PREFACE

In sync with the recent changes in the test pattern and format of **JEE Main** (Joint Engineering Entrance), it is my pleasure to introduce **Master Resource Book in Chemistry for JEE Main**, for the Students aspiring a seat in a reputed Engineering College. JEE Main is a gateway examination for candidates expecting to seek admission in Bachelor in Engineering (BE), Bachelor of Technology (B.Tech) and Bachelor of Architecture (B.Arch) at Indian Institutes of Information Technology (IIITs), National Institutes of Technology (NITs), Delhi Technological University and other Centrally Funded Technical Institutes (CFTIs).

JEE Main is also an examination which is like screening examination for **JEE Advanced** (The gateway examination to India's most reputed Technical Institutes, Indian Institutes of Technology IITs). Only the top 2.2 lacs students passed in JEE Main will be able to attempt JEE Advanced.

Gradually, the number of students aspiring for the seat in the Engineering College has increased rapidly in the last 5 Years or so. This year nearly 10 lacs students appeared for JEE Main and only a few were able to reserve a seat in the college of their choice, so there is a cut throat competition among the aspirants. Thus, it calls for a systematic mastery of all the subjects of the test with paramount importance to problem-solving. Most of the books now in the market have become repetitive with scant respect to the needs of true and effective learning. This book has been designed to fulfill the perceived needs of the students as such.

- This book comprehensively covers all the topics of **JEE Main Chemistry** syllabus. The chapters have been sequenced according to the **syllabus of class 11th & 12th**. Each chapter has essential theoretical discussion of the related concepts with sufficient number of solved examples, practice problems and other solved problems. In each chapter previous years' questions of AIEEE and JEE Main have been included to help students know the difficulty levels and nature of questions asked in competitive exams at this level.
- All types of questions have been included in this book: **Single Correct Answer Types, Multiple Correct Answer Types, Reasoning Types, Matches, Passage-based Questions** etc.
- This is the only book which has its subject matter divided as per class 11th & 12th syllabus. It covers almost all questions of **NCERT Textbook & NCERT Exemplar problems**.

It is hoped this new effort will immensely benefit the students in their goal to secure a seat in the prestigious engineering college, and would be convenient to teachers in planning their teaching programmes. Suggestions for further improvement are welcome from the students and teachers.

Sanjay Sharma

CONTENTS

PART I

Chapters from Class 11th Syllabus

PART II

Chapters from Class 12th Syllabus

JEE Main Solved Papers

SYLLABUS

Section- A *(Physical Chemistry)*

UNIT 1 Some Basic Concepts in Chemistry

Matter and its nature, Dalton's atomic theory; Concept of atom, molecule, element and compound; Physical quantities and their measurements in Chemistry, precision and accuracy, significant figures, S.I. Units, dimensional analysis; Laws of chemical combination; Atomic and molecular masses, mole concept, molar mass, percentage composition, empirical and molecular formulae; Chemical equations and stoichiometry.

UNIT 2 States of Matter

Classification of matter into solid, liquid and gaseous states.

Gaseous State Measurable properties of gases; Gas laws - Boyle's law, Charle's law, Graham's law of diffusion, Avogadro's law, Dalton's law of partial pressure; Concept of Absolute scale of temperature; Ideal gas equation, Kinetic theory of gases (only postulates); Concept of average, root mean square and most probable velocities; Real gases, deviation from Ideal behaviour, compressibility factor, van der Waals'

Equation, liquefaction of gases, critical constants.

Liquid State Properties of liquids - vapour pressure, viscosity and surface tension and effect of temperature on them (qualitative treatment only).

Solid State Classification of solids: molecular, ionic, covalent and metallic solids, amorphous and crystalline solids (elementary idea); Bragg's Law and its applications, Unit cell and lattices, packing in solids (fcc, bcc and hcp lattices), voids, calculations involving unit cell parameters, imperfection in solids; electrical, magnetic and dielectric properties.

UNIT 3 Atomic Structure

Discovery of sub-atomic particles (electron, proton and neutron); Thomson and Rutherford atomic models and their limitations; Nature of electromagnetic radiation, photoelectric effect; spectrum of hydrogen atom, Bohr model of hydrogen atom - its postulates, derivation of the relations for energy of the electron and radii of the different orbits, limitations of Bohr's model; dual nature of matter, de-Broglie's relationship, Heisenberg uncertainty principle.

Elementary ideas of quantum mechanics, quantum mechanical model of atom, its important features, ψ and $\psi2$, concept of atomic orbitals as one electron wave functions; Variation of ψ and $\psi2$ with r for 1s and 2s orbitals; various quantum numbers (principal, angular momentum and magnetic quantum numbers) and their significance; shapes of s, p and d - orbitals, electron spin and spin quantum number; rules for filling electrons in orbitals – aufbau principle, Pauli's exclusion principle and Hund's rule, electronic configuration of elements, extra stability of half-filled and completely filled orbitals.

UNIT 4 Chemical Bonding and Molecular Structure

Kossel Lewis approach to chemical bond formation, concept of ionic and covalent bonds.

Ionic Bonding Formation of ionic bonds, factors affecting the formation of ionic bonds; calculation of lattice enthalpy.

Covalent Bonding Concept of electronegativity, Fajan's rule, dipole moment; Valence Shell Electron Pair Repulsion (VSEPR) theory and shapes of simple molecules.

Quantum mechanical approach to covalent bonding Valence bond theory - Its important features, concept of hybridization involving s, p and d orbitals; Resonance.

Molecular Orbital Theory Its important features, LCAOs, types of molecular orbitals (bonding, antibonding), sigma and pi-bonds, molecular orbital electronic configurations of homonuclear diatomic molecules, concept of bond order, bond length and bond energy.

Elementary idea of metallic bonding. Hydrogen bonding and its applications.

UNIT 5 Chemical Thermodynamics

Fundamentals of thermodynamics System and surroundings, extensive and intensive properties, state functions, types of processes.

First law of thermodynamics Concept of work, heat internal energy and enthalpy, heat capacity, molar heat capacity, Hess's law of constant heat summation; Enthalpies of bond dissociation, combustion, formation, atomization, sublimation, phase transition, hydration, ionization and solution.

Second law of thermodynamics Spontaneity of processes; ΔS of the universe and ΔG of the system as criteria for spontaneity, ΔG° (Standard Gibb's energy change) and equilibrium constant.

UNIT 6 Solutions

Different methods for expressing concentration of solution - molality, molarity, mole fraction, percentage (by volume and mass both), vapour pressure of solutions and Raoult's Law - Ideal and non-ideal solutions, vapour pressure - composition plots for ideal and non-ideal solutions.

Colligative properties of dilute solutions - relative lowering of vapour pressure, depression of freezing point, elevation of boiling point and osmotic pressure; Determination of molecular mass using colligative properties; Abnormal value of molar mass, van’t Hoff factor and its significance.

UNIT 7 Equilibrium

Meaning of equilibrium, concept of dynamic equilibrium.

Equilibria involving physical processes Solid -liquid, liquid - gas and solid - gas equilibria, Henry’s law, general characteristics of equilibrium involving physical processes.

Equilibria involving chemical processes Law of chemical equilibrium, equilibrium constants (K and K) and their significance, significance of ΔG and ΔG° in chemical equilibria, factors affecting equilibrium concentration, pressure, temperature, effect of catalyst; Le -Chatelier’s principle.

Ionic equilibrium Weak and strong electrolytes, ionization of electrolytes, various concepts of acids and bases (Arrhenius, Bronsted - Lowry and Lewis) and their ionization, acid-base equilibria (including multistage ionization) and ionization constants, ionization of water, pH scale, common ion effect, hydrolysis of salts and pH of their solutions, solubility of sparingly soluble salts and solubility products, buffer solutions.

UNIT 8 Redox Reactions and Electrochemistry

Electronic concepts of oxidation and reduction, redox reactions, oxidation number, rules for assigning oxidation number, balancing of redox reactions.

Eectrolytic and metallic conduction, conductance in electrolytic solutions, specific and molar conductivities and their variation with concentration: Kohlrausch's law and its applications.

Electrochemical cells - Electrolytic and Galvanic cells, different types of electrodes, electrode potentials including standard electrode potential, half - cell and cell reactions, emf of a Galvanic cell and its measurement; Nernst equation and its applications; Relationship between cell potential and Gibbs' energy change; Dry cell and lead accumulator; Fuel cells; Corrosion and its prevention.

UNIT 9 Chemical Kinetics

Rate of a chemical reaction, factors affecting the rate of reactions concentration, temperature, pressure and catalyst; elementary and complex reactions, order and molecularity of reactions, rate law, rate constant and its units, differential and integral forms of zero and first order reactions, their characteristics and half - lives, effect of temperature on rate of reactions - Arrhenius theory, activation energy and its calculation, collision theory of bimolecular gaseous reactions (no derivation).

UNIT 10 Surface Chemistry

Adsorption Physisorption and chemisorption and their characteristics, factors affecting adsorption of gases on solids-Freundlich and Langmuir adsorption isotherms, adsorption from solutions.

Catalysis Homogeneous and heterogeneous, activity and selectivity of solid catalysts, enzyme catalysis and its mechanism.

Colloidal state distinction among true solutions, colloids and suspensions, classification of colloids - lyophilic, lyophobic; multi molecular, macromole-cular and associated colloids (micelles), preparation and properties of colloids Tyndall effect, Brownian movement, electrophoresis, dialysis, coagulation and flocculation; Emulsions and their characteristics.

Section- B *(Inorganic Chemistry)*

UNIT 11 Classification of Elements and Periodicity in Properties

Periodic Law and Present Form of the Periodic Table,
s, p, d and *f* Block Elements, Periodic Trends in Properties of Elementsatomic and Ionic Radii, Ionization Enthalpy, Electron Gain Enthalpy, Valence, Oxidation States and Chemical Reactivity.

UNIT 12 General Principles and Processes of Isolation of Metals

Modes of occurrence of elements in nature, minerals, ores; steps involved in the extraction of metals - concentration, reduction (chemical and electrolytic methods) and refining with special reference to the extraction of Al, Cu, Zn and Fe; Thermodynamic and electrochemical principles involved in the extraction of metals.

UNIT 13 Hydrogen

Position of hydrogen in periodic table, isotopes, preparation, properties and uses of hydrogen; physical and chemical properties of water and heavy water; Structure, preparation, reactions and uses of hydrogen peroxide; Classification of hydrides ionic, covalent and interstitial; Hydrogen as a fuel.

UNIT 14 *s* - Block Elements

(Alkali and Alkaline Earth Metals)

Group 1 and 2 Elements

General introduction, electronic configuration and general trends in physical and chemical properties of elements, anomalous properties of the first element of each group, diagonal relationships.

Preparation and properties of some important compounds - sodium carbonate, sodium chloride, sodium hydroxide and sodium hydrogen carbonate; Industrial uses of lime, limestone, Plaster of Paris and cement; Biological significance of Na, K, Mg and Ca.

UNIT 15 p - Block Elements

Group 13 to Group 18 Elements

General Introduction Electronic configuration and general trends in physical and chemical properties of elements across the periods and down the groups; unique behaviour of the first element in each group.

Group wise study of the p – block elements

Group 13 Preparation, properties and uses of boron and aluminium; structure, properties and uses of borax, boric acid, diborane, boron trifluoride, aluminium chloride and alums.

Group 14 Tendency for catenation; Structure, properties and uses of allotropes and oxides of carbon, silicon tetrachloride, silicates, zeolites and silicones.

Group 15 Properties and uses of nitrogen and phosphorus; Allotrophic forms of phosphorus; Preparation, properties, structure and uses of ammonia nitric acid, phosphine and phosphorus halides,(PCl_3, PCl_5); Structures of oxides and oxoacids of nitrogen and phosphorus.

Group 16 Preparation, properties, structures and uses of dioxygen and ozone; Allotropic forms of sulphur; Preparation, properties, structures and uses of sulphur dioxide, sulphuric acid (including its industrial preparation); Structures of oxoacids of sulphur.

Group 17 Preparation, properties and uses of chlorine and hydrochloric acid; Trends in the acidic nature of hydrogen halides; Structures of Interhalogen compounds and oxides and oxoacids of halogens.

Group 18 Occurrence and uses of noble gases; Structures of fluorides and oxides of xenon.

UNIT 16 *d* – and *f* – Block Elements

Transition Elements General introduction, electronic configuration, occurrence and characteristics, general trends in properties of the first row transition elements - physical properties, ionization enthalpy, oxidation states,

atomic radii, colour, catalytic behaviour, magnetic properties, complex formation, interstitial compounds, alloy formation; Preparation, properties and uses of $K_2Cr_2O_7$ and $KMnO_4$.

Inner Transition Elements Lanthanoids Electronic configuration, oxidation states, chemical reactivity and lanthanoid contraction.

Actinoids Electronic configuration and oxidation states.

UNIT 17 Coordination Compounds

Introduction to coordination compounds, Werner's theory; ligands, coordination number, denticity, chelation; IUPAC nomenclature of mononuclear coordination compounds, isomerism; Bonding Valence bond approach and basic ideas of Crystal field theory, colour and magnetic properties; importance of coordination compounds (in qualitative analysis, extraction of metals and in biological systems).

Unit 18 Environmental Chemistry

Environmental pollution Atmospheric, water and soil. Atmospheric pollution Tropospheric and stratospheric.

Tropospheric pollutants : Gaseous pollutants Oxides of carbon, nitrogen and sulphur, hydrocarbons; their sources, harmful effects and prevention; Green house effect and Global warming; Acid rain;

Particulate pollutants Smoke, dust, smog, fumes, mist; their sources, harmful effects and prevention.

Stratospheric pollution Formation and breakdown of ozone, depletion of ozone layer - its mechanism and effects.

Water pollution Major pollutants such as, pathogens, organic wastes and chemical pollutants their harmful effects and prevention.

Soil pollution Major pollutants such as: Pesticides (insecticides, herbicides and fungicides), their harmful effects and prevention.

Strategies to control environmental pollution.

Section- C *(Organic Chemistry)*

UNIT 19 Purification & Characterisation of Organic Compounds

Purification Crystallization, sublimation, distillation, differential extraction and chromatography principles and their applications.

Qualitative analysis Detection of nitrogen, sulphur, phosphorus and halogens.

Quantitative analysis (basic principles only) Estimation of carbon, hydrogen, nitrogen, halogens, sulphur, phosphorus.

Calculations of empirical formulae and molecular formulae; Numerical problems in organic quantitative analysis.

UNIT 20 Some Basic Principles of Organic Chemistry

Tetravalency of carbon; Shapes of simple molecules hybridization (s and p); Classification of organic compounds based on functional groups: —C=C—,—C=C— and those containing halogens, oxygen, nitrogen and sulphur, Homologous series; Isomerism - structural and stereoisomerism.

Nomenclature (Trivial and IUPAC)

Covalent bond fission Homolytic and heterolytic free radicals, carbocations and carbanions; stability of carbocations and free radicals, electrophiles and nucleophiles.

Electronic displacement in a covalent bond Inductive effect, electromeric effect, resonance and hyperconjugation.

Common types of organic reactions Substitution, addition, elimination and rearrangement.

UNIT 21 Hydrocarbons

Classification, isomerism, IUPAC nomenclature, general methods of preparation, properties and reactions.

Alkanes Conformations: Sawhorse and Newman projections (of ethane); Mechanism of halogenation of alkanes.

Alkenes Geometrical isomerism; Mechanism of electrophilic addition: addition of hydrogen, halogens, water, hydrogen halides (Markownikoff's and peroxide effect); Ozonolysis, oxidation, and polymerization.

Alkynes acidic character; addition of hydrogen, halogens, water and hydrogen halides; polymerization.

Aromatic hydrocarbons Nomenclature, benzene structure and aromaticity; Mechanism of electrophilic substitution: halogenation, nitration, Friedel – Craft's alkylation and acylation, directive influence of functional group in mono-substituted benzene.

UNIT 22 Organic Compounds Containing Halogens

General methods of preparation, properties and reactions; Nature of C—X bond; Mechanisms of substitution reactions. Uses/environmental effects of chloroform, iodoform

UNIT 23 Organic Compounds Containing Oxygen

General methods of preparation, properties, reactions and uses.

Alcohols, Phenols and Ethers

Alcohols Identification of primary, secondary and tertiary alcohols; mechanism of dehydration.

Phenols Acidic nature, electrophilic substitution reactions: halogenation, nitration and sulphonation, Reimer - Tiemann reaction.

Ethers Structure.

Aldehyde and Ketones Nature of carbonyl group;

Nucleophilic addition to >C=O group, relative reactivities of aldehydes and ketones; Important reactions such as - Nucleophilic addition reactions (addition of HCN, NH_3 and its derivatives), Grignard reagent; oxidation; reduction (Wolff Kishner and Clemmensen) acidity of α-hydrogen, aldol condensation, Cannizzaro reaction, Haloform reaction; Chemical tests to distinguish between aldehydes and Ketones.

Carboxylic Acids Acidic strength and factors affecting it.

UNIT 24 Organic Compounds Containing Nitrogen

General methods of preparation, properties, reactions and uses.

Amines Nomenclature, classification, structure basic character and identification of primary, secondary and tertiary amines and their basic character. Diazonium Salts Importance in synthetic organic chemistry.

UNIT 25 Polymers

General introduction and classification of polymers, general methods of polymerization-addition and condensation, copolymerization; Natural and synthetic rubber and vulcanization; some important polymers with emphasis on their monomers and uses - polythene, nylon, polyester and bakelite.

UNIT 26 Biomolecules

General introduction and importance of biomolecules.

Carbohydrates Classification: aldoses and ketoses; monosaccharides (glucose and fructose), constituent monosaccharides of oligosacchorides (sucrose, lactose, maltose) and polysaccharides (starch, cellulose, glycogen).

Proteins Elementary Idea of α-amino acids, peptide bond, . polypeptides; proteins: primary, secondary, tertiary and quaternary structure (qualitative idea only), denaturation of proteins, enzymes.

Vitamins Classification and functions.

Nucleic Acids Chemical constitution of DNA and RNA. Biological functions of Nucleic acids.

UNIT 27 Chemistry in Everyday Life

Chemicals in medicines Analgesics, tranquilizers, antiseptics, disinfectants, antimicrobials, antifertility drugs, antibiotics, antacids, antihistamins - their meaning and common examples.

Chemicals in food Preservatives, artificial sweetening agents - common examples.

Cleansing agents Soaps and detergents, cleansing action.

UNIT 28 Principles Related to Practical Chemistry

- Detection of extra elements (N, S, halogens) in organic compounds; Detection of the following functional groups: hydroxyl (alcoholic and phenolic), carbonyl (aldehyde and ketone), carboxyl and amino groups in organic compounds.
- Chemistry involved in the preparation of the following
- Inorganic compounds Mohr's salt, potash alum.
- Organic compounds Acetanilide,
  p-nitroacetan ilide, aniline yellow, iodoform.
- Chemistry involved in the titrimetric excercises - Acids bases and the use of indicators, oxali acid vs $KMnO_4$, Mohr's salt vs $KMnO_4$.
- Chemical principles involved in the qualitative salt analysis
- Cations — Pb^{2+}, Cu^{2+}, Al^{3+}, Fe^{3+}, Zn^{2+}, Ni^{2+}, Ca^{2+}, Ba^{2+}, Mg^{2+} NH^{4+}. Anions – CO_3^{2-}, S^{2-}, SO_4^{2-}, NO_2, NO_3, Cl^-, Br^-, I^- (Insoluble salts excluded).
- Chemical principles involved in the following experiments

1. Enthalpy of solution of $CuSO_4$
2. Enthalpy of neutralization of strong acid and strong base.
3. Preparation of lyophilic and lyophobic sols.
4. Kinetic study of reaction of iodide ion with hydrogen peroxide at room temperature.

PART - I

Chapters from Class 11th Syllabus

1 Some Basic Concepts in Chemistry

JEE Main MILESTONE

- Matter and Its Nature
- Physical Quantities and Their Measurements in Chemistry
- Atomic and Molecular Masses
- Equivalent Mass or Equivalent Weight
- Empirical and Molecular Formulae
- Stoichiometric Problems of Different Kinds

1.1 Matter and Its Nature

Matter is anything which occupies space and has mass. All the things around us *e.g.,* water, air, book, table etc., are matter.

There are five states of matter namely solid, liquid, gases, plasma and Bose-Einstein condensate. Out of these, three states *i.e.,* solid, liquid and gas are general states and taught in our schools. These three states provide a basis for the physical classification of matter.

Solids have a definite volume and shape; liquids have a definite volume but not definite shape; gases have neither a definite volume nor a definite shape.

Chemistry is the branch of science which deals with the composition, properties and interaction of all kinds of matter such as air, water, rocks, plants, earth, etc.

These three states of matter are the result of competition between intermolecular interactions (attractive force between molecules) and thermal energy (responsible for repulsion between molecules).

On heating, a solid usually changes to a liquid and the liquid on further heating changes to the gaseous (or vapour) state. In the reverse process, a gas on cooling liquifies to the liquid and the liquid on further cooling freezes to the solid.

Plasma is seen as a state containing gaseous ions and free electrons and exists when gaseous state is taken to very high temperatures (say 1000 to 1,000,000,000°C). Here, it is necessary that the entire gas as a whole have no charge and is not of too much density. So, in short we can say **plasmas** as **low density ionised gases at very high temperatures**. Plasmas can be seen in northern lights or ball lightenings, flames, lightenings, neon lights, stars in particular sun, clouds of gas and dust around stars.

BE condensate was predicted in 1924 by **Satyendra Nath Bose** and **Albert Einstein** but due to lack of equipments, it was only created in 1935 by **Cornell, Ketterle** and **Weimann.** Its concept and existence is totally opposite to plasmas. The state is conceptualised at supercold conditions.

The supercold above means only a few billionth of a degree above absolute zero. Cornell and Weimann developed BEC at such temperature with **rubidium.**

Dalton's Atomic Theory

J. Dalton in 1803, proposed the atomic theory of matter on the basis of laws of chemical combinations. (which are given later in this chapter)

According to which

(i) matter is made up of indivisible and indestructible particles, called **atoms.**

(ii) all atoms of an element have identical mass and similar chemical properties. (Atoms of different elements have different masses and different chemical properties).

(iii) when atoms combine, they do so in the ratio of small whole numbers to form compound atoms or simply **compounds** or **molecules**. Compounds formed by such combinations are alike in every respect.

(iv) chemical reactions involve only combination, separation or rearrangement of atoms.

(v) atoms are neither created nor destroyed in the course of an ordinary chemical reaction.

Limitations of Dalton's Atomic Theory

(i) It failed to explain how atoms of different elements differ from each other.

(ii) It failed to explain how and why atoms of elements combine with each other to form compound atoms or molecules.

(iii) It failed to explain the nature of forces that bind together different atoms in a molecule.

(iv) It did not make any distinction between ultimate particle of an element that takes part in reaction (atoms) and the ultimate particle that has independent existence (molecules).

The hypothesis of Dalton is even accepted today by the scientific community with two modifications only.

1. Atom is divisible and destructible.
2. All atoms of an element are not identical in mass.

Atoms *and* Molecules

An **atom** is defined as "the smallest particle of matter which may or may not exist independently but can take part in a chemical reaction."

A **molecule** is defined as "the smallest particle of matter which can exist independently but cannot take part in a chemical reaction."

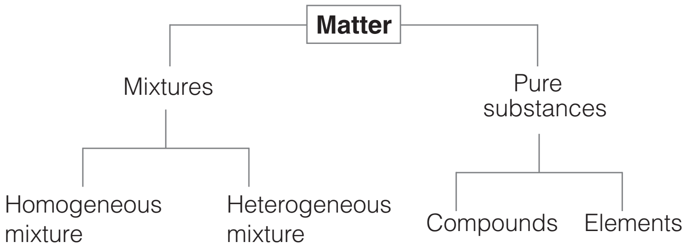
Both atoms and molecules are basic constituents of matter with the condition that atoms combine to form the molecules.

The molecules may be

(i) monoatomic, *i.e.,* contain 1 atom only, *e.g.,* Na, K etc.
(ii) diatomic, *i.e.,* contain 2 atoms, *e.g.,* N_2, O_2 etc.
(iii) triatomic, *i.e.,* contain 3 atoms, *e.g.,* O_3 etc.
(iv) polyatomic, *i.e.,* contain more than 3 atoms *e.g.,* P_4, S_8 etc.

Chemical Classification of Matter

On the basis of chemical composition and properties, matter can be classified as



(a) Mixtures

These have variable composition and variable properties due to the fact that components retain their characteristic properties. These may be separated into pure components by applying physical methods.

These can be of two types

(i) The **homogeneous mixtures**, have same composition throughout and their components are indistinguishable, *e.g.,*a liquid solution of sugar and water etc.

(ii) A **heterogeneous mixture,** on the other hand, do not have the same composition throughout and the components here are distinguishable, *e.g.,* a mixture of grains of sand and salt. Here particles of each component maintain their own identity.

(b) Pure Substances

These have fixed composition and non-variable properties. These cannot be separated into simpler substances by physical methods.

An **element** is a substance that contains only one type of atoms whereas a **compound** is formed when atoms of different elements combine in a fixed ratio.

Compounds and elements can be differentiated as the former can be decomposed into simple substances by chemical methods while later cannot be decomposed into simpler substances by chemical methods.

Sample **Problem 1** *Which one of the following is not an element?*

(a) *Graphite* (b) *Silica*
(c) *Diamond* (d) *Plasma sulphur*

Interpret (*b*) Elements contain only one type of atoms. Graphite and diamond both contain only C (carbon), plastic sulphur contains only S but silica (SiO_2) contains two different atoms, *i.e.*, Si and O, so it is not an element.

1.2 Physical Quantities and Their Measurements in Chemistry

The description, interpretation and prediction of the behaviour of chemical substances can be done on the basis of the knowledge of their physical and chemical properties determined from careful experimental measurements. The properties like mass, length, time, temperature etc., are physical quantities and their measurement does not involve any chemical reaction. These properties are expressed in numerals with suitable units.

The measurement of any physical quantity is represented by a number followed by units in which it is measured. For example length of a room can be represented as 12 m; here 12 is the number and m denotes metre-the unit in which the length is measured.

Precision and Accuracy

Precision is the measure of reproducibility of an experiment while accuracy is the measurement of closeness of a result to its true value. *Good accuracy means good precision but reverse is not always true.*

i.e., precision = individual value – arithmetic mean value

Accuracy = mean value – true value

Sample **Problem 2** *Two students performed the same experiment separately and each one of them recorded two readings of mass which are given below. Correct reading of mass is* 3.0 g. *On the basis of given data mark the correct option out of the following statements.* **[NCERT Exemplar]**

Student	**Readings** (i)	(ii)
A	3.01	2.99
B	3.05	2.95

(a) *Results of both the students are neither accurate nor precise.*
(b) *Results of student A are both precise and accurate.*
(c) *Results of student B are neither precise nor accurate.*
(d) *Results of student B are both precise and accurate.*

Interpret (*b*) Results of student *A* are close to true value as well as to each other, that's why these are precise as well as accurate.

Scientific Notation

In scientific notation, all numbers (however large or small) are expressed as a number between 1.000 and 9.999 multiplied or divided by 10, *i.e.*, here a number is generally expressed in the form

$$N \times 10^n$$

Here, N is called **digit term.** It is a number between 1.000 and 9.999.

n is called an **exponent.** If decimal is shifted towards left, the value of n is positive (and is equal to the number of places by which decimal is shifted) and if decimal is shifted towards right, the value of n is negative.

e.g., 138.42 can be written as 1.3842×10^2

or 0.013842 can be written as 1.3842×10^{-2}

Significant Figures

The digits in a properly recorded measurement are known as **significant figures** or in other words, we can say that significant figures are the meaningful digits in a measured or calculated quantity.

A significant figure includes all those digits that are known with certainty plus one more which is uncertain or estimated. Always remember that **greater the number of significant figures in a reported result, smaller the uncertainty**.

There are certain rules for determining the number of significant figures. These are as follows

1. All non-zero digits are significant. *e.g.*, in 852 cm, there are three significant figures and in 0.25 L there are two significant figures.
2. Zeros preceding to first non-zero digit are not significant. Such zero indicates the position of decimal point. *e.g.*, 0.03 has one significant figure and 0.0052 has one significant figure.
3. Zeros between two non-zero digits are significant *e.g.*, 3.007 has four significant figures.
4. Zeros at the end or right of a number are significant provided they are on the right side of the decimal point. *e.g.*, 0.200 g has three significant figures.

   But, if otherwise, the terminal zeros are not significant if there is no decimal point. *e.g.*, 100 has only one significant figure, but 10.0 has three significant figures and 100.0 has four significant figures. Such numbers are better represented in scientific notation. We can express the number 100 as 1×10^2 for one significant figure, 1.0×10^2 for two significant figures and 1.00×10^2 for three significant figures.
5. Counting numbers of objects, for example, 2 balls or 20 eggs, have infinite significant figures as these are exact numbers and can be represented by writing infinite number of zeros after placing a decimal *i.e.*, 2 = 2.000000 or 20 = 20.000000
6. In numbers written in scientific notation, all digits are significant *e.g.*, 4.01×10^2 has three significant figures.

Significant Figures in Calculations

1. **When adding or subtracting**, the number of decimal places in the answer should not exceed the number of decimal places in either of the numbers. *e.g.*,

$$\begin{array}{rl} 0.13 & \text{2 significant figures} \\ 1.5 & \text{2 significant figures} \\ 20.911 & \text{5 significant figures} \\ \hline 22.541 & \end{array}$$

   1.5 has only one digit after the decimal point and the result should be reported only up to one digit after the decimal point which is 22.5.

2. **In multiplication and division,** the significant figures in the answer should be the same as that in the quantity with the least number of significant figures.

   e.g.,

$$\frac{0.01208}{0.0236} = 0.512$$

   The number 0.0236 has only three significant figures that's why the answer must also be limited to three significant figures. Similarly, the product

$$132.07 \times 0.12 = 15.8484$$

   The answer 15.8484 should be reported as 15 because 0.12 has only two significant figures.

3. **When a number is rounded off,** the number of significant figures is reduced. The last digit retained is increased by 1 only if the following digit is > 5 and is left as such if the following digit is ≤ 4. *e.g.*,

$$12.696 \text{ can be written as } 12.7$$
$$13.93 \text{ can be written as } 13.9$$

   If the following digit is 5, left the number as such if it is even or add 1 if it is odd. *e.g.*,

$$18.35 \text{ can be written as } 18.4$$

Caution Point *While calculating the significant figures of numbers, it is better to convert them into scientific notation because exponential term does not contribute to the significant figures.*

Sample Problem 3 *If the density of a solution is 3.12 g* mL^{-1}*, the mass of 1.5 mL solution in significant figures is*

[NCERT Exemplar]

(a) 4.7 *g*
(b) 4680×10^{-3} *g*
(c) 4.680 *g*
(d) 46.80 *g*

Interpret (*a*) Mass = volume × density = 1.5 mL × 3.12 g mL^{-1}

= 4.68 g

The digit 1.5 has only two significant figures, so the answer must also be limited to two significant figures. Hence, it is rounded off to reduce the number of significant figures. Hence, the answer is reported as 4.7g.

Sample Problem 4 *How many significant figures should be present in the answer of the following calculations?* **[NCERT Exemplar]**

$$\frac{2.5 \times 1.25 \times 3.5}{2.01}$$

(*a*) 1
(*b*) 2
(*c*) 3
(*d*) 4

Interpret (*b*) Since the number with least significant figure *i.e.*, 2.5 or 3.5, has two significant figures, so answer must also be reported in two significant figures.

Note Here is no need to do complete calculation.

Various Systems of Measurement

(a) CGS System

It is also called **Gaussian system** and is based on centimetre (cm), gram (g) and second (s) as the units of length, mass and time respectively.

(b) FPS System

It is a British system which used foot (ft), pound (lb) and second (s) as the fundamental units of length, mass and time.

(c) MKS System

It is called MKSA system later on. It is the system, which uses metre (m), kilogram (kg) and second (s) respectively for length, mass and time; Ampere (A) was added later on for electric current.

(d) SI System

It is internationally accepted system in 1960s, hence called International system of units and contains following 7 basic and 2 supplementary units.

(i) **Basic units** includes metre (m) for length, kilogram (kg) for mass, second (s) for time, ampere (A) for electric current, kelvin (K) for thermodynamic temperature, mole (mol) for amount of substance and candela (Cd) for luminous intensity.

(ii) **Supplementary units** includes radian (rad) for angle and steradian (sr) for solid angle.

Sometimes submultiples and multiples are used to reduce or enlarge the size of the different units. The names and symbols of sub-multiples and multiples are listed in the table given below.

Table 1.1 **SI Prefixes**

Multiple	Prefix	Symbol	Multiple	Prefix	Symbol
10^{24}	yotta	Y	10^{-1}	deci	d
10^{21}	zetta	Z	10^{-2}	centi	c
10^{18}	exa	E	10^{-3}	milli	m
10^{15}	peta	P	10^{-6}	micro	μ
10^{12}	tera	T	10^{-9}	nano	n
10^{9}	giga	G	10^{-12}	pico	p
10^{6}	mega	M	10^{-15}	femto	f
10^{3}	kilo	k	10^{-18}	atto	a
10^{2}	hecto	h	10^{-21}	zepto	z
10	deca	da	10^{-24}	yocto	y

Derived Units

The units of all other quantities, which are derived from the above mentioned units, called the **fundamental units,** are called the derived units. *e.g,*

Units of volume $=$ length $\times$ breadth $\times$ height $= \mathrm{m}\times\mathrm{m}\times\mathrm{m} = \mathrm{m}^3$

Table 1.2 **Some Derived Properties and their Units**

Quantity	Definition of quantity	Expression in terms of SI base units
Area	Length squared	m^2
Volume	Length cubed	m^3
Density	Mass per unit volume	$\mathrm{kg / m^3}$ or $\mathrm{kg\ m^{-3}}$
Velocity	Distance travelled per unit time	m/s or $\mathrm{ms^{-1}}$
Acceleration	Velocity changed per unit time	$\mathrm{m/s^2}$ or $\mathrm{ms^{-2}}$
Force	Mass times acceleration of object	$\mathrm{kg\ m/s^2}$ or $\mathrm{kg\ ms^{-2}}$ (newton, N)
Pressure	Force per unit area	$\mathrm{kg/(ms^2)}$ or $\mathrm{kg\ m^{-1}s^{-2}}$ (pascal, Pa)
Energy (work, heat)	Force times distance travelled	$\mathrm{kg\ m^2/s^2}$ or $\mathrm{kg\ m^2s^{-2}}$ (joule, J)
Electric charge	Ampere times second	A-s (coulomb, C)
Electric potential	Energy per unit charge	J/(A-s) potential difference (volt, V)

Dimensional Analysis

In calculations, generally there is a need to convert units from one system to other. This can be done with the help of conversion factor, so the method used to accomplish this is called **factor label method** or **unit factor method** or **dimensional analysis.**

Information sought $=$ information given $\times$ CF

Some conversion factors [CCF] are as follows.

$$1\,\mathrm{m} = 39.37\ \mathrm{inch}$$
$$1\ \mathrm{inch} = 2.54\,\mathrm{cm}$$
$$1\mathrm{L} = 1000\ \mathrm{mL} = 1000\ \mathrm{cm}^3$$
$$= 10^{-3}\mathrm{m}^3 = 1\mathrm{dm}^3$$
$$1\,\mathrm{lb} = 453.59237\mathrm{g}$$
$$1\mathrm{J} = 1\mathrm{N-m} = 1\ \mathrm{kgm}^2\mathrm{s}^{-2}$$
$$1\mathrm{cal} = 4.184\ \mathrm{J} = 2.613\times 10^{19}\mathrm{eV}$$
$$1\mathrm{eV} = 1.602\times 10^{-19}\mathrm{J}$$
$$1\mathrm{eV/atom} = 96.485\ \mathrm{kJ\ mol^{-1}}$$
$$1\ \mathrm{u} = 1.66\times 10^{-27}\ \mathrm{kg}$$
$$= 931.5\ \mathrm{MeV}$$
$$1\ \mathrm{J} = 10^7\ \mathrm{erg}$$
$$1\ \mathrm{dyne} = 10^{-5}\ \mathrm{N}$$
$$1\ \mathrm{atm} = 101325\ \mathrm{Nm^{-2}} = 101325\ \mathrm{Pa}$$
$$1\ \mathrm{bar} = 1\times 10^5\ \mathrm{Nm^{-2}} = 1\times 10^5\ \mathrm{Pa}$$
$$1\ \mathrm{L\text{-}atm} = 101.3\ \mathrm{J} = 24.21\ \mathrm{cal}$$
$$1\ \mathrm{mol\ (gas)} = 22.4\ \mathrm{L\ at\ STP}$$
$$1\ \mathrm{mol\ (substance)} = N_A\ \mathrm{molecules}$$
$$1\ \mathrm{g\text{-}atom} = N_A\ \mathrm{atoms}$$
$$1\ \mathrm{K} = t^\circ\mathrm{C} + 273.15$$
$$t(^\circ\mathrm{F}) = \frac{9}{5}t^\circ\mathrm{C} + 32$$
$$1\ \mathrm{D\ (Debye)} = 1\times 10^{-18}\ \mathrm{esu\text{-}cm}$$
$$1\ \mathrm{g\text{-}cm^{-3}} = 1000\ \mathrm{kg\ cm^{-3}}$$

Caution Point *Remember that* CF *must always have the numerator and denominator representing equivalent quantities.*

Sample Problem 5 *If the speed of light is* $3.0\times 10^8\mathrm{ms^{-1}}$, *calculate the distance covered by light in* 2.00 *ns.*

[NCERT Exemplar]

(*a*) 6.0×10	(*b*) 0.6×10
(*c*) 0.06×10	(*d*) 60.0×10^{-1}

Interpret (*c*) $1\mathrm{ns} = 10^{-9}\mathrm{s}$

$$\text{Conversion factor} = \frac{10^{-9}\mathrm{s}}{1\mathrm{ns}}$$

$$2.00\mathrm{ns} = 2.00\mathrm{ns}\times\frac{10^{-9}\mathrm{s}}{1\mathrm{ns}}$$
$$= 2.00\times 10^{-9}\mathrm{s}$$

$$\text{Distance covered} = \text{speed x time}$$
$$= 3.0\times 10^8\ \mathrm{ms^{-1}}\times 2.0\times 10^{-9}\mathrm{s}$$
$$= 6.0\times 10^{-1}\ \mathrm{m} = 0.6\ \mathrm{m}$$

Sample Problem 6 *The relationship between picometer (pm) and nanometer (nm) is*

(*a*) 1 *nm* = 100.0 *pm*
(*b*) 1 *nm* = 10 *pm*
(*c*) 1 *pm* = 10 *nm*
(*d*) 1 *pm* = 100 *nm*

Interpret (*a*) $1\ \mathrm{pm} = 10^{-12}\ \mathrm{m}, 1\ \mathrm{nm} = 10^{-9}\ \mathrm{m}$

$$\text{Conversion factor} = \frac{10^{-12}\mathrm{m}}{1\mathrm{pm}}\ \text{and}\ \frac{1\mathrm{nm}}{10^{-9}\mathrm{m}}$$

$$1\mathrm{pm} = 10^{-12}\mathrm{m}\times\frac{1\mathrm{nm}}{10^{-9}\mathrm{m}}$$

$\Rightarrow$ $\quad 1\ \mathrm{pm} = 10^{-3}\mathrm{nm}$

or $\quad 1\ \mathrm{nm} = 1000\ \mathrm{pm}$

Sample Problem 7 *Pressure is determined as force per unit area of the surface. The SI unit of pressure, pascal is as shown below.*

$$1\ \text{Pa} = 1\ \text{Nm}^{-2}$$

If the mass of air at sea level is 1034gcm^{-2}, *calculate the pressure in pascal.* **[NCERT]**

(a) 1.01×10^5
(b) 1.01×10^4
(c) 2.32×10^5
(d) 1.03×10^5

Interpret (a) Pressure is the force or weight per unit area.

$$\text{Pressure} = \frac{1034\text{g}\times 9.8\text{ms}^{-2}}{\text{cm}^2}$$

$$= \frac{1034\ \text{kg}\times 100\times 100\times 9.8\ \text{ms}^{-2}}{1000\ \text{m}^2}$$

$$= 101332.0\ \text{Nm}^{-2} \qquad (1\ \text{N} = \text{kg ms}^{-2})$$

$$= 1.01332\times 10^5\ \text{Pa}$$

Laws of Chemical Combinations

The combination of elements to form compounds is governed by following basic laws.

