while, TeF_4 has polymeric structure.

(v) All hexafluorides have a high degree of covalency and low boiling points.

(vi) The tetrahalides act as Lewis bases (electron donor) and Lewis acids (electron acceptors).

(d) Oxyacids

Among the group, only oxy acids of S, Se and Te are known. S forms many oxy acids while Se and Te forms two oxy acids each.

Some of these oxyacids are given in the following table

Table 7.10 **Oxyacids of S, Se and Te**

S	Se	Te
H_2SO_3 (sulphurous acids)	H_2SeO_3 (selenous acid)	H_2TeO_3 (tellurous acid)
H_2SO_4 (sulphuric acid or oil of vitriol)	H_2SeO_4 (selenic acid)	H_6TeO_6 (telluric acid)
H_2SO_5 (peroxomono sulphuric acid or Caro's acid)		
$H_2S_2O_8$ (peroxodisulphuric acid or Marshall's acid)		

Anomalous Behaviour of Oxygen

Owing to its small size, high charge density and non-availability to *d*-orbitals, oxygen differs from rest of the members in following respects.

1. Oxygen is a diatomic gas while all other members are solid with eight membered puckered ring structure.
2. Most of the compounds of oxygen are ionic and polar covalent due to its high electronegativity.
3. Maximum covalency that can be exhibited by oxygen in its compounds is two while rest of the members can show a maximum covalency of six.
4. Oxygen forms $p\pi$-$p\pi$ multiple bond while, S form $d\pi$-$p\pi$ bonds.
5. Only the hydride of oxygen, *ie*, H_2O is non-poisonous and is a liquid while, the hydrides of other members are poisonous gases.
6. Oxygen is paramagnetic while, rest are not.

Sample Problem 12 *The correct order of thermal stability of the hydrides of group 16 elements is* **[NCERT]**

(a) $H_2Po > H_2Te > H_2Se > H_2S > H_2O$

(b) $H_2O < H_2S > H_2Se > H_2Te > H_2Po$

(c) $H_2O = H_2S = H_2Se = H_2Te = H_2Po$

(d) $H_2O > H_2S > H_2Se > H_2Te > H_2Po$

Interpret (c) Thermal stability ∝ bond dissociation energy,

$$\Delta_{diss}H(H-E)/\text{kJ mol}^{-1} \propto \frac{1}{\text{Size of central atom}}$$

(where, $E = 16$ group elements)

On moving down the group, bond dissociation energy decreases because bond length increases.

Thus, the order of bond dissociation energy is

$$H_2O > H_2S > H_2Se > H_2Te > H_2Po$$

This is also the order of thermal stability.

7.5 Ozone (O_3)

It is formed in the upper layer of atmosphere by the action of UV rays from sun on oxygen. It prevents the UV rays from entering the earth's atmosphere. CFCs, common refrigerants deplete the ozone layer.

Method of Preparation

It is prepared in ozoniser by subjecting dry and cold dioxygen to the action of silent electric discharge.

$$3O_2(g) \xrightleftharpoons{\text{Silent electric discharge}} 2O_3(g)$$

Physical Properties

It is a pale blue gas with a characteristic pungent odour. It condenses to a deep blue liquid (b.p. 161.2 K) and to a violet black solid (m.p. 80.6 K). It is diamagnetic in nature and acts as a powerful oxidising agent due to liberation of O_2. The colour of O_3 is due to intense absorption of red light.

Chemical Properties

Chemical properties of O_3 involves :

1. O_3 is thermodynamically unstable and decomposes to O_2.
$$2O_3 \longrightarrow 3O_2; \quad \Delta G = -163 \text{ kJ mol}^{-1}$$
2. O_3 is an extremely powerful oxidising agent.
$$O_3 + 2H^+ + 2e^- \rightleftharpoons O_2 + H_2O$$
$$O_3 + H_2O + 2e^- \rightleftharpoons O_2 + 2OH^-$$

It oxidises

(i) $3PbS + 4O_3 \longrightarrow 3PbSO_4$

(ii) $6NO_2 + O_3 \longrightarrow 3N_2O_5$

(iii) $S + H_2O + O_3 \longrightarrow H_2SO_4$

(iv) $2KOH + 5O_3 \longrightarrow 2KO_3 + 5O_2 + H_2O$

(Potassium ozonide KO_3 is an orange coloured solid and contains the paramagentic O_3^- ion)

(v) $O_3 + 2KI + H_2O \longrightarrow I_2 + 2KOH + O_2$

The amount of O_3 in a gas mixture can be determined by passing the gas into a KI solution (at a constant pH 9.2 using borate buffer). The iodine that is liberated is titrated with sodium thiosulphate solution.

$$O_3 + 2I^- + H_2O \longrightarrow I_2 + 2OH^- + O_2$$

$$I_2 + 2S_2O_3^{2-} \longrightarrow 2I^- + S_4O_6^{2-}$$

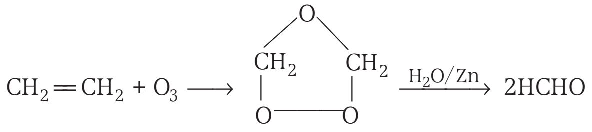
(vi) $3SnCl_2 + 6HCl + O_3 \longrightarrow 3SnCl_4 + 3H_2O$

(vii) $2[Fe(CN)_6]^{4-} + H_2O + O_3 \longrightarrow 2[Fe(CN)_6]^{3-} + O_2 + 2OH^-$

3. O_3 can also be decomposed catalytically and change in volume measured:

$$\underset{\text{(2 volume)}}{2O_3} \longrightarrow \underset{\text{(3 volume)}}{3O_2}$$

4. O_3 also adds to unsaturated organic compounds at room temperature forming ozonides which can be cleaved as aldehydes and ketones in solution.



Uses

Some important uses of ozone are

(i) O_3 is used as a disinfectant.

(ii) It is used to purify drinking water, since it can destroy bacteria and viruses.

(iii) It is better than Cl_2 since, it (O_3) avoids the unpleasant smell and taste of Cl_2 and any excess O_3 soon decomposes to O_2.

(iv) It also absorbs UV light. This is particularly important since, there is a layer of O_3 in the upper atmosphere which absorbs harmful UV radiation from the sun, thus protecting people on the earth. The use of chlorofluorocarbons (CFC) in aerosols and refrigerators, and their subsequent escape into the atmosphere, is blamed for making **holes in the ozone layer** over the Antarctic and Arctic. It is feared that this will allow an excessive amount of UV light to reach the earth which will cause melanoma (skin cancer) in humans. Oxides of nitrogen (from car exhausts) and the halogens can also damage the O_3 layer. Ozone destroying reactions

1. Based on oxides of nitrogen.

$$NO + O_3 \longrightarrow NO_2 + O_2$$
$$O_3 + h\nu \longrightarrow O_2 + O$$
$$NO_2 + O \longrightarrow NO + O_2$$

Net reaction

$$2O_3 + h\nu \longrightarrow 3O_2$$

2. Based on reactive chlorine species from CFC.

$$Cl + O_3 \longrightarrow ClO + O_2$$
$$O_3 + h\nu \longrightarrow O + O_2$$
$$ClO + O \longrightarrow Cl + O_2$$

Net reaction

$$2O_3 + h\nu \longrightarrow 3O_2$$

Structure

Structure of O_3 is best described as a resonance hybrid of following canonical forms

Both the O—O bond here are of equal length, *i.e.,* 128 pm.

Sample Problem 13 *Ozone with* KI *solution produces*

(*a*) IO_3 (*b*) I_2 (*c*) Cl_2 (*d*) HI

Interpret (*b*)

$$\begin{array}{rcl} O_3 & \longrightarrow & O_2 + [O] \\ 2KI + H_2O + [O] & \longrightarrow & 2KOH + I_2 \\ \hline 2KI + H_2O + O_3 & \longrightarrow & 2KOH + I_2 + O_2 \end{array}$$

7.6 Sulphur

It is found in free as well as in combined state. Elemental S mixed with gangue is called **native sulphur**. In combined state, S occurs as sulphides and sulphates in the form of galena (PbS), iron pyrites (FeS_2), gypsum ($CaSO_4 \cdot 2H_2O$) barytes ($BaSO_4$) etc.

Allotropes of sulphur

Sulphur exists in several allotropic forms, The properties of these forms are as follows

1. **Rhombic, octahedral or α-sulphur** is the most common form of sulphur and is stable at temperatures below 95.6°C. Its specific gravity is 2.06. It melts at 114°C. It is soluble in carbon disulphide. Its crystal structure contains cyclic S_8 rings packed in a manner which leads to the formation of rhombic crystals.

2. **Monoclinic, prismatic** or **β-sulphur** is stable above 95.6°C. It is prepared by melting rhombic sulphur in a dish and allowing it to cool until a crust is formed at the surface. On removing the crust, small needle-like crystals of monoclinic sulphur become visible. Its specific gravity is 1.96. It melts at 120°C. It is soluble in carbon disulphide. Like α-sulphur, its crystal structure also contains cyclic S_8 rings but the mode of packing is different than that in α-sulphur. The packing in this case is such that it leads to the formation of monoclinic crystals.

3. γ-**sulphur** is best obtained by decomposing ethylene xanthate of copper (I) in pyridine or by chilling hot solution of sulphur in carbon disulphide. Its crystal structure also consists of cyclic S_8 rings which are packed in lattice in a more compact manner than in the crystals of α or β-sulphur. Its specific gravity is 2.18. γ-sulphur slowly changes into α and β-forms of sulphur.
4. **Colloidal** or δ-**sulphur** is obtained, when hydrogen sulphide is passed through an oxidising solution such as nitric acid, potassium permanganate, etc.

$$2HNO_3 + H_2S \longrightarrow \underset{\substack{\text{colloidal}\\\text{sulphur}}}{S} + 2NO_2 + 2H_2O$$

Colloidal sulphur is also obtained by passing hydrogen sulphide through water containing dissolved sulphur dioxide.

$$2H_2S + SO_2 \longrightarrow 2H_2O + 3S$$

5. **Plastic** or χ-**sulphur** is obtained, when molten sulphur heated to about 350°C is poured into cold water. It is a soft rubber-like mass. It hardens on standing and changes gradually into rhombic sulphur. It is soluble in carbon disulphide and has no sharp melting point. This form is a mixture of allotropes of sulphur containing cyclic S_8 rings and long helical chains of a large number of S atoms. Plastic sulphur can be converted into fibres when it is heated in an atmosphere of nitrogen at 300°C for a few minutes and then quenched in water. Their structure contains open polymeric helical chains of S atoms.

It is also considered as **supercooled liquid,** *i.e.*, the liquid which due to rapid cooling below its freezing point had no time to settle into a crystalline form.

6. Sulphur allotropes containing cyclic S_6, S_7, S_{10}, S_{12}, S_{18} and S_{20} rings are also found. **Cyclohexasulphur** (Engel's sulphur) containing cyclic S_6 rings and can be prepared by the following reaction :

$$S_2Cl_2 + H_2S_4 \longrightarrow S_6 + 2HCl$$

The structure of cyclohexa sulphur consists of closely packed cyclic S_6 rings in chair form. As a result of this close packing the specific gravity (2.2 at −110°C) of this form is higher than specific gravities of all the other forms. This form of sulphur is highly reactive. The cyclosulphurs are quite unstable with the exception of S_{18} and S_{20}.

Properties and Uses

Sulphur is a yellow solid which is tasteless and odourless. It is freely soluble in CS_2, sparingly soluble in alcohol and ether and totally insoluble in water. Its vapours are poisonous for bacteria and fungi but not for other animals or human beings.

Sulphuric Acid (Oil of Vitriol)

In ancient days, it was called **oil of vitriol,** since it was prepared by distilling green vitriol (ferrous sulphate) $FeSO_4 \cdot 7H_2O$.

$$\underset{\text{green vitriol}}{2[FeSO_4 \cdot 7H_2O]} \xrightarrow{\text{Distillation}} Fe_2O_3 + SO_2 + 13H_2O + \underset{\substack{\text{oil of}\\\text{vitriol}}}{H_2SO_4}$$

Methods of Preparation

Sulphur is burnt in air so that it is oxidised to SO_2. SO_2 thus, obtained is oxidised to SO_3 which, when dissolved in H_2O, gives H_2SO_4. The whole process can be summarised as :

$$S \xrightarrow{+O_2} SO_2 \xrightarrow{+\frac{1}{2}O_2} SO_3 \xrightarrow{+H_2O} H_2SO_4$$

Industrial Preparation of H_2SO_4

Sulphuric acid is manufactured these days by the following two processes

1. **Lead chamber process** in which H_2SO_4 is obtained, when a mixture containing SO_2, air and NO is treated with steam (H_2O). In this reaction NO acts as a catalyst.

$$2SO_2 + \underset{\text{(from air)}}{O_2} + 2H_2O + \underset{\text{catalyst}}{[NO]} \rightarrow 2H_2SO_4 + \underset{\text{catalyst}}{[NO]}$$

The steps involved during this process are

Step I **Preparation of SO_2** By heating sulphur or iron pyrites (FeS_2) in the excess of air.

$$S + O_2 \longrightarrow SO_2$$
$$4FeS_2 + 11O_2 \longrightarrow 2Fe_2O_3 + 8SO_2$$

Step II **Oxidation of SO_2 to SO_3 by HNO_3 or by NO_2**

$$2HNO_3 + 2SO_2 \longrightarrow H_2 + NO + NO_2 + 2SO_3$$
$$SO_2 + NO_2 \longrightarrow SO_3 + NO$$

Step III **Preparation of H_2SO_4** By allowing SO_3 obtained in step (II) to react with steam (H_2O).

$$SO_3 + H_2O\text{ (steam)} \longrightarrow H_2SO_4$$

2. **Contact process** *Involves the following steps*

Step I **Preparation of SO_2** By burning sulphur or iron pyrites (FeS_2) in the excess of air.

$$S + O_2 \longrightarrow SO_2$$
$$4FeS_2 + 11O_2 \longrightarrow 2Fe_2O_3 + 8SO_2$$

Step II **Oxidation of SO_2 to SO_3** by the atmospheric O_2 in presence of a catalyst which may be **Pt-asbestos,** V_2O_5 or a mixture of ferric and cupric oxide.

$$2SO_2 + O_2 \overset{V_2O_5}{\rightleftharpoons} 2SO_3;\quad \Delta H = -196.6\text{ kJ}$$

The gases (*i.e.,* SO_2 and O_2) must be purified before allowing them to combine to form SO_3. If they are not purified, the impurities will poison the catalyst used in the reaction. These days V_2O_5 is used as catalyst, as it is cheaper and not poisoned by impurities. The oxidation of SO_2 to SO_3 by atmospheric O_2 as shown at step (II) is a reversible and exothermic process. According to Le Chatelier's principle, the favourable conditions for the maximum yield of SO_3 are

(i) **Low temperature,** since the forward reaction is exothermic, but a minimum temperature of 450°C, called optimum temperature, is needed to get the maximum yield of SO_3. Even at this temperature, the rate of reaction is slow and to accelerate the rate of reaction, a suitable catalyst is required.

(ii) **High pressure,** since the volume of the gaseous product (*i.e.*, SO_3) is less than that of the gaseous reactants (*i.e.*, SO_2 and O_2), But a very high pressure is likely to cause the corrosion of the vessel in which oxidation is carried out. The optimum pressure of 2–3 atmospheres is sufficient for oxidation.

(iii) **Excess of atmospheric** O_2 Maximum yield of SO_3 is obtained when SO_2 and atmospheric O_2 are taken in 2 : 3 ratio.

Step III **Dissolution of SO_3 in 98% H_2SO_4,** to get **oleum,** $H_2S_2O_7$ (fuming sulphuric acid).

$$SO_3 + H_2SO_4 \longrightarrow H_2S_2O_7$$

(**Fuming sulphuric acid** is that acid which contains dissolved SO_3 in it).

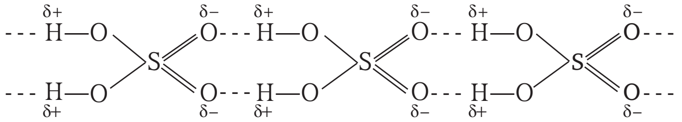
It may be noted that SO_3 cannot be dissolved in water because it produces a dense fog which does not easily condense.

Step IV **Dilution of oleum by water** to get the H_2SO_4 of any desired concentration.

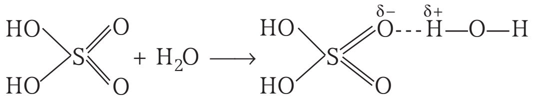
$$H_2S_2O_7 + H_2O \longrightarrow 2H_2SO_4$$

Physical Properties

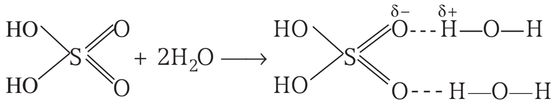
(i) Pure H_2SO_4 is a colourless viscous, heavy and syrupy oily liquid of density 1.84 (at 15°C) which does not fume. It forms a constant boiling mixture with water. This mixture contains 98% H_2SO_4 and its boiling point is 340°C. 95% acid boils at 295°C. High boiling point and high viscosity of H_2SO_4 is due to the fact that H_2SO_4 molecules are associated together by H-bonding as shown below :



(ii) It is highly soluble in water. When water is added to the acid, a large amount of heat is produced and the temperature rises as high as 120°C. The heat produced is so large that the acid spurts out of the container. Therefore, if the acid is to be diluted, the acid should be added to water slowly with constant stirring and not water to the acid. The production of heat is due to the formation of hydrates like $H_2SO_4 \cdot H_2O$ (m.p. = 8.5°C) and $H_2SO_4 \cdot 2H_2O$ (m.p. = 38°C).



monohydrate, $H_2SO_4 \cdot H_2O$



dihydrate, $H_2SO_4 \cdot 2H_2O$

(iii) It is a good conductor of heat and electricity.

Chemical Properties

H_2SO_4 *exhibits the following chemical reactions*

1. (i) **H_2SO_4, when heated undergoes dissociation into steam** (H_2O) **and SO_3**

$$H_2SO_4 \overset{\Delta}{\rightleftharpoons} H_2O \text{ (steam)} + SO_3$$

The dissociation is almost complete at 444°C.

(ii) When the acid vapours are passed through a strongly heated Pt or quartz tube, it gets decomposed into SO_2, steam (H_2O) and O_2.

$$2H_2SO_4 \longrightarrow 2SO_2 + H_2O \text{ (steam)} + O_2$$

2. **The aqueous solution of the acid behaves as a strong dibasic acid,** since it ionises in two stages and gives two H^+ ions.

$$H_2SO_4 \rightleftharpoons H^+ + HSO_4^- \text{ (bisulphate ion)}$$

$$HSO_4^- \rightleftharpoons H^+ + SO_4^{2-} \text{ (sulphate ion)}$$

Thus, H_2SO_4 forms two types of salts which are called bisulphates (*e.g.,* $NaHSO_4$) and sulphates (*e.g.,* Na_2SO_4). The acidic nature of H_2SO_4 is confirmed by the following reactions or properties shown by H_2SO_4 :

(i) H_2SO_4 is sour in taste and turns blue litmus red.

(ii) It neutralises alkalies and forms bisulphates (HSO_4^-) and sulphates (SO_4^{2-}).

$$NaOH + H_2SO_4 \longrightarrow NaHSO_4 + H_2O$$
$$2NaOH + H_2SO_4 \longrightarrow Na_2SO_4 + 2H_2O$$

(iii) It decomposes carbonates and bicarbonates into CO_2.

$$Na_2CO_3 + H_2SO_4 \longrightarrow Na_2SO_4 + H_2O + CO_2$$
$$2NaHCO_3 + H_2SO_4 \longrightarrow Na_2SO_4 + 2H_2O + 2CO_2$$

(iv) Dilute H_2SO_4 usually reacts with all metals (except Pb) such as Al, Sn, Mn, Zn, Fe, Mg etc., evolve H_2 gas.

$$M(M = \text{Zn, Fe, Mg etc.}) + H_2SO_4 \longrightarrow MSO_4 + H_2\uparrow$$

[Less reactive metals like Cu, Ag, Hg, Pb etc, are not attacked by dil H_2SO_4. However, these metals react with hot conc H_2SO_4 (oxidising properties)].

3. H_2SO_4 is a strong acid and hence, decomposes the salts of more volatile acids (*e.g.,* chlorides, nitrates, sulphides, sulphites, carbonates etc.). The more volatile acid is liberated in each case. Some examples are as follows :

$$2NaCl + H_2SO_4 \longrightarrow Na_2SO_4 + 2HCl$$
$$2KNO_3 + H_2SO_4 \longrightarrow K_2SO_4 + 2HNO_3$$
$$FeS + H_2SO_4 \longrightarrow FeSO_4 + H_2S$$
$$Ca_3(PO_4)_2 + 3H_2SO_4 \longrightarrow 3CaSO_4 + 2H_3PO_4$$
$$CaF_2 + H_2SO_4 \longrightarrow CaSO_4 + 2HF$$
$$2NaNO_2 + H_2SO_4 \longrightarrow Na_2SO_4 + \underset{\substack{\downarrow \\ NO + NO_2 + H_2O}}{2HNO_2}$$

4. Hot concentrated H_2SO_4 (not dilute) acts as a **powerful oxidising agent,** since it can lose nascent oxygen quite readily. When H_2SO_4 oxidises any substance, it is reduced to SO_2.

$$\underset{\substack{\text{(hot and} \\ \text{concentrated)}}}{H_2SO_4} \longrightarrow H_2O + SO_2 + [O]$$

Occasionally, H_2SO_4 is also reduced to sulphur, sulphide or H_2S.

$$SO_4^{2-} + 8H^+ + 6e^- \longrightarrow S + 4H_2O$$
$$SO_4^{2-} + 8H^+ + 8e^- \longrightarrow S^{2-} + 4H_2O$$
$$SO_4^{2-} + 10H^+ + 8e^- \longrightarrow H_2S + 4H_2O$$

(i) H_2SO_4 oxidises non-metals like carbon and sulphur to their corresponding oxides *viz,* CO_2 and SO_2.

$$2H_2SO_4 + C \longrightarrow 2H_2O + 2SO_2 + CO_2$$
$$2H_2SO_4 + S \longrightarrow 2H_2O + 3SO_2$$

It oxidises phosphorus to H_3PO_4, since P_2O_5 formed reacts with water to form H_3PO_4.

$$2P + 5H_2SO_4 \longrightarrow 2H_3PO_4 + 5SO_2$$

(ii) Metals like Cu, Ag, Hg, Pb etc., react with hot conc. H_2SO_4 and are oxidised to their oxides which get convert into sulphate. Here, H_2SO_4 is reduced to SO_2 *e.g.,*

$$\begin{array}{rcl} H_2SO_4 & \longrightarrow & H_2O + SO_2 + O \\ Cu + O & \longrightarrow & CuO \\ CuO + H_2SO_4 & \longrightarrow & CuSO_4 + H_2O \\ \hline Cu + 2H_2SO_4 & \longrightarrow & CuSO_4 + SO_2 + 2H_2O \end{array}$$

Some other examples are given below

$$2Ag + 2H_2SO_4 \longrightarrow Ag_2SO_4 + 2H_2O + SO_2$$
$$Hg + 2H_2SO_4 \longrightarrow HgSO_4 + SO_2 + 2H_2O$$
$$Pb + 2H_2SO_4 \longrightarrow PbSO_4 + 2H_2O + SO_2$$

Dil. H_2SO_4 reacts with commercial Zn, evolving H_2. Hot and conc H_2SO_4 attacks Zn, giving off SO_2.

$$Zn + H_2SO_4 \longrightarrow ZnSO_4 + SO_2 + H_2O$$

Moderately conc acid (20%) when heated with Zn metal gives H_2S and precipitates a little sulphur.

$$4Zn + 5H_2SO_4 \longrightarrow 4ZnSO_4 + H_2S + 4H_2O$$
$$3Zn + 4H_2SO_4 \longrightarrow 3ZnSO_4 + S + 4H_2O$$

(iii) H_2SO_4 cannot oxidise HF (or CaF_2) and HCl (or NaCl, KCl etc.) but it can oxidise HBr (or NaBr, KBr) and HI (or NaI, KI) to Br_2 and I_2 respectively. When H_2SO_4 oxidises HBr (or NaBr or KBr), it is reduced to SO_2 but when it oxidises HI (or NaI or KI), it is reduced to SO_2, S or H_2S depending on the amount of HI used in the reaction.

$$H_2SO_4 + 2HBr \longrightarrow SO_2 + 2H_2O + Br_2$$
$$\text{Similarly, } H_2SO_4 + 2HI \longrightarrow SO_2 + 2H_2O + I_2$$
$$H_2SO_4 + 6HI \longrightarrow S + 4H_2O + 3I_2$$
$$H_2SO_4 + 8HI \longrightarrow H_2S + 4H_2O + 4I_2$$

(iv) In presence of Hg (catalyst) naphthalene ($C_{10}H_8$) is oxidised to phthalic acid ($C_8H_6O_4$).

$$9H_2SO_4 + C_{10}H_8 \longrightarrow 10H_2O + 9SO_2 + C_8H_6O_4 + 2CO_2$$

(v) H_2SO_4 oxidises H_2S to S

$$H_2SO_4 + H_2S \longrightarrow 2H_2O + SO_2 + S$$

(vi) H_2SO_4 oxidises H_2 (H = 0) to H_2O(H = +1).

$$H_2SO_4 + H_2 \longrightarrow 2H_2O + SO_2$$

5. **Conc. sulphuric acid is a strong dehydrating agent** It dissolves in water and forms sulphuric acid hydrates, $H_2SO_4 \cdot nH_2O$. Due to this property, conc. H_2SO_4 shows dehydrating properties. Thus, it absorbs water from many organic compounds and dehydrates them. Absorption of water is highly exothermic.

(i) Cane sugar, glucose and starch are dehydrated to carbon.

$$\underset{\text{cane sugar}}{C_{12}H_{22}O_{11}} + H_2SO_4 \longrightarrow \underset{\text{sugar charcoal}}{12C} + \underset{\text{hydrate}}{[H_2SO_4\cdot 11H_2O]}$$

$$\underset{\text{starch}}{(C_6H_{10}O_5)_n} + H_2SO_4 \longrightarrow 6C + [H_2SO_4\cdot 5nH_2O]$$

(ii) Oxalic acid, $(COOH)_2$ is dehydrated to CO and CO_2 and formic acid (HCOOH) gets dehydrated to CO only.

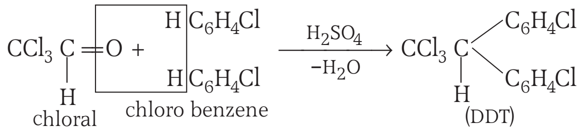
$$(COOH)_2 + H_2SO_4 \longrightarrow CO + CO_2 + [H_2SO_4\cdot H_2O]$$

$$HCOOH + H_2SO_4 \longrightarrow CO + [H_2SO_4\cdot H_2O]$$

(iii) Ethyl alcohol (C_2H_5OH) is dehydrated to diethyl ether.

$$2C_2H_5OH + H_2SO_4 \longrightarrow C_2H_5OC_2H_5 + [H_2SO_4\cdot H_2O]$$

(iv) Dehydration of a mixture of chlorobenzene (C_6H_5Cl) and trichloroacetaldehyde (CCl_3CHO), also called chloral, gives DDT.



It is due to the dehydrating property of conc H_2SO_4 that cloth, wood, starch paper etc [which are largely cellulose $(C_6H_{10}O_5)_x$ materials] get charred in this acid, *i.e.,* conc H_2SO_4 removes water from these substances and thus, chars them. The dehydrating property of conc H_2SO_4 is used :

(i) in drying the gases which do not react with the acid (*e.g.,* Cl_2, SO_2, HCl etc.)

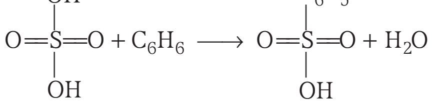
(ii) in many reactions like esterification etc.

(iii) in the manufacture of dyes and explosives.

H_2SO_4 has very corrosive action on skin because it acts as dehydrating agent and absorption of water is accompanied by the release of heat.

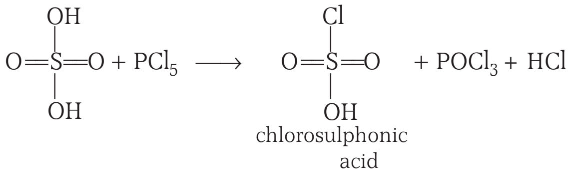
6. The molecule of H_2SO_4 contains two OH groups. One or both these groups can be replaced by other groups or atoms by treating H_2SO_4 with the appropriate compound. *e.g.,* :

(i) When conc H_2SO_4 is heated with C_6H_6, one OH group of H_2SO_4 is replaced by phenyl group (C_6H_5) and benzene sulphonic acid, $C_6H_5(OH)SO_2$ (also called benzene sulphuric acid) is obtained.

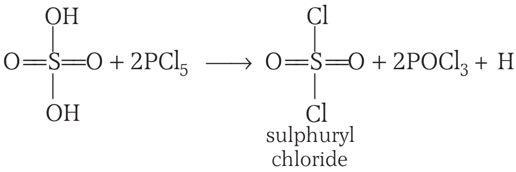


$$O{=}S(OH)_2{=}O + C_6H_6 \longrightarrow O{=}S(C_6H_5)(OH){=}O + H_2O$$

(ii) One or both the —OH groups of H_2SO_4 can be replaced by Cl-atom when H_2SO_4 is treated with PCl_5.



$$O{=}S(OH)_2{=}O + PCl_5 \longrightarrow \underset{\text{chlorosulphonic acid}}{O{=}S(Cl)(OH){=}O} + POCl_3 + HCl$$



$$O{=}S(OH)_2{=}O + 2PCl_5 \longrightarrow \underset{\text{sulphuryl chloride}}{O{=}S(Cl)_2{=}O} + 2POCl_3 + HCl$$

(iii) One Cl-atom can also be replaced by the action of $POCl_3$ on it. Thus, the action of $POCl_3$ on H_2SO_4 produces chlorosulphonic acid.

$$2O_2S(OH)_2 + POCl_3 \longrightarrow 2Cl\cdot SO_2\cdot OH + HCl + HPO_3$$

7. **On heating** $KClO_3$ with conc. H_2SO_4, ClO_2 is evolved with explosion.

$$3KClO_3 + 3H_2SO_4 \xrightarrow{\Delta} 3KHSO_4 + HClO_4 + 2ClO_2 + H_2O$$

8. H_2SO_4 when treated with P_2O_5, loses water which combines with **P_2O_5 and forms HPO_3**.

$$H_2SO_4 \xrightarrow{-H_2O} H_2O + SO_3$$

$$H_2O + P_2O_5 \longrightarrow 2HPO_3$$

$$\overline{H_2SO_4 + P_2O_5 \longrightarrow SO_3 + 2HPO_3}$$

Uses

Sulphuric acid is used

1. as a laboratory reagent.
2. for preparation of important acids such as HCl, HNO_3, H_3PO_4.
3. for making of fertilizers.
4. for sulphonation of organic compounds.
5. for making of lead storage batteries.
6. in the purification of petrolium.

Sample **Problem 14** *Hot conc.* H_2SO_4 *acts as moderately strong oxidising agent. It oxidises both metals and non-metals. Which of the following element is oxidised by conc.* H_2SO_4 *into two gaseous products?* [NCERT]

(*a*) Cu

(*b*) S

(*c*) C

(*d*) Zn

Interpret (*c*) $2H_2SO_4 + Cu \longrightarrow CuSO_4 + SO_2\uparrow + 2H_2O$

$$2H_2SO_4 + S \longrightarrow 2H_2O + SO_2\uparrow$$

$$2H_2SO_4 + C \longrightarrow 2H_2O + 2SO_2\uparrow + CO_2\uparrow$$

$$4H_2SO_4 + Zn \longrightarrow ZnSO_4 + SO_2\uparrow + H_2O$$

Hot Spot 2

OXYACIDS OF Sulphur

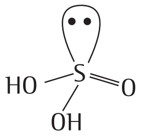
It is an important topic for JEE Main examination. Question of this topic are generally based upon their structures or oxidation state and their level vary from easy to moderate.

Sulphur shows following oxyacids

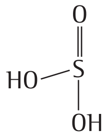
1. Sulphurous acid, H_2SO_3
2. Sulphuric acid or oil of vitroil, H_2SO_4
3. Peroxomono sulphuric acid or Caro's acid, H_25O_5
4. Peroxodisulphuric acid or Marshall's acid, $H_2S_2O_8$
5. Thiosulphuric acid, $H_2S_2O_3$
6. Dithionic acid, $H_2S_2O_5$
7. Pyrosulphuric acid or oleum or disulphuric acid, $H_2S_2O_7$

Among the above written acids, H_2SO_3 (sulphurous acid) and oil of vitriol, *i.e.*, H_2SO_4 are of commercial importance.

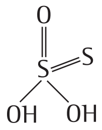
The structure of some of oxyacids of sulphur with their oxidation states are given below



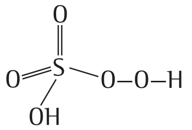
$H_2SO_3(+4)$
(strong reducing agent)



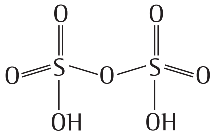
$H_2SO_4(+6)$
(strong dehydrating agent)



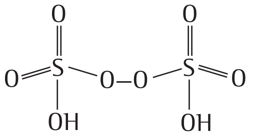
$H_2S_2O_3(+2)$
(reducing agent)



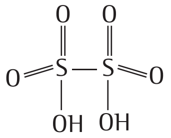
$H_2SO_5(+6)$
(strong oxidising agent)



$H_2S_2O_7(+6)$
(strong oxidising agent)



$H_2S_2O_8(+6)$
(strong oxidising agent)

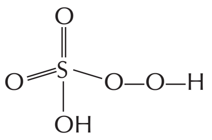


$H_2S_2O_6(+5)$
(oxidising agent)

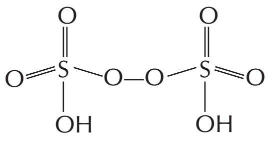
Sample **Problem 15** *Which of the following are peroxoacids of sulphur?* [**NCERT**]

(a) H_2SO_5 *and* $H_2S_2O_8$ (b) H_2SO_5 *and* $H_2S_2O_7$
(c) $H_2S_2O_7$ *and* $H_2S_2O_8$ (d) $H_2S_2O_6$ *and* $H_2S_2O_5$

Interpret (a) In peroxoacids, —O—O— linkage is present H_2SO_5 and $H_2S_2O_8$ are peroxoacids of sulphur.



H_2SO_5
peroxomonosulphuric acid or Caro's acid



$H_2S_2O_8$
peroxodisulphuric acid or Marshall's acid

Check Point 2

1. Why does oxygen exist as O_2 but sulphur as S_8 molecule?
2. H_2S is a gas while H_2O is liquid at room temperature. Explain.
3. Explain, why does addition of HNO_3 to concentrated H_2SO_4 result in the formation of NO_2^+ and NO_3^- ions? How could one test experimentally that such ions exist in H_2SO_4 solution?
4. SO_2 can act as an oxidising agent as well as reducing agent while, SO_3 can act as an oxidising agent. Account for it.
5. SO_2 is a more powerful reducing agent in alkaline medium than in acidic medium. Explain.

Group 17 Elements and Their Compounds

7.7 Group 17 Elements

This group consists of five elements namely **fluorine** (F), **chlorine** (Cl), **bromine** (Br), **iodine** (I) and **astatine** (At). These elements are also called **halogen** (means sea salts), *i.e.,* their salts are abundantly present in sea water.

Occurrence

They do not occur free in nature but in combined state these occur abundantly. Astatine is radioactive and occur very sparsely. These are mainly found as metal halides although iodine also occurs as iodate (IO_3^-). Chlorine is most abundant among halogen and its commercial source is NaCl (common salt). Sources of halogens and their abundance are seen as

Table 7.11 **Sources of Halogens**

Halogen	Abundance		Main sources
	Crystal rocks	Oceans	
Fluorine	5.44×10^{-2}	7.0×10^{-6}	Fluorspar (CaF_2), Fluorapatite [$Ca_5(PO_4)_3F$], Cryolite (Na_3AlF_6) etc.
Chlorine	1.26×10^{-2}	1.9	Sea water, salt wells, salt beds (NaCl, KCl, $MgCl_2$, $CaCl_2$) etc.
Bromine	0.25×10^{-3}	6.5×10^{-3}	Sea water, salt lakes (NaBr, KBr, $MgBr_2$) etc.
Iodine	4.6×10^{-5}	5.0×10^{-6}	Brine wells, sea weeds (I^-), chile salt petre ($NaIO_3$ present as impurity) etc.

General and Physical Properties

Trends of general and physical properties exhibited by these elements are as follows

(a) Electronic Configuration

The general electronic configuration of halogens is ns^2p^5 (where, $n = 2, 3, 4, \ldots$). Due to the presence of 7 electrons in their valence shell, these elements have a high tendency to gain one electron and achieve nearest noble gas configuration.

(b) Atomic and Ionic Radii

Halogens have small atomic radii than the elements of group 16th due to increased effective nuclear charge. On moving down the group, it increases as the number of shells increases by one.

(c) Physical State

On moving down the group, the tendency to form condensed molecules increases. Thus, fluorine and chlorine are gases at ordinary temperature, bromine is a highly fuming liquid while iodine is a volatile solid.

(d) Melting and Boiling Points

On moving down from F to At, there is an increase in melting and boiling points. This is because van der Waals' forces increase as the size increases.

(e) Ionisation Energy

They all have high ionisation energy, *i.e.,* have a little tendency to lose electrons. On moving down the group this tendency and thus, the ionisation energy decreases. Iodine because of the lowest IE, has some tendency to form I^+ ion as it forms compounds like ICl, ICN, etc, which in molten state conduct electricity showing the existence of I^+ cation.

(f) Electronegativity

Halogens have the high values of electronegativities and on moving downward from F to I, electronegativity decreases. Thus, fluorine has the maximum value of electronegativity. As a result of the decrease of electronegativity, the non-metallic character increases from F to I. Hence, somewhat metallic character is observed in iodine, *e.g.,* it forms in a few cases a positive ion and has a metallic lustre.

(g) Electron Gain Enthalpy

These elements have maximum electron gain enthalpies in their respective periods because they have only one electron less than ns^2np^6 configuration. On moving down the group the magnitude of electron gain enthalpy (*i.e.,* electron affinity) usually decreases. But electron affinity of fluorine is unexpectedly lower than Cl. This is because of the smaller size of F. As a result of which the incoming electron does not feel much attraction but feels somewhat repulsion. Chlorine has the highest electron affinity in the periodic table.

(h) Molecular State

Halogens exist as diatomic covalent molecules. In between their atoms weak van der Waals' forces exist. On account of which, the halogens are volatile in nature. With the increase in size, these forces increase and hence, change in physical state occurs from gas (F_2 and Cl_2) to solid (I_2).

(i) Oxidation State

When a halogen atom combines with an element of lesser electronegativity, it shows −1 oxidation state. On the other hand, when it combines with an element having higher electronegativity, it exhibits +1 oxidation state. However, F being most electronegative always shows −1 oxidation state. Other elements show +3, +5 and +7 oxidation states also due to the presence of vacant *d*-orbitals in their valence shell.

(j) Solubility

Halogens, being non-polar molecules, do not dissolve to a considerable extent in a polar solvent like water. However, fluorine reacts with water readily and forms mixture of oxygen and ozone as

$$2F_2 + 2H_2O \longrightarrow 4HF + O_2$$
$$3F_2 + 3H_2O \longrightarrow 6HF + O_3$$

Cl_2, Br_2 and I_2 are more soluble in non-polar solvents like $CHCl_3$, paraffins etc and give yellow, brown and violet colour respectively in chloroform or carbon tetrachloride. In non-polar solvents, halogens exist as free molecules while in nucleophilic solvents like alcohols, liquid SO_2 etc halogens produce brown solution due to the formation of complex. I_2 is more soluble in KI solution due to the formation of KI_3 (I_3^- ion), which also increases its solubility in water.

(k) Oxidising Power

Standard reduction potentials of halogens are positive and decrease down the group. Thus, halogens act as strong oxidising agents and their oxidising power decreases from fluorine to iodine. The strength of an oxidising agent depends on several energy terms as

$$E = \frac{1}{2} H_f + \frac{1}{2} H_{\text{ev}} + \frac{1}{2} H_d - EA - H_{\text{hyd.}}$$

where, H_f = enthalpy of fusion
H_{ev} = enthalpy of evaporation
H_d = enthalpy of dissociation
H_{hyd} = enthalpy of hydration
EA = electron affinity

The value of E decreases from fluorine to iodine. Hence, fluorine is the strongest oxidising agent.

(l) Nature of Bonds

Halogens due to the presence of seven electrons in their valence shell, are highly reactive and form ionic compounds with highly electropositive metals readily. However, with weakly electropositive metals and non-metals, they form covalent bonds. F being most electropositive, form ionic compounds with less electropositive metals.

(m) Bond Dissociation Energy

With the increase of size, the bond length increases from fluorine to iodine. Since, the bond length of fluorine is minimum, its bond dissociation energy should be highest. However, the bond dissociaition energy of fluorine is less than Cl—Cl and Br—Br. It is due to the high interelectronic repulsions between non-bonding electrons in the 2*p*-orbitals of fluorine. Consequently, F—F bond becomes weaker in comparison to Cl—Cl and Br—Br bonds.

(n) Colour

All the halogens are coloured and as the atomic number increases, the colour get deepens.

F	Cl	Br	I
light yellow	yellow green	reddish brown	deep violet

The colour is because of the absorption of energy from visible light by the halogen molecules for excitation of outer electrons to higher energy levels. Fluorine absorbs violet portion of the light and thus, appears yellow while iodine absorbs yellow and green portions of the light and thus, appears violet. Thus, it is clear that on moving down the group the colour changes. This is called **blue shift** or **bathchromic shift.**

The physical properties described above can be summarised as

Table 7.12 **Physical Properties of Halogens**

Property	Fluorine	Chlorine	Bromine	Iodine
Atomic number	9	17	35	53
Atomic mass (u)	18.998	35.453	79.909	126.904
Physical state	Gas	Gas	Liquid	Solid
M.P. (°C)	–218.6	–101.0	–7.2	113.9
B.P. (°C)	–188.1	–34.6	59.5	185.2
Density in liquid state ($g\,cm^{-3}$)	1.108	1.1557	2.948	3.76 (in solid state)
Colour of vapour	Pale yellow	Greenish yellow	Orange red	Violet
Colour of liquid	Clear yellow	Amber yellow	Reddish brown	Shining dark solid
Atomic radius (Å)	0.72	0.99	1.14	1.33
Ionic radius of X^- ion (Å)	1.33	1.84	1.96	2.20
Atomic volume (cc)	17.1	18.7	23.5	25.7
Electronegativity	4.0	3.0	2.8	2.5
Electron affinity ($kJ\,mol^{-1}$)	332.6	348.6	324.5	295.5

Property	Fluorine	Chlorine	Bromine	Iodine
Ionisation energy (kJ mol^{-1})	1680.8	1255.5	1142.8	1008.3
Oxidation states	–1	–1, +1, +3, +4, +5, +6, +7	–1, +1, +3, +4, +5, +6	–1, +1, +3, +4, +5, +6, +7
Bond energy (kJ mol^{-1})	158.8	242.6	192.8	151.1
Standard electrode potential (volt)	+2.8	+1.36	+1.08	+0.54

Chemical Properties

Halogens are most reactive non-metals and their reactivity decreases on moving down the group. The important factors that are responsible for the low reactivity of fluorine are (i) the small size and (ii) the highest electronegativity of fluorine.

(a) Reaction with Water

Fluorine decomposes water very readily even at low temperaure and in dark forming mixture of O_2 and O_3, Cl_2 decomposes water in the presence of sunlight while bromine decomposes water very slowly in presence of sunlight. Iodine, however, does not decompose water.

(b) Reaction with Hydrogen

All the halogens react with hydrogen to form volatile covalent hydrides, of formula H*X*. Since, H-atom has less electronegativity than each of the halogens, the oxidation state of H in these compounds is +1 and that of halogen is −1. It is the positive oxidation state of H and negative oxidation state of halogens due to which these compounds are called hydrogen halides (H^+X^-). Since, these compounds ionise in aqueous solution to produce H^+ (or H_3O^+) these are also called **'halogen acids'.**

$$HX + H_2O \longrightarrow H_3O^+ + X^-$$

These compounds are also known by other names like **hydroacids** or **hydrohalic acid** etc. The reactivity of halogens towards hydrogen decreases from fluorine to iodine. These are colourless, irritating gases at room temperature.

As we move down the group, boiling point increases with increase in size of halogen. However, boiling point of HF is abnormally high due to H-bonding.

Acidic character and reducing character of these hydrides increase on moving from F to I.

(c) Reaction with Metals and Non-metals

Halogens combine with metals and non-metals to form halides such as $MgBr_2$, XeF_6, PCl_3, PCl_5, SF_6 etc. The ionic character of *M*—*X* bond decreases as the size of halogen atom increases.

$$M\text{—F} > M\text{—Cl} > M\text{—Br} > M\text{—I}$$

(d) Reaction with Oxygen

Halogens form binary compounds with oxygen but most of them are unstable. Fluorine forms only two binary compounds, *i.e.*, OF_2 and O_2F_2 (called **oxygen fluorides).** Chlorine, bromine and iodine form oxides in which the oxidation state of halogen varies from +1 to +7. *e.g.*,

Anomalous Behaviour of Fluorine

Fluorine also, because of its small size, high charge density, non-availability of *d*-orbitals and low bond dissociation energy differs from the rest of the halogens in following characteristics

1. Fluorine shows only −1oxidation state due to its maximum electronegativity, whereas the other halogens can show negative as well as positive oxidation state, *i.e.*, between −1 and +7.
2. Maximum covalency of fluorine is one as there is no *d*-orbital in its valence shell. Other members can have maximum covalency of 7 because of vacant *d*-orbitals.
3. Fluorine because of its low bond dissociation energy is very reactive. However, in Cl_2 and Br_2, *X*—*X* bond is stronger.
4. HF has a high tendency to form H-bond, thus, it is a liquid (b.p. 19°C) while HCl, HBr and HI due to lack of such a tendency, are gases under ordinary conditions.
5. Hydrofluoric acid being a dibasic acid (H_2F_2), forms two series of salt such as $NaHF_2$, Na_2F_2 while HCl, HBr and HI are monobasic in nature.
6. Mostly fluorides are ionic and contain F^- ion while other halides have frequently molecular lattices.
7. Fluorine when combines with sulphur, forms SF_6 while no other halogen forms the hexahalide with sulphur.
8. Fluorine does not form any oxo acid but other halogens form a number of oxyacids.
9. Fluorides are more stable than corresponding chlorine compounds.
10. Fluorine does not form polyhalides like F_3^- but other halogens do so, *e.g.*, I_3^-, Br_3^- etc.

7.8 Compounds of Elements of Group 17

Being highly reactive, halogens form several compounds but we will study some important of them which are also included in the syllabus.

Halogen Acids

Methods of Preparation

Halogen acids are prepared by the following methods

1. **By the direct combination of H_2 and** X_2 (X = Cl, Br, I) **under different conditions,**
   (i) HCl is produced by burning Cl_2 in the excess of H_2 or by the action of H_2 on Cl_2 in presence of sunlight.

$$Cl_2 + H_2(\text{excess}) \xrightarrow{\text{Burn}} 2HCl$$

$$Cl_2 + H_2 \xrightarrow{\text{Sunlight}} 2HCl + \text{heat}$$

   (ii) HBr can be prepared by passing a mixture of H_2 and Br_2 over a platinum spiral heated to redness by an electric current.

$$H_2 + Br_2 \xrightarrow[\text{Pt spiral}]{\text{Heat}} 2HBr$$

   (iii) HI can be prepared in small quantities by passing H_2 and I_2 vapours over red hot fine platinum.

$$H_2 + I_2 \underset{\text{Pt}}{\overset{\text{Heat (450°C)}}{\rightleftharpoons}} 2HI$$

2. **By heating an appropriate halide with conc. H_2SO_4 or conc. H_3PO_4.**
   (i) HF and HCl can be prepared by heating CaF_2 and NaCl respectively with conc H_2SO_4.

$$CaF_2 + H_2SO_4 \xrightarrow{\Delta} CaSO_4 + 2HF$$

$$2NaCl + H_2SO_4 \xrightarrow{\Delta} Na_2SO_4 + 2HCl$$

   (ii) When NaBr (or KBr) and NaI (or KI) are heated with conc. H_2SO_4, HBr and HI are produced respectively.

$$2MBr(M = \text{Na, K}) + H_2SO_4 \xrightarrow{\Delta} M_2SO_4 + 2HBr$$

$$2MI(M = \text{Na, K}) + H_2SO_4 \xrightarrow{\Delta} M_2SO_4 + 2HI$$

The HBr and HI so formed react with conc. H_2SO_4 and are oxidised to Br_2 and I_2 respectively. These acids are consumed and hence, are not obtained. In other words, we can say that HBr and HI cannot be prepared by the action of their halides on conc. H_2SO_4.

$$2HBr + H_2SO_4 \longrightarrow SO_2 + 2H_2O + Br_2$$
$$2HI + H_2SO_4 \longrightarrow SO_2 + 2H_2O + I_2$$
$$6HI + H_2SO_4 \longrightarrow S + 4H_2O + 3I_2$$
$$8HI + H_2SO_4 \longrightarrow H_2S + 4H_2O + 4I_2$$

Now as HBr and HI are not able to reduce conc H_3PO_4, these acids are obtained by heating NaBr and NaI respectively with conc H_3PO_4.

$$3NaBr + H_3PO_4 \xrightarrow{\Delta} Na_3PO_4 + 3HBr$$

$$3NaI + H_3PO_4 \xrightarrow{\Delta} Na_3PO_4 + 3HI$$

3. **By the action of water on a mixture of red phosphorus and Br_2 or I_2** (for HBr and HI) *e.g.,* HBr and HI can be prepared in the laboratory by slowly pouring water from a dropping funnel, fitted to a flask containing a mixture of red phosphorus (1 part) and Br_2 or I_2 (20 parts).

$$8H_2O + 2P + 5Br_2 \longrightarrow 10HBr + 2H_3PO_4$$
$$8H_2O + 2P + 5I_2 \longrightarrow 10HI + 2H_3PO_4$$

Methods of Preparation of only HCl

1. HCl can be prepared in the laboratory by heating NaCl with conc. H_2SO_4.

$$2NaCl + H_2SO_4 \xrightarrow{\Delta} Na_2SO_4 + 2HCl$$

The gas HCl obtained as above cannot be dried over P_2O_5 or quick lime (CaO), since HCl reacts with both of these substances.

$$2P_2O_5 + 3HCl \longrightarrow POCl_3 + 3HPO_3$$
$$CaO + 2HCl \longrightarrow CaCl_2 + H_2O$$

2. Pure HCl is obtained by the action of water on $SiCl_4$. (hydrolysis $SiCl_4$).

$$SiCl_4 + 2H_2O \longrightarrow SiO_2 + 4HCl$$

3. Considerable quantities of HCl are obtained as a by-product in the manufacture of Na_2CO_3 from NaCl by **Le-Blanc process.**

Physical Properties of Halogen Acids

1. Hydrofluoric acid exists as a dimeric molecule, (H_2F_2) even in the gaseous state because of intermolecular H-bonding. Due to its dimeric nature, H_2F_2 gives two types of salts which contain HF_2^- and F_2^{2-} ions.

$$2HF \rightleftharpoons HF_2^- + H^+$$

$$HF_2^- \rightleftharpoons F_2^{2-} + H^+$$

Salts (*e.g.,* Na_2F_2 or NaF), which contain F_2^{2-} or F^- ions, are called **"normal salts"** while those (*e.g.,* $NaHF_2$) which contain HF_2^- ions are known as *"acid salts". As an acid,* H_2F_2 *is weaker than* H_3PO_4, *but stronger than* HNO_2.

Other HX molecules (X = Cl, Br, I) are monomeric and hence, form only one type of salts, which contain X^- ion.

$$\text{H}X \rightleftharpoons \text{H}^+ + X^-$$
$$(X = \text{Cl, Br, I})$$

2. Anhydrous HF is a liquid at ordinary temperature and fumes strongly in air, while each of the remaining hydrogen halides, is a colourless gas, with pungent smell and acidic taste.
3. As the size of the halogen atom increases from F to I, **H—*X* bond length in H*X* molecules also increases from H—F to H—I** (HF < H—Cl < H—Br < H—I). The increase in H—*X* bond length decreases the strength of H—*X* bond from H—F to H—I (H—F > H—Cl > H—Br > H—I). Due to successive decrease in the strength of H—*X* bond from H—F to H—I, thermal stability of H*X* (HF > HCl > HBr > HI). Maximum thermal stability of HF is also evident from the fact that this acid is not oxidised even by strong oxidising agents.
4. As we move down the group from HF to HI, the magnitude of van der Waals' forces increases and hence, the boiling point of the hydrides should increase as HF < HCl < HBr < HI. But, this order is not correct. Actually boiling point first decreases from HF to HCl and then increases until we reach HI. The anomaly is due to the presence of H-bonding in HF.
5. HF is the least volatile and HCl is the most volatile. The least volatility of HF molecule is due to much stronger H—F bond and association of HF molecules to form dimer, H_2F_2 through H-bonding. The maximum volatility of HCl is due to its monomeric nature and less strength of H—Cl bond in HCl molecule.
6. All the hydrogen halides are highly soluble in water and give a constant boiling mixture, which is called azeotropic mixture. The azeotropic mixture of each acid contains a particular weight-percentage of the acid and boils at a fixed temperature. The dilute solution of the acid cannot be concentrated by boiling it beyond the weight-percentage of the acid. Dilute solution of HCl cannot be concentrated by boiling beyond 20.2%.
7. All the halogen acids are neither combustible nor supporter of combustion *i.e.*, they are incombustible and non-supporter of combustion.
8. H—*X* bond in gaseous H*X* molecules is largely covalent and has very small amount of ionic character. The covalent character of H—*X* bond is also confirmed by the fact that melting and boiling points of hydrogen halides are low and pure liquid halides are poor conductors of electricity. The ionic character of H–*X* bond in gaseous H*X* molecules is in the order :

   H—F > H—Cl > H—Br > H—I. This order shows that HF is the most ionic and HI is the least.

   The above order of the ionic character of H—*X* bond in gaseous H*X* molecules has been explained on the basis of

   (i) electronegativity difference value, $(\chi_X - \chi_H)$.
   (ii) dipole moment values of H*X* molecules.
   (iii) polarisation in between cations and anions (see chemical bonding).

Acidic Nature of Hydrogen Halides

H*X* molecules in the gaseous state are essentially covalent and hence, are not able to ionise to yield proton (H^+) but in aqueous solution, they give hydrated proton, $H^+(aq)$ and hence, act as Bronsted acids.

$$\text{H}X(g) + \text{H}_2\text{O} \longrightarrow \text{H}_3\text{O}^+ + X^-(aq)$$

The acidic strength (*i.e.,* proton releasing power) of halogen acids in aqueous solution is in the order :

$$\text{HF}(aq) < \text{HI}(aq) < \text{HCl}(aq) < \text{HBr}(aq)$$

However, the relative order of the acidic strength of HX molecules, in methanol solvent, has been found as

$$\text{HF} < \text{HCl} < \text{HBr} < \text{HI}$$

Sample Problem 16 *Afinity for hydrogen decreases in the group from fluorine to iodine. Which of the halogen acids should have highest bond dissociation enthalpy?* **[NCERT]**

(*a*) HF (*b*) HCl
(*c*) HBr (*d*) HI

Interpret (*a*) As the size of the halogen atom increases from F to I, H—*X* bond length in H*X* molecules also increases from H—F to HI (HF < HCl < HBr < HI). The increase in H*X* bond length decreases the strength of H*X* bond from HF to HI (HF > HCl > HBr > HI). Due to decrease in the strength of H*X* bonds, H*X* bond dissociation enthalpy decreases from HF to HI.

HX	HF	>	HCl	>	HBr	>	HI
Bond dissociation enthalpy (kJ/mol)	574.0		428.1		362.5		294.6

The important properties of halogen acids are summarised as

Table 7.13 **Properties of Halogen Acids**

S.N.	Property	HF	HCl	HBr	HI
1.	Monomeric or dimeric	Dimeric (H_2F_2)	Monomeric (HCl)	Monomeric (HBr)	Monomeric (HI)

Chemical Properties of Halogens Acids

Following reactions are common to halogen acids

1. Anhydrous hydrofluoric acid does not show acidic property and hence, does not attack metals except potassium. However, its concentrated solution shows acidic character. A concentrated solution of H_2F_2 reacts with metals (*e.g.,* Zn), their hydroxides, carbonates, oxides etc to form metallic fluorides.

$$\mathrm{Zn + H_2F_2 \longrightarrow ZnF_2 + H_2}$$
$$\mathrm{2NaOH + H_2F_2 \longrightarrow Na_2F_2 + 2H_2O}$$
$$\mathrm{B_2O_3 + 3H_2F_2 \longrightarrow 2BF_3 + 3H_2O}$$

The aqueous solution of HCl, HBr and HI show acidic nature and hence, turn blue litmus red. Each of them reacts with metals, their hydroxides, carbonates, oxides etc to form metallic halides as

$$\mathrm{Zn + 2H}X\ (X = \mathrm{Cl, Br, I}) \longrightarrow \mathrm{Zn}X_2 + \mathrm{H_2}$$
$$\mathrm{NaOH + H}X \longrightarrow \mathrm{Na}X + \mathrm{H_2O}$$
$$\mathrm{Na_2CO_3 + 2H}X \longrightarrow \mathrm{2Na}X + \mathrm{CO_2 + H_2O}$$

2. HCl, HBr and HI do not react with SiO_2 and glass. HF *attacks on* SiO_2 *and gives hydro fluosilicic acid* (H_2SiF_6)

$$\mathrm{SiO_2 + 4HF \longrightarrow SiF_4 + 2H_2O}$$

The white fumes of SiF_4 form a gelatinous mass of H_2SiO_3 or H_4SiO_4 and hydro-fluorosilicic acid (H_2SiF_6) with a drop of water held in these fumes.

$$\mathrm{3SiF_4 + 3H_2O \longrightarrow H_2SiO_3 + 2H_2SiF_6}$$
$$\text{or } \mathrm{3SiF_4 + 4H_2O \longrightarrow H_2SiO_3 \cdot H_2O} \text{ or } \mathrm{H_4SiO_4 + 2H_2SiF_6}$$

(Now, we know that glass is composed of Na_2SiO_3 and $CaSiO_3$. HF reacts with these silicates and form sodium and calcium fluosilicate (Na_2SiF_6 and $CaSiF_6$) respectively.

$$\mathrm{Na_2SiO_3 + 6HF \longrightarrow Na_2SiF_6 + 3H_2O}$$
$$\mathrm{CaSiO_3 + 6HF \longrightarrow CaSiF_6 + 3H_2O}$$

Since, HF *reacts with glass as shown above, it should not be kept in glass vessels; it should be stored in waxed glass vessels because wax prevents the action of* HF *on glass. The property of* HF *to act on glass has been utilised in the etching of glass and in making scales on the glass instruments.* For etching glass, commercial H_2F_2 (40–60%) is used.

3. HCl decomposes the salts of weaker acids like carbonates, bicarbonates, sulphides, sulphites, thiosulphates and nitrites as

$$\mathrm{2Na_2CO_3 + 2HCl \longrightarrow 2NaCl + H_2O + CO_2}$$
$$\mathrm{NaHCO_3 + HCl \longrightarrow NaCl + H_2O + CO_2}$$
$$\mathrm{Na_2S + 2HCl \longrightarrow 2NaCl + H_2S}$$
$$\mathrm{Na_2SO_3 + 2HCl \longrightarrow 2NaCl + H_2O + SO_2}$$
$$\mathrm{Na_2S_2O_3 + 2HCl \longrightarrow 2NaCl + S + H_2O + SO_2}$$
$$\mathrm{2NaNO_2 + 2HCl \longrightarrow 2NaCl + H_2O + NO + NO_2}$$

With metal oxides and hydroxides, HCl forms salt and water.

4. With $AgNO_3$ solution, HF forms AgF which becomes soluble in water. On the other hand, HCl, HBr and HI give the precipitate of AgCl (white), AgBr (pale yellow) and AgI (yellow) respectively.

$$\mathrm{AgNO_3 + HF \longrightarrow \underset{soluble}{AgF} + HNO_3}$$
$$\mathrm{AgNO_3 + H}X\ (X = \mathrm{Cl, Br, I}) \longrightarrow \underset{\text{ppt.}}{\mathrm{Ag}X} + \mathrm{HNO_3}$$

5. HF does not give any precipitate with the solution of Pb (II) salts like $Pb(NO_3)_2$, $(CH_3COO)_2Pb$ etc, HCl, HBr and HI give the precipitate of $PbCl_2$ (white) $PbBr_2$ (white) and PbI_2 (yellow) respectively.

$$\mathrm{Pb(NO_3)_2 + 2H}X(X = \mathrm{Cl, Br, I}) \longrightarrow \mathrm{Pb}X_2 + \mathrm{2HNO_3}$$
$$\mathrm{(CH_3COO)_2Pb + 2H}X \longrightarrow \mathrm{Pb}X_2 + \mathrm{2CH_3COOH}$$

[All the three precipitates (*i.e.,* $PbCl_2$, $PbBr_2$ and PbI_2) are soluble in hot water.]

6. HF does not give any precipitate with mercurous and mercuric salts. HCl forms a white precipitate of Hg_2Cl_2 with $Hg_2(NO_3)_2$ solution.

$$\mathrm{2HCl + Hg_2(NO_3)_2 \longrightarrow Hg_2Cl_2 + 2HNO_3}$$

Hg_2Cl_2 is soluble in aqua-regia. HI forms scarlet precipitate of HgI_2 with $HgCl_2$ solution.

$$\mathrm{2HI + HgCl_2 \longrightarrow HgI_2 + 2HCl}$$

7. HF, HCl and HBr do not react with $CuSO_4$ solution, but HI gives CuI_2 which, being unstable, decomposes into CuI and I_2 as

$$\mathrm{2HI + CuSO_4 \longrightarrow CuI_2 + H_2SO_4}$$
$$\mathrm{2CuI_2 \longrightarrow 2CuI + I_2}$$

8. With the solution of $BaCl_2$, $SrCl_2$ and $CaCl_2$ salts, H_2F_2 forms white precipitate of BaF_2, SrF_2 and CaF_2 respectively. Other acids do not give any precipitate since MX_2 (M = Ba, Sr, Ca; X = Br, I) are soluble.

$$M\mathrm{Cl_2 + H_2F_2} \longrightarrow \underset{\text{ppt.}}{M\mathrm{F_2}} + \mathrm{2HCl}$$
$$M\mathrm{Cl_2 + 2H}X \longrightarrow \underset{\text{soluble}}{MX_2} + \mathrm{2HCl}$$

9. Anhydrous HF does not attack any metal under ordinary conditions except potassium while acid reacts with many metals to form their fluorides with the evolution of H_2. *e.g.,*

$$Zn + 2HF \longrightarrow ZnF_2 + H_2$$
$$Mg + 2HF \longrightarrow MgF_2 + H_2$$

In these reactions, the metal is oxidised and HF is reduced to H_2.

Gaseous HCl reacts with heated metals while aqueous HCl reacts with most metals in cold. The reaction between aqueous HCl and Pt, Au, Ag and Hg is not preceptible. Some examples of the reaction between metal and HCl are as.

(i) Aqueous HCl reacts with Ag in presence of air.

$$4Ag + 4HCl + O_2 \longrightarrow 4AgCl + 2H_2O$$

(ii) Cu dissolves in conc HCl. Fe reacts with HCl and gives lower chloride *viz*, $FeCl_2$ (not $FeCl_3$).

$$Fe + 2HCl \longrightarrow FeCl_2 + H_2$$

HBr dissolves Fe, Zn, Sn, Cu, Ag, Pb etc., with the liberation of H_2 and formation of bromides. HBr attacks Hg very slowly, forming H_2 and $HgBr_2$.

10. When H*X* molecule or X^- ion reacts with an oxidising agent, it reduces the oxidising agent and is itself oxidised to X_2 molecule.

$$2HX + O_2 \longrightarrow 2H_2O + 2X_2 \quad \text{(molecular equation)}$$

It has been found that the tendency of X^- ions to lose electrons increases from F^- to I^- ion. *Accordingly, the reducing power of X^- ions or* H*X* *molecules increases from* F^- *to* I^- *ions or from* HF *to* HI *molecules.*

$$F^- < Cl^- < Br^- < I^- \quad \text{or} \quad HF < HCl < HBr < HI$$

As a matter of fact, HF or F^- does not show reducing properties at all (even with very strong oxidising agent).

The increasing order of the reducing power of H*X* molecules or X^- ion can be explained on the basis of decrease in electronegative character from F to I *i.e.*, **good electron acceptors are bad electron loosers and *vice-versa*.**

As reducing agent, HCl *molecule or* Cl^- *ion is weaker than* HBr *and* HI *both and hence, reduces only strong oxidising agents* and is itself oxidised to Cl_2 which is evolved as a yellowish green gas. Thus, HCl reduces

(i) **MnO_2** (acidified with conc. H_2SO_4) to $MnSO_4$

$$MnO_2 + H_2SO_4 + 2HCl \longrightarrow MnSO_4 + 2H_2O + Cl_2$$

(ii) **MnO_2 to $MnCl_2$**

$$MnO_2 + 4HCl\,(\text{conc.}) \longrightarrow MnCl_2 + 2H_2O + Cl_2$$

(iii) **$KMnO_4$ to $MnCl_2$**

$$2KMnO_4 + 16HCl\,(\text{conc.}) \longrightarrow 2KCl + 2MnCl_2 + 8H_2O + 5Cl_2$$

(iv) **$K_2Cr_2O_7$ to $CrCl_3$**

$$K_2Cr_2O_7 + 14HCl \longrightarrow 2KCl + 2CrCl_3 + 7H_2O + 3Cl_2$$

(v) **PbO_2 to $PbCl_2$**

$$PbO_2 + 4HCl(\text{hot and conc.}) \longrightarrow PbCl_2 + 2H_2O + Cl_2$$

(vi) **Pb_3O_4** (red lead) **to $PbCl_2$**

$$Pb_3O_4 + 8HCl \longrightarrow 3PbCl_2 + 4H_2O + Cl_2$$

(vii) **O_2 to H_2O in presence of Cu-salts** (catalyst)

$$O_2 + 4HCl \longrightarrow 2H_2O + 2Cl_2$$

(viii) **Bleaching powder ($CaOCl_2$) to $CaCl_2$**

$$CaOCl_2 + 2HCl \longrightarrow CaCl_2 + H_2O + Cl_2$$

(ix) **F_2 to HF but neither Br_2 to HBr nor I_2 to HI**

$$\left.2HCl + F_2 \longrightarrow 2HF + Cl_2\right] \text{possible}$$
$$\left.\begin{array}{l}2HCl + Br_2 \longrightarrow 2HBr + Cl_2\\ 2HCl + I_2 \longrightarrow 2HI + Cl_2\end{array}\right] \text{not possible}$$

(x) **HCl cannot reduce H_2SO_4 to SO_2**

Since, HBr or Br^- is a weaker reducing agent than HI or I^-, **it reduces some oxidising agents and is itself oxidised to** Br_2 which is evolved as reddish brown vapour. Thus, HBr reduces

(i) H_2SO_4 to SO_2

$$2HBr + H_2SO_4 \longrightarrow SO_2 + 2H_2O + Br_2$$

(ii) **Atmospheric O_2 to H_2O**

$$4HBr + O_2 \longrightarrow 2H_2O + 2Br_2$$

(iii) **Acidified solution of $KMnO_4$ to $MnSO_4$**

$$2KMnO_4 + 3H_2SO_4 + 10HBr \longrightarrow K_2SO_4 + 2MnSO_4 + 8H_2O + 5Br_2$$

(iv) **Acidified solution of $K_2Cr_2O_7$ to $Cr_2(SO_4)_3$**

$$K_2Cr_2O_7 + 4H_2SO_4 + 6HBr \longrightarrow K_2SO_4 + Cr_2(SO_4)_3 + 7H_2O + 3Br_2$$

(v) **H_2O_2 to H_2O**

$$2HBr + H_2O_2 \longrightarrow 2H_2O + Br_2$$

(vi) **$FeCl_3$ to $FeCl_2$**

$$FeCl_3 + 2HBr \longrightarrow 2FeCl_2 + 2HCl + Br_2$$

(vii) **F_2 to HF and Cl_2 to HCl but not I_2 to HI**

$$\left.\begin{array}{l}2HBr + F_2 \longrightarrow 2HF + Br_2\\ 2HBr + Cl_2 \longrightarrow 2HCl + Br_2\end{array}\right] \text{possible}$$
$$\left.2HBr + I_2 \longrightarrow 2HI + Br_2\right] \text{not possible}$$

(viii) **Acidified MnO_2 to $MnSO_4$**

$$MnO_2 + H_2SO_4 + 2HBr \longrightarrow MnSO_4 + 2H_2O + Br_2$$

Being the strongest reducing agent, HI *or* I^- *reduces even very strong oxidising agents and is itself oxidised to* I_2 which is evolved as violet vapour. Thus, HI or I^- reduces

(i) H_2SO_4 to SO_2, S or H_2S (or S^{2-})

$$2HI + H_2SO_4 \longrightarrow SO_2 + 2H_2O + I_2$$
$$6HI + H_2SO_4 \longrightarrow S + 4H_2O + 3I_2$$
$$8HI + H_2SO_4 \longrightarrow H_2S + 4H_2O + 4I_2$$

(ii) HNO_3 to NO or NO_2

$$2HNO_3 + 6HI \longrightarrow 2NO + 4H_2O + 3I_2$$
$$2HNO_3 + 2HI \longrightarrow 2NO_2 + 2H_2O + I_2$$

(iii) **HNO_2 to NO**

$$2HNO_2 + 2HI \longrightarrow 2NO + 2H_2O + I_2$$

(iv) **$FeCl_3$ to $FeCl_2$**

$$2FeCl_3 + 2HI \longrightarrow 2FeCl_2 + 2HCl + I_2$$

(v) **$CuSO_4$ to CuI**

$$2CuSO_4 + 4HI \longrightarrow 2CuI + 2H_2SO_4 + I_2$$

(vi) **Atmospheric O_2 to H_2O**

$$4HI + O_2 \longrightarrow 2H_2O + 2I_2$$

(due to the liberation of free I_2, the solution of HI turns brown, when kept in air).

(vii) **Acdified MnO_2 to $MnSO_4$**

$$MnO_2 + H_2SO_4 + 2HI \longrightarrow MnSO_4 + 2H_2O + I_2$$

(viii) **Iodic acid (HIO_3) to I_2**

$$5HI + HIO_3 \longrightarrow 3H_2O + 3I_2$$

(ix) **Arsenate** (AsO_4^{3-}) **to arsenite** (AsO_3^{3-})

$$2I^- + AsO_4^{3-} + 2H^+ \longrightarrow AsO_3^{3-} + H_2O + I_2$$

(x) **Acidified solution of $KMnO_4$ to $MnSO_4$**

$$10HI + 2KMnO_4 + 3H_2SO_4 \longrightarrow K_2SO_4 + 2MnSO_4 + 8H_2O + 5I_2$$

Interhalogen Compounds

Halogens react with each other to produce a number of interhalogen compounds (XX_n' where, $n = 1, 3, 5$ or 7). An interhalogen compound, infact, is regarded as the halide of more electropositive halogen, with a halogen with less electropositive character (electropositive character increases down the group). Thus, as far as this trend is concerned, F *cannot form any interhalogen compound as central atom, while* I *has the maximum tendency to form interhalogen compounds*.

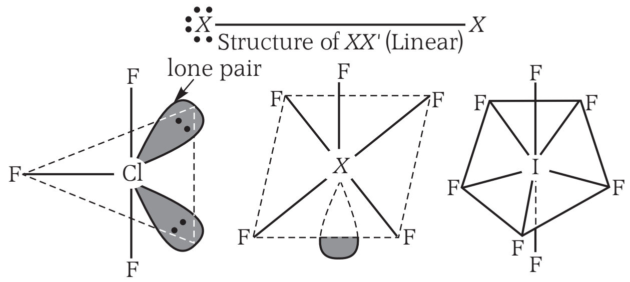
Interhalogens can be grouped into four categories namely XX' (*e.g.*, ClF, BrF etc,) XX'_3 (*e.g.*, ClF_3 BrF_3 etc.) XX'_5 (*e.g.*, ClF_5, IF_5 etc,) and XX'_7 (*e.g.*, IF_7) The oxidation states of *X* atom in these are +1, +3, +5 and +7 respectively.

Some important examples of these are

Table 7.14 **Examples of Interhalogens Compounds**

XX'	XX_3'	XX_5'	XX_7'
ClF	ClF_3	ClF_5	IF_7
BrF	BrF_3	BrF_5	
BrCl	IF_3	IF_5	
ICl	$ICl_3(I_2Cl_6)$		
IBr			
IF			

The stability of interhalogen compounds increases as the size of central atom increases. Out of two halogens the one with smaller size and higher electronegativity assigned negative oxidation state. ***XX′*** *interhalogen compounds have linear structure,* ***XX_3'*** *compounds have bent T structure* ***XX_5'*** *compounds have square pyramidal structure and* **IF_7** *have pentagonal bipyramidal structure.*



Structure of $XX¢_3$ type (T-shape)

Structure of $XX¢_5$ type (Square pyramidal)

Structure of $XX¢_7$ type (Pentagonal bipyramidal)

Fig. 7.14 Structure of interhalogen compounds

Pseudohalides

There are several uni-negative groups which show characteristics of halide ions. These are called **pseudohalides** or **pseudohalide ions.** As the halides of halide ions are called halogens, the covalent dimers of pseudohalide ions are called **pseudohalogens.** Some of them are

Table 7.15 **Some Pseudohalides and their Formulae**

Pseudohalide ions	Formulae	Pseudohalogens	Formulae
Cyanide	CN^-	Cyanogen	$(CN)_2$
Cyanate	OCN^-	Oxocyanogen	$(OCN)_2$
Thiocyanate	SCN^-	Thiocyanogen	$(SCN)_2$
Selenocyanate	$SeCN^-$	Selenocyanogen	$(SeCN)_2$
Azidothiocarbonate	$SCSN_3^-$	Azidocarbon disulphide	$(SCSN_3)_2$
Isocyanate	ONC^-		

Important similarities between halide and pseudohalide ions are

1. Both can form ionic compounds, such as AgCl (AgCN), $PbCl_2$ $[Pb(NCS)_2]$, covalent compounds, *e.g.,* ICl(ICN), $SiCl_4$ $[Si(NCS)_4]$, complex ions with transition metal ions, *e.g.,* $[FeF_6]^{3-}$, $Fe(CN)_6^{3-}$; $[CoCl_4]^{2-}$, $[Co(SCN)_4]^{2-}$ etc.
2. As halide ions combine together to form interhalogen compounds, pseudohalide ions also combine together to form interpseudohalogen compounds like $CN \cdot N_3$, $CN \cdot SCN$ etc.
3. Both of them combine with H_2 to form monobasic hydracids *e.g.,* HCl, HCN etc.
4. Both give insoluble salts with Ag^+, Pb^{2+} and Hg^+ ions.
   e.g.,
   $$Ag^+ + Cl^- \longrightarrow AgCl\downarrow$$
   $$Ag^+ + CN^- \longrightarrow AgCN\downarrow$$
5. Both of them can coordinate with two metal ions simultaneously, *i.e.,* can acts as bridging ligands, *e.g.,* CN^- in $R_2Au(CN)_4$, similarly Cl^- in R_2AuCl_2.

However, halide and pseudohalide ions differ in following respects

1. Pseudohalide ions are stronger ligands than halide ions due to the ability of former to form the σ as well as π-bond.
2. Pseudohalide ions, being made up of two hetero atoms can function as **ambidentate ligands**
   (see coordination compounds for detail). However, halide ions do not show this behaviour.

Similarities between halogens and pseudohalogens are

1. Both are dimeric and fairly volatile (with the exception of polymeric thiocyanogen) in the free state.
2. Pseudohalogens are **isomorphous** to halogens when in the free or solid state. *e.g.,* Cl_2 is isomorphous to $(CN)_2$; Br_2 is isomorphous to $(SCN)_2$.
3. Both can be added to ethylenic double bond linkage as
   $$CH_2{=}CH_2 + Cl_2 \longrightarrow CH_2Cl{-}CH_2Cl$$
   $$CH_2{=}CH_2 + (SCN)_2 \longrightarrow CH_2SCN{-}CH_2SCN$$
4. Both react with alkalies as
   $$(SCN)_2 + 2KOH\text{ (cold and dilute)} \longrightarrow KSCN + KOSCN + H_2O$$
   $$Cl_2 + 2KOH\text{ (cold and dilute)} \longrightarrow KCl + KOCl + H_2O$$

Halogen and pseudohalogens differ from each other in the fact that pseudohalogens have the ability to undergo polymerisation as $n(CN)_2 \xrightarrow{500°C} 2(CN)_n$

Similarly, $n(SCN)_2 \xrightarrow[\text{temp.}]{\text{Room}} 2(SCN)_n$

Halogens on the other hand do not have such a tendency.

Oxides of Halogens

Halogens form following oxides

Table 7.16 **Oxides of Halogens**

Oxides of chlorine	Oxides of bromine	Oxides of iodine
Cl_2O	Br_2O	I_2O_5
ClO_2	BrO_2	
Cl_2O_6	BrO_3	
Cl_2O_7		

In these oxides, bonds are mainly covalent, since there is a very small difference between the electronegativity of oxygen and the halogens.

Oxides of chlorine are acidic and the acidic nature increases as the percentage of oxygen increases. Moreover, these are powerful oxidising agents and decompose explosively when exposed to mechanical shock or on heating.

All the three monoxides *viz,* OF_2, Cl_2O and Br_2O have **tetrahedral structure** involving sp^3 hybridisation of oxygen. The bond angle increases as the size of halogen atom increases. Thus, the bond angle varies in the order **FOF < ClOCl < BrOBr.** This is because electrons in the case of OF_2 are nearer to fluorine due to high electronegativity of F compared to Cl to Br. The bonded electron pairs in Cl_2O and Br_2O are closer to oxygen making the repulsion between them more and thereby reducing the lone pair-lone pair repulsion on oxygen to some extent. Also due to the bulkiness of Cl and Br, the angles ClOCl and BrOBr increase to such an extent that 109°28′, (the tetrahedral angle), is approached.

Oxoacids of Halogens

Because of its high electronegativity and small size, fluorine forms only one oxoacid, HOF (known as **fluoric acid** or **hypofluorous acid).** Other halogens form many oxoacids. These are stable in aqueous solution or in the form of their salts. *These are as follows*

Table 7.17 **Oxoacids of Halogens**

Halogen	Hypohalous acids, HXO ($X = +1$)	Halous acids, HXO_2 ($X = +3$)	Halic acids, HXO_3 ($X = +5$)	Perhalic acids, HXO_4 ($X = +7$)
Chlorine	HClO	$HClO_2$	$HClO_3$	$HClO_4$
Bromine	HBrO	—	$HBrO_3$	—
Iodine	HIO	—	HIO_3	HIO_4, $HIO_4 \cdot 2H_2O$, $HIO_4 \cdot 2H_2O$, $2HIO_4 \cdot H_2O$

Some of the general properties of oxoacids are as follows

1. **Thermal stability** of these oxoacids depends on the oxidation number and electronegativity of the central halogen atom. Greater is the oxidation number or electronegativity of halogen atom, greater will be the thermal stability of the acid and *vice-versa*. Thus, the following two cases may be studied
   (i) **In case of oxoacids of a given halogen atom** since the electronegativity of the central halogen atom *viz*, Cl-atom in this case remains the same, the thermal stability depends only upon the oxidation number of the central atom. As the oxidation number of the central atom increases, *X*—O bond in the acids becomes more and more covalent and hence, thermal stability of the acids increases. *i.e.,* thermal stability of the given acids is in the order : $HClO < HClO_2 < HClO_3 < HClO_4$.

   (ii) **In case of oxoacids, having the same formula and different halogen atom** since, the oxidation number of the halogen atoms remains the same, the thermal stability depends only upon the electronegativity of the halogen atom. Thermal stability decreases with the decrease in electronegativity of halogen atom. Thus, thermal stability of the given acids is in the order :

   $$HClO > HBrO > HIO.$$

   Reaction with alkalies Fluorine reacts with cold dilute alkalies to give OF_2 (oxygen difluoride) while with concentration alkalies, it evolves oxygen.

   $$\underset{\text{(cold and dilute)}}{2NaOH} + 2F_2 \longrightarrow 2NaF + OF_2 + H_2O$$

   $$\underset{\text{(conc.)}}{4NaOH} + 2F_2 \longrightarrow 4NaF + O_2 + 2H_2O$$

   Cl_2, Br_2 and I_2 behaves similarly but differently than fluorine. They form a mixture of halide and hypohalites with cold dilute alkalies while a mixture of halides and halate with concentrated hot alkalies.

   $$\underset{\text{cold and dilute}}{2NaOH} + X_2 \longrightarrow \underset{\text{halide}}{NaX} + \underset{\text{hypohalite}}{NaXO} + H_2O$$

   $$\underset{\text{hot and conc.}}{6NaOH} + 3X_2 \longrightarrow 5NaX + \underset{\text{halate}}{NaXO_3} + 3H_2O$$

   (where, X = Cl, Br, I)

2. **Acidity** (or acid strength) of oxoacids also follows the same trend as thermal stability.
3. **Oxidising power** Here also following two cases may be possible
   (i) **Oxidising power of oxoacids of a given halogen atom** (*e.g.,* $HClO$, $HClO_2$, $HClO_3$, $HClO_4$) decreases with the increase in the oxidation number of the central halogen atom. This is because the *XX*—O bond becomes more and more covalent as the oxidation number of the central atom increases. Thus, the oxidising power of the given acids is in the order

   $$HClO > HClO_2 > HClO_3 > HClO_4.$$

   (ii) **In case of oxoacids, having the same formula and different halogen atom** (*e.g.,* $HClO_3$, $HBrO_3$ and HIO_3), oxidising power decreases with the decrease in the electronegativity of the halogen atom. Thus, oxidising power of the given acids is in the order

   $$HClO_3 > HBrO_3 > HIO_3.$$

4. **Stability and basicity of the oxo-anions of a given halogen atom** (*e.g.,* ClO^-, ClO_2^-, ClO_3^- and ClO_4^-) have been found to be in the following order

   Stability $ClO_4^- > ClO_3^- > ClO_2^- > ClO^-$

   Basicity $ClO_4^- < ClO_3^- < ClO_2^- < ClO^-$

Some important oxyacids of halogens as discussed below.

Hypochlorous Acid, HClO

Hypochlorous acid, HClO is known only in solution.

Methods of Preparation

It is prepared by following methods.

1. By passing Cl_2 into H_2O or into a suspension of $CaCO_3$ in water or into an aqueous solution of potassium hypochlorite (KClO) or bleaching powder ($CaOCl_2$).

   $$Cl_2 + H_2O \longrightarrow HCl + HClO$$

   In this reaction, Cl_2 undergoes disproportionation into HCl and HClO.

2. By the action of atmospheric CO_2 on sodium hypochlorite, NaOCl.

   $$NaOCl + CO_2 + H_2O \longrightarrow NaHCO_3 + HOCl$$

3. By distilling the aqueous solution of bleaching powder ($CaOCl_2$) with a calculated quantity of 5% HNO_3 or by passing CO_2 into aqueous solution of $CaOCl_2$ and then distilling.

   $$2CaOCl_2 + 2HNO_3 \longrightarrow CaCl_2 + Ca(NO_3)_2 + 2HClO$$

   $$CaOCl_2 + H_2O + CO_2 \longrightarrow CaCO_3 + 2HClO$$

4. By shaking Cl_2 water with freshly precipitated HgO (General method for the preparation of hypohalous acids).

   $$2Cl_2 + 2HgO + H_2O \longrightarrow HgCl_2 \cdot HgO\downarrow + 2HClO$$

   The insoluble $HgCl_2 \cdot HgO$ is removed by filtration. The filtrate is distilled when dilute HClO passes over.

Physical Properties

The concentrated solution of HClO is yellow in colour, while the dilute solution is colourless. It is a weak acid, even weaker than H_2CO_3. Its dissociation constant is 3×10^{-8} at 20°C.

Chemical Properties

1. (i) The dilute solution of the acid is fairly stable in the dark, but when concentrated solution is exposed to light, it becomes unstable and hence, undergoes **disproportionation** into Cl_2 (Cl = 0) and $HClO_3$ (Cl = +5).

$$\underset{(Cl\,=\,+1)}{5HClO} \longrightarrow \underset{(Cl\,=\,0)}{2Cl_2} + \underset{(Cl\,=\,+5)}{HClO_3} + 2H_2O$$

(Molecular equation)

The decomposition is accelerated by Pt-black, MnO and CoO.

(ii) When aqueous solution of HClO is heated, it undergoes disproportionation into HCl and $HClO_3$.

$$3HClO \xrightarrow{\Delta} 2HCl + HClO_3$$

2. On distillation, HClO decomposes into H_2O and Cl_2O.

$$2HClO \longrightarrow Cl_2O + H_2O$$

3. It reacts with metals, *e.g.,* it dissolves in Mg, with the evolution of H_2, in Fe and Al, with the evolution of H_2 and Cl_2, while with Co, Ni and Cu, Cl_2 and O_2 are evolved.

$$Mg + 2HClO \longrightarrow Mg(OCl)_2 + H_2$$

When HClO is shaken with Hg, a light brown precipitate of basic mercuric chloride, HgCl(OH), which is soluble in HCl, is obtained

$$2Hg + 2HClO \longrightarrow 2HgCl(OH)\ (\text{Light brown ppt.})$$

4. The aqueous solution of HClO and its salts (*e.g.*, NaOCl) are **oxidising** and **bleaching agents.** This property is due to the fact that HClO or NaOCl decomposes to give nascent oxygen.

$$HClO \xrightarrow{\text{Reduction}} HCl + O$$

$$NaClO \xrightarrow{\text{Reduction}} NaCl + O$$

5. HClO is a **monobasic acid,** since its aqueous solution gives only one H^+ ion on ionisation.

$$HClO\,(aq) \rightleftharpoons H^+(aq) + ClO^-(aq)$$

ClO^- ion is called **hypochlorite ion.** Its monobasic nature shows that HClO molecule has one OH group attached directly with the central Cl-atom. Being an acid, HClO reacts with alkalies to form the salts which are called hypochlorites, *e.g.*,

$$NaOH + HClO \longrightarrow NaOCl + H_2O$$

6. HClO reacts with $AgNO_3$ and gives silver hypochlorite (AgClO). This compound is unstable and hence, undergoes disproportionation into AgCl and $AgClO_3$.

$$HOCl + AgNO_3 \longrightarrow AgOCl + HNO_3$$

$$3AgOCl \longrightarrow AgCl + AgClO_3$$

Chloric Acid, $HClO_3$

This acid is known only in solution.

Methods of Preparation

$HClO_3$ *is prepared by following methods.*

1. By the action of dil H_2SO_4 on $Ba(ClO_3)_2$.

$$Ba(ClO_3)_2 + H_2SO_4 \longrightarrow BaSO_4\ (\text{ppt.}) + 2HClO_3$$

The precipitate of $BaSO_4$ is obtained by filtration. The unused H_2SO_4 is precipitated with baryta water. The filtrate is evaporated in a vacuum desicator over concentrated H_2SO_4 until a 4% solution of $HClO_3$ is obtained.

(If the solution containing $HClO_3$ is evaporated further more, it gets decomposed into perchloric acid, $HClO_4$.

$$3HClO_3 \longrightarrow HClO_4 + Cl_2 + 2O_2 + H_2O$$

2. By the action of hydrofluorosilicic acid (H_2SiF_6) on $KClO_3$.

$$2KClO_3 + H_2SiF_6 \longrightarrow K_2SiF_6(\text{ppt.}) + 2HClO_3$$

Physical and Chemical Properties

1. Concentrated solution of the acid is colourless and is a pungent smelling liquid.
2. It is fairly stable in dark. In light it decomposes and becomes yellow. On heating, $HClO_3$ decomposes to give $HClO_4$.

$$3HClO_3 \xrightarrow{\Delta} HClO_4 + Cl_2 + 2O_2 + H_2O$$

3. When organic substances like cotton, wool, paper etc, come in contact with the acid, they catch fire.
4. The acid is a powerful oxidising and bleaching agent.
5. When iodine is evaporated with 25% $HClO_3$, iodic acid (HIO_3) is obtained.

$$2HClO_2 + I_2 \longrightarrow 2HIO_3 + Cl_2$$

This reaction has been used for the preparation of HIO_3.

6. $HClO_3$ is a monobasic acid.

$$HClO_3 \rightleftharpoons H^+ + ClO_3^-$$

Perchloric Acid, $HClO_4$

Methods of Preparation

Perchloric acid, $HClO_4$ is prepared as

1. By heating $HClO_3$

$$3HClO_3 \xrightarrow{\Delta} HClO_4 + Cl_2 + 2O_2 + H_2O$$

2. By treating $Ba(ClO_4)_2$ with calculated quantity of dil. H_2SO_4 and then removing the insoluble $BaSO_4$ by filtration.

$$Ba(ClO_4)_2 + H_2SO_4 \longrightarrow 2HClO_4 + BaSO_4 \downarrow$$

3. By adding NH_4ClO_4 dissolved in conc. HCl to warm conc HNO_3 and then evaporating.

$$NH_4ClO_4 + 8HCl + 3HNO_3 \longrightarrow HClO_4 + 2N_2O + 4Cl_2 + 7H_2O$$

4. Anhydrous acid is obtained by distilling a mixture of potassium perchlorate ($KClO_4$) with conc. H_2SO_4 under reduced pressure.

$$KClO_4 + H_2SO_4 \longrightarrow HClO_4 + KHSO_4$$

Physical and Chemical Properties

These include

1. Anhydrous $HClO_4$ is a colourless mobile hygroscopic and oily liquid. It fumes strongly in moist air and dissolves in water with hissing sound due to the liberation of much heat.
2. It forms hydrates with 1, 2, 2.5, 3 and 3.5 molecules of water of crystallisation.
3. It is unstable and decomposes with explosion on heating and sometimes merely on standing for a few days even in the dark. Aqueous solution of the acid is quite stable and does not decompose and hence, can be kept indefinitely.
4. It is highly dangerous acid and produces severe wounds on the skin.
5. It is powerful oxidising agent and inflames paper and wood.
6. On dehydration with P_2O_5 at $-10°C$, it gives Cl_2O_7 which is the anhydride of perchloric acid.

$$2HClO_4 + P_2O_5 \longrightarrow Cl_2O_7 + 2HPO_3$$

This reaction has been used for the preparation of Cl_2O_7.

7. $HClO_4$ is the strongest acid of all the acids.
8. The metals like Zn, Fe etc, dissolve in the aqueous solution of the acid and form the soluble perchlorates.

$$Zn + 2HClO_4(aq) \longrightarrow Zn(ClO_4)_2(aq) + H_2 \downarrow$$

9. The acid is not reduced by nascent hydrogen but gets reduced to chloride by strong reducing agents like $SnCl_2$ $CrCl_2$ etc.
10. When a suspension of iodine is heated with $HClO_4$, paraperiodic acid (H_5IO_6) is obtained.

$$2HClO_4 + I_2 + 4H_2O \longrightarrow 2H_5IO_6 + Cl_2$$

Uses

The aqueous solution of the acid is used for the estimation of potassium gravimetrically.

Metaperiodic Acid, HIO_4

Methods of Preparation

1. HIO_4 is obtained by heating paraperiodic acid, H_5IO_6.

$$H_5IO_6 \xrightarrow{100°C} HIO_4 + 2H_2O$$

2. Its salts which are called metaperiodates is prepared by the thermal decomposition of iodates, *e.g.*,

$$4KIO_3 \xrightarrow{\Delta} 3KIO_4 + KI$$

Properties

These include

1. It is a weak acid and dissociates as

$$HIO_4 \rightleftharpoons H^+ + IO_4^-$$

2. When dissolved in water, it changes back to H_2IO_6.

$$HIO_4 + 2H_2O \longrightarrow H_5IO_6$$

3. HIO_4 and its salts are strong oxidising agents in acidic medium.

$$2IO_4^- + 16H^+ + 14e^- \longrightarrow I_2 + 8H_2O$$

Sample **Problem 17** *Which of the following is correct order of acidity of oxoacids of chlorine?* **[NCERT]**

(*a*) $HClO_4 < HClO_3 < HClO_2 < HClO$
(*b*) $HClO < HClO_2 < HClO_3 < HClO_4$
(*c*) $HClO_2 < HClO < HClO_3 < HClO_4$
(*d*) $HClO_4 < HClO_3 > HClO_2 > HClO$

Interpret (*b*) Oxygen is more electronegative than chlorine, therefore dispersal of negative charge present on chlorine increases from ClO^- to ClO_4^- ion because number of oxygen atoms attached to chlorine is increasing. Therefore, stability of ions will increaase in the order given below

$$ClO^- < ClO_2^- < ClO_3^- < ClO_4^-$$

Due to increase in stability of conjugate base, acidic strength of corresponding acid increases in the same order.

$$HClO < HClO_2 < HClO_3 < HClO_4$$

Check Point 3

1. Bond dissociation energy and electron affinity of fluorine are low, nevertheless it is a very good oxidising agent. Explain.
2. Interhalogen compounds, are more reactive than halogens. Why?
3. When a blue litmus is dipped into a solution of hypochalorous acid, it first turns red and later gets decolourised. Explain.
4. Why is HF not stored in glass bottles and kept in wax bottles?

18 Group Elements and Their Compounds

7.9 Group 18 Elements

This group of Periodic Table contains He, Ne, Ar, Kr, Xe and Rn. These were called **inert gases** due to their inert nature. However, these are now called **noble gases** because some of these elements form compounds under specific conditions.

Occurrence

All these gases except radon (Rn) are present in atmosphere. Rn results from disintegration of radium is itself radioactive. The total abundance of these elements in dry air (except Rn) is ~1% by volume, out of which Ar is the major component.

General and Physical Properties

(a) Electronic Configuration

These gases have highly stable $ns^2\ np^6$ configuration thus, have very little tendency to form chemical compounds with other elements (inert gases).

(b) Atomic and Ionic Radii

The atomic radii of 18th group elements correspond to the van der Waals' radii and increases on moving down the group.

(c) Boiling Points

They have low boiling points in comparison to other elements and their boiling point increases with increases in atomic sizes.

(d) Ionisation Energy and Electron Affinity

Noble gases have stable ns^2np^6 (fully filled) configuration, thus, have no tendency to add or lose electron. Therefore, their ionisation energy is very high. On the other hand, their electron affinity is zero.

(e) Heat of Vaporisation and Polarisability

They possess very low values of heat of vaporisation due to the presence of very weak van der Waals' forces of attraction between their monatomic molecules. However, the value of heat of vaporisation increases with atomic number and this shows that there is an increasing polarizability of the larger electronic clouds of the elements with higher atomic number. In other words, the polarizability increases down the group as He < Ne < Ar < Kr < Xe.

(f) Solubility

They are slightly soluble in water and their solubility generally increases on moving down the group.

(g) Adsorption

Except He, all the noble gases are adsorbed by coconut charcoal and the ease of adsorption increases down the group.

(h) Conductivity

They have high electrical conductivity at low pressures.

(i) Spectra

All of them give characteristic spectra, by which they can be identified.

(j) Liquification

Due to the presence of weak van der Waals' forces of attraction, it is difficult to liquify noble gases. Ease of liquification increases down the group from He to Rn due to increase in intermolecular forces.

The above mentioned physical properties can be summarised as

Table 7.18 **Physical Properties of Noble Gases**

Property	Helium	Neon	Argon	Krypton	Xenon	Radon
Atomic number	2	10	18	36	54	86
Molar mass (amu)	4.003	20.183	39.948	83.30	131.30	222
Boiling point (°C)	–268.93	–246.06	–185.86	–153.35	–108.1	–62
Melting point (°C)	–272.1	–246.61	–189.37	–157.2	–111.8	–71

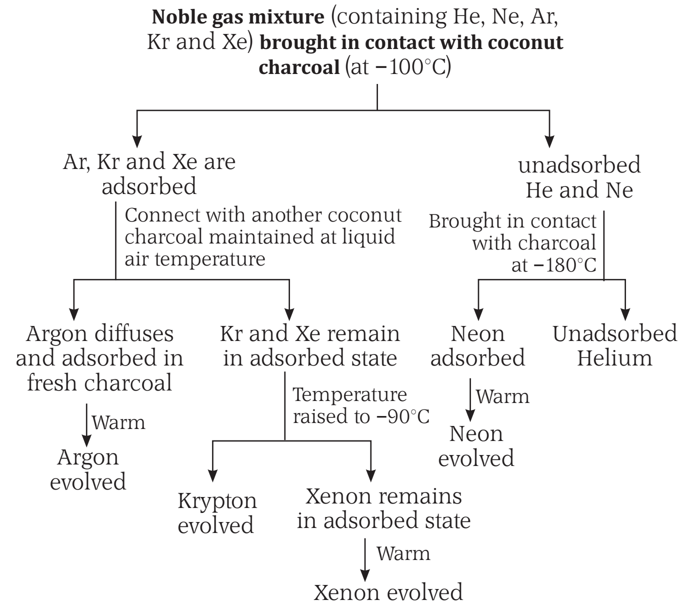
Chemistry of Noble Gases

The real chemistry of noble gases began in 1962 when

Neil Bartlett isolated an orange yellow solid from the reaction of Xe and PtF_6 (the possibility of reaction arise due to similarity in ionisation enthalpies of O_2 and Xe). After this discovery many compounds of Xe were prepared (with oxygen and F only). Kr forms comparatively fewer compounds (only KrF_2 have been studied in detail). Compounds of Rn have not been isolated but are identified with radiotracer techniques.

Extraction of Noble Gas

Helium, argon, neon, krypton and xenon are prepared by the fractional distillation of liquid air. Fractional distillation of air gives O_2, N_2 and mixture of noble gases. The individual gases may be obtained by adsorption of air on coconut charcoal. The charcoal adsorbs different gases at different temperatures and thus, these gases can be collected.



However, radon is obtained by radioactive disintegration of radium (226) as ${}_{88}Ra^{226} \longrightarrow {}_{86}Rn^{222} + {}_{2}\alpha^{4}$

Properties and Uses of Noble gases

The important properties along with the uses and discoverer of noble gases can be summarised as

Table 7.19 **Discovery and Uses of Noble Gases**

Noble gas	Discoverer	Uses	Reasons
He	Lockyer and Janssen (1868)	(i) He/O_2 mixture for deep-sea breathing, instead of N_2/O_2 mixture	Low solubility in blood; prevents nitrogen narcosis and "bends".
		(ii) Diluent for gaseous anaesthetics	Non-flammable, non-reactive.
		(iii) Filling of observation balloons and other lighter air craft	Non-flammable; 93% lifting power as compared to flammable H_2.
		(iv) Liquid He to maintain very low temperature in research (cryogenics)	Extremely low boiling point.
		(v) He/O_2 mixtures for respiratory patients	Low density flows easily through restricted assages.
		(vi) Heat transfer agent in gas cooled nuclear reactors.	Transfers heat readily; does not becomes radioactive; chemically inert.
Ne	Ramsay and Travers	Neon signs.	Even at low pressure Ne, moderate electric current causes bright orange-red glow; can be modified by coloured glass or mixing with Ar or Hg vapour.
Ar	L. Rayleigh and Ramsay	(i) Inert atmosphere for welding	Chemically inert.
		(ii) Filling incandescent light bulbs.	Inert; prevents vaporisation of tungsten and blackening of bulbs.
Kr	Ramsay and Travers (1898)	Airport runway and approach lights	Gives longer life to incandescent lights than Ar, but more expensive.
Xe	Ramsay and Travers (1898)	Xe and Kr mixture in high-intensity, short-exposure photographic flash tubes	Both have fast response to electric current.
Rn	Dorn (1900)	For the treatment of cancer (radiotherapy).	Because of radioactive nature.

7.10 Compounds of Elements of Group 18

Xe because of its low ionisation energy forms several compounds. However no true compounds of He, Ne and Ar are known. Most of the compounds of Xe are with F and O.

Xenon Fluorides

Xe forms three binary fluorides, *i.e.*, XeF_2, XeF_4 and XeF_6 by the direct union of elements under appropriate experimental conditions. In these fluorides, Xe is in +2, +4 and +6 oxidation states respectively.

(a) Xenon Difluorine

XeF_2 is prepared by the following method as

1. $\underbrace{Xe + F_2}_{2\,:\,1 \text{ ratio}} \xrightarrow[\text{tube (400°C)}]{\text{Sealed Ni}} XeF_2$
2. $\underbrace{Xe + F_2}_{2\,:\,1 \text{ ratio}} \xrightarrow[\text{discharge}]{\text{Electric}} XeF_2$
3. $Xe + F_2 \xrightarrow[\text{(Hg vapours)}]{\text{Photochemical combination}} XeF_2$
4. XeF_2 can also be prepared by the fluorination of Xe by oxygen monofluoride, O_2F_2 at −178°C.

$$Xe + O_2F_2 \xrightarrow{-178°C} XeF_2 + O_2$$

The important properties exhibited by XeF_2 are as

1. It is a colourless crystalline solid with m.p. is 140°C.
2. XeF_2 is reduced by H_2O to Xe and H_2O is oxidised to O_2.

$$2XeF_2 + 2H_2O \longrightarrow 2Xe + 4HF + O_2$$

However, it is rapidly hydrolysed by an aqueous solution of a base.

$$2XeF_2 + 4OH^- \longrightarrow 2Xe + 4F^- + 2H_2O + O_2$$

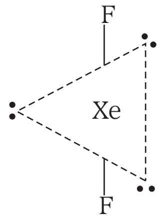
3. XeF_2 is a mild fluorinating agent. Thus, it reacts with C_6H_6 to give C_6H_5F.
4. It can oxidise many substances and itself gets reduced to xenon. *e.g.,*

$$XeF_2 + H_2 \longrightarrow Xe + 2HF$$
$$2XeF_2 + 2H_2O \longrightarrow 2Xe + 4HF + O_2$$
$$XeF_2 + I_2 \xrightarrow{BF_3} Xe + 2IF$$
$$XeF_2 + 2SO_3 \longrightarrow Xe + S_2O_6F_2$$
$$XeF_2 + 2HCl \longrightarrow Xe + 2HF + Cl_2$$
$$XeF_2 + 2Ce^{3+} \longrightarrow 2Ce^{4+} + Xe + 2F^-$$

5. In BrF_3 solution, XeF_2 forms adducts with MF_5 molecules (M = P, A, Sb etc).

$$XeF_2 + MF_5 \longrightarrow XeF_2 \cdot MF_5$$
$$XeF_2 + 2MF_5 \longrightarrow XeF_2 \cdot 2MF_5$$
$$2XeF_2 + MF_5 \longrightarrow 2XeF_2 \cdot MF_5$$

XeF_2 has sp^3d hybridisation and linear geometry (due to the presence of 3 lone pairs) which is represented as



Linear XeF_2

(b) Xenon Tetrafluoride

XeF_4 is prepared as

1. $\underbrace{Xe + 2F_2}_{1\,:\,5 \text{ ratio}} \xrightarrow[\text{400°C, 5–6 atm}]{\text{Ni tube}} XeF_4$
2. $\underbrace{Xe + 2F_2}_{1\,:\,2 \text{ ratio}} \xrightarrow[-80°C]{\text{Electric discharge}} XeF_4$

Its important properties are as

1. It is also a colourless crystalline solid. Its mp is 117.1°C. It sublimes readily.
2. XeF_4 undergoes disproportionation in water, giving XeO_3 which is a highly explosive solid.

$$2XeF_4 + 3H_2O \longrightarrow Xe(g) + XeO_3(s) + 6HF(aq) + F_2(g)$$

If the reaction is carried out at −80°C, $XeOF_2$ is formed. In this reaction, slow and partial hydrolysis of XeF_4 takes place as

$$XeF_4 + H_2O \xrightarrow{-80°C} XeOF_2 + 2HF$$

3. XeF_4 is a stronger fluorinating agent than XeF_2. Thus, it converts Hg to HgF_2, Pt to PtF_4, NO to NOF, NO_2 to NO_2F, SF_4 to SF_6, BCl_3 to BF_3 etc.

$$2Hg + XeF_4 \longrightarrow Xe + 2HgF_2$$
$$Pt + XeF_4 \longrightarrow Xe + PtF_4$$
$$2SF_4 + XeF_4 \longrightarrow Xe + 2SF_6$$
$$4BCl_3 + 3XeF_4 \longrightarrow 3Xe + 4BF_3 + 6Cl_2$$

4. It also acts as an oxidising agent and in these reactions, itself get reduced to Xe.

$$XeF_4 + 2H_2 \longrightarrow Xe + 4HF$$
$$3XeF_4 + 4BCl_3 \longrightarrow 3Xe + 4BF_3 + 6Cl_2$$
$$XeF_4 + 4I^- \longrightarrow Xe + 4F^- + 2I_2$$

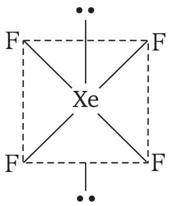
5. **XeF_4 dissolves in molten SbF_5 and gives the addition compound, $XeF_4 \cdot SbF_5$** which is an ionic compound and hence, is represented as $[XeF_3]^+ [SbF_6]^-$.

$$XeF_4 + SbF_5 \longrightarrow XeF_4 \cdot SbF_5 \longrightarrow [XeF_3]^+ [SbF_6]^-$$

It also dissolves in molten TaF_5, giving a straw coloured compound, $Xe(TaF_6)_2$ which is described as an addition compound, $XeF_2 \cdot 2TaF_5$.

$$XeF_4 + 2TaF_5 \longrightarrow Xe(TaF_6)_2 \text{ or } XeF_2 \cdot 2TaF_5 + F_2$$

XeF_4 has sp^3d^2 hybridisation but square planar geometry because of the presence of two lone pairs of electrons.



Square planar XeF_4

(c) Xenon Hexafluoride

XeF_6 can be prepared as

1. $\underbrace{Xe + 3F_2}_{1\,:\,20 \text{ ratio}} \xrightarrow[250\text{–}300°C,\ 50\text{–}60 \text{ atm}]{\text{Ni vessel}} XeF_6$
2. $\underbrace{Xe + 3F_2}_{1\,:\,3 \text{ ratio}} \xrightarrow[\text{low temp.}]{\text{Electric discharge}} XeF_6$
3. XeF_6 can also be prepared by the fluorination of XeF_4 by O_2F_2 or by F_2 under pressure.

$$XeF_4 + O_2F_2 \longrightarrow XeF_6 + O_2$$
$$XeF_4 + F_2 \longrightarrow XeF_6$$

Its properties include

1. It is colourless crystalline solid with melting point 49.5°C.
2. XeF_6 undergoes hydrolysis in water. The final product obtained is XeO_3 (an explosive solid).

$$XeF_6 + H_2O \longrightarrow XeOF_4 + 2HF$$
$$XeF_6 + 2H_2O \longrightarrow XeO_2F_2 + 4HF$$
$$XeF_6 + 3H_2O \longrightarrow XeO_3 + 6HF$$

3. In strongly basic solution, the reaction proceeds as

$$XeF_6 + 7OH^- \longrightarrow 6F^- + 4H_2O + \underset{(Xe\,=\,+\,6)}{HXeO_4^-} \text{ (xenate ion)}$$

$$HXeO_4^- \xrightarrow{+2OH^-} \frac{6}{4} H_2O + \frac{1}{4} Xe + \frac{3}{4} \underset{(Xe\,=\,+8)}{XeO_6^{4-}} \text{ (perxenate ion)}$$

In acidic solution, main species is $XeOF_4$ (Xe = + 6) and H_6XeO_6 (Xe = + 6) H_6XeO_6 is called **xenic acid.**

4. It also acts as an oxidising agent as

$$XeF_6 + 3H_2 \longrightarrow Xe + 6HF$$

XeF_6 can also oxidise NH_3 (N = – 3) to N_2 (N = 0) and HCl (Cl = – 1) to Cl_2 (Cl = 0). In these reactions XeF_6 is reduced to Xe.

$$XeF_6 + 8NH_3 \longrightarrow Xe + 6NH_4F + N_2$$
$$XeF_6 + 6HCl \longrightarrow Xe + 6HF + 3Cl_2$$

5. XeF_6 dissolves in HF, giving a solution which is a good conductor of electricity. The electrical conductivity of the solution is because of the formation of XeF_5^+ and HF_2^+.

$$XeF_6 + HF \longrightarrow XeF_5^+ + HF_2^+$$

6. XeF_6 gives addition compound with AsF_5 and SbF_5 molecules.

$$XeF_6 + \underset{(M\,=\,\text{As, Sb})}{MF_5} \longrightarrow XeF_6 \cdot MF_5 \longrightarrow [XeF_5]^+[MF_6]^-$$

In these reactions, XeF_6 molecule acts as F^- ion donor while MF_5 molecule behaves as F^- ion acceptor.

7. XeF_6 also reacts with alkali metal fluorides (except LiF) and gives species containing XeF_7^- and XeF_8^{2-} ions. Thus, in these reactions XeF_6 molecule acts as F^- ion acceptor and MF molecule (M = Na, K, Rb) behaves as F^- ion donor.

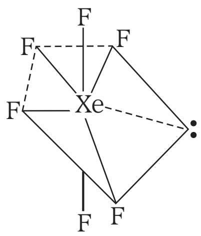
$$XeF_6 + \underset{(M\,=\,\text{Na, K})}{2MF} \longrightarrow \underset{\text{(octafluoro xenate)}}{M_2XeF_8}$$

$$XeF_6 + \underset{\text{molten}}{2RbF} \xrightarrow{200°C} \underset{\text{(heptafluoroxenate)}}{2RbXeF_7} \xrightarrow{50°C} \underset{\text{(octafluoroxenate)}}{Rb_2XeF_8} + XeF_6$$

8. XeF_6 is the most volatile of all the fluorides. Its vapours have a greenish yellow colour.
9. XeF_6 is extremely reactive. Thus, cannot be stored in glass or quartz vessels, since it readily reacts with SiO_2 present in glass as one of its constituents. With SiO_2, XeF_6 gives dangerously explosive XeO_3 as a final product.

$$2XeF_6 + 3SiO_2 \longrightarrow 2XeO_3 + 3SiF_4$$

XeF_6 has sp^3d^3 hybridisation and distorted octahedral geometry because of the presence of one lone pair of electrons.



Distorted octahedral XeF_6

Xenon Oxides

(a) **Xenon Trioxide,** XeO_3

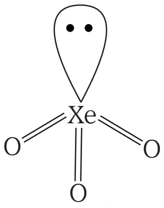
It is prepared by complete hydrolysis of XeF_4 and XeF_6 as

$$6XeF_4 + 12H_2O \longrightarrow 2XeO_3 + 4Xe + 3O_2 + 24HF$$

$$XeF_6 + 3H_2O \longrightarrow XeO_3 + 6HF$$

It is a colourless solid, highly explosive and powerful oxidising agent.

XeO_3 has sp^3 hybridisation trigonal pyramidal geometry because of the presence of one lone pair of electrons over Xe. The molecule has three Xe$=$O double bonds containing $p\pi$ - $d\pi$ overlapping as



Structure of XeO_3

(b) **Xenon Tetraoxide,** XeO_4

It is prepared by the action of conc H_2SO_4 on sodium or barium xenate (Na_4XeO_6; Ba_2XeO_6) at room temperature.

$$Na_4XeO_6 + 2H_2SO_4 \longrightarrow XeO_4 + 2Na_2SO_4 + 2H_2O$$

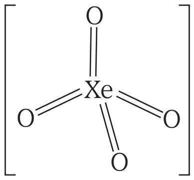
$$Ba_2XeO_6 + 2H_2SO_4 \longrightarrow XeO_4 + 2BaSO_4 + 2H_2O$$

XeO_4 is purified by vacuum sublimation at 195 K.

It is quite unstable gas and decomposes to xenon and oxygen,

$$XeO_4 \longrightarrow Xe + 2O_2$$

XeO_4 has tetrahedral structure due to sp^3 hybridization of Xe. There are four Xe—O double bonds containing $p\pi$ - $d\pi$ overlapping.



Structure of XeO_4

Clathrates

Noble gases form a number of compounds in which these are trapped into the cavities of crystal lattices of certain organic and inorganic compounds. These are called **cage compounds** or **clathrates,** *e.g.*, $Xe \cdot 6H_2O$, quinol clathrate. He and Ne do not form clathrate compounds as the size of the cavity is more than the size of the He or Ne atom.

Uses of Clathrates

Important uses of clathrates include

1. Separation of noble gases. Ne can be separated from other gases (Ar and Kr) as it does not form clathrate with quinol.
2. As an anaesthetic.
3. The clathrates are convenient form of handling. processing and transporting of isotopes of noble gases.

Sample **Problem 18** *Which one of the following does not exist?* [**NCERT**]

(*a*) $XeOF_4$ (*b*) NeF_2
(*c*) XeF_2 (*d*) XeF_6

Interpret (*b*) NeF_2 does not exist due to very high ionization enthalpy (2080 kJ mol^{-1}) of neon (Ne). Ionization enthalpy of xenon is low (1170 kJ mol^{-1}) so, its compounds like $XeOF_4$, XeF_2, XeF_6 etc. exist.

Check Point 4

1. Explain, why are noble gases inert under ordinary conditions?
2. Why do noble gases form compounds with fluorine and oxygen?
3. The boiling points of noble gases increase with increase in atomic number. Explain
4. Why does xenon not form fluorides such as XeF, XeF_3 or XeF_5?

WORKED OUT
Examples

Example 1 *Copper metal on treatment with dilute* HNO_3 *produces a gas* (*X*). (*X*) *when passed through acidic solution of stannous chloride, a nitrogen containing compound* (*Y*) *is obtained.* (*Y*) *on reaction with nitrous acid produces a gas* (*Z*). *Gas* (*Z*) *is*

(*a*) NO (*b*) N_2
(*c*) NO_2 (*d*) N_2O

Solution (*d*) Cu produces NO gas when treated with dil. HNO_3. This gas is reduced by $SnCl_2/HCl$ and then oxidised by HNO_2 to give N_2O. The reactions are as follows:

$$Cu + \text{dil. } HNO_3 \longrightarrow \underset{(X)}{NO} \xrightarrow{SnCl_2/HCl} \underset{(Y)}{NH_2OH \cdot HCl} \xrightarrow{HNO_2} \underset{(Z)}{N_2O}$$

$$\underset{(X)}{NO} \xrightarrow{SnCl_2/HCl} NH_2OH \cdot HCl$$

$$\underset{(Y)}{NH_2OH \cdot HCl} \xrightarrow{HNO_2} \underset{(Z)}{N_2O}$$

Example 2 *White phosphorus on reaction with lime water gives calcium salt of an acid* (*A*) *along with a gas* (*X*). *Which of the following statement is correct with respect to above?*

(*a*) (*A*) *on heating gives* (*X*) *and* O_2
(*b*) *The bond angle in* (*X*) *is less than that in case of ammonia*
(*c*) (*A*) *is a dibasic acid*
(*d*) (*X*) *is more basic than ammonia*

Solution (*b*) $8P + 3Ca(OH)_2 + 6H_2O \rightarrow 3Ca(H_2PO_2)_2 + \underset{(X)}{2PH_3}$

(*A*) is H_3PO_2 (hypophosphorous acid), a monobasic acid. PH_3 is less basic than NH_3. The bond angle in (*X*) is less than that present in NH_3. H_3PO_2 on heating gives orthophosphoric acid and phosphine (*X*).

Example 3 *A certain compound on burning in air produces three oxides. Out of these, one oxide turned lime water milky, the second one turned anhydrous* $CuSO_4$ *blue and the third formed a solution of* $pH = 9$. *The compound is made up of*

(*a*) S, N *and* H (*b*) S, H *and* Na
(*c*) S, *and* N (*d*) S, C *and* H

Solution (*b*) Since, the gas turns lime water milky, it may be CO_2 or SO_2, H_2O turns the colour of anhydrous $CuSO_4$ blue and the oxide of metals are usually alkaline. Thus, the compound is made up of S, H and Na.

Example 4 *An oxide of a non-metal has the following properties*

(*i*) *It acts both as a proton donor as well as proton acceptor*
(*ii*) *It reacts readily with basic and acidic oxides*
(*iii*) *It oxidises* Fe *at its boiling point.*

The oxide is

(*a*) P_2O_5 (*b*) SiO_2
(*c*) H_2O (*d*) CO_2

Solution (*c*) H_2O is a amphoteric oxide. It can accept protons and also can donate them. Thus, it readily reacts with basic as well as acidic oxides. Only water vapour react with Fe.

Example 5 *Which of the following solutions does not change its colour on passing ozone through it?*

(*a*) *Starch iodide solution*
(*b*) *Alcoholic solution of benzidine*
(*c*) *Acidic solution of* $K_2Cr_2O_7$
(*d*) *Acidified solution of* $FeSO_4$

Solution (*c*) Ozone does not react with acidified solution of $K_2Cr_2O_7$, thus, does not change its colour.

Example 6 *A greenish yellow gas reacts with an alkali metal hydroxide to form a halate which can be used in fireworks and safety matches. The gas and the halate are*

(*a*) $Br_2, KBrO_3$ (*b*) $Cl_2, KClO_3$
(*c*) I_2, $NaIO_3$ (*d*) I_2, KIO_3

Solution (*b*) $KClO_3$ is the halate that is used in fireworks and safety matches thus, the gas is Cl_2

$$\underset{\substack{\text{greenish}\\ \text{yellow gas}}}{3Cl_2} + 6KOH \longrightarrow KClO_3 + 5KCl + 3H_2O$$

Example 7 $AgClO_3 + (A) \longrightarrow (B) + (C) + (D)$

$MnO_2 + \underset{\text{conc}}{HCl} \longrightarrow$

The substance (A), (B), (C) and (D) are

(a) Cl_2, AgCl, ClO_2, O_2
(b) Cl_2, Ag, Cl_2O_6, O_2
(c) H_2, AgCl, H_2O, O_2
(d) HClO, AgCl, Cl_2O, O_2

Solution (a) $2AgClO_3 + \underset{(A)}{Cl_2} \longrightarrow \underset{(B)}{2AgCl} + \underset{(C)}{2ClO_2} + \underset{(D)}{O_2}$

Example 8 $KClO_3$ *on reaction with* SO_2 *gives (A) and on reaction with conc.* H_2SO_4 *gives (B). (A) and (B) are*

(a) KCl, $HClO_4$
(b) Cl_2, ClO_2
(c) KCl, $HClO_3$
(d) Cl_2, $HClO_4$

Solution (a) $KClO_3 + 3SO_2 + 3H_2O \longrightarrow \underset{(A)}{KCl} + 3H_2SO_4$

$$3KClO_3 + 3H_2SO_4 \longrightarrow 3KHSO_4 + 3HClO_3$$

$$2HClO_3 \longrightarrow 2ClO_2 + H_2O + O$$

$$HClO_3 + O \longrightarrow HClO_4$$

$$3KClO_3 + 3H_2SO_4 \longrightarrow \underbrace{3KHSO_4 + 2ClO_2 + \underset{(B)}{HClO_4} + H_2O}_{\text{products}}$$

Example 9 *A liquid X is treated with* Na_2CO_3 *solution. A mixture of two salts Y and Z are produced in the solution. The mixture on acidification with sulphuric acid and distillation produces the liquid X again. Identify X.*

(a) Cl_2
(b) Br_2
(c) Hg
(d) I_2

Solution (b) The liquid X is bromine which on treatment with sodium carbonate forms a mixture of NaBr and $NaBrO_3$ (sodium bromate). The mixture with conc. H_2SO_4 on distillation, gives the liquid bromine again.

$$3Br_2 + 3Na_2CO_3 \longrightarrow 5NaBr + NaBrO_3 + 3CO_2$$

$$5NaBr + NaBrO_3 + 3H_2SO_4 \longrightarrow 3Na_2SO_4 + 3Br_2 + 3H_2O$$

Start **Practice** *for* JEE Main

Round I (Topically Divided Problems)

Group 15 Elements and their Compounds

1. Pure nitrogen can be prepared from
(a) NH_4OH (b) NH_4NO_2
(c) $Ba(NO_3)_2$ (d) Ca_3N_2

2. The element which catches fire in air at 30°C and is stored under water is
(a) sodium (b) phosphorus
(c) magnesium (d) zinc

3. By the action of hot conc. H_2SO_4, phosphorus changes to
(a) phosphorous acid
(b) metaphosphoric acid
(c) pyrophosphoric acid
(d) orthophosphoric acid

4. Each of the following is true for white and red phosphorus except that they
(a) can be oxidised by heating in air
(b) are both soluble in CS_2
(c) consists of same kind of atoms
(d) can be converted into one another

5. White phosphorus (P_4) does not contain
(a) six P—P single bond
(b) four P—P single bond
(c) four lone pairs of electrons
(d) P—P—P angle of 60°

6. Which oxide do not act as a reducing agent?
(a) N_2O_5 (b) N_2O
(c) NO (d) NO_2

7. Which of the following is not hydrolysed?
(a) PF_3 (b) $SbCl_3$
(c) $AsCl_3$ (d) NF_3

8. The number of P—O—P bonds in cyclic metaphosphoric acid is
(a) zero (b) three
(c) two (d) four

9. Which of the following will be obtained on heating phosphorus acid? **[NCERT]**
(a) Metaphosphoric acid (b) Orthophosphorous acid
(c) Hypophosphorous acid (d) Phosphene

10. PCl_5 can act as **[NCERT]**
(a) reducing agent
(b) oxidising agent
(c) both reducing as well as oxidising agent
(d) neither reducing nor oxidising agent

11. On comparing with bond angle of PH_3, the bond angle in PH_4^+ ion is **[NCERT]**
(a) greater (b) lesser
(c) equal (d) cannot predict

12. Which of the following oxides of nitrogen is the anhydride of nitrous acid?
(a) NO (b) N_2O_4
(c) N_2O_3 (d) N_2O_5

13. PCl_3 on hydrolysis gives
(a) HPO_3 (b) H_3PO_2
(c) H_3PO_4 (d) H_3PO_3

14. Maximum covalency of nitrogen is **[NCERT Exemplar]**
(a) 3 (b) 5 (c) 4 (d) 6

15. Elements of group-15 form compounds in +5 oxidation state. However, bismuth forms only one well characterised compound in +5 oxidation state. The compound is **[NCERT Exemplar]**
(a) Bi_2O_5 (b) BiF_5 (c) $BiCl_5$ (d) Bi_2S_5

16. In solid state PCl_5 is a **[NCERT Exemplar]**
(a) covalent solid
(b) octahedral structure
(c) ionic solid with $[PCl_6]^+$ octahedral and $[PCl_4]^-$ tetrahedral
(d) ionic solid with $[PCl_4]^+$ tetrahedral and $[PCl_6]^-$ octahedral

17. Nitrogen dioxide
(a) does not dissolve in water
(b) dissolves in water forming nitric acid
(c) dissolves in water to form a mixture of nitrous and nitric acid
(d) dissolves in water to form nitrous acid and gives off oxygen

18. The basicity of orthophosphoric acid is
(a) 2 (b) 4 (c) 3 (d) 5

19. Which oxide is alkaline?
(a) P_2O_3 (b) B_2O_3 (c) Bi_2O_3 (d) As_2O_3

20. Phosphine is produced by adding water to
(a) CaC_2 (b) HPO_3 (c) Ca_3P_2 (d) P_4O_{10}

21. What may be expected to happen when phosphine gas is mixed with chlorine gas?
(a) PCl_5 and HCl are formed and the mixture cools down
(b) $PH_3 \cdot Cl_2$ is formed with warming up
(c) PCl_3 and HCl are formed and the mixture warms up
(d) The mixture only cools down

22. Liquid ammonia is used for refrigeration because
(a) it is basic
(b) it is a stable compound
(c) it has a high dipole moment
(d) it has high heat of vaporisation

23. What would happen when a solution of potassium chromate is treated with an excess of dilute nitric acid?
(a) CrO_4^{2-} is reduced to +3 state of Cr
(b) CrO_4^{2-} is oxidized to +7 state of Cr
(c) $Cr_2O_7^{2-}$ and H_2O are formed
(d) Cr^{3-} and $Cr_2O_7^{2-}$ are formed

24. Which of the following compound show sublimation?
(a) $CaHPO_3$ (b) NH_4Cl
(c) $BaSO_4$ (d) $CaCO_3$

25. In the reaction, $HNO_3 + P_4O_{10} \longrightarrow 4HPO_3 + x$, the product x is
(a) NO_2 (b) N_2O_5 (c) N_2O_3 (d) H_2O

Group 16 Elements and their Compounds

26. The S—S—S bond angle in S_8 molecule is
(a) 109.5° (b) 105° (c) 110° (d) 60°

27. Sulphur in +3 oxidation state is present in
(a) dithionous acid (b) sulphurous acid
(c) thionous acid (d) pyrosulphuric acid

28. Sulphur is present in [NCERT]
(a) Baryte (b) zinc blende
(c) garlic (d) All of these

29. Sulphur on boiling with NaOH solution gives
(a) $Na_2SO_3 + H_2S$ (b) $Na_2S_2O_3 + Na_2S$
(c) $Na_2S_2O_3 + NaHSO_3$ (d) $Na_2SO_3 + SO_2$

30. At room temperature, H_2O is liquid while H_2S is a gas. The reason is
(a) electronegativity of O is greater than S
(b) difference in the bond angles of both the molecules
(c) association takes place in H_2O due to H-bonding while no H-bonding in H_2S
(d) O and S belong to different periods

31. $SO_2 + H_2S \longrightarrow$ product, the final product is
(a) H_2SO_3 (b) H_2SO_4 (c) $H_2S_2O_3$ (d) $H_2O + S$

32. A gas that cannot be collected over water is
(a) SO_2 (b) N_2 (c) O_2 (d) PH_3

33. In the reaction, $HCOOH \xrightarrow{H_2SO_4} CO + H_2O$;

H_2SO_4 acts as
(a) reducing agent (b) oxidising agent
(c) dehydrating agent (d) All of these

34. Which one is known as oil of vitriol?
(a) $H_2S_2O_7$ (b) H_2SO_3 (c) $H_2S_2O_8$ (d) H_2SO_4

35. Bleaching action of SO_2 is due to
(a) reduction (b) hydrolysis
(c) oxidation (d) acidic nature

36. Copper turnings when heated with concentrated sulphuric acid will give
(a) H_2S (b) SO_2 (c) SO_3 (d) O_2

37. Sulphuric acid has great affinity for water because
(a) acid decomposes water
(b) it hydrolyses the acid
(c) it decomposes the acid
(d) acid forms hydrates with water

38. S—S bond is present in
(a) α-$(SO_3)_n$ (b) γ-(S_3O_9)
(c) $H_2S_2O_3$ (d) $H_2S_2O_8$

39. The compound of sulphur used as a solvent in rubber industry is
(a) $SO_2(OH)Cl$ (b) SO_2
(c) SO_3 (d) S_2Cl_2

40. Dry bleach is caused by
(a) Cl_2 (b) SO_2 (c) H_2O_2 (d) O_3

Elements of Group 17 and their Compounds

41. Fluorine reacts with water to give
(a) HF, O_2 and O_3 (b) HF and F_2
(c) HF and O_2 (d) HF and O_3

42. The chief source of iodine in which it is present as sodium iodate is
(a) carnallite
(b) sea weeds
(c) caliche
(d) iodine never exists as sodium iodate

43. Bleaching action of chlorine is due to [NCERT]
(a) Cl (b) O (c) H (d) N

44. Which of the following is strongest oxidising agent?
(a) I_2 (b) Br_2
(c) Cl_2 (d) F_2

45. Chlorine acts as a bleaching agent only in presence of
(a) dry air (b) moisture
(c) sunlight (d) pure oxygen

46. Concentrated HNO_3 reacts with I_2 to gives
(a) HI (b) HOI
(c) HIO_3 (d) $HOIO_2$

47. Among the halogens, the one which is oxidised by nitric acid is
(a) iodine (b) bromine
(c) fluorine (d) chlorine

48. Iodine is formed when potassium iodide reacts with a solution of
(a) $ZnSO_4$ (b) $CuSO_4$
(c) $(NH_4)_2SO_4$ (d) Na_2SO_4

49. Mark the strongest acid
(a) HI (b) HBr
(c) HCl (d) HF

50. Which of the following properties does not correspond to the order?

$$HI < HBr < HCl < HF$$

(a) Thermal stability (b) Reducing power
(c) Ionic character (d) Dipole moment

51. Reduction potentials of some ions are given below. Arrange them in decreasing order of oxidising power.

Ion	ClO_4^-	IO_4^-	BrO_4^-
Reduction potential E^V / V	$E^V = 1.19\,V$	$E^V = 1.65\,V$	$E^V = 1.74\,V$