Law of Conservation of Mass
(by Lavoisier)

According to this law the matter can neither be created nor destroyed in a chemical reaction.

Law of Definite Proportions (by J. Proust)

"A sample of a pure compound always consists of the same elements combined in same proportions by mass, whatever be its source."

e.g., ammonia always has the formula NH_3 *i.e.*, one molecule of NH_3 always contains one atom of nitrogen and three atoms of hydrogen or 17.0 g of NH_3 always contains 14 g of nitrogen and 3 g of hydrogen. These findings always remain the same for NH_3.

Law of Multiple Proportions
(by John Dalton)

An element may form more than one compound with another element. For a given mass of an element, the masses of other elements (in two or more compounds) come in the ratio of small integers."

This is called law of multiple proportions. *e.g.*, in NH_3, 14 g of nitrogen requires 3 g of hydrogen and in hydrazine (N_2H_4) 14 g of nitrogen requires 2 g of hydrogen. Hence, fixed mass of nitrogen requires hydrogen in the ratio 3 : 2 in two different compounds (3 : 2 is a simple ratio). Thus, this is in agreement with "law of multiple proportions".

Gay Lussac's Law of Gaseous Volumes

The volume of reactants and products in a large number of chemical reactions are related to each other by small integers, provided the volumes are measured at same temperature and pressure".

These lines are considered as the law of definite proportions by volume given by Gay-Lussac, a French chemist. *e.g.*, in the reaction of hydrogen with oxygen to produce water, it was found that 2 vol of H_2 combines with 1 vol of O_2 to form 2 vol of H_2O (steam). This simply means that 100 mL of H_2 gas combines with 50 mL of O_2 to produce exactly 100 mL of steam (if volume of all the gases are measured at same temperature and pressure).

Avogadro's Law

"The volume of a gas (at constant pressure and temperature) is proportional to the number of moles (or molecules) of gas present".

According to this law

$$V \propto n$$

where, $n =$ number of moles of gas

In simpler words, the law can also be stated as "equal volumes of all gases, under the same conditions of temperature and pressure contain equal number of molecules" which is infact 6.023×10^{23} or in multiples of it.

Caution Point *Law of definite proportions and law of multiple proportions do not hold good when same compound is prepared by different isotopes of the same element, e.g.,* H_2O *and* D_2O *or* $H_2\overset{16}{O}$ *and* $H_2\overset{18}{O}$. *Moreover, law of conservation of mass does not hold good for nuclear reactions.*

Sample Problem 8 *Which of the following reactions is not correct according to the law of conservation of mass?* **[NCERT Exemplar]**

(a) $2Mg(s) + O_2(g) \longrightarrow 2MgO(s)$
(b) $C_3H_8(g) + O_2(g) \longrightarrow CO_2(g) + H_2O(g)$
(c) $P_4(s) + 5O_2(g) \longrightarrow P_4O_{10}(s)$
(d) $CH_4(g) + 2O_2(g) \longrightarrow CO_2(g) + 2H_2O(g)$

Interpret (b) In equation,

$$\begin{array}{ccc} C_3H_8(g) + O_2(g) & \longrightarrow & CO_2(g) + H_2O(g) \\ 44\text{g}\ +32\text{g} & & 44\ +18 \end{array}$$

i.e., mass of reactants ≠ mass of products. Hence, law of conservation of mass is not followed.

Sample Problem 9 *The following data are obtained when dinitrogen and dioxygen react together to form different compounds.*

S. No.	Mass of dinitrogen	Mass of dioxygen
(*i*)	14g	16g
(*ii*)	14g	32g
(*iii*)	28g	32g
(*iv*)	28g	80g

Which law of chemical combination is obeyed by the above experimental data? [**NCERT**]

(a) *Law of multiple proportions*

(b) *Law of conservation of mass*

(c) *Law of definite proportions*

(d) *All of the above*

Interpret (*a*) On fixing the mass of dinitrogen as 28g, the masses of dioxygen combined are 32, 64, 32 and 80 in the given four oxides. These are in the simple whole number ratio *i.e.*, 2 : 4 : 2 : 5. Hence, the given data obey the law of multiple proportions.

1.3 Atomic and Molecular Masses

Atomic Mass

Dalton gave the idea of atomic masses in relative terms, *i.e.*, the average mass of one atom relative to the average mass of the other. We can make accurate measurement of mass by comparing mass of an atom with the mass of a particular atom chosen as standard. On the present atomic mass scale, ^{12}C is chosen as standard and is arbitrarily assigned the mass of 12 atomic mass unit (amu).

$\therefore$ Atomic mass

$$= \frac{\text{mass of one atom of the element}}{\frac{1}{12}\text{th part of the mass of one atom of C}-12}$$

Therefore, one amu or u (unified mass) is equal to exactly the 1/12th of the mass of ^{12}C atom.

$$1\text{ u} = \frac{1}{12} \times \frac{12\text{ g}}{6.022 \times 10^{23}}$$

$$= 1.66 \times 10^{-24}\text{ g}$$

Since most of the elements have isotopes, the atomic mass of an element is, infact, the average of masses of its all the naturally occurring isotopes, so generally in fractions e.g., If an element exists in three isotopic forms having atomic masses, m_1, m_2 and m_3 in the ratio, x, y and z, the average atomic mass,

$$M_{av} = \frac{m_1 \times x + m_2 \times y + m_3 \times z}{x + y + z}$$

If in place of ratio, relative abundance is given, the

$$M_{av} = \frac{m_1 \times r_1 + m_2 \times r_2 + m_3 \times r_3}{r_1 + r_2 + r_3}$$

Here, r_1, r_2 and r_3 = relative abundances of the isotopes.

The approximate atomic mass of solid elements except Be, B, C and Si, is related to specific heat as

$$\text{Average atomic mass} = \frac{6.4}{\text{specific heat}}$$

This is called **Dulong and Petit's method.**

Mass spectrometer is used to determine the atomic mass experimentally.

Molecular Mass

Molecular mass is the sum of atomic masses of the elements present in a molecule. It is obtained by multiplying the atomic mass of each element by the number of its atoms and adding them together *e.g.*,

Molecular mass of glucose ($C_6H_{12}O_6$)

$$= 6(12.011\text{u}) + 12(1.008\text{u}) + 6(16.00\text{u})$$

$$= (72.066\text{u}) + (12.096\text{u}) + (96.00\text{u})$$

$$= 180.162\text{u}$$

Formula Mass

The formula mass of a substance is the sum of the atomic masses of all atoms in the formula unit of the compound. It is normally calculated for ionic compounds. *e.g.*, formula mass of NH_3 is $14 + 3 = 17$ amu or 17u

or formula mass of NaCl is

$$23 + 35.5 = 58.5\text{ amu or } 58.5\text{u}.$$

Check Point 1

1. How many millimetres are there in 14.0 cm?
2. Explain why in calculations involving more than one arithmetic operation, rounding off to the proper number of significant figures may be done once at the end if all the operations are multiplications or divisions or if they are all additions and subtractions, but not if they are combinations of additions or subtractions with divisions or multiplications?
3. Why do atomic masses of most of the elements in atomic mass unit be in fractions?
4. On analysis it was found that the black oxide of copper and red oxide of copper contain 79.9% and 88.8% of copper respectively. This data is in accordance with which law of combination?

1.4 **Equivalent Mass** or **Equivalent Weight**

The number of parts of a substance that combines with or displaces, directly or indirectly, 1.008 parts by mass of hydrogen or 35.5 parts by mass of chlorine or 8 parts by mass of oxygen is called the equivalent mass of the substance. Mathematically,

$$\frac{\text{Eq. wt. of substance } A}{\text{Eq. wt. of substance } B} = \frac{\text{Wt. of substance } A}{\text{Wt. of substance } B}$$

If A is metal and B is H (or O or Cl) then

$$\text{Eq. wt. of metal } = \frac{\text{mass of metal}}{\text{mass of hydrogen displaced}} \times 1.008$$

$$\text{or} \quad = \frac{\text{mass of metal}}{\text{mass of oxygen combined}} \times 8.0$$

$$\text{or} \quad = \frac{\text{mass of metal}}{\text{mass of chlorine combined}} \times 35.5$$

Equivalent weight of acid

$$= \frac{\text{molecular weight of acid}}{\text{basicity (number of replaceable H}^+)}$$

e.g., Equivalent weight of $H_2SO_4 = \frac{98}{2} = 49$

Equivalent weight of base

$$= \frac{\text{molecular weight of base}}{\text{acidity (number of replaceable OH}^-)}$$

e.g., Equivalent weight of $NaOH = \frac{40}{1} = 40$

$$\text{Eq. wt. of salt} = \frac{\text{molecular weight of salt}}{\text{total positive valency of metal atoms}}$$

e.g., Equivalent weight of $NaCl = \frac{58.5}{1} = 58.5$

Equivalent weight of $Na_2CO_3 = \frac{106}{2} = 53$

Equivalent weight of a substance that undergoes

$$\text{oxidation/ reduction} = \frac{\text{molecular weight}}{\text{change in oxidation number}}$$

e.g., When $KMnO_4$ reacts under acidic conditions, change in oxidation number (from +7 to +2) is 5, hence;

Equivalent weight of $KMnO_4$ in acidic medium

$$= \frac{158}{5} = 31.6$$

For volatile metal chlorides, eq. wt. and atomic weight are related as

$$\text{Atomic wt.} = \text{eq. wt.} \times \text{valency}$$

Caution Points

(*i*) *Atomic and molecular masses of elements and compounds are always constant but equivalent mass may vary with change of valency.*

(*ii*) *The valencies of elements forming isomorphous compounds (i.e., the compounds that have similar constitution and chemical formulae) are same. e.g., valencies of* Cr, Se *and* S *in* K_2CrO_4, K_2SeO_4 *and* K_2SO_4 *are same.*

Sample **Problem 10** 0.5 *g of a metal on oxidation gave* 0.79 *g of its oxide. The equivalent weight of the metal is*

(*a*) 10 (*b*) 14
(*c*) 20 (*d*) 40

Interpret (*b*) $\text{Eq. wt.} = \frac{\text{wt. of metal}}{\text{wt. of oxygen combined}} \times 8$

$$= \frac{0.5}{0.79 - 0.5} \times 8 \approx 14$$

Sample **Problem 11** *The equivalent weight of iron in* Fe_2O_3 *would be*

(*a*) 18.6 (*b*) 28
(*c*) 56 (*d*) 112

Interpret (*a*) $\text{Eq. wt. of metal} = \frac{\text{atomic wt.}}{\text{valency}} = \frac{56}{3} = 18.6$

Hot Spot 1

MOLE Concept

Mole concept is an important topic for JEE Main examination and a small practice can help you in solving problems based on this topic very quickly as the level of questions is easy to average.

While solving problems based on mole concept, always keep in mind

(i) Convert all in same unit, *i.e.*, mol/atoms/mass and then compare.
(ii) Moles $\propto$ molecules

The word **mole** was introduced around 1896 by **W. Ostwald** who derived it from Latin word **moles** means a **heap** or **pile.** In 1967 this word was accepted as a unit of chemical substances under SI system. It is represented by the symbol **mol.**

One mole of object will always mean 6.023×10^{23} of those objects. The number of object per mole, 6.023×10^{23} mol^{-1} is called **Avogadro's Number/Constant** represented by N_A.

Thus, one mole of any substance is defined as

(i) The amount which weighs exactly same as its formula weight in gram or atomic mass in gram or molecular mass in gram.
(ii) The amount which has same number of entities (atoms, molecules or other particles) as there are atoms in exactly 0.012 kg (or 12 g) of carbon-12 isotope (*i.e.,* 6.023×10^{23} entities).
(iii) The amount which occupies 22.4 L at STP (if it is taken for a gas).

The formulae used to convert amount of substance into moles are

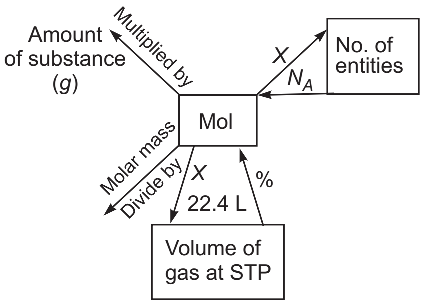
$$\text{Number of moles of molecule} = \frac{\text{weight in gram}}{\text{molecular weight}}$$

$$\text{Number of moles of atoms} = \frac{\text{weight in gram}}{\text{atomic weight}}$$

$$\text{Number of moles} = \frac{\text{number of particles}}{\text{Avogadro's number}}$$

$$\text{or Number of moles of gases} = \frac{\text{volume of gas at STP (in L)}}{22.4}$$

As in atoms and molecules, mole concept is also applicable to ionic compounds, which do not contain molecules. In such cases, the formula of any ionic compound is representation of ratio between constituent ions. One mole of an ionic compound is represented by 6.023×10^{23} formula units.



Flow chart showing conversion of mole in other units

One mole of NaCl = 6.023×10^{23} NaCl units

$= 6.023 \times 10^{23}$ units of $Na^+ + 6.023 \times 10^{23}$ units of Cl^-

Mass of one mole of NaCl $= 23.0\text{g} + 35.5\text{g}$

$= 58.5$ g NaCl

Sample **Problem 12** *The number of atoms present in one mole of an element is equal to Avogadro number. Which of the following element contains the greatest number of atoms?* **[NCERT Exemplar]**

(*a*) 4 g He (*b*) 46 g Na
(*c*) 0.4 g Ca (*d*) 12 g He

Interpret (*d*) For comparing number of atoms, first we calculate the moles as all are monoatomic and hence, moles $\times N_A =$ number of atoms.

$$\text{Moles of 4g He} = \frac{4}{4} = 1 \text{ mol}$$

$$\text{46g Na} = \frac{46}{23} = 2 \text{ mol}$$

$$\text{0.40 g Ca} = \frac{0.40}{40} = 0.1 \text{ mol}$$

$$\text{12g He} = \frac{12}{4} = 3 \text{ mol}$$

Therefore, number of atoms are highest in 12g He as it has the maximum number of moles.

Various Concentration Terms

Different concentration terms are given below:

(a) **Normality** (N)

It is defined as the number of g-equivalents of solute per litre of solution or as the number of mg-equivalents of a substance per millilitre of solution. *e.g.,* 0.12 N H_2SO_4 means a solution which contains 0.12 g-equivalent of H_2SO_4 per litre of solution. This also means that each millilitre of this solution can react, for example, with 0.12 mg eq. of CaO or with 0.12 mg-eq. of Na_2CO_3.

Thus,

$$\text{Normality } N = \frac{\text{g-equivalent of solute}}{\text{volume of solution (in L)}}$$

or

$$= \frac{\text{g-equivalent of solute}}{\text{volume of solution (in mL)}} \times 1000$$

If specific gravity is known, normality is calculated as

$$\text{Normality} = \frac{\text{specific gravity} \times \%\text{ strength} \times 10}{\text{equivalent weight}}$$

(b) **Molarity** (*M*)

It is defined as the number of moles of solute per litre of solution or the same numerically, as the number of mg-molecules per millilitre of solution. The molarity is usually designated by *M, e.g.,* if the molarity of H_3PO_4 is 0.18, it means a concentration corresponding to 0.18 mol of H_3PO_4 per litre of solution.

Thus, molarity is given as

$$\text{Molarity, } M = \frac{\text{moles of solute}}{\text{volume of solution (in L)}}$$

If specific gravity is given,

$$\text{Molarity} = \frac{\text{specific gravity} \times \%\text{ strength} \times 10}{\text{molecular weight}}$$

(c) **Formality** (*F*)

It is practically same as molarity.

$$\text{Formality} = \frac{\text{gram formula weight}}{\text{volume in litre}}$$

(d) **Molality** (*M*)

It is defined as the number of moles of solute dissolved in 1000 g of the solvent. It is designated by *m*. Molality is independent of temperature, as it depends only upon the mass which does not vary with temperature.

$$\text{Molality, } m = \frac{\text{moles of solute}}{\text{weight of solvent (in g)}} \times 1000$$

Formulae Used to Calculate the **Number of Moles**

1. Number of millimoles = molarity × volume in mL

or $$\text{Moles} = \frac{\text{millimoles}}{1000}$$

2. Number of equivalents of a substance

$$= \frac{\text{weight (g)}}{\text{equivalent weight}}$$

3. Number of milli-equivalent

$$(\text{Meq}) = \frac{1000 \times \text{weight (g)}}{\text{equivalent weight}}$$

$$= \text{normality} \times \text{volume (mL)}$$

4. Normality = molarity × balance factor (*y*).
where, *y* = acidity/basicity/number of replaceable H-atoms/change in oxidation number.

5. Number of equivalents = *y* × number of moles

6. Number of milli-equivalents = *y* × number of millimoles
where, *y* is same as for formula (4).

7. Mole fraction of solute in the solution $= \frac{n}{n+N}$

where, *n* = moles of solute, *N* = moles of solvent

For very dilute solutions,

$$\text{Mole fraction of solute in solution} = \frac{Mm}{1000}$$

where, *M* = molecular weight of solvent, *m* = molality

8. Density of solution

$$= \text{molarity}\left(\frac{1}{\text{molality}} + \frac{\text{molecular weight of solute}}{1000}\right)$$

9. Per cent by weight of solute in solution

$$= \frac{\text{weight of solute (g)} \times 100}{\text{weight of solution (g)}}$$

10. Percent by volume of solute in solution

$$= \frac{\text{weight of solute (g)} \times 100}{\text{volume of solution (mL)}}$$

11. 1 mL, 1 N $KMnO_4 \equiv$ 1 mL, 1 N H_2O_2

12. 1 mL, 1 N $Na_2S_2O_3 \equiv$ 1 mL, 1 N I_2 solution

13. 1 volume H_2O_2 = 0.1785 N H_2O_2

14. If two compounds *A* and *B* neutralise completely each other then

milli-equivalents of *A* = milli-equivalents of *B*

15. Molecular weight = 2 × vapour density (for gaseous phase).

Sample Problem 13 *If the concentration of glucose ($C_6H_{12}O_6$) in blood is 0.9 g L^{-1} what will be the molarity of glucose in blood?* **[NCERT Exemplar]**

(*a*) 5 M (*b*) 50 M (*c*) 0.005 M (*d*) 0.5 M

Interpret (*c*) 0.9 gL^{-1} means,

1000 mL (or 1L) solution contains glucose = 0.9 g glucose

$$= \frac{0.9}{180} \text{ mol glucose}$$

$$= 5 \times 10^{-3} \text{ mol glucose}$$

i.e., 1 L solution contains 0.005 mole glucose or the molarity of glucose is 0.005 M.

Sample Problem 14 *Calculate the mass of sodium acetate,* CH_3COONa *required to make 500 mL of 0.375 molar aqueous solution. Molar mass of sodium acetate is* 82.0245 g mol^{-1}. **[NCERT]**

(*a*) 18.12 g (*b*) 15.38 g
(*c*) 16.19 g (*d*) 12.11 g

Interpret (*b*) $\text{Molarity} = \dfrac{w \times 1000}{m \times \text{volume of solution(mL)}}$

where, w = mass of solute and *m* = molar mass of solute
Given, molarity of the solution = 0 .375 M
Molar mass of solute, *M* = 82.0245g mol^{-1}
Volume of solution = 500 mL

$$\therefore \text{ Mass of solute, } w = \frac{0.375 \times 82.0245 \times 500}{1000}$$

$$= 15.379 \text{ g} \approx 15.38\text{g}$$

Sample Problem 15 *Calculate the concentration of nitric acid in mol per litre in a sample which has a density,* 1.41 g mL^{-1} *and the mass per cent of nitric acid in it being* 69%. **[NCERT]**

(*a*) 15.4 M (*b*) 10.9 M (*c*) 5.43 M (*d*) 18.21 M

Interpret (*a*)

Given, $d = 1.14$ g mL^{-1}, mass % of HNO_3 = 69%

69% HNO_3 means 100g of its solution contains 69 g HNO_3 (nitric acid).

Hence, mass of HNO_3 (solute) = 69 g

Molar mass of nitric acid,

$$HNO_3 = 1.0079 + 14.0067 + (3 \times 16.00)$$

$$= 63.0146 \text{ g mol}^{-1}$$

$$\text{Density,} \quad d = \frac{m}{V}$$

$$\text{or} \quad V = \frac{m}{d} = \frac{100 \text{ g}}{1.41 \text{ g mL}^{-1}} = \frac{100}{1.41} \text{ mL}$$

$$\text{Molarity} = \frac{w \times 1000}{m \times \text{volume of solution (mL)}}$$

$$= \frac{69 \times 1000 \times 1.41}{63.0146 \times 100} = 15.439\text{M}$$

Note Concentration of a substance in mol per liter is known as molarity.

Alternative method

$$\text{Molarity} = \frac{\text{density} \times \text{mass per cent} \times 10}{\text{molar mass of solute}}$$

$$= \frac{1.14 \times 69 \times 10}{63.0146} = 15.439 \text{ M}$$

Sample Problem 16 *Sulphuric acid reacts with sodium hydroxide as follows.*

$$H_2SO_4 + 2NaOH \longrightarrow Na_2SO_4 + 2H_2O$$

When 1 L of 0.1 M sulphuric acid solution is allowed to react with 1 L of 0.1 M sodium hydroxide solution, the amount of sodium sulphate formed and its molarity in the solution obtained are **[NCERT Exemplar]**

(*a*) 0.1 mol L^{-1}, 3.55 g (*b*) 0.025 mol L^{-1}, 7.10 g
(*c*) 0.01 mol L^{-1}, 5.33 g (*d*) 0.25 mol L^{-1}, 5.33 g

Interpret (*b*) Moles of H_2SO_4 = 1L × 0.1M = 0.1 mol

moles of NaOH = 1L × 0.1M = 0.1 mol

$$\begin{array}{cccc} H_2SO_4 + & 2NaOH & \longrightarrow & Na_2SO_4 + 2H_2O \\ 1\text{mol} & 2 \text{ mol} & & 1 \text{ mol} \\ 0.1\text{mol} & 0.1\text{mol} & & 0.05 \text{ mol} \end{array}$$

$$\therefore \text{Molarity mass of } Na_2SO_4 = 0.05 \times 142$$

$$= 7.1\text{g } (\because \text{Molar mass of } Na_2SO_4 = 142 \text{ mol g mol}^{-1})$$

$$\text{Molarity} = \frac{\text{moles of } Na_2SO_4}{\text{volume of solution}} = \frac{0.05}{1+1} = 0.025 \text{ mol L}^{-1}$$

Sample Problem 17 *If 500 mL of a 5 M solution is diluted to 1500 mL, what will be the molarity of the solution obtained?* **[NCERT Exemplar]**

(*a*) 1.5 M (*b*) 1.66 M (*c*) 0.017 M (*d*) 1.59 M

Interpret (*b*) For dilution,

$$\underset{\text{(before dilution)}}{M_1V_1} = \underset{\text{(after dilution)}}{M_2V_2}$$

$$500 \times 5\text{M} = 1500 \times M$$

$$M = \frac{5}{3} = 1.66 \text{ M}$$

Sample Problem 18 *Calculate the molarity of a solution of ethanol in water in which the mole fraction of ethanol is* 0.040. **[NCERT]**

(*a*) 2.314 (*b*) 1.123 (*c*) 3.139 (*d*) 1.762

Interpret (*a*) Molarity is defined as the moles of solute (ethanol) in 1 L of the solution.

1 L of ethanol solution (as it is diluted) = 1 L of water

$$\text{Number of moles of } H_2O \text{ in 1 L water} = \frac{1000 \text{ g}}{18} = 55.55 \text{ moles}$$

For a binary solution (binary solution contains two components)

$$X_1 + X_2 = 1$$

$$\text{Hence,} \quad X_{H_2O} = 1 - X_{C_2H_5OH}$$

$$X_{H_2O} = 1 - 0.040 = 0.96$$

$$X_{H_2O} = \frac{n_{H_2O}}{n_{H_2O} + n_{C_2H_5OH}}$$

$$0.96 = \frac{55.55}{55.55 + n_{C_2H_5OH}}$$

$$53.328 \;+ 0.96 n_{C_2H_5OH} \;=\; 55.55$$

$$0.96 n_{C_2H_5OH} \;=\; 55.55 - 53.328 \;=\; 2.222$$

$$n_{C_2H_5OH} \;=\; \frac{2.222}{0.96}\; 2.3145 \text{ mol}$$

Sample Problem 19 *One mole of any substance contains* 6.022×10^{23} *atoms/molecules. Number of molecules of* H_2SO_4 *present in 100 mL 0.02M* H_2SO_4 *solution is* **[NCERT Exemplar]**

(a) 12.044×10^{20} molecules (b) 6.022×10^{23} molecules
(c) 1×10^{23} molecules (d) 12.044×10^{23} molecules

Interpret (a) Number of millimoles of H_2SO_4 = molarity × volume in mL

$$= 0.02 \times 100 = 2 \text{ millimol} = 2 \times 10^{-3} \text{ mol}$$

$$\text{Number of molecules } = \text{Number of moles} \times N_A$$
$$= 2 \times 10^{-3} \times 6.022 \times 10^{23} = 12.044 \times 10^{20} \text{ molecules}$$

Sample Problem 20 *Mole fraction of* I_2 *in benzene is 0.1. The molality of* I_2 *in* C_6H_6 *is*

(a) 1.42 (b) 3.205
(c) 2.06 (d) 1.86

Interpret (a) Mole fraction of $I_2 = \left[\dfrac{n}{n+N}\right] = 0.1$ ...(i)

$$\text{Mole fraction of benzene } = \left[\frac{N}{n+N}\right] = 0.9 \qquad \text{...(ii)}$$

where, n and N are moles of I_2 and C_6H_6 in solution respectively.

$$\text{molality,} \qquad m = \frac{1000 \times \text{mole fraction of } I_2}{(1 - \text{mole fraction of } I_2) \times M}$$

$$= \frac{1000 \times 0.1}{0.9 \times 78} = 1.42 \text{ m}$$

Molar Mass and Molar Volume

Molar mass of an element is defined as mass of 1 mole of that element, *i.e.*, mass of 6.023×10^{23} entities or particles of that element. *e.g.*, molar mass of oxygen = 32 g/mol, that means 6.023×10^{23} molecules of oxygen weigh 32 g, or molar mass of Na = 23 g/mol, that means 6.023×10^{23} monoatomic molecules of Na weigh 23 g.

When molar mass is divided by density, molar volume is obtained. It is the volume of one mole of a substance. Since molar volumes of solids and liquids do not vary much with temperature and pressure, these can be calculated easily by the following relation :

$$\text{Molar volume} = \frac{\text{molar mass}}{\text{density}}$$

The molar volumes of gases, change considerably with temperature and pressure. For an ideal gas, the molar volume at $0°C$ and 1 atm pressure is 22.4 L.

Percentage Composition of Compounds

Percentage composition of the compounds is the relative mass of the each of the constituent elements in 100 parts of it. It is readily calculated from the formula of the compound. Mass percentage of an element

$$= \frac{\text{mass of that element in the compound} \times 100}{\text{molar mass of the compound}}$$

Sample Problem 21 *What is the mass per cent of carbon in carbon dioxide?* **[NCERT Exemplar]**

(a) 0.034% (b) 3.4%
(c) 27.27% (d) 28.7%

Interpret (c) In order to solve such problem, first write the formula of molecule/compound.

The formula of carbon dioxide = CO_2

Molecular mass of $CO_2 = 12.0 + 16.0 \times 2 = 44 \text{ g mol}^{-1}$

$$\text{Atomic mass of C} = 12.0 \text{ g atom}^{-1}$$

$$\text{Percentage of C} = \frac{12}{44} \times 100 = 27.27\%$$

Sample Problem 22 *How much copper can be obtained from 100 g of copper sulphate* $(CuSO_4)$ *?* **[NCERT]**

(a) 63.54 g (b) 31.77 g
(c) 39.81 g (d) 79.62 g

Interpret (c) Molar mass of $CuSO_4 = 63.54 + 32.06 + (4 \times 16)$
$= 159.6 \text{ g mol}^{-1}$

$$159.6 \text{ g } CuSO_4 \text{ contains } 63.54 \text{ g Cu}$$

$$1 \text{ g } CuSO_4 \text{ contains } \frac{63.54}{159.6} \text{ g Cu}$$

$$100 \text{ g } CuSO_4 \text{ contains } \frac{63.54 \times 100}{159.6} = 39.81 \text{g Cu}$$

1.5 Empirical and Molecular Formulae

The chemical formula of a compound which shows relative number of atoms in its simplest ratio is called **empirical formula.**

The chemical formula of a compound which gives the actual number of atoms of each element in a molecule is called its **molecular formula.** It is important to note that the molecular formula is generally an integral multiple of the empirical formula, *i.e.*,

$$\text{Molecular formula} = (\text{empirical formula}) \times n$$

where, $n = 1, 2, 3, \ldots$ etc.

The molecular formula conveys two informations mainly :

1. The relative number of each type of atoms in a molecule.
2. The total of atoms of each element in the molecule.

Deriving Molecular & Empirical Formula

Use the following steps to determine the empirical formula of the compound.

1. Calculate the amount of elements and their percentage composition.
2. Divide the percentage of each element by its atomic mass. It gives atomic ratio of the elements present in the compound.
3. Divide the atomic ratio of each element by the minimum value of atomic ratio as to get simplest ratio of the atoms of elements present in the compound.
4. If the simplest ratio is fractional, then multiply the values of simplest ratio of each element by a smallest integer to get a simplest whole number for each of the element.
5. To get the empirical formula, write symbols of various elements present side by side with their respective whole number ratio as a subscript to the lower right hand corner of the symbol.

Deriving Molecular Formula

The molecular formula of a substance may be determined from the empirical formula if the molecular mass of the substance is known. The molecular formula is always a simple multiple of empirical formula and the value of simple multiple is obtained by dividing molecular mass with empirical formula mass.

Sample **Problem 23** *A welding fuel gas contains carbon and hydrogen only. Burning a small sample of it in oxygen gives* 3.38 *g carbon dioxide,* 0.690 *g of water and no other products. A volume of* 10.0 *L (measured at STP) of this welding gas is found to weigh* 11.6 *g. The molecular formula of the compound is* **[NCERT]**

(*a*) CH (*b*) CH_2

(*c*) C_2H_2 (*d*) CH_4

Interpret (*c*) (i) 44 g CO_2 contains 12 g carbon

$$3.38 \text{ g } CO_2 \text{ contains } \frac{12}{44} \times 3.38 \text{ g} = 0.9218 \text{ g carbon}$$

$$18 \text{ g } H_2O \text{ contains } 2 \text{ g hydrogen}$$

$$0.690 \text{ g } H_2O \text{ contains } \frac{2}{18} \times 0.690 \text{ g} = 0.0767 \text{ g hydrogen}$$

Total mass of compound = 0.9218 + 0.0767 = 0.9985g (because compound contains only carbon and hydrogen).

$$\text{Percentange of C in the compound} = \frac{0.9218}{0.9985} \times 100 = 92.32$$

$$\text{Percentange of H in the compound} = \frac{0.0767}{0.9985} \times 100 = 7.68$$

Calculation for Empirical Formula

Element	Per cent by mass	Atomic mass	Relative number of moles of elements	Simplest molar ratio
C	92.32	12	$\frac{92.32}{12} = 7.69$	$\frac{7.69}{7.68} \approx 1$
H	7.68	1	$\frac{7.68}{1} = 7.68$	$\frac{7.68}{7.68} = 1$

Hence, empirical formula = CH

(ii) Calculation for molar masss of the gas

10.0 L of the given gas at STP weigh = 11.6 g

∴ 22.4 L of the given gas at STP will weigh

$$= \frac{11.6 \times 22.4}{10} = 25.984 \text{ g}$$

$$\text{Molar mass} = 25.984 \approx 26 \text{ g mol}^{-1}$$

(iii) Empirical formula mass (CH) = 12 + 1 = 13

$$\therefore \quad n = \frac{\text{molecular mass}}{\text{empirical formula mass}} = \frac{26}{13} = 2$$

Hence, molecular formula $= n \times CH = 2 \times CH = C_2H_2$

Sample **Problem 24** *A compound having empirical formula* $(C_3H_4O)_n$ *has vapour density* 84. *The molecular formula of this compound is*

(*a*) C_3H_4O

(*b*) $C_6H_8O_2$

(*c*) $C_6H_{12}O_3$

(*d*) $C_9H_{12}O_3$

Interpret (*d*) Molecular mass $= 2 \times VD = 2 \times 84 = 168$

$$n = \frac{\text{molecular mass}}{\text{empirical formula mass}} = \frac{168}{12 \times 3 + 4 + 16} = \frac{168}{56} = 3$$

Thus, molecular formula $= (C_3H_4O)_3 = C_9H_{12}O_3$

Hot Spot 2

CHEMICAL EQUATIONS and Stoichiometry

Stoichiometry is the most important topic of this chapter. Generally questions are seen from this topic. The level of question is from moderate to typical.

Calculations based on the quantitative relationship between the reactants and products are referred as **stoichiometry.** (Stoichiometry from Greek words *stoichion* = element; *metron* = measure). Solving of stoichiometric problems require a firm grasp of mole concept, balancing chemical equations and care in consistent use of units.

The numerals used to balance a chemical equation are called **stoichiometric coefficients.** The goal of these calculations is to predict the relationship between the amounts of the reactants and products of chemical reaction.

Always remember, never lose your goal while solving such problems. Use mole concept carefully and then also find type of stoichiometric problem before solving.

To solve out stoichiometric problems, follow a right approach that is based on a few relatively easy ground rules, which can be understood by following sample problem.

Sample **Problem 25** *Predict the amount of oxygen that must be inhaled to digest (burn) 100 of sugar. The sugar burns according to the following equation.*

$$C_{12}H_{22}O_{11}\,(s) + 12\,O_2\,(g) \longrightarrow 12\,CO_2\,(g) + 11H_2O(l)$$

(*a*) 95.28 *g*
(*b*) 112. 28 *g*
(*c*) 125 *g*
(*d*) 35.12 *g*

Interpret (*b*) Follow the following steps to solve such type of problems.