[NCERT Exemplar]

(a) $ClO_4^- > IO_4^- > BrO_4^-$ (b) $IO_4^- > BrO_4^- > ClO_4^-$
(c) $BrO_4^- > IO_4^- > ClO_4^-$ (d) $BrO_4^- > ClO_4^- > IO_4^-$

52. Metal halide which is insoluble in water is
(a) AgF (b) AgI
(c) KBr (d) $CaCl_2$

53. The mixture of conc. HCl and HNO_3 made in 3 : 1 ratio contains
(a) ClO_2 (b) NOCl
(c) NCl_3 (d) N_2O_4

54. Which one liberates Br_2 from KBr?
(a) I_2 (b) HI (c) Cl_2 (d) SO_2

55. The acid employed for etching of glass is
(a) HCl (b) $HClO_4$
(c) HF (d) aqua regia

56. Which one is the anhydride of $HClO_4$?
(a) ClO_2 (b) Cl_2O_7
(c) Cl_2O (d) Cl_2O_6

57. The reaction of the type $2X_2 + S \longrightarrow SX_4$ is shown by sulphur when X is
(a) fluorine or chlorine
(b) chlorine only
(c) chlorine and bromine only
(d) F, Cl, Br, all

58. The following acids have been arranged in the order of decreasing acid strength. Identify the correct order

ClOH(I) BrOH(II) IOH(III)

(a) I > II > III (b) II > I > III
(c) III > II > I (d) I > III > II

59. Euchlorine is a mixture of
(a) $Cl_2 + ClO_2$ (b) $Cl_2 + Cl_2O$
(c) $Cl_2O_3 + ClO_2$ (d) $Cl_2O + Cl_2O_3$

60. T-shaped interhalogen compound is
(a) ClF_3 (b) ICl
(c) ClF_5 (d) IF_5

61. Which of the following form of interhalogen compounds does not exist?
(a) IF_7 (b) ClF_3
(c) ICl (d) $BrCl_7$

Group 18 Elements and their Compounds

62. Which of the following gases exists more abundantly in nature than the others?
(a) Helium (b) Neon
(c) Argon (d) Krypton

63. Welding of magnesium can be done in an atmosphere of
(a) Xe (b) He (c) Kr (d) Ne

64. Gradual addition of electronic shells in the noble gases causes a decrease in their
(a) ionisation energy (b) density
(c) boiling point (d) atomic radius

65. Noble gases are sparingly soluble in water due to
(a) dipole-dipole interaction
(b) dipole-induced dipole interaction
(c) induced dipole-induced dipole interaction
(d) hydrogen bonding

66. The noble gas which can diffuse through rubber and glass easily is
(a) Xe (b) Ne (c) Ar (d) He

67. The correct order of solubility in water for He, Ne, Ar, Kr, Xe is
(a) Xe > Kr > Ar > Ne > He
(b) Ar > Ne > He > Kr > Xe
(c) He > Ne > Ar > Kr > Xe
(d) Ne > Ar > Kr > He > Xe

68. When the mineral clevite is heated, it give off the inert gas
(a) helium (b) xenon (c) radon (d) argon

69. The noble gas which forms interstitial compounds is
(a) Helium (b) Argon (c) Neon (d) Xenon

70. The noble gas which shows abnormal behaviour in liquid state and behave as super fluid is
(a) Ne (b) He
(c) Ar (d) Xe

71. Which of the following is the life saving mixture for an asthma patient?
(a) Mixture of helium and oxygen
(b) Mixture of neon and oxygen
(c) Mixture of xenon and nitrogen
(d) Mixture of argon and oxygen

72. The noble gas which forms maximum number of compounds is
(a) Ar (b) He (c) Ne (d) Xe

73. XeF_2 on hydrolysis gives
(a) XeO_3 (b) XeO (c) Xe (d) XeO_2

74. Which of the following is not obtained by direct reaction of constituent elements?
(a) XeO_3 (b) XeF_2 (c) XeF_6 (d) XeF_4

75. Which of the following is formed by xenon?
(a) XeF_7 (b) XeF_4 (c) XeF_5 (d) XeF_3

76. Among the following molecule
(i) XeO_3 (ii) $XeOF_4$
(iii) XeF_6
those having same number of lone pairs on Xe are
(a) (i) and (iii) only (b) (i) and (ii) only
(c) (ii) and (iii) only (d) (i), (ii) and (iii)

77. The geometry of $XeOF_4$ molecule is
(a) tetrahedral (b) square pyramidal
(c) square planar (d) octahedral

78. The pair of species having identical shape for molecules of both species is
(a) XeF_2, IF_2^- (b) BF_3, NH_3
(c) CF_4, SF_4 (d) PCl_5, ICl_5

79. Number of $p\pi$ - $d\pi$ bonds present in XeO_4 are
(a) four (b) two (c) three (d) zero

80. Clathrates are
(a) non-stoichiometric compounds
(b) complex compounds
(c) interstitial compounds
(d) ionic compounds

Round II (Mixed Bag)

Only One Correct Option

1. The number of P—O—P bridges in the structure of phosphorus pentoxide and phosphorus trioxide are respectively
(a) 5, 5 (b) 6, 5 (c) 5, 6 (d) 6, 6

2. In compounds of type ECl_3, where E = B, P, As or Bi the angles Cl—E—Cl for different E are in the order
(a) B > P > As > Bi (b) B > P = As = Bi
(c) B < P = As = Bi (d) B < P < As < Bi

3. Ammonia on reaction with hypochlorite anion, can form
(a) NO (b) N_2H_4 (c) NH_4Cl (d) HNO_2

4. Which blue liquid is obtained on reacting equimolar amounts of two gases at –30°C?
(a) N_2O_4 (b) N_2O (c) N_2O_3 (d) N_2O_5

5. The percentage of p-character in the orbitals forming P—P bond in P_4 is
(a) 25 (b) 33
(c) 50 (d) 75

6. $(NH_4)_2Cr_2O_7$ on heating liberates a gas. The same gas will be obtained by
(a) heating NH_4NO_3
(b) heating NH_4NO_2
(c) treating H_2O_2 with $NaNO_2$
(d) treating Mg_3N_2 with H_2O

7. There is no S—S bond in
(a) $S_2O_4^{2-}$ (b) $S_2O_3^{2-}$
(c) $S_2O_5^{2-}$ (d) $S_2O_7^{2-}$

8. What are the conditions to maximize the yield of H_2SO_4 by contact process? **[NCERT]**
(a) Low temperature and high pressure
(b) High temperature and low pressure
(c) High temperature and high pressure
(d) Low temperature and low pressure

9. Sulphur hepto oxide is an anhydride of

(a) $H_2S_2O_8$ (b) $H_2S_2O_7$
(c) H_2SO_4 (d) H_2SO_5

10. The reason why conc. H_2SO_4 is used largely to prepare other acids is that conc H_2SO_4

(a) is highly ionised
(b) is dehydrating agent
(c) has high specific gravity and density
(d) has a high boiling point

11. A substance which gives a yellow precipitate when boiled with an excess of nitric acid and ammonium molybdate and red precipitate with $AgNO_3$ is

(a) orthophosphate (b) pyrophosphate
(c) metaphosphate (d) hypophosphate

12. The following two reactions HNO_3 with Zn are given as (equations are not balanced)

$$\text{Zn} + \text{conc. } HNO_3 \longrightarrow Zn(NO_3)_2 + X + H_2O(A)$$
$$\text{Zn} + \text{dil. } HNO_3 \longrightarrow Zn(NO_3)_2 + Y + H_2O(B)$$

In reactions *A* and *B*, the compounds *X* and *Y* respectively, are

(a) NO_2 and NO (b) NO_2 and NO_2
(c) NO and NO_2 (d) NO_2 and NH_4NO_3

13. Concentrated sulphuric acid can be reduced by

(a) NaCl (b) NaF (c) NaOH (d) NaBr

14. On heating lead (II) nitrate gives a brown gas "*A*". The gas "*A*" on cooling changes to colourless solid "*B*". Solid "*B*" on heating with NO changes to a blue solid "*C*". Identify "*C*". **[NCERT Exemplar]**

(a) NO_2 (b) N_2O_4 (c) N_2O_5 (d) N_2O_3

15. On heating, compound (*A*) gives a gas (*B*) which is a constituent of air. This gas when treated with 3 moles of hydrogen (H_2) in the presence of a catalyst gives another gas (*C*) which is basic in nature. Gas *C* on further oxidation in moist condition gives a compound (*D*) which is a part of acid rain. Identify compound (*D*). **[NCERT Exemplar]**

(a) HNO_2 (b) HNO_3 (c) H_2SO_4 (d) HCl

16. A black compound of manganese reacts with a halogen acid to give greenish yellow gas. When excess of this gas reacts with NH_3 an unstable trihalide is formed. In this process the oxidation state of nitrogen changes from **[NCERT Exemplar]**

(a) -3 to $+3$ (b) -3 to 0
(c) -3 to $+5$ (d) 0 to -3

17. Which of the following dissolves in water but does not give any oxyacid solution?

(a) SO_2 (b) OF_2
(c) SCl_4 (d) SO_3

18. Which one is correct statement?

(a) Basicity of H_3PO_4 and H_3PO_3 is 3 and 3 respectively
(b) Acidity of H_3PO_4 and H_3PO_3 is 3 and 3 respectively
(c) Acidity of H_3PO_4 and H_3PO_3 is 3 and 2 respectively
(d) Basicity of H_3PO_4 and H_3PO_3 is 3 and 2 respectively

19. Correct order of decreasing thermal stability is as

(a) $NH_3 > PH_3 > AsH_3 > SbH_3$
(b) $PH_3 > NH_3 > AsH_3 > SbH_3$
(c) $AsH_3 > PH_3 > NH_3 > SbH_3$
(d) $SbH_3 > AsH_3 > PH_3 > NH_3$

20. Which of the following is not oxidised by O_3?

(a) KI (b) $FeSO_4$
(c) $KMnO_4$ (d) K_2MnO_4

21. NH_3 gas is dried over

(a) CaO (b) HNO_3
(c) P_2O_5 (d) $CuSO_4$

22. The solubility of iodine in water increases in presence of

(a) chloroform (b) alcohol
(c) potassium iodide (d) sodium hydroxide

23. Which is the most volatile compound?

(a) HCl (b) HI (c) HBr (d) HF

24. Which one below is a pseudohalide?

(a) I_3^- (b) IF^- (c) ICl (d) CN^-

25. A dark brown solid (*X*) reacts with NH_3 to form a mild explosive which decomposes to give a violet coloured gas. (*X*) also reacts with H_2 to give an acid (*Y*). (*Y*) can also be prepared by heating its salt with H_3PO_4. *X* and *Y* are

(a) Cl_2, HCl (b) SO_2, H_2SO_4
(c) Br_2, HBr (d) I_2, HI

26. A green yellow gas reacts with an alkali metal hydroxide to form a halate which can be used in fireworks and safety matches. The gas and halate respectively are

(a) Br_2, $KBrO_3$ (b) Cl_2, $KClO_3$
(c) I_2, $NaIO_3$ (d) Cl_2, $NaClO_3$

27. Which reaction is not feasible?

(a) $2KI + Br_2 \longrightarrow 2KBr + I_2$
(b) $2KBr + I_2 \longrightarrow 2KI + Br_2$
(c) $2KBr + Cl_2 \longrightarrow 2KCl + Br_2$
(d) $2H_2O + 2F_2 \longrightarrow 4HF + O_2$

28. The least stable anion of oxo-acids of chlorine is

(a) ClO^- (b) ClO_2^- (c) ClO_3^- (d) ClO_4^-

29. XeO_2F_2 is obtained by partial hydrolysis of

(a) $XeOF_4$ (b) XeF_6
(c) Both (a) and (b) (d) None of these

30. Which of the following compounds can not be stored in glass vessels?

(a) XeF_4 (b) XeF_6
(c) XeO_3 (d) XeF_2

31. Which one of the following statements regarding helium is incorrect?

(a) It is used to produce and sustain powerful super conducting magnets
(b) It is used in gas-cooled nuclear reactors
(c) It is used to fill gas balloons instead of hydrogen because it is lighter and non-inflammable
(d) It is used as a cryogenic agent for carrying out experiments at low temperature

32. Bleaching powder is disinfectant for purification of water, when water born germs are killed, but disinfectant activity is destroyed. It is due to its disproportionation into

(a) $CaCl_2$ and Cl_2 (b) $CaCl_2$ and $Ca(ClO_3)_2$
(c) CaO and Cl_2 (d) CaO, Cl_2 and $CaCl_2$

33. $HClO_4 + P_2O_5 \longrightarrow (A)$ and (B)
A and *B* are

(a) $HClO_3, H_3PO_4$ (b) $Cl_2O_6 + HPO_3$
(c) ClO_2, H_2PO_4 (d) Cl_2O_7, HPO_3

34. Which of the following does not exist?

(a) $KrF^-[SbF_6]^-$ (b) $[KrF_3]^-[SbF_4]^+$
(c) $KrF^+[MoOF_5]$ (d) $KrF^+[WOF_5]^-$

35. Perxenate ion is

(a) XeO_6^{4-} (b) $HXeO_4^-$
(c) XeO_4^{2-} (d) XeO_4^-

36. The stability of interhalogen compounds follows the order

(a) $IF_3 > BrF_3 > ClF_3$ (b) $BrF_3 > IF_3 > ClF_3$
(c) $ClF_3 > BrF_3 > IF_3$ (d) $ClF_3 > IF_3 > BrF_3$

37. Xenon hexafluoride reacts with silica to form a xenon compound *X*. The oxidation state of xenon in *X* is

(a) +2 (b) +4
(c) +6 (d) 0

38. The electron affinity values (in kJ mol^{-1}) of three halogens *X*, *Y* and *Z* are respectively – 349, – 333 and – 325. Then *X*, *Y* and *Z* respectively, are

(a) F_2, Cl_2 and Br_2 (b) Cl_2, F_2 and Br_2
(c) Cl_2, Br_2 and F_2 (d) Br_2, Cl_2 and F_2

39. The formation of $O_2^+[PtF_6]^-$ is the basis for the formation of xenon fluorides. This is because

(a) O_2 and Xe have comparable sizes
(b) both O_2 and Xe are gases
(c) O_2 and Xe have comparable ionisation energies
(d) Both (a) and (b)

40. A metal, *M* forms chlorides in its +2 and +4 oxidation states. Which of the following statements about these chlorides is correct?

(a) MCl_2 is more volatile than MCl_4
(b) MCl_2 is more soluble in anhydrous ethanol than MCl_4
(c) MCl_2 is more ionic than MCl_4
(d) MCl_2 is more easily hydrolysed than MCl_4

41. What products are expected from the disproportionation reaction of hypochlorous acid?

(a) $HClO_3$ and Cl_2O (b) $HClO_2$ and $HClO_4$
(c) HCl and Cl_2O (d) HCl and $HClO_3$

42. Fluorine exhibits an oxidation state of only –1 because

(a) it can readily accept an electron
(b) it is strongly electronegative
(c) it is a non-metal
(d) it belongs to halogen family

43. D_3 line observed in the yellow region of the sun's spectrum is due to

(a) Na (b) Ne
(c) Kr (d) He

More than One Correct Option

44. If chlorine gas is passed through hot NaOH solution, two changes are observed in the oxidation number of chlorine during the reaction. These are … and … [**NCERT** Exemplar]

(a) 0 to +5 (b) 0 to +3
(c) 0 to –1 (d) 0 to +1

45. Which of the following options are not in accordance with the property mentioned against them? [**NCERT** Exemplar]

(a) $F_2 > Cl_2 > Br_2 > I_2$	Oxidising power
(b) $MI > MBr > MCl > MF$	Ionic character of metal halide
(c) $F_2 > Cl_2 > Br_2 > I_2$	Bond dissociation enthalpy
(d) $HI < HBr < HCl < HF$	Hydrogen-halogen bond strength

46. Which of the following statements are correct for SO_2 gas? [**NCERT** Exemplar]

(a) It acts as bleaching agent in moist conditions
(b) Its molecule has linear geometry
(c) Its dilute solution is used as disinfectant
(d) It can be prepared by the reaction of dilute H_2SO_4 with metal sulphide

47. Concentrated sulphuric acid is

(a) oxidising agent (b) hygroscopic
(c) efflorescent (d) sulphonating agent

48. Which of the following statements is/are correct?

(a) He_{II} has much lower entropy

(b) Transition of He_I to He_{II} takes place, across the line $\lambda - \lambda' = 2.2$ K

(c) It has very high viscosity

(d) He_{II} is unique liquid that exhibits superconductivity

Assertion and Reason

Directions (Q. Nos. 49 to 53) *Each of these questions contains two statements : Statement* I (*Assertion*) *and Statement* II (*Reason*). *Each of these questions also has four alternative choices, only one of which is the correct answer. You have to select one of the codes* (*a*), (*b*), (*c*), (*d*) *given below :*

(a) Statement I is true; Statement II is true; Statement II is a correct explanation for Statement I.

(b) Statement I is true; Statement II is true; Statement II is not a correct explanation for Statement I.

(c) Statement I is true; Statement II is false.

(d) Statement I is false; Statement II is true.

49. **Statement I** HNO_3 makes iron passive.

Statement II HNO_3 forms a protective layer of ferric nitrate on the surface of iron. [**NCERT** Exemplar]

50. **Statement I** Red phosphorus is less volatile than white phosphorus.

Statement II Red phosphorus has a discrete tetrahedral structure.

51. **Statement I** Oxygen is more electronegative than sulphur, yet H_2S is acidic, while H_2O is neutral.

Statement II H—S bond is weaker than O—H bond.

52. **Statement I** The aqueous solution of XeF_2 is powerful oxidising agent.

Statement II The hydrolysis of XeF_2 is slow in dilute acid but rapid in basic solution.

53. **Statement I** Helium is the only substance that can't be solidified at atmospheric pressure.

Statement II The zero point energy of helium is very high.

Comprehension Based Questions

Directions (Q. Nos. 54 to 56) Due to the presence of two lone pairs of electrons on the central atom, hydrides of group 16 elements have bent (V) shapes. The central atom in these hydrides is sp^3 hybridized. Due to strong H-bonding m.p. and b.p. of hydride of oxygen are very high. On moving down the group, the covalent character increases. This can be explained on the basis of Fajan's rule, which states that the tendency to form covalent bonds increases as the size of the anion M^{2-} increases. As the size of the atom in H_2M increases, the strength of H—M bond decreases. Hence, the tendency to release hydrogen as proton increases down the group.

54. Bond angle is minimum for

(a) H_2Se (b) H_2S (c) H_2Te (d) H_2O

55. Which one of the following hydrides is most acidic?

(a) H_2S (b) H_2Te (c) H_2O (d) H_2Se

56. Which of the following hydrides has the lowest boiling point?

(a) H_2Se (b) H_2S (c) H_2O (d) H_2Te

Directions (Q. Nos. 57 to 59) The trihalides of this group elements are predominantly covalent and have pyramidal structures, with a lone pair of electrons in the fourth orbital. Except NF_3 and PF_3, the trihalides are readily hydrolysed by water. They are Lewis bases because of the presence of lone pair of electrons. Due to absence of d-orbitals in its valence shell, nitrogen does not form pentahalides, while P, As and Sb form pentahalides due to unsymmetrical shape where some bond angles are of 90° and others are of 120°. PCl_5 is not very stable. It behave as a good chlorinating agent.

57. Which of the following compound is not known?

(a) NCl_5 (b) NI_3

(c) $SbCl_3$ (d) NCl_3

58. Which of the following halides undergoes hydrolysis?

(a) PF_5 (b) NCl_3

(c) NF_3 (d) PF_3

59. Which of the following is the weakest base?

(a) NF_3 (b) NCl_3

(c) NI_3 (d) NBr_3

Previous Years' Questions

60. The molecule having smaller bond angle is [AIEEE 2012]

(a) NCl_3 (b) $AsCl_3$

(c) $SbCl_3$ (d) PCl_3

61. Which of the following on thermal decomposition yields a basic as well as acidic oxide? [AIEEE 2012]

(a) $NaNO_3$ (b) $KClO_3$

(c) $CaCO_3$ (d) NH_4NO_3

62. Which of the following statement is wrong? [AIEEE 2011]

(a) The stability of hydrides increases from NH_3 to BiH_3 in group 15 of the Periodic table

(b) Nitrogen can't from $d\pi$-$p\pi$ bond

(c) Singe N—N bond is weaker than the single P—P bond.

(d) N_2O_4 has two resonance structure

63. Which of the following statements regarding sulphur is incorrect? [AIEEE 2011]

(a) S_2 molecule is paramagnetic

(b) The vapour at 200°C consists mostly of S_8 rings

(c) At 600°C the gas mainly consists of S_2 molecules

(d) The oxidation state of sulphur is never less than +4 in its compounds

64. Which one of the following reaction of xenon compounds is not feasible? [AIEEE 2009]

(a) $XeO_3 + 6HF \longrightarrow XeF_6 + 3H_2O$

(b) $3XeF_4 + 6H_2O \longrightarrow 2Xe + XeO_3 + 12HF + 1.5\,O_2$

(c) $2XeF_2 + 2H_2O \longrightarrow 2Xe + 4HF + O_2$

(d) $XeF_6 + RbF \longrightarrow Rb[XeF_7]$

65. Identify the incorrect statement among the following. [AIEEE 2007]

(a) Ozone reacts with SO_2 to give SO_3

(b) Silicon reacts with NaOH (*aq*) in the presence of air to give Na_2SiO_3 and H_2O

(c) Cl_2 reacts with excess of NH_3 to give N_2 and HCl

(d) Br_2 reacts with hot and strong NaOH solution to give NaBr, $NaBrO_4$ and H_2O

66. Which of the following statements is true? [AIEEE 2006]

(a) H_3PO_3 is a stronger acid than H_2SO_3

(b) In aqueous medium HF is a stroonger acid than HCl

(c) $HClO_4$ is weaker acid than $HClO_3$

(d) HNO_3 is a stronger acid than HNO_2

67. The number of hydrogen atom (s) attached to phosphorus atom in hypophosphorous acid is [AIEEE 2005]

(a) three (b) one (c) two (d) zero

68. The substance used in Holme's signals of the ship is a mixture of [AIEEE 2013]

(a) $CaC_2 + Ca_3P_2$ (b) $Ca_3(PO_4)_2 + Pb_3O_4$

(c) $H_3PO_4 + CaCl_2$ (d) $NH_3 + HOCl$

69. Concentrated hydrochloric acid when kept in open air sometimes produces a cloud of white fumes. The explanation for it is that [AIEEE 2003]

(a) concentrated hydrochloric acid emits strongly smelling HCl gas all the time

(b) oxygen in air reacts with the emitted HCl gas to form a cloud of chlorine gas

(c) strong affinity of HCl gas for moisture in air results in forming of droplets of liquid solution which appears like a cloudy smoke

(d) due to strong affinity for water, concentrated hydrochloric acid pulls moisture of air towards itself. This moisture forms droplets of water and hence, the cloud

70. PCl_3 and PCl_5 both exist; NCl_3 exist but NCl_5 does not exist. It is due to [AIEEE 2002]

(a) lower electronegativity of P and N

(b) lower tendency of N to form covalent bond

(c) availability of vacant *d*-orbital in P but not in N

(d) statement is itslelf incorrect

the Guidance

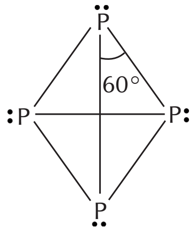
Round I

2. Because of very low ignition temperature (303K) of phosphorus, it is always kept under water.

3. $P_4 + 6H_2SO_4 \longrightarrow 4H_3PO_4 + 6SO_2$

4. White phosphorus, is soluble in CS_2 whereas red phosphorus is insoluble in it.

5. P_4 molecule,



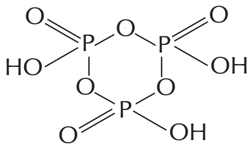
Bond angle = 60°

Six P—P single bonds, lone pair = 4

6. In N_2O_5, the oxidation state of N is +5. Further increase in oxidation state is not possible. That's why its does not behave as reducing agent.

7. Due to absence of *d*-orbitals in N-atom, it cannot accept electrons from H_2O for hydrolysis of NF_3.

8.

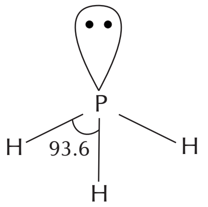


Cyclometa phosphoric acid $(HPO_3)_3$

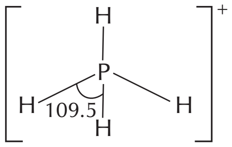
9. $\underset{\text{orthophosphorous acid}}{4H_3PO_3} \longrightarrow \underset{\text{orthophosphoric acid}}{3H_3PO_4} + \underset{\text{phosphene}}{PH_3}$

10. In PCl_5, the oxidation number of P is +5, *i.e.*, maximum which cannot be increased further. So PCl_5 cannot behave as a reducing agent. But it can decrease its oxidation number from +5 to +3, so it can behave as an oxidising agent.

11. In both PH_4^+ and PH_4, P is sp^3 hybridised. In PH_4^+, all the four orbitals are bonded whereas in PH_4, there is a lone pair of electron too. Due to lone pair-bonded pair repulsion in PH_4, the bond angle is less than 109.5°.



PH_3 (pyramidal)



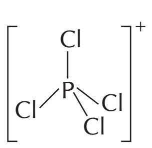
PH_4^+ (tetrahedral)

13. $3H_2O + PCl_3 \longrightarrow H_3PO_3 + 3HCl$

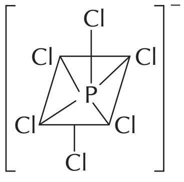
14. Due to absence of *d*-orbital, nitrogen show maximum covalency of 4 in NH_4^+. Rest of group 15 members can show maximum 5 covalency.

15. Bismuth forms BiF_5 only in which its oxidation state is +5.

16. Solid PCl_5 shows ionic lattices. It has tetrahedral cations $[PCl_4]^+$ and octahedral anions $[PCl_6]^-$.



$[PCl_4]^+$



$[PCl_6]^-$

19. $\underbrace{P_2O_3 \quad A_2O_3 \quad B_2O_3}_{\text{acidic oxides}} \quad \underbrace{Bi_2O_3}_{\text{alkaline}}\}$ as Bi is most metallic among the group.

20. $Ca_3P_2 + 6H_2O \longrightarrow 3Ca(OH)_2 + 2PH_3$

21. $PH_3 + 4Cl_2 \longrightarrow PCl_5 + 3HCl$

22. Liquid ammonia is used in refrigeration because it has high heat of vaporisation.

23. $2CrO_4^{2-} + 2H^+ \longrightarrow Cr_2O_7^{2-} + H_2O$

25. $4HNO_3 + P_4O_{10} \longrightarrow 4HPO_3 + 2N_2O_5$

27. Dithionous acid $(H_2S_2O_4)$ has sulphur in +3 oxidation state.

29. $3S + 4NaOH \xrightarrow{\text{Boiling}} Na_2S_2O_3 + Na_2S$

30. H_2O contain hydrogen bond while no hydrogen bonding is present in H_2S.

31. SO_2 acts as an oxidising agent particularly when treated with stronger reducing agents. SO_2 oxidises H_2S into S.

$$SO_2 + 2H_2S \longrightarrow 2H_2O + S$$

32. SO_2 is soluble in water.

$$H_2O + SO_2 \longrightarrow \underset{\text{sulphurous acid}}{H_2SO_3}$$

33. H_2SO_4 acts as dehydrating agent in the following reaction.

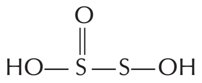
$$HCOOH \xrightarrow{H_2SO_4} CO + H_2O$$

35. $2H_2O + SO_2 \longrightarrow H_2SO_4 + \underset{\text{[nascent hydrogen]}}{2[H]}$

Coloured flower + $2[H] \longrightarrow$ Colourless flower

37. The great affinity of H_2SO_4 for water is because it forms hydrates with water.

38. $H_2S_2O_3$,



$$HO-\overset{\overset{\displaystyle O}{\|}}{S}-S-OH$$

41. $2F_2 + 2H_2O \longrightarrow 4HF + O_2$

$3F_2 + 3H_2O \longrightarrow O_3 + 6HF$

42. Caliche is crude chile salt petre ($NaNO_3$) which contains about 0.02% iodine as sodium iodate ($NaIO_3$), from which iodine is extracted.

44. Fluorine is the strongest oxidising agent. It will oxidise other halide ions to halogens in solution or even in dry.

$$F_2 + 2X^- \longrightarrow 2F^- + X_2$$

45. $Cl_2 + H_2O \longrightarrow 2HCl + [O]$ nascent oxygen

46. $I_2 + 10HNO_3 \longrightarrow 2HIO_3 + 10NO_2 + 4H_2O$

47. Reducing properties increase from F to I so, I is oxidised by nitric acid.

$$I_2 + 10HNO_3 \longrightarrow 2HIO_3 + 10NO_2 + 4H_2O$$

48. $CuSO_4 + 2KI \longrightarrow CuI_2 + K_2SO_4$

$$2CuI_2 \longrightarrow \underset{\text{cuprous iodide}}{2CuI} + I_2$$

49. HI is the strongest acid because H—I bond is weakest bond.

51. Oxidising power of species is directly proportional to reduction potentials. Therefore, order of oxidising power of given ions is as follows

Ion $\quad BrO_4^- > IO_4^- > ClO_4^-$

$E_c(V)\quad 1.74 \quad 1.65 \quad 1.19$

52. AgI is a covalent compound so it is insoluble in water.

54. $Cl_2 + 2KBr \longrightarrow Br_2 + 2KCl$

56. $2HClO_4 \longrightarrow H_2O + Cl_2O_7$

57. Fluorine and chlorine are more electronegative than sulphur, so they can displace it form its salt.

58. Acid strength decreases from HClO to HIO as the electronegativity of halogen decrease.

60. ClF_3, where Cl is sp^3d hybridised, has a T-shape structure due to presence of two lone pairs of electrons on Cl atom.

61. Chlorine, being only a slightly stronger oxidising agent than bromine cannot oxidise it to +7 oxidation state as is required for the formation of the compound $BrCl_7$.

62.

Gas	Abundance in air by volume (ppm)
Helium	5.2
Neon	18.2
Argon	93.4
Krypton	1.1
Xenon	0.09

63. Welding of Mg is done in the atmosphere of He due to its inert and non-inflammable nature.

64. As the number of shells increases, size increases and the effective nuclear charge on the outermost electron decreases. Thus, IE decreases.

65. Dipole of water  induces dipole in noble gases which interact and causes solubility in water.

66. He, because of its small size can diffuse through rubber, glass PVC etc. easily.

67. Solubility increases on moving down the group.

Xe > Kr > Ar > Ne > He

68. Clevite is uranium mineral, on heating it gives He.

69. Only He forms interstitial compounds since, the atomic size of He is smallest and matches the size of the interstices available is the lattice of most of the heavy metals.

73. $2XeF_2 + 2H_2O \longrightarrow 2Xe + 4HF + O_2$

74. XeF_2, XeF_4 and XeF_6 can be directly prepared.

$$Xe + F_2 \xrightarrow[\text{673 K}]{\text{Ni tube}} XeF_2;$$

$$Xe + 2F_2 \xrightarrow[\text{6 atm}]{\text{673 K}} XeF_4$$

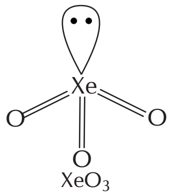
$$Xe + 3F_2 \xrightarrow[\text{50–60 atm}]{\text{523–573 K}} XeF_6$$

XeO_3 is obtained by the hydrolysis of XeF_6.

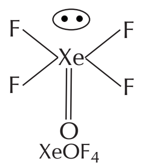
$$XeF_6 + 3H_2O \longrightarrow XeO_3 + 6HF$$

75. XeF_2, XeF_4, XeF_6 are formed by xenon.

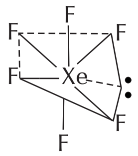
76.



XeO_3



$XeOF_4$



XeF_6

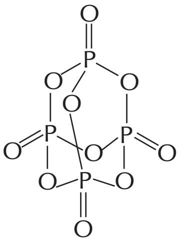
78. Both XeF_2 and IF_2^- are linear species but the central atoms Xe and I undergo sp^3d hybridisation with all the three equatorial positions occupied by the lone pairs of electrons.

79. XeO_4 is formed by promoting one 5*s* and three 5*p*-electrons of Xe to higher energy. 5*d* orbitals giving eight unpaired orbitals hybridize to give sp^3 hybridisation which form sigma bonds with four O atoms. The four unhybridised singly occupied 5*d* orbitals form four $p\pi$ - $d\pi$ bonds with oxygen atoms.

80. Clathrates are non-stoichiometric compounds where the ratio of guest and host molecules does not correspond to ideal chemical formula.

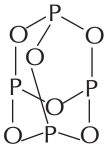
Round II

1. P_2O_5, *i.e.*, P_4O_{10}



$\Rightarrow$ Six P—O—P bridges

P_2O_3 *i.e.*, P_4O_6



$\Rightarrow$ Six P—O—P bridges

2. B > P > As > Bi

As we go down the group, bond angle decreases, since the repulsion between the bonded pairs of electrons decreases.

3. $3NH_3 + OCl^- \longrightarrow NH_2-NH_2 + NH_4Cl + OH^-$

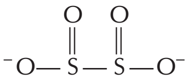
4. $NO(g) + NO_2(g) \longrightarrow N_2O_3(l)$

5. In P_4 each P is sp^3 hybridised so that the percentage of *p*-character in these orbitals is 75%.

6. $(NH_4)_2Cr_2O_7 \xrightarrow{\Delta} N_2\uparrow + Cr_2O_3 + 4H_2O$

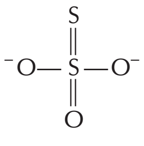
$NH_4NO_2 \longrightarrow N_2\uparrow + 2H_2O$

7. (a) $S_2O_4^{2-}$



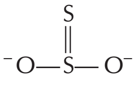
$^-O-\overset{\overset{O}{\|}}{S}-\overset{\overset{O}{\|}}{S}-O^-$

(b) $S_2O_3^{2-}$



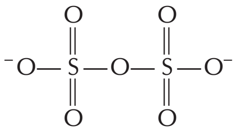
$^-O-\underset{\underset{O}{\|}}{\overset{\overset{S}{\|}}{S}}-O^-$

(c) $S_2O_2^{2-}$



$^-O-\overset{\overset{S}{\|}}{S}-O^-$

(d) $S_2O_7^{2-}$



$^-O-\underset{\underset{O}{\|}}{\overset{\overset{O}{\|}}{S}}-O-\underset{\underset{O}{\|}}{\overset{\overset{O}{\|}}{S}}-O^-$

8. The key step in the manufacture of H_2SO_4 is catalytic oxidation of SO_2 to produce SO_3 in presence of V_2O_5.

$$2\,SO_2\,(g) + O_2\,(g) \underset{}{\overset{V_2O_5,\ 720\text{ K},\ 2\text{ bar}}{\rightleftharpoons}} 2\,SO_3(g)\,;$$

$$\Delta_r H^\circ = -196.6\text{ kJ mol}^{-1}$$

The reaction is exothermic, reversible and the forward reaction results in the decrease in volume. Thus according to Le-Chatelier's principle, the forward reaction should be favoured by **low temperature** and **high pressure**. But the temperature should not be very low otherwise the rate of reaction will become very slow.

In practise, H_2SO_4 is manufactured at 720 K temperature, 2 bar pressure and in the presence of V_2O_5 as catalyst.

9. $S_2O_7 + H_2O \longrightarrow H_2S_2O_8$

10. Concentrated H_2SO_4 is less volatile, *i.e.*, it has high boiling point.

11. Orthophosphate + Amm. molybdate $\xrightarrow[\Delta]{HNO_3}$ yellow ppt.

$\downarrow + AgNO_3$

Red ppt.

12. $Zn + \text{conc. } 4HNO_3 \longrightarrow Zn(NO_3)_2 + 2NO_2 + 2H_2O$

$4Zn + \text{dil. } 10HNO_3 \longrightarrow 4Zn(NO_3)_2 + NH_4NO_3 + 3H_2O$

13. Concentrated sulphuric acid, being a strong acid, oxidises bromides and iodides but not chlorides and fluorides since, the later are more electronegative. Hence, it can be reduced only by NaBr among the given options.

$$H_2\overset{+6}{S}O_4 + 2Na\overset{-1}{Br} \longrightarrow NaH\overset{+6}{S}O_4 + H\overset{-1}{Br}$$

$$2H\overset{-1}{Br} + H_2\overset{+6}{S}O_4 \longrightarrow 2H_2O + \overset{0}{Br_2} + \overset{+4}{S}O_2$$

Reduction

14. $\underset{\text{lead nitrate}}{Pb\,(NO_3)_2} \xrightarrow[673\text{ K}]{\Delta} 2PbO + \underset{\substack{\text{brown}\\ [A]}}{4NO_2(g)}$

$$2NO_2(g) \underset{\text{Heating}}{\overset{\text{Cooling}}{\rightleftharpoons}} \underset{\text{colourless } [B]}{N_2O_4(g)}$$

$$2NO + N_2O_4 \xrightarrow{250\text{ K}} \underset{\text{blue } [C]}{2N_2O_3(s)}$$

15. The main constituent of air are nitrogen (78%) and oxygen (21%). Only N_2 reacts with three moles of H_2 in the presence of a catalyst to give NH_3 (ammonia) which is a gas having basic nature. On oxidation NH_3 gives NO_2 which is a part of acid rain. So the compounds *A* to *D* are as

$$A = NH_4NO_2;\ B = N_2;\ C = NH_3;\ D = HNO_3$$

16. $$\underset{\substack{\text{manganese oxide}\\ \text{(black)}}}{MnO_2} + H_2SO_4 + 2HCl \longrightarrow MnSO_4 + 2H_2O + \underset{\substack{\text{chlorine gas}\\ \text{(greenish yellow)}}}{Cl_2 \uparrow}$$

$$\underset{\text{ammonia}}{NH_3} + 3Cl_2 \longrightarrow \underset{\substack{\text{nitrogen trichloride}\\ \text{(unstable and explosive)}}}{NCl_3} + 3HCl$$

NH_3 Let the oxidation state of $N = x$

$$x + 3(+1) = 0$$
$$x = -3$$

NCl_3 Let the oxidation state of $N = y$

$$y + 3(-1) = 0$$
$$y = +3$$

Hence, in given process, oxidation state of nitrogen changes from −3 to +3.

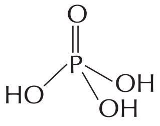
17. OF_2 dissolves in water but does not give any oxyacid solution while SO_2, SCl_4 and SO_3 give oxyacid solution in water.

$$SO_2 + H_2O \longrightarrow \underset{\text{sulphurous acid}}{H_2SO_3}$$

$$SCl_4 + 3H_2O \longrightarrow \underset{\text{sulphurous acid}}{H_2SO_3} + 4HCl$$

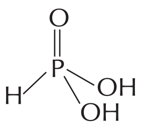
$$SO_3 + H_2O \longrightarrow \underset{\text{sulphuric acid}}{H_2SO_4}$$

18. Orthophosphoric acid (H_3PO_4) is a tribasic acid because it has three replaceable hydrogen atoms. Hence, the basicity of H_3PO_4 is 3. Its structure is as



H_3PO_4 (tribasic acid)

While phosphorous acid (H_3PO_3) is a dibasic acid because it has two replaceable hydrogen atom. Hence, the basicity of H_3PO_3 is 2. Its structure is as



H_3PO_3 (dibasic acid)

19. The thermal stability of the hydrides of nitrogen family or group 15 elements decreases on moving downwards in the group. Therefore, NH_3 is the most stable and BiH_3 is the least stable. The stability of the hydrides of group 15 elements decreases in the order

$$NH_3 > PH_3 > AsH_3 > SbH_3 > BiH_3$$

20. (a) $$2KI + H_2O + O_3 \longrightarrow 2KOH + O_2 + I_2$$

oxidised

(b) $$2FeSO_4 + H_2SO_4 + O_3 \longrightarrow Fe_2(SO_4)_3 + H_2O + O_2$$

oxidised

(c) $$KMnO_4 + O_3 \longrightarrow \text{No reaction}$$

because in $KMnO_4$, oxidation state of Mn is +7 and it is the highest oxidation state of Mn, so $KMnO_4$ is not oxidised by ozone.

(d) $$2K_2MnO_4 + H_2SO_4 + O_3 \longrightarrow 2KMnO_4 + K_2SO_4 + H_2O + O_2$$

oxidised

21. ∵ NH_3 reacts with P_2O_5 or $CaCl_2$ or conc. H_2SO_4.

∴ It cannot be dried over either of them.

$CuSO_4$ and HNO_3 are not drying agent. NH_3 can be dried over CaO only because it is a drying agent with which it does not react.

22. Iodine has the least affinity for water and is only slightly soluble in it. However, it dissolves in 10% aqueous solution of KI due to the formation of a complex ion *i.e.*, I_3^-

$$I_2 + KI \rightleftharpoons KI_3$$

or $$I_2 + I^- \rightleftharpoons I_3^-$$

(Complex ion)

23.

Hydride	HF	HCl	HBr	HI
B. pt (in K)	293	189	206	238

Because of having low boiling point HCl is more volatile..

25. $X = I_2$, $Y = HF$

$$3I_2 + 2NH_3 \longrightarrow \underset{\text{(explosive)}}{NH_3 \cdot NI_3}$$

$$8NI_3 \cdot NH_3 \longrightarrow 5N_2 + I_2 + 6NH_4I$$

$$I_2 + H_2 \longrightarrow \underset{(Y)}{2HI}$$

$$3NaI + H_3PO_4 \xrightarrow{\Delta} Na_3PO_4 + 3HI$$

26. A halate will be formed from halogen and the greenish yellow gas is Cl_2. The halate which is used in fireworks and safety matches is $KClO_3$.

$$3Cl_2 + 6KOH \longrightarrow KClO_3 + 5HCl + 3H_2O$$

27. I_2 cannot oxidise Br^- to Br_2.

28. The thermal stability of the anions of oxo-acids of chlorine increase with increasing oxidation number of halogen.

29. $$XeOF_4 + H_2O \longrightarrow XeO_2F_2 + 2HF$$

$$XeF_6 + 2H_2O \longrightarrow XeO_2F_2 + 4HF$$

30. XeF_6 cannot be stored in glass vessels because it reacts with SiO_2 of the glass to give highly explosive XeO_3.

$$2XeF_6 + 3SiO_2 \longrightarrow 2XeO_3 + 3SiF_4$$

31. Helium is twice as heavy as hydrogen, its lifting power is 92% of that of hydrogen. Helium has the lowest melting point of any element which makes liquid helium an ideal coolant for many extremely low temperature application such as crystals, a sophisticated measuring instrument based on super conducting magnet and cryogenic research where, temperature close to absolute zero are needed.

32. $CaCl(OCl) \longrightarrow Ca(ClO_3)_2 + CaCl_2$

33. $2HClO_4 + P_2O_5 \longrightarrow Cl_2O_7 + 2HPO_3$

34. KrF_2 is a F^- donor and form complexes with F^- acceptors where, only cationic species or Kr will be present.

35. XeO_6^{4-} ion is perxenate.

36. Due to electronegativity difference, the stability of interhalogen compounds follows following the order

$$IF_3 > BrF_3 > ClF_3$$

37. Xenon hexafluoride reacts with silica to form $XeOF_4$ as

$$2XeF_6 + SiO_2 \longrightarrow 2XeOF_4 + SiF_4$$

The oxidation state of xenon in $XeOF_4$ is calculated as

$$\overset{x}{Xe}\,\overset{-2-1}{OF_4}$$

$$x + (-2) + 4 \times (-1) = 0$$
$$x - 2 - 4 = 0$$
$$x = +6$$

38. The electron affinity (in kJ/mol)

Fluorine = 332.6
Chlorine = 348.5
Bromine = 324.7
Iodine = 295.5

Chlorine has highest electron affinity value.

So, according to question the correct order of electron affinity will be

$$Cl_2 > F_2 > Br_2$$

39. The first ionisation energy of xenon is quite close to that of oxygen and the molecular diameter of xenon and oxygen are almost identical.

Based on the above facts it is suggested that as oxygen combines with PtF_6, so xenon should also form similar compound with PtF_6.

40. MCl_2; oxidation state of $M = +2$

MCl_4; oxidation state of $M = +4$

Higher the oxidation state, smaller the size.

Greater the polarizing power, greater the covalent characteristics.

Hence, MCl_4 is more covalent and MCl_2 is more ionic.

41. $3HOCl \longrightarrow 2HCl + HClO_3$

42. Fluorine exhibits an oxidation state of only –1 because it is most electronegative element. (maximum electronegativity in the Periodic Table).

43. In the yellow region of sun's spectrum, observed D_3 lines are due to He.

44. $$3\overset{0}{Cl_2} + \underset{\substack{\text{(hot and}\\\text{concentrated)}}}{6NaOH} \longrightarrow \underset{\substack{\text{sodium}\\\text{chloride}}}{5Na\overset{-1}{Cl^-}} + \underset{\substack{\text{sodium}\\\text{chlorate}}}{Na\overset{+5}{Cl}O_3} + 3H_2O$$

Hence, oxidation number of chlorine changes from 0 to –1 and 0 to +5.

45. The ionic character of $M—X$ bond decreases as the size of halogen atom increases.

$$MF > MCl > MBr > MI$$

with the increase of size, the bond length increases from F to I. Since, the bond length of fluorine is minimum, its bond dissociation enthalpy should be highest. However, the bond dissociation enthalpy of fluorine is less than Cl—Cl and Br—Br due to the high interelectronic repulsions between non-bonding electrons in the 2*p*-orbitals of fluorine. Hence, the correct order of bond dissociation enthalpy is

$$Cl—Cl > Br—Br > F—F > I—F$$

46. (a) In the presence of moisture, SO_2 liberates nascent hydrogen. Due to which it can bleach delicate articles like silk and straw.

$$SO_2 + H_2O \longrightarrow H_2SO_3 \rightleftharpoons 2H^+ + SO_3^{2-}$$

(b) Geometry of SO_2 molecule is bent.

(c) Its dilute solution is used as disinfectant.

(d) SO_2 is prepared by the reaction of conc. H_2SO_4 with metals.

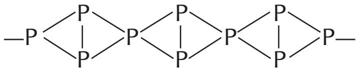
$$Cu + 2H_2SO_4 \longrightarrow CuSO_4 + 2H_2O + SO_2$$

47. Concentrated sulphuric acid (H_2SO_4) is hygroscopic, oxidising agent and sulphonating agent. It is not an efflorescent.

48. He_{II} has extremely low viscosity and readily form films only a few hundred atom thick, which flow without friction.

49. When highly conc. HNO_3 (80%) is reacted with iron, it forms a thin protective layer of ferric oxide (Fe_2O_3) over its surface due to which it makes iron passive.

50. Red phosphorus is less volatile than white phosphorus because it exists in linked tetrahedral structures.



51. H—S bond is weaker than H—O bond hence, H_2S is more acidic than H_2O.

52. XeF_2 oxidises HCl to Cl_2 and Ce(III) to Ce(IV). Its oxidation potential is +2.64 V.

53. Zero point energy of helium is so high that it outweighs the weak interatomic forces which are not strong enough to bind the helium atoms into the crystalline state.

54. Bond angle decreases as the electronegativity of the element M in H_2M decreases. It is minimum for H_2Te.

55. Acidic character increases from top to bottom in a group.

56. H_2S has the lowest boiling point whereas H_2O has the highest boiling point.

57. Due to non-availability of *d*-orbitals in case of nitrogen, NCl_5 is not known.

58. $NCl_3 + 3H_2O \longrightarrow 3HOCl + NH_3$

Other halides do not react with H_2O.

59. Due to high electronegativity of F atom, the bonding pairs of electrons are attracted more towards F atoms in NF_3 and N has a decreased tendency to donate its lone pair of electrons.

60. $$\left.\begin{array}{l} N \\ P \\ As \\ Sb \end{array}\right] \begin{array}{l} \text{Group} = 15 \\ \left.\begin{array}{l}\text{Valence} \\ \text{electrons}\end{array}\right] = 5 \end{array}$$

MCl_3 has sp^3 hybridized *M*-element with one lone pair.

Lone pair and bond pair repulsion decreases bond angle. However, the bond pairs of electrons are much farther away from the central atom than they are in PCl_3, $AsCl_3$ and $SbCl_3$. Thus, bond angle decreases from NCl_3 (maximum) to $SbCl_3$ (minimum).

61. (a) $2NaNO_3 \xrightarrow{\Delta} 2NaNO_2 + O_2$

(b) $2KClO_3 \xrightarrow{\Delta} 2KCl + 3O_2$

(c) $CaCO_3 \xrightarrow{\Delta} \underset{\text{basic}}{CaO} + \underset{\text{acidic}}{CO_2}$

(d) $NH_4NO_3 \xrightarrow{\Delta} N_2O + H_2O$

62. (a) Thermal stability of the hydrides decreases as we go down the group in Periodic Table for group 15 (N-family)

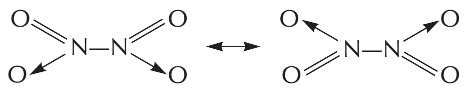
$$BiH_3 < SbH_3 < AsH_3 < PH_3 < NH_3$$

Least stable					
M-H Bond energy kJ mol^{-1}	–	255	247	322	391

(b) Due to absence of *d*-orbital, nitrogen can't from $d\pi$-$d\pi$ bond, thus it is correct.

(c) The N—N bond (BE 160 kJ mol^{-1}) is weaker than P—P bond (BE 209 kJ mol^{-1}). Thus, it is correct.

(d) N_2O_4 can form two resonance structures.



Thus, it is correct.

63. (a) S_2 molecule is paramagnetic due to unpaired electrons in MO configuration and is blue-coloured compound thus true.

(b) The vapour at 200°C consists mostly of S_8 rings, thus correct.

(c) At 600°C, the gas mainly consists of S_2 molecules thus correct.

(d) Oxidation states of sulphur are

–2	in	H_2S
0	in	S_8
+2	in	$S_2O_3^{2-}$
+4	in	SO_2
+6	in	SO_3

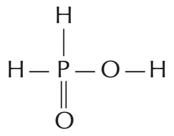
64. XeF_6 has much tendency to hydrolyse. The reverse reaction is more spontaneous.

$$XeF_6 + 3H_2O \longrightarrow XeO_3 + 6HF$$

65. Br_2 reacts with hot and strong NaOH to give NaBr, $NaBrO_3$ and H_2O.

66. 
Polarity along O—H in HNO_3 is more in comparison to —O—H in HNO_2.

67. Hypophosphorus acid (H_3PO_2) is a monobasic acid and has only one ionisable H, two H-atoms are directly attached to phosphorous.



68. In Holmes signals of the ship, mixutre of CaC_2 and Ca_3P_2 is used.

69. $2HCl + \frac{1}{2}O_2 \longrightarrow H_2O + Cl_2$

70. Phosphorus (3rd period element) can raise covalency facilitating vacant *d*-orbitals

$$P\,(\text{ground}) = [\text{Ne}]\,3s^2\ \ 3p^3\ \ 3d^0$$
$$P\,(\text{excited}) = [\text{Ne}]\,3s^1\ \ 3p^3\ 3d^1$$

8 The *d*- and *f*-Block Elements

JEE Main MILESTONE

- *d*-Block Elements
- Potassium Dichromate
- Potassium Permanganate
- *f*-Block Elements

8.1 *d*-Block Elements

These are the elements in which the differentiating electron (*i.e.*, the last electron) enters in the *d*-subshell, *e.g.,* elements of group 3 to 12 (*i.e.*, IB to VIIB and VIII). In Periodic Table, they are placed between *s*- and *p*-blocks and have properties in between of them, *i.e.*, their properties are intermediate between those of *s*- and *p*-block elements. That's why, these elements are called **transition elements.**

Zinc, cadmium and mercury, however, because of the presence of completely filled $(n-1)$ *d*-subshell in their elementary as well as in combined state, do not show much resemblance with other *d*-block elements except for their ability to form complexes with ligands such as NH_3, RNH_2 and halides. Nevertheless, these are studied with the *d*-block elements in order to maintain a rational classification of elements. These elements, thus, are called **non-typical transition elements.**

These are the elements having completely filled outermost shell and incomplete inner shall. If last electron enters in penultimate (n-1) d-orbital the elements are called d-block elements and if enters in (n-2) f-orbital, the elements are called f-block elements.

Elements of IIIB group (*i.e.*, Sc, Y, La and Ac) also differ in their properties from rest of the members, *e.g.,* they form compounds only in +3 oxidation state. Unlike the compounds of other members, these are diamagnetic and colourless. Hence, **these elements are also not considered as transition elements.**

Caution Point *All transition elements are d-block elements but all the d-block elements are not transition elements.*

Classification of *d*-Block Elements

These elements make up three complete rows of ten elements and an incomplete fourth row. These rows are named as 3*d*, 4*d*, 5*d* and 6*d* series respectively as shown below

Table 8.1 **Different Series of *d*-Block Elements**

Series name	3 (IIIB)	4 (IVB)	5 (VB)	6 (VIB)	7 (VIIB)	8 (VIII)	9 (VIII)	10 (VIII)	11 (IB)	12 (IIB)
3*d*-series	21 Sc	22 Ti	23 V	24 Cr	25 Mn	26 Fe	27 Co	28 Ni	29 Cu	30 Zn
4*d*-series	39 Y	40 Zr	41 Nb	42 Mo	43 Tc	44 Ru	45 Rh	46 Pd	47 Ag	48 Cd
5*d*-series	57 La	72 Hf	73 Ta	74 W	75 Re	76 Os	77 Ir	78 Pt	79 Au	80 Hg
6*d*-series	89 Ac	104 Rf	105 Db	106 Sg	107 Bh	108 Hs	109 Mt	110 Ds		

On August 16, 2003 IUPAC approved the name for the element of atomic number 110 as **Darmstadtium** with symbol Ds. It is a super heavy element which was first produced in 1994.

General and Physical Properties

The general and physical properties of *d*-block elements and their trends are discussed

(a) Electronic Configuration

The general electronic configuration of these metals is $(n-1)\, d^{1-10}\, ns^{1-2}$. Here, it is obvious that the electronic configuration of these elements differ only in the number of electrons in their penultimate shell (*i.e.*, in *d*-orbital). Thus, they do not show a regular trend of physical and chemical properties like *s*- and *p*-block elements.

Half and completely filled sets of orbitals are relatively more stable. *e.g.*, $\text{Cr}\,(24) = [\text{Ar}]\, 3d^5\, 4s^1$ and $\text{Cu}(29) = [\text{Ar}]\, 3d^{10}\, 4s^1$.

The electronic configurations of Zn, Cd and Hg are represented by the general formula $(n-1)\, d^{10} ns^2$.

(b) Atomic Radii

In a given series, the atomic radii of these elements generally decreases from group 3 to group 10 and after that increases again towards the end of the series. This is because the nuclear charge increases with increase in atomic number.

Due to this, the electron clouds are attracted more strongly and results in decreased size. However, the decrease in the radii across the period is not uniform, *e.g.,* the radii of elements from Cr to Cu are very close to one another.

This is due to the effective screening of outer *ns*-electrons by the electrons of $(n-1)$ *d* subshell. The reason for the anomalous increase in atomic radii towards the end of the series is predominant repulsion between the added electrons. Presence of completely filled *d*-orbitals also decreases the force of attraction.

On moving downwards in the groups, the atomic radii increases although the increase is not as significant as in the case of *s*- and *p*-block elements.

The members of 4*d* and 5*d* series exhibit near about similar radii which is due to **lanthanide contraction** (filling of 4*f* electrons before 5*d* results in regular decrease of atomic size with increase in atomic number).

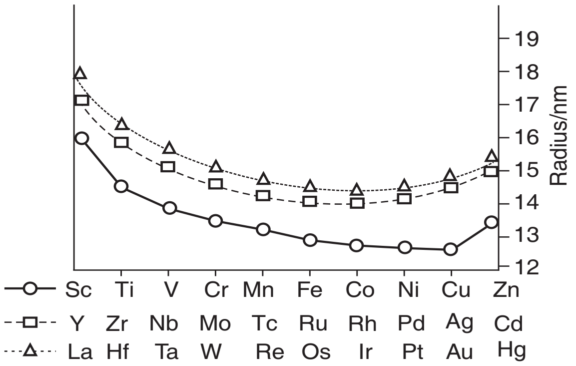


Fig. 8.1 Plot of radii with atomic number of transition elements

Hence, Zr—Hf, Nb—Ta, Mo—W and Tc—Re are called chemical twins. Zr and Hf have very similar physical and chemical properties because of their similar radii (Zr = 160 pm, Hf = 159 pm) which makes their separation difficult.

Sample **Problem 1** *Although zirconium belongs to 4d transition series and hafnium to 5d transition series even then they show similar physical and chemical properties because*

(a) *both belong to d-block*
(b) *both have same number of electrons*
(c) *both have similar atomic radius*
(d) *both belong to the same group of the Periodic Table*

Interpret (c) Because Zr and Hf have the almost same size (Zr = 160, Hf = 159 pm) due to lanthanoid contraction.

(c) Ionic Radii

The ionic radii of these elements follow the same trend as their atomic radii. In case of ions carrying identical charges, the ionic radius decreases slowly with increase in atomic number in a series.

(d) Molar Volume and Density

The molar volumes of *d*-block elements are much lower than those of *s*-and *p*-block elements of neighbouring groups. It is due to the reason that as inner orbitals gets filled, the increased nuclear charge pulls the electrons inward. Due to such decrease in molar volumes, an increase in density is seen. In a series from left to right density increases and attains a maximum value at the middle of the series. On moving down a group,density increases.

Sample Problem 2 *Metallic radii of some transition elements are given below. Which of these elements will have highest density?* **[NCERT Exemplar]**

Elements	Fe	Co	Ni	Cu
Metallic radii/pm	126	125	125	128

(*a*) Fe
(*b*) Ni
(*c*) Co
(*d*) Cu

Interpret (*d*) Copper have the highest density because of low molar volumes.

Elements	Sc	Ti	V	Cr	Mn	Fe	Co	Ni	Cu	Zn
Density ($g\ cm^{-3}$)	3.43	4.1	6.07	7.19	7.21	7.8	8.7	8.8	8.9	7.1

(e) Ionisation Energy

Since, the atoms are smaller in size, their ionisation energies are fairly high. The values in most cases lie in between those of *p*- and *s*-block elements, thus indicating that transition metals are less electropositive than the elements of *s*-block. In a series, the IE increases from left to right but the increase is not so pronounced as in the case of *s-and p*-block elements. *The IE, of 5d series elements is higher than the elements of 4d and 3d series.* This is due to the greater effective nuclear charge acting on outer valence electrons because of the weak shielding of the nucleus by 4*f* electrons.

IE_2 of the first transition series increases almost regularly with increase in atomic number. However, the value for Cr and Cu are sufficiently higher than those of their neighbours. This is due to their stable electronic configurations.

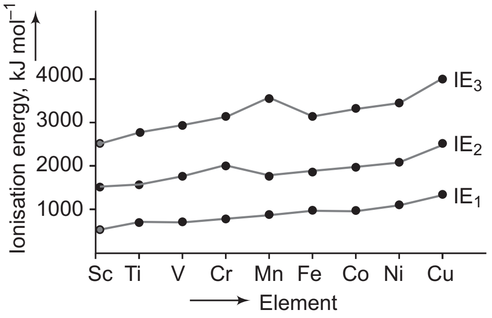

Fig. 8.2 Variation of the IE_1, IE_2 and IE_3 for the first transition metals

The ionisation energy of Zn, Cd and Hg are abnormally higher due to the greater stability of *s*-subshell.

Table 8.2 **Ionisation Energies of *d*-block Elements**

Elements of 3*d*-series	Ionisation energies ($kJ\ mol^{-1}$)	Elements of 4*d*-series	Ionisation energies ($kJ\ mol^{-1}$)	Elements of 5*d*-series	Ionisation energies ($kJ\ mol^{-1}$)
Sc	631	Y	616	La	541
Ti	656	Zr	674	Hf	760
V	650	Nb	664	Ta	760
Cr	653	Mo	685	W	770
Mn	717	Tc	703	Re	759
Fe	762	Ru	711	Os	840
Co	758	Rh	720	Ir	900
Ni	736	Pd	804	Pt	870
Cu	745	Ag	731	Au	889
Zn	906	Cd	876	Hg	1007

The sum of first three ionisation energies for Sc is a little less than the sum for Al. Thus, the properties of Sc are similar in some ways to those of Al.

The magnitude of ionisation energies give an idea about the relative stabilities of various oxidation states of transition elements. *e.g.,* Ni (II) compounds are thermodynamically more stable than platinum (II) while platnium (IV) compounds are relatively more stable than nickle (IV) compounds.

	$IE_1 + IE_2$	$IE_3 + IE_4$	Total
Ni	2.49×10^3	8.80×10^3	11.29×10^3
Pt	2.66×10^3	6.70×10^3	9.36×10^3

Sample Problem 3 *For d-block elements the first ionisation potential is of the order*

(a) Zn > Fe > Cu > Cr

(b) Sc = Ti < V = Cr

(c) Zn < Cu < Ni < Co

(d) V > Cr > Mn > Fe

Interpret (a) The ionisation energies increase with increasing atomic number. The trend is irregular among *d*-block elements.

Zn > Fe > Cu > Cr is correct order.

Sample Problem 4 *First IE of 5d elements are higher than those of 3d and 4d elements. This is due to*

(a) *greater effective nuclear charge acting on outer valence electrons*

(b) *greater effective nuclear charge is experienced because of the weak shielding of the nucleus by 4f electrons*

(c) *Both (a) and (b)*

(d) *None of the above*

Interpret (b) The first ionisation enthalpies of 5*d* elements are higher than those of 3*d* and 4*d* series. This is because of weak shielding of nucleus by 4*f* electrons in the 5*d* series.

(f) Nature of Bond

Unlike alkali and alkaline earth metals, the transition elements have the tendency to form covalent bond also along with the ionic bonds. Generally the compounds in which smaller valency is exercised are ionic while those in which higher valency is exercised are covalent compounds.

(g) Metallic Character

Nearly all transition elements show typical metallic properties such as high tensile strength, ductility, malleability, high thermal and electrical conductivity and metallic lusture (except Hg, which is a liquid at room temperature).

With the exception of Zn, Cd and Hg, all the transition elements are much harder and less volatile. Although hardness and brittleness are associated with covalent bonding between metal atoms, the existence of metallic bonding cannot be denied. While the overlapping of unfilled *d*-orbitals of metals causes covalent bonding, the valence *s*-electrons are responsible for metallic bonding. Cu, Ag and Au are particularly outstanding in their thermal and electrical conductivities.

(h) Enthalpy of Atomisation

Since the atoms of transition elements are closely packed and held together by strong metallic bonds because of large number of unpaired electrons in their atoms, they possess high enthalpy of atomisation.

The metals of 2nd and 3rd series have greater enthalpies of atomisation than the corresponding elements of the first series.

(i) Melting and Boiling Points

Their melting and boiling points are high which is attributed to strong interatomic bonding involving participation of *ns* and $(n-1)\,d$ electron, *i.e.,* **metallic bonding is stronger in them.** In any row, the melting points of these metals rise to a maximum at d^5 except for anomalous values of Mn and Tc and fall regularly as the atomic number increases. However, Zn, Cd and Hg due to the presence of completely filled $(n-1)\,d$ orbital are not expected to have covalent bonding, thus their melting and boiling points are relatively low, as compared to the other elements of this block.

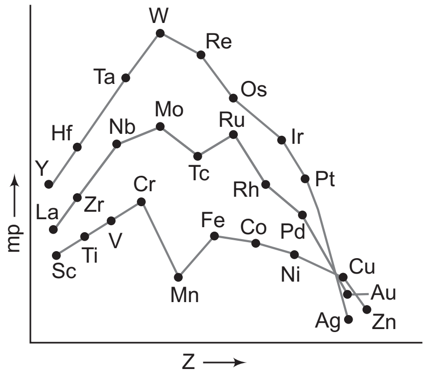

Fig. 8.3 Melting point of 3*d*, 4*d* and 5*d*-series elements (not according to scale)

Hot Spot 1

OXIDATION State

It is an important topic for JEE Main examination. Generally questions are asked from this topic. The level of question vary from easy to average.

Transition elements show a large number of oxidation states differing usually by unit of one. This is due to the fact that $(n-1)$ d electrons may get involved along with ns-electrons in bonding as electrons in $(n-1)$ d-orbitals are in an energy state comparable to ns-electrons. The stability of a given oxidation state depends on the nature of the element with which the transition metal is combined.

The highest oxidation states are found in the compounds of fluorides and oxides because of the most electronegative nature of F and O. The different oxidation states of 3d-series have been given below

Table 8.3 **Oxidation States of First Transition Series**

Elements	Outer electronic configuration	Oxidation states
Sc	$3d^1 4s^2$	+2, +3
Ti	$3d^2 4s^2$	+2, +3, +4
V	$3d^3 4s^2$	+2, +3, +4, +5
Cr	$3d^5 4s^1$	+1, +2, +3, +4, +5, +6
Mn	$3d^5 4s^2$	+2, +3, +4, +5, +6, +7
Fe	$3d^6 4s^2$	+2, +3, +4, +5, +6
Co	$3d^7 4s^2$	+2, +3, +4
Ni	$3d^8 4s^2$	+2, +3, +4
Cu	$3d^{10} 4s^1$	+1, +2
Zn	$3d^{10} 4s^2$	+2

The oxidation states of elements of 2nd and 3rd transition series are

Table 8.4 **Oxidation States of Second Transition Series**

Elements	Y	Zr	Nb	Mo	Tc	Ru	Rh	Pd	Ag	Cd
Oxidation states									+1	
						+2		+2	(+2)	+2
	+3		+3	+3		+3	+3	(+3)	(+3)	
		+4		+4	+4	+4	+4	(+4)		
			+5	+5		+5				
				+6	(+6)	+6	+6			
					+7	(+7)				
						(+8)				

Table 8.5 **Oxidation States of Third Transition Series**

Elements	La	Hf	Ta	W	Re	Os	Ir	Pt	Au	Hg
Oxidation states									+1	+1
				(+2)		(+2)	(+2)	+2		+2
	+3			(+3)	(+3)	(+3)	+3	(+3)	+3	
		+4	(+4)	+4	+4	+4	+4	+4		
			+5	+5	+5	+5				
				+6	+6	+6	+6			
					+7					
						+8				

Caution Point *First member of each transition series does not show variable valency. It generally shows only + 3 oxidation state.*

Except scandium, the most common oxidation state of first row transition elements is (+ 2) which arises due to the loss of two 4s electrons.

In (II) and (III) oxidation states, bonds formed are mostly ionic. In the compounds of the higher oxidation states (MnO_4^-), the bonds formed are essentially covalent.

Some transition elements also show an oxidation of zero in their compounds *e.g.*, $[Ni(CO)_4]$ and $[Fe(CO)_5]$.

In general for the first four elements of a transition series, higher oxidation states are more stable than lower oxidation states. For the next five elements lower oxidation states are more stable than higher oxidation states *e.g.*, Cr (III) is more stable than Cr(II) but Mn (II) is more stable than Mn (III).

Among the group of d-block elements, the higher oxidation states are favoured by heavier members (the opposite is true in p-block) *e.g.*, in group 6 Mo (VI) and W (VI) are found to be more stable than Cr (VI). Thus, Cr (VI) In the form of dichromate in acidic medium is a strong oxidising agent whereas MoO_3 and WO_3 are not.

Only Ru and Os show + 8 oxidation states in their compounds.

While solving problems based on oxidation state, always keep in mind

(i) Atomic number of the elements and their electronic configuration

(ii) Minimum oxidation state is generally + 2 but it is + 3 for Sc and Cr and +1 for Cu and Ag.

(iii) For d-block elements up to 7 group, maximum oxidation state $= nse^- + (n-1)\,d$ unpaired e^-

Sample **Problem 5** *The 3d-element that exhibits maximum number of oxidation states is*

(*a*) Sc (*b*) Ti (*c*) Mn (*d*) Zn

Interpret (*c*) Mn exhibits the maximum number of oxidation states Mn(25) = [Ar] $3d^5\ 4s^2$ because of the presence 5 unpaired *d*-electrons and two paired *s*-electrons.

It can show + 2, + 3, + 4, + 5, + 6 and + 7 oxidation states.

Sample **Problem 6** *A transition metal exists in its highest oxidation state. It is expected to behave as*

(*a*) *a chelating agent*
(*b*) *a central metal in a coordination compound*
(*c*) *an oxidising agent*
(*d*) *a reducing agent*

Interpret (*c*) A transition metal ion existing in the highest oxidation state behave as an oxidising agent because in such a condition its further oxidation is not possible but it can be reduced. Thus, it itself undergo reduction and oxidises the other species.

Remember ! All Cu (II) halides are known except the iodide as Cu^{2+} oxidises I^- to I_2. However, many copper (I) compounds are unstable in aqueous solution and undergo disproportionation

$$2Cu^+ \longrightarrow Cu^{2+} + Cu$$

The stability of Cu^{2+} (*aq*) rather than Cu^+(*aq*) is due to much more negative $\Delta H°$ of Cu^{2+} (aq) than Cu^+, which is more than that compensates for the second ionisation enthalpy of Cu.

(j) Standard Electrode Potentials

The $E°$ values of all the transition metals (except Cu) is lower (negative) than that of hydrogen (taken as zero). Thus, all the transition elements, with negative reduction potential, liberate hydrogen from dilute acids.

Table 8.6 ***E°* Values for First Row Transition Metals**

Elements	V	Cr	Mn	Fe	Co	Ni	Cu
$E°(M^{2+}/M)$ in volts	–1.18	– 0.91	–1.18	– 0.44	– 0.28	–0.5	+0.34

Most transition metals are inert towards acids or react slowly with them because of a protective layer of oxide. In case of Cr, despite a negative $E°$, it is quite inert chemically because of the formation of chromium (III) oxide, Cr_2O_3 on its surface.

$E°\ (M^{2+}/M)$ values are not regular for 3*d* series elements. It can be explained from the irregular variation of ionisation enthalpies $(\Delta_i H_1 + \Delta_i H_2)$ and also the sublimation enthalpies which are relatively much less for Mn and V.

Sample **Problem 7** *Which one of the following is a stronger reducing agent?*

(*a*) Cr^{2+}
(*b*) Fe^{2+}
(*c*) Cu
(*d*) *None of the above*

Interpret (*a*) Cr^{2+} is a stronger reducing agent than Fe^{2+} and Cu because $E°$ values for (Cr^{3+}/Cr^{2+}) are more negative than that of $E°$ for Fe^{3+}/Fe^{2+}. Further more, transition $\underset{(3d^4)}{Cr^{2+}} \longrightarrow \underset{(3d^3)}{Cr^{3+}}$ is easier than $\underset{(3d^6)}{Fe^{2+}} \longrightarrow \underset{(3d^5)}{Fe^{3+}}$ because in latter, an electron is removed from the paired orbital.

(k) Reducing Property

All these elements (of 3*d*-series) except Cu has SRP (standard reducing potential) lower than H, hence, all of them (except Cu) are good reducing agents. However, they are not as good reducing agents as the metals of 1st, 2nd and 13th group.

Hot Spot 2

COLOUR and Magnetic Properties

Colour and magnetic properties both are the important topic for JEE Main examination. In general, the level of question is easy, so a small practice can help you in scoring marks.

Colour

Most of the compounds of transition metals are coloured in solid state or solutions. The colour of transition metal ions arises from the excitation of electron from *d*-orbitals of lower energy to *d*-orbitals of higher energy (*d*-*d*) transition. The transition metal ions which have either completely filled *d*-orbitals or completely empty *d*-orbitals are colourless because they are not capable of showing *d*-*d* transition.

The colour of a transition metal complex is dependent on how big the energy difference in between the two *d*-levels. This in turn depends on the nature of the ligand, and the type of the complex formed.

The colour which we see is the colour of the transmitted wavelength and is complimentary colour absorbed by the complex.

In the series Sc^{3+}, Ti^{4+}, V^{5+}, Cr^{6+} and Mn^{7+} all have empty *d*-orbitals, hence, *d*-*d* spectra are impossible and they should be colourless. But VO_2^{2+} (V^{5+}), CrO_4^{2-} (Cr^{6+}) and MnO_4^- (Mn^{7+}) ions in aqueous solution are coloured. The colour arise due to charge transfer.

Sample **Problem 8** *Generally transition elements form coloured salts due to the presence of unpaired electrons. Which of the following compounds will be coloured in solid state ?*

(a) Ag_2SO_4 (b) CuF_2

(c) ZnF_2 (d) Cu_2Cl_2

Interpret (*b*) In Ag_2SO_4, Ag is in + 1 oxidation state ($4d^{10}$), so colourless. In CuF_2, Cu is in + 2 oxidation state ($3d^9$), so it is coloured. In ZnF_2, Zn is in +2 oxidation state ($3d^{10}$) colourless. In Cu_2Cl_2, Cu is in + 1 oxidation state ($3d^{10}$), so it is colourless. The transition metal ions having d^1 to d^9 configuration are coloured whereas the transition metal ions having d^0 and d^{10} configuration are colourless. Thus, among the given only CuF_2 is coloured.

Magnetic Properties

Many of the transition metal ions are paramagnetic due to the presence of unpaired electrons in them. Each such unpaired electron have a magnetic moment associated with its **spin angular momentum and orbital angular momentum.** In transition elements, the orbital motion of unpaired electron is severely disturbed by the electrons of surrounding ligands. Therefore, here the contribution of spin angular momentum becomes much more significant than orbital angular momentum contribution *i.e.*, μ-orbital contribution may be neglected. Thus, effective magnetic moment (μ_{eff}) is given by the expression

$$\mu_{eff} \approx \mu_{spin} \approx \sqrt{n\,(n+2)}$$

where, *n* is the number of unpaired electrons.

Magnetic moment ∝ number of unpaired electrons.

Species having unpaired electrons are paramagnetic whereas the species having all paired electrons are diamagnetic.

Magnetic moment is given in Bohr-magneton (BM) which is given by the expression

$$\text{BM} = \frac{eh}{4\pi mc}$$

where, h = Planck's constant, e = electronic charge

c = velocity of light, m = mass of electron

Sample **Problem 9** *The magnetic nature of elements depends on the presence of unpaired electrons. Identify the configuration of transition element, which shows highest magnetic moment.*

(a) $3d^7$ (b) $3d^5$

(c) $3d^8$ (d) $3d^2$

Interpret (*b*) Magnetic moment increases with the increasing number of unpaired electrons. Hence, $3d^5$ configuration of transition element shows highest magnetic moment.

Sample **Problem 10** *The magnetic moment is associated with its spin angular momentum and orbital angular momentum. Spin only magnetic moment value of* Cr^{3+} *ion is*

(a) 2.87 *BM*

(b) 3.87 *BM*

(c) 3.47 *BM*

(d) 3.57 *BM*

Interpret (*b*) $\mu = \sqrt{n\,(n+2)}$; where n = number of unpaired electrons

$$Cr^{3+} = 1s^2, 2s^2 2p^6, 3s^2 3p^6 3d^3, 4s^0;$$

$$\mu = \sqrt{3(3+2)} = 3.872 \text{ BM}$$

(l) Catalytic Property

Most of the transition metals and their compounds have good catalytic properties, *e.g.,* Pt, Fe, V_2O_5, Ni etc. According to modern theory of catalysis, a catalytic substance is capable of forming an unstable intermediate which readily decomposes yielding the product and regenerating the catalyst, *i.e.*,

$$A + B + \text{catalyst} \longrightarrow \underset{\substack{\text{intermediate} \\ \text{(unstable)}}}{AB\,\text{catalyst}} \longrightarrow C + \text{catalyst}$$

Transition elements on account of their variable valency have the ability to form intermediate compounds very readily thus, acting as good catalysts.

Sample Problem 11 *Which one of the following characteristics of the transition metals is associated with their catalytic activity?*

(a) *Colour of hydrated ions*
(b) *Variable oxidation states*
(c) *High enthalpy of atomisation*
(d) *Paramagnetic behaviour*

Interpret (*b*) Catalytic activity of transition elements is due to their ability to adopt multiple oxidation states and to form complexes.

(m) Complex Formation

The transition metals are almost unique in their tendency to form coordination complexes, which is due to following factors

(i) Very small size,
(ii) High positive charge density,
(iii) Vacant orbitals with suitable energy to accept lone pair of electrons.

(n) Alloy Formation

Since, transition elements have almost similar radii, they have a tendency to replace each other from their lattice and form solid solutions over an appreciable composition range. These solid solutions are called alloy. These and are hard, and have high melting point as compared to the host metal, *e.g.,* some important alloys of copper and steel along with their properties and uses are tabulated below.

Table 8.7 **Some Alloys of Copper**

S.N.	Name	Composition	Important properties	Uses
1.	Brass	Cu = 60–80% Zn = 20–40%	Harder, paler and more brittle with more zinc, can be moulded, malleable and ductile, high tensile strength	Domestic utensils, condensers, tubes, casting cartridges.
2.	Bronze	Cu = 75–90% Sn = 10–25%	Hard, brittle, tenacious, durable, resistant to corrosion, takes high polish.	Statues, coins, utensils, bells, machine parts, propellers, blades.
3.	Aluminium bronze	Cu = 90% Al = 10%	Light, strong, tenacious, resistant to corrosion, golden yellow.	Utensils, coins, frames, statues, jewellery, bearings and castings.
4.	Phosphorus bronze	Cu = 85% Sn = 13% P = 2%	Very hard, tough, elastic, resistant to corrosion.	Suspension wire instrument, gears, aerials, ships, propellers.
5.	Silica bronze	Cu = 97% Sn = 2% Si = 1%	Very hard, tensile, tough, non-corrosive, good conductor.	Telephone and telegraph wires, suspension wires.
6.	German silver or nickel silver	Cu = 50% Zn = 30% Ni = 20%	White shining, malleable and ductile, tough, resistance to corrosion.	Utensils, plates, ornaments.
7.	Gun metal	Cu = 88% Sn = 10% Zn = 2%	Strength increases with the increase of the percentage of Sn, very hard and strong, resistant to corrosion.	For making cannons, guns, machine parts.
8.	Monel metal	Cu = 30% Ni = 67% Fe + Mn = 3%	Very resistant to chemical action, high tensile strength.	Alkali industry resistance wires, domestic wires, valves, automobile engine parts.

Table 8.8 **Some Important Alloys of Steels**

S.N.	Name of the alloy (steel)	Metal added	Properties	Uses
1.	Manganese steel	1.2–15% Mn	Hard, tough, resistant to wear	Rock crushing machinery, safes, helmets.
2.	Nickel steel	2.5–5% Ni	Hard, tough, rustless	Armour plate, cables, propeller shafts, automobile parts, heavy guns.
3.	Invar	3.6% Ni	Same coefficient of expansion as glass	Pendulum, measuring tapes, instruments.
4.	Chrome steel	1.5–2% Cr	Extremely hard	Cutting tools, crushing machinery.
5.	Stainless steel	13–14% Cr, 1% Ni	Resists corrosion	Cutlery, food processing machinery.
6.	Tungsten steel	14 –20% W	Hard and strong	High speed tools.
7.	Chrome-vanadium steel	1% Cr, 0.15% V	High tensile strength	For making spring, shafts, axles.

(o) Interstitial Compounds

Transition elements also have some tendency to trap small atoms like H, B, C, N etc., in the interstitial space and thus, forming some interstitial or non-stoichiometric compounds. FeC, Fe_8N are the examples of interstitial compounds and $Fe_{0.98}O$, $Ni_{0.98}O$, $TiH_{1.7}$ are the examples of both interstitial as well as non-stoichiometric compounds.

The principal physical and chemical characteristics of these compounds are as follows :

1. Their melting points are higher than that of pure metals.
2. They are very hard *e.g.*, some borides approach diamond in hardness.
3. They are chemically inert.
4. They retain metallic conductivity.

(p) Reactivity

The transition elements have small tendency to react due to their high heats of sublimation, high ionisation energies and low heats of hydration. They have rather a tendency to remain unreactive or **noble** *e.g.,* Pt, Au etc.

(q) Nature of Oxides and Hydroxides

While moving along a period from Sc and Zn, basic nature decreases and acidic nature increases. Behaviour differs when oxidation states are different. Sc_2O_3, TiO_2, V_2O_5, Cr_2O_3, MnO_2 and ZnO are amphoteric while Fe_2O_3, Co_2O_3, NiO and CuO are basic.

With increase in the oxidation state of a given transition metal, the covalent character of its compound increases and thus, acidic character also increases.

	MnO	Mn_3O_4	Mn_2O_3	MnO_2	MnO_3	Mn_2O_7
Oxidation state of Mn	+2	+8/3	+3	+4	+6	+7
	↑ basic	amphoteric			weakly acidic	strongly acidic

	VO	V_2O_3	VO_2	V_2O_5
Oxidation state of V	+2	+3	+4	+5
	basic		amphoteric	

	CrO	Cr_2O_3	CrO_3
Oxidation state of Cr	+2 basic	+3 amphoteric	+6 acidic

As we move along a given transition series, +2 oxidation state of the metals becomes more and more stable and hence, the tendency of these metals to lose electrons increases hence, reducing nature of the metal oxide increases. VO and CrO are strong reducing agents.

The basic and amphoteric oxides dissolve in non-oxidising acids and form hexaquo ions $[M(H_2O)_6]^{n+}$. The acidic oxides like CrO_3 and Mn_2O_3 dissolve in water to form oxyacids. These oxides also react with bases to form oxosalts.

$$2CrO_3 + H_2O \longrightarrow H_2Cr_2O_7 \quad \text{(dichromic acid)}$$

$$2CrO_3 + 2KOH \longrightarrow K_2Cr_2O_7 + H_2O$$

$$Mn_2O_7 + H_2O \longrightarrow 2HMnO_4 \quad \text{(permanganic acid)}$$

$$Mn_2O_7 + 2KOH \longrightarrow 2KMnO_4 + H_2O$$

Caution Point *Mercury can't from any hydroxide, because alkali, dilute non-oxidising acids and water or steam have no effect on mercury.*

Sample Problem 12 *Which oxide of* Mn *is acidic in nature ?*

(*a*) MnO (*b*) Mn_2O_7 (*c*) Mn_2O_3 (*d*) MnO_2

Interpret (*b*) Transition metal oxide in higher oxidation states are acidic in nature. Thus, Mn_2O_7 is most acidic among the given.

(r) Halides of 3*d* Series of Transition Elements

The reactivity order for halogen for a given transition metal is $F_2 > Cl_2 > Br_2 > I_2$. Metals usually posses maximum oxidation state in their fluorides. Fluorides of all transition metals are ionic. The ionic character of halides decreases in the order : fluorides > chlorides > bromides > iodides.

To make the trihalides of the *d*-block elements, direct reaction of the element with the halogen is needed. The dihalides are obtained by reacting the element with hydrogen halides.

Sample Problem 13 *Transition elements form binary compounds with halogens. Which of the following elements will form MF_3 type compounds ?* [**NCERT** Exemplar]

(*a*) Cr (*b*) Co

(*c*) Cu (*d*) Ni

Interpret (*a,b*) The +3 oxidation state is more stable only for Cr and Co. Cu exhibits only +1 and +2 oxidation states. Ni generally exhibits +2 oxidation state. This is the reason for the fact that Cr and Co form MF_3 (where, M = Cr and Co) whrereas Cu and Ni do not.

Check Point 1

1. Zinc, cadmium and mercury are not regarded as transition elements, why ?
2. Zn^{2+} salts are white whereas Cu^{2+} salts are blue. Explain.
3. Why do transition metals generally form alloy ?
4. Why IE_1 of Cr is lower than that of Zn? [**NCERT** Exemplar]
5. Although fluorine is more electronegative than oxygen, but the ability of oxygen to stabilise higher oxidation states exceeds that of fluorine, why ?
6. Although Zr belongs to 4*d* and Hf belongs to 5*d* -series but it is quite difficult to separate them, Why ?

8.2 Potassium Dichromate

Its chemical formula is $K_2Cr_2O_7$. It contains ionic as well as covalent bonds.

Methods of Preparation

$K_2Cr_2O_7$ is manufactured from chromite ore, $FeO \cdot Cr_2O_3$ by a method which consists of four steps *viz*

Step I Concentration of the chromite ore by wilfley table method.

Step II Conversion of the concentrated chromite ore into Na_2CrO_4 (roasting of the concentrated ore). Concentrated chromite ore is fused with molten Na_2CO_3 in the presence of air when Na_2CrO_4 and Fe_2O_3 are formed.

$$4FeCr_2O_4 + 8Na_2CO_3 + 7O_2 \xrightarrow{1100^\circ C} \underset{\text{water soluble}}{8Na_2CrO_4} + \underset{\text{water insoluble}}{2Fe_2O_3} + 8CO_2\uparrow$$

Step III Conversion of Na_2CrO_4 into $Na_2Cr_2O_7$.

Aqueous solution of Na_2CrO_4 is acidified to obtain $Na_2Cr_2O_7$.

$$2Na_2CrO_4 + \underset{\text{dil.}}{H_2SO_4} \longrightarrow Na_2Cr_2O_7 + H_2O.$$

Step IV Conversion of $Na_2Cr_2O_7$ to $K_2Cr_2O_7$. Hot solution of $Na_2Cr_2O_7$ obtained as above in step (III) is treated with the calculated quantity of KCl whereby less soluble $K_2Cr_2O_7$ separates out from the solution on crystallisation.

$$Na_2Cr_2O_7 + 2KCl \longrightarrow \underset{\substack{\text{more}\\\text{soluble}}}{2NaCl} + \underset{\substack{\text{less}\\\text{soluble}}}{K_2Cr_2O_7}$$

Physical and Chemical Properties

General poperties exhibited by $K_2Cr_2O_7$ *are as follows*:

1. $K_2Cr_2O_7$ forms orange-red prismatic crystals which melt at 396°C.
2. It is moderately soluble in cold water and freely soluble in hot water.
3. When heated to a white heat, it decomposes to give potassium chromate, K_2CrO_4 and O_2 gas is evolved.
$$4K_2Cr_2O_7 \xrightarrow{\Delta} 4K_2CrO_4 + 2Cr_2O_3 + 3O_2\uparrow$$
4. $K_2Cr_2O_7$ is a powerful oxidising agent. In the presence of dil H_2SO_4, one molecule of this compound gives three atoms of oxygen as shown below
$$\underset{\text{orange}}{K_2Cr_2O_7} + 4H_2SO_4\,(\text{dil.}) \longrightarrow K_2SO_4 + \underset{\text{green}}{Cr_2(SO_4)_3} + 4H_2O + 3O$$
Thus, in presence of dil H_2SO_4, it liberates I_2 from KI solution, oxidises Fe(+2) salts to Fe(+3) salts, H_2S to S, SO_2 to H_2SO_4 as
$$K_2Cr_2O_7 + 7H_2SO_4 + 6KI \longrightarrow 4K_2SO_4 + Cr_2(SO_4)_3 + 7H_2O + 3I_2$$
$$K_2Cr_2O_7 + 7H_2SO_4 + 6FeSO_4 \longrightarrow K_2SO_4 + Cr_2(SO_4)_3 + 7H_2O + 3Fe_2(SO_4)_3$$
$$K_2Cr_2O_7 + 4H_2SO_4 + 3H_2S \longrightarrow K_2SO_4 + Cr_2(SO_4)_3 + 7H_2O + 3S$$
$$K_2Cr_2O_7 + H_2SO_4 + 3SO_2 \longrightarrow K_2SO_4 + Cr_2(SO_4)_3 + H_2O$$
5. With cold H_2SO_4, red crystals of chromium trioxide, CrO_3 are formed. When $K_2Cr_2O_7$ is heated with H_2SO_4, O_2 gas is evolved.
$$K_2Cr_2O_7 + H_2SO_4(\text{cold}) \longrightarrow \underset{\text{red crystals}}{2CrO_3} + K_2SO_4 + H_2O$$
$$2K_2Cr_2O_7 + 8H_2SO_4 \xrightarrow{\Delta} 2K_2SO_4 + 2Cr_2(SO_4)_3 + 8H_2O + 3O_2$$
6. **Chromyl chloride test** When solid $K_2Cr_2O_7$ is heated with conc. H_2SO_4 and a soluble chloride like NaCl, deep red vapours of chromyl chloride, CrO_2Cl_2 are produced.

$$K_2Cr_2O_7 + 4NaCl + 3H_2SO_4 \text{ (concentrated)} \xrightarrow{\Delta} \underset{\text{red vapours}}{2CrO_2Cl_2} + K_2SO_4 + 2Na_2SO_4 + 3H_2O$$

When vapours of chromyl chloride are passed into aqueous NaOH solution, yellow colour solution of Na_2CrO_4 is obtained which is on reaction with acetic acid and lead acetate gives yellow ppt of $PbCrO_4$. This test is called chromyl chloride test. It is used to identify Cl^- in inorganic salt analysis.

7. When $K_2Cr_2O_7$ is heated with conc. HCl, Cl_2 is given off and chromic chloride $(CrCl_3)$ is obtained.

$$K_2Cr_2O_7 + 14HCl \longrightarrow 2KCl + 2CrCl_3 + 7H_2O + 3Cl_2\uparrow$$

When Zn metal is added to the above solution, nascent hydrogen is evolved which reduces $CrCl_3$ to blue chromous chloride, $CrCl_2$.

$$CrCl_3 + H(\text{from Zn / HCl}) \longrightarrow CrCl_2 + HCl$$

When a saturated solution of CH_3COONa is added to the blue solution of $CrCl_2$ obtained as above, a red precipitate of chromous acetate, $(CH_3COO)_2Cr$ is obtained.

$$CrCl_2 + 2CH_3COONa \longrightarrow \underset{\text{red ppt.}}{(CH_3COO)_2Cr\downarrow} + 2NaCl$$

8. When an alkali is added to an orange-red solution of $K_2Cr_2O_7$, a yellow solution results.

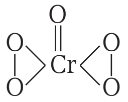
$$\underset{\text{orange-red}}{K_2Cr_2O_7} + 2KOH \longrightarrow \underset{\text{yellow}}{2K_2CrO_4} + H_2O$$

$$\underset{\text{orange-red}}{K_2Cr_2O_7} + 2NaOH \longrightarrow \underset{\text{yellow}}{K_2CrO_4} + H_2O + Na_2CrO_4$$

9. When H_2O_2 is added to an acidified solution of a dichromate, a complicated reaction occurs. The products depend on the pH and concentration of Cr(VI) ion.

$$Cr_2O_7^{2-} + 2H^+ + 4H_2O_2 \longrightarrow \underset{\substack{\text{chromic peroxide}\\\text{(deep blue-violet)}}}{2CrO(O_2)_2} + 5H_2O$$

A deep blue-violet coloured chromic peroxide is formed which is decomposed rapidly in aqueous solution into Cr^{3+} and oxygen.



chromic peroxide
(Oxidation state + 6 due to the presence of two peroxide linkages)

Uses

1. Potassium dichromate finds extensive use in dyeing, calico-printing and chrome-tanning.
2. It is used as an oxidising agent and in the preparation of various chromium compounds like Cr_2O_3, CrO_3 $K_2SO_4 \cdot Cr_2(SO_4)_3 \cdot 24H_2O$, CrO_2Cl_2, K_2CrO_4, $CrCl_3$, $Cr(CH_3COO)_2$ etc.
3. It is also used in photography.
4. A mixture of $K_2Cr_2O_7$ and conc. H_2SO_4, usually known as chromic acid mixture, has strong oxidising properties and is used as a cleaning agent for glassware etc.
5. It is also used in leather industry (chrome tanning).

Interconversion of K_2CrO_4 and $K_2Cr_2O_7$

On acidifying, the yellow colour of K_2CrO_4 again changes to orange-red due to the reformation of $K_2Cr_2O_7$.

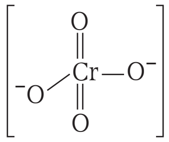
$$\underset{\text{yellow}}{2K_2CrO_4} + H_2SO_4 \longrightarrow \underset{\text{orangered}}{K_2Cr_2O_7} + K_2SO_4 + H_2O$$

This interconversion is explained on the basis of the fact that in $K_2Cr_2O_7$ solution, orange-red $Cr_2O_7^{2-}$ ions are in equilibrium with yellow CrO_4^{2-} ions.

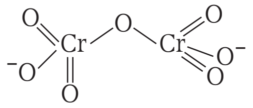
$$\underset{\text{orange-red}}{Cr_2O_7^{2-}} + H_2O \rightleftharpoons \underset{\text{yellow}}{2CrO_4^{2-}} + 2H^+$$

On adding an alkali, the concentration of H^+ ions decreases and hence, the above reaction proceeds in the forward direction producing yellow solution containing CrO_4^{2-} ions. On the other hand, when an acid is added, the concentration of H^+ ions increases and hence, the above reaction proceeds in the backward direction producing the orange solution containing $Cr_2O_7^{2-}$ ions.

Structures of Chromate and Dichromate Ions



tetrahedral
(chromate ion)



(dichromate ion)

In $Cr_2O_7^{2-}$ two CrO_3 units have been joined by O.

The above description makes it evident that since both $Cr_2O_7^{2-}$ and CrO_4^{2-} ions are present in a dichromate solution, $K_2Cr_2O_7$ will precipitate a salt of lower solubility product with Pb^{2+} or Ba^{2+} ions. Thus, when $K_2Cr_2O_7$ is treated with $Pb(NO_3)_2$, $PbCrO_4$ and not $PbCr_2O_7$ is precipitated. This is because of the fact that $PbCrO_4$ has less solubility product than $PbCr_2O_7$.

$$K_2Cr_2O_7 + 2Pb(NO_3)_2 + H_2O \longrightarrow 2PbCrO_4 + 2KNO_3 + 2HNO_3$$

Caution Point *In less acidic solution* $K_2Cr_2O_7$ *and* H_2O_2 *give violet coloured diamagnetic salt* $[CrO(O_2)(OH)]^-$. *In alkaline solution with* 30% H_2O_2, *a red brown compound* K_3CrO_8 *is formed.*

Estimation of $Cr_2O_7^{2-}$

$K_2Cr_2O_7$ can be estimated volumetrically by iodometric titration. Acidified $K_2Cr_2O_7$ is treated with KI and liberated I_2 is titrated using hypo ($Na_2S_2O_3$ solution) with starch indicator.

$$Cr_2O_7^{2-} + 14H^+ + 6I^- \longrightarrow 2Cr^{3+} + 7H_2O + 3I_2$$

$$I_2 + 2S_2O_3^{2-} \longrightarrow S_4O_6^{2-} + 2I^-$$

$$Cr_2O_7^{2-} \equiv 3I_2 \equiv 6I^- \equiv 6e^-$$

$$\text{Equivalent weight of } K_2Cr_2O_7 = \frac{\text{molecular wt.}}{6} = \frac{294}{6}$$

$$2S_2O_3^{2-} \equiv I_2 \equiv 2I^- \equiv 2e^-$$

$$\text{Equivalent weight of } Na_2S_2O_3 \cdot 5H_2O = \frac{248}{1}$$

Sample **Problem 14** *When acidified* $K_2Cr_2O_7$ *solution is added to* Sn^{2+} *salts then* Sn^{2+} *changes to* **[NCERT** Exemplar]

Electron per Cr atom = 3

8.3 Potassium Permanganate

Its formula is $KMnO_4$. It is the salt of permanganic acid, $HMnO_4$ which is an unstable acid and exists only in solution.

Methods of Preparation

1. It may be prepared by acidifying the solution of potassium manganate, K_2MnO_4 by H_2SO_4.

$$3K_2MnO_4 + 2H_2SO_4 \longrightarrow 2K_2SO_4 + 2KMnO_4 + MnO_2\downarrow + 2H_2O$$

2. On a large scale, it is prepared from the mineral **pyrolusite,** MnO_2. The finely powdered pyrolusite mineral is fused with KOH in presence of air or an oxidising agent like KNO_3, $KClO_3$, etc. This treatment gives us fused green coloured potassium manganate, K_2MnO_4.

$$2MnO_2 + 4KOH + O_2 \longrightarrow 2K_2MnO_4 + 2H_2O$$

$$MnO_2 + 2KOH + KNO_3 \longrightarrow K_2MnO_4 + KNO_2 + H_2O$$

$$3MnO_2 + 6KOH + KClO_3 \longrightarrow 3K_2MnO_4 + KCl + 3H_2O$$

The fused K_2MnO_4 obtained as above is extracted with water and the solution, after filtration, is converted into potassium permanganate ($KMnO_4$) by any of the following methods

(i) In **Stadeler's process** Cl_2 is passed through the green solution of K_2MnO_4 until it becomes purple due to the formation of $KMnO_4$. Here, Cl_2 oxidises K_2MnO_4 into $KMnO_4$.

$$2K_2MnO_4 + Cl_2 \longrightarrow 2KCl + 2KMnO_4$$

(ii) By passing CO_2 or O_3 through the green solution of K_2MnO_4 until it becomes purple.

$$\underset{\text{green}}{3K_2MnO_4} + 2H_2O + 4CO_2 \rightarrow \underset{\text{purple}}{2KMnO_4} + MnO_2 + 4KHCO_3$$

$$2K_2MnO_4 + H_2O + O_3 \longrightarrow \underset{\text{purple}}{2KMnO_4} + 2KOH + O_2$$

(iii) Now-a-days the conversion of K_2MnO_4 into $KMnO_4$ is done by **the electrolytic oxidation process** in alkaline medium.

$$K_2MnO_4 \longrightarrow 2K^+ + MnO_4^{2-}$$

$$H_2O \rightleftharpoons H^+ + OH^-$$

$$\text{At anode} \quad MnO_4^{2-} \longrightarrow MnO_4^- + e^-$$

$$\text{At cathode} \quad 2H + 2e^- \longrightarrow H_2\uparrow$$

Physical and Chemical Properties

1. Potassium permanganate forms dark purple lustrous crystals giving deep pink colour in solution.
2. It is isomorphous with potassium perchlorate, $KClO_4$.
3. Its solubility in water at 20°C is only about 7% while it dissolves more at higher temperature (25% at 63°C).
4. It gives off O_2 at 200°C.

$$2KMnO_4 \xrightarrow[200°C]{\Delta} K_2MnO_4 + MnO_2 + O_2$$

At red heat, K_2MnO_4 formed as above is decomposed into permanganite, K_2MnO_3 and O_2.

$$2K_2MnO_4 \rightleftharpoons 2K_2MnO_3 + O_2$$

5. When an alkaline solution of $KMnO_4$ is heated, O_2 is evolved.

$$4KMnO_4 + 4KOH \xrightarrow{\Delta} 4K_2MnO_4 + 2H_2O + O_2$$

6. With well cooled conc. H_2SO_4, it gives Mn_2O_7 which decomposes on warming.

$$2KMnO_4 + 2H_2SO_4 \longrightarrow Mn_2O_7 + 2KHSO_4 + H_2O$$

$$2Mn_2O_7 \xrightarrow{\Delta} 4MnO_2 + 3O_2$$

With warmed conc. H_2SO_4, oxygen gas is evolved.

$$4KMnO_4 + 6H_2SO_4 \longrightarrow 2K_2SO_4 + 4MnSO_4 + 6H_2O + 5O_2$$

7. When heated in a current of H_2, solid $KMnO_4$ gives KOH, MnO and steam.

$$2KMnO_4 + 5H_2 \longrightarrow 2KOH + 2MnO + 4H_2O$$

8. A mixture of $KMnO_4$ with sulphur and charcoal burns when heated, and explodes like a gun powder when rubbed.
9. A well-powdered mixture of $KMnO_4$ and oxalic acid catches fire spontaneously in a few seconds.

Hot Spot 3

OXIDISING Nature of $KMnO_4$

$KMnO_4$ as an oxidising agent is another important topic for JEE Main examination. The level of question vary from easy to average.

$KMnO_4$ is a powerful oxidising agent. The course of reaction depends on whether the oxidation takes place in alkaline, neutral or acid solution.

(i) In alkaline solution, MnO_4^- ion (Mn = +7) is first reduced to MnO_4^{2-} ion (Mn = +6) and then to insoluble MnO_2 (Mn = +4). The solution first changes from purple (due to MnO_4^-) to green (due to MnO_4^{2-}) and finally it becomes colourless (MnO_2).

$$\underset{\substack{\text{purple}\\(\text{Mn} = +7)}}{2KMnO_4} + 2KOH \longrightarrow \underset{\substack{\text{green}\\(\text{Mn} = +6)}}{2K_2MnO_4} + H_2O + O \quad \text{...(i)}$$

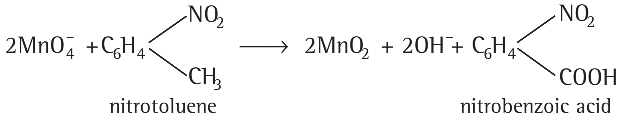
$$\underset{\substack{\text{green}\\(\text{Mn} = +6)}}{2K_2MnO_4} + 2H_2O \longrightarrow \underset{\substack{\text{colourless}\\(\text{Mn} = +4)}}{2MnO_2} + 4KOH + 2O \quad \text{...(ii)}$$

$$\underset{\substack{\text{purple}\\(\text{Mn} = +7)}}{2KMnO_4} + H_2O \longrightarrow \underset{\substack{\text{colourless}\\(\text{Mn} = +4)}}{2MnO_2} + 2KOH + 3O \quad (1)$$

Change in oxidation number of Mn = 3

In alkaline medium, $KMnO_4$ oxidises iodides (I^-) to iodates (IO_3^-), NH_3 to N_2 and nitrotoluene to nitrobenzoic acid as

$$2MnO_4^- + H_2O + I^- \xrightarrow{\text{Alkali}} 2MnO_2 + 2OH^- + IO_3^-$$



$$2MnO_4^- + C_6H_4\begin{cases} NO_2 \\ CH_3 \end{cases} \longrightarrow 2MnO_2 + 2OH^- + C_6H_4\begin{cases} NO_2 \\ COOH \end{cases}$$

nitrotoluene　　nitrobenzoic acid

$$2MnO_4^- + 2NH_3 \longrightarrow 2MnO_2 + 2OH^- + N_2 + 2H_2O$$

(ii) In neutral solution, $KMnO_4$ is directly reduced to MnO_2.

$$2K\overset{+7}{M}nO_4 + H_2O \longrightarrow 2KOH + 2\overset{+4}{Mn}O_2 + 3O \quad (2)$$

Change in oxidation number (Mn) = 3

In neutral medium, $KMnO_4$ oxidises Mn^{2+} salt to MnO_2, $Na_2S_2O_3$ to Na_2SO_4, H_2S to S as

$$2MnO_4^- + 3Mn^{2+} + 2H_2O \longrightarrow 5MnO_2 + 4H^+$$

$$8MnO_4^- + 3S_2O_3^{2-} + H_2O \longrightarrow 8MnO_2 + 6SO_4^{2-} + 2OH^-$$

$$2MnO_4^- + 4H_2S \longrightarrow 2MnS + S + SO_4^{2-} + 4H_2O$$

(iii) In acidic medium (dil H_2SO_4), MnO_4^- ion is reduced to Mn^{2+} ion and five O-atoms are rendered available from two MnO_4^- ions as :

$$2KMnO_4 + 3H_2SO_4 \longrightarrow K_2SO_4 + 2MnSO_4 + 3H_2O + 5O \quad (3)$$

In acidic medium, $KMnO_4$ oxidises Fe (II) salts to Fe (III) salts, oxalic acid to CO_2, H_2S to S, SO_2 to H_2SO_4, sulphites to sulphates, KI to I_2, H_2O_2 to O_2, halogen acids to halogens as

$$MnO_4^- + 8H^+ + 5Fe^{2+} \longrightarrow Mn^{2+} + 5Fe^{3+} + 4H_2O$$

$$2MnO_4^- + 16H^+ + 5C_2O_4^{2-} \longrightarrow 2Mn^{2+} + 10CO_2 + 8H_2O$$

$$2MnO_4^- + 16H^+ + 5S^{2-} \longrightarrow 2Mn^{2+} + 5S + 8H_2O$$

$$2MnO_4^- + 2H_2O + 5SO_2 \longrightarrow 2Mn^{2+} + 5SO_4^{2-} + 4H^+$$

$$2MnO_4^- + 6H^+ + 5SO_3^{2-} \longrightarrow 2Mn^{2+} + 5SO_4^{2-} + 3H_2O$$

$$2MnO_4^- + 16H^+ + 10I^- \longrightarrow 2Mn^{2+} + 5I_2 + 8H_2O$$

$$2MnO_4^- + 6H^+ + 5H_2O_2 \longrightarrow 2Mn^{2+} + 5O_2 + 8H_2O$$

$$2MnO_4^- + 16H^+ + 10X^- \longrightarrow 2Mn^{2+} + 5X_2 + 8H_2O$$

Equivalent Weight of $KMnO_4$

In different mediums, equivalent weight of $KMnO_4$ *is different.*

(a) In Alkaline Medium

From the equation (1), it is evident that two molecules of $KMnO_4$ in alkaline solution give three oxygen atoms (*i.e.*, six equivalents) and, therefore, the equivalent weight of $KMnO_4$ as an oxidising agent in alkaline solution is one-third of its molecular weight.

$$\text{Eq. wt. of } KMnO_4 = \frac{\text{mol. wt.}}{3} = \frac{158}{3} = 52.67$$

(Change in oxidation no = 3)

(b) In Neutral Medium

Equation (2) is the same as for alkaline medium. Evidently, in neutral medium as well, the equivalent weight of $KMnO_4$ is one-third of its molecular weight.

$$\text{Eq. wt. of } KMnO_4 = \frac{\text{mol. wt.}}{3} = \frac{158}{3} = 52.67$$

(Change in oxidation number = 3)

(c) In Acidic Medium

It is obvious that in acid solution, the equivalent weight of $KMnO_4$ is one-fifth of its molecular weight.

$$\text{Eq. wt. of } KMnO_4 = \frac{\text{mol. wt.}}{5} = \frac{158}{5} = 31.6$$

(Change in oxidation number of Mn = 5)

Sample Problem 16 $KMnO_4$ *acts as an oxidising agent in acidic medium. The number of moles of* $KMnO_4$ *that will be needed to react with one mole of sulphide ions in acidic solution is* **[NCERT Exemplar]**

(a) $\frac{2}{5}$ (b) $\frac{3}{5}$ (c) $\frac{4}{5}$ (d) $\frac{1}{5}$

Interpret (a) $2MnO_4^- + 16H^+ + 5S^{2-} \longrightarrow 2Mn^{2+} + 5S + 8H_2O$

5 moles of S^{2-} ions react with 2 moles of $KMnO_4$

So, 1 mole of S^{2-} ion will react with $\frac{2}{5}$ mole of $KMnO_4$.

Sample **Problem 17** $KMnO_4$ *acts as an oxidising agent in alkaline medium. When alkaline* $KMnO_4$ *is treated with* KI, *iodide ion is oxidised to*

(*a*) I_2

(*b*) IO^-

(*c*) IO_3^-

(*d*) IO_4^-

Interpret (c) $2MnO_4^- + H_2O + I^- \xrightarrow{\text{Alkali}} 2MnO_2 + 2OH^- + IO_3^-$

Sample **Problem 18** MnO_4^{2-} *changes to* MnO_2 *and* MnO_4^- *in acidic medium. The equivalent wt. of* MnO_4^{2-} *will be*

(*a*) $\frac{M}{2}$ (*b*) $\frac{2M}{3}$ (*c*) $\frac{3M}{2}$ (*d*) $\frac{M}{5}$

Interpret (c) $3\overset{+6}{Mn}O_4^{2-} + 4H^+ \longrightarrow \overset{+4}{Mn}O_2 + 2\overset{+7}{Mn}O_4^- + 2H_2O$

(disproportionation reaction) Eq. wt. of the species undergoing disproportionation = eq. wt. (in oxidation) + eq. wt. (in reduction)

$$\overset{+6}{Mn}O_4^{2-} \longrightarrow \overset{+4}{Mn}O_2; \quad \text{eq. wt. (reduction)} = \frac{M}{2}$$

$$\overset{+6}{Mn}O_4^{2-} \longrightarrow \overset{+7}{Mn}O_4^-; \quad \text{eq. wt. (oxidation)} = \frac{M}{1}$$

$$\therefore \text{ Eq. wt. of } MnO_4^{2-} = \frac{M}{2} + \frac{M}{1} = \frac{3M}{2}$$

Uses

It is used

1. as an oxidising agent in the laboratory as well as in industry.
2. in volumetric estimations of ferrous salts, oxalic acid, H_2O_2 etc.
3. as a disinfectant and a germicide on account of its oxidising property.
4. in qualitative analysis for detecting halides and oxalates.
5. in the manufacture of saccharin, benzoic acid, acetaldehyde etc.
6. for bleaching waxes.
7. for the detection of double bond in organic compounds. (For this purpose alkaline $KMnO_4$ solution under the name Baeyer's reagent is used.)
8. as a source of reactive form of MnO_2 which is used in place of pyrolusite in the manufacture of dry cells.

8.4 *f*-Block Elements

The elements in which last electron enters into *f*-orbitals of the anti-penultimate (inner to the penultimate shell), *i.e.,* $(n-2)$ shell, are called ***f*-block elements.** Since, they constitute transition series within transition series and the last electron occupies the antipenultimate shell, they are named as **inner-transition elements.** They all belong to III-B group (3 group) of Periodic Table. In these elements, both the *d* and *f* subshells are incomplete. The general outer electronic configuration of these elements is $(n-2)f^{1-14}$, $(n-1)d^{10}ns^2$. Depending upon the nature of *f*-orbital of the antipenultimate shell in which the differentiating electron enters, they are divided into two series, *viz*, 4*f* and 5*f* series.

4*f*-Series or First Inner-Transition Series

In this series, the last electron occupies the 4*f* orbital. This series includes next fourteen elements after lanthanum $(Z = 57)$, *i.e.,* from cerium $(Z = 58)$ to lutetium $(Z = 71)$. These are commonly called **lanthanides** or **lanthanons** or **rare earths.** The name lanthanides or lanthanons was given because they are closely related with lanthanum ($_{57}$La) in their properties. However, the name rare earth was given because these elements were difficult to obtain. But now this term is obsolete.

The general characteristics of lanthanoids are as follows

(a) Electronic Configuration

General electronic configuration of these elements is $[Xe]\ 4f^{1-14}, 5d^{0-1}, 6s^2$.

Table 8.9 **Electronic Configuration of Lanthanides**

Name	Symbol	Atomic no.	Configuration
Cerium	Ce	58	[Xe] $4f^2 5d^0 6s^2$
Praseodymium	Pr	59	[Xe] $4f^3 5d^0 6s^2$
Neodymium	Nd	60	[Xe] $4f^4 5d^0 6s^2$
Promethium	Pm	61	[Xe] $4f^5 5d^0 6s^2$
Samarium	Sm	62	[Xe] $4f^6 5d^0 6s^2$
Europium	Eu	63	[Xe] $4f^7 5d^0 6s^2$
Gadolinium	Gd	64	[Xe] $4f^7 5d^1 6s^2$
Terbium	Tb	65	[Xe] $4f^9 5d^0 6s^2$
Dysprosium	Dy	66	[Xe] $4f^{10} 5d^0 6s^2$
Holmium	Ho	67	[Xe] $4f^{11} 5d^0 6s^2$
Erbium	Er	68	[Xe] $4f^{12} 5d^0 6s^2$
Thulium	Tm	69	[Xe] $4f^{13} 5d^0 6s^2$
Ytterbium	Yb	70	[Xe] $4f^{14} 5d^0 6s^2$
Lutetium	Lu	71	[Xe] $4f^{14} 5d^1 6s^2$

(b) Physical State

All of them are silvery white soft metals with high density and melting point. These get tarnish readily in air. The hardness of these metals increases with rise in atomic number.

(c) Atomic and Ionic Radii

In 4*f* series, as the atomic number increases from La to Lu, the atomic and ionic radii decreases gradually. This decrease in atomic and ionic size from lanthanum (at. no. 57) to lutetium (at. no. 71) is a unique feature and is known as **lanthanide contraction.** This contraction is attributed to imperfect shielding of electrons of *f*-orbital. It is even less than the shielding shown by *d*-electron.

As a result of lanthanide contraction, the normal increase in size from Sc → Y → La disappears after the lanthanide and the pairs of elements such as Zr—Hf, Nb—Ta and Mo—W have nearly same size. The properties of these elements are very similar.

The similarities in properties within these pairs make their separation very difficult.

Due to lanthanide contraction, the elements of 5*d* and 4*d* series resemble each other much more closely than do the elements of 4*d* and 3*d* series.

Sample **Problem 19** *The radius of* La^{3+} *(atomic number of* La= 57) *is* 1.06 Å. *Which one of the following given values will be closest to the radius of* Lu^{3+}?
(Atomic number of Lu = 71)

(*a*) 1.60 Å (*b*) 1.40 Å
(*c*) 1.06 Å (*d*) 0.85 Å

Interpret (*d*) Due to lanthanoid contraction there occurs net decrease in size. Only one 0.85 Å is smaller one.

(d) Oxidation State

All of them show variable valency or oxidation state. However, +3 oxidation state is most stable. Some of these elements also exhibit +2 and +4 oxidation states along with +3 oxidation state. Higher oxidation states are not possible because there is a large energy gap beween 4*f* and 5*d* subshells.

Following stable ions also exist as

$$4f^0 = La^{3+}$$
$$4f^7 = Eu^{2+}, Gd^{3+}, Tb^{4+}$$
$$4f^{14} = Yb^{2+}, Lu^{3+}$$

Stability of these ions depend on

(i) ionisation energy (ii) sublimation energy
(iii) lattice energy

(e) Colour

Many trivalent lanthanide ions are coloured in both solid state as well as aqueous solutions (not shown by La^+, Ce^{3+}, Gd^{3+}, Yb^{3+} and Lu^{3+}). The colour of these ions is because of *f*-*f* transition due to the presence of partly filled *f*-orbitals.

Ce^{4+} is orange red ($4f^0$, isoelectronmic of La^{3+}) and Yb^{2+} is yellow ($4f^{14}$ isoelectronic of Lu^{3+}).

(f) Magnetic Properties

Except Lu^{3+}, Yb^{3+} and Ce^{4+}, all other lanthanoid ions are paramagnetic. However, the point of difference from transition elements is that here, both spin as well as orbital moments give contribution and the μ_{eff} is calculated as

$$\mu_{eff} = \sqrt{4S(S+1) + L(L+1)} \text{ BM}$$

The paramagnetism increases to maximum in neodymium (Nd) (atomic number 60).

(g) Ionisation Energy

These elements have low ionisation energy and thus, have high electropositive character.

(h) Complex Formation

Because of their low charge density lanthanoids have very less tendency to form complexes. They form complexes with strong chelating agents like EDTA oxime but not with π-bonding ligands.

(i) Alloy Formation

They form alloy with other metals like iron, *e.g.,* misch metal which consists of lanthanoid metal (~ 95%), iron (~ 5%) and traces of S, C, Ca, Al, etc.

(j) Reactivity

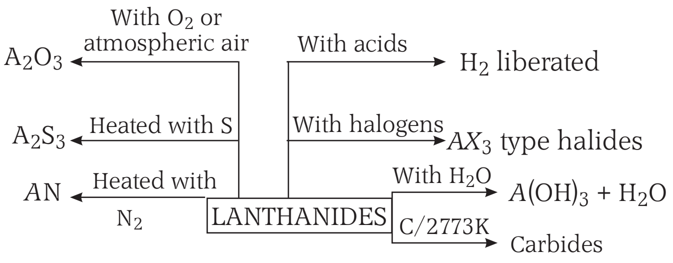
As far as their chemical behaviour is concerned, their earlier members are quite reactive (similar in behaviour to Ca) but with increasing atomic number they behave more like Al.

These elements easily combine with hydrogen forming hydrides.

The carbides (with C) of the type A_2C, A_2C_3 and AC_2 are reported where, A = lanthanide.

They liberate H_2 with dilute acids and form halides with halogens.

Their oxides (M_2O_3) and hydroxides [$M(OH)_3$] are stable. The hydroxides are ionic and basic. They are less basic than $Ca(OH)_2$ but more basic than amphoteric $Al(OH)_3$. The basic strength decreases from $Ce(OH)_3$ to $Lu(OH)_3$. Their generalised reactions can be summarised as



Here, A = lanthanides

Carbonyls are not formed by lanthanides due to non-availability of d-electrons for π-bonding. However, an unstable $Nd(CO)_6$ has been prepared.

Ce and Tb give CeF_4 and TbF_4 instead of CeF_3 and TbF_3 respectively.

Eu and Yb dissolve in liquid ammonia and form blue solution (which give spectra characteristic of M^{2+} and ammoniated electrons). The solution decolourises slowly but the concentrated solution appear golden.

Sample Problem 20 *Match the property given in Column I with the element given in Column II.*

	Column I (Property)		**Column II** (Element)
(I)	Lanthanoid which shows +4 oxidation state	(A)	Pm
(II)	Lanthanoid which can show +2 oxidation state	(B)	Ce
(III)	Radioactive lanthanoid	(C)	Lu
(IV)	Lanthanoid which has $4f^7$ electronic configuration in +3 oxidation state	(D)	Eu
(V)	Lanthanoid which has $4f^{14}$ electronic configuration in +3 oxidation state	(E)	Gd
		(F)	Dy

(*a*) I-B, II-D, III-A, IV-E, V-C
(*b*) I-B, II-C, III-E, IV-A, V-D
(*c*) I-E, II-F, III-C, IV-A, V-D
(*d*) I-F, II-A, III-B, IV-C, V-D

Interpret (*a*) Ce = + 4 oxidation state, Eu = + 2 oxidation state

Pm = radioactive lanthanoid, $Gd^{3+} = 4f^7$

$Lu^{3+} = 4f^{14}$

5*f*-Series or Second Inner-Transition Series

If the last electron (*i.e.,* the differentiating electron) occupies $5f$ orbital, the element is said to belong **5*f*-series**. This series also includes fourteen elements but here, the elements are after actinium, Ac ($Z = 89$) *i.e.,* from thorium ($Z = 90$) to lawrencium ($Z = 103$). These are called **actinides** or **actinones** because of their close resemblance in properties with actinium.

Except thorium, protactinium and uranium, all other actinides are synthetic elements (*i.e.,* man made elements) These all are radioactive.

Important characteristics of actinides include

(a) Electronic Configuration

Their general electronic configuration is $[Rn]\,5f^{1-14}6d^{0-1}7s^2$. These elements along with their electronic configuration are tabulated below

Table 8.10 **Electronic Configuration of Actinides**

Name	Symbol	Atomic no.	Configuration
Thorium	Th	90	$[Rn]\,5f^0 6d^2 7s^2$
Protactinium	Pa	91	$[Rn]\,5f^2 6d^1 7s^2$
Uranium	U	92	$[Rn]\,5f^3 6d^1 7s^2$
Neptunium	Np	93	$[Rn]\,5f^4 6d^1 7s^2$
Plutonium	Pu	94	$[Rn]\,5f^6 6d^0 7s^2$
Americium	Am	95	$[Rn]\,5f^7 6d^0 7s^2$
Curium	Cm	96	$[Rn]\,5f^7 6d^1 7s^2$
Berkelium	Bk	97	$[Rn]\,5f^8 6d^1 7s^2$
Californium	Cf	98	$[Rn]\,5f^{10} 6d^0 7s^2$
Einsteinium	Es	99	$[Rn]\,5f^{11} 6d^0 7s^2$
Fermium	Fm	100	$[Rn]\,5f^{11} 6d' 7s^2$
Mendelevium	Md	101	$[Rn]\,5f^{13} 6d^0 7s^2$
Nobelium	No	102	$[Rn]\,5f^{14} 6d^0 7s^2$

Sample Problem 21 *General electronic configuration of actinoids is $(n-2)f^{1-14}(n-1)d^{0-2}\,ns^2$. Which of the following actinoids have one electron in 6d orbital?* [**NCERT** Exemplar]

(*a*) U (Atomic no. 92)
(*b*) Np (Atomic no. 93)
(*c*) Pu (Atomic no. 94)
(*d*) Am (Atomic no. 95)

Interpret (*a, b*) $U = 5f^3, 6d^1, 7s^2$

$Np = 5f^4, 6d^1, 7s^2$

(b) Physical State

These metals are silvery white in appearance and display a variety of structures. Except thorium and americium, all actinides have high density.

(c) Oxidation State

For them, there is a greater range of oxidation states (*i.e.*, +4, +5, +6 along with +3) seen which in part attributed to the fact that the $5f$, $6d$ and $7s$ levels are of comparable energy. The maximum oxidation state increases from + 4 in Th to + 5 in Pa, + 6 in U and + 7 in Np and Pu and then decreases in succeding elements. However, here also the predominant oxidation state is +3, which is more stable in case of heavier elements.

(d) Atomic and Ionic Radii

There is seen a gradual decrease in the size of atoms or ions (actinide contraction) which is like lanthanide contraction but less prone. The contraction is infact attributed to the shielding effect of $5f$ electrons.

(e) Magnetic Property

The magnetic properties of them are even more complex than those of lanthanides. These are also paramagnetic in nature due to unpaired $5f$ electrons.

(f) Colour

Actinides are also coloured because of *f*-*f* transition, from the *f*-orbital of lower energy to the *f*-orbital of higher energy. The ions having $5f^0$, $5f^7$ and $5f^{14}$ are colourless. The colour of some other ions are as

$$U^{3+}\ (5f^3) : \text{Red};\quad Np^{3+}\ (5f^4) : \text{Bluish}$$
$$Pu^{3+}\ (5f^5) : \text{Blue};\quad Am^{3+}\ (5f^6) : \text{Pink}$$

(g) Ionisation Energies

Their ionisation energies are very low and thus, they have high electropositive character and behave as strong reducing agents.

In actinoids $5f$ electrons are more effectively shielded from the nuclear charge than $4f$ electrons of corresponding lanthanoids. Hence, outer electrons are less firmly held and they are available for bonding in the actinoids.

(h) Complex Formation

Because of their higher nuclear charge and small size, these elements form complex.

(i) Reactivity

Actinoids metals are reactive. Their reactivity increase with increase in atomic number. They tarnish rapidly. Protective covering is formed only in case of Th. Conc. HCl reacts rapidly with these metals but conc. HNO_3 makes Th, U and Pu passive.

Check Point 2

1. Actinoid contraction is greater from element to element than lanthanoid contraction. why?
2. Explain, why among the lanthanides, Ce(III) can be easily oxidised to Ce(IV)? (Ce = 50)
3. Ionisation energy of Ce, Pr, Nd are higher than Th, Pa and U. Why? **[NCERT Exemplar]**
4. The magnetic properties of actinides are more complex than those of lanthanides. Explain it.

WORKED OUT
Examples

Example 1 *Which one of the following arrangement of ions in order of increasing strength as a reducing agent is correct?*

(a) $Cr_2O_7^{2-} < Cr^{3+} < Cr^{2+}$
(b) $Cr_2O_7^{2-} < Cr^{2+} < Cr^{3+}$
(c) $Cr^{3+} < Cr^{2+} < Cr_2O_7^{2-}$
(d) $Cr^{2+} < Cr^{3+} < Cr_2O_7^{2-}$

Solution (a) $Cr_2O_7^{2-} < Cr^{3+} < Cr^{2+}$

Smaller the oxidation state of element in the ion, greater the reducing nature.

Example 2 *The magnetic moment of* Mn *in* MnO_4^- *is*

(a) *zero BM*
(b) $\sqrt{3}$ *BM*
(c) $\sqrt{8}$ *BM*
(d) $\sqrt{15}$ *BM*

Solution (b) Oxidation number of Mn in $MnO_4^- = +7$

So, it should have [Ar] configuration and it should be colourless and diamagnetic. But one electron is transferred to Mn from oxygen and thus Mn in MnO_4^- has one unpaired electron making it paramagnetic.

$$\text{Magnetic moment} = \sqrt{n(n+2)} = \sqrt{1(1+2)} = \sqrt{3}\ \text{BM}$$

Example 3 *Black coloured solid (A)* $\xrightarrow[\Delta]{KNO_3\ +\ KOH}$ *green colour solution (B)* $\xrightarrow{CO_2} \underset{\text{pink}}{(C)} + (A)$

Pink compound (C) is decolourised by Fe^{2+}. *The compound A, B and C are*

(a) MnO_2, K_2MnO_4, $KMnO_4$
(b) MnO_2, $KMnO_4$, K_2MnO_4
(c) $KMnO_4$, MnO_2, K_2MnO_4
(d) K_2MnO_4, MnO_4, $KMnO_4$

Solution (c) Black colour compound is $MnO_2(A)$.

When it is fused with KOH and KNO_3, potassium manganate (K_2MnO_4) is formed. It is indicated by its green colour.

In acidic medium, K_2MnO_4 is unstable and disproportionates

$$\underset{(A)}{MnO_2} + KOH + O_2(KNO_3) \xrightarrow{\Delta} \underset{\text{green colour }(B)}{K_2MnO_4}$$

$$CO_2 + H_2O \rightleftharpoons H_2CO_3 \rightleftharpoons H^+ + HCO_3^-$$

$$3MnO_4^{2-} + 4H^+ \longrightarrow MnO_2 + 2MnO_4^- + 2H_2O$$

(disproportionation reaction)

Example 4 *Possible oxidation state of last element in the series of the actinoids will be* **[NCERT]**

(a) $+2$
(b) $+3$
(c) $+4$
(d) $+5$

Solution (b) Actinoids = ${}_{89}Ac$ to ${}_{103}Lr$

Lawrencium (Lr; $Z = 103$) is the last element of actinoids series.

Electronic configuration of ${}_{103}Lr = [Rn]\,5f^{14}6d^17s^2$

Its possible oxidations state = $+3$

Because after losing three electrons lawrencium acquire stable configuration $5f^{14}$.

Example 5 *Which one of the following species is the most stable in aqueous solution?* **[NCERT]**

(a) Mn^{3+}
(b) Cr^{3+}
(c) V^{3+}
(d) Ti^{3+}

Solution (a) $Mn^{3+}(Z = 25) = [Ar]\,3d^4$; $Cr^{3+}(Z = 24) = [Ar]\,3d^3$
$V^{3+}(Z = 23) = [Ar]\,3d^2$; $Ti^{3+}(Z = 22) = [Ar]\,3d^1$

Out of these species, Cr^{3+} is most stable in aqueous solution due to its tendency of complex formation.

Example 6 *Transition metals form alloys easily. The reason for this is*

(a) *their occurrence*
(b) *similar size*
(c) *magnetic nature*
(d) *do not form easily*

Solution (b) Transition metals are quite similar in atomic size. Therefore, the atoms of one metal can substitute the atoms of other metal in its crystal lattice. Thus, on cooling a mixture, solution of two or more transition metals, *i.e.*, smooth solid alloy, is formed.

Example 7 *The correct statement about ionisation energies of* Cu *and* Zn *is/are*

(a) IE_1 *of* Cu *is less than that of* Zn
(b) IE_2 *of* Cu *is more than that of* Zn
(c) IE_2 *of* Zn *is more than that of* Cu
(d) *Both* (a) *and* (b)

Solution (d) IE_1 of Cu ($3d^{10}4s^1$) is less than that of Zn ($3d^{10}4s^2$) because it is easy to remove an electron from a half-filled *s*-orbital as compared to fully-filled *s*-orbital. However, in case of IE_2, the electron is lost from 3*d* orbital of Cu and 4*s* orbital of Zn and loss of electron from 4*s* orbital is easier as compared to fully-filled 3*d* orbital.