Step I	Identify the goal of the problem. *e.g.,* in the above problem.	Find out how many grams of O_2 are consumed when 100 g of sugar is burned?
Step II	Write down the key elements of the problem, or draw a simple picture that summarizes the key information in the problem.	We have 100 g of sugar. Sugar has formula $C_{12}H_{22}O_{11}$. We know molar equation.
Step III	Try to do what can be done.	We can convert the mass (100 g) in moles, as we know molar mass of $C_{12}H_{22}O_{11}$. *i.e.,* $\frac{100}{342} = 0.29$ mol
Step IV	Do not try to do impossible.	There is no way to get moles of oxygen directly form moles of sugar in one step.
Step V	Never lose sight of what you have accomplished.	*What else we can do*? We know the molar relationship of O_2 and sugar in balance chemical equation. We can calculate the number of moles of oxygen needed to burn 0.29 mole of sugar as, $0.29 \times \frac{12}{1} = 3.48$ mole of O_2.
Step VI	Don't try to work the problem in your head. Write down all the intermediate steps.	Now we can calculate the weight of O_2 as $3.48 \times 32 = 112.28$ g O_2

Limiting Reactant or Limiting Reagent

If a reaction involves two or more reactants, the reactant that is consumed first is called **limiting reagent** or **limiting reactant** as it limits the amount of product formed. *e.g.,* A limiting reactant is like a part in an automobile factory, if there are 1000 head lights and 600 car bodies, then the maximum number of automobile will be limited by the number of headlights. Because each body requires two headlights and the headlights are available only for 500 cars. So the headlights play the role of limiting reagents.

Calculation of Limiting Reagent

This can be best understood by considering the following sample problem.

Sample **Problem 26** *Dinitrogen and dihydrogen react with each other to produce ammonia according to the following chemical equation,*

$$N_2(g) + 3H_2\,(g) \longrightarrow 2NH_3(g)$$

Calculate the mass of ammonia produced if 2.00×10^3 *g dinitrogen reacts with* 1.00×10^3 *g of dihydrogen.*

[NCERT]

(*a*) 8.1 *g*
(*b*) 3.4 *g*
(*c*) 1.8 *g*
(*d*) 2.4 *g*

Interpret (*d*) To find the limiting reagent, we have to follow the following sequence of steps

Step I Consider the possibility that there may be a limiting amount of one of the reactants. *e.g.,* in the above problem, dihydrogen appears as a limiting reagent because its amount is less than dinitrogen.

Step II Assume that one of the reactants is the limiting reagent. Let dihydrogen is the limiting reagent.

Step III See if you have enough of the other reactant to consume the material you have assumed to be the limiting reactant. If you do, your original assumption was correct.

$$\underset{\substack{1\text{ mol}\\28\text{ g}}}{N_2(g)} + \underset{\substack{3\text{ mol}\\6\text{ g}}}{3H_2(g)} \longrightarrow \underset{\substack{2\text{ mol}\\34\text{ g}}}{2NH_3(g)}$$

$\because$ 6g dihydrogen (H_2) reacts with dinitrogen (N_2) = 28 g

$$\because\ 1\times10^3\text{ g } H_2 \text{ will react with } N_2 = \frac{28\times1\times10^3}{6}\text{ g}$$

$$= 4.66\times10^3\text{ g}$$

But the available amount of N_2 is = 2.00×10^3 g which is less than 4.66×10^3 g. That means, our assumption is not correct.

Note If your assumption is true, left the step IV.

Step IV If you don't, assume that another reagent is the limiting reagent and test this assumption.

$$\underset{\substack{1\text{ mol}\\28\text{ g}}}{N_2(g)} + \underset{\substack{3\text{ mol}\\6\text{ g}}}{3H_2(g)} \longrightarrow \underset{\substack{2\text{ mol}\\34\text{ g}}}{2NH_3(g)}$$

28 g N_2 reacts with 6 g H_2

1 g N_2 reacts with $\frac{6}{28}$ g H_2

$$\therefore\ 2000\text{ g } N_2 \text{ will reacts with } \frac{2000\times6}{28}$$

$$= 428.57\text{ g } H_2$$

Hence, N_2 is the limiting reagent and H_2 is in excess. N_2 limits the amount of ammonia produced.

Amount of H_2 remain unreacted

$$=1000 - 428.57 = 571.43\text{ g}$$

Step V Once you have identified the limiting reagent, calculate the amount of the product formed.

28 g N_2 produces 34 g NH_3

1 g N_2 produces $\frac{34}{28}$ g NH_3

$$\therefore\ 2000\text{ g } N_2 \text{ will produce } \frac{34}{28}\times2000 = 2428.57\text{ g } NH_3$$

$$= 2.42\text{ kg } NH_3$$

Thus, the amount of NH_3 produced by the reaction of 2.00×10^3 g N_2 and 1.00×10^3 g H_2 = 2.42 kg

Sample **Problem 27** *The reactant which is entirely consumed in reaction is known as limiting reagent. In the reaction $2A + 4B \rightarrow 3C + 4D$, whein 5 moles of A react with 6 moles of B, then the amount of C formed is* **[NCERT Exemplar]**

(a) 3 *mol* (b) 4 *mol*

(c) 5.5 *mol* (d) 4.5 *mol*

Interpret (*d*) $2A + 4B \rightarrow 3C + 4D$

According to the above equation, 2 moles of '*A*' require 4 moles of '*B*' for the reaction.

Hence, for 5 moles of '*A*' the moles of '*B*' required

$$= 5\text{moles of } A \times \frac{4\text{ moles of } B}{2\text{ moles of } A}$$

$$= 10\text{ mol } B$$

But we have only 6 moles of '*B*' hence, '*B*' is the limiting reagent. So amount of '*C*' formed is determined by amount of '*B*'.

Since 4 moles of '*B*' give 3 moles of '*C*'.

Hence, 6 moles of '*B*' will give

$$6\text{ moles of } B \times \frac{3\text{ moles of } C}{4\text{ moles of } B} = 4.5\text{ moles of } C$$

1.6 Stoichiometric Problems of Different Kinds

Depending on the units, stoichiometric problems may be classified into the following relationship

(a) mass-mass relationship-gravimetric analysis
(b) mass-volume relationship
(c) volume-volume relationship

Such relations further be classified as

(i) Gas-gas analysis or eudiometry
(ii) Solutions-volumetric analysis or titration

I Calculations Based on Mass-mass Relationship

In making necessary calculations, following methods can be used

(a) **Mole Method** (Based on mole concept)

It involves the following steps

Step I Write the complete and balanced chemical reaction concerned in the problem.

Step II The stoichiometric coefficients in the balanced chemical reactions represent the relative number of moles of the different reaction components. Relate the amounts of the reaction components concerned, with the help of mole.

Step III Calculate the unknown amount of substance using unitary method.

Sample **Problem 28** *Calculate the weight of carbon dioxide formed by complete combustion of* 1.5 g *ethane.*

(*a*) 22 *g* (*b*) 2.2 *g* (*c*) 44 *g* (*d*) 4.4 *g*

Interpret (*d*) $\underset{\substack{1\text{ mol}\\=30\text{ g}}}{C_2H_6} + \frac{7}{2}O_2 \longrightarrow \underset{\substack{2\text{ mol}\\=2\times44\text{ g}}}{2CO_2} + 3H_2O$

$\because$ 30 g C_2H_6 produces 2×44 g CO_2 on complete combustion

$\therefore$ 1.5 g C_2H_6 will produce $\frac{2\times44}{30}\times1.5 = 4.4$ g CO_2

(b) Principle of Atomic Conservation (POAC) Method

This is another approach of solving problems by mole method, without balancing the reaction. As the reactions are balanced by conserving the atoms of each element, the mole of atoms of each element in the reactant side should be equal to that in the product side. On applying the conservation of atoms of each element with the help of mole, we may get relations needed to solve the problem.

For example, the sample problem 28 may be solved by POAC method as

Moles of C-atoms in C_2H_6 = moles of C- atoms in CO_2

or $2\times$ mole of C_2H_6 = $1\times$mole of CO_2

or $$2\times\frac{1.5}{30} = 1\times\frac{w}{44}$$

$\therefore$ $$w = 4.4\,\text{g}$$

(c) Factor-label Method

In this method, the required amount is determined directly by first converting the given amount of substance into its moles, then relating the moles of given substance with the moles of required substance as per balanced chemical equation or atomic conservation and finally converting the moles into the amount of the required substance.

For example, the sample problem 28 may be solved by factor label method as

Procedure

$$\text{Mass of } C_2H_6 \text{ (given)} \xrightarrow[\text{into}]{\text{Convert}} \text{Moles of } C_2H_6$$

$$\xrightarrow[\text{moles of } CO_2]{\text{Relate with}} \text{moles of } CO_2$$

$$\xrightarrow[\text{into}]{\text{Convert}} \text{Mass of } CO_2 \text{ (required)}$$

Application

$$\text{Mass of } CO_2 = (1.5\text{g } C_2H_6)\times\left(\frac{1 \text{ mol } C_2H_6}{30\text{ g } C_2H_6}\right)\times\left(\frac{2\text{ mol } CO_2}{1\text{ mol } C_2H_6}\right)\times\left(\frac{44\text{g } CO_2}{1\text{ mol } CO_2}\right)$$

$$= 4.4\,\text{g}$$

(d) Equivalent Method

(Based on equivalent concept)

The number of gram-equivalents of each reactants reacted will be same and the same number of gram-equivalents of each products will form. The sample problem 28 may be solved by equivalent concept as

no. of g-equivalents of C_2H_6 = no. of g-equivalents of CO_2

or $$\frac{1.5}{\left(\frac{30}{14}\right)} = \frac{w}{\left(\frac{44}{7}\right)}$$

$$w = 4.4\,\text{g}$$

$\therefore$ The factors 14 and 7 are changes in oxidation states of carbon for C_2H_6 and CO_2 respectively.

Sample **Problem 29** *Oxygen is prepared by catalytic decomposition of potassium chlorate* ($KClO_3$). *Decomposition of potassium chlorate gives potassium chloride* (KCl) *and oxygen* (O_2). *How many grams of* $KClO_3$ *are required to produce* 2.4 *moles of* O_2?

(*a*) 122.5 *g* (*b*) 196 *g* (*c*) 245 *g* (*d*) 98 *g*

Interpret (*b*) Decomposition of $KClO_3$ takes place as,

$$2KClO_3(s) \longrightarrow 2KCl(s) + 3O_2(g)$$

$$2 \text{ moles of } KClO_3 \equiv 3\text{moles of } O_2$$

$\because$ 3 moles of O_2 are formed by 2 moles of $KClO_3$

$\therefore$ 2.4 moles of O_2 will be formed by $\left(\frac{2}{3}\times2.4\right)$ moles of $KClO_3$

$$= 1.6 \text{ mol } KClO_3$$

$$\text{Mass of } KClO_3 = \text{Number of moles}\times\text{molar mass}$$

$$= 1.6\times122.5 = 196\text{ g}$$

Sample **Problem 30** *How many grams of oxygen are required to burn completely* 570 *g of octane?*

(*a*) 570 *g* (*b*) 5 *mol* (*c*) 25×32 *g* (*d*) 2000 *g*

Interpret (*d*) Balanced equation,

$$\underset{\substack{2\text{ mol}\\=2\times114}}{2C_8H_{18}} + \underset{\substack{25\text{ mol}\\=25\times32}}{25O_2} \longrightarrow 16CO_2 + 18H_2O$$

$\therefore$ ***First method*** For burning 2×114 g of octane, oxygen required

$$= 25\times32\text{ g}$$

For burning 1g octane, oxygen required $= \frac{25\times32}{2\times114}$ g

Thus, for burning 570 g of octane, oxygen required

$$= \frac{25\times32}{2\times114}\times570\text{g} = 2000\text{ g}$$

Mole method Number of moles of octane in 570 g $= \frac{570}{114} = 5.0$

For burning 2.0 moles of octane, oxygen required

$$= 25\text{ mol} = 25\times32\text{ g}$$

For burning 5 moles octane, oxygen required

$$= \frac{25\times32}{2.0}\times5.0\text{g} = 2000\text{ g}$$

Proportion method Let x g of oxygen be required for burning 570.0 g of octane. It is known that 2×114 g of the octane require 25×32 g of oxygen; then, the proportion,

$$\frac{25\times 32\text{ g oxgen}}{2\times 114\text{g octane}}=\frac{x}{570.0\text{ g octane}}$$

$$x=\frac{25\times 32\times 570}{2\times 114}=2000\text{ g}$$

Calculation Involving Per cent Yield

In general, when a reaction is carried out in the laboratory we do not obtain actually the theoretical amount of the product. The amount of the product that is actually obtained is called the **actual yield**. Knowing the actual yield and theoretical yield the per cent yield can be calculated by using the formula,

$$\text{Per cent yield}=\frac{\text{Actual yield}}{\text{Theoretical yield}}\times 100$$

Sample **Problem 31** *For the reaction,*

$$CaO + 2HCl \longrightarrow CaCl_2 + H_2O$$

1.23 *g of* CaO *is reacted with excess of hydrochloric acid and* 1.85 *g of* $CaCl_2$ *is formed. What is the per cent yield?*

(*a*) 76.1 (*b*) 86.3
(*c*) 95.1 (*d*) *None of these*

Interpret (*a*) The balanced equation is

$$\underset{\substack{1\text{ mol}\\56\text{ g}}}{CaO} + 2HCl \longrightarrow \underset{\substack{1\text{ mol}\\111\text{ g}}}{CaCl_2} + H_2O$$

56 g of CaO produces $CaCl_2$ = 111 g

1.23 g of CaO will produce $CaCl_2=\frac{111}{56}\times 1.23 = 2.43$ g

Thus, theoretical yield = 2.43 g

Actual yield = 1.85 g

$$\text{Per cent yield}=\frac{1.85}{2.43}\times 100=76.1$$

Calculations Involving Per cent Purity

Depending upon the mass of the product, the equivalent amount of the reactant present can be determined with the help of a chemical equation. Knowing the actual amount of the reactant taken and the amount calculated with the help of a chemical equation, the percentage purity can be determined as

$$\%\text{ purity}=\frac{\text{wt. of reactant required}}{\text{wt. of reactant taken}}\times 100$$

Sample **Problem 32** *Chlorine evolved by the reaction of* 45.31 *g of pyrolusite (impure) and excess of* HCl *is found to combine completely with the hydrogen produced by the reaction of* 10 *g of magnesium and excess of dilute hydrochloric acid. Find the percentage purity of* MnO_2 *in the given pyrolusite.*

(*a*) 98 (*b*) 95 (*c*) 70 (*d*) 80

Interpret (*d*) $\underset{24\text{ g}}{Mg} + \underset{(2\times 36.5)\text{ g}}{2HCl} \longrightarrow MgCl_2 + \underset{2\text{ g}}{H_2}$

$$\underset{87\text{ g}}{MnO_2} + 4HCl \longrightarrow MnCl_2 + \underset{71\text{ g}}{Cl_2} + 2H_2O$$

$$\underset{2\text{ g}}{H_2} + \underset{71\text{ g}}{Cl_2} \longrightarrow 2HCl$$

2g of hydrogen obtained by using 24 g of Mg will combine completely with 71 g of chlorine produced from 87 g of pure MnO_2. Thus, when 10 g of Mg are used,

the mass of pure MnO_2 required is $=\frac{87}{24}\times 10=36.25$ g

So, 45.31 g of pyrolusite contain MnO_2 (pure) = 36.25 g

$\therefore$ 100 g of pyrolusite contain MnO_2 (pure)

$$=\frac{36.25}{45.31}\times 100=80.004\text{ g}$$

$\therefore$ Percentage of purity = 80.00

Analysis of Mixtures

In such problems, one of the components is supposed to be x g and the other will be the difference from the total. Balanced chemical equations for the reactions of both the components are now written and the total amount of the common product produced by the components of the mixture is calculated. It is equated with the data given and the unknown factors are, thus, worked out.

Sample **Problem 33** *A solid mixture* (5.0 g) *consisting of lead nitrate and sodium nitrate was heated below* 600° C *until the mass of the residue was constant. If the loss in mass is* 28.0 *per cent, find the amount of lead nitrate in the mixture.*

(*a*) 1.67 (*b*) 3.32 (*c*) 1.40 (*d*) 5.00

Interpret (*b*) Let the amount of $NaNO_3$ in the mixture be xg.

$\therefore$ The amount of $Pb(NO_3)_2$ in the mixture = $(5.0-x)$ g

$$\underset{(2\times 85)\text{ g}}{2NaNO_3} \xrightarrow{\text{Heat}} 2NaNO_2 + \underset{32\text{ g}}{O_2}$$

$$\underset{\substack{(2\times 331)\text{ g}\\662\text{ g}}}{2Pb(NO_3)_2} \xrightarrow{\text{Heat}} 2PbO + \underbrace{\underset{(4\times 46)\text{ g}}{4NO_2} + \underset{32\text{ g}}{O_2}}_{216\text{ g}}$$

170 g of $NaNO_3$ evolve oxygen = 32 g

x g of $NaNO_3$ evolve oxygen $=\frac{32}{170}\ x$g

662 g of $Pb(NO_3)_2$ evolve gases = 216 g

$(5.0-x)$ g of $Pb(NO_3)_2$ evolve gases $=\frac{216}{662}\times(5.0-x)$ g

$\therefore$ Total loss $=\frac{32}{170}\times x+\frac{216}{662}\times(5.0-x)$

Loss given in the problem $=\frac{28}{100}\times 5=1.4$ g

$\therefore$ Total loss $=\frac{32}{170}x+\frac{216}{662}(5.0-x)=1.4$

On solving, x=1.676 g

Thus, mass of $NaNO_3$ = 1.676 g

Mass of $Pb(NO_3)_2$ = (5.0 −1.676)g = 3.324 g

Reactions in Succession

In such problems, the amount of any one of the reaction component belonging from a reaction is to be determined from the given amount of some other reaction component belonging from some other reaction with the help of some common components.

Sample **Problem 34** *How many gram of ethylene can be burnt completely by the oxygen gas produced from complete decomposition of* 49 g $KClO_3$*?*

(*a*) 96 g (*b*) 9.6 g
(*c*) 5.6 g (*d*) 6.5 g

Interpret (*c*) **Method I** Solve each concerned reaction separately. First determine the amount of oxygen gas produced by the complete decomposition of $KClO_3$.

$$\begin{array}{ccc} 2KClO_3 & \longrightarrow 2KCl + & 3O_2 \\ 2\text{ mol} & & 3\text{ mol} \\ = 2\times 122.5\text{ g} & & = 3\times 32\text{ g} \\ = 245\text{ g} & & = 96\text{ g} \end{array}$$

$\because$ 245 g $KClO_3$ will produce 96 g O_2

$$\therefore \quad 49\text{ g } KClO_3 \text{ will produce } O_2 = \frac{96}{245}\times 49$$

$$= 19.2\text{ g } O_2$$

Now, determine the amount of ethane which can be burnt completely by the oxygen gas produced.

$$\begin{array}{ccc} C_2H_4 & + \; 3O_2 & \longrightarrow 2CO_2 + 2H_2O \\ 1\text{ mol} & 3\text{ mol} & \\ = 28\text{ g} & = 3\times 32\text{ g} & \\ & = 96\text{ g} & \end{array}$$

$\because$ 96 g O_2 will burn 28g C_2H_4

$\therefore$ 19.2 g O_2 will burn $\dfrac{28}{96}\times 19.2 = 5.6\text{ g } C_2H_4$

Method II Add or subtract the concerned reactions properly such that the common compound, by which the reactions are related cancels out. The reaction, thus obtained, may be a hypothetical reaction but it will give the true molar relation.

$$\begin{array}{l} 2KClO_3 \longrightarrow 2KCl + 3O_2 \\ C_2H_4 + 3O_2 \longrightarrow 2CO_2 + 2H_2O \\ \hline 2KClO_3 + C_2H_4 \longrightarrow 2KCl + 2CO_2 + 2H_2O \\ \;\;2\text{ mol} \qquad\; 1\text{ mol} \end{array}$$

$= 2\times 122.5$ g $= 28$ g

$$\therefore 49\text{ g } KClO_3 \text{ will react with } \frac{28}{2\times 122.5}\times 49 = 5.6\text{ g } C_2H_4$$

Method III Relate the moles of the component of given amount with the component of required amount, with the help of common substance, with the help of balanced chemical reactions.

$2\text{ mol } KClO_3 \equiv 3\text{ mol } O_2 \equiv 1\text{ mol } C_2H_4$

$= 2\times 122.5\text{ g} = 28\text{ g}$

$\therefore$ 49 g $KClO_2$ will react with

$$\frac{28}{2\times 122.5}\times 49 = 5.6\text{ g } C_2H_4$$

Method IV Factor-Lable method

Mass of C_2H_4

$$= (49\text{ g } KClO_3)\times\left(\frac{1\text{ mol } KClO_3}{122.5\text{ g } KClO_3}\right)\times\left(\frac{3\text{ mol } O_2}{2\text{ mol} KClO_3}\right)\times\left(\frac{1\text{ mol } C_2H_4}{3\text{ mol } O_2}\right)\times\left(\frac{28\text{ g } C_2H_4}{1\text{ mol } C_2H_4}\right)$$

$= 5.6$ g

Sample **Problem 35** 0.2415 g *sample of a mixture of* $MgSO_4\cdot 7H_2O$ *and* $MgCl_2\cdot 6H_2O$ *containing inert impurities was subjected to suitable treatment, as a result of which there were obtained* 0.1362 g *of* $BaSO_4$ *and* 0.1129 g *of* $Mg_2P_2O_7$. *Calculate the percentage impurity in the original mixture.*

(*a*) 5% (*b*) 4% (*c*) 3% (*d*) 8%

Interpret (*b*) Let the original sample contains *a* mol $MgSO_4\cdot 7H_2O$ and *b* mol $MgCl_2\cdot 6H_2O$. As $BaSO_4$ will form only from $MgSO_4\cdot 7H_2O$, from the conservation of SO_4^{2-} ion, a mole of $BaSO_4$ will form.

From question, $a\times 233 = 0.1362$ ... (i)

Now, as $Mg_2P_2O_7$ will form from both $MgSO_4\cdot 7H_2O$ and $MgCl_2\cdot 6H_2O$, from the conservation of Mg-atom, mole of $Mg_2P_2O_7$ formed $= a/2 + b/2$.

From question, $\left(\dfrac{a}{2}+\dfrac{b}{2}\right)\times 222 = 0.1129$ ...(ii)

From Eq. (i) and (ii), $a = 0.000585$ and $b = 0.000432$

Hence, the composition of original mixture

$MgSO_4\cdot 7H_2O = 0.000585\text{ mol} = 0.000585\times 246 = 0.1439\text{ g}$

$$\text{Percentage purity} = \frac{0.1439}{0.2415}\times 100 = 59.59\%$$

$$MgCl_2\cdot 6H_2O = 0.000432\text{ mol} = 0.000432\times 203 = 0.0877\text{ g}$$

$$\text{Percentage purity} = \frac{0.0877}{0.2415}\times 100 = 36.31\%$$

$$\text{Impurity} = 100 - (59.59 + 36.31) = 4.1\%$$

(ii) Calculations Involving Mass-volume Relationship

In such calculations masses of reactants are given and volume of the product is required and *vice-versa*. 1 mole of a gas occupies 22.4 L volume at STP thus, mass of a gas can be related to volume according to the following gas equation

$$pV = nRT$$

$$pV = \frac{w}{m}RT$$

Sample **Problem 36** *Hydrogen gas is prepared in the laboratory by reacting dilute* HCl *with granulated zinc. Following reaction takes place*

$$Zn + 2HCl \longrightarrow ZnCl_2 + H_2$$

Calculate the volume of hydrogen gas liberated at STP when 32.65 g *of zinc reacts with* HCl. *I mole of a gas occupies 22.7 L volume at STP; atomic mass of* Zn = 65.3 *u*. **[NCERT Exemplar]**

(a) 22.7 L (b) 22.4 L (c) 11.3L (d) 5.2 L

Interpret (*c*) From the equation, 65.3 g of zinc liberates 22.7 L of hydrogen. So 32.65 g zinc will liberate

$$32.65 \text{ g Zn} \times \frac{22.7 \text{ L } H_2}{65.3 \text{ g Zn}} = \frac{22.7}{2} \text{ L} = 11.35 \text{L}$$

Sample Problem 37 *A vessel contains* 1.6 *g of dioxygen at STP* (273.15 *K*, 1 *atm pressure*). *The gas is now transferred to another vessel at constant temperature, where pressure becomes half of the original pressure. The volume of the new vessel, and number of molecules of dioxygen, are respectively.* **[NCERT Exemplar]**

(*a*) $2.24, 6.02 \times 10^{23}$ (*b*) $1.12, \ 3.01 \times 10^{22}$

(*c*) $2.24, 3.01 \times 10^{21}$ (*d*) $2.24, \ 3.01 \times 10^{22}$

Interpret (*d*) (i) $p_1 = 1$ atm $T_1 = 273 \text{K}, \ V_1 = ?$

32 g of oxygen occupies 22.4 L of volume at STP.

Hence, 1.6 g of oxygen will occupy,

$$1.6 \text{ g oxygen} \times \frac{22.4 \text{ L}}{32 \text{ g oxygen}} = 1.12 \text{ L volume}$$

$$V_1 = 1.12 \text{L}$$

$$p_2 = \frac{p_1}{2} = \frac{1}{2} = 0.5 \text{ atm.}$$

$$V_2 = ?$$

According to Boyle's law

$$p_1V_1 = p_2V_2$$

$$\therefore \quad V_2 = \frac{p_1 \times V_1}{p_2} = \frac{1 \text{ atm} \times 1.12 \text{ L}}{0.5 \text{ atm}} = 2.24 \text{L}$$

(ii) Number of molecules of oxygen in the vessel

$$= \frac{6.022 \times 10^{23} \times 1.6}{32} = 3.011 \times 10^{22}$$

(iii) Calculations Based on Volume-volume Relationship

For Gases

These calculations are based on two laws

(i) Avogadro's law (ii) Gay-Lussac's law

(See Topic 1.3 for laws.)

Sample Problem 38 *What volume of air containing* 21% *oxygen by volume is required to completely burn* 1 *kg of carbon containing* 100% *combustible substances?*

(*a*) 888.85 *L* (*b*) *8.8885 L*

(*c*) 88.885 *L* (*d*) *None of these*

Interpret (*b*) Combustion of carbon may be given as

$$\underset{\substack{1 \text{ mol} \\ 12 \text{ g}}}{C(s)} + \underset{\substack{1 \text{ mol} \\ 1 \text{ mol}}}{O_2(g)} \longrightarrow CO_2(g)$$

$\because$ 12 g carbon requires 1 mole of O_2 for complete combustion.

$\therefore$ 1000 g carbon will require $\frac{1}{12} \times 1000$ mol O_2 for combustion, *i.e.*, 83.33 mol O_2

Volume of O_2 at NTP $= 83.33 \times 22.4 \text{ L} = 1866.592 \text{ L}$

$\because$ 21 L O_2 is present in 100 L air

$\therefore$ 1866.592 L O_2 will be present in $\frac{100}{21} \times 1866.592$ L air

$$= 8888.5 \text{ L} = 8.8885 \times 10^3 \text{ L}$$

For Solutions

(i) **Simple titrations** In a simple titration, a solution of substance *A* of unknown concentration is made to react with a solution of *B* whose concentration is known, so that the concentration of *A* may be calculated. The two are reacted in such a way that the volume of *B* required to completely react with *A* can be found out by using some indicators.

If the normality of *B* is N_1 and its volume used is V_1 then the gram-equivalents of *B* reacted $= N_1V_1$.

According to the law of equivalents, the gram-equivalents of *A* would be equal to that of *B*.

$\therefore$ Gram equivalents of $A = N \times V$

If the volume of *A* is *V* then the normality of *A* would be $\frac{N_1V_1}{V}$.

Sample Problem 39 *What volume of* 2.5 *M* H_2SO_4 *is required to neutralize a solution containing* 2.5 *g* NaOH?

(*a*) 10.2 *mL* (*b*) 18.4 *mL*

(*c*) 12.5 *mL* (*d*) 11.89 *mL*

Interpret (*c*) 2.5 g NaOH $= \frac{2.5}{40}$ equivalent of

$$\text{NaOH} = \left(\frac{2.5}{40} \times 1000\right) \text{mill. equivalents of NaOH} = 62.5$$

Now meq of H_2SO_4 = Meq of NaOH

Let the volume of H_2SO_4 required is *V* mL

or $2.5 \times 2 \times V = 62.5$

($\because$ *n* factor for $H_2SO_4 = 2$)

$$V = \frac{62.5}{5} = 12.5 \text{ mL}$$

(ii) **Back titration** Let us assume that we have a solid *C* which is impure and we want to calculate the percentage purity. We are given two reagents *A* and *B*, where the concentration of *A* is unknown while that of *B* is known (N_1).

A certain volume of *A* is taken in a beaker and it is titrated with *B*. Let the volume of *B* used be V_1. Again fresh *A* (same volume) is taken in a beaker and the solid *C* is added to it. The resulting solution is again titrated with *B* and let the volume of *B* consumed be V_2.

For back titration to work the following *two conditions should be satisfied.*

I. *A*, *B* and *C* should be such that *A* reacts with *B*, *A* reacts with *C* and the product of *A* and *C* cannot react with *B*.

II. The amount of *A* taken in the beaker before adding *C* to it should be such that the gram-equivalents of *A* in it should be either greater than or equal to gram-equivalent of *C*.

$\therefore$ It can be seen that the gram-equivalents of *B* that reacted with *A* in the first titration = N_1V_1 which is also equal to the gram-equivalents of *A*. The gram equivalents of *B* in the second titration = N_2V_2 which is equal to the gram-equivalents of *A* that were left in excess after reacting with *C*.

$\therefore$ Gram-equivalents of *A* consumed by $C = N_1V_1 - N_2V_2$ which is also equal to gram-equivalents of *C*. If the '*n*' factor of *C* is × then the moles of *C* is $\left(\frac{N_1V_1 - N_2V_2}{x}\right)$.

The mass of *C* would be $\left(\frac{N_1V_1 - N_2V_2}{x}\right)\times M = m$.

If the sample of *C* weighed *W* grams then the percentage of *C* in it $= \frac{m}{W}\times 100$.

Sample Problem 40 *1.6 g of pyrolusite ore was treated with 50 cc of 1.0 N oxalic acid and some sulphuric acid. The oxalic acid left undecomposed was raised to 250 cc in a flask. 25 cc of this solution when titrated with 0.1 N* $KMnO_4$ *required 32 cc of the solution. Find out the percentage of pure* MnO_2 *in the sample.*

(a) 49% (b) 50% (c) 81% (d) 62%

Interpret (a) Meq of excess dil oxalic acid in 25 cc = Meq. of $KMnO_4 = 0.1\times 32$

$\therefore$ Meq of oxalic acid in 250 cc dilute solution = 32

Meq of MnO_2 = Meq. of oxalic acid added − Meq of excess oxalic acid $= 1\times 50 - 32 = 18$

$\therefore$ Let the weight of MnO_2 is *Wg*.

$$\therefore \qquad \frac{W}{E}\times 1000 = 18$$

$$\therefore \qquad \frac{W}{87/2}\times 1000 = 18 \quad \text{or} \quad W = \frac{18\times 87}{2000} = 0.783\text{ g}$$

$$\%\text{ of } MnO_2 = \frac{0.783}{1.6}\times 100 = 48.93$$

(iii) **Double titration** This is a titration of specific compound using different indicators.

This method involves two indicators namely phenolphthalein and methyl orange. These indicators are weak organic acids or bases which shows completion of reaction by changing its colour. Phenolphthalein acts as an indicator in weakly basic medium, but not in acidic medium. But methyl orange acts as an indicator both in acidic medium as well as in basic medium.

Extent of different bases with acid (HCl) using these two indicators is summarized as below.

Table 1.3 **Indicators Used with Different Bases**

	Indicators	
Bases	Phenolphthalein	Methyl orange
NaOH	100% reaction is indicated	100% reaction is indicated
Na_2CO_3	50% of reaction up to $NaHCO_3$ stage is indicated	100% reaction is indicated
$NaHCO_3$	No reaction is indicated	100% reaction is indicated $NaHCO_3 + HCl \longrightarrow NaCl + H_2O + CO_2$

Suppose, the volume of given standard acid solution (HCl) is required,

for complete reaction of NaOH $= V_a$ mL

for complete reaction of $Na_2CO_3 = V_b$ mL

for complete reaction of $NaHCO_3 = V_c$ mL

There may be different combinations of mixture of bases are possible. We will opt the following two methods,

Method I We carry two titration separately with two different indicators.

Method II We carry single titration but adding second indicator after first end point is reached.

Table 1.4 **Results with Two Indicators**

Mixture	Method I		Method II	
	Volume of HCl used with indicator		Volume of HCl used with indicator	
	Phenolphthalein	Methyl orange	Phenolphthalein	Methyl orange added after the first end point is reached
$NaOH + Na_2CO_3$	$V_a + \frac{V_b}{2}$	$V_a + V_b$	$V_a + \frac{V_b}{2}$	$\frac{V_b}{2}$
$NaOH + NaHCO_3$	V_a	$V_a + V_c$	V_a	V_c
$Na_2CO_3 + NaHCO_3$	$\frac{V_b}{2}$	$V_a + V_c$	$\frac{V_b}{2}$	$\frac{V_b}{2} + V_a$

If mixture contains NaOH, Na_2CO_3 *and* $NaHCO_3$, *then these are the following cases with the following cases with the indicators.*

***Case* 1** The titre readings of HCl, using phenolphthalein from beginning $= V_a + \dfrac{V_b}{2}$

***Case* 2** If methyl orange is added after the first end point, then the titre readings of HCl $= \dfrac{V_b}{2} + V_c$

***Case* 3** If methyl orange is added from the very beginning, the titre readings of HCl $= V_a + V_b + V_c$

Sample Problem 41 *A solution contains a mixture of* Na_2CO_3 *and* NaOH. *Using phenolphthalein as indicator,* 25 *mL of mixture required* 19.5 *mL of* 0.995 *N* HCl *for the end point. With methyl orange, 25mL of solution required 25 mL of the same* HCl *for the end point. The grams per litre of* Na_2CO_3 *in the mixture is*

(*a*) 23.2 (*b*) 18.5 (*c*) 19.9 (*d*) 12.8

Interpret (*a*) Let the moles of Na_2CO_3 and NaOH in 25 mL mixture be *x* and y respectively.

***Case* 1** when HPh is used as indicator.

$$\underset{x}{NaOH} + \underset{x}{HCl} \longrightarrow NaCl + H_2O$$

$$\underset{y}{Na_2CO_3} + \underset{y}{HCl} \rightarrow NaHCO_3 + NaCl$$

So, $$x + y = 19.5 \times 10^{-3} \times (0.995 \times 1) \qquad \ldots(i)$$

***Case* 2** when MeOH is used as indicator.

$$\underset{x}{NaOH} + \underset{x}{HCl} \longrightarrow NaCl + H_2O$$

$$\underset{y}{Na_2CO_3} + \underset{2y}{2HCl} \longrightarrow 2NaCl + H_2O + CO_2 \qquad \ldots(ii)$$

$$x + 2y = 25 \times 10^{-3} \times 0.995 \times 1$$

On solving Eqs. (i) and (ii), we get,

$$x = 13.93 \times 10^{-3} \text{ mol and } y = 5.4725 \times 10^{-3} \text{ mol}$$

Now, weight of NaOH in 25 mL mixture

$$= 13.93 \times 10^{-3} \times 40 = 557.2 \times 10^{-3} \text{ g}$$

Weight of Na_2CO_3 in 25 mL mixture $= 5.4725 \times 10^{-3} \times 106$ $= 580.085 \times 10^{-3}$ g

$$\therefore \text{ Weight of NaOH per litre} = \frac{557.2 \times 10^{-3} \times 1000}{25} = 22.288 \text{ g/L}$$

$$\text{weight of } Na_2CO_3 \text{ per litre} = \frac{580.085 \times 10^{-3} \times 1000}{25}$$

$$= 23.2034 \text{ g/L}$$

(iv) **Iodimetry** This is a simple redox titration between a solution of iodine and $Na_2S_2O_3$ solution.

$$\underset{n\,=\,2}{I_2} + \underset{n=1}{2S_2O_3^{2-}} \longrightarrow 2I^- + S_4O_6^{2-}$$

(v) **Iodometry** This is an indirect way of doing iodimetry. An oxidizing agent *A* is made to react with excess of solid KI. The oxidizing agent oxidizes I^- to I_2. This iodine is then made to react with $Na_2S_2O_3$ solution. As can be seen the gram-equivalents of $Na_2S_2O_3$ would be equal to I_2 which in turn will be equal to that of reacted KI and this would be equal to the number of gram equivalents of *A*.

Sample Problem 42 5.7*g of bleaching powder was suspended in* 500*mL* of water . 25*mL* of this solution *on treatment with* KI *in the presence of* HCl *liberated iodine which reacted with* 24.35 *mL of* N/10 $Na_2S_2O_3$. *Calculate the percentage of available chlorine in the bleaching powder.*

(*a*) 30% (*b*) 25%

(*c*) 80% (*d*) 70%

Interpret (*a*) Millieq. of $Na_2S_2O_3 = 24.35 \times 1/10 = 2.435$

This would be the milliequivalent of I_2 and therefore that of Cl_2 (which liberates I_2 from KI).

Milliequivalents of Cl_2 in 500mL $= 2.435 \times 20 = 48.7$

Meq of Cl_2 = meq. of bleaching powder = Meq of available Cl_2 in the bleaching powder.

$$\text{Percentage of chlorine} = \frac{48.7}{1000} \times \frac{35.5}{5.7} \times 100$$

$$= 30.33\%$$

Check Point 2

1. How are 0.50 mole Na_2CO_3 and 0.50 M Na_2CO_3 different?
2. Write the empirical formula of the compounds having molecular formulae H_2O_2, B_2H_6 and Fe_2O_3.
3. Which reactant checks the amount of barium phosphate formed, when 2 moles each of barium chloride and sodium phosphate react?