Start Practice for JEE Main

Round I (Topically Divided Problems)

Characteristics of Transition Elements

1. Which of the following is amphoteric oxide?

Mn_2O_7, CrO_3, Cr_2O_3, CrO, V_2O_5, V_2O_4 **[NCERT Exemplar]**

(a) V_2O_5, Cr_2O_3 (b) Mn_2O_7, CrO_3
(c) CrO, V_2O_5 (d) V_2O_5, V_2O_4

2. Which of the following statements is not correct? **[NCERT Exemplar]**

(a) Copper liberates hydrogen from acids
(b) In its higher oxidation states, manganese forms stable compounds with oxygen and fluorine
(c) Mn^{3+} and Co^{3+} are oxidising agents in aqueous solution
(d) Ti^{2+} and Cr^{2+} are reducing agents in aqueous solution

3. Paramagnetism is given by the relation $\mu = 2\sqrt{s(s+1)}$ magnetons where 's' is the total spin. On this basis, the paramagnetism of Cu^+ ion is

(a) 3.88 magnetons (b) 2.83 magnetons
(c) 1.41 magnetons (d) zero

4. Ti^{2+} is purple whereas Ti^{4+} is colourless, because

(a) there is no crystal field effect in Ti^{4+}
(b) Ti^{2+} has $3d^2$ configuration
(c) Ti^{4+} has $3d^2$ configuration
(d) Ti^{4+} is a very small cation when compared to Ti^{2+} and hence, does not absorb any radiation

5. Magnetic moment of $Cr(Z = 24)$, $Mn^+(Z = 25)$ and $Fe^{2+}(Z = 26)$ are x, y, z. They are in order

(a) $x < y < z$ (b) $x = y < z$
(c) $z < x = y$ (d) $x = y = z$

6. VO_2 is an amphoteric oxide and in acidic medium it forms

(a) VO^{2+} (b) VO_2^+
(c) V^{3+} (d) VO_2^{2+}

7. Which of the following is most stable among Cu^+, Fe^+, Fe^{2+} and Fe^{3+}?

(a) Cu^+ (b) Fe^+
(c) Fe^{2+} (d) Fe^{3+}

8. Select the incorrect statement about transition elements.

(a) The last electron enters in the *d*-orbital
(b) Their properties are in between *s* and *p*-block elements
(c) Scandium is the transition element with smallest atomic radii
(d) Their common oxidation state is +3

9. Transition elements exhibit variable valencies because they release electrons from the following orbits

(a) *ns* (b) *ns* and *np*
(c) $(n-1)d$ and *ns* (d) $(n-1)\,d$

10. The transition elements are more metallic than the representative elements because they have

(a) electron pairs in *d*-orbitals
(b) availability of *d*-orbitals for bonding
(c) the electron in *d*-orbitals
(d) unpaired electron in metallic orbitals

11. Which of the following is not a property of transition elements?

(a) Fixed valency
(b) Catalytic property
(c) Paramagnetism
(d) Colour

12. Coinage metals show the properties of

(a) inert elements
(b) normal elements
(c) typical elements
(d) transition elements

13. The valence shell electronic configuration of Cr^{2+} ion is

(a) $4s^0, 3d^4$ (b) $3p^6, 4s^2$

(c) $4s^2, 3d^2$ (d) $4s^2, 3d^0$

14. Zinc does not show variable valency like *d*-block elements because

(a) it is low melting

(b) *d*-orbital is complete

(c) it is a soft metal

(d) two electrons are present in the outermost orbit

15. The catalytic activity of the transition metals and their compounds is ascribed to their

(a) magnetic behaviour

(b) chemical reactivity

(c) ability to adopt multiple oxidation states and their complexing ability

(d) unfilled *d*-orbitals

16. Transition elements are coloured

(a) due to unpaired *d*-electrons

(b) due to small size

(c) due to metallic nature

(d) All of the above

17. Which of the following has the maximum number of unpaired *d*-electrons?

(a) Fe^{2+} (b) Cu^+ (c) Zn (d) Ni^{3+}

18. Cuprous ion is colourless, while cupric ion is coloured because

(a) both have half-filled *p* and *d*-orbitals

(b) cuprous ion has a completed *d*-orbital and cupric ion has incomplete *d*-orbital

(c) cuprous ion has incomplete *d*-orbital and cupric ion has a complete *d*-orbital

(d) both have unpaired electrons in *d*-orbital

19. Of the ions Zn^{2+}, Ni^{2+} and Cr^{3+},
(atomic number of $Zn = 30, Ni = 28, Cr = 24$)

(a) all three are coloured

(b) all three are colourless

(c) only Zn^{2+} is colourless and Ni^{2+} and Cr^{3+} are coloured

(d) only Ni^{2+} is coloured and Zn^{2+} and Cr^{3+} are colourless

20. Which of the following ionic species will impart colour to an aqueous solution?

(a) Cu^+ (b) Zn^{2+}

(c) Cr^{3+} (d) Ti^{4+}

21. In which of the following metallic bond is strongest?

(a) V (b) Fe

(c) Cr (d) Sc

22. Which of the following ions has the highest magnetic moment?

(a) Ti^{3+} (b) Sc^{3+}

(c) Mn^{2+} (d) Zn^{2+}

23. Which of the following is the correct sequence of atomic weights of given elements?

(a) Co > Ni > Fe (b) Fe > Co > Ni

(c) Fe > Ni > Co (d) Ni > Co > Fe

24. Which of the following elements has the maximum first ionisation potential?

(a) V (b) Ti

(c) Mn (d) Cr

25. Which oxide of manganese is amphoteric?

(a) MnO (b) MnO_2

(c) Mn_2O_7 (d) Mn_2O_3

26. Which of the following is correct?

(a) Duralumin : Al + Cu + Mg + Ag

(b) German silver : Cu + Zn +C

(c) Gun metal : Cu + Zn + Sn

(d) Solder : Pb + Al

27. Which one of the following is a diamagnetic ion?

(a) Co^{2+} (b) Cu^{2+}

(c) Mn^{2+} (d) Sc^{3+}

Compounds of Transition Elements

28. $K_2Cr_2O_7 \xrightarrow{\Delta} K_2CrO_4 + O_2 + X$. In the above reaction X is

(a) CrO_3 (b) Cr_2O_7

(c) Cr_2O_3 (d) CrO_5

29. One of the product formed when $K_2Cr_2O_7$ reacts with conc. H_2SO_4 in cold is

(a) CrO_3 (b) $Cr_2(SO_4)_3$

(c) Cr_2O_3 (d) CrO_4Cl_2

30. The reaction of $K_2Cr_2O_7$ with NaCl and conc. H_2SO_4 gives

(a) CrO_2Cl_2 (b) Cr_2O_3

(c) $CrCl_3$ (d) $CrOCl_2$

31. Why is HCl not used to make the medium acidic in oxidation reactions of $KMnO_4$ in acidic medium? **[NCERT Exemplar]**

(a) Both HCl and $KMnO_4$ act as oxidising agents.

(b) $KMnO_4$ oxidises HCl into Cl_2 which is also an oxidising agent.

(c) $KMnO_4$ is a weaker oxidising agent that HCl.

(d) $KMnO_4$ acts as a reducing agent in the presence of HCl.

32. $Cr_2O_7^{2-} \xrightarrow{pH = x} CrO_4^{2-} \xrightarrow{pH = y} Cr_2O_7^{2-}$ pH values x and y can be

(a) 4 and 5
(b) 4 and 8
(c) 8 and 4
(d) 8 and 9

33. In dilute alkaline solution, MnO_4^- changes to

(a) MnO_4^{2-}
(b) MnO_2
(c) Mn_2O_3
(d) MnO

34. What are the species A and B in the following

$$CrO_3 + H_2O \longrightarrow A \xrightarrow{OH^-} B$$

(a) H_2CrO_4, $H_2Cr_2O_7$
(b) $H_2Cr_2O_7$, Cr_2O_3
(c) CrO_4^{2-}, $Cr_2O_7^{2-}$
(d) H_2CrO_4, CrO_4^{2-}

35. Which statement is not correct?

(a) Potassium dichromate oxidises a secondary alcohol into a ketone
(b) Potassium permanganate is a weaker oxidising substance than potassium dichromate
(c) Potassium permanganate is a stronger oxidising substance
(d) All of the above statements are correct

Inner-Transition Elements

36. Lanthanum is grouped with f-block elements because

(a) it has partially filled f-orbitals
(b) it has both partially filled f and d-orbitals
(c) the properties of lanthanum are very similar to the elements of 4*f*-block
(d) it is just before Ce in the Periodic Table

37. Cerium ($Z = 58$) is an important member of the lanthanides. Which of the following statements about cerium is incorrect?

(a) The common oxidation states of cerium are +3 and +4
(b) Cerium (IV) acts as an oxidising agent
(c) The +4 oxidation state of cerium is not known in solutions
(d) The +3 oxidation state of cerium is more stable than the +4 oxidation state

38. Which one of the following acts as an oxidising agent?

(a) Np^{4+}
(b) Sm^{2+}
(c) Eu^{2+}
(d) Yb^{2+}

39. Gadolinium belongs to $4f$ series. atomic number is 64. Which of the following is the correct electronic configuration of gadolinium? **[NCERT** Exemplar**]**

(a) $[Xe]4f^7 5d^1 6s^2$
(b) $[Xe]4f^6 5d^2 6s^2$
(c) $[Xe]4f^8 6d^2$
(d) $[Xe]4f^9 5s^1$

40. Which of the following oxidation state is common for all lanthanoids? **[NCERT** Exemplar**]**

(a) +2
(b) +3
(c) +4
(d) +5

41. There are 14 elements in actionoid series. Which of the following elements does not belong to this series? **[NCERT** Exemplar**]**

(a) U
(b) Np
(c) Tm
(d) Fm

42. Lanthanide for which +2 and +3 oxidation states are common is

(a) La
(b) Nd
(c) Ce
(d) Eu

43. Which pair of lanthanides is used in glass, blowers, goggles?

(a) Np, Pu
(b) Pu, Gd
(c) Fm, Ho
(d) Pr, Ho

44. Which of the following trivalent ion has the largest atomic radii in the lanthanide series?

(a) Ce
(b) Pm
(c) La
(d) Lu

45. Across the lanthanide series, the basicity of lanthanide hydroxides

(a) increases
(b) decreases
(c) first increases and then decreases
(d) first decreases and then increases

46. The +3 ion of which one of the following has half-filled $4f$ subshell?

(a) La
(b) Lu
(c) Gd
(d) Ce

47. Actinides

(a) have variable valency
(b) include 12 elements
(c) are all synthetic elements
(d) have only short lived isotopes

48. Actinides and lanthanides resemble in

(a) formation of complexes
(b) oxidation state
(c) ionisation energy
(d) electronic configuration

49. Lanthanide contraction occurs because

(a) *f*-orbitals are incompletely filled
(b) *f*-orbital electrons are easily lost
(c) *f*-orbital do not come out on the surface of atom and are buried inside
(d) *f*-orbital electrons are poor shielders of nuclear charge

50. Which of the following ion is diamagnetic?
(a) Nd^{3+} (b) La^{3+} (c) Tb^{3+} (d) Er^{3+}

51. The colour of $_{62}Sm^{3+}$ is yellow. The expected colour of $_{66}Dy^{3+}$ is
(a) yellow (b) red
(c) blue (d) green

52. The actinoids showing +7 oxidation state are
(a) U, Np (b) Pu, Am
(c) Np, Pu (d) Am, Cm

53. The lanthanoids contraction relates to
(a) atomic radii
(b) atomic as well as M^{3+} radii
(c) valence electrons
(d) oxidation states

54. In aqueous solution Eu^{2+} ion acts as
(a) an oxidising agent (b) a reducing agent
(c) an acid (d) All of these

55. A reduction in atomic size with increase in atomic number is a characteristic of elements of
(a) *f*-block (b) *d*-block
(c) high atomic masses (d) radioactive series

56. Which of the following statement is not correct?
(a) $La(OH)_3$ is less basic than $Lu(OH)_3$
(b) In lanthanide series ionic radius of Ln^{3+} ions decreases
(c) Zn, Cd, Hg are colourless and are diamagnetic
(d) Mn shows maximum oxidation state +7

57. Misch metal is
(a) an alloy of lanthanoid and copper
(b) an alloy of lanthanoid and nickel
(c) an alloy of lanthanoid, iron and carbon
(d) an alloy of actinoid and copper

58. Uranium reacts with conc. HNO_3
(a) to give $U(NO_3)_4$ and H_2
(b) to give $U(NO_3)_2$ and NO_2
(c) $UO_2(NO_3)_2$ and H_2
(d) to make metal passive

59. Select the correct statements.
(a) Pu^{4+} disproportionates to Pu^{3+} and PuO_2^{2+} in strongly acidic medium
(b) Maximum oxidation state of Np is +7
(c) UO_2^{2+} is stable
(d) All of the above are correct statements

60. Which one of the following elements shows maximum number of different oxidation states in its compounds?
(a) Eu
(b) La
(c) Gd
(d) Am

Round II (Mixed Bag)

Only One Correct Option

1. Transition metal with low oxidation number will act as
(a) an oxidising agent (b) a base
(c) an acid (d) None of these

2. Which of the following pair will have effective magnetic moment equal?
(a) Ti^{2+} and V^{2+} (b) Cr^{2+} and Fe^{2+}
(c) Cr^{3+} and Mn^{2+} (d) V^{2+} and Sc^{3+}

3. Consider the following statements.
(I) $La(OH)_3$ is the least basic among hydroxides of lanthanides.
(II) Zr^{4+} and Hf^{4+} possess almost the same ionic radii.
(III) Ce^{4+} can act as an oxidizing agent.

Which of the above is/are true?
(a) I and III (b) II and III
(c) II only (d) I and II
(e) I only

4. Most basic hydroxide among the following is
(a) $Lu(OH)_3$ (b) $Eu(OH)_3$
(c) $Yb(OH)_3$ (d) $Ce(OH)_3$

5. Arrange Ce^{3+}, La^{3+}, Pm^{3+} and Yb^{3+} in increasing order of their ionic radii.
(a) $Yb^{3+} < Pm^{3+} < Ce^{3+} < La^{3+}$
(b) $Ce^{3+} < Yb^{3+} < Pm^{3+} < La^{3+}$
(c) $Yb^{3+} < Pm^{3+} < La^{3+} < Ce^{3+}$
(d) $Pm^{3+} < La^{3+} < Ce^{3+} < Yb^{3+}$

6. The basic character of the transition metal monoxide follows the order
(At. no. of Ti = 22, V = 23, Cr = 24, Fe = 26)
(a) TiO > VO > CrO > FeO (b) VO > CrO > TiO > FeO
(c) CrO > VO > FeO > TiO (d) TiO > FeO > VO > CrO

7. When MnO_2 is fused with KOH, a coloured compound is formed. The product and its colour is
(a) K_2MnO_4, purple colour (b) Mn_2O_3, brown
(c) Mn_2O_4, black (d) $KMnO_4$, purple

8. Which of the following weighs less when weighted in magnetic field?

(a) $ScCl_3$
(b) $FeCl_3$
(c) $TiCl_3$
(d) VCl_3

9. An element is in M^{3+} form. Its electronic configuration is $[Ar]3d^1$, the ion is

(a) Ca^{2+} (b) Sc^+ (c) Ti^{4+} (d) Ti^{3+}

10. Transuranic elements begins with

(a) Np (b) Cm (c) Pu (d) U

11. Which among the following metals does not dissolve in aqua regia?

(a) Pt (b) Pd (c) Au (d) Ir

12. If M is element of actinoids series, the degree of complex formation decreases in the order

(a) $M^{4+} > M^{3+} > MO_2^{2+} > MO_2^+$
(b) $MO_2^+ > MO_2^{2+} > M^{3+} > M^{4+}$
(c) $M^{4+} > MO_2^{2+} > M^{3+} > MO_2^+$
(d) $MO_2^{2+} > MO_2^+ > M^{4+} > M^{3+}$

13. The electronic configuration of actinoids cannot be assigned with degree of certainty because of

(a) overlapping of inner orbitals
(b) free movement of electrons over all the orbitals
(c) small energy difference between $5f$ and $6d$ levels
(d) None of the above

14. Which lanthanoid compound is used as a most powerful liquid lasers after dissolving it in selenium oxychloride?

(a) Cerium oxide
(b) Neodymium oxide
(c) Promethium sulphate
(d) Ceric sulphate

More than One Correct Option

15. Generally transition elements and their salts are coloured due to the presence of unpaired electrons in metal ions. Which of the following compounds are coloured? **[NCERT Exemplar]**

(a) $KMnO_4$
(b) $Ce(SO_4)_2$
(c) $TiCl_4$
(d) Cu_2Cl_2

16. Which of the following will not act as oxidising agents? **[NCERT Exemplar]**

(a) CrO_3 (b) MoO_3 (c) WO_3 (d) CrO_4^{2-}

17. Although +3 is the characteristic oxidation state for lanthanoids but cerium also shows +4 oxidation state because **[NCERT Exemplar]**

(a) it has variable ionisation enthalpy
(b) it has a tendency to attain noble gas configuration
(c) it has a tendency to attain f^0 configuration
(d) it resembles Pb^{4+}

18. Transition elements show magnetic moment due to spin and orbital motion of electrons. Which of the following metallic ions have almost same spin only magnetic moment? **[NCERT Exemplar]**

(a) Co^{2+}
(b) Cr^{2+}
(c) Mn^{2+}
(d) Cr^{3+}

19. In the form of dichromate, Cr (VI) is a strong oxidising agent in acidic medium but Mo (VI) in MoO_3 and W (VI) in WO_3 are not because **[NCERT Exemplar]**

(a) Cr (VI) is more stable than Mo(VI) and W(VI).
(b) Mo(VI) and W(VI) are more stable than Cr(VI).
(c) Higher oxidation states of heavier members of group-6 of transition series are more stable.
(d) Lower oxidation states of heavier members of group-6 of transition series are more stable.

Assertion and Reason

Directions (Q. Nos. 20 to 24) *Each of these questions contains two statements : Statement* I *(Assertion) and Statement* II *(Reason). Each of these questions also has four alternative choices, only one of which is the correct answer. You have to select one of the codes* (*a*), (*b*) (*c*), (*d*) *given below :*

(a) Statement I is true; Statement II is true; Statement II is a correct explanation for Statement I.
(b) Statement I is true; Statement II is true; Statement II is not a correct explanation for Statement I.
(c) Statement I is true; Statement II is false.
(d) Statement I is false; Statement II is true.

20. **Statement I** Cu^{2+} iodide is not known.

Statement II Cu^{2+} oxidises I^- to iodine. **[NCERT Exemplar]**

21. **Statement I** Separation of Zr and Hf is difficult.

Statement II Zr and Hf lie in the same group of the Periodic Table. **[NCERT Exemplar]**

22. **Statement I** Actinoids form relatively less stable complexes as compared to lanthanoids.

Statement II Actinoids can utilise their $5f$ orbitals along with $6d$ orbitals in bonding but lanthanoids do not use their $4f$ orbital for bonding. **[NCERT Exemplar]**

23. **Statement I** Cu cannot liberate hydrogen from acids.

Statement II It has positive electrode potential. **[NCERT Exemplar]**

24. **Statement I** The highest oxidation state of osmium is +8.

Statement II Osmium is a $5d$-block element. **[NCERT Exemplar]**

Comprehension Type Questions

Directions (Q. Nos. 25 to 27) A characteristic property of the *d*-transition metals is the ability to exhibit several oxidation states. The stability of a given oxidation state depends on the nature of the element with which the transition metal is combined. The highest oxidation states are found in the compounds of fluorides and oxides because of the most electronegative nature of F and O (oxygen).

25. Nickel also shows zero (0) oxidation state. This oxidation state is in

(a) nitriles
(b) carbonyls
(c) cyclopentadienyl
(d) All of these

26. In which case there is a change in oxidation number?

(a) Aqueous solution of CrO_4^{2-} is acidified
(b) SO_2 gas is passed into $Cr_2O_7^{2-}/H^+$
(c) $Cr_2O_7^{2-}$ solution is made alkaline
(d) CrO_2Cl_2 is dissolved in NaOH

27. Most transition metals are inert towards acids or react slowly with them because of

(a) negative standard reduction potential
(b) protective layer of oxide
(c) Both (a) and (b)
(d) None of the above

Directions (Q. Nos. 28 to 29) Many ionic and covalent compounds of transition elements and also inner-transition elements are coloured. Colour may arise from an entirely different cause in ions with incomplete *d*-or *f* shells. In a free isolated gaseous ion, the five-*d*-orbitals are degenerate, that is they are identical in energy. The surrounding groups, which can be solvent molecules in solution or ligands in a complex or other ions in a crystal lattice, affect the energy of some *d*-orbitals more than others.

28. Consider the following statements

I. Colour of a transition metal complex is dependent on energy difference between two *d*-levels.
II. Colour of the complex is dependent on the nature of the ligand and the type of complex formed.
III. $ZnSO_4$ and TiO_2 are white as in both *d*-*d* spectra are impossible.

Select the correct statements.

(a) I, II, III
(b) I, II
(c) II, III
(d) I, III

29. MnO_4^- is of intense pink colour, though Mn is in (+7) oxidation state. It is due to

(a) oxygen gives colour to it
(b) charge transfer when oxygen gives its electron to Mn making it Mn (+ VI) hence, coloured
(c) charge transfer when Mn gives its electron to oxygen
(d) None of the above is correct

Previous Years' Questions

30. Iron exhibits +2 and +3 oxidation states. Which of the following statements about iron is incorrect? [AIEEE 2012]

(a) Ferrous oxide is more basic in nature than the ferric oxide
(b) Ferrous compounds are relatively more ionic than the corresponding ferric compounds
(c) Ferrous compounds are less volatile than the corresponding ferric compounds
(d) Ferrous compounds are more easily hydrolysed than the corresponding ferric compounds

31. In the context of lanthanoids, which of the following statements is not correct? [AIEEE 2011]

(a) There is a gradual decrease in the radii of the members with increasing atomic number in the series
(b) All the members exhibit +3 oxidation state
(c) Because of similar properties the separation of lanthanoids is not easy
(d) Availability of 4*f*-electrons results in the formation of compounds in +4 state for all members of the series

32. Larger number of oxidation states are exhibited by the actinoides than those by the lanthanoides, the main reason being [AIEEE 2008]

(a) 4*f* orbitals are more diffused than the 5*f* orbitals
(b) lesser energy difference between 5*f* and 6*d* than between 4*f* and 5*d* orbitals
(c) more energy difference between 5*f* and 6*d* than between 4*f* and 5*d* orbitals
(d) more reactive nature of the actinoids than the lanthanoids

33. Identify the incorrect statement among the following. [AIEEE 2007]

(a) *d*-block elements show irregular and erratic chemical properties among themselves
(b) La and Lu have partially filled *d* orbitals and no other partially filled orbitals
(c) The chemistry of various lanthanoids is very similar
(d) 4*f* and 5*f* orbitals are equally shielded

34. The actinoids exhibit more number of oxidation states in general than the lanthanoids. This is because [AIEEE 2007]

(a) the 5*f* orbitals are more buried than the 4*f* orbitals
(b) there is a similarity between 4*f* and 5*f* orbitals in their angular part of the wave function
(c) the actinoids are more reactive than the lanthanoids
(d) the 5*f* orbitals extend farther from the nucleus than the 4*f* orbitals

35. The 'spin-only' magnetic moment [in units of Bohr magneton, (μ_β)], of Ni^{2+} in aqueous solution would be (Atomic number of Ni = 28) [AIEEE 2006]

(a) 2.84 (b) 4.90 (c) 0 (d) 1.73

36. Lanthanoid contraction is caused due to [AIEEE 2006]

(a) the appreciable shielding on outer electrons by 4*f* electrons from the nuclear charge
(b) the appreciable shielding on outer electrons by 5*d* electrons from the nuclear charge
(c) the same effective nuclear charge from Ce to Lu
(d) the imperfect shielding on outer electrons by 4*f* electrons from the nuclear charge

37. Which of the following factors may be regarded as the main cause of lanthanide contraction? [AIEEE 2005]

(a) Greater shielding of 5*d* electron by 4*f* electrons
(b) Poor shielding of 5*d* electron by 4*f* electrons
(c) Effective shielding of one of 4*f* electrons by another in the sub shell
(d) Poor shielding of one of 4*f* electron by another in the sub-shell

38. The lanthanide contraction is responsible for the fact that [AIEEE 2003, 05]

(a) Zr and Zn have the same oxidation state
(b) Zr and Hf have about the same radius
(c) Zr and Nb have similar oxidation state
(d) Zr and Y have about the same radius

39. The oxidation state of chromium in the final product formed by the reaction between KI and acidified potassium dichromate solution is [AIEEE 2005]

(a) +3
(b) +2
(c) +6
(d) +4

the Guidance

Round I

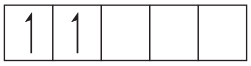
1. V_2O_5 and Cr_2O_3 are amphoteric because both react with alkalies as well as acids. (In lower oxides, the basic character is predominant while in higher oxides, the acidic character is predominant).

2. Copper does not liberate hydrogen from acids because it has positive $E°$.

3. $Cu^+ = [Ar]3d^{10}$

No unpaired electron, thus $s = 0$. Paramagnetism of ion is also zero.

4. $Ti(22) = [Ar]4s^2 3d^2$



$Ti^{2+} = [Ar]3d^2$

$Ti^{4+} = [Ar]3d^0$

Ti^{2+} has two unpaired electrons in $3d$ and thus d-d transition is possible due to absorption of light in visible region.

5. Magnetic moment, $\mu = \sqrt{N(N+2)}$ BM

where, N = unpaired electrons

$Cr(24) = [Ar]3d^5, 4s^1$; $N = 6, \mu = \sqrt{48}$ BM $= x$

$Mn^+ = [Ar]3d^5\ 4s^1$; $N = 6, \mu = \sqrt{48}$ BM $= y$

$Fe^{2+} = [Ar]3d^6$; $N = 4, \mu = \sqrt{24}$ BM $= z$

Thus, $z < x = y$

6. $VO_2 + 2H^+ \longrightarrow VO^{2+} + H_2O$

7. $Cu^+ = [Ar]3d^{10}; Fe^+ = [Ar]3d^5$

9. Variable valency is due to the participation of electron from $(n-1)d$ and ns levels in bond formation.

10. Transition elements are more metallic than representative elements due to the availability of d-orbitals for bonding.

12. Coinage metals (Cu, Ag, Au) shows the properties of transition elements as in their common oxidation states they possess partially filled d-subshells.

14. ${}_{30}Zn \longrightarrow [Ar]\ 3d^{10}4s^2$

$\because$ Its d-orbital is complete.

$\therefore$ It does not show variable valency.

15. The ability of transition elements to adopt multiple oxidation states and complexing ascribed their catalytic activity.

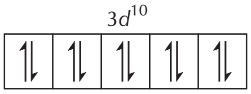
17. $Fe^{2+} = [Ar]\ 3d^6 4s^0 \Rightarrow$ 4 unpaired electrons

$Cu^+ = [Ar]\ 3d^{10}4s^0 \Rightarrow$ 0 unpaired electron

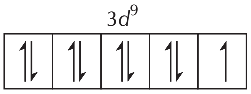
$Zn = [Ar]\ 3d^{10}4s^2 \Rightarrow$ 0 unpaired electron

$Ni^{3+} = [Ar]\ 3d^7 4s^0 \Rightarrow$ 3 unpaired electrons

18. Cuprous ion (Cu^+) $3d^{10}$ (completely filled d-subshell)



Cupric ion (Cu^{2+}) $3d^9$ (one unpaired electron)



19. Ni^{2+} and Cr^{3+} are coloured due to the presence of unpaired electrons. But Zn^{2+} is colourless because of the absence of unpaired electrons.

21. Strength of metallic bond depends upon number of unpaired electrons. As number of unpaired electrons increases, the bond strength increases. So, Cr, Mo, W show stronger bonding due to maximum number of unpaired electrons.

22. $Ti^{3+} \longrightarrow 3d^1, 4s^0$

$Sc^{3+} \longrightarrow 3d^0$

$Mn^{2+} \longrightarrow 3d^5, 4s^0$

$Zn^{2+} \longrightarrow 3d^{10}, 4s^0$

In Mn^{2+} number of unpaired electrons = 5. So, it has maximum magnetic moment according to the formula

$$\mu = \sqrt{n(n+2)}\ \text{BM}$$

23. The atomic weight of, Co, Ni and Fe are 59.90, 58.60, 55.85 respectively. Therefore, Co > Ni > Fe is the correct sequence of atomic weights.

24. Among the given, manganese has the most stable electronic configuration, thus it is very hard to remove an electron from its outer shell. Hence, a large amount of energy is required. Therefore, manganese has the maximum first ionisation potential.

25. MnO_2 forms amphoteric oxide due to intermediate oxidation state.

28. Potassium dichromate on heating gives oxygen and chromic oxide (Cr_2O_3).

$$4K_2Cr_2O_7 \xrightarrow{\Delta} 4K_2CrO_4 + 3O_2 + 2Cr_2O_3$$

29. $K_2Cr_2O_7 + 2H_2SO_4 \xrightarrow{\text{Cold}} 2CrO_3 + 2KHSO_4 + H_2O$

CrO_3 is highly acidic and oxidising and is called chromic acid.

30. $4NaCl + 3H_2SO_4 + K_2Cr_2O_7 \longrightarrow \underset{\text{chromyl chloride}}{2CrO_2Cl_2} + K_2SO_4 + 2Na_2SO_4 + 3H_2O$

31. Because hydrochloric acid is oxidised to chlorine.

32. $Cr_2O_7^{2-} + 2OH^- \longrightarrow 2CrO_4^{2-} + H_2O$ pH > 7(x > 7)

$2CrO_4^{2-} + 2H^+ \longrightarrow Cr_2O_7^{2-} + H_2O$ pH < 7 (y < 7)

33. $MnO_4^- + e^- \longrightarrow MnO_4^{2-}$

34. $CrO_3 + H_2O \longrightarrow \underset{(A)}{H_2CrO_4} \xrightarrow{OH^-} \underset{(B)}{CrO_4^{2-}}$

35. In acidic medium, $KMnO_4$ gives 5 oxygen while, acidic $K_2Cr_2O_7$ gives 3 oxygen.

38. All those inner-transition elements having +2 oxidation state, changes to +3, and act as reducing agents. While those having +4 oxidation state tend to change to +3 oxidation state and act as oxidising agents. Therefore, Np^{4+} acts as an oxidising agent.

39. Gadolinium, $Gd = 4f^7\,5d^1\,6s^2$

41. Tm (thulium) does not belong to actinoids.

45. Basicity of lanthanide hydroxides decreases along the lanthanides series from left to right.

46. $Gd = [Xe]\,4f^7 5d^1 6s^2$,

$Gd^{3+} = [Xe]\,4f^7$ (half-filled)

47. Actinides have variable valency due to very small difference in energies of $5f$, $6d$ and $7s$ orbitals.

49. The size of lanthanides are smaller than expected. This is associated with the filling up of 4*f* orbitals which must be filled before the 5*d* orbitals. The electrons in *f*-orbitals are not effective in screening other electrons from the nuclear charge.

50. Paramagnetism is shown by the positive ions of lanthanides except $La^{3+}(4f^0)$ and $Lu^{3+}(4f^{14})$. These ions are diamagnetic.

51. The electronic configuration of ${}_{62}Sm^{3+}$ is $4f^4$ and that of ${}_{66}Dy^{3+}$ is $4f^9$. The colour of f^n and f^{14-n} are often identical.

52. Np and Pu in NpO_3^+ and PuO_3^+ oxocations show +7 oxidation state which are not so stable.

53. Lanthanide contraction relates to decrease in atomic as well as ionic size of M^{3+} ions.

55. A reduction in atomic size with increase in atomic number is a characteristics of elements of *f*-block. This is due to lanthanide contraction.

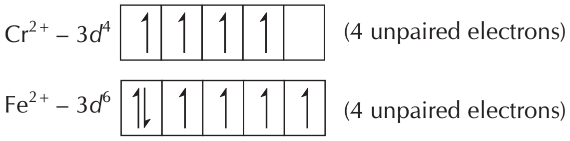
56. $La(OH)_3$ is more basic than $Lu(OH)_3$. This is because ionic size of La^{3+} ion is more than Lu^{3+} ion.

60. Oxidation states of Americium are +3, +4, +5 and +6.

Round II

1. Transition metal which have low oxidation number acts as reducing agent because of greater tendency to lose the electron. Moreover, they behave like a base.

2. Cr^{2+} and Fe^{2+}



$Cr^{2+} - 3d^4$ (4 unpaired electrons)

$Fe^{2+} - 3d^6$ (4 unpaired electrons)

3. (a) The basic character of hydroxides decreases from $La(OH)_3$ to $Lu(OH)_3$. Due to smaller size of Lu, The Lu—OH bond attains more covalent character. $La(OH)_3$ is the most basic among hydroxides of lanthanoids. Statement II and III are true.

4. Due to lanthanide contraction, the size of M^{3+} ions [*i.e.*, Lu^{3+}, Eu^{3+}, Yb^{3+} and Ce^{3+}] decreases and thus, the basic strength of their hydroxides decreases.

The order of size of given M^{3+} ions is

$$Ce^{3+} > Eu^{3+} > Yb^{3+} > Lu^{3+}$$

∴ The order of basic strength of hydroxides is

$$\underset{\text{(most basic)}}{Ce(OH)_3} > Eu(OH)_3 > Yb(OH)_3 > Lu(OH)_3$$

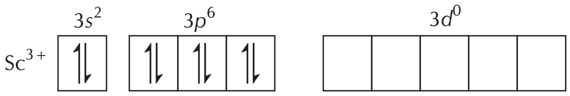
5. Due to lanthanoid contraction order will be

$$Yb^{3+} < Pm^{3+} < Ce^{3+} < La^{3+}$$

6. Basic character of oxides decreases from left to right in a period of Periodic Table.

7. $2MnO_2 + 4KOH + O_2 \longrightarrow \underset{\text{purple green}}{2K_2MnO_4} + 2H_2O$

8. $ScCl_3 \longrightarrow Sc^{3+} + 3Cl^-$



No unpaired electron, so will show diamagnetic character so, will weigh less in magnetic field.

9. $[Ar]\,3s^1$, + 3 = Ti, it means M^{3+} from Ti^{3+} ion.

10. Transuranic elements start after uranium and begin with Np (Neptunium).

11. Ir does not dissolve in aqua-regia as it is much more noble than Au and Pt.

12. The higher the charge on the metal ion, smaller is the ionic size and more is the complex forming ability. Thus, the degree of complex formation decreases in the order

$$M^{4+} > MO_2^{2+} > M^{3+} > MO_2^+$$

The higher tendency of complex formation of MO_2^{2+} as compared to M^{3+} is due to high concentration of charge on metal atom *M* in MO_2^{2+}.

13. There is very small difference in energies of $5f$, $6d$ and $7s$ orbitals of actinoids, therefore their electronic configuration cannot assigned with a degree of certainty.

14. Neodymium oxide (Nd_2O_3) dissolved in selenium oxychloride is one of the most powerful liquid lasers known so far.

15. $KMnO_4$ and $Ce(SO_4)_2$ are coloured due to charge transfer spectra.

16. In group 6, Mo (VI) and W (VI) are found to be more stable than Cr (VI). (Higher oxidation state is more stable in heavier members, the opposite is true in *p*-block.) Thus, Cr (VI) in the form of dichromate in acidic medium is a strong oxidising agent, whereas MoO_3 and WO_3 are not.

17. $Ce = [Xe]\,4f^1\,5d^1\,6s^2$

$Ce^{4+} = [Xe]\,4f^0$

Ce also shows + 4 oxidation state because it has the tendency to attain noble gas configuration and $4f^0$ configuration.

18. $Co^{2+} = 3d^7$, $Cr^{2+} = 3d^4$, $Mn^{2+} = 3d^5$ and $Cr^{3+} = 3d^3$

Co^{2+} and Cr^{3+} have same number of unpaired electrons *i.e.*, 3 therefore these ions have almost same spin only magnetic moment.

29. In the form of dichromate, Cr (VI) is a strong oxidising agent in acidic medium but Mo (VI) in MoO_3 and W (VI) in WO_3 are not because Mo (VI) and W (VI) are more stable than Cr (VI). Further more, in heavier members of group-6 higher oxidation states are more stable.

20. Cu^{2+} iodide is not known because Cu^{2+} oxidises I^- to iodine.

$$2Cu^{2+} + 4I^- \longrightarrow Cu_2I_2 + I_2$$

21. Separation of Zr and Hf is difficult because both have very similar physical and chemical properties. Both the elements have almost similar atomic radii (Zr = 160 pm) and (Hf = 159 pm) due to lanthanoid contraction.

22. Actinoids possess greater tendency for complexion and form more stable complexes as compared to lanthanoids.

23. Statement II is the correct explanation for statement I.

24. Higher oxidation state in heavier members among the groups of *d*-block elements are found to be more stable. Hence, highest oxidation state shown by Os is + 8.

25. Nickel shows zero oxidation state in carbonyls.

26. (a) $2\overset{+6}{Cr}O_4^{2-} + 2H^+ \longrightarrow \overset{+6}{Cr_2}O_7^{2-} + H_2O$

(No change in oxidation state of Cr.)

(b) $\overset{+6}{Cr_2}O_7^{2-} + 2H^+ + 3SO_2 \longrightarrow 2Cr^{3+} + H_2O + 3SO_4^{2-}$

(Oxidation state of Cr changes from + 6 to + 3 in this reaction.)

(c) $\overset{+6}{Cr_2}O_7^{2-} + 2OH^- \longrightarrow 2\overset{+6}{Cr}O_4^{2-} + H_2O$

(No change in oxidation state of Cr)

(d) $\overset{+6}{Cr}O_2Cl_2 + 2NaOH \longrightarrow Na_2\overset{+6}{Cr}O_4 + 2HCl$

(No change in oxidation state of Cr)

27. Most transition metals are inert towards acids or react slowly with them because of a protective layer of oxide.

28. The colour of a transition metal complex is dependent on how big the energy difference in between the two *d*-levels. This in turn depends on the nature of the ligands and the type of the complex formed. The colour which we see is the colour of the transmitted wavelength.

$ZnSO_4$ and TiO_2 are white. $Zn^{2+} = 3d^{10}$, $Ti^{4+} = 3d^0$.

d-d spectra are impossible in those ions which have d^0 or d^{10} configuration.

29. The colour arise by charge transfer. In MnO_4^-, an electron is momentarily transferred from oxygen to the metal and thus oxygen changes from O^{2-} to O^- and Mn from (+ 7) to (+ 6).

30. (a) $FeO > Fe_2O_3$ (basic) thus, true.

(b) $FeCl_2 > FeCl_3$ (ionic), larger the charge, greater the polarizing power and thus greater the covalent nature. Thus, true.

(c) Fe^{2+} salts are more ionic thus less volatile than Fe^{3+} salts. Thus, true.

(d) Greater the covalent nature, more easily they are hydrolyzed. Thus, $FeCl_3$ is more hydrolyzed than $FeCl_2$. Thus, statement (d) is incorrect.

31. Formation of + 4 state requires very high energy, thus incorrect.

32. Lanthanoides : $[Xe]4f^{1-14}5d^{0-1}6s^2$

Actinoides : $[Rn]\,5f^{1-14}6d^{0-1}7s^2$

Lathanoides and actinoides use core *d* and *f* orbitals also to show higher oxidation state. As actinoides have comparatively low energy difference between *f* and *d* orbitals, they show more oxidation states.

33. $4f$ and $5f$ belong to different shell, thus experience different amount of shielding.

34. The actinoid ($5f$-elements) exhibit more number of oxidation states in general than the lanthanoid because $5f$-orbitals extend farther from the nucleus than the $4f$-orbitals.

35. $Ni^{2+} = [Ar]\,3d^8$

Number of unpaired electrons = 2

Hence, magnetic moment = $\sqrt{n(n+2)} = \sqrt{8} = 2.84$

36. Lanthanoid contraction is due to ineffective shielding produced by larger *f*-subshell.

37. Lanthanide contraction is due to poor shielding of one of $4f$ electron by another in the sub-shell.

38. Lanthanide contraction, cancels almost exactly the normal size increase on descending a group of transition elements, thus Nb and Ta and, Zr and Hf have same covalent and ionic radii.

39. $Cr_2O_7^{2-} + 14H^+ + 6I^- \longrightarrow 2Cr^{3+} + 7H_2O + 3I_2$

$Cr_2O_7^{2-}$ is reduced to Cr^{3+}.

Thus, final state of Cr is + 3.

9 Coordination Compounds

JEE Main MILESTONE

- Molecular or Addition Compounds
- Terminology Used in Coordination Compounds
- Werner's Theory
- IUPAC Nomenclature of Mononuclear Coordination Compounds
- Isomerism
- Bonding in Coordination Compounds
- Stability of Complexes
- Importance of Coordination Compounds

9.1 Molecular or Addition Compounds

When solutions containing two or more stable salts in simple molecular (stoichiometric) proportions, are evaporated, crystals of new compounds may separate out. These new compounds are called **molecular** or **addition compounds.**

e.g., $K_2SO_4 + Al_2(SO_4)_3 + 24H_2O \longrightarrow \underset{\text{potash alum crystals}}{K_2SO_4Al_2(SO_4)_3 \cdot 24H_2O}$

$$AgCN + KCN \longrightarrow \underset{\text{potassium argentocyanide}}{K[Ag(CN)_2]}$$

$$Fe(CN)_2 + 4KCN \longrightarrow \underset{\text{potassium ferrocyanide}}{K_4[Fe(CN)_6]}$$

The addition compounds can be divided into two classes

(a) Those which Loose their Identity in Solution *i.e.,* Double Salts

In aqueous solution these addition compounds break down into simpler ions, thus, exhibit the properties of their constituent ions. *e.g.*, an aqueous solution of carnallite $KCl \cdot MgCl_2 \cdot 6H_2O$ shows the properties of K^+, Mg^{2+} and Cl^- simpler ions. Such addition compounds, which loose their identity in solution, are called **'double salts.'** They only exist in the crystalline state. Some other examples of double salts are potash alum $K_2SO_4 \cdot Al_2(SO_4)_3 \cdot 24H_2O$ and Mohr salt $FeSO_4 \cdot (NH_4)_2SO_4 \cdot 6H_2O$

Coordination compounds are those compounds in which a central metal atom or ion is attached with a fixed number of groups or molecules (ligands) through coordinate bonds. In other words, these compounds contain complex ions. These are generally formed by transition elements because of their small radii.

(b) Those which Retain their Identity in Solution *i.e.,* Complex Compounds

In aqueous solution, these addition compounds do not furnish all simple ions but instead give more complex ions having complicated structure *e.g.,* potassium ferrocyanide does not give properties of simple

K^+, Fe^{2+} and CN^- ions but gives the properties of K^+ ions and complex ferrocyanide ions, $[Fe(CN)_6]^{4-}$. In other words, in these compounds, the **complex ions** retains their identity in the solution. Other example of coordination compounds are $[Co(NH_3)_6]Cl_3$, $K_2[PtCl_6]$, etc.

Actually complexes or coordination compounds are the result of acceptance of lone pair of electrons of ligands by the empty orbitals of the metal atom or ion.

9.2 Terminology Used in Coordination Compounds

The important terms used to define a complex completely are as follows

1. Complex Ions

A complex ion may be defined as an electrically charged radical which is formed by the combination of a simple cation with one or more neutral molecules or one or more simple anions or in some cases positive groups also. It exists as a single entity and is usually indicated within square bracket, *i.e.,* [ ]

e.g., $[Cu(NH_3)_4]^{2+}$ is a complex ion, which is formed by the combination of four neutral molecules of ammonia with a simple Cu^{2+} cation. Similarly, $[Fe(CN)_6]^{4-}$ is a complex ion formed by the combination of six CN^- anions with a simple Fe^{2+} cation. In nitroprusside ion, $[Fe(CN)_5NO]^{2+}$, five CN^- ions and one NO^+ (a positively charged ligand) ion are coordinated to Fe^{2+} ion.

The complex ion carrying a positive charge *e.g.,*, $[Cu(NH_3)_4]^{2+}$, is called **cationic complex,** the one with a negative charge *e.g.,* $[Fe(CN)_6]^{4-}$ is called **anionic complex** and the one with no charge *e.g.,* $[PtCl_2(NH_3)_2]$ is called a **neutral complex.**

Complex ions do not give tests of their constituent ions. *e.g.,* $[Cu(NH_3)_4]^{2+}$ does not give test of Cu^{2+} or NH_3.

Homoleptic complex have only one type of ligands linked to the central metal atom/ion. *e.g.,* $[Co(NH_3)_6]^{3+}$ whereas **heteroleptic complex** have more than one type of ligands linked to the central metal atom/ion. *e.g.,* $[Co(NH_3)_4Cl_2]$

Sample **Problem 1** *Which of the following complexes are homoleptic?* **[NCERT Exemplar]**

(*a*) $[Co(NH_3)_6]^{3+}$
(*b*) $[Co(NH_3)_4Cl_2]^+$
(*c*) $[Ni(CN)_4]^{2-}$
(*d*) $[Ni(NH_3)_4Cl_2]$

Interpret (*a,c*) Homoleptic complexes have ligands of only one kind. e.g., $[Co(NH_3)_6]^{3+}$, $[Ni(CN)_4]^{2-}$

2. Central Metal Atom or Ion

Every complex ion contains a metal atom or ion to which one or more neutral molecules or ions are attached. This is known as the **central metal atom** or **ion.** It is sometimes known as the **nuclear atom.** In a complex, the central metal atom or ion behaves as the **electron pair acceptor** or **Lewis acid.**

3. Ligands

The central metal ion is surrounded by a number of the anions or the neutral molecules or sometimes positively charged ions possessing at least one lone pair. These surrounded ions are called **ligands.** The ligands are attached to the central metal ion or atom through coordinate bonds or dative linkage. In the formation of coordination complexes, the ligands act as the **electron-pair donors** or **Lewis bases.**

e.g., in the complex ions $[Cu(NH_3)_4]^{2+}$ and $[Fe(CN)_6]^{4-}$, NH_3 and CN^- are the ligands. Ligands invariably contain one or more atoms (called **donor atoms**) having lone pairs of electrons.

The number of donor groups, from a given ligand, attached to the same central atom, is called the **denticity of the ligand.** Ligands like NH_3, CH_3NH_2, PH_3 can form only one coordinate bond with the central metal ion. So, their denticity is one. $H_2N—CH_2—CH_2—NH_2$, $NH_2CH_2COO^-$ have two donor atoms in each molecule or ion and each can form two coordinate bonds with the central metal ion and hence, their denticity is two.

Depending upon the number of donor atoms (or sites), the ligands may be classified into various categories as follows

(a) Unidentate or Monodentate Ligands

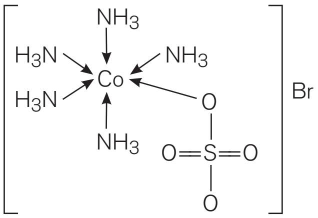
These ligands contain only one donor atom (or site) which is capable of donating an electron pair and thus, attach to the central metal ion only at one point *e.g.,* CN^-, F^-, Cl^-, Br^-, OH^-, H_2O, NH_3, NO_2^-, C_2H_5N (pyridine) etc.

(b) Polydentate or Multidentate Ligands

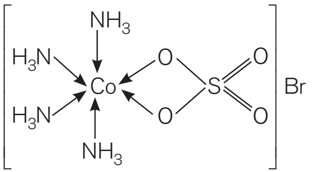
Ligands which contain two or more such atoms which can simultaneously serve as donor atoms are called **polydentate or multidentate ligands.** Such ligands attach to the central metal ion at more than one point. Polydentate ligands with two donor sites are called bidentate, and with three, four, five and six donor sites are called tri (or ter), tetra (or quadri), penta and hexa-(or sexi) dentate ligands respectively.

Certain polydentate ligands have flexi dentate character, *i.e.,* they do not use all the donor atoms to form a complex *e.g.,* EDTA is a hexadentate ligand but it can also act as a pentadentate or a tetradentate ligand.

Caution Point *Some ligands like* SO_4^{2-} *ion etc., can act both as a monodentate as well as a bidentate ligand. This is clear from the following examples.*



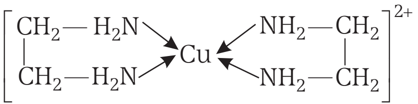
SO_4^{2-} as monodentate



SO_4^{2-} as bidentate

(c) Chelating Ligands

Polydentate ligands, the structures of which permeates the attachment of two or more donor sites at the terminals of a chain to the same metal ion simultaneously, thus, closing one or more rings are called **chelating ligands** and the compounds formed are known as **chelate compounds.** Thus, a chelate may be defined as a ring structure formed by the combination of a polydentate ligand having two or more donor atoms at the terminals with a metal ion forming part of the ring. The process of formation of chelates is called **chelation.**



Chelate formation

Chelate complexes are more stable than ordinary complexes in which the ligand is monodentate. This increased stability of the compound due to chelation is called the chelate effect.

Generally the chelate complexes with five or six membered rings are more stable. Out of these, five membered rings are very stable when they involve saturated ligands, *e.g.,* ethylene diamine contains only single bonds and forms five membered stable ring structures.

On the other hand, six membered ring structures acquire maximum stability when they involve unsaturated ligands containing conjugate double bonds. This is due to the resonance effects involving metal *d*-orbitals and ligand π-orbital electrons. The stability of the chelate complex is explained on the basis of **entropy effect.** When one end of en (ethylene diamine) is coordinated, the probability of the coordination of the other end is high because this end is bound to stay close to the cation. This shows that it is easier to form a chelate ring than coordinate to two independent molecules. Thermodynamically, the increased stability due to chelation can be attributed to an increase in the degree of freedom of the system. A large entropy change but only small heat of reaction generally accompany the chelation process.

The complex compound having maximum number of rings formed with the ligands, is most stable. A complex $[M(en)_3]^{3+}$ is less stable than a complex $[M(EDTA)]^-$ because in the former there are three rings while, the latter involves five rings.

Sample Problem 2 *The stabilisation of coordination compounds due to chelation is called the chelate effect. Which of the following is the most stable complex species?*

[NCERT Exemplar]

(*a*) $[Fe(CO)_5]$ (*b*) $[Fe(CN)_6]^{3-}$

(*c*) $[Fe(C_2O_4)_3]^{3-}$ (*d*) $[Fe(H_2O)_6]^{3+}$

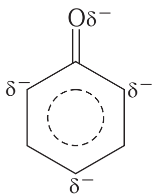
Interpret (*c*) $(C_2O_4)^{2-}$ is a chelating agent $\begin{bmatrix} COO^- \\ | \\ COO^- \end{bmatrix}$, so its complex is more stable than the other given due to chelation.

(d) Ambidentate Ligands

There are certain ligands, which have two or more donor atoms but in forming complexes only one donor atom is attached to metal ion. Such ligands are called ambidentate ligands. Some examples of such ligands are

$M \leftarrow NO_2$ (Nitro)	$M \leftarrow ONO$ (Nitrito)
$M \leftarrow CN$ (Cyano)	$M \leftarrow NC$ (Isocyano)
$M \leftarrow SCN$ (Thiocyano)	$M \leftarrow NCS$ (Isothiocyano)

Phenoxide ion also serves as an ambidentate ligand due to resonance. *o*- and *p*- positions of the benzene ring in the phenoxide ion also become electron donors.



phenoxide ion

4. Coordination Sphere

The central atom and ligands which are directly attached to it, are enclosed in square brackets, called the coordination sphere. *The ligands and the metal atom shown inside the square bracket actually behave as a single constituent unit.* The bonding between the central metal ion/atom, and the ligands in its coordination sphere is non-ionisable.

5. Coordination Number

The total number of ligands attached to the central metal ion through coordinate bond is called the **coordination number** (CN) of the metal ion, *e.g.,* in the complex ion $[Cu(NH_3)_4]^{2+}$, the coordination number of Cu^{2+} is 4 and that of Fe^{2+} ion in $[Fe(CN)_6]^{4-}$ is 6. The coordination numbers of most common metals are 4 and 6. Ag^+, Pt^{2+}, Cr^{3+}, Fe^{2+}, Fe^{3+}, Co^{3+} and Pt^{4+} ions show only one coordination number, *e.g.,* Ag^+ shows CN = 2, Pt^{2+} CN = 4 and Cr^{3+} Fe^{2+}, Fe^{3+}, Co^{3+} and Pt^{4+} show CN = 6 only.

In case of polydentate ligands,

Coordination number = No. of ligand × its denticity

e.g., in $[CoBr_2(en)_2]^+$. CN *wrt* Br = 2

CN *wrt* en = 2 × 2 = 4

Total CN = 2 + 4 = 6

6. Oxidation Number or Oxidation State

It is a number that represents an electric charge in which a metal atom or ion has or appears to have when combined with ligands, *e.g.,* oxidation number of copper in $[Cu(NH_3)_4]^{2+}$ is +2 but its coordination number is 4. Similarly, the oxidation number of Fe in $[Fe(CN)_6]^{3-}$ is +3 but its coordination number is 6.

7. Charge on the Complex Ions

The charge carried by a complex ion is the algebraic sum of the charges carried by central metal ion and the ligands coordinated to the central metal ion, *e.g.,* in the complex ion, $[Ag(CN)_2]^-$, Ag^+ ion carries a charge of +1. Therefore, the net charge on the complex ion $[Ag(CN)_2]$ is + 1 – 2 = – 1. Similarly, in the complex ion, $[Cu(NH_3)_4]^{2+}$, Cu ion carries charge equal to +2 and as NH_3 molecules are neutral, therefore, the net charge on the complex is +2.

8. Representation of a Complex Ion

The terms ligand, central metal, charge on complex ion and coordination number can be illustrated as

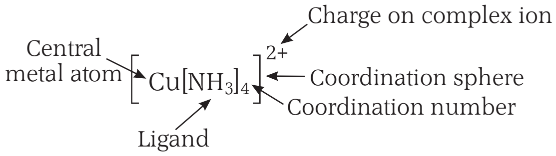


Fig. 9.1 A complex Ion

9. Effective Atomic Number [EAN]

In order to explain the stability of the complex **Sidgwick** proposed effective atomic number abbreviated as EAN, which is defined as the *resultant number of electrons with the metal atom or ion after gaining electrons from the donor atoms of the ligand. The effective atomic number* (EAN) generally coincides with the atomic number of next inert gas except in some cases.

Calculation of EAN EAN can be calculated by the following relation

EAN = *Z* (atomic number of the metal) – number of electrons lost in the ion formation + number of electrons gained from the donor atoms of the ligands

The EAN's of various metals in their respective complexes is tabulated below

Table 9.1 **EAN of Some Species**

Complex	Oxidation state of metal ion	Atomic number of metal (*Z*)	Coordination number	Effective atomic number
$[Co(NH_3)_6]Cl_3$	+3	27	6	(27 – 3) + (6 × 2) = 36 (Kr)
$K_4[Fe(CN)_6]$	2	26	6	(26 – 2) + (6 × 2) = 36 (Kr)
$Ni[CO]_4$	0	28	4	(28 – 0) + (4 × 2) = 36 (Kr)
$K_2[PtCl_6]$	+4	78	6	(78 – 4) + (6 × 2) = 86 (Rn)
$K_3[Fe(CN)_6]$	+3	26	6	(26 – 3) + (6 × 2) = 35

Sample **Problem 4** *Using the EAN rule predict the value of x in* $Cr(CO)_x$.

(*a*) 4 (*b*) 5

(*c*) 6 (*d*) 8

Interpret (c) EAN = 24 – 0 + 2*x* = 36

$2x = 12$ [*i.e.,* atomic number of nearest noble gas]

$x = 6$

Therefore, the formula of the compound is $Cr(CO)_6$.

9.3 Werner's Theory

Werner proposed a theory called **Werner's coordination theory** for which he was awarded Nobel prize in 1913. It was the first successful theory, which explained the properties of complexes.

The main postulates of this theory are

1. Metals possess two types of linkages (valencies)
   (i) primary or principal linkage and
   (ii) secondary linkage
2. **Primary linkages** (valencies) **are ionisable** and are exhibited by a metal in the formation of its simple salts such as $CoCl_3$, $CuSO_4$ and AgCl. In these salts, the primary valencies of Co, Cu and Ag are 3, 2 and 1 respectively. Now a days, **primary valency** is referred to as **oxidation state** of the metal ion.
3. **Secondary linkages** (valencies) **are non-ionisable** and are exhibited by a metal in the formation of its complex ions such as $[Co(NH_3)_6]^{3+}$, $[Cu(NH_3)_4]^{2+}$ and $[Ag(NH_3)_2]^+$. In these complexes, the secondary valencies of Co^{3+}, Cu^{2+} and Ag^+ are 6, 4 and 2 respectively. The secondary valency is also referred to as **coordination number** (CN) of the metal cation.
4. **Primary linkages** (valencies) *are satisfied by negative ions while, secondary linkages (valencies) can be satisfied by neutral molecules or negative ions or in some cases positive ions* (ligands) **also.** This happens in case of mixed complexes.
5. *Every metal atom or ion has a fixed number of secondary linkages. In other words, the coordination number of the metal atom is fixed.* Thus, the coordination number gives the total number of neutral molecules of negative or positive groups, which may be directly linked to the metal cation in the formation of its complexes.
6. *Every metal has a tendency to satisfy both its primary and secondary linkages (valencies).* The ligands satisfying secondary linkages (valencies) are always directed towards fixed positions in space about the central metal atom or ion. Thus, the coordination compounds have a definite geometry (structure or shape).

Werner's Representation

Consider the case of $CoCl_3 \cdot xNH_3$

where maximum value of x = CN of Co(III) = 6

and minimum value of x = CN − ON = 3

Various structures are summarized in Table 9.3.

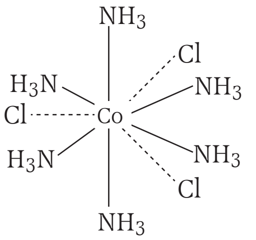
Table 9.2 **Werner's Coordination Compounds**

Werner complex	Modern notation	Ionisation	Secondary valency satisfied by	Primary valency satisfied by
(A) $CoCl_3 \cdot 6NH_3$	$[Co(NH_3)_6]Cl_3$	$[Co(NH_3)_6]^{3+} + 3Cl^-$	six (NH_3)	three (Cl^-)
(B) $CoCl_3 \cdot 5NH_3$	$[Co(NH_3)_5Cl]Cl_2$	$[Co(NH_3)_5Cl]^{2+} + 2Cl^-$	five (NH_3) and one (Cl^-)	three (Cl^-) including one (Cl^-) with **dual nature**
(C) $CoCl_3 \cdot 4NH_3$	$[Co(NH_3)_4Cl_2]Cl$	$[Co(NH_3)_4Cl_2]^+ + Cl^-$	four (NH_3) and two (Cl^-)	three (Cl^-) including two (Cl^-) with **dual nature**
(D) $CoCl_3 \cdot 3NH_3$	$[Co(NH_3)_3Cl_3]$	$[Co(NH_3)_3Cl_3]$ (single species)	three (NH_3) and three (Cl^-)	three (Cl^-) all with **dual nature**

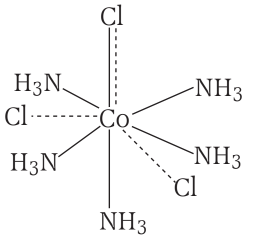
From the Table 9.3, it is clear that conduction of the complexes which depends on the number of ions will be in order: *D* < *C* < *B* < *A*

They are represented as :

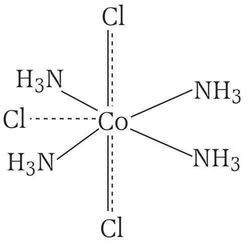
[only Cl^- ions joined by (........) will ionise].



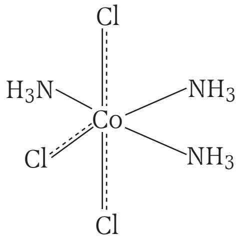
(*A*)



(*B*)



(*C*)



(*D*)

Sample Problem 5 *When* 0.1 *mole* $CoCl_3(NH_3)_5$ *is treated with excess of* $AgNO_3$, 0.2 *mole of* AgCl *are obtained. The conductivity of solution will correspond to*

[NCERT Exemplar]

(*a*) 1 : 3 *electrolyte* (*b*) 1 : 2 *electrolyte*
(*c*) 1 : 1 *electrolyte* (*d*) 3 : 1 *electrolyte*

Interpret (*b*) Formation of 0.2 mole of AgCl, from 0.1 mole complex suggest the presence of two Cl^- outside the coordination sphere. Thus, the formula of the complex should be $[Co(NH_3)_5Cl]Cl_2$.

This complex ionises as

$$[Co(NH_3)_5Cl]Cl_2 \longrightarrow \underset{1}{[Co(NH_3)_5Cl]^{2+}} + \underset{2}{2Cl^-}$$

Hence, it is 1 : 2 electrolyte.

Sample **Problem 6** *Arrange the following complexes in the increasing order of conductivity of their solution :*

I. $[Co(NH_3)_3Cl_3]$ *II.* $[Co(NH_3)_4Cl_2]Cl$, *III.* $[Co(NH_3)_6]Cl_3$,
IV. $[Cr(NH_3)_5Cl]Cl_2$ **[NCERT Exemplar]**

(*a*) $I < II < III < IV$
(*b*) $II < I < IV < III$
(*c*) $I < II < IV < III$
(*d*) $II < I < III < IV$

Interpret (*c*) Ions or molecules present outside the coordination sphere are ionisable. A complex which gives more ions on dissolution, is more conducting.

$$\underset{\substack{\text{(1 ion)}\\ \text{(I)}}}{[Co(NH_3)_3Cl_3]} < \underset{\substack{\text{(2 ions)}\\ \text{(II)}}}{[Co(NH_3)_4Cl_2]Cl} < \underset{\substack{\text{(3 ions)}\\ \text{(IV)}}}{[Cr(NH_3)_5Cl]Cl_2} < \underset{\substack{\text{(4 ions)}\\ \text{(III)}}}{[Co(NH_3)_6]Cl_3}$$

Check Point 1

1. Why does NH_4^+ ion not form complexes?
2. A freshly prepared aqueous solution of $Pd(NH_3)_2Cl_2$ does not conduct electricity. Is this compound is regarded as a weak electrolyte?
3. $CuSO_4$ on mixing with NH_3 (ratio 1: 4) does not give test for Cu^{2+} ions but gives test for SO_4^{2-} ions; why?
4. Why is $K_4[Fe(CN)_6]$ more conducting as compared to $[Cr(NH_3)_6]Cl_3$?

9.4 IUPAC Nomenclature of Mononuclear Coordination Compounds

The various rules are applied in naming the coordination compounds according to the IUPAC (International Union of Pure and Applied Chemistry) system are

Order of Naming Ions

If the complex compound is ionic, the positive ion (cation) whether simple or complex, is named first followed by the negative ion (anion). *e.g.,* $K[BF_4]$ ionises to K^+ and BF_4^- ions. Here cation (K^+) is simple and it is named first followed by anionic part. Thus, $K[BF_4]$ is named as potassium tetrafluoroborate (III). The complex $[Ag(NH_3)_2]Cl$ ionises as

$$[Ag(NH_3)_2]Cl \longrightarrow [Ag(NH_3)_2]^+ + Cl^-$$

Here, the cation $[Ag(NH_3)_2]^+$ is not a simple one but a complex. Therefore, it is named first and then the anionic part. Thus, $[Ag(NH_3)_2]Cl$ is named as diamminesilver (I) chloride. But one word name is given to non-ionic and molecular complexes.

Naming Ligands

1. The number of each kind of ligand is specified using the Greek **prefixes** like di, tri, tetra, penta, and hexa. The term mono is generally not mentioned. If the name of ligand itself is complex, *i.e.,* it includes a numerical prefix, *e.g.,* in case of organic molecules such as dipyridyl or ethylenediamine, then the terms **bis** (for two), **tris** (for three), **tetrakis** (for four), **pentakis** (for five), etc., are used followed by the name of the ligand placed without brackets. *e.g.,* $[Cu(NH_3)_4]^{2+}$ is named as tetramminecopper (II) ion and $[Co(en)_3]^{3+}$ is named as tris (ethylenediamine) cobalt (III) ion.
2. **Negative ligands** are normally end in –o, *e.g.,*

Table 9.3 **Different Negative Ligands, Their Charge and Donor Atoms**

	Name	Formula	Charge	Name of ligand in the complex	Donor atom/ atoms
Monodenate ligands with one unit negative charge	Halide ion	(X = Cl, Br, I)	– 1	Halo or halido	X
	Hydroxide ion	$:OH^-$	– 1	Hydroxo	O
	Cyanide ion	$-C\equiv N$	– 1	Cyano	C
	Isocyanide	$N^+\equiv C^-$	– 1	Isocyano	N
	Nitro ion	NO_2^-	– 1	Nitro	N
	Nitrito ion	ONO^-	– 1	Nitrito	O
	Thiocyanate ion	SCN^-	– 1	Thiocyanato	S
	Isothiocyanate ion	NCS^-	– 1	Isothiocyanato	N
	Hydride ion	H^-	– 1	Hydrido	H
	Amide ion	NH_2^-	– 1	Amido	N
	Acetate ion	CH_3COO^-	– 1	Acetato	O
	Nitrate ion	NO_3^-	– 1	Nitrato	O
	Cyanate	ONC^-	– 1	Cyanato	O
	Isocyanate	NCO^-	– 1	Isocyanato	N
Monodentate ligands with two negative charges	Sulphate ion	SO_4^{2-}	–2	Sulphato	O
	Oxide ion	O^{2-}	–2	Oxo	O
	Peroxide ion	O_2^{2-}	–2	Peroxo	O
	Carbonate ion	CO_3^{2-}	–2	Carbonato	O
	Sulphite ion	SO_3^{2-}	–2	Sulphito	O
	Sulphide ion	S^{2-}	–2	Sulphido	S
	Thiosulphate ion	$S_2O_3^{2-}$	–2	Thiosulphato	S
	Imide ion	NH^{2-}	–2	Imido	N
Bidentate ligands with one/two negative charges	Oxalate ion (o*x)	 $\begin{array}{l}COO^-\\ \vert\\ COO^-\end{array}$	– 2	Oxalato	Two O-atoms
	Acetyl acetonate (a*cac)	 $CH_3-\underset{\overset{\Vert}{O}}{C}-CH=\underset{\overset{\vert}{O^-}}{C}-CH_3$	– 1	Acetyl acetonato	Two O-atoms
	Glycinate ion (g*ly)		– 1	Glycinato	One N-atom and one O-atom
	* Symbol used				
Polydentate ligands with high negative charges	Ethylenediamine triacetate ion (a pentadentate ligand)		–3	$EDTA^{3-}$	Two N-atoms and three O-atoms
	Ethylenediamine tetra-acetate ion (a hexadentate ligand)		–4	$EDTA^{4-}$	Two N-atoms and four O-atoms

3. **Neutral ligands** have no special ending *e.g.,*

Table 9.4 **Neutral Ligands**

	Name and symbol of ligand	Formula	Charge	Name of ligand on the complex	Donor atom
Neutral monodentate ligands	Ammonia	NH_3	Zero	Ammine	N
	Water	H_2O	Zero	Aqua	O
	Phosphine	PH_3	Zero	Phosphine	P
	Nitrogen oxide	NO	Zero	Nitrosyl	N
	Carbon monoxide	CO	Zero	Carbonyl	C
	Pyridine (py)	C_6H_5N or 	Zero	Pyridine	N
	Thiourea (tu)	 $H_2N-\overset{\overset{S}{\|}}{C}-NH_2$	Zero	Thiourea	S
	Triphenyl phosphine	$(C_6H_5)_3P$	Zero	Triphenyl phosphone	P
	Thiocarbonyl	CS	Zero	Thiocarbonyl	S
Neutral polydentate ligands	Ethylenediamine (en) (a bidentate ligand)	$NH_2CH_2CH_2NH_2$	Zero	Ethylene diamine	Two N-atoms
	2,2-dipyridyl (dipy) (a bidentate ligand)		Zero	Dipyridyl	Two N-atoms
	Diethylene triamine (dien) (a tridentate ligand)	$NH_2CH_2CH_2NHCH_2CH_2NH_2$	Zero	Diethylene triamine	Three N-atoms
	Triethylene tetramine (trien) (a tetradentate ligand)	$NH_2(CH_2)_2NH(CH_2)_2$ $-NH-(CH_2)_2NH_2$	Zero	Triethylene tetramine	Four N-atoms

Caution Point *In old system, word aquo was used.*

4. **Positive ligands** (which are very few) end in -ium *e.g.,*

Table 9.5 **Positive Ligands**

Name and symbol of ligand	Formula	Charge	Name given in the complex	Donor atom
Nitronium ion	NO_2^+	+ 1	Nitronium	N
Nitrosonium ion	NO^+	+ 1	Nitrosonium	N
Hydrazinium ion	$NH_2NH_3^+$	+ 1	Hydrazinium	N

5. The order of the preference of the ligands in the complexes according to the old system was as

   (i) Negative ligands; (ii) Neutral ligands;

   (iii) Positive ligands

   There should be no hyphen in between. In case, there are more than one negative or positive ligands, they are listed alphabetically. Thus, Cl^-, NO_2^- are written in the order as chloro, nitro etc.

IUPAC rules 1991 recommended that all ligands whether anions, neutral or positive be arranged alphabetically without any preference order. But the old system has also been retained. Some examples are as

Formula of the complex	Old IUPAC Name	Latest IUPAC Name
$[PtCl(NO_2)(NH_3)_4]SO_4$	Chloronitrotetrammine platinum (IV) sulphate	Tetramminechloridonitro platinum (IV) sulphate
$[CoCl(NH_3)_4(H_2O)]Cl_2$	Chloroaquotetrammine cobalt (III) chloride	Tetrammineaquachloridocobalt (III) chloride

Note Always follows latest IUPAC conventions.

6. Certain ligands like NO can act as a neutral as well as unipositive (NO^+) ligand. In such case, it is very difficult to find the oxidation state and the charge on the ligand from the given formula of the complex.

Hot Spot 1

NAMING of the Complex Ion

It is an important topic for JEE Main examination. The level of questions is generally easy so a small practice can help you to solve the problems based on naming and formula writing.

While naming the complex ion, number and name of the ligands are given first, then the central metal atom followed by its oxidation state indicated by Roman numeral in parenthesis.

(i) **If the complex ion is a cation,** the name of the central metal ion is given as such followed by its oxidation state indicated by numerals (such as II, III, IV) in the parenthesis at the end of the name of the complex without a space between the two. Some examples are as follows

[Ni(DMG)$_2$]	Bisdimethylglyoximatonickel (II)
[Pt(NH$_3$)$_2$Cl$_4$]	Diamminetetrachloridoplatinum (IV)

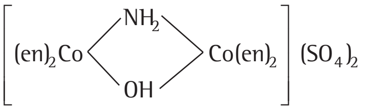
(ii) **If the complex ion is an anion,** the name of the central atom, is made to end in –ate followed by the oxidation number in brackets without any space between them, *e.g.,*

Na$_3$[AlF$_6$]	Sodium hexafluoridoaluminate (III)
[Ag(CN)$_2$]$^-$	Dicyanoargentate (I) ion
[Pb(OH)$_4$]$^{2-}$	Tetrahydroxoplumbate (II) ion

For an acid we have a characteristic ending (ic) *e.g.,*

H$_4$[Pt(CN)$_6$] Hexacyanoplatinic (II) acid.

If the complex contains two or more metal ions, it is termed as polynuclear complex. The ligands, which link the two metal atoms, are called bridge groups and are separated from the rest complex by hyphens and denoted by the prefix μ placed before their names, *e.g.*,



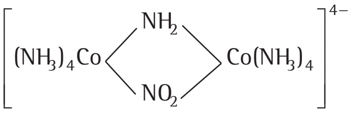
$$\left[(en)_2Co\overset{NH_2}{\underset{OH}{\diamond}}Co(en)_2\right](SO_4)_2$$

is named as

bis (ethylenediamine) cobalt (III) -μ - amido -μ - hydroxo bis (ethylenediamine) cobalt (III) sulphate

[It can also be named as tetrakis (ethylenediamine) μ-amido-μ-hydroxocobalt (III) sulphate.]

Similarly,



$$\left[(NH_3)_4Co\overset{NH_2}{\underset{NO_2}{\diamond}}Co(NH_3)_4\right]^{4-}$$

is named as octaammine-μ-amido-μ-nitrodicobalt (III) ion

It can also be named as

[tetramminecobalt (III)-μ-amido-μ-nitrotetrammine cobalt (III) ion].

The following examples illustrate the nomenclature of complexes

1.	[Cr(H$_2$O)$_4$Cl$_2$]Cl	Tetraaquadichloridochromium (III) chloride
2.	[Co(NH$_3$)$_5$CO$_3$]Cl	Pentaamminecarbonatocobalt (III) chloride
3.	[Ag(NH$_3$)$_2$]Cl	Diamminesilver (I) chloride
4.	[Co(en)$_2$Cl$_2$]$_2$SO$_4$	Dichloridobis (ethylenediamine) cobalt (III) sulphate
5.	[Co(NH$_3$)$_4$(NO$_2$)Cl]NO$_3$	Tetraamminechloridonitrocobalt (III) nitrate
6.	[Co(NH$_3$)$_3$(NO$_2$)$_3$]	Triamminetrinitrocobalt (III)
7.	[Pt(NH$_3$)$_6$]Cl$_4$	Hexaammineplatinum (IV) chloride
8.	[Cr(H$_2$O)$_3$(NH$_3$)$_3$]Cl$_3$	Triamminetriaquachromium (III) chloride
9.	[CoF$_2$(en)$_2$]ClO$_4$	Bis (ethylenediammine) difluoridocobalt (III) perchlorate
10.	Na$_2$[SiF$_6$]	Sodium hexafluoridosilicate (IV)
11.	Fe$_4$[Fe(CN)$_6$]$_3$	Iron (III) hexacyanoferrate (II) or ferric hexacyanoferrate (II)
12.	Na$_2$[CrF$_4$O]	Sodium tetrafluoridooxochromate (IV)
13.	K[BF$_4$]	Potassium tetrafluoridoborate (III)
14.	K$_2$[OsCl$_5$N]	Potassium pentachloridonitridoosmate (VI)
15.	Ni(CO)$_4$	Tetracarbonyl nickel (0)
16.	K$_4$[Ni(CN)$_4$]	Potassium tetracyanonickelate (0)
17.	[Ni(dmg)$_2$]	Bis (dimethylglyoximato) nickel (II)
18.	[Pt(NH$_3$)$_2$Cl$_2$]	Diamminedichloridoplatinum (II)

19.	$[Cr(PPh_3)(CO)_5]$	Pentacarbonyltriphenylphosphinechromium (0)
20.	$[Co(NH_3)_4Cl_2]_3[Cr(CN)_6]$	Tetraamminedichloridocobalt (III) hexacyanochromate (III)
21.	$[Pt(NH_3)_4Cl_2][PtCl_4]$	Tetraammine dichloridoplatinum (IV) tetrachloridoplatinate (II)
22.	$[(NH_3)_5Cr-OH-Cr(NH_3)_5]Cl_5$	Pentaamminechridomium (III)-μ-hydroxopentaamminechromium (III) chloride
23.		Chloridotriphenylphosphinepalladium (II)-μ-dichloro chloridotriphenylphoshinepalladium (II)
24.	$[(NH_3)_5Co-NH_2-Co(NH_3)_5](NO_3)_5$	Decammine-μ-amidodicobalt (III) nitrate
25.		Octaaqua-μ-hydroxo-μ-nitrodiiron (III) sulphate
26.	$[Mn_3(CO)_{12}]$	Dodecacarbonyltrimanganese (0)
27.	$[Fe(C_5H_5)_2]$	Bis(cyclopentadienyl)iron (II) or ferrocene
28.	$[PtBrClI(NO_2)(NH_3)(Py)]$	Amminebromidochloridoiodidonitropyridineplatinum (IV)
29.	$[VO(acac)_2]$	Bis(acetylacetonato)oxovanadium (IV)
30.	$Na_3[Ag(S_2O_3)_2]$	Sodium bis(thiosulphato) argentate (I)
31.	$Na_2[Ni(EDTA)]$	Sodium ethylenediaminetetraacetatonickelate (II)
32.	$Hg[Co(SCN)_4]$	Mercuric tetrathiocyanatocobaltate (II)

Sample Problem 7 *Select the incorrect match(s) of IUPAC names with the following coordination compounds :*

(i) $[Co(NH_3)_6]Cl_3$	*Hexaaminocobalt (III) chloride*
(ii) $[Co(NH_3)_5Cl]Cl_2$	*Pentaamminechloridocobalt (III) chloride*
(iii) $K_3[Fe(CN)_6]$	*Potassium hexacyanoferrate (III)*
(iv) $K_3[Fe(C_2O_4)_3]$	*Potassium trioxalatoferrate (III)*
(v) $K_2[PdCl_4]$	*Potassium tetrachlorido palladate (II)*
(vi) $[Pt(NH_3)_2Cl(NH_2CH_3)]Cl$	*Diamminechlorido (methylamine) platinum (II) chloride* **[NCERT]**

(a) *(i) only* (b) *(i), (v) and (vi)*
(c) *(i), (ii) and (iii) only* (d) *(v) only*

Interpret *(a)*

(i) To write the name of cationic complex, the general formula is

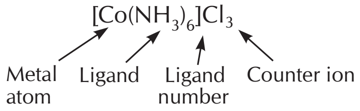
ligand number + ligand names (alphabetically) + metal name + metal oxidation state in parenthesis + counter ion name (counter ion is present outside the coordination sphere.)

(ii) To write the name of anionic complex, the general formula is

counter ion + number of ligands + ligand names (alphabetically) + metal name + 'ate' + (oxidation state of metal).

So write, the name according to above formula

(i)



$[Co(NH_3)_6]Cl_3$

Let the oxidation state of Co be x.

$$x + (0)6 + (-1) \times 3 = 0$$
$$x + 0 - 3 = 0$$
$$x = +3$$

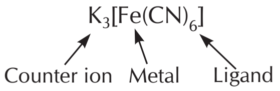
So, the name of this complex is hexaamminecobalt (III) chloride.

(ii) $[Co(NH_3)_5Cl]Cl_2$

$$x + (0) \times 5 + (-1) \times 1 + (-1) \times 2 = 0$$
$$x + 0 - 3 = 0$$
$$x = +3$$

So, the name of the complex is pentaamminechloridocobalt (III) chloride.

(iii)



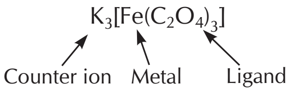
$K_3[Fe(CN)_6]$

Let the oxidation state of Fe is x.

$$(+1)3 + x + (-1)6 = 0$$
$$+3 + x - 6 = 0$$
$$x = +3$$

So, the name of the complex is potassium hexacyanoferrate (III).

(iv)



$K_3[Fe(C_2O_4)_3]$

Let the oxidation state of Fe is x.

$$(+1)3 + x + (-2)3 = 0$$

[∵ Oxalate ion ($C_2O_4^{2-}$) bears – 2 charge.]

$$3 + x - 6 = 0$$
$$x = +3$$

So, the name of the complex is potassium trioxalatoferrate (III).

(v) $\underset{\text{Counter ion}}{K_2}[\underset{\text{Metal atom}}{Pd}\underset{\text{Ligand}}{Cl_4}]$

Let the oxidation state of Pd is x.

$$\begin{aligned}(+1)\,2 + x + (-1)\,4 &= 0\\ 2 + x - 4 &= 0\\ x &= +2\end{aligned}$$

So, the name of the complex is potassium tetrachloridopalladate (II).

(vi) $[\underset{\text{Metal}}{Pt}\ \underset{\text{Ligands}}{\underbrace{(NH_3)_2Cl(NH_2CH_3)}}]\underset{\text{Counter ion}}{Cl}$

Let the oxidation state of Pt is x.

$$\begin{aligned}x + (0)\,2 + (-1)\times 1 + 0 + (-1)\times 1 &= 0\\ x + 0 - 1 + 0 - 1 &= 0\\ x - 2 &= 0\\ x &= +2\end{aligned}$$

So, the name of the complex is diamminechlorido (methylamine) platinum (II) chloride.

Exceptions

Common names in place of IUPAC are used when

(i) Structure of the complex is not certain, *e.g.*, zincate ion $[ZnO_2]^{2-}$

(ii) They are more convenient than the IUPAC names *e.g.*, ferrocyanide rather than hexacyanoferrate for $[Fe(CN)_6]^{4-}$; similarly ferricyanide in place of hexacyanoferrate (III) for $[Fe(CN)_6]^{3-}$; cobaltinitrite in place of hexanitrocobaltate (III) ion for $[Co(NO_2)_6]^{3-}$.

Caution Point *During naming of ligands, when organic free radicals act as ligands, the ligands are named as usual, e.g.,* CH_3 *as methyl,* C_2H_5 *as ethyl etc.*

Formula Writing of Complexes

From the IUPAC name for writing the formula of complexes, following rules may be observed

1. Cation whether simple or complex is written first followed by the anion.
2. The order of formulating a complex ion is reverse to that adopted in naming *i.e.*, the central metal atom is written first followed by the ligand.
3. When there are more than one type of ligands present, they are arranged in the reverse order to that adopted in naming the complexes. *i.e.*,, they are written in the order as anionic ligands first, then neutral and then cationic ligands in the last. For example, $[PdCl_2(H_2O)(N_2H_5)]^+$ where, $N_2H_5^+$ is a cationic ligand. Cl^- is an anionic ligand. This order of ligands in the formula is not yet being fully followed. If there are a number of anionic ligands, they are written alphabetically according to the first symbol of their formulae. Same principle is followed for neutral ligands or positive ligands.
4. Whole of the complex ion is enclosed in a square bracket.
5. The charge on the complex species is equal to the charge on the central metal atom *i.e.*, its oxidation state plus the total charge carried by all the ligands coordinated to the metal atom thus the formula of tetraamminecopper (II) chloride is $[Cu(NH_3)_4]Cl_2$.

Sample Problem 8 *Select the match of formulae for the following coordination compounds :*

(i) Tetraamminediaquacobalt (III) chloride $[Co(NH_3)_4(H_2O)_2]Cl_2$

(ii) Potassium tetracyanonickelate (II) $K_2[Ni(CN)_4]$

(iii) Tris(ethane-1,2-diamine) chromium (III) chloride $[Cr(en)_3]Cl_2$

(iv) Amminebromidochloridonitrito-N-platinate (II) $[Pt(NH_3)_2BrCl(NO_2)]^-$

(v) Dichloridobis-(ethane-1,2-diamine) platinum (IV) nitrate $[PtCl_2(en)_2]NO_3$

(vi) Iron (III) hexacyanoferrate (II) $Fe_3[Fe(CN)_6]$ **[NCERT]**

(a) *(ii) only* (b) *(i), (ii) and (iii) only*

(c) *(ii), (iii), (iv), (v) only* (d) *All the given*

Interpret (a) If complex name starts with metal, it is an anionic complex and if starts with ligand name or number, the complex is cationic.

I. The formula of the cationic complex is written as [metal symbol + ligand (with their number as subscript)] counter ion satisfying the valency of metal or oxidation state of complex.

II. The formula of the anionic complex is written as counter ion satisfying valency of metal [metal symbol + ligand (with their number as subscript)]

(i) $\underset{\text{Ligand}}{\underline{\text{Tetraamminediaqua}}}\ \underset{\text{Metal}}{\underline{\text{Cobalt(III)}}}\ \underset{\text{Counter ion}}{\underline{\text{Chloride}}}$

$$\overset{III}{[Co(NH_3)_4(H_2O)_2]Cl_x}$$

To find the value of x, we have to find the charge on the complex.

$$\overset{III}{[Co(NH_3)_4(H_2O)_2]^{x+}}$$

$$\begin{aligned}+3 + 4\times 0 + 2\times 0 &= x\\ x &= +3\end{aligned}$$

So, the formula of the complex is $[Co(NH_3)_4(H_2O)_2]Cl_3$.

(ii) $\underset{\text{Counter ion}}{\underline{\text{Potassium}}}\ \underset{\text{Ligand}}{\underline{\text{Tetracyano}}}\ \underset{\text{Metal}}{\underline{\text{Nickelate (II)}}}$

$$K_x[\overset{II}{Ni}(CN)_4]$$

To find the value of x, find the charge on the complex.

$$[Ni(CN)_4]^{x-} \quad (\text{as } K^+ \text{ is positive})$$

$$\begin{aligned}+2 + (-1)\times 4 &= -x\\ -x = -2 \text{ or } x &= +2\end{aligned}$$

So, the formula of the complex is $K_2[Ni(CN)_4]$.

Similarly

(iii) $[Cr(en)_3]Cl_3$ (iv) $[Pt(NH_3)\ BrCl(NO_2)]^-$

(v) $[PtCl_2(en)_2]\ (NO_3)_2$ (vi) $Fe_4[Fe(CN)_6]_3$

9.5 Isomerism

It is a phenomenon, in which compounds have the same molecular formula but different physical and chemical properties on account of different structures. These compounds are called **isomers.** The complexes in which ligands undergo rapid displacement by other ligands, cannot exhibit isomerism as the arrangement is not stable. Such complexes are known as **labile complexes.**

There are two main types of isomerism as seen in coordination compound namely :

(i) Structural isomerism, (ii) Space or stereoisomerism

Structural Isomerism

Structural isomerism is mainly of the following types

(a) Ionisation Isomerism

Ionisation isomers yield different ions in solution although they have same composition. This type of isomerism is due to the exchange of groups between the complex ion and the ions outside it, *e.g.,* $[Co(NH_3)_5Br]SO_4$ is red-violet and in solution gives a precipitate of $BaSO_4$ with $BaCl_2$ confirming the presence of SO_4^{2-} ion. On the other hand, $[Co(NH_3)_5SO_4]Br$ is red, and does not give test for sulphate ion in the solution, but instead gives a precipitate of AgBr with $AgNO_3$. Other examples are

(i) $[Pt(NH_3)_4(OH)_2]SO_4$ and $[Pt(NH_3)_4SO_4](OH)_2$
(ii) $[Pt(NH_3)_4Cl_2]Br_2$ and $[Pt(NH_3)_4Br_2]Cl_2$
(iii) $[Co(NH_3)_5NO_3]SO_4$ and $[Co(NH_3)_5SO_4]NO_3$

(b) Hydrate Isomerism

Since, water is one of the most effective coordinating agents, therefore the number of water molecules, which may enter into the coordination sphere, may vary resulting in the formation of hydrate isomers, *e.g.,* there are three different hexa-hydrates of chromic chloride with an empirical formula of $CrCl_3 \cdot 6H_2O$. One of these hydrates is violet and the other two are green in colour. All the three differ in the number of molecules of water in the coordination sphere. The formulae, which have been assigned to these hydrate isomers, are

$[Cr(H_2O)_6]Cl_3$
Violet (three ionic chlorine)

$[Cr(H_2O)_5Cl]Cl_2 \cdot H_2O$
Bluish green (two ionic chlorine)

$[Cr(H_2O)_4Cl_2]Cl \cdot 2H_2O$
Dark green (one ionic chlorine)

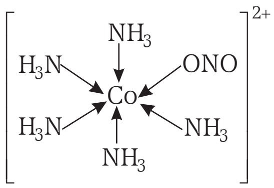
Similarly, other compounds in which hydrate isomerism is observed are

(i) $[Co(NH_3)_4(H_2O)Cl]Cl_2$ and $[Co(NH_3)_4Cl_2]Cl \cdot H_2O$
(ii) $[Co(NH_3)_4(H_2O)Cl]Br_2$ and $[Co(NH_3)_4Cl \cdot Br]Br \cdot H_2O$

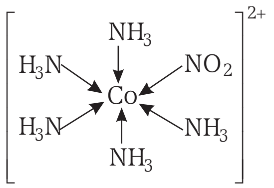
(c) Linkage Isomerism

Isomerism of this type occurs when two or more atoms in a monodentate ligand may function as a donor *i.e.,* when an ambidentate ligand is present. For example, in the case of NO_2^- ion either a nitrogen or an oxygen atom may act as donor giving two different isomers. Thus, two different isomers with molecular formula $[Co(NO_2)(NH_3)_5]^{2+}$ have been prepared. One isomer has N-atom of NO_2 group linked to cobalt atom and the other has O-atom linked to cobalt.

This behaviour is analogous to the behaviour of organic nitrites *R*—ONO and nitro compounds *R*— NO_2. The two isomers are represented below



pentaamminenitritocobalt (III) ion



pentaamminenitrocobalt (III) ion

Other example is

$[Cr(H_2O)_5SCN]^{2+}$ and $[Cr(H_2O)_5NCS]^{2+}$

(d) Coordination Isomerism

This type of isomerism is possible when both positive and negative ions of a salt are complex ions. The two isomers differ in the **distribution of ligands** in the cation and the anion.

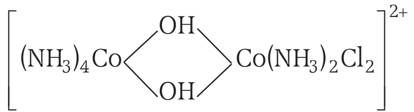
Some important examples are

(i) $[Co(NH_3)_6][Cr(CN)_6]$ and $[Cr(NH_3)_6][Co(CN)_6]$
(ii) $[Cr(NH_3)_6][Co(C_2O_4)_3]$ and $[Co(NH_3)_6][Cr(C_2O_4)_3]$

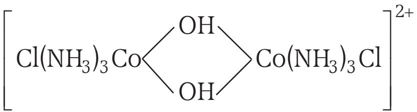
This type of isomerism may be caused by **interchange of ligand between the two complex ions.**

(e) Coordination Position Isomerism

This type of isomerism is due to the difference in the distribution of ligands in two coordination centres. Generally, the bridged complexes involving different ligands show this isomerism *e.g.,*



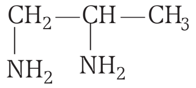
unsymmetrical



symmetrical

(f) Ligand Isomerism

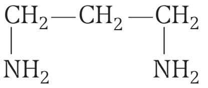
This isomerism arises in those complexes in which the two ligands are isomers themselves *e.g.,*



$CH_2(NH_2)—CH(NH_2)—CH_3$

1,2-diamino propane

and



$CH_2(NH_2)—CH_2—CH_2(NH_2)$

1,3-diamino propane

When these form the complexes, we get ligand isomers. *e.g.,* $[Co(1,2\text{-diaminopropane})_2 Cl_2]^+$ $[Co(1,3\text{-diaminopropane})_2Cl_2]^+$. This type of isomerism is quite rare.

Stereoisomerism

This is due to the different relative positions of the ligands. *It is of two types*

(a) Geometrical isomerism,

(b) Optical isomerism

Out of these two, the most thoroughly investigated is the geometrical isomerism.

(a) Geometrical Isomerism

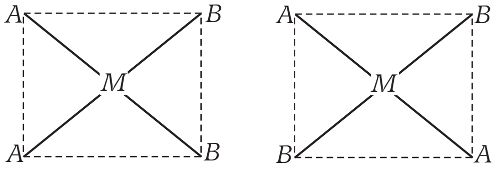
Geometrical isomers differ in the spatial distribution of atoms or groups about the central atom or atom in polynuclear compounds. Those complexes in which the two same ligands occupy adjacent positions to each other or opposite to each other (cis or *trans* respectively) are able to show this isomerism.

This isomerism cannot be exhibited by coordination compounds having 2 or 3 coordination number as it is not possible to have more than a single arrangement of ligands in space around the central ion in these cases. Geometrical isomerism with respect to the metal has also not been found among **tetrahedral** complexes of type MA_4 or MA_3B or MA_2B_2 because all the four ligands are equidistant from each other.

Only square planar and octahedral complexes show this type of isomerism.

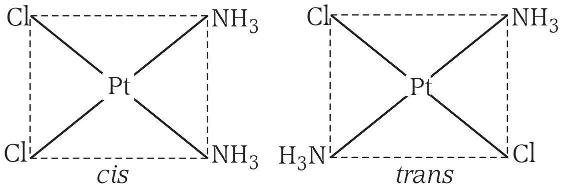
1. ***cis-trans* isomerism in square planar complexes is of various types**

   (i) Any complex of the type MA_2B_2 can exist in *cis-trans* form.



cis *trans*

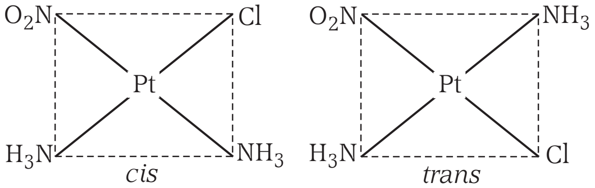
e.g., cis-platin or dichlorodiammineplatinum (II), $[Pt(NH_3)_2Cl_2]$ can exist as under



cis *trans*

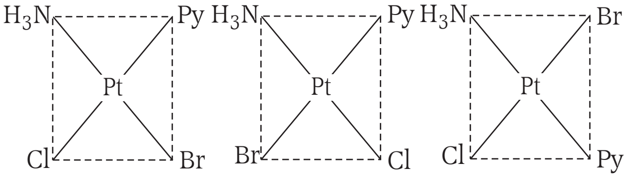
Caution Point *Square planar complexes of the type $[M(AA)_2]$, MA_4, MA_3B and MAB_3 do not show this isomerism since, all possible spatial arrangements for any of these complexes are identical.*

(ii) In a complex of the type MA_2BC, also there are *cis*- and *trans*-isomers, *e.g.,* $[Pt(NH_3)_2ClNO_2]$ can exist as

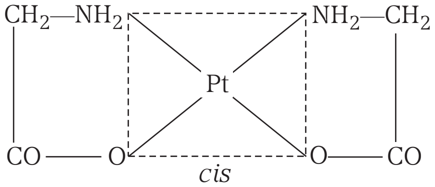


cis *trans*

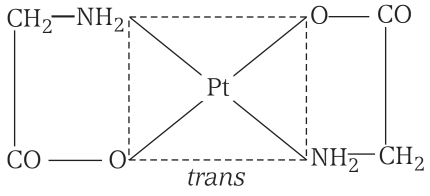
(iii) For a complex of the type *MABCD*, three geometrical isomers are possible, *e.g.,* $[Pt(Py)(NH_3)BrCl]$ can exist as



(iv) The geometrical isomerism can also occur in square planar complexes if the chelate group is not symmetrical, *e.g.,* complex of glycine (NH_2CH_2COOH) and platinum *i.e.,* $[Pt(gly)_2]$

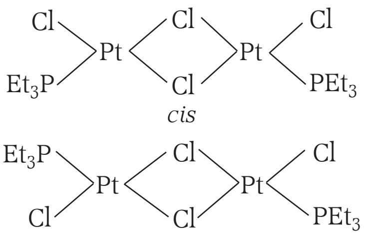


cis



trans

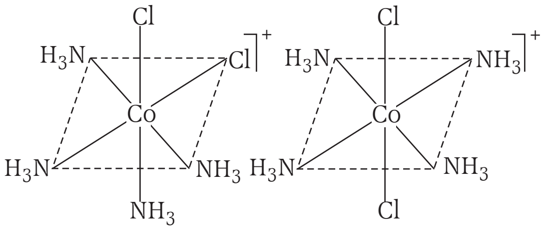
(v) Geometrical isomerism is also shown by **bridged binuclear** planar complexes of the type, $M_2A_4X_2$, *e.g.,* $[PtCl_2PEt_3]_2$



cis

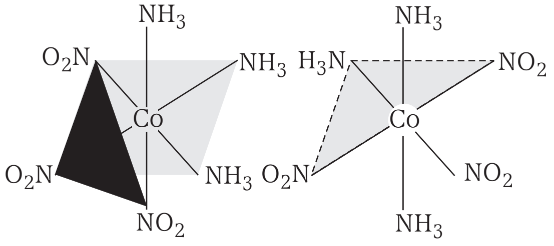
trans

2. Various octahedral complexes that show geometrical isomerism are as follows
   (i) Octahedral complexes of MA_4B_2 type show *cis-trans* isomerism, *e.g.,* dichlorotetramminecobalt (III) complex ion, $[Co(NH_3)_4Cl_2]^+$ shows *cis-trans* isomerism as



cis (violet) *trans* (green)

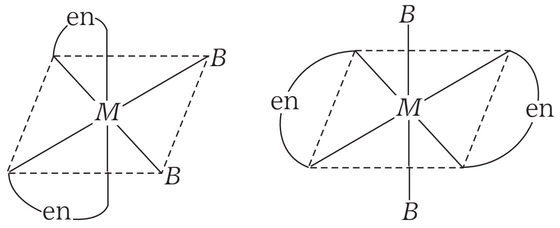
   (ii) An another type of geometrical isomerism called by *fac*-and *mer*-isomerism also occurs in octahedral coordination entities of the type $[Ma_3b_3]$ like $[Co(NH_3)_3(NO_2)_3]$. If three donor atoms of the same ligands occupy adjacent positions at the corners of an octahedral face, we have the **facial** (fac) **isomer.** When the positions are around the meridian of the octahedron, we get **meridional** (mer) **isomer.**



fac- *mer-*

Fig. 9.2 The facial (*fac*) and meridional (*mer*) isomers of $[Co(NH_3)_3(NO_2)_3]$

   (iii) Even $M(AA)_2B_2$ type octahedral complexes also show *cis* and *trans* isomerism where, $A–A$ can be any symmetrical bidentate ligand like ethylenediamine (en) and B can be any anionic ligand, such as Cl^-, CN^-, NO_2^- etc.



cis *trans*

An example of this type is $[Pt(en)_2Cl_2]$.

Octahedral complexes of $[MA_5B]$ or $M(AA)_3$ (where, AA = symmetrical bidentate ligand) do not exhibit geometrical isomerism.

   (iv) Complexes having six different ligands $[M(ABCDEF)]$ shall exhibit geometrical isomerism. Theoretically, fifteen different isomers should be possible. In practice, three isomers of the complex $[Pt(C_5H_5N)(NH_3)(NO_2)(Cl)(Br)(I)]$ have actually been isolated.

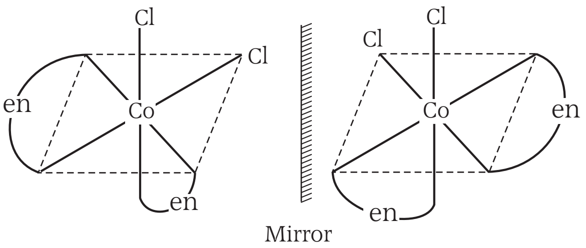
   (v) As was observed in square planar complexes, unsymmetrical bidentate ligands also give rise to geometrical isomerism in octahedral complexes of the type $[M(AB)_3]$.

(b) Optical Isomerism

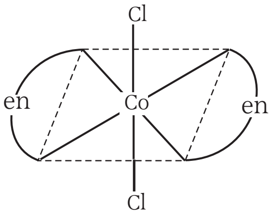
Optical isomerism arises when a compound can be represented by two asymmetrical structures (known as optical isomers). The two isomers are structurally the mirror images of each other (just as in the organic chemistry). Further, it has been found that these mirror image compounds are non-superimposable on each other and they do not possess the plane of symmetry.

Optical isomerism is common in octahedral complexes involving 2 or 3 symmetrical bidentate groups (*i.e.,* a group attached to the central atom by two coordinate bonds of the type $[M(AA)_2X_2]$ and $[M(AA)_3]$ where, AA = bidentate ligand. This is illustrated as under :

   (i) **Example of $M(AA)_2X_2$ type** *cis*-dichloridobis (ethylenediamine) cobalt (III) ion, $[Co(en)_2Cl_2]^+$, the *cis*-form of this complex is optically active and exists in *d* and *l*-forms. Its *trans* form is optically inactive due to the presence of a plane of symmetry as shown below.



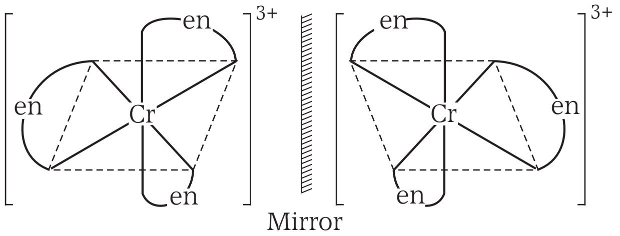
(a) optically active forms



(b) Optically inactive form

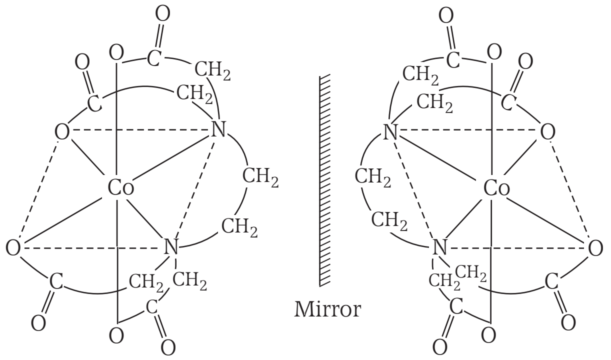
Fig. 9.3 (a) *cis*-dichloro bis(ethylenediamine) cobalt (III) ion
(b) *trans*-dichloro bis (ethylenediamine) cobalt (III) ion

(ii) **Example of $M(AA)_3$ type** octahedral complexes $[Cr(en)_3]^{3+}$, *tris* (ethylenediamine) chromium (III) ion and $[Cr(C_2O_4)_3]^{3-}$, trioxalatochromate (III) ion etc.

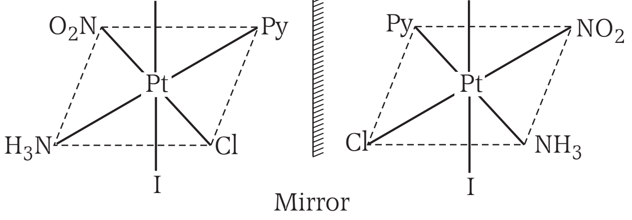


(iii) **Examples of $[M(AA)B_2X_2]$ type** $[CoCl_2(NH_3)_2(en)]^+$,

(iv) **Complexes containing hexadentate ligand** (*e.g.*, ethylenediaminetetraacetic acid) show optical activity, *e.g.*, the anion $[Co(EDTA)]^-$ exists in two forms.

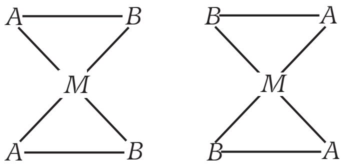


(v) **Example of $ML_aL_bL_cL_dL_eL_f$ type** is $[Pt(Py)(NH_3)(NO_2)(Cl)(Br)(I)]$. The optical activity in such complexes is due to the presence of six different ligands around the central atoms.

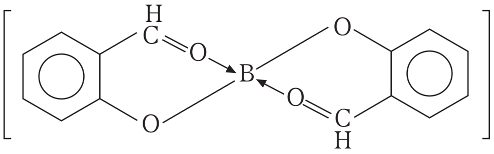


In such a compounds fifteen geometrical isomers are possible which can be resolved into optical isomers. Resolution of all the isomers is not achieved.

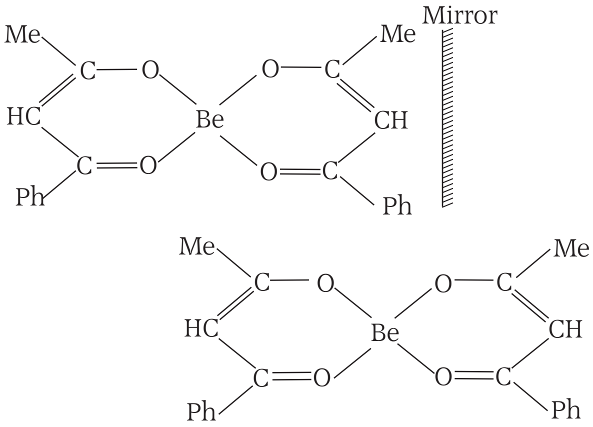
The optical activity has been observed for chelated tetrahedral and square planar complexes but only rarely. *In tetrahedral complexes only the type, which occurs in bis-chelates with unsymmetrical ligand has been detected*. These have been found in Be(II), B(III), Zn(II) and Cu(II) complexes. They are of the general type as represented below :



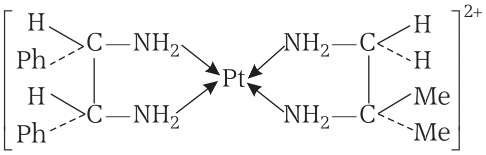
Thus, bis(salicylaldehyde) boron (III) cation has been found to be racemic and resolution has been accomplished.



The two enantiomers of bis (benzoylacetonato) beryllium (II) are shown below :



Square planar complexes are seldom optically active. One such compound which has been resolved into two forms is shown below. As can be seen, it has no plane or axis of symmetry.



Hot Spot 2

FINDING NUMBER of Stereoisomerism

Questions based on stereoisomers are frequently asked in JEE Main examination. The level of question is generally average and by a small practice, the question can be solved easily.

In order to find number of stereoisomers or whether a compound exhibit stereoisomerism or not, first find the general formula of the complex, and then compare with the following facts.

1. Geometrical isomerism is possible in square planar complexes of the type MA_2BC, MA_2B_2, $MABCD$. It is also possible in bridged binuclear planar complexes of the type $M_2A_4X_2$. Octahedral complexes of the type MA_3B_3, MA_4B_2, $M(AA)_2B_2$, $[M(ABCDEF)]$ exhibit geometrical isomerism.
2. Geometrical isomerism is not possible in square planar complexes of type MA_4 and MA_3B, tetrahedral complexes of type MA_4, MA_2B_2 and $MABCD$ and octahedral complexes of type MA_6 and MA_5B. In case of octahedral complexes of the types MA_3B_3, the *cis-trans* isomers are also called *fac-mer* isomers.
3. Octahedral complexes of the type $[M(AA)_2X_2]$, $[M(AA)_3]$, $[M(AA)B_2X_2]$ [where, AA = bidentate ligand] generally exhibits optical isomerism. $[M(\text{EDTA})]$ and $MABCDEF$ also exhibit optical isomerism. (A, B, C, D, E, F are different monodentate ligands)

Sample **Problem 9** *The number of geometrical isomers possible the following coordination entities are respectively.*

(i) $[Cr(C_2O_4)_3]^{2-}$ *(ii)* $[Co(NH_3)_3]Cl_3$ **[NCERT]**

(*a*) 2, 2 (*b*) 0, 2 (*c*) 2, 0 (*d*) 1, 2

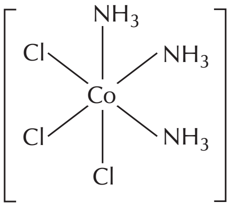
Interpret (*b*) In order to solve such problem recall the following facts

- I. Geometrical isomerism is exhibited by octahedral complexes of the type $[MA_3B_3]$, $[MA_2B_4]$ etc., where A and B are monodentate ligands.
- II. $[M(AA)_3]$ type complex does not exhibit geometrical isomerism, they exhibit optical isomerism.
- III. When the similar groups occupy adjacent positions, the isomer is called *fac* or *cis*-form, if not, it is called *mer* or *trans*-form.

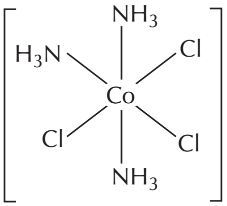
Thus,

(i) No geometrical isomer is possible.

(ii) Two geometrical isomers are possible for $[Co(NH_3)_3Cl_3]$



Facial (*fac*)



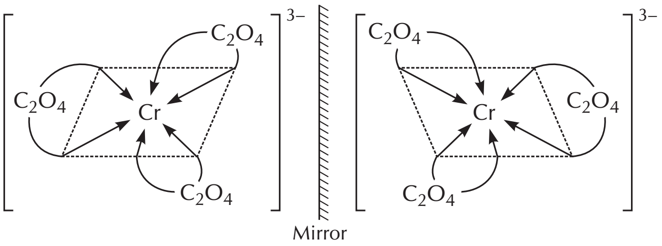
Meridional (*mer*)

Sample **Problem 10** *Trans form of which of the following is optically inactive?*

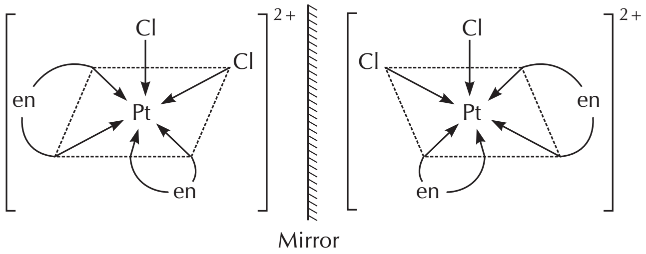
(*a*) $[Cr(C_2O_4)_3]^{3-}$ (*b*) $[PtCl_2(en)_2]^{2+}$

(*c*) $[Cr(NH_3)_2Cl_2(en)]^{+}$ (*d*) *All of these*

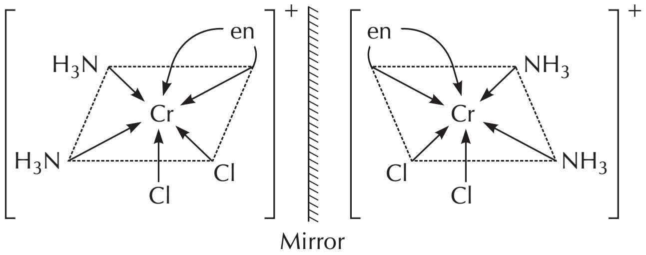
Interpret (*b*) (a) $[Cr(C_2O_4)_3]^{3-}$



(b) *Cis*-$[PtCl_2(en)_2]^{2+}$



(c) *Cis*-$[Cr(NH_3)_2Cl_2(en)]^{+}$



Thus, *trans*-$[PtCl_2(en_2)]^{2+}$ is optically inactive.

Sample **Problem 11** *Which of the following has largest number of isomers? (R = alkyl group, en = ethylenediamine)*

(*a*) $[Ru(NH_3)_4Cl_2]^{+}$ (*b*) $[Co(NH_3)_5Cl]^{2+}$

(*c*) $[Ir(PR_3)_2H(CO)]^{2+}$ (*d*) $[Co(en)_2Cl_2]^{+}$

Interpret (*d*) Among the given $[Co(en)_2Cl_2]^{+}$ is a $[M(AA)_2A_2]$ type complex, thus, it is possible for it to exhibit optical as well geometrical isomerism, which is not possible in case of other given complexes. Thus, it exhibits largest number of isomers.

Check Point 2

1. Why do ambidentate ligands show linkage isomerism?
2. Name a ligand, presence of which causes difficulty in finding the oxidation state and charge on the ligands.
3. Why do the complexes in which ligands undergo rapid displacement by other ligands, not show isomerism?
4. Why do the complexes with 2 or 3 coordination number not exhibit geometrical isomerism?
5. *Trans*-dichlorobis (en) cobalt (III) ion is optically inactive while its *cis*-form is optically active. Explain, why?

9.6 Bonding in Coordination Compounds

The formation of coordination compounds can be explained electronically by a number of theories like
(i) valence bond approach (ii) crystal field theory

Valence Bond Approach

This was evolved largely through the efforts of **Linus Pauling** based on attempted Lewis-Sidgwick ideas of the coordinate covalent bond. In this approach, the basic assumption made is that the metal ligand bonds arise by the donation of pairs of electron from ligands to the metal *i.e.,* through forming the coordinate covalent bond. In order to accommodate these electrons, the metal ion must possess requisite number of vacant orbitals of similar energy. These metal orbitals undergo hybridisation to give a set of hybrid orbitals of equal energy with the approach of the ligands.

The main assumptions of valence bond approach are

1. The ions of the transition elements have some incompletely filled *d*-orbitals.
2. Some or all the electrons in the incompletely filled *d*-orbitals are unpaired.
3. It was suggested that sometimes, the unpaired $(n-1)$ *d*-electrons couple as fully as possible prior to bond formation. In this process some $(n-1)$ *d*-orbitals become vacant.

   The central metal atom thus, makes available a number of empty orbitals equal to its coordination number for the formation of coordinate bonds with suitable ligand orbitals.
4. Since, the energy of the $(n-1)$ *d*-orbitals is only slightly less than that of *s*-and *p*-orbitals of the *n*th orbitals, these vacant orbitals mix together to form new equivalent orbitals, called **hybrid orbitals.**
5. Each ligand has at least one sigma orbital containing a lone pair of electrons.
6. The hybrid orbitals formed, take part in the formation of hybrid bonds with the ligands by overlapping. The bond formation takes place by accepting the lone pair of electrons by the hybrid orbitals of the metal from the ligands. Especially the orbitals that would be used for a metal ion of the first series, are the two 3*d*, one 4*s* and the three 4*p*-orbitals. The rest 3*d* or **inner orbitals on the metal ion do not** participate in the bonding. When $(n-1)$ *d*-orbitals are used in bond formation, the complex formed is called **inner orbital complex.**
7. Sometimes, in place of $(n-1)$ *d*-orbitals, outer *nd*-orbitals are used for hybridisation. The complex, thus, formed is called **outer orbital complex.**
8. The bond hybridisation involved and the resulting geometrical shapes of the complexes are given in the following table

Table 9.6 **Relation Between Hybridisation and Geometry of Complexes**

Bond hybridisation	Geometrical shape	*d*-orbital used	Typical example
d^2sp^3	octahedral (inner orbital complex)	d_{z^2} and $d_{x^2-y^2}$	$[Fe(CN)_6]^{3-}$
sp^3d^2	octahedral (outer orbital complex)	$d_{x^2-y^2}$ and d_{z^2}	$[FeF_6]^{3-}$
sp^3	tetrahedral		$[Zn(NH_3)_4]^{2+}$
dsp^2 or sp^2d	square planar	$d_{x^2-y^2}$	$Ni(CN)_4]^{2-}$

9. *A given complex is paramagnetic, if one or more unpaired electrons are present in the d-subshell. However, if there is no unpaired electrons, then complex is termed as diamagnetic.* Pauling made extensive use of magnetic measurements to discover the number of unpaired electrons in a complex and he also differentiated between complexes in which the bonding could be considered as ionic or those in which it was probably covalent.

   In deciding whether the hybridisation at the central metal ion of octahedral complexes is sp^3d^2 (outer orbital) or d^2sp^3 (inner orbital) we must know the results of magnetic measurements. These indicate the number of unpaired electrons (N). Magnetic moment is given by

$$\mu = \sqrt{N(N+2)}\ \text{BM}$$

(BM is Bohr Magneton)

Hot Spot 3

FINDING GEOMETRY and Magnetic Character of Complexes

Questions based on geometry, hybridisation, magnetic character and number of unpaired electrons were frequently asked in the AIEEE and JEE Main examination, thus it is a very important topic for the examination. The level of question is generally average.

In order to find the geometry, hybridisation and magnetic character, follow the following steps

Step I Find the oxidation number of central metal atom and write the electronic configuration of **central metal ion.**

Step II Find the nature of ligand,

(i) If it is CN^-, NH_3^-, CO, pair up the unpaired electrons of the metal ion (if they are more than 4 and less than 8 in case of octahedral complex.)

(ii) If it is Cl^-, Br^-, I^-, H_2O, etc., leave the unpaired electrons of the metal ion as such.

Step III Now fill the ligand's electrons in empty available orbitals. The orbitals occupied by ligands give an idea about the hybridisation.

Step IV From the hybridisation, find geometry (see table 9.7).

Step V Also see whether unpaired electrons are present, or not. If they are present, species is paramagnetic, otherwise diamagnetic.

Step VI If inner $[(n-1)d]$ orbital takes part in hybridisation, the complex is inner orbital, otherwise outer orbital.

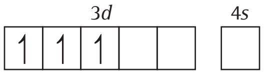
The above procedure can be best understood by following examples.

1. $[Cr(NH_3)_6]^{3+}$ ion

In this ion, oxidation state of Cr is +3.

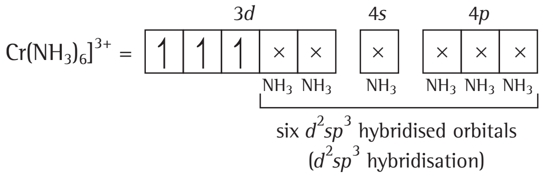
$$[x + 6 \times 0 = +3 \quad \text{or } x = +3]$$

$$Cr^{3+} = [Ar]\, 3d^3 4s^0$$



NH_3 is a strong field ligand but unpaired electrons are < 4. So, pairing does not occur.

Since, there are six NH_3 ligands, fill their electrons as



(Here x = a pair of electrons from ligand)

Since, hybridisation is d^2sp^3, geometry is octahedral. Because of the presence of three unpaired electrons, it is a paramagnetic complex.

Since $(n-1)\,d$ (3d orbital) takes part in hybridisation, it is an inner orbital complex.

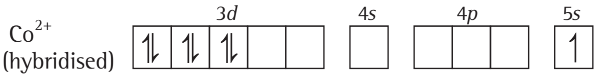
Other complexes of Cr with similar inner structure are $[Cr(CN)_6]^{3-}$ and $[Cr(H_2O)_6]^{3+}$. In a similar way, structure of $[V(H_2O)_6]^{3+}$ with d^2-configuration of V^{3+} ion can be explained.

2. $[Co(NH_3)_6]^{2+}$

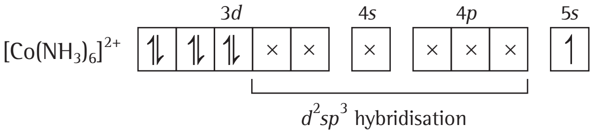
Co is present in +2 oxidation state, so

$$Co^{2+} = [Ar] \quad 3d^7 \quad 4s^0$$

NH_3 being strong field ligand pair up the unpaired electrons of Co and also transfers one remained unpaired electron into higher energy state, as



The inner two d-orbitals are made available for the required d^2sp^3 hybridisation after maximum pairing of electrons within the 3d level followed by promotion of one d-electrons to the higher energy level (5s). This is shown below



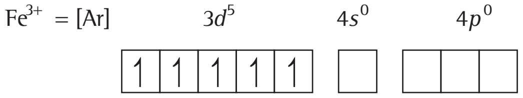
Thus, its geometry is octahedral. It is a paramagnetic complex. Moreover, it is an inner orbital complex.

As the promoted electron (shown above) has low ionisation energy, the complexed central metal ion Co^{2+} has a tendency to undergo oxidation easily to Co^{3+}. Thus, the paramagnetic complex changes to diamagnetic after oxidation. It should be noted however, that the **formation of such inner orbital**

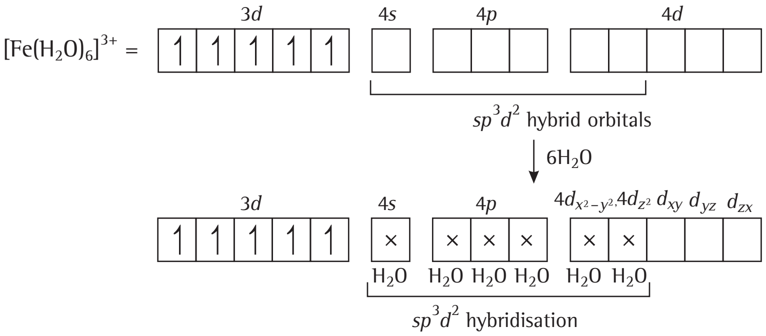
complex and promotion of electron can be brought about only by very strong ligands.

3. $[Fe(H_2O)_6]^{3+}$

Here, Fe is present as Fe^{3+}.



H_2O being weak field ligand is unable to pair up its unpaired electrons, thus, occupy the 4*s*, 4*p* and 4*d* empty orbitals as



Thus, its geometry is octahedral.

Because of the presence of five unpaired electrons, it is paramagnetic.

Since *nd* orbitals (4*d* orbitals) take part in hybridisation (bonding), it is an **outer orbital or high spin complex.**

Caution Points

(i) *Electrons of ligands are only the bonding electrons. None of the* 3*d-electron of* Fe *take part in bonding.*

(ii) *In* d^5 *electronic configuration, an octahedral complex can exist in both high spin and low spin forms.*

Table 9.7 **Geometry and Hybridisation of Some Other Complexes on the Basis of VBT**

S.N.	Atom/Ion Complex	Configuration	Oxidation state of metal	Type of hybridisation	Geometry (Shape)	No. of unpaired electrons	Magnetic nature
1.	$Ni^{2+}(d^8)$ $[NiCl_4]^{2-}$ $[Ni(CN)_4]^{2-}$		+2 +2 +2	sp^3 dsp^2	Tetrahedral Square planar	2 2 0	Paramagnetic Paramagnetic Diamagnetic
2.	$Ni\ (d^8s^2)$ $[Ni(CO)_4]$		0 0	sp^3	Tetrahedral	2 0	Paramagnetic Diamagnetic
3.	$[Mn^{2+}(d^5)]$ $[Mn(CN)_6]^{4-}$ $[MnCl_4]^{2-}$		+2 +2 +2	d^2sp^3 (inner) sp^3	Octahedral Tetrahedral	5 1 5	Paramagnetic Paramagnetic Paramagnetic
4.	$Cu^{2+}(d^9)$ $[CuCl_4]^{2-}$ $[Cu(NH_3)_4]^{2+}$	 One electron is shifted from 3*d* to 4*p*-orbital	+2 +2 +2	sp^3 dsp^2	Tetrahedral Square planar	1 1 1	Paramagnetic Paramagnetic Paramagnetic
5.	$Cr^{3+}(d^3)$ $[Cr(NH_3)_6]^{3+}$ $[Cr(H_2O)_6]^{3+}$		+3 +3 +3	d^2sp^3(Inner) d^2sp^3(Inner)	Octahedral Octahedral	3 3 3	Paramagnetic Paramagnetic Paramagnetic
6.	$Co^{3+}(d^6)$ $[Co(NH_3)_6]^{3+}$ $[CoF_6]^{3-}$		+3 +3 +3	d^2sp^3(Inner) sp^3d^2(Outer)	Octahedral Octahedral	4 0 4	Paramagnetic Diamagnetic Paramagnetic

S.N.	Atom/Ion Complex	Configuration	Oxidation state of metal	Type of hybridisation	Geometry (Shape)	No. of unpaired electrons	Magnetic nature
7.	$Co^{2+}(d^7)$ $[Co(H_2O)_6]^{2+}$		+2 +2	 sp^3d^2(Outer)	 Octahedral	3 3	Paramagnetic Paramagnetic
8.	$Fe^{2+}(d^6)$ $[Fe(CN)_6]^{4-}$ $[Fe(H_2O)_6]^{2+}$ $[Fe(NH_3)_6]^{2+}$	  Same	+2 +2 +2 +2	 d^2sp^3(Inner) sp^3d^2(Outer) sp^3d^2(Outer)	 Octahedral Octahedral Octahedral	4 0 4 4	Paramagnetic Diamagnteic Paramagnetic Paramagnetic
9.	$Fe^{3+}(d^5)$ $[Fe(CN)_6]^{3-}$		+3 +3	 d^2sp^3 (Inner)	 Octahedral	5 1	Paramagnetic Paramagnetic
10.	$Fe(d^6, s^2)$ $[Fe(CO)_5]$		0 0	 dsp^3 (Inner)	 Trigonal bipyramidal	4 0	Paramagnetic Diamagnetic

Sample Problem 12 *Which of the following options are correct for* $[Fe(CN)_6]^{3-}$ *complex?* **[NCERT Exemplar]**

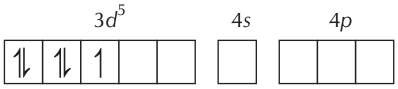
(i) d^2sp^3 *hybridisation* *(ii)* sp^3d^2 *hybridisation*
(iii) Paramagnetic *(iv) Diamagnetic*
(a) *(i) and (iii)* (b) *(i) and (iv)*
(c) *(ii) and (iii)* (d) *(ii) and (iv)*

Interpret (a) In $[Fe(CN)_6]^{3+}$, Fe is present as Fe^{3+}.

Fe^{3+} = [Ar] $3d^5$ $4s^0$

CN^- being strong field ligand pair up these unpaired electrons, so that now the complex have only one unpaired electron as

$[Fe(CN)_6]^{3-}$



Now, the two $3d$, one $4s$ and three $4p$ orbitals hybridise to give six d^2sp^3 hybridised orbitals which are occupied by electrons of CN^-

Since, the complex contain one unpaired electron, it is paramagnetic in nature.

Sample Problem 13 *Atomic number of* Mn, Fe *and* Co *are 25, 26 and 27 respectively. Which of the following inner orbital octahedral complex ions are diamagentic?* **[NCERT Exemplar]**

(i) $[Co(NH_3)_6]^{3+}$ *(ii)* $[Mn(CN)_6]^{3-}$
(iii) $[Fe(CN)_6]^{4-}$ *(iv)* $[Fe(CN)_6]^{3-}$
(a) *(i) and (ii) only* (b) *(ii) and (iii) only*
(c) *(i) and (iii) only* (d) *All of these*

Interpret (c) Co^{3+} and Fe^{2+} contains d^6 configuration and the unpaired electrons are paired by strong field ligands, *i.e.*, NH_3 and CN^-, so $[Co(NH_3)_6]^{3+}$ and $[Fe(CN)_6]^{4-}$ are diamagnetic complexes.

In Fe^{3+} and Mn^{3+} unpaired electrons remain even after pairing, so these are paramagnetic.

Sample Problem 14 *Amongst the following ions which one has the highest magnetic moment value?* **[NCERT]**

(a) $[Cr(H_2O)_6]^{3+}$
(b) $[Fe(H_2O)_6]^{2+}$
(c) $[Zn(H_2O)_6]^{2+}$
(d) *All have same magnetic moment*

Interpret (*b*) More the number of unpaired electrons, higher is the magnetic moment. So, first find the number of unpaired electrons to find magnetic moment.

The oxidation states of metals in the complexes along with the electronic configuration are given

(a) Cr^{3+} : $3d^3$ configuration; no. of unpaired electrons (n) = 3

(b) Fe^{2+} : $3d^6$ configuration; $n = 4$

(c) Zn^{2+} : $3d^{10}$ configuration; $n = 0$

Thus, the complex $[Fe(H_2O)_6]^{2+}$ with maximum number of unpaired electrons has the highest magnetic moment.

Sample Problem 15 *The spin only magnetic moment of* $[MnBr_4]^{2-}$ *is 5.9 BM. Predict the geometry of the complex ion?*

(a) *Tetrahedral* (b) *Square planar*

(c) *Octahedral* (d) *Trigonal pyramidal*

Interpret (*a*) Since, the coordination number of Mn^{2+} ion in the complex ion is 4, it will be either tetrahedral (sp^3 hybridisation) or square planar (dsp^2 hybridisation). But the fact that the magnetic moment of the complex ion is 5.9 BM suggests that it should be tetrahedral in shape rather than square planar because of the presence of five unpaired electrons in the *d*-orbitals.

Limitations of Valence Bond Theory

Although this theory described the formation, structure and magnetic behaviour of complexes sucessfully but it suffers from the following short comings :

1. It involves a number of assumptions.
2. It describes bonding in coordination compounds only qualitatively.
3. It does not offer any explanation for the optical absorption spectra of complexes.
4. It does not describe the detailed magnetic properties of coordination compounds.
5. It does not give a quantitative interpretation of the thermodynamic or kinetic stabilities of coordination compounds.
6. It does not make exact predictions regarding the tetrahedral and square planar structures of 4-coordinate complexes.
7. It does not distinguish between weak and strong ligands.

Crystal Field Theory

Most of the shortcomings of VBT of coordination compounds were removed in **Crystal Field Theory** (CFT). It attributes partial covalent character and partial ionic character to bonds. This **theory** was developed by **H. Bethe** and **V. Vleck** (1935) and proved to be more successful in explaining the bonding and properties of coordination complexes. **The theory is based upon the fact that the degenerate** (meaning energetically alike) ***d*-orbitals of** *metal ions are splitted energy wise due to the concentration of point charges in certain specific positions. This is seen because the energy of the orbitals lying in the direction of point charges increases more in comparison to orbitals lying in between the point charges as the electrons in former case experience greater repulsion than in latter case.* Thus, energy wise, two groups of orbitals are seen now, one with higher energy and other with lower energy. This splitting of 5 degenerate orbitals of metal ion into two sets of orbitals having different energies is called **crystal field splitting.** In case of octahedral complexes, e_g set ($d_{x^2-y^2}$, d_{z^2}) is of higher energy while in case of tetrahedral complexes t_{2g} set (d_{xy}, d_{yz}, d_{zx}) has higher energy.

The splitting of *d*-orbitals in octahedral and tetrahedral complexes is shown below

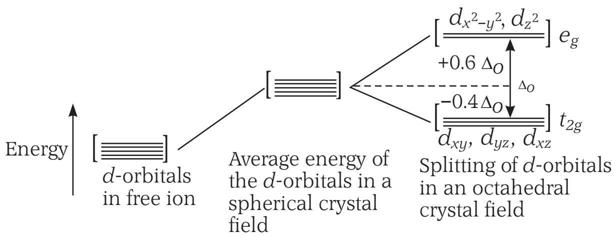


Fig. 9.4 *d*-orbital splitting in an octahedral crystal field.

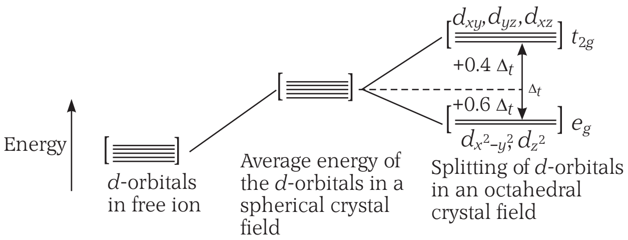

Fig. 9.5 *d*-orbital splitting in a tetrahedral crystal field

The difference in energy levels is arbitrarily taken to be Δ. The set of lower energy stabilises the complex ion by 0.4 units and that with higher energy destabilises the ion by 0.6 units. The gain in energy achieved by preferential filling of electrons in orbitals is called *crystal field stabilisation energy* (CFSE). *Higher the amount of* CFSE, *greater is the stability of the complex.*

The tetrahedral crystal field splitting is only 4/9 of the octahedral splitting and there is no known low spin tetrahedral complex.