WORKED OUT
Examples

Example 1 *10 g of hydrogen fluoride gas occupies 5.6 L of volume at NTP. The molecular formula of the gas is (at. mass of* F = 19)

(*a*) HF (*b*) H_3F_3 (*c*) H_2F_2 (*d*) H_4F_4

Solution (*c*) ∵ 5.6 L of volume is occupied by 10g hydrogen fluoride gas

∴ 22.4 L volume will be occupied by hydrogen fluoride

$$\text{gas} = \frac{10}{5.6} \times 22.4 = 40 \text{ g}$$

Among the given molecular formulae, molecular mass of H_2F_2 is 40. Thus, the molecular formula of the gas is H_2F_2.

Example 2 *A sample of pure compound contains* 2.04 g *of sodium,* 2.65×10^{22} *atoms of carbon and* 0.132 *mol of oxygen atoms. Its empirical formula is*

(*a*) $NaCO_2$ (*b*) $Na_2C_2O_4$
(*c*) Na_2CO_3 (*d*) *None of these*

Solution (*c*) Number of moles of

$$\text{Na} = \frac{2.04 \text{ g}}{23 \text{ g mol}^{-1}} = 0.0887 \text{ mol}$$

$$\text{Number of moles of C} = \frac{2.65 \times 10^{22} \text{ atoms}}{6.02 \times 10^{23} \text{ atoms mol}^{-1}} = 0.0440 \text{ mol}$$

Number of moles of O = 0.132 mol

Ratio of number of moles =

Na	:	C	:	0
0.0887	:	0.0440	:	0.132
2	:	1	:	3

∴ Empirical formula of the compound is Na_2CO_3.

Example 3 *One volume hydrogen combines with sulphur to give one volume of a gas X. If the vapour density of X is* 17*, the number of sulphur atoms in the gas X is*

(*a*) 1 (*b*) 2
(*c*) 3 (*d*) 4

Solution (*a*)

$$\underset{\substack{1 \text{ vol} \\ 1 \text{ molecule} \\ 2 \text{ atoms}}}{\text{Hydrogen}} + \text{Sulphur} \longrightarrow \underset{\substack{1 \text{ vol} \\ 1 \text{ molecule} \\ 1 \text{ molecule}}}{X}$$

∴ The formula of *X* is H_2S_n.

$$\begin{aligned} \text{Molecular mass of } X &= 1 \times 2 + n \times 32 = 2 + 32n \\ &= 2 \times \text{VD} \\ &= 2 \times 17 = 34 \\ \Rightarrow \quad 2 + 32n &= 34 \\ n &= 1 \end{aligned}$$

Example 4 *A cylinder of compressed gas contains nitrogen and oxygen in the ratio* 3 : 1*by mole. If the cylinder is known to contain* 2.5×10^4 *g of oxygen, what is the total mass of the gas mixture?*

(*a*) 781.25 (*b*) 6.5625×10^4
(*c*) 9.06×10^4 (*d*) 6.023×10^5

Solution (*c*) Number of moles of oxygen in the cylinder

$$= \frac{\text{mass in gram}}{\text{molecular mass in gram mol}^{-1}}$$

$$= \frac{2.5 \times 10^4}{32} = 781.25$$

∴ Number of moles of $N_2 = 3 \times 781.25 = 2343.75$

$$\begin{aligned} \text{Mass of nitrogen in the cylinder} &= 2343.75 \times 28 \\ &= 65625 \text{ g} = 6.5625 \times 10^4 \text{ g} \end{aligned}$$

Total mass of the gas in the cylinder

$$\begin{aligned} &= 2.5 \times 10^4 + 6.5625 \times 10^4 \\ &= 9.0625 \times 10^4 \text{ g} \end{aligned}$$

Example 5 *Two metallic oxides contain 27.6% and 30.0% oxygen respectively. If the formula of the first oxide is* M_3O_4, *then that of the second will be*

(*a*) M_2O_5 (*b*) M_2O_3 (*c*) MO (*d*) MO_2

Solution (*b*) As first oxide is M_3O_4,

72.4 parts of *M* = 3 atoms of *M*

and 27.6 parts of O = 4 atoms of O.

$$\therefore \quad 70 \text{ parts of } M = \frac{3}{72.4} \times 70 \text{ atoms of } M$$

$$= 2.9 \text{ atoms of } M$$

$$30 \text{ parts of O} = \frac{4}{27.6} \times 30 \text{ atoms of O}$$

$$= 4.35 \text{ atoms of O}$$

∴ Ratio of *M* : O in the second oxide

$$= 2.9 : 4.35 = 1 : 1.5 \text{ or } 2 : 3$$

Hence, the formula is M_2O_3.

Example 6 *The density of a gaseous element is 5 times that of oxygen under similar conditions. If the molecule of the element is triatomic, what will be its atomic mass?*

(*a*) 53.33 (*b*) 55.84 (*c*) 43.47 (*d*) 78.86

Solution (*a*) Molecular mass of oxygen = 32

$$\text{Vapour density of oxygen} = \frac{32}{2} = 16$$

Thus, vapour density of the gaseous element = 16 × 5 = 80

Molecular mass of the gaseous element = 80 × 2 = 160

$$\text{As the molecule is triatomic, its atomic mass} = \frac{\text{mol. mass}}{\text{atomicity}}$$

$$= \frac{160}{3} = 53.33$$

Example 7 *What is the empirical formula of vanadium oxide if 2.74 g of metal oxide contains 1.53 g of metal?*

(*a*) V_2O_3 (*b*) VO (*c*) V_2O_5 (*d*) V_2O_7

Solution (*c*) $\% \text{ of V} = \frac{1.53}{2.74} \times 100 = 55.84$

∴ % of O = 44.16

Element	Percentage	Atomic ratio	Simplest ratio
V	55.83	$\frac{55.84}{52} = 1.1$	$\frac{1.1}{1.1} = 1$
O	44.17	$\frac{44.16}{16} = 2.76$	$\frac{2.76}{1.1} = 2.5$

V : O = 2 : 5

Thus, empirical formula = V_2O_5

Example 8 *The sulphate of a metal contains 20% metal. This sulphate is isomorphous with zinc sulphate hepta hydrate. The atomic mass of the metal is*

(*a*) 30 (*b*) 12 (*c*) 24 (*d*) 36

Solution (*c*) $\frac{\text{mass of metal sulphate}}{\text{mass of metal}}$

$$= \frac{\text{eq. mass of } M + \text{eq. mass of } SO_4^{2-}}{\text{eq. mass of } M}$$

$$\frac{100}{20} = \frac{E + 48}{E}$$

$$5E = E + 48$$

$$4E = 48 \quad \text{or} \quad E = 12$$

As metal sulphate is isomorphous with $ZnSO_4 \cdot 7H_2O$,

Valency of *M* = Valency of Zn = 2

Hence, At. mass of *M* = Eq. mass × valency

$$= 12 \times 2 = 24$$

Example 9 *Hydrated sulphate of a divalent metal of atomic weight 65.4 loses 43.85% of its weight on dehydration. The number of molecules of water of crystallisation in the salt is*

(*a*) 5 (*b*) 7

(*c*) 14 (*d*) 9

Solution (*b*) Let the number of molecules of water of crystallisation is *x*.

Formula of divalent hydrated metal sulphate will be

$$MSO_4 \cdot xH_2O$$

Molecular mass of salt = 65.4 + 96 + 18*x*

= (161.4 + 18*x*)

$$\text{Percentage of water} = \frac{18x}{161.4 + 18x} \times 100 = 43.85$$

On solving, $x = 7$

Example 10 *1.020 g of metallic oxide contains 0.540 g of the metal. If the specific heat of the metal, M is 0.216 cal* $deg^{-1}g^{-1}$*, the molecular formula of its oxide is*

(*a*) *MO* (*b*) M_2O_3

(*c*) M_2O_4 (*d*) M_2O

Solution (*b*) Mass of oxygen in the oxide

= (1.020 − 0.540) = 0.480 g

$$\text{Equivalent mass of the metal} = \frac{0.540}{0.480} \times 8 = 9.0$$

According to Dulong and Petit's law,

$$\text{Approx, atomic mass} = \frac{6.4}{\text{sp. heat}} = \frac{6.4}{0.216} = 29.63$$

$$\text{Valency of the metal} = \frac{\text{at. mass}}{\text{eq. mass}} = \frac{29.63}{9.0} = 3$$

Hence, the formula of the oxide is M_2O_3.

Example 11 *The atomicity of a molecule, M, if 10 g of it combine with 0.8 g of oxygen to form an oxide, is (specific heat of the molecule, M is 0.033 cal* $deg^{-1}\ g^{-1}$ *and molecular mass of molecule is 199.87 g)*

(*a*) 1 (*b*) 2

(*c*) 3 (*d*) 8

Solution (*a*) Equivalent mass of *M*

$$= \frac{\text{mass of metal}}{\text{mass of oxygen}} \times 8$$

$$= \frac{10}{0.8} \times 8 = 100$$

$$\text{Approximate atomic mass} = \frac{6.4}{\text{sp. heat}} = \frac{6.4}{0.033}$$

$$= 193.93 \text{ g}$$

$$\text{Valency of } M = \frac{193.93}{100} = 2 \text{ (nearest whole number)}$$

So, accurate atomic mass = eq. mass × valency

$$= 100 \times 2 = 200 \text{ g}$$

$$\text{Atomicity} = \frac{\text{mol. mass}}{\text{at. mass}}$$

$$= \frac{199.87}{200} = 1$$

Start Practice for JEE Main

Round I (Topically Divided Problems)

Units and Significant Figures

1. The units J Pa^{-1} is equivalent to
(a) m^3 (b) cm^3
(c) dm^3 (d) None of these

2. In which of the following numbers all zeros are significant?
(a) 0.500 (b) 30.000
(c) 0.00030 (d) 0.0050

3. A measured temperature on Fahrenheit scale is 200F. What will this reading be on celsius scale? **[NCERT Exemplar]**
(a) 40°C (b) 94°C
(c) 93.3°C (d) 30°C

4. The number of significant figures in Avogadro's number is
(a) four (b) two
(c) three (d) can be any of these

5. In multiplication and division, the significant figures of answer must be same as that in the quantity with .... number of significant figures.
(a) maximum (b) 3
(c) 2 (d) minimum

6. Convert the following into basic units.
(i) 28.7 pm (ii) 15.15 µs
(iii) 25365 mg
The correct answer is **[NCERT]**
(a) 28.7×10^{-11}, 1.515×10^{-6}, 2.5365×10^{-3}
(b) 2.87×10^{-11}, 1.515×10^{-5}, 2.5365×10^{-2}
(c) 2.87×10^{-10}, 1.515×10^{-5}, 2.5365×10^{-3}
(d) 2.87×10^{-10}, 1.515×10^{-6}, 2.5365×10^{-2}

7. The result of which of the following has least significant figures? **[NCERT]**
(a) $\dfrac{0.02856\times 298.15\times 0.112}{0.5785}$
(b) 5×5.364
(c) $0.0125+0.7864+0.0215$
(d) All have same number of significant figures

Matter and its Classification

8. The smallest matter particle that can take part in chemical reaction is
(a) atom (b) molecule
(c) Both (a) and (b) (d) None of these

9. Matter is anything which occupies ...*A*... and has...*B*.... Here *A* and *B* are
(a) density and mass (b) volume and mass
(c) space and mass (d) None of these

10. The solid like conducting state of gases with free electrons is called
(a) sol state (b) gel state
(c) plasma state (d) All of these

11. Which of the following statements about a compound is incorrect? **[NCERT Exemplar]**
(a) A molecule of a compound has atoms of different elements
(b) A compound cannot be separated into its constituent elements by physical methods of separation
(c) A compound retains the physical properties of its constituent elements
(d) The ratio of atoms of different elements in a compound is fixed

12. Which of the following is not a mixture?
(a) Gasoline (b) Distilled alcohol
(c) LPG (d) Iodized table salt

Laws of Chemical Combinations

13. Which of the following statements is correct about the reaction given below? **[NCERT Exemplar]**

$$4Fe(s) + 3O_2(g) \longrightarrow 2Fe_2O_3(g)$$

(a) Total mass of iron and oxygen in reactants = total mass of iron and oxygen in product therefore it follows law of conservation of mass

(b) Total mass of reactants = total mass of product; therefore, law of multiple proportions is followed

(c) Amount of Fe_2O_3 can be increased by taking any one of the reactants (iron or oxygen) in excess

(d) Amount of Fe_2O_3 produced will decrease if the amount of any one of the reactants (iron or oxygen) is taken in excess

14. Carbon dioxide contains 27.27% of carbon, carbon disulphide contains 15.79% of carbon and sulphur dioxide contains 50% of sulphur. This data is an agreement with

(a) law of conservation of mass

(b) law of definite proportions

(c) law of multiple proportions

(d) law of reciprocal proportions

15. If 6.3 g of $NaHCO_3$ are added to 15.0 g CH_3COOH solution, the residue is found to weigh 18.0 g. What is the mass of CO_2 released in the reaction?

(a) 4.5 g (b) 3.3 g

(c) 2.6 g (d) 2.8 g

16. 45.4L of dinitrogen reacted with 22.7L of dioxygen and 45.4L of nitrous oxide was formed. The reaction is given below

$$2N_2(g) + O_2(g) \longrightarrow 2N_2O(g)$$

Which law is being obeyed in this experiment? **[NCERT Exemplar]**

(a) Law of definite proportion

(b) Law of conservation of mass

(c) Law of multiple proportion

(d) None of the above

17. The mass of nitrogen per gram hydrogen in the compound hydrazine is exactly one and half times the mass of nitrogen in the compound ammonia. The fact illustrates the

(a) law of conservation of mass

(b) multiple valency of nitrogen

(c) law of multiple proportions

(d) law of definite proportions

18. Zinc sulphate contains 22.65% of zinc and 43.9% of water of crystallization. If the law of constant proportions is true then the weight of zinc required to produce 20 g of the crystals will be

(a) 45.3 g (b) 4.53 g

(c) 0.453 g (d) 453 g

Mole Concept

19. What will be the molarity of a solution, which contains 5.85 g of NaCl(s) per 500 mL? **[NCERT Exemplar]**

(a) 4 mol L^{-1} (b) 20 mol L^{-1}

(c) 0.2 mol L^{-1} (d) 2 mol L^{-1}

20. The mass of 112 cm^3 of CH_4 gas at STP is

(a) 0.16 g (b) 0.8 g

(c) 0.08 g (d) 1.6 g

21. Out of 1.0 g dioxygen, 1.0 g (atomic) oxygen and 1.0 g ozone, the maximum number of molecules are contained in

(a) 1.0 g of atomic oxygen

(b) 1.0 g of ozone

(c) 1.0 g of oxygen gas

(d) All contain same number of atoms

22. The number of water molecules present in a drop of water (volume 0.0018 mL) at room temperature is

(a) 6.023×10^{19} (b) 1.084×10^{18}

(c) 4.84×10^{17} (d) 6.023×10^{23}

23. The number of sodium atoms in 2 moles of sodium ferrocyanide is

(a) 12×10^{23} (b) 26×10^{23}

(c) 34×10^{23} (d) 48×10^{23}

24. A signature written with carbon pencil weighs 1 mg. What is the number of carbon atoms present in the signature?

(a) 6.02×10^{20} (b) 0.502×10^{20}

(c) 5.02×10^{23} (d) 5.02×10^{20}

25. What will be the mass of one ^{12}C atom in gram?

(a) 6.02×10^{23} (b) 1.6×10^{-19}

(c) 1.99×10^{-23} (d) 1.67×10^{-23}

26. What will the molality of the solution containing 18.25 g of HCl gas in 500 g of water? **[NCERT Exemplar]**

(a) 0.1 m (b) 1 M (c) 0.5 m (d) 1 m

27. A sample of AlF_3 contains 3.0×10^{24} F^- ions. The number of formula units of this sample are

(a) 9.0×10^{24} (b) 3.0×10^{24}

(c) 0.75×10^{24} (d) 1.0×10^{24}

28. Which one of the following will have the largest number of atoms? **[NCERT]**

(a) 1 g Au (s) (b) 1 g Na (s)

(c) 1 g Li (s) (d) 1 g Cl_2 (g)

29. 19.7 kg of gold was recovered from a smuggler. How many atoms of gold were recovered (Au = 197)?

(a) 100 (b) 6.02×10^{23}

(c) 6.02×10^{24} (d) 6.02×10^{25}

30. Which of the following pairs contains equal number of atoms?

(a) 11.2 cc (STP) of nitrogen and 0.015 g of nitric oxide
(b) 22.4 L (STP) of nitrous oxide and 22.4 L of nitric oxide
(c) 1 millimole of HCl and 0.5 millimole of H_2S
(d) 1 mole of H_2O_2 and 1 mole of N_2O_4

31. The molecular weight of air will be (the components of air given as N_2—78%, O_2—21%, Ar—0.9% and CO_2—0.1%)

(a) 18.64 (b) 24.968
(c) 28.964 (d) 29.864

32. Calculate the number of moles left after removing 10^{21} molecules from 200 mg of CO_2.

(a) 0.00454 (b) 0.00166
(c) 2.88×10^{-3} (d) None of these

33. If H_2SO_4 ionises as

$$H_2SO_4 + 2H_2O \longrightarrow 2H_3O^+ + SO_4^{2-}$$

then total number of ions produced by 0.1 M H_2SO_4 will be

(a) 9.03×10^{21} (b) 3.01×10^{22}
(c) 6.02×10^{22} (d) 1.8×10^{23}

34. One atom of an element X weigh 6.643×10^{-23} g. Number of moles of atom in 20 kg is

(a) 140 (b) 150
(c) 250 (d) 500

35. The density of 3 molal solution of NaOH is 1.110 g mL^{-1} Calculate the molarity of the solution. **[NCERT Exemplar]**

(a) 2.97 M (b) 1.67 M
(c) 3.64 M (d) 2.32 M

36. If the density of methanol is 0.793 kg L^{-1}, what is its volume needed for making 2.5L of its 0.25M solution? **[NCERT]**

(a) 5 mL (b) 25.2 mL
(c) 50 mL (d) 2.525 mL

37. A sample of drinking water was found to be severely contaminated with chloroform, $CHCl_3$, supposed to be carcinogenic in nature. The level of contamination was 15 ppm (by mass) Determine the molarity of chloroform in the water sample. **[NCERT]**

(a) 1.45×10^{-4} (b) 1.27×10^{-4}
(c) 1.89×10^{-6} (d) 1.34×10^{-5}

38. Which of the following contains the maximum number of atoms? **[NCERT]**

(a) 52 moles of Ar
(b) 52 u of He
(c) 52 g of He
(d) All have equal number of atoms

39. A sample of ammonium phosphate, $(NH_4)_3PO_4$ contains 6.36 moles of hydrogen atoms. The number of moles of oxygen atom in the sample is

(atomic mass of N = 14.04, H = 1, P = 31, O = 16)

(a) 0.265 (b) 0.795
(c) 2.12 (d) 4.14

40. A sample of copper sulphate pentahydrate contains 8.64 g of oxygen. How many gram of Cu is present in this sample ? (Atomic mass of Cu = 63.6, S = 32.06, O = 16)

(a) 0.952 g (b) 3.816 g
(c) 3.782 g (d) 8.64 g

41. Cortisone is a molecular substance containing 21 atoms of carbon per molecule. The molecular weight of cortisone is 360.4. What is the percentage of carbon in cortisone?

(a) 59.9% (b) 75%
(c) 69.98% (d) None of these

42. How many moles of $MgIn_2S_4$ can be made from 1 g each of Mg, In and S? (Atomic mass : Mg = 24, In = 114.8, S = 32)

(a) 6.47×10^{-4} (b) 3.0×10^{-1}
(c) 9.17×10^{-2} (d) 8.7×10^{-3}

43. If an iodized salt contains 1% KI and a person takes 2 g of the salt every day, the iodide ions going into his body every day would be approximately

(a) 7.2×10^{21} (b) 7.2×10^{19}
(c) 3.6×10^{21} (d) 9.5×10^{19}

44. If the density of water is 1 g cm^{-3} then the volume occupied by one molecule of water is approximately

(a) 18 cm^{-3} (b) 22400 cm^{-3}
(c) 6.02×10^{-23} cm^3 (d) 3.0×10^{-23} cm^3

Masses, Chemical Stoichiometry, Molecular and Empirical Formulae

45. Which property of an element is always a whole number?

(a) Atomic volume (b) Atomic weight
(c) Atomic number (d) Equivalent weight

46. If w_1 g of a metal X displaces w_2 g of another metal Y from its salt solution and if the equivalent weights are E_1 and E_2 respectively, the correct expression for the equivalent weight of X is

(a) $E_1 = \frac{w_1}{w_2} \times E_2$ (b) $E_1 = \frac{w_2 \times E_2}{w_1}$
(c) $E_1 = \frac{w_1 \times w_2}{E_2}$ (d) $E_1 = \sqrt{\frac{w_1}{w_2} \times E_2}$

47. The empirical formula and molecular mass of a compound are CH_2O and 180 g mol^{-1} respectively. What will be the molecular formula of the compound? **[NCERT Exemplar]**

(a) $C_9H_{18}O_9$ (b) CH_2O
(c) $C_6H_{12}O_6$ (d) $C_2H_4O_2$

48. For the reaction,

$$X + 2Y \longrightarrow Z$$

5 moles of X and 9 moles of Y will produce

(a) 5 moles of Z (b) 8 moles of Z
(c) 14 moles of Z (d) 4 moles of Z

49. Calculate the mass per cent of Na present in sodium sulphate, Na_2SO_4. **[NCERT]**

(a) 32.37 (b) 22.57
(c) 16.18 (d) 45.06

50. If 0.5 mole of $BaCl_2$ is mixed with 0.2 mole of Na_3PO_4, the maximum number of moles of $Ba_3(PO_4)_2$ that can be formed is

(a) 0.7 (b) 0.5 (c) 0.03 (d) 0.10

51. In the reaction,

$$I_2 + 2S_2O_3^{2-} \longrightarrow 2I^- + S_4O_6^{2-}$$

equivalent weight of iodine will be equal to

(a) molecular weight (b) 1/2 of molecular weight
(c) 1/4 of molecular weight (d) twice of molecular weight

52. 2.76 g of silver carbonate on being strongly heated yields a residue weighing

(a) 3.54 g (b) 3.0 g (c) 1.36 g (d) 2.16 g

53. An organic compound contains 20.0% C, 6.66% H, 47.33% N and the rest was oxygen. Its molar mass is 60 g mol^{-1}. The molecular formula of the compound is

(a) CH_4N_2O (b) $C_2H_4NO_2$
(c) CH_3N_2O (d) $CH_4N_2O_2$

54. Use the data given in the following table to calculate the molar mass of naturally occurring argon.

Isotope	Isotopic molar mass	Abundance
^{36}Ar	35.96755 g mol^{-1}	0.337%
^{38}Ar	37.96272 g mol^{-1}	0.063%
^{40}Ar	39.9624 g mol^{-1}	99.600%

The molar mass of argon is **[NCERT]**

(a) 39.948 (b) 39.665 (c) 38.678 (d) 38.442

55. In the following reaction,

$$MnO_2 + 4HCl \longrightarrow MnCl_2 + 2H_2O + Cl_2$$

2 moles of MnO_2 react with 4 moles of HCl to form 11.2 L Cl_2 at STP. Thus, per cent yield of Cl_2 is

(a) 25% (b) 50%
(c) 100% (d) 75%

56. Consider the reaction, $A + B_2 \longrightarrow AB_2$, A acts as the limiting reagent, in which of the following reactions are mixtures? **[NCERT]**

(a) 300 atoms of A + 200 molecules of B
(b) 2 moles of A + 3 moles of B
(c) 100 atoms of A + 100 molecules of B
(d) 5 moles of A + 2.5 moles of B

57. What is the number of moles of $Fe(OH)_3(s)$ that can be produced by allowing 1 mole of Fe_2S_3, 2 moles of H_2O and 3 moles of O_2 to react as

$$2Fe_2S_3 + 6H_2O + 3O_2 \longrightarrow 4Fe(OH)_3 + 6S\ ?$$

(a) 1 mol (b) 1.84 mol
(c) 1.34 mol (d) 1.29 mol

58. Calcium carbonate reacts with aqueous HCl to give $CaCl_2$ and CO_2 according to the reaction,

$$CaCO_3(s) + 2HCl(aq) \longrightarrow CaCl_2(aq) + CO_2(g) + H_2O(l)$$

What mass of $CaCO_3$ is required to react completely with 25 mL of 0.75 M HCl? **[NCERT]**

(a) 0.6844 (b) 0.9375
(c) 0.4265 (d) 0.2795

59. One atom of an element weighs 1.8×10^{-22} g. Its atomic mass is

(a) 29.9 (b) 18 (c) 108.36 (d) 154

60. Determine the molecular formula of an oxide of iron in which the mass per cent of iron and oxygen are 69.9 and 30.1 respectively. Given that molar mass of the oxide is 159.89 g mol^{-1}. **[NCERT]**

(a) FeO (b) FeO_2 (c) Fe_2O_3 (d) Fe_3O_2

61. Arsenic forms two oxides, one of which contains 65.2% and the other 75.7% of the element. Hence, equivalent masses of arsenic are in the ratio

(a) 1 : 2 (b) 3 : 5 (c) 13 : 15 (d) 2 : 1

62. The equivalent mass of chlorine is 35.5 and the atomic mass of copper is 63.5. The equivalent mass of copper chloride is 99.0. Hence, formula of copper chloride is

(a) CuCl (b) Cu_2Cl
(c) $CuCl_2$ (d) None of these

63. Insulin contains 3.4% sulphur. What will be the minimum molecular weight of insulin?

(a) 94.117 (b) 1884
(c) 941.176 (d) 976

64. Two oxides of a metal contain 50% and 40% metal (M) respectively. If the formula of first oxide is MO_2, the formula of second oxide will be

(a) MO_2 (b) MO_3 (c) M_2O (d) M_2O_5

65. Chlorine is prepared in the laboratory by treating manganese dioxide (MnO_2) with aqueous hydrochloric acid according to the reaction.

$$4HCl(aq) + MnO_2(s) \longrightarrow 2H_2O(l) + MnCl_2(aq) + Cl_2(g)$$

How many grams of HCl reacts with 5.0g of manganese dioxide? **[NCERT]**

(a) 36.5 g (b) 4.12 g
(c) 8.39 g (d) 13.25 g

66. If ten volumes of dihydrogen gas react with five volumes of dioxygen gas, how many volumes of water vapour would be produced? **[NCERT]**

(a) 5 (b) 10 (c) 2 (d) 20

67. 100 tons of Fe_2O_3 containing 20% impurities will give iron by reduction with H_2 equal to

(a) 112 tons (b) 80 tons
(c) 160 tons (d) 56 tons

68. Cyclohexanol is dehydrated to cyclohexene on heating with conc H_2SO_4. The cyclohexene obtained from 100 g cyclohexanol will be (if yield of reaction is 75%)

(a) 61.5 g (b) 75.0 g
(c) 20.0 g (d) 41.0 g

69. Equal weights of Zn metal and iodine are mixed together and I_2 is completely converted to ZnI_2. What fraction by weight of original Zn remains unreacted? ($Zn = 65, I = 127$)

(a) 0.34 (b) 0.74
(c) 0.84 (d) Unable to predict

70. 100 mL of 0.1 N hypo decolourised iodine obtained by the addition of x gram of crystalline copper sulphate to excess of KI. The value of 'x' is

(Molecular wt. of $CuSO_4 \cdot 5H_2O$ is 250.)

(a) 5.0 g (b) 1.25 g
(c) 2.5 g (d) 4 g

71. On analysis a certain compound was found to contain iodine and oxygen in the ratio of 254 g of iodine (at. mass 127) and 80 g oxygen (at. mass 16). What is the formula of the compound?

(a) IO (b) I_2O
(c) I_5O_3 (d) I_2O_5

Round II (Mixed Bag)

Only One Correct Option

1. A box contains some identical red coloured balls. labelled as *A*, each weighing 2g. Another box contains identical blue coloured balls, labelled as *B*, each weighing 5 g. In the combinations AB, AB_2, A_2B and A_2B_3 which law is applicable. **[NCERT Exemplar]**

(a) Law of definite proportion
(b) Law of multiple proportion
(c) Law of conservation of mass
(d) None of the above

2. The law of definite proportions is not applicable to nitrogen oxide because

(a) nitrogen atomic weight is not constant
(b) nitrogen molecular weight is variable
(c) nitrogen equivalent weight is variable
(d) oxygen atomic weight is variable

3. A 400 mg iron capsule contains 100 mg of ferrous fumarate, $(CHCOO)_2Fe$. The percentage of iron present in it is approximately

(a) 33% (b) 25% (c) 14% (d) 8%

4. The number of water molecules in 1 L of water is

(a) 18 (b) 18×1000
(c) N_A (d) $55.55\,N_A$

5. Haemoglobin contains 0.33% of iron by weight. The molecular weight of haemoglobin is approximately 67200. The number of iron atoms (at. wt. of $Fe = 56$) present in one molecule of haemoglobin is

(a) 6 (b) 1 (c) 4 (d) 2

6. If isotopic distribution of C-12 and C-14 is 98% and 2% respectively then the number of C-14 atoms in 12 g of carbon is

(a) 1.032×10^{22} (b) 3.01×10^{22}
(c) 5.88×10^{23} (d) 6.023×10^{23}

7. The number of moles of oxygen in 1 L of air containing 21% oxygen by volume, in standard conditions, is

(a) 0.186 mol (b) 0.21 mol
(c) 2.10 mol (d) 0.0093 mol

8. There are two isotopes of an element with atomic mass z. Heavier one has atomic mass $z + 2$ and lighter one has $z - 1$, then abundance of lighter one is

(a) 66.6% (b) 96.7% (c) 6.67% (d) 33.3%

9. Which of the following statements indicates that law of multiple proportion is being followed? **[NCERT Exemplar]**

(a) Sample of carbon dioxide taken from any source will always have carbon and oxygen in the ratio 1:2.

(b) Carbon forms two oxides namely CO_2 and CO, where masses of oxygen which combine with fixed mass of carbon are in the simple ratio 2:1
(c) When magnesium burns in oxygen, the amount of magnesium taken for the reaction is equal to the amount of magnesium in magnesium oxide formed
(d) At constant temperature and pressure 200 mL of hydrogen will combine with 100 mL oxygen to produce 200 mL of water vapour

10. A certain amount of a metal whose equivalent mass is 28 displaces 0.7 L of H_2 at STP from an acid. Hence, mass of the element is
(a) 1.75 g (b) 0.875 g
(c) 3.50 g (d) 7.00 g

11. 1.520 g of the hydroxide of a metal on ignition gave 0.995 g of oxide. The equivalent weight of metal is
(a) 1.520 (b) 0.995
(c) 19.00 (d) 9.00

12. 100 mL of 20.8% $BaCl_2$ solution and 50 mL of 9.8% H_2SO_4 solution will form $BaSO_4$
($Ba = 137, Cl = 35.5, S = 32, H = 1, O = 16$)

$$BaCl_2 + H_2SO_4 \longrightarrow BaSO_4 + 2HCl$$

(a) 23.3 g (b) 11.65 g
(c) 30.6 g (d) None of these

13. Calcium carbonate reacts with aqueous HCl to give $CaCl_2$ and CO_2 according to the reaction,

$$CaCO_3(s) + 2HCl(aq) \longrightarrow CaCl_2(aq) + CO_2(g) + H_2O(l)$$

In this reaction, 250 mL of 0.76 M HCl reacts with 1000 g of $CaCO_3$. Calculate the mass of $CaCl_2$ formed in the reaction. **[NCERT Exemplar]**
(a) 11.1 g (b) 10.54 g
(c) 5.25 g (d) 2.45 L

14. One gram of hydrogen is found to combine with 80 g of bromine. One gram of calcium (valency=2) combines with 4 g of bromine. The equivalent weight of calcium is
(a) 10 (b) 20
(c) 40 (d) 80

15. What quantity of ammonium sulphate is necessary for the production of NH_3 gas sufficient to neutralize a solution containing 292 g of HCl? [$HCl = 36.5$, $(NH_4)_2SO_4 = 132, NH_3 = 17$]
(a) 272 g (b) 403 g
(c) 528 g (d) 1056 g

16. The percentage of P_2O_5 in diammonium hydrogen phosphate, $(NH_4)_2HPO_4$ is
(a) 23.48 (b) 46.96
(c) 53.78 (d) 71.00

17. A mixture of CH_4, N_2 and O_2 is enclosed in a vessel of one litre capacity at 0°C. The ratio of partial pressures of gases is 1 : 4 : 2. Total pressure of the gaseous mixture is 2660 mm. The number of molecules of oxygen present in the vessel is
(a) $\frac{6.02\times 10^{23}}{22.4}$ (b) 6.02×10^{23}
(c) 22.4×10^{22} (d) 1000

18. An ore contains 1.34% of the mineral argentite, Ag_2S, by mass. How many gram of this ore would have to be processed in order to obtain 1.00 g of pure solid silver, Ag?
(a) 74.6 g (b) 85.7 g
(c) 107.9 g (d) 134.0 g

19. x g of Ag was dissolved in HNO_3 and the solution was treated with excess of NaCl when 2.87 g of AgCl was precipitated. The value of x is
(a) 1.08 g (b) 2.16 g (c) 2.70 g (d) 1.62 g

20. What weight of silver chloride will be precipitated when a solution containing 4.77 g of NaCl is added to a solution of 5.77 g of $AgNO_3$? ($Na = 23$, $Cl = 35.5$, $Ag = 108, N = 14$ and $O = 16$)
(a) 4.37 g (b) 4.87 g (c) 5.97 g (d) 3.87 g

21. 0.75 mole of a solid A_4 and 2 moles of $O_2(g)$ are heated in a sealed vessel, completely using up the reactants and produces only one compound. It is found that when the temperature is used to initial temperature, the contents of the vessel exhibit a pressure equal to $\frac{1}{2}$ of the original pressure. The formula of the product will be
(a) A_2O_3 (b) A_3O_8 (c) A_3O_4 (d) AO_2

22. A sample of a mixture of $CaCl_2$ and NaCl weighing 4.22 g was treated to precipitate all the Ca as $CaCO_3$. This $CaCO_3$ is then heated and quantitatively converted into 0.959g of CaO. Calculate the percentage of $CaCl_2$ in the mixture.
(Atomic mass of $Ca = 40, O = 16, C = 12$, and $Cl = 35.5$)
(a) 31.5% (b) 21.5% (c) 45.04% (d) 68.48%

More than One Correct Option

23. One of the statements of Dalton's atomic theory is given below:

"Compounds are formed when atoms of different elements combine in a fixed ratio."

Which of the following laws is not related to this statement? **[NCERT Exemplar]**
(a) Law of conservation of mass
(b) Law of definite proportions
(c) Law of multiple proportions
(d) Avogadro law

24. If 4 g of NaOH dissolves in 36 g of H_2O, calculate the mole fraction of component in the solution. Also, determine the molarity of the solution (Specific gravity of solution is 1 g mL^{-1}) **[NCERT Exemplar]**

(a) 0.9524, 2.5 M (b) 0.239, 1.5 M
(c) 0.0476, 2.5 M (d) 0.9524, 1.5 M

25. Which of the following pairs have the same number of atoms? **[NCERT Exemplar]**

(a) 16 g of $O_2(g)$ and 4 g of $H_2(g)$
(b) 16 g of O_2 and 44 g of CO_2
(c) 28 g of $N_2(g)$ and 32 g of O_2
(d) 12 g of C(*s*) and 23 g of Na(*s*)

26. Which of the following solutions have the same concentration? **[NCERT Exemplar]**

(a) 20 g of NaOH in 200 mL of solution
(b) 0.5 mol of KCl in 200 mL of solution
(c) 40 g of NaOH in 100 mL of solution
(d) 20 g of KOH in 200 mL of solution

27. 16 g of oxygen has same number of molecules as in **[NCERT Exemplar]**

(a) 16 g of CO (b) 28 g of N_2
(c) 14 g of N_2 (d) 1.0 g of H_2

Assertion and Reason

Directions (Q. No. 28 to 32) *Each of these questions contains two statements : Statement* I *(Assertion) and Statement* II *(Reason). Each of these questions also has four alternative choices, only one of which is the correct answer. You have to select one of the codes (a), (b), (c), (d) given below :*

(a) Statement I is true, Statement II is true; Statement II is a correct explanation for Statement I.
(b) Statement I is true, Statement II is true; Statement II is not a correct explanation for Statement I.
(c) Statement I is true; Statement II is false.
(d) Statement I is false; Statement II is true.

28. **Statement I** Weight of 1 molecule of O_2 = 32 u.

Statement II 1 g-molecule = 6.023×10^{23} molecules.

29. **Statement I** The empirical mass of ethene is half of its molecular mass.

Statement II The empirical formula represents the simplest whole number ratio of various atoms present in a compound. **[NCERT Exemplar]**

30. **Statement I** One atomic mas unit is defined as one twelfth of the mass of one carbon-12 atom.

Statement II Carbon-12 isotope is the most abundant isotope of carbon and has been chosen as standard. **[NCERT Exemplar]**

31. **Statement I** Significant figures for 0.200 is 3 where as for 200 it is 1.

Statement II Zero at the end or right of a number are significant provided they are not on the right side of the decimal point. **[NCERT Exemplar]**

32. **Statement I** Combustion of 16 g of methane gives 18 g of water.

Statement II In the combustion of methane, water is one of the products. **[NCERT Exemplar]**

Comprehension Based Questions

Directions (Q. Nos. 33 to 35) Mole is a unit which represents 6.02×10^{23} particles (atoms, molecules or ions etc.) irrespective of the nature. The number 6.023×10^{23} is called Avogadro's number and is represented by N_0. The calculation of the number is based on the Faraday's law of electrolysis. A mole also represents gram molecular mass (GMM) of the substance.