Here, one point must always be kept in mind that **crystal field theory** considers purely electrostatic attractions between central metal ion and ligands. Factors which affect the magnitude of crystal field splitting are

1. Nature of ligands (the ligands with smaller size, large negative charge, with good σ donor and π acceptor properties will give large crystal field splitting). The

ligands are arranged in **spectro chemical series** on the basis of their crystal field splitting power as

$$I^- < Br^- < Cl^- < F^- < ox^- \approx H_2O < Py \approx NH_3 < en < NO_2^- < CN^- < CO$$

It is an experimentally determined series based on the absorption of light by complexes with different ligands. Let us assign electrons in the d-orbitals of metal ion in octahedral coordination entities. Obviously, the single d electron occupies one of the lower energy t_{2g} orbitals. In d^2 and d^3 coordination entities, the d-electrons occupy the t_{2g} orbitals singly in accordance with the Hund's rule. For d^4 ions, two possible patterns of electron distribution arise (i) the fourth electron could either enter the t_{2g} level and pair with an existing electron, or (ii) it could avoid paying the price of the pairing energy by occupying the e_g level. Which of these posibilities occurs, depends on the relative magnitude of the crystal field splitting, Δ_o and the pairing energy, P (P represents the energy required for electron pairing in a single orbital). *The two options are :*

(i) If $\Delta_o < P$, the fourth electron enters in one of the e_g orbitals giving the configuration $t_{2g}^3 e_g^1$. Ligands for which $\Delta_o < P$ are known as **weak field ligands** and form high spin complexes.

(ii) If $\Delta_o > P$, it becomes more energetically favourable for the fourth electron to occupy a t_{2g} orbital with configuration $t_{2g}^4 e_g^0$. Ligands which produce this effect are known as **strong field ligands** and form low spin complexes.

2. Oxidation state of metal ion (More crystal field splitting is seen in metal ions with higher oxidation states).
3. Size of d-orbital (larger the size, more crystal field splitting is seen).
4. Geometry of the complex (as splitting is different for tetrahedral and octahedral complexes).

The number of unpaired electrons in octahedral and tetrahedral complex having different configuration can be summarised in table 9.9

Table 9.8 **Number of Unpaired Electrons in Octahedral and Tetrahedral Complexes**

Electronic configuration	Octahedral complex		Number of unpaired electrons	Tetrahedral complex		Number of unpaired electrons
	(t_{2g} set)	(e_g set)		(e_g set)	(t_{2g} set)	
d^1	t_{2g}^1	e_g^0	1	e^1	t_2^0	1
d^2	t_{2g}^2	e_g^0	2	e^2	t_2^0	2
d^3	t_{2g}^3	e_g^0	3	e^2	t_2^1	3
d^4 (a)*	t_g^3	e_g^1	4	e^2	t_2^2	4
(b)*	t_g^4	e_g^0	2	e^4	t_2^0	0
d^5 (a)*	t_{2g}^3	e_g^2	5	e^2	t_2^3	5
(b)*	t_{2g}^5	e_g^0	1	e^4	t_2^1	1
d^6 (a)*	t_{2g}^4	e_g^2	4	e^3	t_2^3	4
(b)*	t_{2g}^6	e_g^0	0	e^4	t_2^2	2
d^7 (a)*	t_{2g}^5	e_g^2	3	e^4	t_2^3	3
(b)*	t_{2g}^6	e_g^1	1	e^4	t_2^3	3
d^8	t_{2g}^6	e_g^2	2	e^4	t_2^4	2
d^9	t_{2g}^6	e_g^3	1	e^4	t_2^5	1
d^{10}	t_{2g}^6	e_g^4	0	e^4	t_2^6	0

*[(a) is the configuration for high spin and (b) is the configuration for low spin complexes]

Sample **Problem 16** *The CFSE for octahedral* $[CoCl_6]^{4-}$ *is* 18,000 *cm*$^{-1}$. *The CFSE for tetrahedral* $[CoCl_4]^{2-}$ *will be*

[NCERT Exemplar]

(*a*) 18000 cm^{-1} (*b*) 16000 cm^{-1}
(*c*) 8000 cm^{-1} (*d*) 20000 cm^{-1}

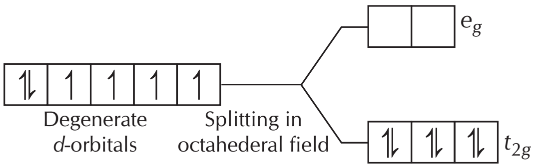
Interpret (*c*)

$$\Delta_t = -\frac{4}{9}\Delta_o$$
$$= -\frac{4}{9} \times 18000 = 8000 \text{ cm}^{-1}$$

Sample **Problem 17** *The electronic configuration of central matal atom/ion in* $[Co(CN)_6]^{3-}$ *is*

(*a*) $t_{2g}^5 e_g^0$ (*b*) $t_{2g}^4 e_g^2$ (*c*) $t_{2g}^6 e_g^0$ (*d*) $t_{2g}^4 e_g^3$

Interpret (*c*) $[Co(CN)_6]^{3-}$ *i.e.*, Co^{3+}



$$Co^{3+} = 3d^6 \text{ (or } t_{2g}^6 e_g)$$

There is no unpaired electron, so it is diamagnetic.

Sample **Problem 18** *Arrange the following complex ion in increasing order of crystal field splitting energy.* (Δ_o).
I. $[Cr(Cl)_6]^{3-}$, *II.* $[Cr(CN)_6]^{3-}$, *III.* $[Cr(NH_3)_6]^{3+}$

[NCERT Exemplar]

(*a*) *I* < *II* < *III* (*b*) *II* < *I* < *III*
(*c*) *III* < *II* < *I* (*d*) *I* < *III* < *II*

Interpret (*d*) CFSE is higher when the complex contains strong field ligand. Thus, crystal field splitting energy increases in the order $[Cr(Cl)_6]^{3-} < [Cr(NH_3)_6]^{3+} < [Cr(CN)_6]^{3-}$.

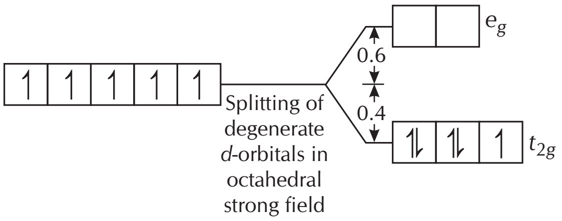
Because the order of field strength is

$$Cl^- < NH_3 < CN^-$$

Sample **Problem 19** *The CFSE for* $[Fe(CN)_6]^{3-}$ *is*

(*a*) −1.2 (*b*) −2.0 (*c*) −1.8 (*d*) +1.2

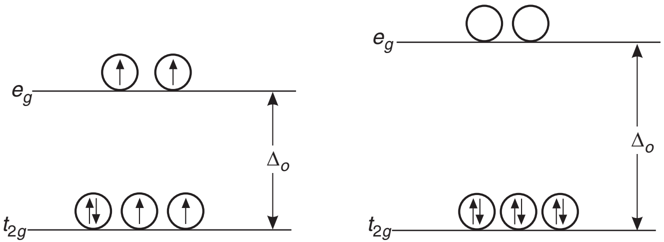
Interpret (*c*) $Fe^{3+} = [Ar]\,3d^5$



$$CFSE = -(0.4 \times t_{2g}e^-) + 0.6 \times e_g\, e^-$$
$$= -(0.4 \times 5) + 0.6 \times 0 = -2.0$$

Magnetic Properties

The diamagnetic (repulsion from applied magnetic field due to paired electrons) and **paramagnetic** (attraction from applied magnetic field due to unpaired electron) behaviour of coordination compounds can be explained on the basis of crystal field theory, *e.g.*, Co (III) shows diamagnetic properties in $[Co(NH_3)_6]^{3+}$ complex and paramagnetic properties in $[CoF_6]^{3-}$ complex. Such a difference in behaviour show that there must be some unpaired electrons in latter while former have all paired electrons (magnetic measurement shows the presence of four unpaired electrons in latter). This can be explained on the basis of crystal field theory if you observe the diagrams given below carefully.



(a) $[CoF_6]^{3-}$ complex (b) $[Co(NH_3)_6]^{3+}$ complex

Fig. 9.6 In fig. (a) as Δ_o is small, the energy required to pair up the 4th and 5th electron with the electrons in lower *d*-orbitals (t_{2g}) is higher as compared to that required to place the electron in higher *d*-orbital (e_g).
In fig. (b) as Δ_o is higher, the energy required to pair up the 4th and 5th electron with the electrons in lower *d*-orbitals (t_{2g}) is lower as compared to that required to place the electron in higher *d*-orbitals (e_g).

Magnetic moment (μ) is related to number of unpaired electrons '*n*' as, μ $\mu = \sqrt{n(n+2)}$ BM

Caution Point *The values of n calculated by applying the above formula for different magnetic moments are given in the following table :*

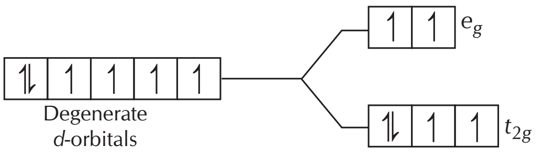
Magnetic moment (BM)	Number of unpaired electrons
1.73	1
2.83	2
3.87	3
4.90	4
5.92	5

Sample **Problem 20** *The magnetic moment of* $[CoF_6^{3-}]$ *by using CFT is*

[NCERT Exemplar]

(*a*) 0 (*b*) 4.9 (*c*) 5.9 (*d*) 1.73

Interpret (*b*) $[CoF_6]^{3-}$ *i.e.*, Co^{3+}



$$\text{Configuration of } Co^{3+} = 3d^6 \text{ (or } t_{2g}^4 e_g^2)$$

Number of unpaired electrons $(n) = 4$

$$\text{Magnetic moment } (\mu) = \sqrt{n(n+2)} = \sqrt{4\,(4+2)}$$
$$= \sqrt{24} = 4.9 \text{ BM}$$

Colour of the Complexes

A substance appears coloured because it absorbs light at specific wavelengths in the visible part of the electromagnetic spectrum (400 to 700 nm) and transmits or reflects the rest of the wavelength. Each wavelength of visible light represents a different colour. White light, such as sunlight, is a combination of all colours; an object that absorbs all visible light appears black.

When the energy of the photon ($h\nu$) is equal to the difference between the lower and higher *d*-orbital energy levels, an electtron is promoted from a lower to higher level. If the wavelength of the photon absorbed by an ion lies outside the visible region, then the transmitted light looks the same as the incident light white and the ion appears colourless.

The coloured nature of solutions of coordination compounds can also be explained on the basis of crystal field theory, because in coordination compounds the energy difference between two sets of *d*-orbitals is usually small (as explained by crystal field splitting) thus, excitation of an electron from lower energy to higher energy is very easy and can be achieved even by the absorption of low energy radiations of visible region. As a result of the absorption of such selected wavelengths of visible light, the complexes appeared coloured. Relationship between the λ of light absorbed and the colour observed can be examplified as

Table 9.9 **Wavelength Associated with Different Colours**

Coordination entity	Wavelength of light absorbed (nm)	Colour of light absorbed	Colour of coordination entity
$[CoCl(NH_3)_5]^{2+}$	535	Yellow	Violet
$[Co(NH_3)_5(H_2O)]^{3+}$	500	Blue green	Red
$[Co(NH_3)_6]^{3+}$	475	Blue	Yellow orange
$[Co(CN)_6]^{3-}$	310	Ultraviolet	Pale yellow
$[Cu(H_2O)_4]^{2+}$	600	Red	Blue
$[Ti(H_2O)_6]^{3+}$	498	Blue green	Purple

It is important to note that in the absence of ligand, crystal field splitting does not occur and hence, the substance is colourless. For example, removal of water from $[Ti(H_2O)_6]Cl_3$ on heating renders it colourless. Similarly, anhydrous $CuSO_4$ is white, but $CuSO_4 \cdot 5H_2O$ is blue in colour.

Sample **Problem 21** *The colour of the coordination compounds depends on the crystal field splitting. What will be the correct order of absorption of wavelength of light in the visible region, for the complexes,* $[Co(NH_3)_6]^{3+}$, $[Co(CN)_6]^{3-}$, $[Co(H_2O)_6]^{3+}$? **[NCERT Exemplar]**

(a) $[Co(CN)_6]^{3-} > [Co(NH_3)_6]^{3+} > [Co(H_2O)_6]^{3+}$

(b) $[Co(NH_3)_6]^{3+} > [Co(H_2O)_6]^{3+} > [Co(CN)_6]^{3-}$

(c) $[Co(H_2O)_6]^{3+} > [Co(NH_3)_6]^{3+} > [Co(CN)_6]^{3-}$

(d) $[Co(CN)_6]^{3-} > [Co(NH_3)_6]^{3+} > [Co(H_2O)_6]^{3+}$

Interpret (c) CFSE (Crystal field stabilisation energy) depends upon the strength of ligands.

Since, the order of splitting tendency of different ligands is as

$$H_2O < NH_3 < CN^-$$

Hence, the order of CFSE of different complexes is

$$[Co(H_2O)_6]^{3+} < [Co(NH_3)_6]^{3+} < [Co(CN)_6]^{3-}$$

Since, $$\text{Energy} \propto \frac{1}{\text{wavelength } (\lambda)}$$

$\therefore$ The order of absorption of wavelength is

$$[Co(H_2O)_6]^{3+} > [Co(NH_3)_6]^{3+} > [Co(CN)_6]^{3-}$$

Limitations of CFT

The crystal field theory can explain the spectra of the metal ions and complexes on the assumption that these arise from the transition of electrons from lower energy *d*-orbitals to higher energy *d*-orbitals. However, the position and intensities of spectral bands calculated on the basis of crystal field theory do not always coincide with those determined experimentally.

Apart from this, a pure electrostatic interaction between central metal ion and ligand fails to explain the relative positions of ligands in spectrochemical series. Along with this there is clear evidence that covalent bonding too makes a significant contribution towards the metal ligand bonding.

In the light of above written facts the crystal field theory was modified so as to include the contribution of covalent bonding in the metal ligand bond and is called **ligand field theory,** which assumes that the extent of covalent character in metal ligand bond is generally low as compared to the extent of the ionic character of the bond that means the conclusions arrived by the crystal field theory are still valid to a larger extent.

9.7 Stability of Complexes

The stability of a complex in solution is infact the degree of association between the two species involved in the state of equilibrium. The magnitude of the (stability or formation) equilibrium constant for the association, quantitatively expresses the stability. Thus, if we have a reaction of the type :

$$M + 4L \rightleftharpoons ML_4$$

then the *larger the stability constant K, the higher the proportion of* ML_4 *that exists in solution.* Alternatively $1/K$ values, called the **instability constant,** explain the dissociation of the complex into metal ion and ligands in the solution.

A coordination compound is formed in solution by the stepwise addition of ligands to a metal ion. Thus, the formation of the complex, ML_n (M = central metal cation, L = monodentate ligand and n = coordination number of metal ion) may be supposed to take place by the following n consecutive steps.

$$M + L \rightleftharpoons ML$$

$$K_1 = \frac{[ML]}{[M][L]}$$

$$ML + L \rightleftharpoons ML_2$$

$$K_2 = \frac{[ML_2]}{[M][L]}$$

$$ML_2 + L \rightleftharpoons ML_3$$

$$K_3 = \frac{[ML_3]}{[ML_2][L]}$$

$$\dots\ \dots\ \dots\ \dots\ \dots\ \dots\ \dots$$

$$\dots\ \dots\ \dots\ \dots\ \dots\ \dots\ \dots$$

$$ML_{n-1} + L \rightleftharpoons ML_n$$

$$K_n = \frac{[ML_n]}{[ML_{n-1}][L]}$$

$K_1, K_2, K_3, \dots, K_n$ are called stepwise stability constants. With a few exceptions, the values of successive stability constants decrease regularly from K_1 to K_n.

Alternatively, we can write the **overall stability constant** thus

$$M + 4L \rightleftharpoons ML_4$$

$$\beta_4 = \frac{[ML_4]}{[M][L]^4}$$

The stepwise and overall stability constant are therefore related as follows

$\beta_4 = K_1 \times K_2 \times K_3 \times K_4$ or more generally,

$\beta_i = K_1 \times K_2 \dots \times K_i$

Factors Affecting Stability of Complexes

The strength of a complex ion depends upon the following factors

(i) **Higher charge** of the central metal ion *i.e.,* greater ionic potential $\left(\frac{\text{ionic charge}}{\text{ionic radius}}\right)$ and greater is the stability.

(ii) **Greater base strength** of the ligand, greater will be the stability.

(iii) **Ring formation** (chelation) in structure of the complexes is the chief factor, which **increases** the stability of the complexes in solution.

(iv) If a multidentate ligand happens to be cyclic without any steric effects, a further increase in stability occurs. This is called **macrocyclic effect.**

Sample **Problem 22** *Which of the following complexes formed by* Cu^{2+} *ions is most stable?* **[NCERT Exemplar]**

(*a*) $Cu^{2+} + 4NH_3 \rightleftharpoons [Cu(NH_3)_4]^{2+}$, $\log K = 11.6$

(*b*) $Cu^{2+} + 4CN \rightleftharpoons [Cu(CN)_4]^{2-}$, $\log K = 27.3$

(*c*) $Cu^{2+} + 2en \rightleftharpoons [Cu(en)_2]^{2+}$, $\log K = 15.4$

(*d*) $Cu^{2+} + 4H_2O \rightleftharpoons [Cu(H_2O)_4]^{2+}$, $\log K = 8.9$

Interpret (*b*) Stability of complexes depends upon stability constant. Higher the value of *K*, more stable is the complex. Since, *K* is highest when log *K* is 27.3.

Thus, $[Cu(CN)_4]^{2-}$ is the most stable complex among the given.

9.8 Importance of Coordination Compounds

Some important applications of coordination compounds are as follows

1. In Qualitative and Quantitative Analysis

(i) Nickel is detected and estimated as its red dimethyl glyoxime complex which is a chelate complex.

(ii) Mg and Al are estimated as complexes of 8-hydro-oxyquinoline (oxime).

(iii) The separation of Ag^+ from Hg_2^{2+} in the first group of analysis is based on the fact that while, silver chloride is soluble in aqueous ammonia, Hg_2Cl_2 forms a black insoluble material.

$$AgCl + 2NH_4OH \longrightarrow \underset{\text{soluble}}{[Ag(NH_3)_2]Cl} + 2H_2O$$

$$Hg_2Cl_2 + NH_4OH \longrightarrow \underset{\text{(black insoluble)}}{Hg(NH_2)Cl} + Hg + HCl + H_2O$$

(iv) The separation of IIB group sulphides from IIA group sulphides is based on the fact that sulphides of IIB group form, complex sulphides with yellow ammonium sulphide which are soluble while, sulphides of IIA group do not react.

$$As_2S_5 + 3(NH_4)_2S \longrightarrow 2(NH_4)_3[AsS_4]$$
$$Sb_2S_5 + 3(NH_4)_2S \longrightarrow 2(NH_4)_3[SbS_4]$$
$$SnS_2 + (NH_4)_2S \longrightarrow (NH_4)_2[SnS_3]$$

(v) The detection of Cu^{2+} is based on the formation of a blue tetra-ammine copper sulphate complex, which gives a deep blue coloured solution upon addition of NH_3 to Cu^{2+} ions.

$$CuSO_4 + 4NH_3 \longrightarrow [Cu(NH_3)_4]SO_4$$

It also forms a chocolate coloured precipitate with potassium ferrocyanide.

$$2CuSO_4 + K_4Fe(CN)_6 \longrightarrow \underset{\text{chocolate ppt.}}{Cu[Fe(CN)_6]} + 2K_2SO_4$$

(vi) Fe^{3+} is detected by formation of a blood red coloured complex with KSCN.

$$Fe^{3+} + KSCN \longrightarrow \underset{\substack{\text{blood red}\\\text{colour}}}{[Fe(SCN)]^{2+}} + K^+$$

(vii) S^{2-} is detected by the formation of a violet-coloured complex with sodium nitroprusside.

$$Na_2S + \underset{\substack{\text{sodium}\\\text{nitroprusside}}}{Na_2[Fe(CN)_5NO]} \longrightarrow \underset{\text{violet colour}}{Na_4[Fe(CN)_5NOS]}$$

(viii) EDTA is used in the complexometric determination of several metal ions such as Ca^{2+}, Zn^{2+}, Fe^{2+}, Co^{2+}, Ni^{2+}, etc.

2. In the Extraction of Metals

The formation of complex compounds is used in the extraction of some metals *e.g.,* Ag and Au are extracted as follows

$$2K[Ag(CN)_2] + Zn \longrightarrow K_2[Zn(CN)_4] + \underset{\text{silver}}{2Ag}$$

It is due to more electropositive nature of Zn as compared to Ag and Au.

Nickel tetracarbonyl complex is used for the extraction and purification of nickel.

$$\underset{\substack{\text{(associated with}\\\text{other elements)}}}{Ni} + 4\,CO \longrightarrow [Ni(CO)_4] \xrightarrow{\text{Heating}} Ni + 4CO$$

3. In Biological World

Cyclic ligands impart extra stability to coordinate compounds. Thus, Mg in chlorophyll and iron in haemoglobin are stable towards dissociation due to the formation of coordination compounds. Haemoglobin of the blood gets oxygenated through the binding of dioxygen, O_2 to the ferrous ions in haemoglobin.

4. Role of Coordination Compounds in Medicinal Chemistry

(i) The platinum complex *cis*-$[Pt(NH_3)_2Cl_2]$ (*cis*-platin) is used in the treatment of cancer.

(ii) EDTA complex of calcium is used in the treatment of lead poisoning. Ca-EDTA is a weak complex, when it is administered, calcium in the complex is replaced by the lead present in the body and is eliminated in the urine.

(iii) The excess of copper and iron present in animal system are removed by the chelating ligands *D*-penicillamine and desferroxime *B via* the formation of complexes.

5. In Estimation of Hardness of Water

EDTA is a hexadentate ligand and forms complex with various metal ions. This is used in the estimation of hardness of water by a volumetric method. Hardness of water is due to Ca^{2+} and Mg^{2+} ions. Since, stability constant values of EDTA complex with Ca^{2+} and Mg^{2+} are 10^7 and 10^8 respectively, it helps in selective estimation of different ions.

6. In Electroplating of Metals

Coordination compounds are used in **electroplating industry** *e.g.,* gold and silver are electroplated from their coordination compounds, such as $K[Ag(CN)_2]$ or $K[Au(CN)_4]$.

7. As Catalysts

A coordination complex of Ti and Al is used as a catalyst to convert ethylene and propylene into polyethene. *Ziegler-Natta* catalyst is $TiCl_4 + (C_2H_5)_3Al$ or $(CH_3)_3Al$.

8. In Pigments

Many pigments such as phthalocyanines used in paints are the coordination compounds.

Check Point 3

1. The hexaaqua complex $[Ni(H_2O)_6]^{2+}$ is green whereas, the corresponding ammonia complex $[Ni(NH_3)_6]^{2+}$ is violet. Explain.
2. Explain $[CoF_6]^{3-}$ is paramagnetic but $[Co(CN)_6]^{3-}$ is diamagentic.
3. Why is ligand field theory also called crystal field theory?
4. All the octahedral complexes of Ni^{2+} must be outer orbital complexes. Explain, why?

WORKED **OUT**
Examples

Example 1 *Which of the following complexes do not follow EAN rule?*

(a) $[Fe(CN)_6]^{4-}$ (b) $[Fe(CN)_6]^{3-}$

(c) $Ni(CO)_4$ (d) $[PdCl_4]^{2-}$

Solution (b) According to Sidgwick,

EAN = atomic number of nearest noble gas

In case of $[Fe(CN)_6]^{3-}$,

$$\begin{aligned}\text{EAN} &= 26 - 3 + 2 \times 6\\ &= 35\end{aligned}$$

While, the atomic number of nearest noble gas is 36. Thus, it does not follow EAN rule.

Example 2 *An aqueous solution of titanium chloride, when subjected to magnetic measurement, measured zero magnetic moment. The formula of the complex assuming it to be octahedral in aqueous solution is*

(a) $[Ti(H_2O)_6]Cl_4$ (b) $[Ti(H_2O)_6]Cl_3$

(c) $[Ti(H_2O)_5Cl]Cl_2$ (d) $[Ti(H_2O)_6]Cl$

Solution (a) $Ti_{22} = [Ar]\,3d^2 4s^2$

Since, its magnetic moment is zero, it is present in the form of Ti^{4+}. Thus, the formula of the complex is $[Ti(H_2O)_6]Cl_4$ as only in it the oxidation state of Ti is +4.

Example 3 *A metal complex having composition* $Cr(NH_3)_4Cl_2Br$ *has been isolated in two forms A and B. A reacts with* $AgNO_3$ *producing a white precipitate which was soluble in dilute ammonia solution. B reacts with* $AgNO_3$ *producing a pale yellow precipitate soluble in concentrated ammonia solution. The formulae of A and B are respectively*

(a) $[Cr(NH_3)_4Br]Cl_2$; $[Cr(NH_3)Cl_2]Br$

(b) $[Cr(NH_3)_4BrCl]Cl$; $[Cr(NH_3)_3Cl_2Br]NH_3$

(c) $[Cr(NH_3)_4Cl_2]Br$; $[Cr(NH_3)_4BrCl]Cl$

(d) $[Cr(NH_3)_4BrCl]Cl$; $[Cr(NH_3)_4Cl_2]Br$

Solution (d) Since, the compound *A* gives white precipitate with $AgNO_3$, which is soluble in dilute ammonia solution, it contains at least one Cl atom outside the coordination sphere. Thus, its formula is $[Cr(NH_3)_4BrCl]Cl$.

$$[Cr(NH_3)_4BrCl]Cl \longrightarrow [Cr(NH_3)_4BrCl]^+ + Cl^-$$

$$AgNO_3 + Cl^- \longrightarrow \underset{\text{white ppt}}{AgCl} + NO_3^-$$

Similarly, compound *B* gives a yellow precipitate which is soluble in concentrated ammonia solution, it contains a Br atom outside the sphere. Thus, its formula must be $[Cr(NH_3)_4Cl_2]Br$.

$$[Cr(NH_3)_4Cl_2]Br \longrightarrow [Cr(NH_3)_4Cl_2]^+ + Br^-$$

$$Br^- + AgNO_3 \longrightarrow \underset{\substack{\text{pale yellow}\\ \text{ppt}}}{AgBr} + NO_3^-$$

Example 4 *The complex ion which has no d-electrons in the central metal atom is*

(a) $[MnO_4]^-$ (b) $[Co(NH_3)_6]^{3+}$

(c) $[Fe(CN)_6]^{3-}$ (d) $[Cr(H_2O)_6]^{3+}$

Solution (a) In $[MnO_4]^-$, the oxidation state of Mn is +7.

$$Mn\,(25) = [Ar]\,3d^5 4s^2$$

$$Mn^{7+} = [Ar]$$

Thus, in $[MnO_4]^-$ no *d*-electron is present.

Example 5 *Amongst the following, the lowest degree of paramagnetism per mole of the compound at 298 K will be shown by*

(a) $MnSO_4 \cdot 4H_2O$ (b) $NiSO_4 \cdot 6H_2O$

(c) $FeSO_4 \cdot 6H_2O$ (d) $CuSO_4 \cdot 5H_2O$

Solution (d) In $MnSO_4 \cdot 4H_2O$, Mn is present as Mn^{2+}.

$$Mn^{2+} = \overset{3d^5}{\begin{array}{|c|c|c|c|c|}\hline \uparrow & \uparrow & \uparrow & \uparrow & \uparrow \\ \hline\end{array}}\quad \overset{4s^0}{\begin{array}{|c|}\hline \\ \hline\end{array}}\quad \text{(unpaired electrons = 5)}$$

In $CuSO_4 \cdot 5H_2O$, Cu is present as Cu^{2+}.

$$Cu^{2+} = \overset{3d^9}{\begin{array}{|c|c|c|c|c|}\hline \uparrow\downarrow & \uparrow\downarrow & \uparrow\downarrow & \uparrow\downarrow & \uparrow \\ \hline\end{array}}\quad \overset{4s^0}{\begin{array}{|c|}\hline \\ \hline\end{array}}\quad \text{(unpaired electron = 1)}$$

In $FeSO_4 \cdot 6H_2O$, Fe is present as Fe^{2+}

$$Fe^{2+} = \overset{3d^6}{\begin{array}{|c|c|c|c|c|}\hline \uparrow\downarrow & \uparrow & \uparrow & \uparrow & \uparrow \\ \hline\end{array}}\quad \overset{4s^0}{\begin{array}{|c|}\hline \\ \hline\end{array}}\quad \text{(unpaired electrons = 4)}$$

In $NiSO_4 \cdot 6H_2O$, Ni is present as Ni^{2+}

$$Ni^{2+} = \overset{3d^8}{\begin{array}{|c|c|c|c|c|}\hline \uparrow\downarrow & \uparrow\downarrow & \uparrow\downarrow & \uparrow & \uparrow \\ \hline\end{array}}\quad \overset{4s^0}{\begin{array}{|c|}\hline \\ \hline\end{array}}\quad \text{(unpaired electrons = 2)}$$

Since, paramagnetic character $\propto$ unpaired electrons.

Thus, $CuSO_4 \cdot 5H_2O$ has the lowest degree of paramagnetism among the given at 298 K.

Example 6 *Which of the following compounds has same oxidation state of the central metal atom in the cationic and anionic part?*

(*a*) $[Pt(NH_3)_4][PtCl_6]$ (*b*) $[Pt(py)_4][PtCl_4]$

(*c*) $[Pt(NH_3)_4Cl_2][PtCl_4]$ (*d*) $K_4[Ni(CN)_6]$

Solution (*b*) $[Pt(py)_4][PtCl_4]$

Let the oxidation state of Pt is *x*.

$$x + 0 \times 4 + x + (-1) \times 4 = 0$$
$$2x = 4$$
$$x = +2$$

Thus, it is the complex in which the central metals atom in cationic and anionic parts have same oxidation state.

Example 7 *The most stable ion is*

(*a*) $[Fe(OH)_5]^{3-}$ (*b*) $[FeCl_6]^{3-}$

(*c*) $[Fe(CN)_6]^{3-}$ (*d*) $[Fe(H_2O)_6]^{3+}$

Solution (*c*) Stability of complex increases with increase in charge on the central metal ion and with increase in basic strength of ligand.

In $[Fe(CN)_6]^{3-}$, oxidation state of Fe is $+3$ and basicity of CN^- is higher than that of OH^-, Cl^- and H_2O. Thus, $[Fe(CN)_6]^{3-}$ is the most stable ion among the given.

Example 8 *The pair in which both species have same magnetic moment (spin only value) is*

(*a*) $[Cr(H_2O)_6]^{2+}, [CoCl_4]^{2-}$

(*b*) $[Cr(H_2O)_6]^{2+}, [Fe(H_2O)_6]^{2+}$

(*c*) $[Mn(H_2O)_6]^{2+}, [Cr(H_2O)_6]^{2+}$

(*d*) $[CoCl_4]^{2-}, [Fe(H_2O)_6]^{2+}$

Solution (*b*) Species having the same number of unpaired electrons, have same magnetic moment because magnetic moment is related with number of unpaired electrons (*n*) as, $\mu = \sqrt{n(n+2)}$

$Cr^{2+} = [Ar]\,3d^4$ (4 unpaired electrons)

$Co^{2+} = [Ar]\,3d^7$ (3 unpaired electrons)

$Mn^{2+} = [Ar]\,3d^5$ (5 unpaired electrons)

$Fe^{2+} = [Ar]\,3d^6$ (4 unpaired electrons)

Thus, $[Cr(H_2O)_6]^{2+}$ and $[Fe(H_2O)_6]^{2+}$ have same magnetic moment.

Example 9 *Identify the complexes which is expected to be coloured.*

(*a*) $[Ti(NO_3)_4]$ (*b*) $[Cu(NCCH_3)]^+BF_4$

(*c*) $[Fe(CN)_6]^{4-}$ (*d*) $K_3[VF_6]$

Solution (*d*) (a) In $[Ti(NO_3)_4]$, ON of Ti is $+4$.

Hence, in Ti(IV) $(1s^2, 2s^2, 2p^6, 3s^2, 3p^6)$ incomplete *d*-orbital is not present, so it is colourless.

(b) In $[Cu(NCCH_3)]^+ BF_4^-$, ON of Cu is $+1$.

Hence, in Cu(I) $[1s^2, 2s^2 2p^6, 3s^2, 3p^6, 3d^{10}]$ incomplete *d*-orbital is not present, so it is also colourless.

(c) In $[Fe(CN)_6]^{4-}$, ON of Fe is $+2$.

Hence, Fe(II) $[1s^2, 2s^2, 2p^6, 3s^2, 3p^6, 3d^6]$ But CN^-, being a strong field ligand, causes pairing, thus no unpaired electron is present in *d*-orbital. Hence, it is also colourless.

(d) In $K_3[VF_6]$, ON of V is $+3$.

Hence, V(III) $(1s^2, 2s^2, 2p^6, 3s^2, 3p^6, 3d^2)$ incomplete *d*-orbitals are present, so it is coloured.

Example 10 *A solution made by dissolving* 0.875 g *of compound* $Co(NH_3)_4Cl_3$ *in* 25 g *of water freezes at* $-0.56°C$. *The structural formula of the complex, if cryoscopic constant of water is* 1.86 *K kg mol*$^{-1}$, *is*

(*a*) $[Co(NH_3)_4]Cl_3$ (*b*) $[Co(NH_3)_4Cl]Cl_2$

(*c*) $[Co(NH_3)_4Cl_2]Cl$ (*d*) $[Co(NH_3)_3Cl_3]NH_3$

Solution (*c*) $-\Delta T_f = 0.56 = i \times 1.86 \times \dfrac{0.875}{233.5} \times \dfrac{1000}{25}$

$[\because \ \Delta T_f = i\,k_f \cdot m]$

$\therefore \quad i = 2$

Hence, the formula of the complex ion is $[Co(NH_3)_4Cl_2]Cl$.

[For details see chapter 2 'solutions']

Start **Practice** *for* JEE Main

Round I (Topically Divided Problems)

General Terms Related to Coordination Compounds

1. Potassium ferrocyanide is a

(a) complex salt (b) double salt
(c) normal salt (d) mixed salt

2. In the compound lithium tetrahydroaluminate, the ligand is

(a) H (b) H^+
(c) H^- (d) None of these

3. A chelating agent has two or more than two donor atoms to bind to a single metal ion. Which of the following is not a chelating agent? **[NCERT Exemplar]**

(a) Thiosulphato
(b) Oxalato
(c) Glycinato
(d) Ethane-1,2-diamine

4. Which of the following species is not excepted to be a ligand? **[NCERT Exemplar]**

(a) NO (b) NH_4^+
(c) $NH_2CH_2CH_2NH_2$ (d) CO

5. The oxidation number of cobalt in $K[Co(CO)_4]$ is **[NCERT]**

(a) +1 (b) +3
(c) −1 (d) −3

6. The coordination number of Pt in $[Pt(NH_3)_4Cl_2]^{2+}$ ion is

(a) 2 (b) 4
(c) 6 (d) 8

7. EDTA has coordination number

(a) 3 (b) 4 (c) 5 (d) 6

8. The effective atomic number of cobalt in the complex $[Co(NH_3)_6]^{3+}$ is

(a) 36 (b) 24
(c) 33 (d) 30

9. The pair of the compounds in which both the metals are in the higher possible oxidation state is

(a) CrO_2Cl_2, MnO_4^- (b) $[Co(CN)_6]^{3-}, MnO_3$
(c) TiO_3, MnO_2 (d) $[Fe(CN)_6]^{3-}, [Co(CN)_6]^{3-}$

10. Given the molecular formula of the hexa coordinated complexes (*A*) $CoCl_3 \cdot 6NH_3$ (*B*) $CoCl_3 \cdot 5NH_3$ (*C*) $CoCl_3 \cdot 4NH_3$. If the number of coordinated NH_3 molecules in *A*, *B*, and *C* respectively are 6, 5 and 4, primary valency in (*A*), (*B*) and (*C*) are

(a) 0, 1, 2 (b) 3, 2, 1
(c) 6, 5, 4 (d) 3, 3, 3

11. In the complex $K_2Fe[Fe(CN)_6]$

(a) the complex is high spin complex
(b) both Fe atoms are in the same oxidation state
(c) the coordination number of iron is 4
(d) both Fe atoms are in different oxidation state

12. Complex salt can be made by the combination of $[Co^{III}(NH_3)_5Cl]^x$ with

(a) Cl^- (b) $2Cl^-$
(c) PO_4^{3-} (d) $2K^+$

13. How many ions are produced, from the complex, $Co(NH_3)_6Cl_2$ in solution? **[NCERT]**

(a) 6 (b) 4 (c) 3 (d) 2

14. What is the coordination entity formed when excess of aqueous KCN is added to an aqueous solution of copper sulphate? **[NCERT]**

(a) CuCN (b) $K_3[Cu(CN)_6]$
(c) $K[Cu(CN)_4]$ (d) $K_2[Cu(CN)_4]$

15. When 1 mole of $CrCl_3 \cdot 6H_2O$ is treated with excess of $AgNO_3$, 3 moles of AgCl are obtained. The formula of the complex is **[NCERT Exemplar]**

(a) $[CrCl_3(H_2O)_3] \cdot 3H_2O$ (b) $[CrCl_2(H_2O)_4]Cl \cdot 2H_2O$
(c) $[CrCl(H_2O)_5]Cl_2 \cdot H_2O$ (d) $[Cr(H_2O)_6]Cl_3$

16. Which of the following ions forms most stable complex compound?
(a) Fe^{3+} (b) Mn^{2+}
(c) Ni^{2+} (d) Cu^{2+}

17. Ammonia forms the complex ion $[Cu(NH_3)_4]^{2+}$ with copper ions in alkaline solution but not in acidic solution. What is the reason for it?
(a) In acidic solutions, hydration protects copper ions.
(b) In alkaline solution, insoluble $Cu(OH)_2$ is precipitated.
(c) Copper hydroxide is an amphoteric substance
(d) In acidic solutions, protons coordinate with ammonia molecules forming NH_4^+ ions and NH_3 molecules are not available

18. Amongst the following, the most stable complex is **[NCERT]**
(a) $[Fe(H_2O)_6]^{3+}$ (b) $Fe(NH_3)_6]^{3+}$
(c) $[Fe(C_2O_4)_3]^{3-}$ (d) $[FeCl_6]^{3-}$

Nomenclature of Coordination Compounds

19. The correct IUPAC name of $[Pt(NH_3)_2Cl_2]$ is **[NCERT Exemplar]**
(a) diamminedichloridoplatinum (II)
(b) diamminedichloridoplatinum (IV)
(c) diamminedichloridoplatinum (0)
(d) dichloridodiammineplatinum (IV)

20. IUPAC name of $[Pt(NH_3)_2Cl(NO_2)]$ is **[NCERT Exemplar]**
(a) platinum diaminechloronitrite
(b) chloronitrito-N-ammineplatinum (II)
(c) diamminechloridonitrito-N-platinum (II)
(d) diamminechloronitrito-N-platinate (II)

21. The IUPAC name of the coordination compound $K_2[Zn(OH)_4]$ is
(a) potassium tetrahydroxozinc (II)
(b) dipotassium tetrahydroxo zinc (II)
(c) potassium tetrahydroxozincate (II)
(d) potassium tetrahydroxozincate (III)

22. Pick the correct name of $[Co(NH_3)_5Cl]Cl_2$.
(a) chloropentamminecobalt (III) chloride
(b) chloropentamminecobalt (III)
(c) chloropentamminecobalt (II) chloride
(d) pentamminechloridocobalt (III) chloride

23. The IUPAC name of $K_2[Cr(CN)_2O_2(O)_2(NH_3)]$ is
(a) potassium amminedicyanodioxoperoxochromate (VI)
(b) potassium amminecyanoperoxodioxochromatic (IV)
(c) potassium amminecyanoperoxodioxochromium (IV)
(d) potassium amminecyanoperoxodioxochromium (IV)

24. The correct name of $[Pt(NH_3)_4Cl_2][PtCl_4]$ is
(a) tetrachloridoplatinum (II) dichloridotetrammine platinate
(b) dichloridotetrammineplatinum (IV) tetrachlorido platinate (II)
(c) tetramminedichloridoplatinum (IV) tetrachlorido platinate (II)
(d) tetrachloridoplatinum (II) tetrammineplatinate (IV)

25. The IUPAC name of $[Ni(NH_3)_4][NiCl_4]$ is
(a) tetrachloridonickel (II) tetraamminenickel (II)
(b) tetraamminenickel (II) tetrachloridonickel (II)
(c) tetraamminenickel (II) tetrachloridonickelate (II)
(d) tetrachloridonickel (II) tetraamminenickel (0)

Isomerism in Coordination Compounds

26. The compounds $[Co(SO_4)(NH_3)_5]Br$ and $[Co(SO_4)(NH_3)_5]Cl$ represent **[NCERT Exemplar]**
(a) linkage isomerism
(b) ionisation isomerism
(c) coordination isomerism
(d) no isomerism

27. The complexes $[Co(NH_3)_6][Cr(C_2O_4)_3]$ and $[Cr(NH_3)_6][Co(C_2O_4)_3]$ exhibit
(a) geometrical isomerism
(b) ionisation energy
(c) coordination isomerism
(d) linkage isomerism

28. Which of the following cannot show linkage isomerism?
(a) NO_2^- (b) NH_3
(c) CN^- (d) SCN^-

29. Due to the presence of ambidentate ligands coordination compounds show isomerism. Palladium complexes of the type $[Pd(C_6H_5)_2(SCN)_2]$ and $[Pd(C_6H_5)_2(NCS)_2]$ are **[NCERT Exemplar]**
(a) linkage isomers (b) coordination isomers
(c) ionisation isomers (d) geometrical isomers

30. What kind of isomerism exists between $[Cr(H_2O)_6]Cl_3$ (violet) and $[Cr(H_2O)_5Cl]Cl_2 \cdot H_2O$ (greyish-green)? **[NCERT Exemplar]**
(a) Linkage isomerism (b) Solvate isomerism
(c) Ionisation isomerism (d) Coordination isomerism

31. Optical isomerism is shown by octahedral complexes
(a) having all monodentate ligands
(b) having all the three bidentate ligands
(c) having two *trans* bidentate ligands
(d) having two *trans* monodentate ligands

32. Which of the following will exhibit optical isomerism?
(a) $[Cr(en)(H_2O)_4]^{3+}$ (b) $[Cr(en)_3]^{3+}$
(c) *trans*-$[Cr(en)_2Cl_2]^+$ (d) $[Cr(NH_3)_6]^{3+}$

33. Which one of the following is expected to exhibit optical isomerism [en = ethylenediamine]?
(a) *Trans*-$[Co(en)_2Cl_2]$
(b) *Cis*-$[Pt(NH_3)_2Cl_2]$
(c) *Cis*-$[Co(en)_2Cl_2]$
(d) *Trans*-$[Pt(NH_3)_2Cl_2]$

34. Indicate the complex ion which shows geometrical isomerism. **[NCERT Exemplar]**
(a) $[Cr(H_2O)_4Cl_2]^+$ (b) $[Pt(NH_3)_3Cl]$
(c) $[Co(NH_3)_6]^{3+}$ (d) $[Co(CN)_5(NCl)]^{3-}$

35. The total number of possible isomers for the complex compound $[Cu(NH_3)_4][PtCl_4]$
(a) 6 (b) 5
(c) 4 (d) 3

36. For square planar complex of platinum (II), $[Pt(NH_3)(Br)(Cl)Py)]^{2+}$, how many isomeric forms are possible?
(a) Two (b) Three
(c) Four (d) Six

37. Among the geometrical isomers of $[Pt(NH_3)(Br)(Cl)(Py)]$ how many will exhibit optical isomers? **[NCERT]**
(a) 0 (b) 1
(c) 2 (d) All

38. A complex of the type $[M(AA)_2X_2]^{n+}$ is known to be optically active. What does this indicate about the structure of the complex? **[NCERT Exemplar]**
(a) It has an octahedral geometry
(b) It is a tetrahedral complex
(c) It is a *trans* complex
(d) None of the above

Bonding in Coordination Compounds

39. Among the following ions, which one has the highest unpaired electrons?
(a) $[Cr(H_2O)_6]^{3+}$ (b) $[Zn(H_2O)_6]^{2+}$
(c) $[Fe(H_2O)_6]^{2+}$ (d) $[Fe(H_2O)_6]^{3+}$

40. $[Pt(NH_3)_4]Cl_2$ is
(a) pyramidal (b) pentagonal
(c) tetrahedral (d) square planar

41. Which one is an example of octahedral complex?
(a) $Cu(NH_3)_4^{2+}$ (b) FeF_6^{3-}
(c) $Zn(NH_3)_4^{2+}$ (d) $Ni(CN)_4^{2-}$

42. The species having tetrahedral shape is
(a) $[NiCl_4]^{2-}$ (b) $[Ni(CN)_4]^{2-}$
(c) $[PdCl_4]^{2-}$ (d) $[Pd(CN)_4]^{2-}$

43. The geometry of $Ni(CO)_4$ and $Ni(PPh_3)_2Cl_2$ are
(a) square planar and tetrahedral respectively
(b) Both tetrahedral
(c) tetrahedral and square planar respectively
(d) Both square planar

44. What is the magnetic moment of $K_3[FeF_6]$?
(a) 3.87 BM (b) 4.89 BM
(c) 5.91 BM (d) 6.92 BM

45. The value of 'spin only' magnetic moment for one of the following configuration is 2.84 BM. The correct one is
(a) d^4 (in weak ligand field)
(b) d^4 (in strong ligand field)
(c) d^3 (in weak as well as in strong field)
(d) d^5(in strong ligand field)

46. Why do compounds having similar geometry have different magnetic moment? **[NCERT Exemplar]**
(a) Due to different reactivity
(b) Due to their labile nature
(c) Due to the presence of weak and strong field ligands
(d) None of the above

47. $CuSO_4 \cdot 5H_2O$ is blue in colour while $CuSO_4$ is colourless why? **[NCERT Exemplar]**
(a) Because H_2O is a strong field ligand than SO_4^{2-}
(b) Because SO_4^{2-} is a strong field ligand
(c) Because $CuSO_4$ is not a complex
(d) Because no *d-d* transition is possible in $CuSO_4$

48. Among $[Fe(H_2O)_6]^{3+}$, $[Fe(CN)_6]^{3-}$, $[Fe(Cl)_6]^{3-}$ species, the hybridisation state of the Fe atom are, respectively.
(a) d^2sp^3, d^2sp^3, sp^3d^2
(b) sp^3d^2, d^2sp^3, d^2sp^3
(c) sp^3d^2, d^2sp^3, sp^3d^2
(d) None of the above

49. Amongst $Ni(CO)_4$, $[Ni(CN)_4]^{2-}$ and $[NiCl_4]^{2-}$
(a) $Ni(CO)_4$ is diamagnetic, $[NiCl_4]^{2-}$ and $[Ni(CN)_4]^{2-}$ are paramagnetic
(b) $Ni(CO)_4$ and $[NiCl_4]^{2-}$ are diamagnetic and $[Ni(CN)_4]^{2-}$ is paramagnetic
(c) $Ni(CO)_4$ and $[Ni(CN)_4]^{2-}$ are diamagnetic and $[NiCl_4]^{2-}$ is paramagnetic
(d) $[NiCl_4]^{2-}$ and $[Ni(CN)_4]^{2-}$ are diamagnetic and $Ni(CO)_4$ is paramagnetic

50. $[Fe(CN)_6]^{4-}$ and $[Fe(H_2O)_6]^{2+}$ are of different colours in dilute solutions. This is because of **[NCERT]**

(a) difference in the nature of ligands
(b) the presence of unpaired electrons
(c) the *d-d* transition
(d) All of the above

51. On the basis of VBT, find which is an inner orbital complex with 0 magnetic moment? **[NCERT Exemplar]**

(a) $[Mn(CN)_6]^{3-}$
(b) $[Co(NH_3)_6]^{3+}$
(c) $[Cr(H_2O)_6]^{3+}$
(d) $[FeCl_6]^{4-}$

52. The low spin tetrahedral complexes are not formed because

(a) $\Delta_t > P$
(b) $\Delta_t < P$
(c) $\Delta_t \geq P$
(d) $\Delta_t > \Delta_0$

53. The correct order for the wavelengths of absorption in the visible region for the following is
I. $[Ni(NO_2)_6]^{4-}$ II. $[Ni(NH_3)_6]^{2+}$ III. $[Ni(H_2O)_6]^{2+}$ **[NCERT]**

(a) I > II > III
(b) II > I > III
(c) III > II > I
(d) III > I > II

54. Calculate the overall complex dissociation equilibrium constant for the $Cu(NH_3)_4^{2+}$ ions, given that β_4 for this complex is 2.1×10^{13}.

(a) 8.27×10^{-13}
(b) 4.7×10^{-14}
(c) 2.39×10^{-7}
(d) 1.83×10^{14}

55. Which of the following pair is not correctly matched?

(a) Absorption peak for $[Cr^{III}(NH_3)_6]^{3+} = 21680\ cm^{-1}$
(b) Effective atomic no. of Pt in $[PtCl_6]^{2-} = 84$
(c) Crystal field stabilisation energy of d^2 in weak ligand field $= (-)0.8\ \Delta_o$
(d) Example of weak ligand field for d^5 configuration $= [Mn^{II}F_6]^{4-}$

Applications of Coordination Compounds

56. Coordination compounds have great importance in biological systems. In this context which of the following statements is incorrect?

(a) Haemoglobin is the red pigment of blood and contains iron
(b) Cyanocobalamin is B_{12} and contains cobalt
(c) Chlorophylls are green pigments in plants and contains calcium
(d) Carboxypeptidase-A, an enzyme, contains zinc

57. The complex used as an anticancer agent is

(a) *cis*-$[PtCl_2(NH_3)_2]$
(b) Na_2CO_3
(c) *trans*-$[Co(NH_3)_3Cl_3]$
(d) *cis*-$K_2[PtCl_2Br_2]$

58. Dimethyl glyoxime gives a red precipitate with Ni^{2+} which is used for its detection. To get this precipitate readily, the best pH range is

(a) < 1
(b) 3–4
(c) 9–11
(d) 2–3

59. When EDTA solution is added to Mg^{2+} ion solution, then which of the following statements is not true?

(a) Four coordinate sites of Mg^{2+} are occupied by EDTA and remaining two sites are occupied by water molecules
(b) All six coordinate sites of Mg^{2+} are occupied
(c) pH of the solution is decreased
(d) Colourless $[Mg\text{-}EDTA]^{2-}$ chelate is formed

Round II (Mixed Bag)

Only One Correct Option

1. The coordination number and oxidation state of Cr in $K_3[Cr(C_2O_4)_3]$ are respectively

(a) +6 and +3
(b) 3 and 0
(c) 4 and +2
(d) 3 and +3

2. The oxidation state of Fe in the brown ring complex $[Fe(H_2O)_5NO]SO_4$ is

(a) +3
(b) 0
(c) +2
(d) +1

3. Which of the following statements is correct?

(a) In $K_3[Fe(CN)_6]$, the ligand has satisfied both primary and secondary valencies of ferric ion.
(b) In $[Cu(NH_3)_4]SO_4$, the ligand has satisfied only the secondary valency of copper.
(c) In $K_3[Fe(CN)_6]$, the ligand has satisfied only the secondary valency of ferric ion.
(d) Both (b) and (c)

4. According to IUPAC nomenclature sodium nitroprusside is named as

(a) sodium pentacyanonitrosylferrate (II)
(b) sodium pentacyanonitrosylferrate (III)
(c) sodium nitroferricyanide
(d) sodium nitroferrocyanide

5. I. $K_4[Fe(CN)_6]$ II. $K_3[Cr(CN)_6]$
III. $K_3[Co(CN)_6]$ IV. $K_2[Ni(CN)_4]$

Select the complexes which are diamagnetic.

(a) I, II and III (b) II, III and IV
(c) I, III and IV (d) I, II and IV

6. In spectrochemical series chlorine is above than water, *i.e.*, Cl > H_2O, this is due to

(a) good π-acceptor properties of Cl
(b) strong σ-donor and good π-acceptor properties of Cl
(c) good π-donor properties of Cl
(d) larger size of Cl than H_2O

7. Mixture $X = 0.02$ mole of $[Co(NH_3)_5SO_4]Br$ and 0.02 mole of $[Co(NH_3)_5Br]SO_4$ was prepared in 2 L of solution

1 L of mixture X + excess $AgNO_3 \longrightarrow Y$
1 L of mixture X + excess $BaCl_2 \longrightarrow Z$

Number of moles of Y and Z are

(a) 0.01, 0.01 (b) 0.01, 0.02
(c) 0.02, 0.01 (d) 0.02, 0.02

8. The hybridisation of central metal ion and shape of Wilkinson's catalyst is

(a) sp^3d, trigonal bipyramidal
(b) sp^3, tetrahedral
(c) dsp^2, square planar
(d) d^2sp^2, octahedral

9. An aqueous solution of $CoCl_2$ on addition of excess of concentrated HCl turns blue due to formation of

(a) $[CoCl_4]^{2-}$ (b) $[Co(H_2O)_2Cl_4]^{2-}$
(c) $[Co(H_2O)_2 2Cl_4]^{2-}$ (d) $[Co(H_2O)_4Cl_2]$

10. Which one of the following complexes is an outer orbital complex?

(a) $[Fe(CN)_6]^{4-}$ (b) $[Co(NH_3)_6]^{3+}$
(c) $[Ni(NH_3)_6]^{2+}$ (d) None of these

11. Which one of the following has highest number of isomers?

(a) $[Co(NH_3)_5Cl]^{2+}$
(b) $[Co(en)_2Cl_2]^+$
(c) $[Ru(NH_3)_4Cl^-]$
(d) $[In(Ph_3)_2H(CO)]^{2+}$

12. In which of the following pairs both the complex show optical isomerism?

(a) *Cis*-$[Cr(C_2O_4)_2Cl_2]^{3-}$; *cis*-$[Co(NH_3)_4Cl_2]$
(b) $[PtCl(dien)]Cl$, $[NiCl_2Br_2]^{2-}$
(c) $[Co(NO_3)_3(NH_3)_3]$, *cis*-$[Pt(en)_2Cl_2]$
(d) $[Co(en)_3]Cl_3$, *cis*-$[Co(en)_2Cl_2]Cl$

13. Match the complex ions given in Column I with the colours given in Column II and assign the correct code : **[NCERT Exemplar]**

	Column I (Complex ion)		Column II (Colour)
A.	$[Co(NH_3)_6]^{3+}$	1.	Violet
B.	$[Ti(H_2O)_6]^{3+}$	2.	Green
C.	$[Ni(H_2O)_6]^{2+}$	3.	Pale blue
D.	$[Ni(H_2O)_4(en)]^{2+}(aq)$	4.	Yellowish orange
		5.	Blue

Codes

	A	B	C	D		A	B	C	D
(a)	1	2	4	5	(b)	4	3	2	1
(c)	3	2	4	1	(d)	4	1	2	3

14. Match the complex species given in Column I with the possible isomerism given in Column II and assign the correct code : **[NCERT Exemplar]**

	Column I (Complex species)		Column II (Isomerism)
A.	$[Co(NH_3)_4Cl_2]^+$	1.	Optical
B.	*cis* - $[Co(en)_2Cl_2]^+$	2.	Ionisation
C.	$[Co(NH_3)_5(NO_2)]Cl_2$	3.	Coordination
D.	$[Co(NH_3)_6][Cr(CN)_6]$	4.	Geometrical
		5.	Linkage

Codes

	A	B	C	D		A	B	C	D
(a)	1	2	4	5	(b)	4	3	2	1
(c)	4	1	5	3	(d)	4	1	3	2

15. Match the complex ions given in Column I with the hybridisation number of unpaired electrons given in Column II and assign the correct code : **[NCERT Exemplar]**

	Column I (Complex ion)		Column II (Hybridisation and number of unpaired electrons)
A.	$[Cr(H_2O)_6]^{3+}$	1.	dsp^2, 1
B.	$[Co(CN)_4]^{2-}$	2.	sp^3d^2, 5
C.	$[Ni(NH_3)_6]^{2+}$	3.	d^2sp^3, 3
D.	$[MnF_6]^{4-}$	4.	sp^3, 4
		5.	sp^3d^2, 2

Codes

	A	B	C	D		A	B	C	D
(a)	3	1	5	2	(b)	4	3	2	1
(c)	3	2	4	1	(d)	4	1	3	2

16. Match the coordination compounds given in Column I with the central metal atoms given in Column II and assign the correct code : **[NCERT Exemplar]**

	Column I (Coordination compound)		Column II (Central metal atom)
A.	Chlorophyll	1.	Rhodium
B.	Blood pigment	2.	Cobalt
C.	Wilkinson catalyst	3.	Calcium
D.	Vitamin B_{12}	4.	Iron
		5.	Magnesium

Codes

	A	B	C	D
(a)	5	4	1	2
(b)	3	4	5	1
(c)	4	3	2	1
(d)	3	4	1	2

More than One Correct Option

17. Which of the following complexes are heteroleptic? **[NCERT Exemplar]**

(a) $[Cr(NH_3)_6]^{3+}$ (b) $[Fe(NH_3)_4Cl_2]^+$

(c) $[Mn(CN)_6]^{4-}$ (d) $[Co(NH_3)_4Cl_2]$

18. In which of the following, the chemical formula and the name correctly matched?

(a) $K_3[Cr(C_2O_4)_3]$ — Potassium trioxalatochromate (III)

(b) $K[Pt(NH_3)Cl_5]$ — Potassium amminepentachlorido platinate (IV)

(c) $Na_2[Ni(EDTA)]$ — Sodium ethylenediaminetetra acetatonickel (I)

(d) $[Ag(CN)_2]^-$ — Dicyanoargentate (I) ion

19. Which of the following statements is/are false?

(a) $[Ni(CO)_4]$ is high spin complex

(b) Weak ligands like F^-, Cl^- and OH^- usually form low spin complexes

(c) $[FeF_6]^{3-}$ is a high spin complex

(d) Strong ligand like CN^- and NO_2^-, generally form high spin complexes

20. An aqueous pink solution of cobalt (II) chloride changes to deep blue on addition of excess of HCl. This is because …… **[NCERT Exemplar]**

(a) $[Co(H_2O)_6]^{2+}$ is transformed into $[CoCl_6]^{4-}$

(b) $[Co(H_2O)_6]^{2+}$ is transformed into $[CoCl_4]^{2-}$

(c) tetrahedral complexes have smaller crystal field splitting than octahedral complexes

(d) tetrahedral complexes have larger crystal field splitting than octahedral complex

21. Identify the optically active compounds from the following **[NCERT Exemplar]**

(a) $[Co(en)_3]^{3+}$

(b) *trans*-$[Co(en)_2Cl_2]^+$

(c) *cis*-$[Co(en)_2Cl_2]^+$

(d) $[Cr(NH_3)_5Cl]$

Assertion and Reason

Directions (Q. Nos. 22 to 26) *Each of these questions contains two statements : Statement* I (*Assertion*) *and Statement* II (*Reason*). *Each of these questions also has four alternative choices, only one of which is the correct answer. You have to select one of the codes* (*a*), (*b*), (*c*), (*d*) *given below :*

(a) Statement I is true, Statement II is true; Statement II is a correct explanation for Statement I.

(b) Statement I is true, Statement II is true; Statement II is not a correct explanation for Statement I.

(c) Statement I is true; Statement II is false.

(d) Statement I is false; Statement II is true.

22. **Statement I** Ions with more than five $3d$ electrons have usually slightly larger magnetic moment than calculated on the basis of $\mu = \sqrt{n(n+2)}$.

Statement II The maximum number of unpaired d-electrons is five as in Mn^{2+} and Fe^{3+} and so, $\mu = 5.92$ for 5 unpaired electrons.

23. **Statement I** Toxic metal ions are removed by the chelating ligands. **[NCERT Exemplar]**

Statement II Chelate complexes tend to be more stable.

24. **Statement I** $[Cr(H_2O)_6]Cl_2$ and $[Fe(H_2O)_6]Cl_2$ are reducing in nature. **[NCERT Exemplar]**

Statement II Unpaired electrons are present in their d-orbitals.

25. **Statement I** Complexes of MX_6 and MX_5L type (X and L are unidentate) do not show geometrical isomerism. **[NCERT Exemplar]**

Statement II Geometrical isomerism is not shown by complexes of coordination number 6.

26. **Statement I** d-d transition is not possible in $[Sc(H_2O)_6]^{3+}$.

Statement II $[Ti(H_2O)_6]^{4+}$ is coloured while $[Sc(H_2O)_6]^{3+}$ is colourless.

Comprehension Based Questions

Directions (Q. Nos. 27 to 29) $CoSO_4Cl \cdot 5NH_3$ exists in two isomeric forms 'A' and 'B'. Isomer 'A' reacts with $AgNO_3$ to give white precipitate, but does not react with $BaCl_2$. Isomer 'B' gives white precipitate with $BaCl_2$ but does not react with $AgNO_3$. Answer the following questions. **[NCERT Exemplar]**

27. Write the structural formulae of A and B respectively

(a) $[Co(NH_3)_5SO_4]Cl$, $[Co(NH_3)_5SO_4]Cl_2$

(b) $[Co(NH_3)_5Cl]SO_4$, $[Co(NH_3)_5SO_4]Cl$

(c) $[Co(NH_3)_5SO_4]Cl$, $[Co(NH_3)_5Cl]SO_4$

(d) $[CoClSO_4(NH_3)_3](NH_3)_2$, $[CoSO_4(NH_4)_4]NH_3 \cdot Cl$

28. Name the type of isomerism involved.

(a) Solvated (b) Coordination

(c) Ionisation (d) Geometrical

29. Give the IUPAC name of 'B'.

(a) Pentaamminesulphatocobalt (III) chloride

(b) Pentaamminechloridocobalt (III) sulphate

(c) Pentaamminesulphatocobalt (II) chloride

(d) tetraamminesulphatecobalt (III) ammonium chloride

Directions (Q. Nos. 30 to 32) Splitting energy (Δ_o) can usually be measured from the absorption spectra of the complex ions. In simple cases when light is absorbed by a complex ion, an electron in one of the lower energy orbitals is excited to one of the higher energy orbital. The energy corresponding to the frequency of absorbed light is equal to Δ_o. If value of Δ_o for the complex is in visible region, the complex is coloured and the value of Δ_o lies in ultraviolet or infrared region, the complex is colourless. For octahedral complexes, the crystal field stabilisation energy is given by $CFSE = [-0.4\, t_{2g}N + 0.6 e_g\, N']\Delta_o$, where N and N' are number of electrons in t_{2g} and e_g orbitals respectively.