33. The number of moles of SO_2Cl_2 in 13.5 g is

(a) 0.25 (b) 1.5
(c) 0.4 (d) 0.1

34. How many atoms are present in a mole of H_2SO_4?

(a) $7\times 6.02\times 10^{23}$ (b) $1.5\times 6.02\times 10^{23}$
(c) 6.02×10^{23} (d) $2\times 6.02\times 10^{23}$

35. The number of potassium atoms in 2 moles of potassium ferricyanide is

(a) 36.13×10^{23} (b) 6.02×10^{23}
(c) 24.08×10^{23} (d) 2×10^{23}

Directions (Q. Nos. 36 to 38) The atomic mass of an atom (element) is not its actual mass. It is relative mass as compared with an atom of carbon taken as 12. It is expressed in amu (u). The actual mass of an atom means its mass in grams which is obtained by dividing the atomic mass of the element by Avogadro's number (6.02×10^{23}) because one gram atom contains Avogadro's number of atoms.

36. Which of the following has maximum mass?

(a) 0.1 moles of ammonia
(b) 1120 cc of carbon dioxide
(c) 0.1 g atom of carbon
(d) 6.02×10^{22} molecules of H_2 gas

37. The mass of one atom of hydrogen is approximately

(a) 1 g (b) 3.2×10^{-24} g
(c) 1.6×10^{-24} g (d) 0.5 g

38. 5.6 L of a gas at NTP are found to have a mass of 11 g. The molecular mass of the gas is

(a) 36 (b) 48
(c) 40 (d) 44

Previous Years' Questions

39. The mass of potassium dichromate crystals required to oxidise 750 cm^3 of 0.6 M Mohr's salt solution is (Given, molar mass : Potassium dichromate = 294, Mohr's salt = 392) [AIEEE 2011]

(a) 0.49 g (b) 0.45 g (c) 22.05 g (d) 2.2 g

40. The density (in g mL^{-1}) of a 3.60 M sulphuric acid solution that is 29% H_2SO_4 (molar mass = 98 g mol^{-1}) by mass will be [AIEEE 2007]

(a) 1.64 (b) 1.88
(c) 1.22 (d) 1.45

41. How many moles of magnesium phosphate, $Mg_3(PO_4)_2$ will contain 0.25 moles of oxygen atoms? [AIEEE 2006]

(a) 0.02 (b) 3.125×10^{-2}
(c) 1.25×10^{-2} (d) 2.5×10^{-2}

the Guidance

Round I

1. $JPa^{-1} = \dfrac{J}{Pa} = \dfrac{\text{work}}{\text{pressure}} = \dfrac{N\text{-}m}{N/m^2} = m^3$

3.
$$°F = \frac{9}{5} t° C + 32$$
$$200 - 32 = \frac{9}{5} t° C \Rightarrow \frac{9}{5} t° C = 168$$
$$t° C = \frac{168 \times 5}{9} = 93.3 °C$$

6. (a) $28.7 pm \times \dfrac{10^{-12} m}{1 pm} = 2.87 \times 10^{-11} m$

(b) $15.15 \mu s \times \dfrac{10^{-6} s}{1 \mu s} = 1.515 \times 10^{-5} s$

(c) $25365 mg \times \dfrac{1 g}{1000 mg} \times \dfrac{1 kg}{1000 g} = 2.5365 \times 10^{-2} kg$

7. (a) In multiplication and division, the least precise term 0.112 has 3 significant figures. Hence, the answer should not have more than three significant figures.

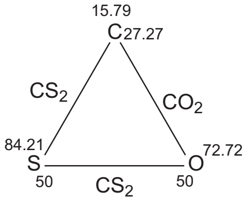
(b) In multiplication, 5 is the exact number and the other number has 4 significant figures. Hence, the answer should have 4 significant figures.

(c) In addition (or in subtraction), the answer cannot have more digits to the decimal point than either of the original members. Hence, the answer should have 4 significant figures.

11. The properties of a compound are quite different from the properties of constituent elements.

13. According to the law of conservation of mass,
Total mass of reactants = total mass of products
Amount of Fe_2O_3 is decided by limiting reagent.

14. In CS_2



C : S mass ratio is 15.79 : 84.21

15.79 parts of carbon combine with sulphur = 84.21

$\therefore$ 27.27 parts of carbon will combine with

$$S = \frac{84.21}{15.79} \times 27.27 = 145.434$$

Hence, ratio of S : O is 145.434 : 72.73 *i.e.*, 2 : 1

In SO_2, the ratio of S : O is 1 : 1

Since, the ratio of S : O is a simple whole number ratio, therefore law of reciprocal proportions is proved.

15. According to law of conservation of mass,

mass of reactants = mass of products

$\therefore \quad 6.3 + 15.0 = 18.0 + x$ or $x = 21.3 - 18.0 = 3.3$ g

16. $\underset{2V}{2N_2(g)} + \underset{IV}{O_2(g)} \longrightarrow \underset{2V}{2N_2O(g)}$

$$\frac{45.4}{22.7} = 2 \quad \frac{22.7}{22.7} = 1 \quad \frac{45.4}{22.7} = 2$$

Hence, the ratio between the volumes of the reactants and the product in the given question is simple *i.e.*, 2:1:2, It proves the Gay- Lussac's law of gaseous volumes, which states that when gases combine or are produced in a chemical reaction, they do so in a simple ratio by volume provided all gases are at same temperature and pressure.

17. As ratio of masses of nitrogen per gram of hydrogen in hydrazine and $NH_3 = 1\frac{1}{2} : 1 = \frac{3}{2} : 1$ or $3 : 2$

i.e., the law of multiple proportions.

18. To prepare 20 g zinc sulphate crystals, zinc required

$$= \frac{22.65}{100} \times 20 = 4.53 \text{ g}$$

19. $\text{Molarity} = \dfrac{\text{wt.} \times 1000}{\text{mol. wt.} \times \text{volume (mL)}} = \dfrac{5.85 \times 1000}{58.5 \times 500}$

$= 0.2 \text{ mol} L^{-1}$

20. $\because$ Mass of 22400 cm^3 CH_4 = 16 g

$\therefore \quad$ Mass of 112 cm^3 $CH_4 = \dfrac{16 \times 112}{22400} = 0.08$ g

21. $\text{Number of molecules} = \dfrac{\text{mass} \times N_A}{\text{molar mass}}$

22. $\text{Number of moles} = \dfrac{\text{weight}}{\text{molecular wt.}} = \dfrac{0.0018}{18} = 1 \times 10^{-4}$

[$\because$ 0.0018 mL = 0.0018 g]

$\therefore$ Number of water molecules $= 1 \times 10^{-4} \times 6.02 \times 10^{23}$

$= 6.023 \times 10^{19}$

24. $\text{Number of C atoms} = \dfrac{1 \times 10^{-3}}{12} \times N_A = 0.50 \times 10^{20}$

25. Mass of 1 atom of $^{12}C = \dfrac{\text{Atomic mass of C}}{\text{Avogadro's number}}$

$$= \frac{12 \text{ g}}{6.022 \times 10^{23}} = 1.9927 \times 10^{-23} \text{ g}$$

26. Molality, $m = \dfrac{\text{moles of solute}}{\text{mass of solvent (in kg)}}$

Mass of solvent (H_2O) = 500 g = 0.5 kg

$$\text{Moles of HCl} = \frac{18.25}{36.5} = 0.5$$

$$\therefore \qquad m = \frac{0.5}{0.5} = 1 \text{m}$$

27. $3F^- \equiv 1$ Formula unit (AlF_3)

3.0×10^{24} $F^- = 1 \times 10^{24}$ Formula units (AlF_3)

28. (a) 1g $Au = \dfrac{1}{197}$ mol-atoms of

$Au = \dfrac{1}{197} \times 6.022 \times 10^{23}$ atoms of Au

(b) 1g $Na = \dfrac{1}{23}$ mol-atoms of Na

$= \dfrac{1}{23} \times 6.022 \times 10^{23}$ atoms of Na

(c) 1 g $Li = \dfrac{1}{7}$ mol-atoms of Li

$= \dfrac{1}{7} \times 6.022 \times 10^{23}$ molecules of Li

(d) 1g $Cl_2 = \dfrac{1}{71}$ mole-molecules of $Cl_2 = \dfrac{1}{71}$

$\times 6.022 \times 10^{23}$ molecules of Cl_2

$= \dfrac{2}{71} \times 6.022 \times 10^{23}$ atoms of Cl

($\because$ 1 molecule of chlorine contains 2 atoms)

Therefore, 1 g of Li has largest number of atoms.

Note If a substance exists in atomic form, it contains mol-atoms and if a substance exists in molecular form, it contains mol-molecules.

30. Number of atoms in $N_2 = \dfrac{11.2 \times 10^{-3} \times 6.023 \times 10^{23} \times 2}{22.4}$

$= 6.023 \times 10^{20}$

Number of atoms in NO $= \dfrac{0.015 \times 2 \times 6.023 \times 10^{23}}{30}$

$= 6.023 \times 10^{20}$

31. In air

$$\text{molecular weight of } N_2 = \frac{28 \times 78}{100} = 21.84$$

$$\text{molecular weight of } O_2 = \frac{32 \times 21}{100} = 6.72$$

$$\text{molecular weight of Ar} = \frac{18 \times 0.9}{100} = 0.162$$

$$\text{molecular weight of } CO_2 = \frac{44 \times 0.1}{100} = 0.044$$

So, molecular weight of air = 21.84 + 6.72 + 0.162 + 0.044

= 28.766

32. Molecular mass of $CO_2 = 12 + 32 = 44$

$$44 \text{ g of } CO_2 \text{ has } 6.023 \times 10^{23} \text{ molecule}$$

$$0.2 \text{ g of } CO_2 \text{ has } \frac{6.023 \times 10^{23}}{44} \times 0.2$$

$$= 0.0273 \times 10^{23}$$

If 10^{21} molecules are removed then number of molecules

$$= 1.73 \times 10^{21}$$

$$\because \quad 6.023 \times 10^{23} \text{ molecules} = 1 \text{ mol}$$

$$\therefore \quad 1.73 \times 10^{21} \text{ molecules} = \frac{1}{6.023 \times 10^{23}} \times 1.73 \times 10^{21}$$

$$= 0.0028 \text{ mol}$$

33. 1 mole of H_2SO_4 gives 3 moles of ions or $3 \times 6.023 \times 10^{23}$ ions

$\therefore$ 0.1 mole of H_2SO_4 will give $0.1 \times 3 \times 6.023 \times 10^{23}$ ions

$$= 1.8 \times 10^{23} \text{ ions}$$

34. Atomic weight of the element

$$X = 6.643 \times 10^{-23} \times N_A = 40$$

$$\text{Number of moles of } X = \frac{20 \times 1000}{40} = 500$$

35. 3 molal solution of NaOH means 3 moles of NaOH are dissolved in 1 kg solvent. So, the mass of solution

= 1000 g solvent + 120 g NaOH = 1120 g solution

(Molar mass of NaOH = 23 + 16 + 1 = 40 g;

3 moles of NaOH = 3 × 40 = 120 g)

$$\text{Volume of solution} = \frac{\text{Mass of solution}}{\text{Density of solution}}$$

$$V = \frac{1120 \text{ g}}{1.110 \text{ g mL}^{-1}} = 1009 \text{ mL}$$

$$\text{Molarity} = \frac{\text{moles of solute} \times 1000}{\text{volume of solution (mL)}} = \frac{3 \times 1000}{1009} = 2.973 \text{ M}$$

36. Given, $d = 0.793 \text{ kg L}^{-1} = 0.793 \times 10^3 \text{ g L}^{-1}$

Molar mass of methanol,

$CH_3OH = (1 \times 12.01) + (4 \times 1.0079) + 16.00 = 32.0416 \approx 32$

$$\text{Molarity} = \frac{0.793 \times 10^3 \text{ g L}^{-1}}{32 \text{ g mol}^{-1}} = 24.781 \text{ mol}^{-1}$$

$$M_1 V_1 = M_2 V_2$$

$$24.781 \times V_1 = 0.25 \times 2.5$$

$$V_1 = \frac{0.25 \times 2.5}{24.781} = 0.02522 \text{ L} = 25.22 \text{ mL}$$

37. 15 ppm means 15 parts in one million (10^6) parts.

$$\text{Therefore, \% by mass} = \frac{15 \times 100}{10^6} = 1.5 \times 10^{-3}\%$$

Molar mass of $CHCl_3 = 12.01 + 1.0079 + (3 \times 35.45)$

$$M_{CHCl_3} = 119.367 \approx 119 \text{ g mol}^{-1}$$

1.5×10^{-3} % means 1.5×10^{-3} g chloroform is present in 100 g sample.

$$\text{Molarity, } M = \frac{w \times 1000}{m \times \text{ volume of sample}}$$

(For water, density = 1g cm^{-3}, so mass = volume)

$$M = \frac{1.5 \times 10^{-3} \times 1000}{119 \times 100} = 0.000126 = 1.26 \times 10^{-4} \text{ M}$$

38. (a) 1 mole of Ar = 6.022×10^{23} atoms.

$$52 \text{ moles of Ar} = 52 \times 6.022 \times 10^{23} \text{ atoms}$$

$$= 313.144 \times 10^{23} \text{ atoms}$$

$$= 3.131 \times 10^{25} \text{ atoms}$$

(b) 4 u of He = 1 He atom

$$\therefore \text{ 52 u of He} = \frac{52}{4} \text{ He atoms} = 13 \text{ He atoms}$$

(c) 1 mole atom of He = 4 g = 6.022×10^{23} atoms

$$52 \text{ g of He} = \frac{52 \times 6.022 \times 10^{23}}{4} \text{ atoms}$$

$$= 78.286 \times 10^{23} \text{ atoms}$$

$$= 7.8286 \times 10^{24} \text{ atoms}$$

39. 1 mole of $(NH_4)_3PO_4$ contains 12 moles of hydrogen atoms.

$\therefore$ 12 moles of hydrogen atoms $\equiv$ 1 mole of $(NH_4)_3PO_4$.

$$\therefore \quad 1 \text{ mole of hydrogen atom} = \frac{1}{12} \text{ mole of } (NH_4)_3PO_4$$

$$\therefore \quad 6.36 \text{ moles of hydrogen atom} = \frac{1}{12} \times 6.36$$

$$= \frac{6.36}{12} \text{ mole of } (NH_4)_3PO_4$$

1 mole of $(NH_4)_3PO_4$ = 4 moles of oxygen

$$\text{So,} \quad \frac{6.36}{12} \text{ mole of } (NH_4)_3PO_4 = \frac{4 \times 6.36}{12} = 2.12 \text{ mol}$$

40. $CuSO_4 \cdot 5H_2O$ has 1 mole of copper and 9 moles of oxygen atoms.

$$63.5 \text{ g Cu} \simeq 9 \times 16 \text{ g of oxygen}$$

$$8.64 \text{ g of oxygen} = \frac{63.5 \times 8.64}{9 \times 16} = 3.81 \text{ g}$$

41. Molecular weight of cortisone = 360.4

Molecular weight of 21 carbon atom = 21 × 12 = 252

$$\text{Percentage of carbon in cortisone} = \frac{252 \times 100}{360.4} = 69.9\%$$

43. $$\text{The mass of KI in 2g salt} = \frac{2 \times 1}{100} = 0.02 \text{ g}$$

$$= \frac{0.02}{39 + 127} \text{ mol}$$

$$= \frac{0.02}{166} \times 6.02 \times 10^{23} \text{ ions}$$

$$= 7.2 \times 10^{19} \text{ ions}$$

44. Mass of one molecule of water

$$= \frac{\text{mol. mass}}{N_0} = \frac{18}{6.02 \times 10^{23}} \text{ g}$$

$$\therefore \text{ Volume of 1 molecule of water} = \frac{\text{mass}}{\text{density}}$$

$$= \frac{18 \times 10^{-23}}{6.02 \times 1}$$

$$= 3 \times 10^{-23} \text{ mL}$$

46. $$\frac{\text{wt. of metal } X}{\text{wt. of metal } Y} = \frac{\text{Eq. wt. of metal } X}{\text{Eq. wt. of metal } Y}$$

$$\frac{w_1}{w_2} = \frac{E_1}{E_2} \text{ or } E_1 = \frac{w_1}{w_2} \times E_2$$

47. Empirical formula mass $= CH_2O$

$$= 12 + 2 \times 1 + 16 = 30$$

Molecular mass = 180

$$n = \frac{\text{molecular mass}}{\text{empirical formula mass}}$$

$$= \frac{180}{30} = 6$$

$\therefore$ Molecular formula $= n \times$ empirical formula

$$= CH_2O \times 6 = C_6H_{12}O_6$$

48. In a chemical reaction, coefficient represents mole of that substance.

$$X + 2Y \longrightarrow Z$$

This indicates 1 mole of X reacts with 2 moles of Y to form 1 mole of Z.

So, 5 moles of X will require 10 moles of Y. But we have taken only 9 moles of Y.

Hence, Y is in limiting quantity. Hence, we determine product from Y.

Thus, 5 moles of X react with 9 moles of Y to form 4 moles of Z.

49. Mass per cent of an element

$$= \frac{\text{Mass of that element in the compound} \times 100}{\text{Molar mass of the compound}}$$

Molar mass of $Na_2SO_4 = (2 \times 22.99) + 32.06 + (4 \times 16.00)$

$$= 142.04 \text{ g}$$

$$\text{Mass per cent of sodium} = \frac{45.98 \times 100}{142.04} = 32.37$$

50. $$\underset{3 \text{ mol}}{3BaCl_2} + \underset{2 \text{ mol}}{2Na_3PO_4} \longrightarrow \underset{1 \text{ mol}}{Ba_3(PO_4)_2} + 6NaCl$$

Here, Na_3PO_4 is the limiting reactant.

2 moles of Na_3PO_4 gives 1 mole of $Ba_3(PO_4)_2$

So, 0.2 mole of Na_3PO_4 will give 0.1 mole of $Ba_3(PO_4)_2$.

52. $$\underset{276 \text{ g}}{Ag_2CO_3} \xrightarrow{\Delta} \underset{216 \text{ g}}{2Ag} + CO_2 + \frac{1}{2}O_2$$

As 276 g of Ag_2CO_3 will give = 216 g of Ag

$$\text{So, } \quad 2.76 \text{ g of } Ag_2CO_3 \text{ will give} = \frac{2.76 \times 216}{276} = 2.16 \text{ g}$$

53. Ratio of atoms

$$C : H : N : O :: \frac{20.0}{12} : \frac{6.66}{1} : \frac{47.33}{14} : \frac{26.01}{16}$$

$$= 1.67 : 6.66 : 3.38 : 1.63$$

$$= 1 : 4 : 2 : 1$$

Empirical formula $= CH_4N_2O$

Empirical formula mass = 60 g

Molar mass $= 60 \text{g mol}^{-1}$

$\therefore$ Molecular formula $= CH_4N_2O$

54. Average molar mass of

$$Ar = \sum f_i \times A_i = (0.00337 \times 35.96755)$$

$$+ (0.00063 \times 37.96272) + (0.99600 \times 39.9624)$$

$$= 0.121 + 0.024 + 39.803 = 39.948 \text{ g mol}^{-1}$$

55. $$\underset{2 \text{ mol}}{MnO_2} + \underset{4 \text{ mol}}{4HCl} \longrightarrow MnCl_2 + 2H_2O + \underset{\substack{1 \text{ mol} \\ 22.4 \text{ L}}}{Cl_2}$$

But the yield is 11.2.

$$\therefore \quad \text{Percentage yield} = \frac{11.2}{22.4} \times 100 = 50\%$$

56. $$A + B_2 \longrightarrow AB_2$$

(a) According to the above reaction, 1 atom of A reacts with 1 molecule of B.
$\therefore$ 200 atoms of A will react with 200 molecules of B. In this case, B is the limiting reagent, so A is in excess.

(b) According to the above reaction, 1 mole of A reacts with 1 mole of B.
$\therefore$ 2 moles of A will react with 2 moles of B. In this case, A is the limiting reagent, so B is in excess.

(c) No limiting reagent.

(d) 2.5 moles of B requires only 2.5 moles of A to react. So, B is the limiting reagent and A is in excess.

57. H_2O is the limiting reagent for the given equation.

$\because$ 6 moles H_2O produces $Fe(OH)_3$ = 4 mol

$$\therefore 2 \text{ moles } H_2O \text{ will produce } Fe(OH)_3 = \frac{4 \times 2}{6} = 1.34 \text{ mol}$$

58. (i) Calculation for mass of HCl in 25 mL of 0.75 M HCl

$$\text{Molarity} = \frac{w \times 1000}{m \times \text{vol (mL)}}$$

$$0.75 = \frac{w \times 1000}{36.5 \times 25}$$

(Molar mass of HCl = 1 + 35.5 = 36.5 g/mol)

$$w = 0.75 \times 36.5 \times 25 / 1000 = 0.6844 \text{ g}$$

(b) Calculation for required mass of $CaCO_3$ to react completely with 0.6844 g HCl

$$\underset{100 \text{ g}}{CaCO_3(s)} + \underset{2 \times 36.5 = 73 \text{ g}}{2HCl(aq)} \longrightarrow CaCl_2(aq) + CO_2(g) + H_2O(l)$$

According to balanced chemical equation,

73 g HCl completely reacts with 100 g $CaCO_3$

1 g HCl completely reacts with $\frac{100}{73}$ g $CaCO_3$

$\therefore$ 0.6844 g HCl will completely reacts with

$$\frac{100 \times 0.6844}{73} = 0.9375 \text{ g}$$

59. Mass of 1 atom $= 1.8 \times 10^{-22}$ g

Mass of 6.02×10^{23} atoms

$$= 6.02 \times 10^{23} \times 1.8 \times 10^{-22} \text{ g}$$
$$= 6.02 \times 1.8 \times 10 \text{ g}$$
$$= 108.36 \text{ g}$$

$\therefore$ Atomic mass of element $= 108.36$

60.

Element	Symbol	%by mass	Atomic mass	Relative number of moles of element	Simple molar ratio	Simple whole number molar ratio
Iron	Fe	69.9	55.85	$\frac{69.9}{55.85} = 1.25$	$\frac{1.25}{1.25} = 1$	$1 \times 2 = 2$
Oxygen	O	30.1	16.00	$\frac{30.1}{16.00} = 1.88$	$\frac{1.88}{1.25} = 1.5$	$1.5 \times 2 = 3$

$\therefore$ Empirical formula $= Fe_2O_3$

Empirical formula mass of

$$Fe_2O_3 = (2 \times 55.85) + (3 \times 16.00)$$
$$= 159.7 \text{ g mol}^{-1}$$
$$n = \frac{\text{molar mass}}{\text{empirical formula mass}}$$
$$= \frac{159.8}{159.7} = 1$$

Hence, molecular formula is same as empirical formula; Fe_2O_3.

61. In first oxide,

Mass of arsenic $= 65.2$

Mass of oxygen $= 34.8$

$\therefore$ Eq. mass of arsenic $= \frac{65.2}{34.8} \times 8 = 14.99$

In second oxide,

Mass of arsenic $= 75.7$ g

Mass of oxygen $= 24.3$ g

$\therefore$ Equivalent mass of arsenic $= \frac{75.7}{24.3} \times 8 = 24.92$

Equivalent mass of arsenic : Equivalent mass of arsenic
(oxide I) (oxide II)

14.99 : 24.92

or 3 : 5

62. Eq. mass of copper chloride $= 99$

Eq. mass of chlorine $= 35.5$

$\therefore$ Eq. mass of copper $= 99 - 35.5 = 63.5$

$\therefore$ Valency of copper $= \frac{\text{at. mass of copper}}{\text{eq. mass of copper}} = 1$

$\therefore$ Formula of copper chloride is CuCl.

63. For minimum molecular mass, there must be one S atom per insulin molecule.

If 3.4 g S is present, the molecular mass $= 100$

$\therefore$ If 32 g S is present, the molecular mass $= \frac{100 \times 32}{3.4}$

$= 941.176$

64.

	Oxide I	Oxide II
Metal, *M*	50%	40%
Oxygen, O	50%	60%

As first oxide is MO_2

Let atomic mass of $M = x$

$$\therefore \quad \% \text{ O} = \frac{32}{x + 32} \times 100$$

or $\quad \frac{50}{100} = \frac{32}{x + 32}$ or $0.5 = \frac{32}{x + 32}$

or $\quad 0.5x + 16 = 32$

$$0.5x = 16$$
$$x = 32$$

$\therefore$ At. mass of metal $M = 32$

Let formula of second oxide is M_2O_n

$$\% M = \frac{2x}{2x + 16n} \times 100 = \frac{64}{64 + 16n} \times 100$$
$$\frac{40}{100} = \frac{64}{64 + 16n}$$

or $\quad \frac{100}{40} = \frac{64 + 16n}{64}$

$$2.5 = 1 + 0.25n$$
$$n = \frac{1.5}{0.25} = 6$$

Therefore, formula of second oxide $= M_2O_6$

or $= MO_3$

65. $\underset{4 \times 36.5}{4HCl(aq)} + \underset{87 \text{ g}}{MnO_2(s)} \longrightarrow 2H_2O(l) + MnCl_2(aq) + Cl_2(g)$

According to the balanced chemical equation,

87 g of MnO_2 react with 4×36.5 g HCl

5 g of MnO_2 will react with $\frac{4 \times 36.5 \times 5}{87} = 8.39$ g HCl

Note Amounts of one reactant required to react a particular amount of another reactant can be determined by using stoichiometric calculations.

66. $\underset{2V}{2H_2(g)} + \underset{1V}{O_2} \longrightarrow \underset{2V}{2H_2O(g)}$

According to Gay-Lussac's law of gaseous volume, 2 volumes of dihydrogen react with 1 volume of O_2 to produce 2 volumes of water vapour. Therefore, 10 volumes of dihydrogen on reaction with 5 volumes of dioxygen will produce 10 volumes of water vapour.

67. In 100 tons of Fe_2O_3, pure Fe_2O_3

$$= 100 - \frac{100 \times 20}{100}$$

$$= 80 \text{ tons}$$

$$\underset{\substack{2 \times 56 + 48 \\ 160}}{Fe_2O_3} + 3H_2 \longrightarrow \underset{\substack{2 \times 56 \\ 2 \times 56}}{2Fe} + 3H_2O$$

$\because$ 160 g Fe_2O_3 gives $Fe = 2 \times 56$ g

$\therefore$ 80 tons Fe_2O_3 will give $Fe = \dfrac{2 \times 56 \times 80}{160}$

$= 56$ tons

69. By the equation

$$\begin{array}{lccc} & Zn & + \; I_2 \longrightarrow & ZnI_2 \\ \text{Initial moles} & \frac{x}{65} & \frac{x}{254} & 0 \end{array}$$

(If x be the wt. of Zn and I_2 each initially)

$$\begin{array}{lccc} \text{No. of moles at the end of reaction} & \left(\frac{x}{65} - \frac{x}{254}\right) & 0 & \frac{x}{254} \end{array}$$

So, fraction of Zn unreacted $= \dfrac{\frac{x}{65} - \frac{x}{254}}{\frac{x}{65}} = 0.74$

Round II

1.

Combination	Mass of *A* (g)	Mass of *B* (g)
AB	2	5
AB_2	2	10
A_2B	4	5
A_2B_3	4	15

Mass of *B* which is combined with fixed mass of *A* (say 1 g) will be 2.5 g, 5 g, 1.25 g and 3.75 g. They are in the ratio 2 : 4 : 1:3 which is simple whole number ratio. Hence, the law of multiple proportions is applicable.

2. Nitrogen shows variable valency and thus, have variable equivalent weight.

3. Molecular mass of $(CHCOO)_2Fe = 170$

$\therefore$ In 100 g $(CHCOO)_2Fe$, iron present $= \dfrac{56}{170} \times 100$ mg

$= 32.9$ mg

Since, this quantity of Fe is present in 400 mg of capsule,

$\therefore$ % of Fe in capsule $= \dfrac{32.9}{400} \times 100 = 8.2\%$

4. For water, 1 g = 1 mL ($\because$ *d* for water = 1)

$\therefore$ 18 g = 18 mL

18 mL water $= 6.02 \times 10^{23}$ molecules $= N_A$ molecules

$\because$ In 1000 mL, number of water molecules $= \dfrac{N_A \times 1000}{18}$

$= 55.55\, N_A$

5. In 100 g haemoglobin, mass of iron = 0.33 g

$\therefore$ In 67200 g haemoglobin, mass of iron $= \dfrac{67200 \times 0.33}{100}$

$= 672 \times 0.33$ g

$\therefore$ The number of Fe atoms in one Hb molecule

$$= \frac{672 \times 0.33}{56}$$

$= 4$

6. In 12 g carbon, mass of C-14 isotope $= 12 \times \dfrac{2}{100} = 0.24$ g

$\therefore$ Number of C-14 atoms in 12 g of C $= \dfrac{0.24}{14} \times 6.02 \times 10^{23}$

$= 1.032 \times 10^{22}$

7. In 1 L air, volume of $O_2 = 210$ cc

$\because$ $22400 \text{ cm}^3 = 1$ mol

$\therefore$ $210 \text{ cm}^3 = \dfrac{210}{22400} = 0.0093$ mol

8. Let the per cent abundance of lighter isotope is x.

$\therefore$ Atomic mass, $z = \dfrac{x(z-1) + (100 - x)(z + 2)}{x + 100 - x}$

$3x = 200$ or $x = 66.6\%$

9. (CO_2 and (O)) This is an example of law of multiple proportion.

10. Mass of hydrogen $= \dfrac{0.7}{22.4} \times 2 = \dfrac{14}{224}$ g $= 0.0625$ g

$\because$ 0.0625 g of hydrogen is displaced by x g metal.

$\therefore$ 1 g of hydrogen is displaced by $\dfrac{x}{0.0625}$ g of metal

$\Rightarrow$ $\dfrac{x}{0.0625} = 28$

Eq. mass of metal, $x = 28 \times 0.0625 = 1.75$ g

11. $\dfrac{\text{Wt. of metal hydroxide}}{\text{Wt. of metal oxide}} = \dfrac{\text{Eq. wt. of metal + Eq. wt. of } OH^-}{\text{Eq. wt. of metal + Eq. wt. of } O_2^{2-}}$

$\Rightarrow$ $\dfrac{1.520}{0.995} = \dfrac{E + 17}{E + 8}$

On solving, $E = 9.0$

12. $\underset{208\text{ g}}{BaCl_2} + \underset{98\text{ g}}{H_2SO_4} \longrightarrow \underset{233\text{ g}}{BaSO_4} + 2HCl$

100 mL of 20.8% $BaCl_2$ solution contains 20.8 g $BaCl_2$

50 mL of 9.8% H_2SO_4 solution contains 4.9 g H_2SO_4

Here, H_2SO_4 is the limiting reactant.

$\because$ 98 g H_2SO_4 gives $BaSO_4 = 233$ g

$\therefore$ 4.9 g H_2SO_4 will give $BaSO_4 = \dfrac{233 \times 4.9}{98}$

$= 11.65$ g

13. Molar mass of $CaCO_3 = 40 + 12 + 3 \times 16 = 100 \text{ g mol}^{-1}$

Moles of $CaCO_3$ in 1000 g,

$$n_{CaCO_3} = \frac{\text{Mass (g)}}{\text{Molar mass}}$$

$$n_{CaCO_3} = \frac{1000 \text{ g}}{100 \text{ g mol}^{-1}} = 10 \text{ mol}$$

$$\text{Molarity} = \frac{\text{Moles of solute (HCl)} \times 1000}{\text{Volume of solution}}$$

$$0.76 = \frac{n_{HCl} \times 1000}{250}$$

$$n_{HCl} = \frac{0.76 \times 250}{1000}\ 0.19 \text{ mol}$$

$$\underset{1\text{ mol}}{CaCO_3(s)} + \underset{2\text{ mol}}{2HCl(aq)} \longrightarrow CaCl_2(aq) + CO_2\,(g) + H_2O(l)$$

According to the equation,

1 mole of $CaCO_3$ reacts with 2 moles of HCl

$\therefore$ 10 moles of $CaCO_3$ will react with $\dfrac{10 \times 2}{1} = 20$ moles of HCl.

But we have only 0.19 moles HCl, so HCl is the limiting reagent and it limits the yield of $CaCl_2$.

2 moles of HCl, produces 1 mole of $CaCl_2$.

0.19 mole of HCl will produce $\dfrac{1 \times 0.19}{2} = 0.095$mol $CaCl_2$.

Molar mass of $CaCl_2 = 40 + (2 \times 35.5) = 111 \text{ g mol}^{-1}$

$\therefore$ 0.095 mole of $CaCl_2 = 0.095 \times 111 = 10.54$ g

14. Since, 1g hydrogen combines with 80 g bromine, the equivalent weight of bromine $= 80$

$\because$ 4 g bromine combines with Ca $= 1$ g

$\therefore$ 80 g bromine will combine with Ca $= \dfrac{1 \times 80}{4} = 20$ g

$\therefore$ Eq. wt. of Ca is 20 g.

15. $(NH_4)_2SO_4 \longrightarrow 2NH_3 + H_2O + SO_3$

$2NH_3 + 2HCl \longrightarrow 2NH_4Cl$

$$\underset{132\text{ g}}{(NH_4)_2SO_4} \equiv 2NH_3 \equiv \underset{73\text{ g}}{2HCl}$$

$$73 \text{ g HCl} \equiv 132 \text{ g } (NH_4)_2SO_4$$

$$292 \text{ g HCl} \equiv \frac{132 \times 292}{73} \text{ g } (NH_4)_2SO_4$$

$$= 528 \text{ g } (NH_4)_2SO_4$$

16. $\underset{264\text{ g}}{2(NH_4)_2HPO_4} \equiv \underset{142\text{ g}}{P_2O_5}$

$$\text{Percentage of } P_2O_5 = \frac{\text{wt. of } P_2O_5}{\text{wt. of salt}} \times 100$$

$$= \frac{142}{264} \times 100 = 53.78\%$$

17. Partial pressure of oxygen $= \dfrac{2}{1 + 4 + 2} \times 2660$

$= 760$ mm

Thus, 1 L oxygen gas is present at 0°C and 760 mm pressure.

$\therefore$ Number of oxygen molecules $= \dfrac{6.023 \times 10^{23}}{22.4}$

18. $\underset{248\text{ g}}{Ag_2S} \equiv \underset{2 \times 108\text{ g}}{2Ag}$

2×108 g Ag is obtained from $Ag_2S = 248$ g

1 g Ag will be obtained from $Ag_2S = \dfrac{248 \times 1}{2 \times 108}$

$= \dfrac{248}{216}$ g

But, the ore contains only 1.34% Ag_2S.

Thus, 1 g Ag is obtained from ore $= \dfrac{248}{216} \times \dfrac{100}{1.34}$ g

$= 85.68$ g

19. $2Ag + 2HNO_3 \longrightarrow 2AgNO_3 + H_2$

$2AgNO_3 + 2NaCl \longrightarrow 2AgCl + NaNO_3$

$$\underset{143.5\text{ g}}{AgCl} \equiv \underset{170\text{ g}}{AgNO_3} \equiv \underset{108\text{ g}}{Ag}$$

$\because$ 143.5g AgCl is obtained from Ag $= 108$ g

$\therefore$ 2.87 g AgCl is obtained from Ag $= \dfrac{108 \times 2.87}{143.5}$

$= 2.16$ g

20. According to the equation,

$$NaCl + AgNO_3 \longrightarrow NaNO_3 + AgCl$$

$$\text{Number of moles of NaCl} = \frac{4.77}{58.5} = 0.08154$$

$$\text{Number of moles of } AgNO_3 = \frac{5.77}{170} = 0.03394$$

Thus, $AgNO_3$ is the limiting reagent in the reaction.

Now, applying POAC for Ag (as Ag atoms are conserved in the reaction)

Moles of Ag in $AgNO_3$ = moles of Ag in AgCl

or $1 \times$ moles of $AgNO_3 = 1 \times$ moles of AgCl

or 0.03394×143.5 (for AgCl) $= 4.87$ g

21. As both the reactants are consumed completely, thus the ratio of stoichiometric coefficients would be 0.75 : 2 or 3 : 8.

So, $3A_4 + 8O_2 \longrightarrow$ Product

Now as final pressure is half of oxygen initially, thus the molecular formula will be A_3O_4 to balance the equation correctly, *i.e.*,

$$3A_4 + 8O_2 \longrightarrow 4A_3O_4$$

22. $\underset{111\text{ g}}{CaCl_2} + CO_3^{2-} \longrightarrow \underset{100\text{ g}}{CaCO_3} + 2Cl^-$

$$\underset{100\text{ g}}{CaCO_3} \xrightarrow{\Delta} \underset{56\text{ g}}{CaO} + CO_2$$

$\because$ 56 g CaO is obtained by the decomposition of

$$CaCO_3 = 100 \text{ g}$$

$\therefore$ 0.959 g CaO will be obtained by the decomposition of

$$CaCO_3 = \frac{100 \times 0.959}{56}$$

$$= 1.71 \text{ g}$$

Further,

$$100 \text{ g } CaCO_3 \equiv 111 \text{ g } CaCl_2$$

$$1.71 \text{ g } CaCO_3 = \frac{111 \times 1.71}{100}$$

$$= 1.89 \text{ g } CaCl_2$$

$$\text{Percentage of } CaCl_2 \text{ in the mixture} = \frac{1.89}{4.22} \times 100$$

$$= 44.78$$

$$\approx 45\%$$

23. Law of conservation of mass and Avogadro's law are not related to the given statement.

24. Number of moles of NaOH,

$$n_{NaOH} = \frac{4}{40} = 0.1 \text{mol} \left\{ n = \frac{\text{mass (g)}}{\text{molar mass (g mol}^{-1})} \right\}$$

$$\text{Similarly, } n_{H_2O} = \frac{36}{18} = 2 \text{ mol}$$

Mole fraction of NaOH,

$$x_{NaOH} = \frac{\text{moles of NaOH}}{\text{moles of NaOH} + \text{moles of } H_2O}$$

$$x_{NaOH} = \frac{0.1}{0.1 + 2} = 0.0476$$

$$\text{Similarly, } \quad x_{H_2O} = \frac{n_{H_2O}}{n_{NaOH} + n_{H_2O}} = \frac{2}{0.1 + 2} = 0.9524$$

Total mass of solution = mass of solute + mass of solvent = 4 + 36 = 40 g

$$\text{Volume of solution } = \frac{\text{mass of solution}}{\text{sp. gravity}} = \frac{40 \text{ g}}{1 \text{ g mL}^{-1}} = 40 \text{mL}$$

$$\text{Molarity} = \frac{\text{moles of solute} \times 1000}{\text{volume of solution (mL)}}$$

$$= \frac{0.1 \times 1000}{40} = 2.5 \text{ M}$$

25. (c) Number of atoms in 28 g of $N_2 = \frac{28}{28} \times N_A \times 2$

$$= 2 N_A$$

Number of atoms in 32 g of $O_2 = \frac{32}{32} \times N_A \times 2$

$$= 2 N_A$$

(d) 12 g of C (*s*) contains atoms = $\frac{12}{12} \times N_A \times 1$

$$= N_A$$

No. of atoms in 23 g of Na = $\frac{23}{23} \times N_A \times 1 = N_A$

26. (a) Molarity $M = \frac{\text{wt. of NaOH} \times 1000}{\text{mol. wt. of NaOH} \times V \text{ (mL)}}$

$$= \frac{20 \times 1000}{40 \times 200} = 2.5 \text{ M}$$

(b) Molarity, $M = \frac{0.5 \times 1000}{200} = 2.5$ M

(c) $M = \frac{40 \times 1000}{40 \times 100} = 10$ M

(d) $M = \frac{20 \times 1000}{56 \times 200} = 1.785 M$

Thus, 20 g NaOH in 200 mL of solution and 0.5 mole of KCl in 200 mL have the same concentration.

27. Number of molecules = $\frac{\text{mass}}{\text{molar mass}} \times N_A$

Number of molecules, in 16 g oxygen = $\frac{16}{32} \times N_A$

$$= \frac{N_A}{2}$$

in 16 g of CO = $\frac{16}{28} \times N_A = \frac{N_A}{1.75}$

in 28 g of $N_2 = \frac{28}{28} \times N_A = N_A$

in 14g of $N_2 = \frac{14}{28} \times N_A = \frac{N_A}{2}$

in 1 g of $H_2 = \frac{1}{2} N_A = \frac{N_A}{2}$

28. Gram molecular weight is the weight of N_A molecules in gram.

29. The molecular formula of ethene is C_2H_4 and its empirical formula is CH_2.

Thus, empirical formula ×2 = molecular formula.

30. Both the statements are correct but statement II is not the correct explanation of statement I.

31. 0.200 contains 3 while 200 contains only one SF as zero at the end or right of a number are significant provided they are on the right side of the decimal point.

32.
$$\underset{\substack{1 \text{ mol} \\ =16 \text{ g}}}{CH_4} + 2O_2 \longrightarrow CO_2 + \underset{\substack{2 \text{ mol} \\ =36 \text{ g}}}{2H_2O}$$

33. Mol. mass of $SO_2Cl_2 = 32 + 32 + 71 = 135$

$$13.5 \text{ g } SO_2Cl_2 = 0.1 \text{ mol}$$

34. 1 mol of $H_2SO_4 = 6.02 \times 10^{23}$ molecules

$$= 7 \times 6.02 \times 10^{23} \text{ atoms}$$

35. 2 moles of $K_3[Fe(CN)_6] = 2 \times 6.02 \times 10^{23}$ molecules

$$= 3 \times 2 \times 6.02 \times 10^{23} \text{ atoms of K}$$

$$= 36.13 \times 10^{23} \text{ atoms of K.}$$

36. 0.1 g-atom of C = 1.2 g

0.1 mol of NH_3 = 1.7 g

6.022×10^{22} molecules of H_2 = 0.2 g

$$1120 \text{ cc of } CO_2 = \frac{44}{22400} \times 1120 = 2.2 \text{ g}$$

37. $$\text{Mass of 1 atom of H} = \frac{1}{6.02 \times 10^{23}} \text{ g}$$

$$= 1.6 \times 10^{-24} \text{ g}$$

38. $\because$ 5.6 L of a gas at NTP have mass = 11 g

$$\therefore \text{ 22.4 L of gas at NTP have mass} = \frac{11 \text{ g}}{5.6} \times 22.4$$

$$= 44 \text{ g}$$

39. Mohr's salt is $FeSO_4 \cdot (NH_4)_2SO_4 \cdot 6H_2O$

Only oxidizable part is Fe^{2+}

$$[Fe^{2+} \longrightarrow Fe^{3+} + e^-] \times 6$$

$$Cr_2O_7^{2-} + 14H^+ + 6e^- \longrightarrow 2Cr^{3+} + 7H_2O$$

$$6Fe^{2+} + Cr_2O_7^{2-} + 14H^+ \longrightarrow 6Fe^{3+} + 2Cr^{3+} + 7H_2O$$

Millimoles of Fe^{2+} = $750 \times 0.6 = 450$

$$\text{Moles of } Fe^{2+} = \frac{450}{1000} = 0.450 \text{ mol}$$

$$6 \text{ mol } Fe^{2+} \equiv 1 \text{mol } Cr_2O_7^{2-}$$

$$\therefore 0.450 \text{ mol } Fe^{2+} \equiv \frac{0.450}{6}$$

$$= 0.075 \text{ mol } Cr_2O_7^{2-}$$

$$= 0.075 \times 294 \text{ g}$$

$$= 22.05 \text{ g}$$

40. $$\text{Molarity} = \frac{10 \times \text{density} \times \text{wt. of solute}}{\text{mol. wt. of the solute}}$$

$$\therefore \text{ Density} = \frac{3.60 \times 98}{10 \times 29} = 1.21 \text{g mL}^{-1}$$

41. In $Mg_3(PO_4)_2$ molecule,

8 moles of O-atom are contained by 1 mole $Mg_3(PO_4)_2$

Hence, 0.25 mole of O atom are contained by

$$Mg_3(PO_4)_2 = \frac{1}{8} \times 0.25$$

$$= 3.125 \times 10^{-2}$$

2 States of Matter

Gaseous and Liquid States

JEE Main MILESTONE

- Different States of Matter
- Gaseous state
- Gas Laws
- Kinetic Theory of Gases
- Molecular Velocities
- Ideal and Real Gases
- van der Waal's
- Liquefaction of Gases
- Joule-Thomson Effect
- Liquid State

2.1 Different States of Matter

Solids, liquids and gases are three general states of matter which show difference in the several characteristics.

Table 2.1 **Characteristics of Different States of Matter**

S. No.	Solids	Liquids	Gases
1.	They are rigid, have a definite shape and a definite volume.	They are not rigid, shape is not definite but have a definite volume.	They are not rigid, have neither definite shape nor volume.
2.	The position of molecules are almost fixed. They can only vibrate to and fro about their mean position.	The position of molecules are not fixed, they can slide over one another but cannot escape the boundary in normal conditions.	The positions of molecules are not fixed at all. They can move freely and cannot be confined to definite boundary.
3.	Molecules are closely packed.	Molecules are closely packed.	Molecules are wide apart.
4.	Molecules are associated with minimum energy due to motion.	Molecules are associated with intermediate energy due to motion.	Molecules are associated with maximum energy.
5.	The intermolecular forces are very strong.	The intermolecular forces are weak.	The intermolecular forces are very weak.

Anything that occupies space and has weight is called matter or substance. Almost all substances exist in three states under appropriate conditions of temperature and pressure. The physical state of a substance is largely determined by temperature and pressure considerations.

Forces Responsible for Solid, Liquid and Gaseous States of Matter

There are following two factors which determine the physical state of matter. These are

(a) Thermal Agitation

Due to kinetic energy of the particles, the atoms (or molecules) of a matter are in a state of continuous vibration and agitation. This behaviour of them is called **thermal agitation.** An increase in temperature, increases the kinetic energy thus, results in increased randomness or disorder. A decrease in temperature, results in decrease of kinetic energy, thus the frequency of collisions and disorder reduce.

(b) Cohesive Forces

The cohesive forces can be **coulombic forces** or **van der Waals' forces,** depending on the type of molecules involved. van der Waals' forces are very short lived intermolecular attractive forces which are believed to exist between all kinds of molecules when they are sufficiently close to each other.

These forces are of following types

(i) **Dipole-dipole interactions** These are seen between polar molecules with permanent polarity in them. When polar molecules are brought nearer to each other, they orient themselves in such a way that positive end of one dipole attracts the negative end of other dipole and *vice-versa* as :

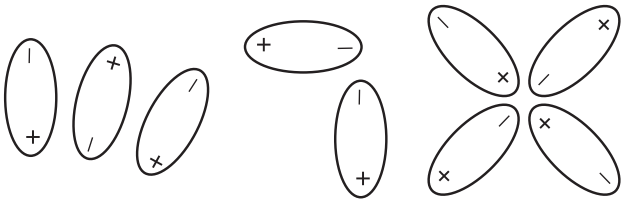


Fig. 2.1 Illustration of dipole-dipole interaction

These forces are strongest of all van der Waals' forces and are called **keesom** forces. The intensity of these forces is generally hampered by an increase in temperature.

(ii) **Ion-induced dipole interactions** Polar molecules are attracted towards ions and this interaction between ion and dipoles is called **ion-dipole interactions.** Ions however, can attract neutral molecules also and have the ability of causing polarity in them. Such interactions are called **ion-induced** dipole interactions.

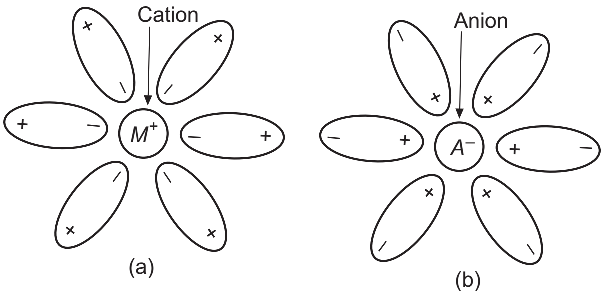

Fig. 2.2 Ion-dipole interaction **(a)** Cation (M^+) attracts the negative end of dipole **(b)** Anion (A^-) attracts the positive end

(iii) **Dipole-induced dipole interactions** When a dipole comes near the non-polar molecule, it can induce polarity in non-polar molecule resulting to **dipole-induced dipole interactions** which can be seen as

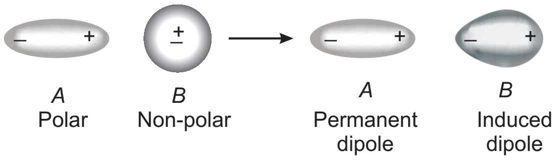

Fig. 2.3 Dipole-induced dipole interaction

(iv) **Instantaneous dipole-induced dipole interactions** Even non-polar molecules in themselves are polarised temporarily due to displacement of electron cloud with respect to nucleus (instantaneously). Such a instantaneous polar dipole when interact with non-polar molecule, the result is seen in the form of instantaneous dipole-induced dipole interaction which can be seen as

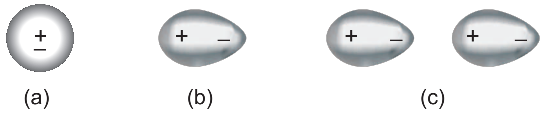

Fig. 2.4 Instantaneous dipole-induced dipole interaction :

(a) Non-polar molecule with a positive centre surrounded by a symmetrical negative electron cloud.

(b) The displacement of electron cloud makes the non-polar molecule temporarily polar.

(c) Temporarily polar molecules polarises the neighbouring molecule and creates in it the induced dipole.

Hence, the state of a matter is decided as follows

(i) In a solid, the cohesive forces predominate the effect of thermal agitation. Consequently, the particles are held together in rigid, highly-oriented and close-packed structure.

(ii) In a liquid, the cohesive forces are no longer strong enough, however, these are still sufficient, so that particles cannot escape each other's environment, they have sufficient mobility.

(iii) In a gas, the thermal agitation dominates the effect of cohesive forces, thus the gas molecules acquire the unrestricted and independent mobility in the vapour state.

Caution Points

(i) *The constituent particles of a gas undergo all types of motion, that is translational, rotational and vibrational. Liquid molecules possess translational and vibrational. While solid particles possess only vibrational motion.*

(ii) *The temperature and pressure at which all the three states of a substance can exist together in equilibrium is called triple point. e.g., ice, liquid water and water vapours can coexist (i.e., ice* $\rightleftharpoons$ water $\rightleftharpoons$ vapour) *at* 0.0098°C *and* 4.58 *mm.*

2.2 Gaseous State

It is the most disordered state of matter. In this state, matter neither have fixed volume nor fixed shape. It takes the shape and volume of the container. In which it is placed.

Characteristic Properties of Gases

Gases exhibit following characteristic properties

(a) **Expansibility** Gases expand indefinitely and fill any vessel, no matter how large, in which these are placed.

(b) **Compressibility** Gases are readily compressible. A large amount may be compressed into a small space by applying pressure.

(c) **Diffusion** Gases intermix freely with one another or move from one place to other without any difficulty.

(d) **Homogeneity** Pure gases or their mixtures are all homogeneous in composition.

(e) **Density** Gases possess very low density. The density of gas when compared to that of hydrogen is termed as **relative density.**

(f) **Gases exert pressure** Due to collision of molecules on the walls of container, gases exert certain amount of pressure, which obviously increases due to increase in temperature.

(g) **Kinetic energy** Gaseous molecules move very rapidly in all directions in a random manner, *i.e.,* gases have highest kinetic energy.

Measurable Properties of Gases

The characteristics of gases are described fully in terms of four parameters *i.e.,* pressure (p), volume (V), temperature (T) and mass or mole, which are termed as measurable properties.

(a) Mass

It is expressed in gram or kg and is equal to the difference in masses of empty vessel and vessel containing gas.

(b) Volume

It is equal to the volume of the container and is expressed in terms of litre (L), millilitre (mL), cubic centimetre (cm^3), cubic metre (m^3) or cubic decimetre (dm^3).

$$1 \text{ L} = 1000 \text{ mL} = 1000 \text{ cm}^3 = 1 \text{dm}^3$$

$$1 \text{ m}^3 = 10^3 \text{dm}^3 = 10^6 \text{cm}^3 = 10^6 \text{mL} = 10^3 \text{L}$$

(c) Pressure

It is defined as force divided by the area to which the force is applied.

$$\text{Pressure} = \frac{\text{force}}{\text{area}}$$

The greater the force acting on a given area, the greater the pressure. The origin of the force exerted by a gas is the continuous collisions of the molecules against the walls of the container. The collisions are so numerous that they exert an effectively steady force, which is experienced as a steady pressure.

The units of pressure are atm, mm Hg, torr etc.

1 atm = 76 cm of Hg = 760 mm of Hg = 760 torr

$$1 \text{ atm} = 101.325 \text{ kPa} = 101325 \text{ Pa} = 101.325 \text{ Nm}^{-2}$$

$$= 1.01325 \text{ bar}$$

$$1 \text{ bar} = 10^5 \text{ Pa} = 0.987 \text{ atm.}$$

$$\text{Atmospheric pressure} \quad p = hdg.$$

where, ***h*** is the height of the mercury column supported by the barometer, ***d*** is the density of mercury and ***g*** acceleration due to gravity.

(The pressure is obtained in pascal when h, d and g are expressed in SI unit.)

Pressure is measured by using a **manometer** which is a simple device with a horizontal arm and a U-tube carrying mercury or any other suitable liquid.

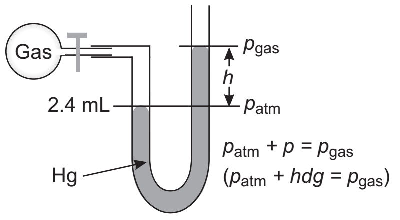

Fig. 2.5 An open arm manometer

However, atmospheric pressure is measured by **barometer.**

There are two types of manometers

(i) closed end and

(ii) open end manometer

Closed end manometer is normally used to measure pressure below atmospheric pressure whereas open end manometer is used to measure pressure above atmospheric pressure.

In an open end manometer

(i) If the level of Hg in the two limbs is same, the gas pressure (p_{gas}) = atmospheric pressure (p_{atm})

(ii) If the level of Hg is higher in the longer limb $p_{gas} = p_{atm} + p_h$

(iii) If the level of Hg is higher in the shorter limb,

$$p_{gas} = p_{atm} - p_h$$

where, p_h = difference in the Hg levels in the two columns of density (d) of a gas.

In case of close end manometer,

$$p_{gas} = p_h$$

Sample Problem 1 *How high a column of air would be necessary to cause the barometer to read 76 cm Hg if the atmosphere were of uniform density 1.7 kg/m^3? (density of mercury is 13.6×10^3 kg/m^3)*

(a) 13.6×10^3 (b) 6.08×10^5

(c) 7.62×10^4 (d) 1.7×10^3

Interpret (b) At a place where barometer uses air and mercury, pressure is same

$$p = h_1 d_1 g = h_2 d_2 g$$

$$\underset{\text{(mercury)}}{h_1 d_1} = \underset{\text{(air)}}{h_2 d_2}$$

$$76 \times 13.6 \times 10^3 = h_2 \times 1.7$$

$$h_2 = 6.08 \times 10^5 \text{ cm}$$

(d) Temperature

It is measured in terms of hotness or coldness. The measurement is based on the expansion of certain material (mostly it is mercury) with increasing temperature. It is measured in celsius scale or absolute scale (Kelvin scale). Celsius scale was earlier known as the **centigrade scale.**

Note

(i) **Standard temperature and pressure** (STP or NTP) mean 273.15 K (0°C) temperature and 1 bar (*i.e.*, exactly 10^5 pascal) pressure. At STP, molar volume of an ideal gas is 22.71098 L mol^{-1}.

(ii) The standard temperature for gas measurements (0°C or 273.15 K) is not the same as that usually assumed for thermodynamic measurements (25°C or 298 K is said to be SATP condition or Standard Ambient Temperature and Pressure).

2.3 Gas Laws

Gases exhibit dependency on temperature, pressure, volume and mass. The inter-relationship of these factors can be analysed through gas laws, which are

Boyle's Law (by Robert Boyle-1662)

According to this law, "At a given temperature, the volume of a given mass of a gas is inversely proportional to its pressure,"

i.e., $V \propto \frac{1}{p}$ or $pV = \text{constant}$, (the value of the constant depends on the amount of gas and temperature.)

or $$p_1V_1 = p_2V_2$$

(If temperature T remains constant, the process is called **isothermal process.**)

Alternatively, Boyle's law can also be stated as follows: "Temperature remaining constant, the product of pressure and volume of a given mass of a gas is constant".

We know that,

$$\text{mass, } m = \text{volume } (V) \times \text{density } (d)$$

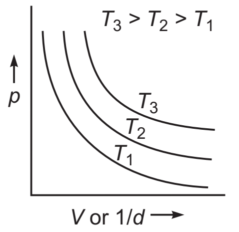
or $$d = \frac{m}{V}$$

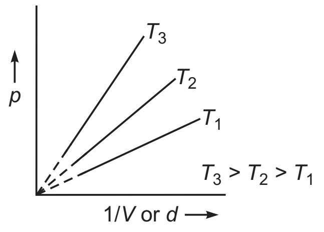
Therefore, at constant temperature and mass,

$$d \propto \frac{1}{V} \propto p \qquad \left(\because p \propto \frac{1}{V}\right)$$

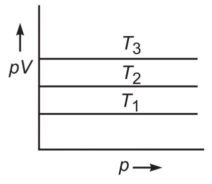
Thus, $$\frac{d_1}{d_2} = \frac{p_1}{p_2} = \frac{V_2}{V_1}$$

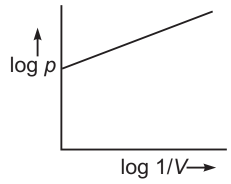
Graph between p and V at constant temperature is called **isotherm** and is an equilateral hyperbola. By plotting p *versus* $\frac{1}{V}$, this hyperbola is converted to a straight line. Other types of isotherm are also shown below



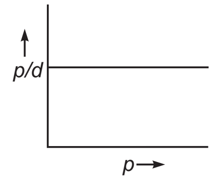


Similarly, the relationship between pV vs p and log p vs log $\frac{1}{V}$ looks like





and the plot of p *vs* p/d is



Practical Importance of Boyle's Law

The Boyle's law expresses in quantities an important experimental fact that gases are compressible. For example, air at the sea level is denser because it is compressed by the mass of air above it. However, density and pressure decrease with an increase in altitude.

The atmospheric pressure at Mount Everest is only about 0.5 atm. The decrease in pressure at high altitudes causes altitude sickness (sluggish feeling, headache, etc.,) due to a decrease in the oxygen intake in each breath.

The inside of jet airplanes, which normally fly at a height of about 10000m, is specially maintained at normal pressure. The planes are also equipped with emergency oxygen supply in case the pressure falls.

Sample **Problem 2** *A vessel of 120 mL capacity contains a certain amount of gas at 35°C and 1.2 bar pressure. The gas is transferred to another vessel of volume 180 mL at 35°C. What would be its pressure?* **[NCERT]**

(a) 0.6 *bar* (b) 1.2 *bar* (c) 0.8 *bar* (d) 0.4 *bar*

Interpret (c) $p_1 = 1.2$ bar, $p_2 = ?$, $V_1 = 120$ mL, $V_2 = 180$ mL

From Boyle's law, $p_1V_1 = p_2V_2$

$$p_2 = \frac{p_1V_1}{V_2} = \frac{1.2 \text{ bar} \times 120 \text{ mL}}{180 \text{ mL}}$$

$$p_2 = 0.8 \text{ bar.}$$

Charles' Law (by Jacques Charles'-1787)

According to this law, "At a constant pressure, the volume of a given mass of a gas is directly proportional to its absolute temperature." (The constant pressure process is referred to as **isobaric process**).

$V \propto T$ or $\frac{V}{T}$ = constant (the value of the constant depends upon the amount of gas and pressure.)

or $$\frac{V_1}{T_1} = \frac{V_2}{T_2}$$

At constant pressure and mass, density of a gas is inversely proportional to its absolute temperature.

$$d \propto \frac{1}{T} \propto \frac{1}{V}$$

Thus, $$\frac{d_1}{d_2} = \frac{T_2}{T_1} = \frac{V_2}{V_1}$$

Charles' obtained experimentally that at constant pressure, for 1°C increment/decrement in temperature of a gas, the volume increase/ decrease by a fraction of $\frac{1}{273}$.

Hence, if V_0 be the volume of a gas at 0°C and it is recorded to be V at t° C then

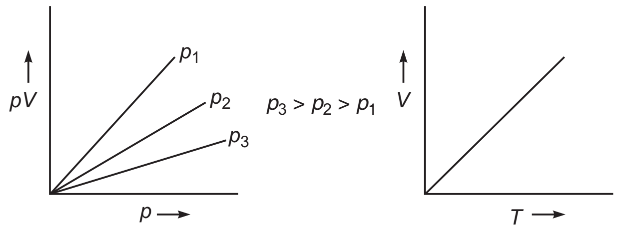
$$V = V_0 + \frac{1}{273} t\, V_0 = V_0\left(1 + \frac{t}{273}\right) = V_0\left(\frac{273 + t}{273}\right) = \frac{V_0}{273} T$$

At this stage, we define a new scale of temperature such that t°C on the new scale is given by $T = 273.15 + t$ and 0°C is given by $T_0 = 273.15$. This new temperature scale is called the *Kelvin temperature scale or absolute temperature scale*.

The volume of the gas at $-t$° C is given by $V_{-t} = V_0\left(1 - \frac{t}{273}\right)$

Thus, a decrease in temperature results in a decrease in the volume of the gas, and ultimately the volume becomes zero at −273° C. It means that any further lowering of temperature is impossible because it will correspond to negative volume, which is meaningless. Hence, an important conclusion can be drawn from the above discussion that the lowest possible temperature is −273° C. *This lowest possible temperature at which all gases are supposed to occupy zero volume is called absolute zero.* A scale of temperature based upon this choice of zero is called absolute scale of temperature.

The relationship can be shown graphically as



These curves are known as *isobars* or isoplestics and is always a straight line.

Practical Importance of Charles' Law

The use of hot air balloons in sports and for meteorological observations is an interesting application of Charles' law. According to Charles' law, gases expand on heating. Since the mass of a gas is unchanged, larger volume corresponds to lower density. Thus, hot air is less dense than cold air. This causes hot air balloons to rise by displacing cooler air of the atmosphere.

Sample **Problem 3** *It is desired to increase the volume of 80 cm^3 of a gas by 20% without changing pressure. To what temperature the gas be heated if its initial temperature is 25°C?*

(a) 35.6°C (b) 84.6°C
(c) 630.6°C (d) 35°C

Interpret (b) The desired increase in the volume of gas is

20% of 80 cm^3 $= \frac{80}{100} \times 20 = 16$ cm^3

Thus, the final volume of the gas is $80 + 16 = 96$ cm^3

Now, $V_1 = 80$ cm^3, $V_2 = 96$ cm^3

$T_1 = 25°$ C = 298 K, $T_2 = ?$

Applying Charles' law, we get

$$\frac{V_1}{T_2} = \frac{V_2}{T_2}$$

$$T_2 = \frac{V_2T_2}{V_1} = \frac{96 \text{ cm}^3 \times 298 \text{ K}}{80 \text{ cm}^3} = 357.6\text{K}$$

$$= 357.6 - 273 = 84.6° \text{ C}$$

Sample **Problem 4** *If V_0 is the volume of the given mass of a gas at 273 K and pressure p, then according to Charles' law the volume of the same mass of gas at 10°C and pressure, p will be*

(a) $V_0 + \frac{10}{273}$ (b) $10V_0$

(c) $\frac{283}{273} \cdot V_0$ (d) $\frac{[V_0 + 10]}{273}$

Interpret (c) From Charles' law,

$$\frac{V_1}{V_2} = \frac{T_1}{T_2}$$

$$\frac{V_0}{V} = \frac{273}{273 + 10}$$

$$V = \frac{283}{273} V_0$$

Gay-Lussac's Law (Pressure-Temperature Equation) (by Joseph Gay-Lussac-1802)

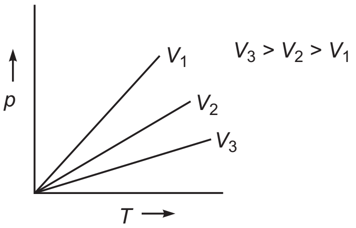
According to this law, "At a constant volume, the pressure of a given mass of a gas is directly proportional to its absolute temperature".

(If volume V remains constant, the process is called *isochoric process*.)

i.e., $$p \propto T \quad \text{or} \quad \frac{p}{T} = \text{constant}$$

or $$\frac{p_1}{T_1} = \frac{p_2}{T_2}$$

The relationship between p and T can be seen as



These curves are called *isochores*.

Sample **Problem 5** *The pressure exerted by 12 g of an ideal gas at temperature t°C in a vessel of V L is one atmosphere. When the temperature is increased by 10°C at the same volume, the pressure increases by 10%. The value of temperature t is*

(a) 173°C (b) 173 K
(c) 100°C (d) 100 K

Interpret (c) From Gay-Lussac's law,

$$\frac{p_1}{T_1} = \frac{p_2}{T_2}$$

$$\frac{1}{t + 273} = \frac{1.1}{t + 283}$$

$$t + 283 = 1.1t + 300.3$$

$$0.1t = -17.3$$

$$t = -173 \text{ K}$$

$$t = 273 - 173 = 100° \text{ C}$$

Avogadro's Law

According to this law, "Equal volumes of all gases at the same temperature and pressure contain the same number of molecules."

or

"At a given temperature and pressure, the volume of any gas is directly proportional to the number of moles of gas."

If p and T remain constant,

$$V \propto n \quad \text{or} \quad \frac{V}{n} = \text{constant}$$

or $$\frac{V_1}{n_1} = \frac{V_2}{n_2}$$

where, n = the number of moles, *i.e.*, $n = \frac{m}{M}$,

m = mass of substance in grams,
M = molecular mass of substance.

One mole of any gas contains the same number of molecules (6.023×10^{23}) and by this law, must occupy the same volume at a given temperature and pressure. The volume of one mole of a gas is called *molar volume*, V_m which is 22.4 L mol^{-1} at STP or NTP.

Sample **Problem 6** *Total number of electrons in 1.4 g dinitrogen gas is*

(a) 4.2×10^{23} (b) 6.02×10^{23}
(c) 3.01×10^{23} (d) 8.4×10^{24}

Interpret (a) $$1.4 \text{ g } N_2 = \frac{1.4}{28} \text{ mol } N_2$$

$$1 \text{ mole } N_2 \text{ contains } 14 \times 6.02 \times 10^{23} \text{ electrons}$$

$$\frac{1.4}{28} \text{ mole } N_2 \text{ will contain } \frac{14 \times 6.023 \times 10^{23} \times 1.4}{28}$$

$$= 4.2 \times 10^{23} \text{ electrons}$$

Ideal Gas Equation

From Boyle's law and Charles' law, we have

$$\frac{pV}{T} = \text{constant} \qquad \text{...(i)}$$

For 1 mole,

$$\frac{p_1V_1}{T_1} = \frac{p_2V_2}{T_2} \qquad \text{...(ii)}$$

This relation is known as *gas equation*.

From equation (i), *the value of constant depends on the amount of gas and the units in which pressure and volume are measured.*

If the amount of gas taken is 1 mole, the constant is represented by 'R'. So, for 1 mole of gas, the gas equation is

$$\frac{pV}{T} = R \quad \text{or} \quad pV = RT$$

For 'n' moles of gas, the equation is written as

$$pV = nRT = \frac{m}{M} RT$$

This is called *ideal gas equation*. This equation is obeyed by isothermal and adiabatic processes, where, R is called *universal gas constant*.

$$\text{Units of } R = \frac{\text{(energy unit)}}{\text{(mol)(temperature unit)}}$$

$$R = 8.314 \text{ J/mol-K} = 0.08205 \text{ L-atm/mol-K}$$
$$= 1.99 \text{ cal/mol-K} = 5.189 \times 10^{19} \text{ eV mol}^{-1} \text{ K}^{-1}.$$

Gas constant, R for a single molecule is called *Boltzmann constant* (K).

$$K = \frac{R}{N} = \frac{8.314 \times 10^{7}}{6.023 \times 10^{23}}$$
$$= 1.38 \times 10^{-16} \text{ erg mol}^{-1} \text{ degree}^{-1}$$
$$= 1.38 \times 10^{-23} \text{ J mol}^{-1} \text{ degree}^{-1}$$

Again from $pV = nRT$

$$pV = \frac{m}{M} RT$$
$$\frac{m}{V} = \frac{pM}{RT}$$
$$\because \quad \frac{m}{V} = d \text{ (density)}$$
$$\text{So,} \quad d = \frac{pM}{RT}$$

M and R are constant for a particular gas, so for two or more different temperatures and pressure,

$$\frac{d_1T_1}{p_1} = \frac{d_2T_2}{p_2} = \text{constant}$$

Sample **Problem 7** *Pressure of a mixture of 4 g of* O_2 *and 2 g of* H_2 *confined in a bulb of 1 L at 0°C is*

(a) 25 *atm* (b) 45 *atm*
(c) 15 *atm* (d) 31 *atm*

Interpret (a) Number of moles of $O_2 = \frac{4}{32} = 0.125$

$$\text{Number of moles of } H_2 = \frac{2}{2} = 1$$

$$\text{Total number of moles} = 1 + 0.125 = 1.125$$

$$p = \frac{nRT}{V}$$
$$= \frac{1.125 \times 0.082 \times 273}{1}$$
$$= 25.184 \text{ atm}$$

Sample **Problem 8** *Pressure of 1 g of an ideal gas A at 27°C is found to be 2 bar. When 2 g of another ideal gas B is introduced in the same flask at same temperature, the pressure becomes 3 bar. Find a relationship between their molecular masses.*

(a) $M_A = 2\,M_B$ (b) $M_B = 2\,M_A$
(c) $M_A = \frac{M_B}{4}$ (d) $M_B = 6\,M_A$

Interpret (c) $pV = nRT$

For A gas, $p_AV = n_ART$ ...(i)

Similarly for B gas, $p_BV = n_BRT$ ...(ii)

(V is same because the gases are taken in the same flask)

Number of moles of A gas; $n_A = \frac{1}{M_A}$

(M_A = molar mass of gas A)

Number of moles of B gas; $n_B = \frac{2}{M_B}$

(M_B = molar mass of gas B)

Pressure of gas A, $p_A = 2$ bar

Total pressure, $p_{\text{total}} = p_A + p_B = 3$ bar

Pressure of gas B, $p_B = p_{\text{total}} - p_A = 3 - 2 = 1$ bar

V, R and T are same for both the gases.

Hence, from Eqs. (i) and (ii),

$$\frac{p_A}{p_B} = \frac{n_A}{n_B} = \frac{1 \times M_B}{M_A \times 2}$$
$$\frac{M_B}{M_A} = \frac{2p_A}{p_B}$$
$$\frac{M_B}{M_A} = \frac{2 \times 2}{1}$$
$$M_B = 4M_A$$

Dalton's Law of Partial Pressure

According to this law, "If two or more gases, which do not react chemically, are enclosed in a vessel, the total pressure exerted by the gaseous mixture is the sum of partial pressures exerted by the constituent gases"

If $p_1, p_2 \ldots\ldots\ldots, p_n$ be partial pressures of 'n' gases present in a vessel, then total pressure

$$p_{\text{total}} = p_1 + p_2 + \ldots\ldots\ldots + p_n$$

(Partial pressure is the pressure, which each gas will individually exert if present alone in the vessel.)

Let two gases are enclosed in a container of volume V and their numbers of moles be n_1 and n_2. If their partial pressures be measured at temperature T, then

$$p_1V = n_1RT \Rightarrow \frac{RT}{V} = \frac{p_1}{n_1}$$

The total pressure of the gas mixture will be given by

$$p_{\text{total}} V = (n_1 + n_2)\, RT$$

We then get

$$p_1 = \frac{n_1}{n_1 + n_2}\, p_{\text{total}} = \chi_1 p_{\text{total}},$$

$$p_2 = \frac{n_2}{n_1 + n_2}\, p_{\text{total}} = \chi_2 p_{\text{total}}$$

where, $\chi_1 = \frac{n_1}{n_1 + n_2}$ is the mole fraction of the one gas

and $\chi_2 = \frac{n_2}{n_1 + n_2}$ is the mole fraction for other gas.

Application of Dalton's Law

Important applications of Dalton's law are as follows

(i) It is used to calculate mole fraction of gas as

$$\text{Mole fraction of a gas } (X) = \frac{\text{partial pressure of gas } (p)}{\text{total pressure } (p)}$$

(ii) It is used to calculate percentage of a gas in mixture as

$$\% \text{ of gas in mixture} = \frac{\text{partial pressure of gas } (p_1)}{\text{total pressure } (p)} \times 100$$

(iii) It is used to calculate pressure of gas collected over water. If a gas is collected over water, water vapour is mixed with the collected gas. Hence, the corrected pressure of the gas must be used, as given below :

$$p_{\text{Gas (dry)}} = p_{\text{Total (moist gas)}} - p_{\text{water vapour}}$$

(iv) It is also used to calculate relative humidity (R_{H}) at a given temperature as

$$R_{\text{H}} = \frac{\text{partial pressure of water in air}}{\text{vapour pressure of water}}$$

Limitations of Dalton's Law

This law is applicable only when the component gases in the mixture do not react with each other. *e.g.*, $N_2 + O_2, CO + CO_2, N_2 + Cl_2, CO + N_2$.

But this law is not applicable to gases which combine chemically. *e.g.*, $H_2 + Cl_2, CO + Cl_2, Cl_2 + NH_3 +$ HBr and HCl $+ NO + O_2$, etc.

Sample Problem 9 *A mixture of dihydrogen and dioxygen at one bar pressure contains 20% by weight of dihydrogen. Calculate the partial pressure of dihydrogen.* **[NCERT]**

(a) 0.8 (b) 0.4 (c) 0.6 (d) 0.2

Interpret (a) A mixture of H_2 and O_2 contains 20% by weight of H_2 means

$H_2 = 20$ g and $O_2 = 80$ g

$$\text{Moles of hydrogen, } n_{H_2} = \frac{20}{2} = 10 \text{ mol}$$

$$\text{Moles of oxygen, } n_{O_2} = \frac{80}{32} = 2.5 \text{ mol}$$

Mole fraction of hydrogen,

$$x_{H_2} = \frac{n_{H_2}}{n_{H_2} + n_{O_2}} = \frac{10}{10 + 2.5} = 0.8$$

$$\text{Partial pressure of } H_2, p_{H_2} = p_{\text{total}} \times X_{H_2}$$

$$p_{H_2} = 1 \text{ bar} \times 0.8$$

$$p_{H_2} = 0.8 \text{ bar}$$

Sample Problem 10 *1500 mL flask contains 400 mg O_2 and 60 mg H_2 at 100°C. What is the total pressure in the flask?*

(a) 0.66 atm (b) 0.867 atm
(c) 8.67 atm (d) 13.47 atm

Interpret (c) Number of moles of $O_2 = \frac{w}{m} = \frac{400 \times 10^{-3}}{32}$

$$= 0.0125$$

$$\text{Number of moles of } H_2 = \frac{w}{m} = \frac{60 \times 10^{-3}}{2} = 0.03$$

From $pV = nRT$,

$$\text{Partial pressure of } O_2 = \frac{0.0125 \times 0.0821 \times 373}{1500 \times 10^{-3}} = 0.255 \text{ atm}$$

$$\text{Partial pressure of } H_2 = \frac{0.03 \times 0.0821 \times 373}{1500 \times 10^{-3}} = 0.612 \text{ atm}$$

$$\text{Total pressure} = 0.255 + 0.612 = 0.867 \text{ atm}$$

Amagat Law of Partial Volume

According to this law, "When two or more gases, which do not react chemically are kept in a closed vessel, the total volume exerted by the mixture is equal to the sum of the partial volumes of individual gases".