30. Among the following pairs of complexes, in which case the Δ_o value is higher for the first one?

(a) $[CoF_6]^{3-}$ and $[Co(NH_3)_6]^{3+}$

(b) $[Co(H_2O)_6]^{2+}$ and $[Co(H_2O)_6]^{3+}$

(c) $[Rh(H_2O)_6]^{3+}$ and $[Co(H_2O)_6]^{3+}$

(d) $[Co(NH_3)_6]^{3+}$ and $[Co(CN)_6]^{3-}$

31. Which of the following statements is correct?

(a) Zinc (II) ion has a zero CFSE for any geometry

(b) A solution of $[Fe(CN)_6]^{4-}$ and $[Fe(H_2O)_6]^{2+}$ appear colourless in dil solutions

(c) A solution of $[Ni(H_2O)_6]^{2+}$ is green as the value of Δ for the H_2O complex is in the visible region

(d) All of the above

32. In which of the following complex ion, the metal ion will have t_{2g}^6, e_g^0 configuration according to CFT?

(a) $[Fe(CN)_6]^{3-}$ (b) $[FeF_6]^{3-}$

(c) $[Fe(CN)_6]^{4-}$ (d) None of these

Previous Years' Questions

33. Which among the following will be named as dibromidobis (ethylenediamine) chromium (III) bromide? **[AIEEE 2012]**

(a) $[Cr(en)_3]Br_3$

(b) $[Cr(en)_2Br_2]Br$

(c) $[Cr(en)Br_4]^-$

(d) $[Cr(en)Br_2]Br$

34. Which of the following facts about the complex $[Cr(NH_3)_6]Cl_3$ is wrong? **[AIEEE 2011]**

(a) The complex involves d^2sp^3 hybridisation and is octahedral in shape

(b) The complex is paramagnetic

(c) The complex is an outer orbital complex

(d) The complex gives white precipitate with silver nitrate solution

35. The magnetic moment (spin only) of $[NiCl_4]^{2-}$ is **[AIEEE 2011]**

(a) 1.82 BM (b) 5.46 BM

(c) 2.82 BM (d) 1.41 BM

36. Among the ligands NH_3, en, CN^- and CO, the correct order of their increasing field strength, is **[AIEEE 2011]**

(a) $CO < NH_3 < en < CN^-$ (b) $NH_3 < en < CN^- < CO$

(c) $CN^- < NH_3 < CO < en$ (d) $en < CN^- < NH_3 < CO$

37. Which one of the following complex ions has geometrical isomers? **[AIEEE 2011]**

(a) $[Co(en)_3]^{3+}$ (b) $[Ni(NH_3)_5Br]^+$

(c) $[Co(NH_3)_2(en)_2]^{3+}$ (d) $[Cr(NH_3)_4(en)]^{3+}$

38. Which of the following has an optical isomer? **[AIEEE 2009]**

(a) $[Co(NH_3)_3Cl]^+$ (b) $[Co(en)(NH_3)_2]^{2+}$

(c) $[Co(H_2O)_4(en)]^{3+}$ (d) $[Co(en)_2(NH_3)_2]^{3+}$

39. Which of the following pairs represents linkage isomers? **[AIEEE 2009]**

(a) $[Cu(NH_3)_4][PtCl_4]$ and $[Pt(NH_3)_4][CuCl_4]$

(b) $[Pd(PPh_3)_2(NCS)_2]$ and $[Pd(PPh_3)_2(SCN)_2]$

(c) $[Co(NH_3)_5NO_3]SO_4$ and $[Co(NH_3)_5SO_4]NO_3$

(d) $[PtCl_2(NH_3)_4]Br_2$ and $[PtBr_2(NH_3)_4]Cl_2$

40. The coordination number and the oxidation state of the element 'E' in the complex $[E(\text{en})_2(C_2O_4)]\,NO_2$ (where (en) is ethylene diamine) are, respectively. **[AIEEE 2008]**

(a) 6 and 2 (b) 4 and 2
(c) 4 and 3 (d) 6 and 3

41. In which of the following octahedral complexes of Co (at. no. 27), will the magnitude of Δ_o be the highest? **[AIEEE 2008]**

(a) $[Co(CN)_6]^{3-}$ (b) $[Co(C_2O_4)_3]^{3-}$
(c) $[Co(H_2O)_6]^{3+}$ (d) $[Co(NH_3)_6]^{3+}$

42. Which one of the following has a square planar geometry? **[AIEEE 2007]**

(At. no. Co = 27, Ni = 28, Fe = 26, Pt = 78)

(a) $[CoCl_4]^{2-}$ (b) $[FeCl_4]^{2-}$
(c) $[NiCl_4]^{2-}$ (d) $[PtCl_4]^{2-}$

43. The IUPAC name for the complex $[Co(NO_2)(NH_3)_5]\,Cl_2$ is **[AIEEE 2006]**

(a) nitrito-N-pentamminecobalt (III) chloride
(b) nitrito-N-pentamminecobalt (II) chloride
(c) pentaamminenitrito-N-cobalt (II) chloride
(d) pentaamminenitrito-N-cobalt (III) chloride

44. Nickel ($Z = 28$) combines with a uninegative monodentate ligand X^- to form a paramagnetic complex $[NiX_4]^{2-}$. The number of unpaired electron (s) in the nickel and geometry of this complex ion are, respectively **[AIEEE 2006]**

(a) one, tetrahedral (b) two, tetrahedral
(c) one, square planar (d) two, square planar

45. Which of the following compounds shows optical isomerism? **[AIEEE 2005]**

(a) $[Co(CN)_6]^{3-}$ (b) $[Cr(C_2O_4)_3]^{3-}$
(c) $[ZnCl_4]^{2-}$ (d) $[Cu(NH_3)_4]^{2+}$

46. The coordination number of a central metal atom in a complex is determined by **[AIEEE 2004]**

(a) the number of ligands around a metal ion bonded by sigma bonds
(b) the number of ligands around a metal ion bonded by pi bonds
(c) the number of ligands around a metal ion bonded by sigma and pi bonds both
(d) the number of only anionic ligands bonded to the metal ion

47. The correct order of magnetic moments (spin only values in BM) among the following is
(At. no. Mn = 25, Fe = 26, Co = 27) **[AIEEE 2004]**

(a) $[MnCl_4]^{2-} > [CoCl_4]^{2-} > [Fe(CN)_6]^{4-}$
(b) $[MnCl_4]^{2-} > [Fe(CN)_6]^{4-} > [CoCl_4]^{2-}$
(c) $[Fe(CN)_6]^{4-} > [MnCl_4]^{2-} > [CoCl_4]^{2-}$
(d) $[Fe(CN)_6]^{4-} > [CoCl_4]^{2-} > [MnCl_4]^{2-}$

48. One mole of the complex compound $Co(NH_3)_5Cl_3$, gives 3 moles of ions on dissolution in water. One mole of the same complex reacts with two moles of $AgNO_3$ solution to yield two moles of AgCl(s). The structure of the complex is **[AIEEE 2003]**

(a) $[Co(NH_3)_5Cl]Cl_2$ (b) $[Co(NH_3)_3Cl_3]\cdot 2NH_3$
(c) $[Co(NH_3)_4Cl_2]Cl\cdot NH_3$ (d) $[Co(NH_3)_4Cl]Cl_2\cdot NH_3$

49. A square planar complex is formed by hybridisation of the following atomic orbitals **[AIEEE 2002]**

(a) s, p_x, p_y, p_z (b) s, p_x, p_y, p_z, d
(c) d, s, p_x, p_y (d) s, p_x, p_y, p_z, d, d

Answers

the Guidance

Round I

1. In $K_4Fe(CN)_6$, the species retains its identity in solid as well as solution state so, it is a complex salt.

2. Lithium tetrahydroaluminate is $Li[Al(H)_4]$.

3. Chelating agent coordinates through more than one coordinating sites. Thiosulphate ($S_2O_3^{2-}$) although coordinate through only one coordinating site, so it is not referred as chelating agent.

4. Ligands have tendency to donate its lone pair. NH_4^+ ion have no lone pair so it is unable to behave like a ligand.

5. Oxidation number of Co : $K[Co(CO)_4]$

$$x + (4 \times 0) = -1; x = -1$$

8. CO ligand has zero oxidation state, that is why $[Ni(CO)_4]$ is a zero valent metal complex.

10. The complexes can be written as follows

$$[Co(NH_3)_6]Cl_3, [Co(NH_3)_5Cl]Cl_2, [Co(NH_3)_4Cl_4]Cl$$

Hence, number of primary valencies are 3, 2 and 1 respectively.

11. In the complex $K_2Fe[Fe(CN)_6]$ both the iron atoms are present in the same oxidation state *i.e.,* +2.

12. $[Co(NH_3)_5Cl]^{2+} + 2Cl^- \longrightarrow [Co(NH_3)_5Cl]Cl_2$

13. The complex will dissociate in aqueous solution to produce 3 ions.

$$Co(NH_3)_6Cl_2 \xrightarrow{aq} [Co(NH_3)_6]^{2+} + 2Cl^-$$

14. When excess of KCN(*aq*) is mixed with $CuSO_4(aq)$, a complex named potassium tetracyanocuprate (II) is formed. Since, CN^- ions are strong ligands, the complex is quite stable. It is evident from the stability constant value ($K = 2.0 \times 10^{27}$).

$$\underset{\text{(excess)}}{4KCN(aq)} + CuSO_4(aq) \longrightarrow \underset{\text{(soluble)}}{K_2[Cu(CN)_4](aq)} + K_2SO_4(aq)$$

$$\downarrow + H_2S$$

No cleavage and no production of Cu^{2+} ions

15. Formation of 3 mol AgCl from 1 mole complex suggests the presence of all the three Cl^- outside the coordination sphere. Thus, the formula of the complex should be $[Cr(H_2O)_6]Cl_3$.

16. Mn^{2+} will have half filled more stable d^5 configuration and without distributing it an outer orbital complex can be formed.

17. In acidic solution, proton coordinates with ammonia to form NH_4^+. NH_4^+ does not act as ligand because nitrogen atom has no lone pair of electrons which it can donate to metal atom.

18. In all these complexes, Fe is in +3 oxidation state. However, the complex (c) is a chelate because three $C_2O_4^{2-}$ ions act as the chelating ligands. Thus, the most stable complex is $[Fe(C_2O_4)_3]^{3-}$.

19. IUPAC name of $[Pt(NH_3)_2Cl_2]$ is diamminedichloridoplatinum (II).

20. IUPAC name of $[Pt(NH_3)_2Cl(NO_2)]$ is diamminechlorido nitrito-N-platinum (II).

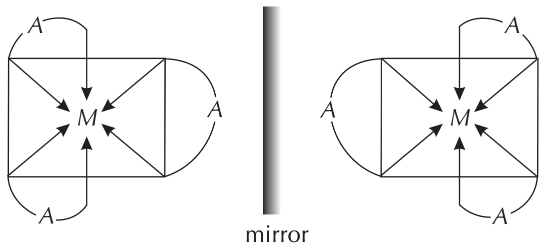
26. The given complexes are not isomers as their composition is not same. (Isomers have same composition but different arrangement and properties.)

27. Coordination isomerism is possible when both positive and negative ions of a salt are complex ions and the two isomers differ in distribution of ligands in the cation and the anion.

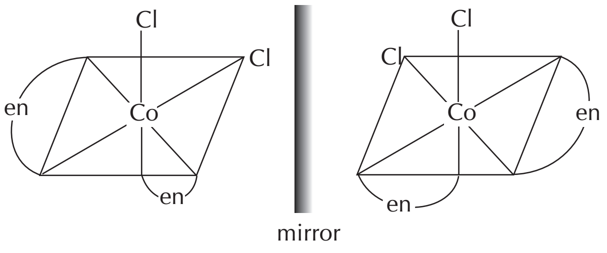
29. Complexes having ambidentate ligands like SCN exhibit linkage isomerism.

30. Since the two complexes differ in number of water (solvent) molecules inside and outside the coordination sphere, so they exhibit solvate isomerism.

31. Octahedral complexes containing three bidentate ligands shows optical isomerism. If *A* is a bidentate ligand then complex of type MA_3 show optical isomerism.



33.

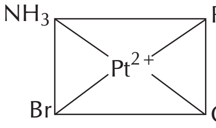


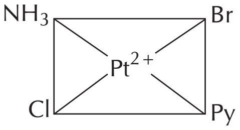
34. Octahedral complexes of the type $[MA_4B_2]^+$ [where A and B are two different monodentate ligands] exhibit geometrical isomerism.

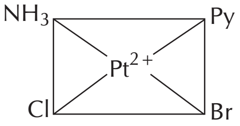
Hence, among the given only $[Cr(H_2O)_4Cl_2]^+$ exhibit geometrical isomerism.

35. 1. $[Cu(NH_3)_4][PtCl_4]$
2. $[Cu(NH_3)_3Cl]\cdot[PtCl_3(NH_3)]$
3. $[Cu(NH_3)_2Cl_2]\cdot[PtCl_2(NH_3)_2]$ *cis*
4. $[Cu(NH_3)_2Cl_2][PtCl_2(NH_3)_2]$ *trans*
5. $[Cu(NH_3)Cl_3]\cdot[Pt(Cl)(NH_3)_3]$
6. $[Pt(NH_3)_4]\cdot[CuCl_4]$

36. [*Mabcd*] type complexes exist in three isomeric forms.

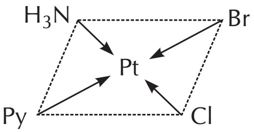




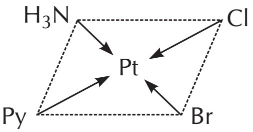


37. Three geometrical isomers are possible for

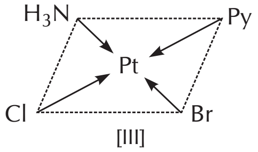
$[Pt(NH_3)(Br)(Cl)(Py)]$



[I]



[II]



[III]

Optical isomerism is not exhibited by this compound with CN = 4 and square planar geometry, because of the presence of horizontal plane of symmetry.

38. An optically active complex of the type $[M(AA)_2X_2]^{n+}$ indicates *cis*-octahedral structure, *e.g., cis*-$[Pt(en)_2Cl_2]^{2+}$ or *cis*-$[Cr(en)_2Cl_2]^+$

39. $[Fe(H_2O)_6]^{3+}$ has five unpaired electrons.

40. Since, hybridisation is dsp^2 so, it is square planar.

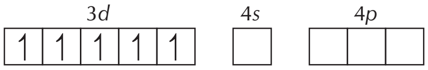
41. The coordination number in $[FeF_6]^{3-}$ is 6, hence it is a octahedral complex.

42. $[NiCl_4]^{2-}$ has tetrahedral shape. In this complex, Ni is in the +2 oxidation state and Ni^{2+} ion always forms tetrahedral complexes.

43. Both $Ni(CO)_4$ and $Ni(PPh_3)_2Cl_2$ have sp^3-hybridisation but later is square planar.

44. $K_3[FeF_6]$

$$Fe^{3+} = [Ar]\,3d^5\,4s^0$$



Number of unpaired electrons = 5

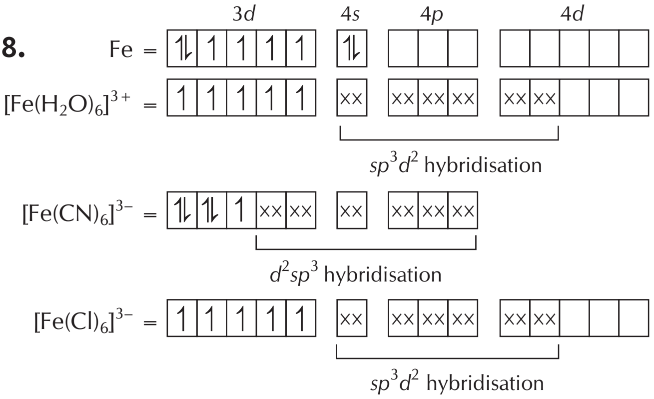
Magnetic moment $= \sqrt{5(5+2)} = \sqrt{s(s+2)}$

$= \sqrt{35} = 5.91$ BM

46. It is due to the presence of weak and strong field ligands in complexes. If CFSE is high, the complex will show low value of magnetic moment and *vice-versa, e.g.* $[CoF_6]^{3-}$ and $[Co(NH_3)_6]^{3+}$, the former is paramagnetic, and the latter is diamagnetic because F^- is a weak field ligand and NH_3 is a strong field ligand.

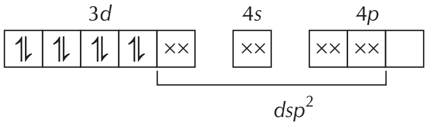
47. In $CuSO_4\cdot5H_2O$ water acts as ligand as a result it causes crystal field splitting. Hence, *d-d* transition is possible thus $CuSO_4\cdot5H_2O$ is coloured. In the anhydrous $CuSO_4$ due to the absence of water (ligand), crystal field splitting is not possible and hence, it is colourless.

48.

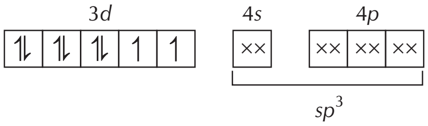


49. The electronic configuration of Ni in $[Ni(CN)_4]^{2-}$, $[NiCl_4]^{2-}$ and $Ni(CO)_4$ are as follows

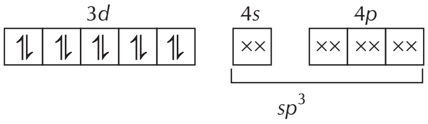
Ni^{2+} in $[Ni(CN)_4]^{2-}$



Ni^{2+} in $[NiCl_4]^{2-}$



Ni in $[Ni(CO)_4]$

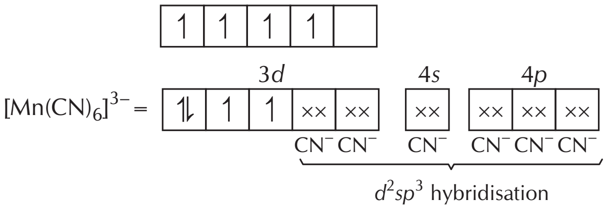


CO and CN^- are strong ligands so, they induces pairing of electrons so, their complexes are diamagnetic while, Cl^- is a weak field ligand so, it does not induce the pairing of electrons so, its complex is paramagnetic.

50. In both the complex compounds, Fe is in +2 oxidation state with configuration $3d^6$, *i.e.,* it has four unpaired electrons. In the presence of weak H_2O ligands, the unpaired electrons do not pair up. But in the presence of strong ligand CN^-, they get paired up. Then, no unpaired electron is left. Due to this difference in the number of unpaired electrons, both complex ions have different colours.

51. (a) $[Mn(CN)_6]^{3-}$

$$Mn^{3+} = 3d^4$$



(i) d^2sp^3 hybridisation

(ii) Inner orbital complex because $(n-1)\,d$-orbitals are used.

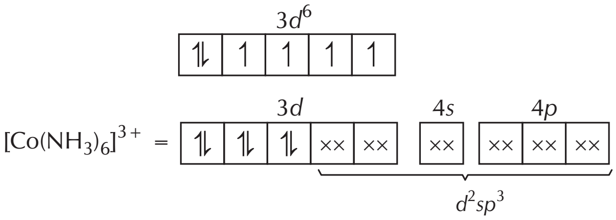
(iii) Paramagnetic, as two unpaired electrons are present.

(iv) Spin only magnetic moment

$$(\mu) = \sqrt{2\,(2+2)} = \sqrt{8} = 2.82 \text{ BM}$$

(b) $\mathbf{[Co(NH_3)_6]^{3+}}$

$$Co^{3+} = 3d^6\ 4s^0$$



(NH$_3$ pair up the unpaired $3d$ electrons.)

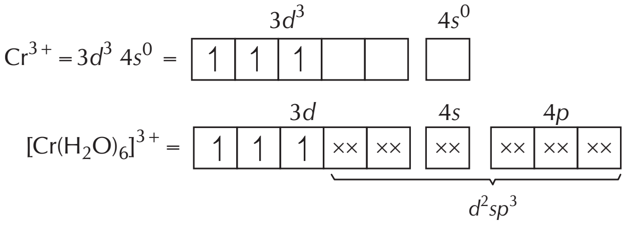
(i) d^2sp^3 hybridisation

(ii) Inner orbital complex because of the involvement of $(n-1)$ d-orbital in bonding.

(iii) Diamagnetic, as no unpaired electron is present.

(iv) $\mu = \sqrt{n\,(n+2)} = \sqrt{0\,(0+2)} = 0$ (Zero)

(c) $\mathbf{[Cr(H_2O)_6]^{3+}}$



(i) d^2sp^3 hybridisation

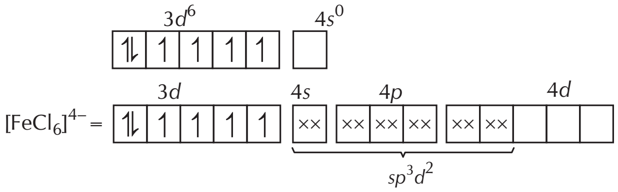
(ii) Inner orbital complex (as $(n-1)$ d-orbitals take part.)

(iii) Paramagnetic (as three unpaired electrons are present.)

(iv) $\mu = \sqrt{n\,(n+2)} = \sqrt{3\,(3+2)} = \sqrt{15} = 3.87$ BM

(d) $\mathbf{[Fe(Cl)_6]^{4-}}$

$$Fe^{2+} = 3d^6$$



(i) sp^3d^2 hybridisation

(ii) Outer orbital complex because nd-orbitals are involved in hybridisation.

(iii) Paramagnetic (because of the presence of four unpaired electrons).

(iv) $\mu = \sqrt{n\,(n+2)} = \sqrt{4\,(4+2)} = \sqrt{24} = 4.9$ BM

52. For tetrahedral complexes, the crystal field stabilisation energy is lower than pairing energy, so they are not formed in low spin state.

53. We know that, CFSE is higher for the complex having strong field ligand and varies inversely with wavelength.

In all the given complexes, the metal ion is Ni^{2+}. The increasing field strengths of the ligands present as per electrochemical series are in the order :

$$H_2O < NH_3 < NO_2^-$$

The energies absorbed for excitation will be in the order :

$$[Ni(H_2O)_6]^{2+} < [Ni(NH_3)_6]^{2+} < [Ni(NO_2)_6]^{4-}$$

As $E = \dfrac{hc}{\lambda}$, *i.e.,* $E \propto \dfrac{1}{\lambda}$; the wavelengths will be in the opposite order, that is as follows

$$[Ni(H_2O)_6]^{2+} > [Ni(NH_3)_6]^{2+} > [Ni(NO_2)_6]^{4-}$$

54. Dissociation constant is the reciprocal of β_4, the stability constant.

Overall complex dissociation equilibrium constant $= \dfrac{1}{\beta_4}$

$$= \frac{1}{2.1 \times 10^{13}} = 4.7 \times 10^{-14}$$

55. EAN of Pt in $[PtCl_6]^{2-} = 86$

56. Chlorophyll are green pigment in plant and contain magnesium instead of calcium.

57. *Cis*-isomer of $[Pt(NH_3)_2Cl_2]$ is used as an anticancer drug for treating several type of malignant tumours. When it is injected into the blood stream, the more reactive Cl groups are lost so, the Pt atom bonds to a N-atom in guanosine (a part of DNA). This molecule can bond to two different guanosine units and by bridging between them it upsets the normal reproduction of DNA.

58. The reaction carried out in alkaline pH, *i.e.,* 9 – 11.

59. $[H_2EDTA]^{2-} + Mg^{2+} \longrightarrow [MgEDTA]^{2-} + 2H^+$

(a) In this complex, four donor sites are occupied by oxygen and two donor sites are occupied by nitrogen.

(b) This complex is six coordinated.

(c) Complex $[MgEDTA]^{2-}$ is colourless.

(d) Increase in $[H^+]$ decreases pH of the solution.

Round II

1. Its coordination number will be 6 because it is bonded with three bidentate ligands.

Let x be the oxidation state of Cr.

$\therefore \quad x + 3(-2) + 3(+1) = 0 \Rightarrow x = +3$

2. Let the oxidation state of Fe in $[Fe(H_2O)_5NO]SO_4$ is x.

$$[Fe(H_2O)_5NO]^{2+}$$

$$\Rightarrow \quad x + 0 + 1 = 2$$

$$\therefore \quad x = +1$$

Hence NO exists as nitrosyl ion (NO^+).

3. In $K_3[Fe(CN)_6]$, the ligands are negative which is present in coordination spheres shows a dual behaviour. It may satisfied both primary and secondary valencies while neutral ligand satisfied only secondary valencies.

4. IUPAC name of sodium nitroprusside $Na_2[Fe(CN)_5NO]$ is sodium pentacyanonitrosoyl ferrate (III) because in it NO is neutral ligand and the oxidation number of Fe is III, which is calculated as

$$2 \times \text{O.N. of Na} + \text{O.N. of Fe} + 5 \times \text{O.N. of CN} + 1 \times \text{O.N. of NO} = 0$$

$$2 \times (+1) + \text{O.N. of Fe} + 5 \times (-1) + 1 \times 0 = 0$$

$$\therefore \quad \text{O.N. of Fe} = 5 - 2 = +3$$

5. Structure $K_4[Fe(CN)_6]$, $K_3[Co(CN)_6]$, $K_2[Ni(CN)_4]$ are diamagnetic.

6. When ligands are arranged in ascending order of crystal field splitting energy, Δ, they produced a spectrochemical series.

In comparison to H_2O, Cl is a strong σ donor and good π-acceptor, therefore, it is a strong ligand than H_2O. Hence, in the spectrochemical series is Cl is above than water.

7. $$[Co(NH_3)_5SO_4]Br + AgNO_3 \longrightarrow [Co(NH_3)_5SO_4] + \underset{(Y)}{\underset{0.02\text{ mol}}{AgBr}}$$

$$\underset{\frac{0.02}{2}\text{ mol L}^{-1}}{[Co(NH_3)_5Br]SO_4} + BaCl_2 \longrightarrow [Co(NH)_5Br]Cl_2 + \underset{0.01\text{ mol L}^{-1}}{\underset{(Z)}{BaSO_4}}$$

8. Wilkinson's catalyst, $(Ph_3P)_3RhCl$

$$Rh^+ = [Kr]\,4d^8\,s^0$$

i.e., dsp^2 hybridisation.

Rh atom in Wilkinson's catalyst is dsp^2 hybridised giving a square planar shape to the molecule.

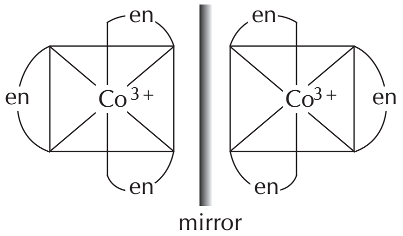
9. $CoCl_2$ is a weak Lewis acid, It reacts with chloride ions to produce salt containing the tetrahedral $[CoCl_4]^{2-}$ ion. $CoCl_2$ is blue when anhydrous, and a deep magenta colour when hydrated, for this reason it is widely used as an indicator for water.

10.

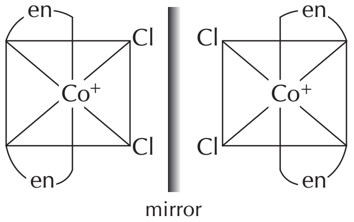
Complex ion	Hybridisation of central atom
$[Fe(CN)_6]^{4-}$	d^2sp^3 (inner)
$[Co(NH_3)_6]^{3+}$	d^2sp^3 (inner)
$[Ni(NH_3)_6]^{2+}$	sp^3d^2 (outer)

11. $[Co(en)_2Cl_2]^+$ shows geometrical as well as optical isomerism.

12. $[Co(en)_3]Cl_3$ *i.e.,* $[Co(en)_3]^{3+}$



cis-$[Co(en)_2Cl_2]Cl$ *i.e.,* *cis* $[Co(en)_2Cl_2]^+$



13. In $[Co(NH_3)_6]^{3+}$, Co is present as $Co^{3+}(d^6)$ and NH_3 is a strong field ligand, so unpaired electrons = 0.

So, it is yellowish orange.

In $[Ti(H_2O)_6]^{3+}$, Ti is present as $Ti^{3+}(d^1)$ so it contains one unpaired electron. It is pale blue in colour.

In $[Ni(H_2O)_6]^{2+}$, Ni is present as Ni^{2+} (d^8) so it have two unpaired electrons. It is of green colour.

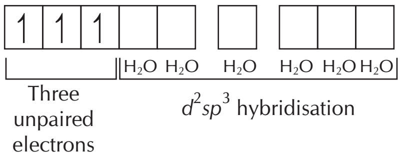
$[Ni(H_2O)_4(en)]^{2+}$ is violet as en is a strong field ligand.

14. $[Co(NH_3)_4Cl_2]^+$ exhibits geometrical isomerism. *Cis* $[Co(en)_2Cl_2]^+$ because of the absence of symmetry elements exhibits optical isomerism.

$[Co(NH_3)_5(NO_2)]Cl_2$ because of the presence of ambidentate (NO_2) ligand exhibit linkage isomerism. $[Co(NH_3)_6][Cr(CN)_6]$ exhibits coordination isomerism because here cation and anion both are complex.

15. In $[Cr(H_2O)_6]^{3+}$, Cr is present as Cr^{3+}.

$$Cr^{3+} = 3d^3, \quad 4s^0, \quad 4p^0$$

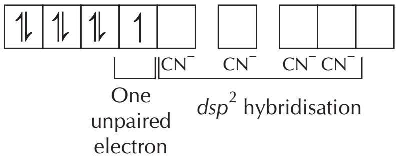


In $[Co(CN)_4]^{2-}$, Co is present as Co^{2+}

$$Co^{2+} = 3d^7, 4s^0, 4p^0$$

[CN^- being strong field ligand pair up the unpaired *d* electrons.]

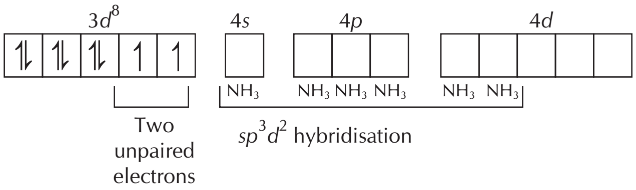
$[Co(CN)_4]^{2-} =$



(c) In $[Ni(NH_3)_6]^{2+}$, Ni is present as Ni^{2+}.

$$Ni^{2+} = [Ar]\,3d^8, 4s^0$$

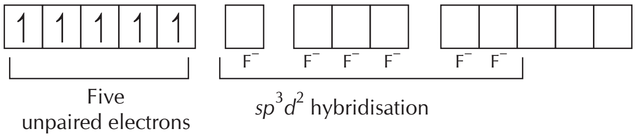
$[Ni(NH_3)_6]^{2+} =$



(d) In $[MnF_6]^{4-}$, Mn is present as Mn^{2+}.

$$Mn^{2+} = 3d^5\ 4s^0$$

$[MnF_6]^{4-} =$



16. Chlorophyll contains Mg, blood pigment, *i.e.,* haemoglobin contains iron (Fe), Wilkinson catalyst contains Rh (rhodium) and vitamin B_{12} have cobalt metal.

17. Heteroleptic complexes are those in which more than one kind of ligands are present. *e.g.,* $[Fe(NH_3)_4Cl_2]^{4+}$, $[Co(NH_3)_4Cl_2]$ etc.

18. Three names and formulas are correctly matched.

$K_3[Cr(C_2O_4)_3]$ — Potassium trioxalatochridomate (III)

$K[Pt(NH_3)Cl_5]$ — Potassium amminepentachloroplatinate (IV)

$[Ag(CN)_2]^-$ — Dicyanoargentate (I) ion

19. F^-, Cl^- and OH^- are weak field ligands usually form high spin complexes. CN^- and NO_2^- are strong field ligands usually form low spin complexes. $[Ni(CO)_4]$ is a low spin complex.

20. $$\underset{\text{(octahedral)}}{\underset{\text{pink}}{[Co(H_2O)_6]^{2+}}} \xrightarrow{HCl} \underset{\text{(tetrahedral)}}{\underset{\text{deep blue}}{[CoCl_4]^{2-}}}$$

The colour changes because crystal field splitting is more in case of octahedral complexes as compared to tetrahedral complexes.

21. $[Co(en)_3]^{3+}$ and *cis*-$[Co(en)_2Cl_2]^+$ are optically active compounds because of the absence of symmetry elements.

22. The slightly larger value of μ than expected from the formula $\mu = \sqrt{n(n+2)}$ is due to a small contribution from the orbital angular momentum of the electrons to the magnetic moment.

23. Chelating agents form more stable complexes thus, these are used to remove toxic metal ions.

24. $[Cr(H_2O)_6]Cl_2$ contains Cr as Cr^{2+}, which is less stable than Cr^{3+}, so it have higher tendency to get oxidised or it is a better reducing agent.

Similar is true for $[Fe(H_2O)_6]Cl_2$. Both the complex have unpaired electrons in their *d*-orbitals.

25. MX_6 and MX_5L type complexes do not exhibit geometrical isomerism although many 6 coordinated complexes like complex of the type MA_3B_3 exhibits geometrical isomerism.

26. Both $[Ti(H_2O)_6]^{4+}$ and $[Sc(H_2O)_6]^{3+}$ are colourless due to the absence of free electrons in 3*d* subshell.

27. '*A*' gives precipitate with $AgNO_3$, so in it Cl is present outside the coordination sphere.

'*B*' gives precipitate with $BaCl_2$, so in it SO_4^{2-} is present outside the coordination sphere.

So, *A*-$[Co(NH_3)_5SO_4]$ Cl

B-$[Co(NH_3)_5Cl]$ SO_4

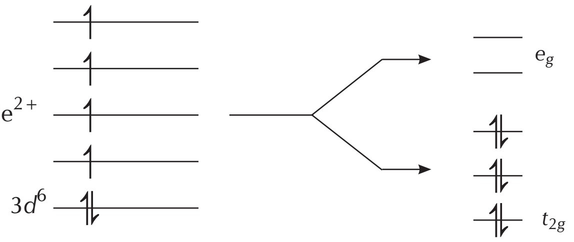
28. Ionisation isomerism (as give different ions when subjected to ionisation.)

29. [*B*], Pentaamminechloridocobalt (III) sulphate.

30. In complexes $[Rh(H_2O)_6]^{3+}$ and $[Co(H_2O)_6]^{3+}$, central metal cations have same oxidation state as well as same ligands and they fall in same group, but Δ_o of $[Rh(H_2O)_6]^{3+} > \Delta_o$ of $[Co(H_2O)_6]^{3+}$ because Rh^{3+} has high Z_{eff} value than Co^{3+}.

31. Δ_o is so large for $[Fe(CN)_6]^{4-}$ that its absorption peak is in ultraviolet region. Δ_o for $[Fe(H_2O)_6]^{2+}$ is so small that its absorption peak is in infrared region.

32. Fe^{2+}



CN^- is a strong field ligand, therefore $\Delta_o > \Delta P$ and hence, pairing of electrons takes place.

33. Two Br, two (en) and one Cr are parts of complex. Charge on the complex is

$$\left.\begin{array}{r} 2\,(\text{Br}) = -2 \\ 2\,(\text{en}) = 0 \\ 1\,(\text{Cr}) = +3 \end{array}\right\} = +1$$

Thus, complex ion is $[Cr(en)_2Br_2]^+$.

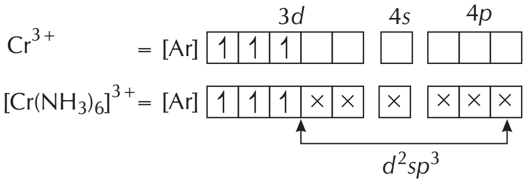
Since, anion is bromide thus, complex is $[Cr(en)_2Br_2]Br$.

34. $\underbrace{[Cr(NH_3)_6]}_{\text{coordinate sphere}} \quad \underbrace{Cl_3}_{\text{ionisable}} \rightleftharpoons$

$$[Cr(NH_3)_6]^{3+} + 3Cl^- \xrightarrow{AgNO_3} \underset{\text{white precipitate}}{AgCl\downarrow}$$

$$Cr(24) = [Ar]3d^5\,4s^1$$

$$Cr^{3+} = [Ar]\,3d^3\,4s^0$$



☒ Indicates lone-pair of NH_3 donated to Cr

(a) d^2sp^3-hybridisation, octahedral. Thus, correct.

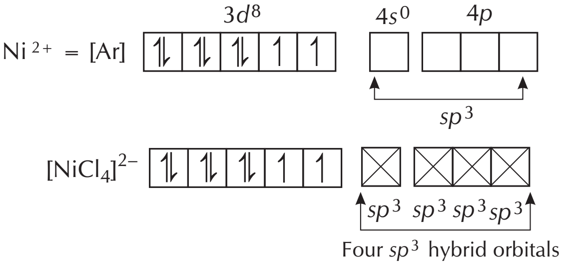
(b) There are three unpaired electrons, hence paramagnetic. Thus, correct.

(c) d^2sp^3-inner orbital complex, thus incorrect.

(d) Due to ionisable Cl^- ions, white precipitate with $AgNO_3$, thus, correct.

35. $[NiCl_4]^{2-}$; oxidation number of Ni, $x - 4 = -2$

$\therefore \quad x = +2, Ni_{(28)}\ [Ar]\ 3d^8, 4s^2$



sp^3-hybrid orbitals, tetrahedral

Cl^- is a weak field ligand and thus, unpaired electrons are not paired. Lone pairs from 4 Cl^- are accomodated in four sp^3 hybrid orbitats.

N = unpaired electrons = 2 , paramagnetic

Magnetic moment (spin only)

$$= \sqrt{N\,(N+2)}\ \text{BM}$$

$$= \sqrt{8} = 2.828\ \text{BM}$$

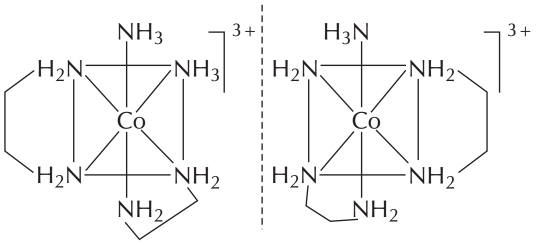
36. Based on spectrochemical series, ligands arranged in increasing order of crystal field strength are as

$$NH_3 < en < CN^- < CO$$

37.

	Complex	Isomerism shown
(a)	$[Co(en)_3]^{3+}$	Optical only
(b)	$[Ni(NH_3)_5Br]^+$	No geometrical isomer
(c)	$[Co(NH_3)_2(en)_2]^{3+}$	*Cis* and *trans*
(d)	$[Cr(NH_3)_4(en)]^{3+}$	No geometrical isomer

38. *Cis*-form of $[Co(en)_2(NH_3)_2]^{3+}$ is optically active.



39. Linkage isomerism are caused due to presence of ambidentate ligands. $[Pd(PPh_3)_2(NCS)_2]$ and $[Pd(PPh_3)_2(SCN)_2]$ are linkage isomers due to SCN, ambidentate ligands.

40. en, $\begin{array}{l} CH_2\text{—}NH_2 \\ | \\ CH_2\text{—}NH_2 \end{array}$ is a bidentate ligand.

$C_2O_4^{2-}$ is also a bidentate ligand.

Hence, coordinating head are six

(en : 2 × 2 = 4 + (ox) 2)

Coordination number 6

Complex can be ionised as

$$[E\,(en)_2(C_2O_4)]\,NO_2 \longrightarrow [E\,(en)_2\,(C_2O_4)]^+ NO_2^-$$

Oxidation number $x + 0 + (-2) = +1$

$\Rightarrow$ Oxidation number, $x = 3$

41. CFSE (crystal field splitting energy) for octahedral complex, Δ_o depends on the strength of negative ligand. Spectrochemically it has been found that the strength of splitting is as follows:

$$CO > \underline{CN^-} > NO_2^- > en > \underline{NH_3} > py >$$

$$NCS^- > H_2O > O^{2-} > OX^{2-} > OH^- > F^- >$$

$$Cl^- > SCN^- > S^{2-} > Br^- > I^-$$

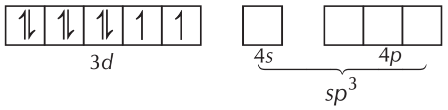
42. Cl^- is a weak ligand but Cl^- cause the pairing of electrons with large Pt^{2+} and consequently give dsp^2 hybridisation and square planar geometry.

43. $[Co(NO_2)\,(NH_3)_5]\,Cl_2$

Pentaamminenitrito-N-cobalt (III) chloride

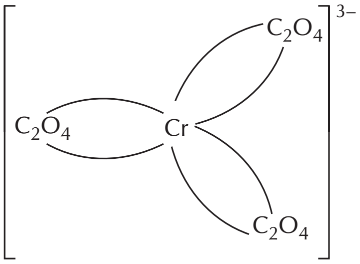
44. $_{28}Ni = [Ar]\ 4s^2, 3d^8$

$Ni^{2+} = [Ar]\ 3d^8$



Nickel has two unpaired electrons and geometry is tetrahedral due to sp^3 hybridisation.

45.



Mirror image is not superimposable, hence optical isomerism is possible.

46. Coordination number is the maximum covalency shown by a metal or metal ion. It is the maximum number of ligands attached to metal by sigma bonds or coordinate bonds.

47. Number of unpaired electrons in $[Fe(CN)_6]^{4-}$ is zero.

Thus, magnetic moment $= \sqrt{n(n+2)} = 0$ BM

(n = unpaired electrons)

n in $[MnCl_4]^{2-} = 5, \sqrt{35}$ BM

n in $[CoCl_4]^{2-} = 3, \sqrt{15}$ BM

48. $$[Co(NH_3)_5Cl]Cl_2 \rightleftharpoons \underbrace{[Co(NH_3)_5Cl]^{2+} + 2Cl^-}_{\text{three ions}}$$

$$\underset{\text{free}}{2Cl^-} + 2Ag^+ \longrightarrow 2AgCl$$

2 mol 2 mol 2 mol

49. A square planar geometry is the result of dsp^2 hybridisation where inner d sub-shell ($d_{x^2-y^2}$ orbital) participates.

10 Organic Compounds Containing Halogens

JEE Main MILESTONE

- Classification of Halogen Derivatives
- Nomenclature of Halogen Derivatives
- Monohaloalkanes
- Dihaloalkanes
- Trihaloalkanes
- Polyhaloalkanes
- Aryl halides

10.1 Classification of Halogen Derivatives

Halogen compounds are classified into several classes depending upon the mode of classification.

On the Basis of Nature of Carbon Atom

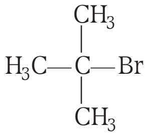
Halogen derivatives can be classified as primary, secondary and tertiary halides depending upon the fact that hydrogen is attached to primary, secondary or tertiary C-atom. *e. g.*,

$H_3C—Br$
methyl bromide
(1°)

$H_3C—CH_2Br$
primary
(1°)

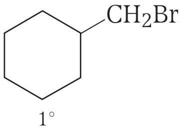
$H_3C—\overset{\overset{\large CH_3}{|}}{C}H—Br$

secondary
(2°)

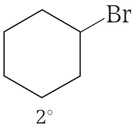


$H_3C—\underset{\underset{\large CH_3}{|}}{\overset{\overset{\large CH_3}{|}}{C}}—Br$

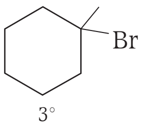
tertiary
(3°)



1°



2°



3°

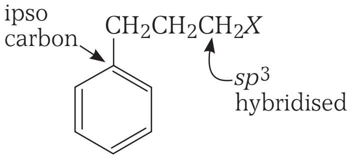
The halogen derivatives are called vinylic and allylic derivatives, if the halogen atom is attached to vinyl and allyl group respectively.

$CH_2{=}CHCl$
vinyl chloride

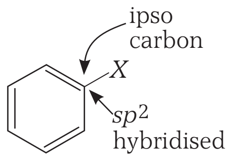
$CH_2Cl—CH{=}CH_2$
allyl chloride

If halogen atom is attached to aliphatic chain, it is called **aliphatic halogen compound** or **haloalkanes** and if it is attached to aromatic carbon, it is called **aromatic halogen compound** or **haloarenes.**

Organic compounds formed by the replacement of one or more hydrogen atoms of the aliphatic and aromatic hydrocarbons by an equal number of halogen atoms are called ***aliphatic*** *and* ***aromatic halogen*** *derivatives respectively. Term alkyl halide is used for aliphatic halogen derivatives and aryl halide is used for aromatic halogen derivatives. Here halogen atom serves as a functional group.*



aliphatic halogen compound (because X is attached with the aliphatic chain, not with the aromatic chain)

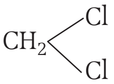


aromatic halogen compound (As X is attached directly to the benzene nucleus)

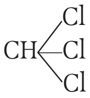
On the Basis of Number of Halogen Atoms

The halogen derivatives (both aliphatic and aromatic) can also be classified as mono, di, tri and tetra halogen derivatives depending upon the number of halogen atoms present in the molecule, *i.e.*,

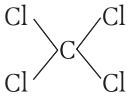
CH_3Cl
(one halogen atom)
monohalogen
derivative



(two halogen atoms)
(dihalogen derivative)



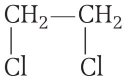
trihalogen derivative
(chloroform)



tetrahalogen derivative
(carbon tetrachloride)

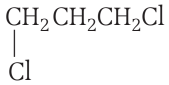
Remember in halogen derivatives, if both the halogen atoms are present at the same carbon atom, it is called geminal (*gem*-) dihalides and if present at adjacent carbon atoms, it is called vicinal (*vic*) dihalides. An another kind of dihalide, in which the two halogen atoms neither occupy the same nor the successive carbon atoms are also known. These are named as α or ω dihalogen derivatives (usually in these the halogen atoms occupy the terminal positions). *e. g.*,

CH_3CHCl_2
gem dihalide



$\underset{Cl}{CH_2}—\underset{Cl}{CH_2}$

vic dihalide



$\underset{Cl}{CH_2}CH_2CH_2Cl$

ω–dihalogen derivatives

10.2 Nomenclature of Halogen Derivatives

In trivial system of nomenclature, halogen derivatives are named as alkyl halide. *e. g.*,

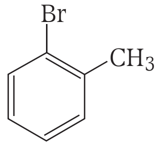
CH_3Cl methyl chloride
$CH_2{=}CHCl$ vinyl chloride
$CH_2Br—CH_2Br$ ethylene dibromide

In IUPAC system, alkyl halides are named as 'haloalkanes' and aryl halides as 'haloarenes'. The longest chain is numbered so that the smallest number is used to indicate the positions of the substituent and different substituents are named alphabetically. *e. g.*,

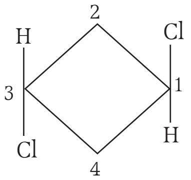
$\overset{5}{CH_3}\overset{4}{CH_2}\overset{3}{CH_2}\overset{2}{CH_2}\overset{1}{CH_2}Br$
1-bromopentane

$\overset{1}{CH_2}Br_2$
1, 1-dibromomethane

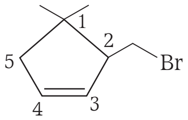
$CHCl_3$
1,1,1-trichloromethane



1-bromo-2-methyl benzene or 2-bromotoluene (*o*-bromotoluene; general name)



trans-1, 3-dichloro cyclobutane



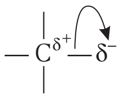
2-bromomethyl-1, 1-dimethyl cyclopentane

10.3 Monohaloalkanes

These are the compounds in which only one halogen atom is attached to the alkyl chain. Their general formula is $C_nH_{2n+1}X$.

Nature of C—*X* Bond

Since, there is a large difference in the electronegativity of halogen atom and carbon, the C atom of the halogen derivative acquires partial positive charge while the halogen atom gets partial negative charge. Hence, the C—X bond is polar in nature. This polar nature of halogen derivatives is responsible for their high reactivity and makes them useful organic compound.



Methods of Preparation

Important methods used to prepare monohaloalkanes are as follows

(a) Halogenation of Alkanes

This reaction takes place in the presence of heat or light and follows free radical mechanism. The reaction looks as

$$RH + X_2 \xrightarrow{h\nu} RX + HX \quad (\text{where, } X = \text{Cl, Br, I})$$

The free radical mechanism of the reaction is fully described in chapter "some basic principles of organic chemistry" under free radical substitution mechanism, (also see properties of alkanes) Remember that

(i) iodination occurs only in the presence of an oxidising agent such as HgO, HIO_3, HNO_3 because direct iodination is a reversible reaction.

(ii) reaction of F_2 with alkanes is explosive therefore, fluorides are generally prepared by halogen exchange method which we shall discuss later.

In the presence of light and trace of peroxide, allylic bromination takes place with NBS (It occurs by free radical mechanism.)

$$CH_3CH{=}CH_2 + NBS \longrightarrow BrCH_2CH{=}CH_2 + HCl$$

(b) Addition of Halogen Acids to Alkenes

It is an electrophilic addition reaction. In case of unsymmetrical alkene, addition takes place according to Markownikoff's rule *i.e.*, negative part goes to more hindered carbon.

$$RCH{=}CH_2 + HBr \longrightarrow RCHBrCH_3$$

The reaction is fully described in alkenes properties and mechanism is fully described in 'some basic prinicples of organic chemistry' under electrophilic addition, Markownikoff rule and Kharasch effect.

At high temperature the addition of halogens to alkenes becomes reversible and hence, does not occur.

(c) Substitution of —OH Group of Alcohol

These reactions are infact nucleophilic substitution reactions and follow S_N1 or S_N2 accordingly depending upon the alcohol used. The mechanisms are fully described in chapter some basic principles of organic chemistry under nucleophilic substitutions. The reactions are

(i) $3ROH + PX_3 \longrightarrow 3RX + H_3PO_3$

(ii) $ROH + PX_5 \longrightarrow RX + POX_3 + HX$

(PBr_5 and PI_5 are highly unstable compounds due to steric hindrance therefore, only chlorides are prepared by this method.)

(iii) $ROH + \text{dry HCl} \xrightarrow{\text{Anh. } ZnCl_2} RCl + H_2O$

Mixture of (1 : 1) dry HCl and anhydrous $ZnCl_2$ is called **Lucas reagent**.

(iv) $R{—}OH + HX \longrightarrow RX + H_2O$

The reactivity of alcohols towards HX is allyl, benzyl > 3° > 2° > 1° and the reactivity of halogen acids is HI > HBr > HCl > HF.

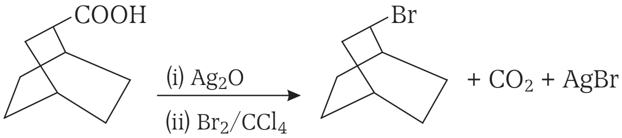
(v) $ROH + SOCl_2 \xrightarrow{\text{Pyridine}} RCl + HCl + SO_2$

The reaction of $SOCl_2$ is called Darzens procedure. Bromide and iodide are not prepared by this method, because thionyl bromide is unstable and thionyl iodide does not exist.

(d) Borodine-Hunsdicker Method

This is the decarboxylation of silver salt of fatty acids, when these are treated with Br_2 in refluxing CCl_4.

$$CH_3COOAg + Br_2 \xrightarrow{CCl_4} CH_3Br + AgBr + CO_2$$



The yield of halide is 1° > 2° > 3°

The reaction follows free radical mechanism; yield of alkyl chloride is less than alkyl bromide.

If iodine is used in the place of Br_2, the reaction is modified as

$$2RCOOAg + I_2 \longrightarrow RCOOR + CO_2 + 2AgI$$

This modified reaction is called **Birnbaurn Simonini reaction.**

(e) Halide Exchange Method

Alkyl chloride and bromides are converted into their iodides or fluorides as :

Alkyl chloride or bromide $\xrightarrow{\text{NaI/acetone}}$ Alkyl iodide + Na chloride or bromide

$\xrightarrow{\text{Inorganic fluorides like } Hg_2F_2}$ Alkyl fluoride + Hg chloride or bromide

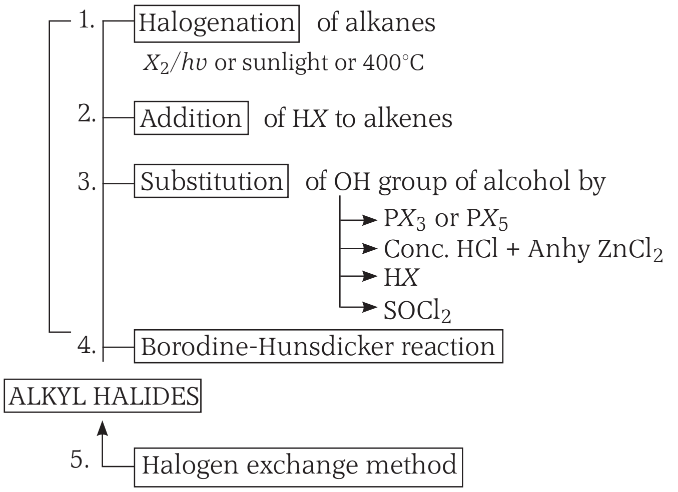
This reaction is called **Finkelstein reaction**.

Alkyl fluorides which can't be prepared by the **Finkelstein reaction** may be obtained from corresponding chlorides by the action of mercurous fluoride or antimony trifluoride or AgF **(Swarts reaction)**.

$$2CH_3Cl + Hg_2F_2 \longrightarrow 2CH_3F + Hg_2Cl_2$$

$$CH_3Br + AgF \longrightarrow CH_3F + AgBr$$

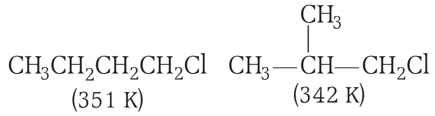
The outline of the methods of preparation of monohaloalkanes looks like (All methods give chloride and bromide in good yield but fluorides or iodides in poor yield.



FINKELSTEIN method for converting chlorides and bromides to iodides.

Physical Properties

1. Chloride, bromide and fluoride of methane and chloride of ethane are gases at room temperature, rest alkyl halides up to C_{18} are colourless liquids and beyond it, these are colourless solids. Bromides and particularly iodides develop colour when exposed to light.
2. Haloalkanes have polar nature but are insoluble in polar solvents like water as they have no ability of forming H-bonding with water. However, these are soluble in organic solvents like ether, benzene etc.
3. Fluoro and chloro compounds are lighter than water whereas bromo and iodo derivatives are heavier. The density of alkyl halides decreases, as the size of alkyl group increases.
4. These have higher boiling point than alkanes of comparable molecular weight. *For a given alkyl group their boiling points follow the order* $RI > RBr > RCl > RF$*; while for a given halogen atom the boiling points of alkyl halides increase with increase in the size of alkyl group. Boiling point decreases with branching e.g.,*



$$\underset{(351\ K)}{CH_3CH_2CH_2CH_2Cl} \qquad \underset{(342\ K)}{CH_3-\overset{\overset{\large CH_3}{|}}{C}H-CH_2Cl}$$

5. The dipole moment of halogen derivatives is due to the polar nature of C—X bond. Vinyl chloride and chlorobenzene showing resonance, have low dipole moment (as compared to alkyl halide) because unusual positive charge decreases the electronegativity of Cl atom and thus, the polarity of the bond. Dipole moment of alkyl halides decreases as the electronegativity of halogen atom decreases. However, the dipole moment of fluorides is lower than that of chlorides because of very small size of fluorine.

Sample Problem 1 *Arrange the given set of compounds in order of increasing boiling points.*

I. I-chloropropane, II. iso-propyl chloride, III 1-chlorobutane.

[**NCERT**]

(a) I < II < III   *(b)* II < III < I
(c) I < III < II   *(d)* II < I < III

Interpret (*d*) As the size of *R* group (alkyl group) or halogen atom increases, boiling point increases, because, now more surface area is available. Boiling point decreases with branching due to decrease in van der Waals' forces. Thus, the correct order of boiling point is

$$\underset{\substack{\text{isopropyl chloride}\\ \text{or}\\ \text{2-chloropropane}}}{(CH_3)_2CHCl} < \underset{\text{1–chloropropane}}{ClCH_2CH_2CH_3} < \underset{\text{1–chlorobutane}}{ClCH_2CH_2CH_2CH_3}$$

Chemical Properties

Because of the presence of polar C–X bond, alkyl halides readily undergo nucleophilic substitution, elimination, reduction etc. So, their reactions can be studied under the following headings.

1. Nucleophilic substitution reaction
2. Reduction
3. Reaction with metals
4. Elimination reactions
5. Friedel-Crafts alkylation

Hot Spot 1

NUCLEOPHILIC SUBSTITUTION Reactions

It is an important topic for JEE Main examination point of view. For solving problems based on the topic, deep understanding of the topic is required. The questions are mainly based only mechanism and sometimes on direct reactions.

When a methyl halide or primary alkyl halide reacts with a Lewis base such as sodium ethoxide, Lewis base replaces the halogen as halide. This is an example of a very general type of reaction, called a **nucleophilic substitution reaction,** or nucleophilic **displacement reaction** (S_N). The ethoxide ion is the nucleophile and it substitutes for the bromide which is called the leaving group.

$$\overset{\text{nucleophile}}{\overset{\downarrow}{Na^+CH_3CH_2O^-}} + \underset{\text{leaving group}}{\underset{\uparrow}{Br}}—CH_2CH_3 \longrightarrow CH_3CH_2O—CH_2CH_3 + Na^+Br^-$$

Alkyl halides react with a large number of nucleophilic reagents, both organic and inorganic, to form various other products. (Detailed mechanism of S_N1 and S_N2 was discussed in chapter "some basic principles of organic chemistry").

$$R—X \overset{\text{slow}}{\rightleftharpoons} \overset{\delta+}{R}\cdots\overset{\delta-}{X} \xrightarrow{\text{fast}} R^+ + X^- \xrightarrow[\text{fast}]{OH^-} R—OH$$

$$\left(\frac{dx}{dt}\right) = k[R—X], \text{ a case of } S_N1 \text{ reaction.}$$

The order of reactivity of alkyl halide for such reaction is 3° > 2° > 1° because 3° carbocation is most stable and involve as intermediate.

$$OH^- + R—X \overset{\text{slow}}{\rightleftharpoons} \overset{\delta-}{HO}\cdots R\cdots\overset{\delta-}{X} \xrightarrow{\text{fast}} R—OH + X^-$$

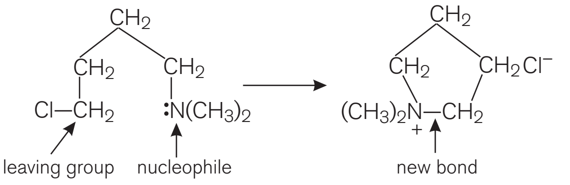
$$\left(\frac{dx}{dt}\right) = k[R—X]\,[OH^-], \text{ a case of } S_N2 \text{ reaction.}$$

The order of reactivity of alkyl halides for S_N2 reaction is 1° > 2° > 3° because transition state is involved which is more stable in case of unhindered carbons.

In all cases, X^- is a good leaving group which is in an increasing order (easiness, leaveability).

$$H^-, R^- <<< MeO^-, OH^- < CN^- < MeCOO^- < ROSO_2^-, ArSO_2O^-$$

Caution Point *The given reaction is an example of an intramolecular nucleophilic substituion reaction—a reaction in which the nucleophile and the leaving group are a part of the same molecule. In this case, S_N reaction causes ring formation.*



Some nucleophilic substitution reactions have been summarised below.

(i) **With aqueous alkali** It is also called "hydrolysis of alkyl halide".

$$RX + KOH(aq) \longrightarrow ROH + KX$$

(ii) **With moist silver oxide** Moist silver oxide is AgOH and the reactions look like

$$RX + AgOH \longrightarrow ROH + AgX$$

(iii) **With dry silver oxide** Ether are formed by heating alkyl halides with dry silver oxide.

$$2RX + Ag_2O \longrightarrow ROR + 2AgX$$

(iv) **With sodium alkoxide** This reaction is also called "Williamson's ether synthesis".

$$R'O^-Na^+ + R''X \longrightarrow R'OR'' + Na^+X^-$$

(v) **With NH_3** The reaction proceeds

$$RX + NH_3 \longrightarrow RNH_2 + HX;$$
$$RNH_2 + RX \longrightarrow R_2NH + HX$$
$$R_2NH + RX \longrightarrow R_3N + HX;$$
$$R_3N + RX \longrightarrow R_4N^+X^-$$

Thus, a mixture of primary amine (RNH_2), secondary amine (R_2NH), tertiary amine (R_3N) and quaternary ammonium salt ($R_4N^+X^-$) is obtained.

This reaction is called **Hofmann ammonolysis** of alkyl halides.

(vi) **With NaCN and AgCN** With NaCN, alkyl cyanide and with AgCN, alkyl isocyanide is produced. The reason is **electrovalent nature of NaCN and covalent linear structure of AgCN** as Ag—C≡N**:** Ag—C≡N etc., where Ag atom is linked to C and N both, thus both the isomers are possible. The reactions looks like

$$RX + Na^+CN^- \longrightarrow RCN + Na^+X^-$$

$$RX + AgCN \longrightarrow N \overset{\rightarrow}{\equiv} C + AgX$$

The cyanide obtained are of great importance and are used to prepare many other types of compounds.

1. Amides are obtained by partial hydrolysis of cyanides with alk. H_2O_2 or conc. HCl.

$$RC\equiv N + H_2O \xrightarrow[\text{or conc. HCl}]{\text{Alk. } H_2O_2} RCONH_2$$

2. Acids are obtained by hydrolysis of cyanides with mineral acids or alkalies.

$$RC\equiv N \xrightarrow[\text{conc. HCl}]{H_2O} RCONH_2 \xrightarrow{H_2O,\ \text{dil. HCl}} \underset{\text{acid}}{RCOOH} + NH_3$$

3. Primary amines are obtained by the reduction of cyanides with nascent hydrogen (Mendius reaction)

$$RC\equiv N + 4[H] \longrightarrow RCH_2NH_2$$

4. Aldehydes are obtained by partial reduction of cyanides with $SnCl_2$ and HCl and then steam distillation. (Stephen's reaction).

$$RC\equiv N + 2H \xrightarrow[\text{HCl}]{SnCl_2} R\text{—}CH{=}NH\cdot HCl \xrightarrow[H^+]{H_2O} RCHO + NH_4Cl$$

(vii) **With *R*COOAg** This reaction looks like

$$RCOO\,Ag + X\,R' \longrightarrow RCOOR' + AgX$$

(viii) **With sodium salt of alkynes** This method is used to prepare higher alkynes and has already been described in methods of preparation of alkynes.

(ix) **With KSH** The reaction looks like

$$R\,X + K\,SH \longrightarrow \underset{\substack{\text{thioalcohol or}\\ \text{mercaptan}}}{RSH} + KX$$

(x) **With K_2S** The reaction looks like

$$2RX + K_2S \longrightarrow \underset{\text{thioether}}{RSR} + 2KX$$

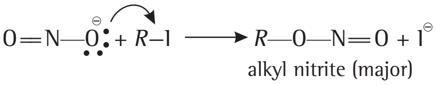
(xi) **With KNO_2 and $AgNO_2$** With KNO_2 (ionic), alkyl nitrites (R—O—N=O) and with $AgNO_2$ (covalent), nitro alkanes are produced.

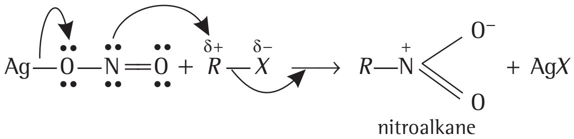
Alkali metal nitrites are predominantly ionic to give $NO_2^{\ominus}$ ion. The reaction can occur through either O or N, which can give both nitrites and nitro compounds. But since (C—O) bonds are stronger than (C—N) bonds, alkyl nitrites are the main products.

On the other hand, silver nitrite is a covalent compound and only electron pair of nitrogen is available for bond formation. As a result nitroalkanes are the chief products.

Silver nitrite exibits small amount of ionic character which also explains the formation of alkyl nitrite in small amount.

$$NaNO_2 \longrightarrow Na^+ + NO_2^{\ominus}$$





(xii) **With $(C_6H_5)_3P$** The reaction looks like

$$RX + (C_6H_5)_3P \longrightarrow [R(C_6H_5)_3P]^+X^-$$

(xiii) **With NaN_3** NaN_3 is the sodium salt of hydrazoic acid (HN_3) in which N have oxidation state of $-\frac{1}{3}$.

$$R\,\boxed{X + Na}\,N_3 \longrightarrow RN_3 + NaX$$

All the above written reactions proceed through S_N1 or S_N2 mechanisms depending upon the type of alkyl halide.

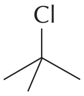
Sample Problem 2 *Which of the following alkyl halides will undergo S_N1 reaction most readily?* **[NCERT Exemplar]**

(*a*) $(CH_3)_3C$—F
(*b*) $(CH_3)_3C$—Cl
(*c*) $(CH_3)_3C$—Br
(*d*) $(CH_3)_3C$—I

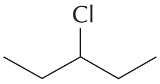
Interpret (*d*) Among the given $(CH_3)_3C-I$ is most reactive because C—I bond is weakest due to the large size of I atom among halogens.

Sample Problem 3 *In the following compounds which compound undergo faster S_N1 reaction?* **[NCERT]**

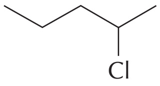
(*a*)



(*b*)



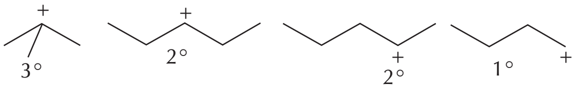
(*c*)



(*d*)

Interpret (*a*) In S_N1 mechanism, carbocation intermediate is involved, so the alkyl halide that gives more stable carbocation readily undergo faster S_N1 reaction.

The order of stability of carbocations is 3° > 2° > 1°



Thus,  readily undergoes S_N1 reaction.

Reduction

With Zn/acid or LiAlH$_4$ or catalytic hydrogenation Alkyl halides on reduction with these reagents give alkanes.

$$RX \xrightarrow[\text{or LiAlH}_4 \text{ or catalytic hydrogenation}]{\text{Zn/acid}} R\text{—H}$$

The reaction is completely described in alkanes (methods of preparation).

Reaction with Metals

(i) With Mg

The reactions proceed as

$$RX + \text{Mg} \xrightarrow{\text{Dry ether}} R\text{Mg}X \qquad \text{(Grignard's reagent)}$$