Thus,

$$V_{\text{Total}} = V_1 + V_2 + V_3 + \dots$$

Sample Problem 11 *Two gas bulbs A and B are connected by a tube having a stopcock. Bulb A has a volume of 100 mL and contains hydrogen. After opening the gas from A to the evacuated bulb B, the pressure falls down to 40%. The volume of B (in mL) must be*

(a) 75 (b) 150
(c) 200 (d) 250

Interpret (b) From Dalton's partial pressure law,

$$p_A V_A + p_B V_B = p_{\text{total}} V_{(A+B)}$$

Let $p_A = 100$ atm

$p_B = 0$

$p_{\text{total}} = 40$ atm

$$\therefore \quad 100 \times 100 + 0 \times V_2 = 40\,(100 + V_2)$$

$$V_2 = 250 - 100 = 150 \text{ mL}$$

Graham's Law of Diffusion (or Effusion)

According to this law, "If a gas is allowed to escape from its container through a small hole into vacuum, the process is called *effusion.* On the other hand *diffusion*, is the passage of gas through a porous partition".

"Rate of diffusion", is defined as the volume, which diffuses in unit time,

$$\text{Rate of diffusion} = \frac{\text{volume of the gas diffused}}{\text{time taken for diffusion}}$$

The relationship between rates of diffusion of various gases can be given by *Graham's law of diffusion* (effusion) which states that :

"The **rates of effusion** (diffusion) of non-reactive gases under similar conditions of temperature and pressure are inversely proportional to the square roots of their densities."

$$\text{Rate of diffusion} \propto \frac{1}{\sqrt{d}} \propto \sqrt{\frac{1}{M}}$$

$$[\because \text{Molar mass} = 2 \times \text{vapour density}]$$

If r_1 and r_2 are the rates of diffusion of two gases of molecular weights M_1 and M_2 and their densities are d_1 and d_2 respectively then

$$\frac{r_1}{r_2} = \sqrt{\frac{d_2}{d_1}} = \sqrt{\frac{M_2}{M_1}}$$

If equal volume V of two gases diffuse or effuse in t_1 and t_2 second respectively, then

$$\frac{r_1}{r_2} = \frac{\frac{V}{t_1}}{\frac{V}{t_2}} = \frac{t_2}{t_1} = \sqrt{\frac{d_2}{d_1}} = \sqrt{\frac{M_2}{M_1}}$$

When p is not constant,

then $\quad r \propto p$

or $\quad \dfrac{r_1}{r_2} = \dfrac{p_1}{p_2}\sqrt{\dfrac{M_2}{M_1}} \qquad \left(\because\ r \propto \dfrac{p}{\sqrt{M}}\right)$

If the volumes and moles of two gases are V_1, V_2 and n_1, n_2 respectively then, $\frac{r_1}{r_2} = \frac{n_1 t_2}{n_2 t_1} = \frac{V_1 t_2}{V_2 t_1}$.

When a gas at a pressure p and temperature T is separated from vacuum by a small hole, the rate of escape of its molecules is equal to the rate at which they strike the area of the hole.

Therefore, for a hole of area A_0,

$$\text{rate of effusion} = \frac{pA_0}{(2pMKT)^{1/2}}$$

$$= \frac{pA_0 N_A}{(2pMRT)^{1/2}}.$$

Applications of Graham's law

Graham's law is applicable

1. to determine vapour densities and molecular weights of gases.
2. to prepare Ausell's marsh gas indicator which is used in mines.

Caution Point *The gas with highest rate of diffusion in hydrogen.*

Sample **Problem 12** *Calculate the relative rates of diffusion of* $^{235}UF_6$ *and* $^{238}UF_6$ *in the gaseous state.*

(Atomic mass of $F = 19$*).*

(a) 0.9915 : 1.0000 (b) 0.9957 : 1.0000

(c) 1.0043 : 1.0000 (d) 1.0086 : 1.0000

Interpret (c) Molecular mass of $^{235}UF_6 = 235 + 6 \times 19 = 349$

Molecular mass of $^{238}UF_6 = 238 + 6 \times 19 = 352$

From Graham's law of diffusion,

$$\frac{r_1}{r_2} = \sqrt{\frac{M_2}{M_1}}$$

$$= \sqrt{\frac{352}{349}} = 1.0043$$

$$\therefore \qquad r_1 : r_2 = 1.0043 : 1$$

Sample **Problem 13** *At what temperature, the rate of effusion of* N_2 *would be* 1.625 *times that of* SO_2 *at* 50°C*?*

(a) 373 K (b) 273 K

(c) 473 K (d) 127 K

Interpret (a)

$$\frac{r_{N_2}}{r_{SO_2}} = \sqrt{\frac{T_{N_2}}{T_{SO_2}} \cdot \frac{M_{SO_2}}{M_{N_2}}}$$

$$\frac{1.625}{1} = \sqrt{\frac{T_{N_2}}{323} \times \frac{64}{28}}$$

$$T_{N_2} = \frac{(1.625)^2 \times 323 \times 28}{64}$$

$$= 373\text{ K}$$

Check Point 1

1. In terms of Charles' law, explain why –273°C is the lowest possible temperature?
2. If the number of moles of a gas were doubled and the pressure and temperature remained the same, what would happen to the volume?
3. Why is Dalton's law of partial pressure not applicable to a mixture of HCl and NH_3 gas?
4. Both propane and carbon dioxide diffuse at the same rate under identical conditions. Explain, why?

2.4 Kinetic Theory of Gases

The molecular details regarding gases can be visualised with the help of *kinetic molecular theory of gases* which is based on following assumptions

1. A gas consists of extremely small discrete particles, called the molecules, dispersed throughout the container.
2. Molecules are so small and so far apart that the actual volume of the molecules is negligible as compared to the total volume of gas.
3. Gas molecules are in constant random motion with high velocities. They move in straight lines with uniform speed and change directions on collision with other molecules or with the walls of container.
4. The intermolecular forces are negligible. Thus, the gas molecules can move freely, independent of each other.
5. All collisions are perfectly elastic, hence there is no loss of kinetic energy during the collision. However, there may be redistribution of energy during such a collision.
6. The effect of gravity on the motion of the molecules is negligible in comparison to the effect of collision.
7. The pressure of a gas is caused by the hits recorded by molecules on the walls of the container.

   $\because$ Pressure $\propto$ Number of collisions per unit time per unit area by the molecules on the wall of the container.
8. At a particular instance, different molecules in a sample have different speeds and hence, different kinetic energies. However, the average kinetic energy of the molecules is assumed to be directly proportional to the absolute temperature.

   Kinetic energy $\propto$ absolute temperature

Kinetic Gas Equation

On the basis of postulates of kinetic theory of gases, the following gas equation was derived

$$pV = \frac{1}{3} mnv_{\text{rms}}^2$$

where, p = pressure exerted by the gas

V = volume of the gas

m = average mass of each molecule

n = number of molecules

v_{rms} = root mean square velocity of the gas.

Calculation of kinetic energy, According to kinetic gas equation

$$pV = \frac{1}{3} mnv_{\text{rms}}^2$$

But $\quad pV = RT$

and, for 1 mole of a gas, $n = N$ (Avogadro's number)

$$\therefore \quad RT = \frac{1}{3} mNv_{\text{rms}}^2 = \frac{1}{3} Mv_{\text{rms}}^2 \qquad (\because\ m \times N = M)$$

$$= \frac{2}{3} \cdot \frac{1}{2} Mv_{\text{rms}}^2 = \frac{2}{3} \cdot \text{KE} \qquad \left[\because\ E = \frac{1}{2} mv^2\right]$$

$$\therefore \quad \text{KE} = \frac{3}{2} RT$$

Average kinetic energy per molecule

$$= \frac{\text{average kinetic energy per mole}}{N}$$

$$= \frac{3}{2} \frac{RT}{N} = \frac{3}{2} \cdot \frac{R}{N} \cdot T = \frac{3}{2} kT$$

where, $k = \frac{R}{N}$ = constant and is known as **Boltzmann constant**. Its numerical value is 1.38×10^{-23} J/mol-K.

Maxwell generalisation From $\text{KE} = \frac{3}{2} RT \Rightarrow \text{KE} \propto T$

$$\text{KE} = \frac{1}{2} mv_{\text{rms}}^2 \Rightarrow \text{KE} \propto v^2{}_{\text{rms}}$$

It gives, $\quad v_{\text{rms}}^2 \propto T$ or $v_{\text{rms}} \propto \sqrt{T}$

Hence, molecular velocity of a gas is directly proportional to the square root of the absolute temperature. When $T = 0$, $v_{\text{rms}} = 0$. Hence, at absolute zero temperature, all molecular motion ceases and total kinetic energy of the molecules is zero.

Above relations shows that KE of a gas is independent of nature, pressure and volume of the gas, but depends on the temperature. This is known as *Maxwell generalisation*.

***Sample* Problem 14** *At what temperature is the kinetic energy of a gas molecule becomes half of its value at 327°C?*

(*a*) 27 *K* (*b*) 27°C (*c*) 927 *K* (*d*) 927°C

Interpret (*b*) From kinetic energy, $E = \frac{3}{2} RT$, we have

$$\frac{E_1}{E_2} = \frac{\frac{3}{2} RT_1}{\frac{3}{2} RT_2} \Rightarrow \frac{1}{\frac{1}{2}} = \frac{600}{T_2}$$

$$T_2 = 300\ \text{K} = 27°\ \text{C}$$

2.5 Molecular Velocities

Different kinds of velocities of molecules can be calculated. These are

Average Velocity ($\overline{V}$)

It is the arithmetic mean of the various speeds of the molecules.

Let there be 'N' molecules of gas having velocities $v_1, v_2 \ldots\ldots, v_N$.

Then, average velocity, $\bar{v}(\text{or } v_{av}) = \dfrac{v_1 + v_2 + \ldots.. + v_N}{N}$

Maxwell established that $v_{av} = \sqrt{\dfrac{8RT}{\pi M}} = \sqrt{\dfrac{8KT}{\pi M}}$

Root Mean Square Velocity (u or v_{rms})

It is the square root of the mean of the squares of the velocity of a larger number of molecules of the same gas.

$$u = \sqrt{\frac{v_1^2 + v_2^2 + \ldots + v_N^2}{N}}$$

From the kinetic gas equation, we find that

$$u = \sqrt{\frac{3RT}{M}} = \sqrt{\frac{3KT}{M}} = \sqrt{\frac{3p}{d}}$$

For the same gas at two different temperatures, the ratio of RMS velocity will be $\dfrac{u_1}{u_2} = \sqrt{\dfrac{T_1}{T_2}}$

For two different gases at the same temperature, the ratio of RMS velocities will be $\dfrac{u_1}{u_2} = \sqrt{\dfrac{M_2}{M_1}}$

Caution Point *The gas with high RMS velocity with have high rate of diffusion while the gas with high molecular weight will have low RMS velocity.*

Most Probable Velocity (v_p)

It is the velocity, which the largest number of molecules possess.

$$v_p = \sqrt{\frac{2RT}{M}} = \sqrt{\frac{2pV}{M}} = \sqrt{\frac{2p}{d}}$$

Caution Point *With increase in temperature, most probable velocity increases but fraction possessing it decreases.*

Relation between different molecular velocities

$$v_p : v_{\text{av}} : u = \sqrt{\frac{2RT}{M}} : \sqrt{\frac{8RT}{\pi M}} : \sqrt{\frac{3RT}{M}}$$

$$= \sqrt{2} : \sqrt{\frac{8}{\pi}} : \sqrt{3} = 1 : 1.128 : 1.224$$

Therefore, $v_p < \bar{v} < u$.

We also get, $v_p = 0.816\,u, \bar{v} = 0.9213\,u$ or $u = 1.085 \times \bar{v}$

Sample **Problem 15** *The ratio of most probable velocity to that of average velocity is*

(a) $\dfrac{\sqrt{\pi}}{2}$ (b) $\dfrac{2}{\pi}$ (c) $\dfrac{2}{\sqrt{\pi}}$ (d) $\dfrac{\pi}{2}$

Interpret (a) $\dfrac{V_p}{V_{\text{av}}} = \dfrac{\sqrt{\dfrac{2RT}{M}}}{\sqrt{\dfrac{8RT}{\pi M}}} = \dfrac{\sqrt{\pi}}{2}$

Sample **Problem 16** *The ratio between the root mean square velocity of* H_2 *at 50 K and that of* O_2 *at 800 K is*

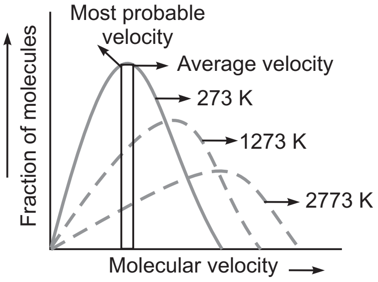
(a) 1 (b) 4 (c) 2 (d) 1/4

Interpret (a) $\dfrac{v_{H_2}}{v_{O_2}} = \sqrt{\dfrac{T_{H_2}}{T_{O_2}} \cdot \dfrac{M_{O_2}}{M_{H_2}}} = \sqrt{\dfrac{50}{2} \cdot \dfrac{32}{800}} = 1$

Maxwell's Distribution of Molecular Speeds (Velocities)

Maxwell and Boltzmann proposed that gas molecules are always in rapid random motion colliding with each other and with the walls of container. Because of such collisions, their velocities change. A fraction of molecules have a particular molecular velocity at a time. James Clark Maxwell calculated the distribution of velocity among fraction of total number of molecules, on the basis of probability.

The distribution of velocities of different gas molecules may be shown by the following curve.



From the curve it may be concluded that

(i) Only a small fraction of molecules have either very low or very high velocity.
(ii) Curve becomes flat when temperature is raised *i.e.,* distribution around average velocity becomes wider. Average molecular velocity increases with rise in temperature.
(iii) Most of the molecules have velocity close to most probable velocity, represented by the top of the curve.
(iv) At higher temperature, greater number of molecules have high velocity, while few molecules have lower velocity.

2.6 Ideal and Real Gases

The gas which obeys gas laws is called an **ideal gas,** while others are **real gases.** Real gases obey the gas laws under moderate conditions of temperature and pressure. *At very low temperature and high pressure, the real gases show considerable deviation from the ideal gas behaviour* (*i.e.*, ideal gas laws).

Table 2.2 **Differences Between Ideal and Real Gases**

S. No.	Ideal Gas	S. No.	Real Gas
1.	An ideal gas obeys all the gas laws at all temperatures and pressures.	1.	A real gas obeys gas laws only at very low pressures and high temperatures.
2.	The volume of molecules is negligible as compared to the total volume of the gas.	2.	The volume of molecules is not negligible.
3.	Attractive forces among the molecules do not exist.	3.	Attractive forces among the molecules do not exist particularly at high pressures and low temperatures.
4.	It obeys the equation of state $pV = nRT$.	4.	It satisfies the van der Waals' equation $\left(p + \frac{a_{n^2}}{V^2}\right)(V - nb) = nRT$
5.	It is hypothetical.	5.	All existing gases are real.

Cause of Deviation from Ideal Behaviour

The ideal gas laws were derived from following two assumptions of kinetic theory of gases which did not hold good in all conditions

(i) The intermolecular forces of attraction between gaseous molecules is negligible.

(ii) The volume occupied by the gas molecules is negligible in comparison to the total volume of the gas.

(a) Evidence for Molecular Attraction

If assumption (i) is correct, the gas will never liquefy. However, we know that gases do liquefy when cooled and compressed. The molecules of gases have weak van der Waals' forces of attraction. This is also supported by the fact that when a compressed gas is passed through a porous plug of silk or cotton in adiabatic conditions, the emerging gas is found to be cooler than the entering gas (**Joule-Thomson effect**). This is because on expansion some work has to be done against the internal forces of attraction, which requires energy. This energy comes from the system itself.

(b) Evidence for Molecular Volume

The molecules of a gas, however, do occupy a certain volume as can be seen from the fact that gases can be liquefied and solidified at a low temperature and high pressure. In the solid state, however, there is a considerable resistance to any further attempt at compression. It is, therefore, apparent that the molecules of a gas must have an appreciable volume, which is probably of the same order as that occupied by the same number of molecules in the solid state.

Compressibilty Factor : Explanation Deviation from Ideal Behaviour

The deviation of gases from ideal behaviour can be understood better by evaluating the effect of pressure and temperature on *compressibility factor* (Z) *i.e.,* $Z = \frac{pV}{RT}$, for one mole of gas. *When*

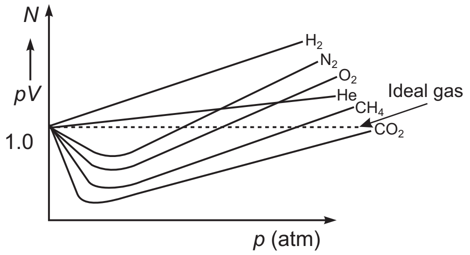
(i) $Z = 1$, the gas is ideal at all temperatures and pressures.

(ii) $Z > 1$, the gas is less compressible than expected from ideal behaviour and shows *positive deviation*, usually at high pressure, *i.e.,* $pV > RT$.

(iii) $Z < 1$, the gas is more compressible than expected from ideal behaviour and shows *negative deviation*, usually at low pressure, *i.e.,* $pV < RT$.

The extent of deviation at any given temperature depends upon the nature of the gas. For example, CO_2 and N_2 are more compressible at low pressures and show negative deviation, but they are less compressible at high pressures and show positive deviation.

Variation of Z with pressure for different gases is shown in the following graph drawn at a constant temperature (300 K).



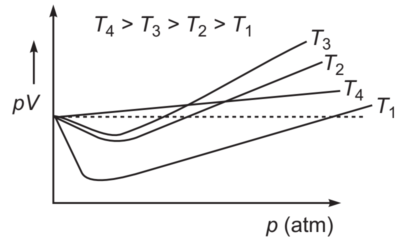
Variation of Z with pressure for different gases

It may be noted from the figure that the value of Z is approximately 1 at very low pressure (up to 10 atm). For H_2 and He the value of Z is always greater than 1 while the value first decreases and then increases for other gases.

Above graph shows the regions where two effects (attraction forces and size) predominate. For hydrogen at 0°C, the molecular attractive forces are weak and the size effect dominates its behaviour. For N_2 at 0°C, the attractive forces are large enough to cause negative deviation $\left(Z\left(= \frac{pV}{nRT}\right) < 1\right)$ up to about 150 atm, beyond which the size effect dominates $(Z < 1)$. For CO_2, intermolecular attraction is large even at 40°C. In N_2 and CO_2, the two effects compensate each other at 150 atm and 600 atm respectively and thus $Z = 1$.

At very low pressure, gas molecules are widely separated and both these effects become negligible. At high temperatures, molecules have greater kinetic energy, and attractive forces are smaller and the behaviour of gases is close to the ideal gas behaviour.

The variation of Z with temperature is shown in the following graph



Variation of Z with temperature

It may be noted that at high temperature, the curve approaches more and more to the ideal nature. **The temperature at which $\frac{pV}{RT}$ is unity for a gas up to appreciable range of pressure is called Boyle's temperature (T_b).**

$$\text{Boyle's temperature } (T_b) = \frac{a}{bR} = \frac{1}{2} T_i$$

Where a and b are van der Waals' constant and T_i is called *inversion temperature*.

Easily liquefiable gas has high T_b (T_b for $O_2 = 40$ K). The gases, which are difficult to liquefy have low T_b (T_b for H_2 23 K).

Caution Points

1. *The gases having low critical temperature are called permanent gases. While gases above critical temperature and under high pressure are known as supercritical fluids.*
2. *Ideal gases do not show any cooling or heating on adiabitic expansion becomes there are no intermolecular forces of attraction present in them.*

2.7 van der Waals' Equation

To rectify the errors caused by ignoring the intermolecular forces of attraction and the volume occupied by molecules, **Johannes van der Waals'** proposed following equation, which is valid for real gases upto a large range of temperature and pressure

$$\left(p + \frac{n^2a}{V^2}\right)(V - nb) = RT$$

where, a and b are constants and are called correction terms for pressure and volume.

Constant 'a' is a indirect measure of magnitude of attractive forces between the molecules. **Greater is the value of 'a', more easily the gas can be liquefied.**

Unit of a are at $mL^2\ mol^{-2}$ or atm. $m^6\ mol^{-2}$ or $Nm^4\ mol^{-2}$.

The constant b is introduced to correct that portion of gas which is not compressible. It is also called **excluded volume** or **co-volume.** If closest distance of approach of two molecules be $2r$, (r is the radius of one molecule), the excluded volume for two molecules is

$$\left(\frac{4}{3}\right) \pi (2r)^3 = 8\left(\frac{4}{3}\pi r^3\right) = 8 \times \text{volume of one molecule}$$

Hence, for one molecule the excluded volume, $b = 4 \times \left(\frac{4}{3}\pi r^3\right)$

For N molecules,

$$b = N \times \text{total volume of one molecule, or } b = 4N\left(\frac{4}{3}\pi r^3\right)$$

b is measured in cm^3/mol or $L\ mol^{-1}$ or $m^3\ mol^{-1}$.

Significance of van der Waals' Constants

Since an easily liquefiable gas has greater intermolecular attraction, hence the value of 'a' is a measure of the intermolecular attraction. In other words, we can say that the value of 'a' indicates the strength of van der Waals' forces. Thus, for high value of 'a', the ease with which a gas can be liquefied will be high. The easily liquefiable gases (like SO_2, NH_3, H_2S, CO_2 etc.) have high value of 'a' than the permanent gases (such as H_2, N_2, O_2, etc).

The constant value of 'b' for any gas indicates that the gas molecules are incompressible.

Sample Problem 17 *N_2 molecule is spherical with radius 100 pm. The value of van der Waals' constant b and the actual volume of the gas at STP are respectively*

(a) $1.0 \times 10^{-2}, 2.2 \times 10^3$ (b) $1.0 \times 10^{-3}, 2.2 \times 10^4$

(c) $1.0 \times 10^{-2}, 2.2 \times 10^4$ (d) $1.0 \times 10^{-3}, 2.2 \times 10^3$

Interpret (c) $100\ \text{pm} = 100 \times 10^{-12}\ \text{m} = 1 \times 10^{-8}\ \text{cm}$

(i) Volume of N_A molecules, $V = \frac{4}{3}\pi r^3 N_A$

$$= \frac{4}{3} \times \frac{22}{7} \times (1 \times 10^{-8})^3 \times 6.022 \times 10^{23}$$

$$= 2.52\ \text{cm}^3 = 2.52 \times 10^{-3}\ \text{dm}^3\ \text{mol}^{-1}$$

$$b = 4V = 4 \times 2.52 \times 10^{-3}\ \text{dm}^3\ \text{mol}^{-1}$$

$$= 10.08 \times 10^{-3}\ \text{dm}^3\ \text{mol}^{-1}$$

Actual volume = volume at STP – volume occupied by molecules mol^{-1}

$$= 22400 - 2.52 = 22.397.48\ \text{cm}^3$$

Sample Problem 18 *The Boyle's law can't be used to calculate the volume of a real gas from its initial state to final state during adiabatic expansion because*

(*a*) *temperature increases*
(*b*) *pressure decreases*
(*c*) *pressure remains the same*
(*d*) *temperature decreases*

Interpret (*d*) No, we cannot use Boyle's law to calculate volume during adiabatic expansion because temperature is lowered during adiabatic expansion, *i.e.*, temperature does not remain constant, which violates Boyle's law.

Sample Problem 19 *Two van der Waals' gases have the same value of b but different values of a. Which of these will occupy greater volume under identical conditions? If the gases have the same value of a but different values of b, which of them will be more compressible?*

Interpret When two gases have the same value of *b* but different values of *a*, the gas having a larger value of *a* will occupy lesser volume. This is because the gas with a larger value of *a* will have larger foces of attraction and hence, lesser distance between its molecules.

When two gases have the same value of *a* but different values of *b*, the smaller the value of *b*, the larger the compressibility because the gas with the smaller value of *b* will occupy lesser volume and hence, will be more compressible.

Sample Problem 20 *The compression factor (compressibility factor) for* 1 *mole of a van der Waals' gas at* 0°*C and* 100 *atm pressure is found to be* 0.5. *Assuming that the volume of a gas molecule is negligible, the value of van der Waals' constant 'a' is*

(*a*) $0.253\ L^2 mol^{-2}$ *atm*
(*b*) $0.53\ L^2 mol^{-2}$ *atm*
(*c*) $1.251 L^2 mol^{-2}$ *atm*
(*d*) $1.83\ L^2 mol^{-2}$ *atm*

Interpret (*c*) From, $Z = \frac{pV}{nRT}$

$$0.5 = \frac{100 \times V}{1 \times 0.0821 \times 273}$$

$$V = 0.112 \text{ L}$$

Now from van der Waals' equation,

$$\left(p + \frac{a}{V^2}\right)(V - b) = RT$$

$$\left\{100 + \frac{a}{(0.112)^2}\right\}(0.112 - 0) = 0.0821 \times 273$$

$$\left(100 + \frac{a}{0.0125}\right) \times (0.112) = 22.4133$$

$$100 + \frac{a}{0.0125} = 200.1187$$

$$\frac{a}{0.0125} = 100.1187$$

$$a = 100.1187 \times 0.0125$$

$$= 1.2515 \text{ L}^2 \text{ mol}^{-2} \text{ atm}$$

Sample Problem 21 *For real gases the relation between p,V and T is given by van der Waals' equation* $\left(p + \frac{an^2}{V^2}\right)(V - nb) = nRT$ *where, 'a' and 'b' are van der Waals' constants, 'nb' is approximately equal to the total volume of the molecules of a gas, 'a' is the measure of magnitude of intermolecular attraction.*

(i) Arrange the following gases in the increasing order of 'b'.

O_2, CO_2, H_2, He

(*a*) $O_2 < CO_2 < He < H_2$
(*b*) $He < H_2 < O_2 < CO_2$
(*c*) $H_2 < He < CO_2 < O_2$
(*d*) $H_2 < He < O_2 < CO_2$

(ii) Arrange the following gases in the decreasing order of magnitude of 'a'. [**NCERT**]

CH_4, O_2, H_2

(*a*) $CH_4 > O_2 > H_2$
(*b*) $CH_4 > H_2 > O_2$
(*c*) $H_2 > CH_4 > O_2$
(*d*) $O_2 > CH_4 > H_2$

Interpret (i) (*d*) Molar volume occupied by the gas molecules is proportional to the size of molecules and van der Waals' constant '*b*' represents molar volume of the gas molecules. Hence, value of '*b*' increases in the following order

$$H_2 < He < O_2 < CO_2$$

(ii) (*a*) van der Waals' constant '*a*' is the measure of magnitude of intermolecular attraction. The magnitude of intermolecular attractions increases with increase in size of electron cloud in a molecule. Hence, for the given gases, magnitude of '*a*' decreases in the following order

$$CH_4 > O_2 > H_2$$

Greater the size of electron cloud, greater is the polarisability of the molecule and greater is the dispersion forces or London forces.

Hot Spot

VAN DER Waals' Equation at Different Conditions

Although the chapter is not very important for JEE Main examination but the questions if asked may be based on this topic as it is some what more important than the others topics of this chapter. The level of questions vary from easy to average.

(a) When Pressure is Low

At low pressure, volume V is very large and hence, the correction term b (a constant of small value) can be neglected in comparison to very large value of V. Hence, it can be neglected from van der Waals' equation for 1 mole of gas, *i.e.,*

$$\left(p + \frac{a}{V^2}\right)(V - b) = RT$$

$$\left(p + \frac{a}{V^2}\right)V = RT$$

$$pV + \frac{a}{V} = RT$$

$$pV = RT - \frac{a}{V} \text{ or } \frac{pV}{RT} = 1 - \frac{a}{VRT}$$

or $$Z = 1 - \frac{a}{VRT} = \frac{pV}{RT}$$

where, Z is compressibility factor.

At extremely low pressure At extremely low pressure, V is very large, therefore, the value of $\frac{a}{V}$ is very small and hence, can be neglected. Thus,

$$pV = RT$$

This explains why the real gases behaviour ideally at extremely low pressure.

(b) When Pressure is High

At high pressure, volume V is quite small and hence, the term b cannot be neglected in comparison to V. Again, as the term $\frac{a}{V^2}$ is quite large but it is so small in comparison to high pressure p that it can be neglected. Thus, the van der Waals' equation may be written as

$$p(V - b) = RT$$

$$pV = RT + pb$$

or $$\frac{pV}{RT} = 1 + \frac{pb}{RT} \text{ or } Z = 1 + \frac{pb}{RT}$$

(c) When Temperature is High

At any given pressure, if the temperature is extremely high, V is very large and hence, the terms $\frac{a}{V^2}$ and b can be neglected. Thus, the van der Waals' equation reduces to

$$pV = RT$$

This explains why the real gases behave like ideal gas at high temperature.

(d) When Temperature is Low

At low temperature both p and V are small, hence both pressure and volume corrections are appreciable, so that the deviations are more pronounced.

Merits of van der Waals' Equation

(i) This equation explains behaviour of real gases upto moderately high pressure.

(ii) This equation represents the trend of the isotherms representing the variation of pV with p for various gases.

(iii) With the help of this equation, values of Boyle's temperature, critical constants and inversion temperatures may be calculated in terms of 'a' and 'b'.

(iv) This equation is also helpful in obtaining a 'reduced equation of state' which being a general equation of state has the advantage that a single curve can be obtained for all gases when the equation is graphically represented by plotting the variables.

Limitations of van der Waals' Equation

(i) Although van der Waals' equation is much more accurate than the ideal gas equation, appreciable deviation at too low temperatures and pressures have been observed.

(ii) The values of van der Waals' constant 'a' and 'b' do not remain constant over the entire ranges of temperature and pressure.

Hence, van der Waals' equation is valid only over specific range of temperature and pressure.

2.8 Liquefaction of Gases

A gas can be liquefied when its temperature is below critical temperature, *i.e.*, by cooling or compressing it.

As a gas is compressed at a given temperature, the intermolecular distance decreases and intermolecular forces come into effect. The motion and hence, kinetic energy of the molecules gradually decreases and the gas is said to be undergoing *liquefaction*. During liquefaction, the pressure remains constant. The process of liquefaction spreads over a definite time interval.

Gases which have high critical temperatures (such as CO_2, SO_2, NH_3, Cl_2 etc.) can be liquefied by applying a suitable pressure alone. Permanent gases (such as H_2, N_2, O_2 etc.) cannot be liquefied by the action of pressure and cooling.

A gas can be liquefied by "lowering the temperature" or "increasing the pressure".

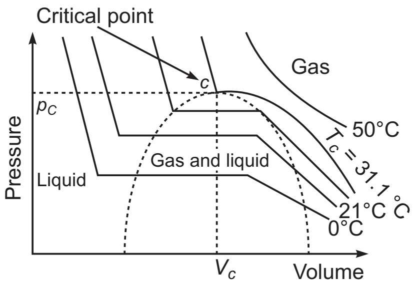


Fig. 2.6 Isotherms of CO_2 at different temperatures

Methods of Liquefaction of Gases

Two modern methods of cooling the gas to or below their T_c and hence of liquefaction of gases are Linde's method and Claude's method.

(a) Linde's Method

This process is based upon Joule-Thomson effect which states that "When a gas is allowed to expand adiabatically from a region of high pressure to a region of extremely low pressure, it is accompanied by cooling."

(b) Claude's Method

This process is based upon the principle that when a gas expands adiabatically against an external pressure (as a piston in an engine), it does some external work. Since work is done by the molecules at the cost of their kinetic energy, the temperature of the gas falls causing cooling.

Caution Point Adiabatic demagnetisation is also used to liquefy a gas.

Uses of Liquefied Gases

Liquefied gases compressed under a high pressure are of great importance in industries such as

(i) Liquid ammonia and liquid sulphur dioxide are used as refrigerants.
(ii) Liquid carbon dioxide finds use in soda fountains.
(iii) Liquid chlorine is used for bleaching and disinfectant purposes.
(iv) Liquid air is an important source of oxygen in rockets, jet-propelled planes and bombs.
(v) Compressed oxygen is used for welding purposes.
(vi) Compressed helium is used in airships.

Critical State

A state for every substance at which its vapour and liquid states are indistinguishable is known as *critical state*.

At this state, following conditions are achieved

Critical Temperature

There is a temperature below which the gas can be liquefied but above it the gas defies liquefaction. This temperature is called critical temperature (T_c).

It is given by,

$$T_c = \frac{8a}{27Rb}$$

Critical Pressure

The critical pressure (p_c) is the minimum pressure required to liquefy the gas at its critical temperature. It is given by, $p_c = \dfrac{a}{27b^2}$

Critical Volume

The critical volume (V_c) is the volume occupied by a mole of the gas at the critical temperature and critical pressure. It is given by $V_c = 3b$

From the above, the critical compressibility factor (Z_c) is given by

$$Z_c = \frac{p_c V_c}{RT_c} = \frac{3}{8} = 0.375$$

All the gases behaves as a van der Waals' gas if its critical compressibility factor (Z_c) is equal to 0.375.

Sample Problem 22 *The value of critical temperature, T_c and critical pressure, p_c for some gases are given, which of the gases can be liquefied at 100 K and 50 atm?*

Gases	A	B	C	D
p_c (atm)	2.2	14	35	45
T_c (K)	5.1	33	127	140

(a) *D only* (b) *A only*
(c) *A and B* (d) *C and D*

Interpret (c) For liquefaction, the critical temperature, T_c must be less than 100 K.

The gases *A* and *B* have low values of critical temperature, thus these can be liquefied at 100 K.

2.9 Joule-Thomson Effect

According to Joule-Thomson, when a real gas is allowed to expand adiabatically through a porous plug or a fine hole into a region of low pressure, it is accompanied by cooling (except for hydrogen and helium which get warmed up)."

Cooling takes place because some work is done to overcome the intermolecular forces of attraction. As a result, the internal energy decreases and so does the temperature.

Ideal gases do not show any cooling or heating because there are no intermolecular forces of attraction, *i.e.,* they do not show Joule-Thomson effect.

During Joule-Thomson effect, enthalpy of the system remains constant.

Joule-Thomson coefficient, $\mu = \left(\frac{\partial T}{\partial p}\right)_H$.

For cooling, $\mu = +$ ve (because dt and dp will be $-$ve)

For heating, $\mu = -$ ve (because $dt = +$ ve, $dp = -$ ve)

For no heating or cooling, $\mu = 0$ (because $dT = 0$).

Check Point 2

1. What is the significance of different values of Boyle's temperature, T_b ?
2. On comparing the values of the van der Waals' constants for NH_3 and N_2, the value of '*a*' is larger for NH_3 but that of '*b*' is larger for N_2. Why?
3. Explain why ideal gases do not show any cooling or heating?

2.10 Liquid State

It is the state of matter in which the molecules are held close to each other and execute random motion through intervening spaces. Most of the physical properties of liquids are controlled by the strengths of intermolecular attractive forces.

On the basis of kinetic molecular theory of liquids, liquids may be described as

(i) A liquid is made up of molecules.

(ii) Molecules of a liquid are closely packed.

(iii) There are appreciable cohesive forces between the molecules.

(iv) The molecules are in constant random motion and slide upon one another.

(v) Liquids are virtually incompressible.There are very slight changes in volume with change in temperature or pressure. This is due to strong forces of attraction and very small free space available in liquids.

(vi) The average kinetic energy of the molecules in liquid is proportional to its Kelvin temperature.

(vii) Normal boiling point (T_b) of the liquid is nearly two-thirds of its critical temperature (T_c) when both are expressed on the absolute scale. This is called **Guldberg's rule.**

$$T_b = \frac{2}{3} T_c$$

(viii) For non-associated liquids which do not have too high boiling points, the ratio of the heat of vaporisation (in joules) to the normal boiling point of the liquid on the absolute scale is approximately equal to 88. *i.e.,* $\frac{\Delta H_v}{T_{bp}} \approx 88 \text{ J K}^{-1} \text{ mol}^{-1}$ or 21 cal K^{-1} mol^{-1}. The above statement is called *Trouton's rule.*

The liquids exhibit following characteristic properties

1. Shape and Volume

The liquid state is intermediate in character between the complete molecular randomness (in gases) and the orderly arrangement of molecules (in crystalline solids). In liquids, the molecules are moving sufficiently slow for the intermolecular forces of attraction to hold them together in a **definite volume.**

However, the molecular motion is too rapid for the attraction force to fix the molecules into definite positions of a crystal lattice. *Hence a liquid retains its volume but not its shape*. The liquid therefore, flows to assume the shape of the container in which it is placed.

2. Density

The molecules in a liquid are closely packed, thus their densities are many times more than the vapours. However, the density is low as compared to solids. An increase in temperature increases the volume of most liquids slightly and consequently decreases the liquid density.

3. Evaporation

The process of change of liquids into vapour at any temperature below the boilng point is termed as *evaporation*. Like gases, the liquids too have a distribution of kinetic energy ranging from very low values to very high values. As a result of this, the highly energetic fractions of molecules at the surface overcome the intermolecular attraction and escape as vapour.

Kinetic energy of a given molecule of a liquid is continuously changing as it colloids with other molecules, but at any given instance some of the molecules of total collection, have relatively high energies and some have relatively low energies. The molecules with kinetic energies sufficiently high to overcome the attractive forces of surrounding molecules, can escape from the liquid and enter the gas phase.

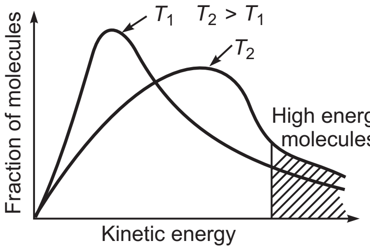

Fig. 2.7 Kinetic energy distribution in liquids

The loss of a number of high energy molecules causes the average kinetic energy of the molecules remaining in liquid to fall and temperature of liquids falls proportionately.

The rate of evaporation increases as the temperature is raised, since the average kinetic energy of molecules increases.

Heat of Vaporisation and Condensation

The evaporation of a liquid involves the loss of energy by the liquid, thus the temperature of the remaining liquid would fall. The heat required to evaporate a unit mass of a given liquid at constant temperature is called the *heat of vaporisation.*

The value of heat of vaporisation generally **decreases with increase in temperature reaching zero at the critical temperature.** The heat of vaporisation depends on the strength of intermolecular forces.

The reverse of evaporation is **condensation.** The heat corresponding to this process is called the **heat of condensation** and is numerically equal to heat of evaporation.

Molar Heat of Vaporisation (ΔH_v)

When a liquid and its vapour are in equilibrium, the temperature of vapour and the temperature of liquid are same. Hence, molecules in each phase have same kinetic energy, however the two phases differ in total internal energy.

When the liquid is converted into gas, energy must be supplied to separated the molecules. Thus, the energy of the gas phase is higher than that of the liquid phase by the amount of this difference. Also the volume of a gas is considerably larger than the volume of the liquid from which it is derived hence, energy must be supplied to do the work to make room for the vapour by pushing back the atmosphere.

The heat of vaporisation includes both, the energy required to overcome intermolecular cohesive forces and the energy needed to expand the vapour.

The molar heat of vaporisation (ΔH_v) decreases with increase in temperature and $\Delta H_v = 0$ at critical temperature. At the critical temperature, all the molecules have sufficient energy to vaporise.

4. Vapour Pressure

The process by which molecules of liquids go into the gaseous state (vapour) is called *vaporisation* or **evaporation.** The reverse process whereby gas molecules become liquid molecules is called **condensation.**

There is a dynamic equilibrium estabilished between the liquid and the vapour at a given temperature.

$$\text{Liquid} \rightleftharpoons \text{Vapour}$$

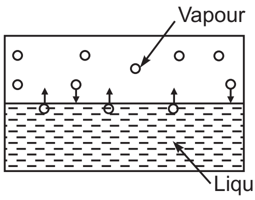

Fig. 2.8 Equilibrium between liquid and gaseous state

The pressure exerted by the vapours in equilibrium with liquid at a fixed temperature is called *vapour pressure*.

The vapour pressure of liquids depends on the type of intermolecular forces operating among the molecules *e.g.*, ethanol will have higher vapour pressure than water at a given temperature, as ethanol has a weaker hydrogen bonding than water.

Assuming vapour to be acting as an ideal gas, the pressure of the vapour at a given temperature 'T' is given by

$$pV = nRT$$

$$p = \frac{n}{V} RT = CRT$$

where 'C' is concentration of vapour (in mol/L). Variation of vapour pressure with temperature is also given by *Clausius Clapeyron equation* as

$$\log_{10} \frac{p_2}{p_1} = \frac{\Delta H_{\text{vap}}}{2.303R}\left(\frac{1}{T_1} - \frac{1}{T_2}\right)$$

The vapour pressure increases with rise in temperature. This is so because at higher temperature more molecules in liquids will have the larger kinetic energy and will break away from the liquid surface.

Caution Point *Since evaporation is a surface phenomenon, the increase in surface area increases the rate of evaporation/vapour pressure.*

Sample **Problem 23** *Two vessels have different base area. They are filled with water to the same height. If the amount of water in one be 4 times that in the other, then the ratio of pressure on their bottoms will be*

(*a*) 4 : 1
(*b*) 1 : 1
(*c*) 8 : 1
(*d*) 16 : 1

Interpret (*b*) Pressure depends only on the height of liquid column.

5. Boiling Point

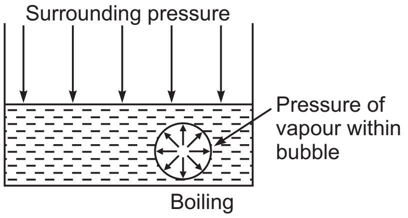

Fig. 2.9 Boiling of a liquid

When a liquid is heated, tiny bubbles are formed in it throughout the volume. These rise to the surface and burst. The liquid is said to be *boiling* and the temperature at which it happens is called the *boiling point* of the liquid.

The pressure within the bubble is equal to the vapour pressure of the liquid at that temperature. When the vapour pressure of the liquid is equal to the external pressure acting on the surface of the liquid, the bubbles increases in size and burst. Hence, *the boiling point is the temperature at which the vapour pressure becomes equal to the surrounding pressure.*

The boiling point of a liquid can be lowered by reducing the external pressure and can be increased by raising the external pressure.

The domestic pressure cookers work on this principle. The pressure inside the pressure cooker is maintained above one atmosphere and the liquid contained then would boil at a higher temperature than 100° C thus, the food is cooked in a shorter time.

Sample **Problem 24** *A person living in Shimla observed that cooking food without using pressure cooker takes more time. The reason for this observation is that at high attitude.*

[**NCERT** Exemplar]

(*a*) *pressure increases* (*b*) *temperature decreses*
(*c*) *pressure decreases* (*d*) *temperature increases*

Interpret (*c*) Food takes more time to cook that means its vapour pressure becomes equal to atomspheric pressure at a lower temperature. That is at high altitude, pressure is lower or pressure decreases (as $p \propto T$ at constant v and n)

6. Surface Tension

A molecule in the interior of a liquid is attracted equally in all directions by the molecules around it. However, a molecule on the surface of a liquid is attracted only sideways and towards the interior. The liquid surface is, therefore, under tension and tends to contract to the smallest possible area in order to have the minimum number of molecules at the surface. The surface acts like a stretched membrane. The force acting along the surface of a liquid at right angle to any line per unit length is called *surface tension.*

$$\text{Surface tension, } Y = \frac{\text{work } (W)}{\text{change in area } (\Delta A)} = \frac{\text{Force } (F)}{\text{Length } (L)}$$

In order to increase the surface area, force must be exerted to overcome the surface tension. The work (energy) required to expand the surface of a liquid by unit area may also be defined as *surface tension.*

Unit of surface tension is N/m.

Effects of Surface Tension

(i) Due to surface tension a liquid tends to have a minimum surface area. For a given volume of a liquid, sphere has the minimum surface area. Therefore, **the small drops of liquids are spherical.**

(ii) Due to surface tension, liquids rise or fall in capillary tubes.

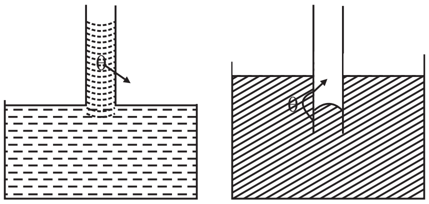

Fig. 2.10 Rise of liquid in capillary tube

The height of liquids in column rise in the capillary is given by

$$h = \frac{2T \cos\theta}{r\rho g}$$

where, r = radius of capillary,
ρ = the density of liquid,
T = the surface tension and
θ = contact angle.

(iii) Cleaning action of soap and detergents is due to lowering of interfacial tension between water and greasy substances.

(iv) Efficiency of toothpaste, nasal jellies and mouth washed depends, in part, on the fact that they contain substances, which can lower surface tensions.

Characteristics of Surface Tension

Important characteristics of surface tension are

(i) It decreases with rise in temperature up to the critical temperature of the liquid at which there is no distinction. Variation of Y with temperature is given by **Evtvos equation.**

$$Y\left(\frac{M}{d}\right)^{2/3} = K(t_c - t)$$

where, M = molar mass, d = density,
t = temperature in °C
t_c = critical temperature

(ii) Addition of a surface active agent (*e.g.,* soap) decreases surface tension.

(iii) Surface tension is different for different liquids due to different intermolecular forces.

(iv) It results in rise and fall of liquid in capillary tube. This is called **capillary action.** Adhesive forces between liquid and walls of tube tend to increase surface area of liquid. The surface tension tends to reduce area, thereby pulling the liquid up in tube. The liquid climbs until the adhesive and cohesive forces are balanced by force of gravity.

- (i) If adhesive forces are stronger than cohesive forces → **meniscus acquires U-shape.**
- (ii) If cohesive forces are stronger than adhesive forces → **meniscus is convex.**

Sample Problem 25 *A liquid of density* $850\,kg/m^3$ *having a surface tension of* 0.055 *N/m, will rise how far in a glass capillary of* 1.40 *mm inside diameter?*

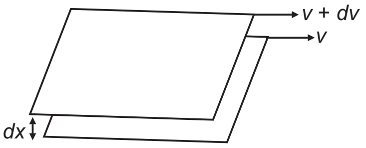
(a) 21 *mm* (b) 32 *mm* (c) 19 *mm* (d) 24 *mm*

Interpret (c) $h = \dfrac{2Y}{rgd} = \dfrac{2 \times 0.055}{0.70 \times 10^{-3} \times 850 \times 9.8}$

$= 0.019\ \text{m} = 19\ \text{mm}$

7. Viscosity and Fluidity

Different liquids flow at different rates, *e.g.*, glycerine and honey flow very slowly while ether and water flow rapidly. The property of liquid, which determines their rate of flow is called *viscosity* of the liquid. A liquid may be considered to be consisting of molecular layer arranged one over the other. The friction forces between the layers (the van der Waals' force of intermolecular attraction) offer resistance to flow of liquids when a shearing force is applied. *Viscosity of a liquid is a measure of its frictional resistance.*



Consider a liquid flowing on a glass surface. The molecular layer in contact with the stationary surface has zero velocity. The successive layers above it move with increasingly higher velocities.

Consider two adjacent layers of a liquid, separated by a distance dx, moving with velocities 'v' and $v + dv$. The force of friction (F) resisting the relative motion of two layers is proportional to the area 'A' of the layer and the velocity gradient $\left(\dfrac{dv}{dx}\right)$, *i.e.*,

$$F \propto A\,\frac{dv}{dx} \quad \text{or} \quad F = \eta\,A\,\frac{dv}{dx} \quad \text{or} \quad \eta = \frac{F}{A}\,\frac{dx}{dv}$$

Where, η is the proportionality constant known as *coefficient of viscosity*, which is constant for a given liquid at a given temperature.

$$\left(\frac{dv}{dx}\right) = \text{velocity gradient.}$$

The coefficient of viscosity (η) *may be defined as the force of resistance per unit area which will maintain unit velocity gradient between two liquid layers.*

With increase in temperature, viscosity of a liquid decreases as the rise in temperature results in increase in kinetic energy of molecules, thus the interlayer friction is reduced.

Units of viscosity $\eta = \dfrac{F}{A}\,\dfrac{dx}{dv} = \text{mass / length - time}$

In CGS system, unit of η is g/cm-s, this is called **poise.**

$$1\ \text{poise} = \frac{1}{10}\ \text{kg/m-s}$$

Viscosity (η) of a liquid decreases with rise in temperature. Variation of η with temperature, T is given by

$$\log_{10}\eta = \log_{10} A + \frac{E_a}{2.303\,RT}$$

The reciprocal of viscosity is called **fluidity** denoted by ϕ.

$$\phi = \frac{1}{\eta}$$

Effects of Viscosity

(i) Lubricating oils are graded according to their viscosity. For good quality of all weather lubricants **long chain coiling polymers** are added to the oil, which uncoil on increasing the temperature thus viscosity of oil also increases.

(ii) In **arteriosclerosis,** the arterial walls contract and get hardened resulting in decrease of the diameter of capillaries, which then offer resistance to the flow of blood due to its viscosity. This result in a condition of high blood pressure and strain on the heart.

(iii) In fever, an increased circulation of blood is needed. Rise of body temperature decreases the viscosity of blood by about **3% per degree kelvin**. Lowering of viscosity result in a more flow of blood without any extra strain on the heart.

(iv) In case of **asphyxia,** concentration of carbon dioxide in blood increases. This result in swelling of the corpuscles thereby increasing the viscosity of the blood.

Check Point 3

1. Water menisus in a glass tube is concave while that of mercury is convex, why?
2. Why does the boiling point of liquid rise on increasing pressure?
3. All other factors being equal, which will cool to room temperature faster, a closed container of water of 100°C or an open container of water at 100°C?
4. Why are drops of liquids spherical in nature?

WORKED OUT

Examples

Example 1 1.22 *g of a gas measured over water at* 15°C *and a pressure of* 775 *mm of mercury occupied* 900 *mL. Calculate the volume of dry gas at NTP (vapour pressure of water at* 15°C *is* 14 *mm).*

(a) 372.21 *mL* (b) 854.24 *mL*
(c) 869.96 *mL* (d) 917.76 *mL*

Solution (*b*) Pressure of dry gas = Pressure of moist gas − Vapour pressure of water

$$= 775 - 14 = 761 \text{ mm}$$

From,
$$\underset{\text{(initial)}}{\frac{p_1V_1}{T_1}} = \underset{\text{(NTP)}}{\frac{p_2V_2}{T_2}}$$

So,
$$V_2 = \frac{p_1V_1T_2}{T_1\,p_2} = \frac{761 \times 900 \times 273}{288 \times 760}$$

$$= 854.24 \text{ mL}$$

Example 2 *An open flask contains air at* 27°C. *The temperature at which it should be heated so that 1/3rd of air measured at* 27°C *escapes out will be*

(a) 450°*C* (b) 200°*C* (c) 177°*C* (d) −73°*C*

Solution (c) Let the initial number of moles of air at 27°C (300 K) be *n*

Number of moles of air left when the air is heated to the temperature $T\text{ K} = n - \frac{n}{3} = \frac{2n}{3}$

At constant pressure and constant volume,

$$n_1T_1 = n_2T_2$$

or
$$n \times 300 = \frac{2n}{3} \times T$$

or
$$T = 450 \text{ K} = (450 - 273) = 177°\text{ C}$$

Example 3 3.7 *g of a gas at* 25°C *occupied the same volume as* 0.184 *g of hydrogen at* 17°C *and at the same pressure. The molecular mass of the gas is*

(a) 0.024 (b) 39.14
(c) 41.33 (d) 59.14

Solution (c) For hydrogen,

$$w = 0.184 \text{ g},\ T = 17 + 273 = 290 \text{ K},\ M = 2$$

From
$$pV = \frac{w}{M}RT = \frac{0.184}{2} \times R \times 290 \qquad \text{...(i)}$$

For unknown gas,

$$w = 3.7 \text{ g},\ T = 25 + 273 = 298 \text{ K},\ M = ?$$

$$pV = \frac{3.7}{M} \times R \times 298 \qquad \text{...(ii)}$$

From Eqs. (i) and (ii)

$$\frac{3.7}{M} \times R \times 298 = \frac{0.184}{2} \times R \times 290$$

or
$$M = \frac{3.7 \times 298 \times 2}{0.184 \times 290} = 41.33$$

Example 4 *What percentage of a sample of nitrogen must be allowed to escape if its temperature, pressure and volume are changed from* 220°C, 3.0 *atm and* 1.65 *L to* 110°C, 0.7 *atm and* 1.0 *L respectively?*

(a) 18.13% (b) 34%
(c) 62% (d) 81.77%

Solution (*d*) From $pV = \frac{w}{m}RT$

$$w = \frac{pVm}{RT}$$

$$\text{Mass of gas before escaping} = \frac{3.0 \times 1.65 \times 28}{0.0821 \times 493} = 3.42 \text{ g}$$

$$\text{Mass of gas after escaping} = \frac{0.7 \times 1.0 \times 28}{0.0821 \times 383} = 0.62 \text{ g}$$

Percentage of nitrogen allowed to escape

$$= \frac{(3.42 - 0.62)}{3.42} \times 100 = 81.77\%$$

Example 5 *At* 27°C, *hydrogen is leaked through a tiny hole into a vessel for* 20 *min. Another unknown gas at the same temperature and pressure as that of hydrogen leaked through the same hole for* 20 *min. After the effusion of the gases the mixture exerts a pressure of* 6 *atm. The hydrogen content of the mixture is* 0.7 *mol. If the volume of the container is* 3 *L, the molecular mass of the unknown gas is*

(a) 2 (b) 10.33 (c) 103 (d) 1033

Solution (*d*) Let p_{H_2} and p_{un} be the partial pressures of hydrogen and unknown gas respectively and *w* be the number of moles of unknown gas.

From $$pV = nRT$$

$$p_{H_2} = \frac{0.7}{3} \times 0.0821 \times 300$$

$$p_{un} = \frac{w}{3} \times 0.0821 \times 300$$

Adding both,

$$p_{H_2} + p_{un} = \left(\frac{1}{3}\right) \times 0.0821 \times 300 \; (0.7 + w) = 6$$

$$6 = 8.21(0.7 + w)$$

$$0.7 + w = 0.7308$$

$$w = 0.0308 \text{ mol}$$

From Graham's law of diffusion,

$$\frac{\frac{0.7}{20}}{\frac{0.0308}{20}} = \sqrt{\frac{M}{2}} \quad \text{or} \quad M = 1033 \text{ g mol}^{-1}$$

Example 6 *The ratio of velocities of diffusion of gases A and B is* 1 : 4. *If the ratio of their masses present in the mixture is* 2 : 3, *the ratio of their mole fractions is*

(*a*) 1 : 4 (*b*) 1 : 24 (*c*) 4 : 1 (*d*) 24 : 3

Solution (*b*) $\frac{r_A}{r_B} = \sqrt{\frac{M_B}{M_A}} = \frac{1}{4}$ or $\frac{M_B}{M_A} = \frac{1}{16}$

Let W_A and W_B be the masses of A and B respectively,

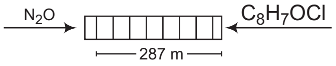
$$\text{Mole fraction of } A = \frac{\frac{W_A}{M_A}}{\frac{W_A}{M_A} + \frac{W_B}{M_B}}$$

$$\text{Mole fraction of } B = \frac{\frac{W_B}{M_B}}{\frac{W_A}{M_A} + \frac{W_B}{M_B}}$$

$$\text{Ratio of mole fractions of } A \text{ and } B = \frac{W_A}{M_A} \times \frac{M_B}{W_B}$$

or
$$\frac{W_A}{W_B} \times \frac{M_B}{M_A} = \frac{2}{3} \times \frac{1}{16} = \frac{1}{24}$$

Example 7 *A cinema hall has equidistant rows 1 m apart. The length of the cinema hall is 287 m and it has 287 rows. From one side of the cinema hall, laughing gas* (N_2O) *is released and from the other side, tear gas* ($C_6H_5COCH_2Cl$) *is released. In which rows, spectators will be laughing and weeping simultaneously?*



(*a*) 187th *from* N_2O *and* 100th *row from* $C_6H_5COCH_2Cl$

(*b*) 100th *row from tear gas and* 187th *from* N_2O

(*c*) 287 *from* N_2O *and* 287 *from* $C_6H_5COCH_2Cl$

(*d*) 100th *row from both*

Solution (*a*) Molar mass of

$$C_8H_7OCl = 8 \times 12 + 7 \times 1 + 16 + 35.5 = 154.5 \text{ g}$$

Molar weight of $N_2O = 2 \times 14 + 16 = 44\ g$

According to Graham's law of diffusion.

$$\frac{r_{N_2O}}{r_{C_8H_7OCl}} = \sqrt{\frac{M_{C_8H_7OCl}}{M_{N_2O}}} = \sqrt{\frac{154.5}{44}} = \sqrt{3.5} = 1.87 : 1$$

$$d_{N_2O} = \frac{1.87}{2.87} \times 287 = 187^{th} \text{ row from } N_2O \text{ side}$$

$$d_{C_8H_7OCl} = \frac{1.0}{2.87} \times 287 = 100^{th} \text{ row tear from gas side.}$$

Therefore, the spectator from the side of N_2O in the 187th row will be laughing and weeping simultaneously. Alternatively, the spectator from the side of tear gas in the 100th row will be laughing and weeping simultaneously.

Example 8 *A gas bulb of* 1 *mL capacity contains* 2.0×10^{21} *molecules of nitrogen exerting a pressure of* $7.57 \times 10^3\ Nm^{-2}$. *The root mean square speed of the gas molecules is*

(*a*) 274 ms^{-1} (*b*) 494 ms^{-1}

(*c*) 690 ms^{-1} (*d*) 988 ms^{-1}

Solution (*b*) Number of moles of the gas $= \frac{2.0 \times 10^{21}}{6.023 \times 10^{23}}$ mol

$$= 3.32 \times 10^{-3} \text{ mol}$$

From, $pV = nRT$

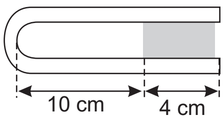
$$T = \frac{pV}{nR} = \frac{7.57 \times 10^3 \times 10^{-3}}{3.32 \times 10^{-3} \times 8.314} = 274.25 \text{ K}$$

$\because$ Root mean square speed, $v_{rms} = \sqrt{\frac{3RT}{M}}$

$$\therefore \quad v_{rms} = \sqrt{\frac{3 \times 8.314 \times 274.25}{28 \times 10^{-3}}}$$

$$= 494.26 \text{ ms}^{-1}$$

Example 9 *A 10.0 cm gas column is trapped by a column of* Hg *4 cm long in capillary tube of uniform bore. The tube is held horizontally in a room at 1 atm. Length of the air column when the tube is held vertically with the open end up is*



(*a*) 3.50 *cm* (*b*) 9.95 *cm* (*c*) 6.20 *cm* (*d*) 4.80 *cm*

Solution (*b*) If A is the area of cross section of the tube, then

$$V_1 = 10\ A \text{ cm}^3$$

$V_2 = ?, p_1 = 760$ mm Hg, $p_2 = (760 + 4)$ mmHg

We know that,

$$p_1V_1 = p_2V_2$$

$$V_2 = \frac{760 \times 10A}{764} = 9.95\,A$$

$$\therefore \quad \text{Length of air column} = \frac{9.95\,A}{A} = 9.95 \text{ cm}$$

Start Practice for JEE Main

Round I (Topically Divided Problems)

Characteristics of Gases and Gas Laws

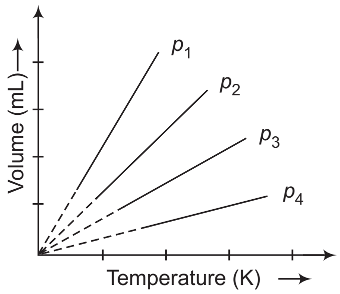
1. Physical properties of ice, water and steam are very different. What is the chemical composition of water in all the three states? **[NCERT Exemplar]**

(a) H_2O^{16}, H_2O^{18}, H_2O^{16} (b) H_2O, D_2O, T_2O
(c) D_2O, T_2O, H_2O (d) H_2O in all states

2. 300 mL of a gas at 27°C is cooled to –3°C at constant pressure, the final volume is

(a) 270 mL (b) 340 mL
(c) 150 mL (d) 240 mL

3. A plot of volume (V) *versus* temperature (T) for a gas at constant pressure is a straight line passing through the origin. The plots at different values of pressure are shown in the figure. Which of the following order of pressure is correct for this gas? **[NCERT Exemplar]**



(a) $p_1 > p_2 > p_3 > p_4$ (b) $p_1 = p_2 = p_3 = p_4$
(c) $p_1 < p_2 < p_3 < p_4$ (d) $p_1 < p_2 = p_3 < p_4$

4. If two moles of an ideal gas at 246 °C occupy a volume of 44.8 L, the pressure must be

(a) 4 atm (b) 2 atm
(c) 8 atm (d) 6 atm

5. 380 mL of a gas at 27°C, 800 mm of Hg weighs 0.455 g. The molecular weight of the gas is

(a) 46 (b) 38 (c) 28 (d) 24

6. Dalton's law of partial pressure is not applicable to

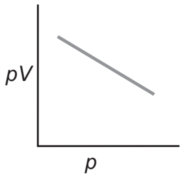
(a) H_2 and N_2 mixture (b) H_2 and Cl_2 mixture
(c) H_2 and CO_2 mixture (d) None of these

7. The density of neon will be highest at

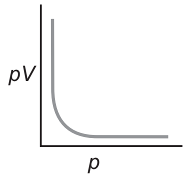
(a) STP (b) 0°C, 2 atm
(c) 273°C, 1 atm (d) 273°C, 2 atm

8. Which of the following is a Boyle's plot at very low pressure?

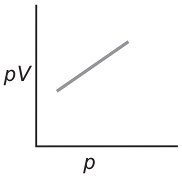
(a)



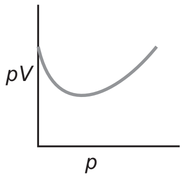
(b)



(c)



(d)



9. Which gas has the highest partial pressure in atmosphere?

(a) CO_2 (b) H_2O
(c) O_2 (d) N_2

10. The rates of diffusion of SO_2, CO_2, PCl_3 and SO_3 are in the following order

(a) $PCl_3 > SO_3 > SO_2 > CO_2$ (b) $CO_2 > SO_2 > PCl_3 > SO_3$
(c) $SO_2 > SO_3 > PCl_3 > CO_2$ (d) $CO_2 > SO_2 > SO_3 > PCl_3$

11. The pressure of a 1 : 4 mixture of dihydrogen and dioxygen enclosed in a vessel is one atmosphere. What would be the partial pressure of dioxygen? **[NCERT Exemplar]**

(a) 0.8×10^5 atm (b) $0.008\ Nm^{-2}$
(c) $8 \times 10^4\ Nm^{-2}$ (d) 0.25 atm

12. The equation of state corresponding to 8g of O_2 is

(a) $pV = 8RT$ (b) $pV = RT/4$
(c) $pV = RT$ (d) $pV = RT/2$

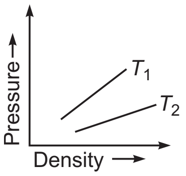
13. At 0°C, the density of a certain oxide of a gas at 2 bar is same as that of dinitrogen at 5 bar. What is the molecular mass of the oxide? **[NCERT]**

(a) 10 u (b) 20 u
(c) 40 u (d) 70 u

14. What will be the molar volume of nitrogen and argon at 273.15K and 1 atm? **[NCERT** Exemplar**]**

(a) 11.2, 22.4 respectively (b) 22.4, 22.4 respectively
(c) 11.2, 11.2 respectively (d) 22.4, 11.2 respectively

15. Figure shows graphs of pressure *versus* density for an ideal gas at two temperatures T_1 and T_2. Which is correct?



(a) $T_1 > T_2$ (b) $T_1 = T_2$
(c) $T_1 < T_2$ (d) None of these

16. The density of a gas A is twice that of a gas B at the same temperature. The molecular weight of gas B is thrice that of A. The ratio of the pressures acting on B and A will be

(a) $\frac{1}{6}$ (b) $\frac{7}{8}$
(c) $\frac{2}{5}$ (d) $\frac{1}{4}$

17. 1.0 L of N_2 and 7/8 L of O_2 at the same temperature and pressure were mixed together. What is the relation between the masses of the two gases in the mixture?

(a) $M_{N_2} = 3M_{O_2}$ (b) $M_{N_2} = 8M_{O_2}$
(c) $M_{N_2} = M_{O_2}$ (d) $M_{N_2} = 16M_{O_2}$

18. What will be the pressure of the gaseous mixture when 0.5 L of H_2 at 0.8 bar and 2.0 L of dioxygen at 0.7 bar are introduced in a 1L vessel at 27°C? **[NCERT]**

(a) 0.4 (b) 1.5
(c) 1.8 (d) None of these

19. 2.9 g of a gas at 95°C occupied the same volume as 0.184 g of dihydrogen at 17°C at the same pressure. What is the molar mass of the gas? **[NCERT]**

(a) 20 g mol^{-1} (b) 10 g mol^{-1}
(c) 40 g mol^{-1} (d) 80 g mol^{-1}

20. A gaseous mixture containing He, CH_4 and SO_2 was allowed to effuse through a fine hole then find what molar ratio of gases coming out initially? (Given mixture contains He, CH_4 and SO_2 in 1 : 2 : 3 mole ratio).

(a) $\sqrt{2} : \sqrt{2} : 3$ (b) 2 : 2 : 3
(c) 4 : 4 : 3 (d) 1 : 1 : 3

21. An open vessel at 27°C is heated until 3/8th of the air in it has been expelled. Assuming that the volume remains constant, calculate the temperature at which the vessel was heated.

(a) 307°C (b) 107°C
(c) 480°C (d) 207°C

22. A bottle of dry ammonia and one of dry hydrogen chloride are connected through a long tube. The stoppers at both ends of the tube are opened simultaneously. The white ammonium chloride ring first formed will be

(a) at the centre of the tube
(b) near the hydrogen chloride bottle
(c) near the ammonia bottle
(d) throughout the length of the tube

23. Two closed vessels of equal volume containing air at pressure p_1 and temperature T_1 are connected to each other through a narrow tube. If the temperature in one of the vessels is now maintained at T_1 and that in the other at T_2, what will be the pressure in the vessels?

(a) $\frac{2p_1T_1}{T_1 + T_2}$ (b) $\frac{T_1}{2p_1T_2}$
(c) $\frac{2p_1T_2}{T_1 + T_2}$ (d) $\frac{2p_1}{T_1 + T_2}$

24. Two different gases 'A' and 'B' are filled in separate containers of equal capacity under the same conditions of temperature and pressure. On increasing the pressure slightly the gas 'A' liquefies but gas B does not liquify even on applying high pressure untill it is cooled. This is because **[NCERT]**

(a) gas A is above critical temperature while gas B is below it
(b) gas B is above critical temperature while gas A is below it
(c) Both the gases are above critical temperature
(d) Both the gases are below critical temperature

25. Air at sea level is dense, this is a practical implementation of

(a) Boyle's law (b) Charles' law
(c) Avogadro's law (d) Dalton's law

26. Oxygen gas generated by the decomposition of potassium chlorate is collected. The volume of oxygen collected at 24°C and atmospheric pressure of 760 mm Hg is 128 mL. Calculate the mass of oxygen gas obtained. The pressure of the water vapour at 24°C is 22.4 mm Hg.

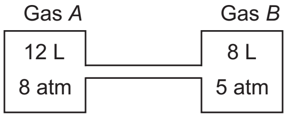
(a) 0.123 g (b) 0.163 g
(c) 0.352 g (d) 1.526 g

27. When a sample of gas is compressed at constant temperature from 15 atm to 60 atm, its volume changes from 76 cm^3 to 20.5 cm^3. Which of the following statements are possible explanations of this behaviour?

I. The gas behaves non-ideally.
II. The gas dimerises.
III. The gas is absorbed into the vessel walls.

(a) I, II and III (b) I and II only
(c) II and III only (d) Only I

28. Two vessels containing gases *A* and *B* are interconnected as shown in the figure. The stopper is opened, the gases are allowed to mix homogeneously. The partial pressures of *A* and *B* in the mixture will be, respectively



(a) 8 and 5 atm (b) 9.6 and 4 atm
(c) 4.8 and 2 atm (d) 6.4 and 4 atm

Kinetic Theory of Gases and Deviation from Ideal Behaviour

(Including Liquefaction of Gases)

29. A gas that follows Boyle's law, Charles' law and Avogadro's law is called an ideal gas. Under what conditions a real gas whould behave ideally?

[**NCERT** Exemplar, **NCERT**]

(a) High pressure and low temperature
(b) Low pressure and high temperature
(c) High pressure and high temperature
(d) Low pressure and low temperature

30. Based on kinetic theory of gases following laws can be proved

(a) Boyle's law
(b) Charles' law
(c) Avogadro's law
(d) All of the above

31. The pressure of a real gas is less than the pressure of an ideal gas because of

(a) increase in the number of collisions
(b) finite size of the molecules
(c) increase in the kinetic energy
(d) intermolecular forces

32. The average kinetic energy of an ideal gas per molecule in SI units at 25°C will be

(a) 6.17×10^{-21} kJ (b) 6.17×10^{-21} J
(c) 6.17×10^{-20} J (d) 7.16×10^{-20} J

33. Which one of the following statements is not true about the effect of an increase in temperature on the distribution of molecular speeds in a gas?

(a) The area under the distribution curve remains the same as under the lower temperature
(b) The distribution becomes broader
(c) The fraction of the molecules with the most probable speed increases
(d) The most probable speed increases

34. The pressure of 2 moles of ammonia at 27° when its volume is 5 L according to van der Waals' equation is (Given, $a = 4.17, b = 0.03711$)

(a) 10.33 atm (b) 9.33 atm
(c) 9.74 atm (d) 9.2 atm

35. If temperature of 1 mole of a gas is increased by 50°C, calculate the change in kinetic energy of the system.

(a) 623.25 J (b) 6.235 J
(c) 623.5 J (d) 6235.0 J

36. The liquefaction behaviour of temporary gases like CO_2 approaches that of permanent gases like N_2, O_2 etc., as we go to

(a) below critical temperature
(b) above critical temperature
(c) above absolute zero
(d) below absolute zero

37. At low pressure, the van der Waals' equation is reduced to

(a) $Z = \frac{pV_m}{RT} = 1 - \frac{ap}{RT}$ (b) $Z = \frac{pV_m}{RT} = 1 + \frac{b}{RT}p$
(c) $pV_m = RT$ (d) $Z = \frac{pV_m}{RT} = 1 - \frac{a}{RT}$

38. At what temperature the rms speed of hydrogen molecules is same as that of oxygen molecules at 1327°C?

(a) 173 K (b) 100 K (c) 400 K (d) 523 K

39. In a closed flask of 5 L, 1.0 g of H_2 is heated from 300 to 600 K. Which statement is not correct?

(a) Pressure of the gas increases
(b) The rate of collision increases
(c) The number of mole of gas increases
(d) The energy of gaseous molecules increases

40. The ratio of average speed of an oxygen molecule to the rms speed of a nitrogen molecule at the same temperature is

(a) $\left(\frac{3\pi}{7}\right)^{1/2}$ (b) $\left(\frac{7}{3\pi}\right)^{1/2}$

(c) $\left(\frac{3}{7\pi}\right)^{1/2}$ (d) $\left(\frac{7\pi}{3}\right)^{1/2}$

41. The rms speed of hydrogen is $\sqrt{7}$ times the rms speed of nitrogen. If T is the temperature of the gas, then

(a) $T_{H_2} = T_{N_2}$ (b) $T_{H_2} > T_{N_2}$

(c) $T_{H_2} < T_{N_2}$ (d) $T_{H_2} = \sqrt{7}T_{N_2}$

42. Which of the following is correct for critical temperature?

(a) It is the lowest temperature at which liquid and vapour can coexist

(b) Beyond the critical temperature, there is no distinction between the two phases and a gas cannot be liquefied by compression

(c) At critical temperature, the surface tension of the system is not zero

(d) At critical temperature, the gas and the liquid phases have different critical densities

43. According to kinetic theory of gases for a diatomic molecule

(a) the pressure exerted by the gas is proportional to the mean square speed of the molecules

(b) the pressure exerted by the gas is proportional to the root mean square speed of the molecules

(c) the root mean square speed is inversely proportional to the temperature

(d) the mean translational KE of the molecule is directly proportional to the absolute temperature

44. At lower temperatures, all gases except H_2 and He show

(a) negative deviation

(b) positive deviation

(c) positive and negative deviation

(d) None of the above

45. The most probable speed of 8 g of H_2 200 ms^{-1}. Average kinetic energy of H_2 gas is

(a) 240 J (b) 180 J (c) 320 J (d) 360 J

46. At what temperature will most probable speed of the molecules of the second number of alkyne series be the same as that of SO_2 at 527°C?

(a) 347°C (b) 227°C (c) 800°C (d) 254°C

47. A helium atom is two times heavier than a hydrogen molecule. At 298 K, the average kinetic energy of a helium atom is

(a) two times that of a hydrogen molecule

(b) four times that of a hydrogen molecule

(c) half that of a hydrogen molecule

(d) same as that of a hydrogen molecule

48. Positive deviation from ideal behaviour takes place because of

(a) molecular interaction between atoms and $pV/nRT > 1$

(b) molecular interaction between atoms and $pV/nRT < 1$

(c) finite size of atoms and $pV/nRT > 1$

(d) finite size of atoms and $pV/nRT < 1$

49. At STP, the order of root mean square velocities of molecules of H_2, N_2, O_2 and HBr is

(a) $H_2 > N_2 > O_2 > HBr$ (b) $HBr > O_2 > N_2 > H_2$

(c) $HBr > H_2 > O_2 > N_2$ (d) $N_2 > O_2 > H_2 > HBr$

50. The density of a gas filled electric lamp is 0.75 kg/m^3. After the lamp has been switched on, the pressure in it increases from 4×10^4 Pa to 9×10^4 Pa. What is increase in U_{rms}?

(a) 100 (b) 300 (c) 200 (d) 400

51. At low pressure, van der Waals' equation is reduced to $\left[p + \frac{a}{V^2}\right]V = RT$. The compressibility factor can be given as

(a) $1 + \frac{a}{RTV}$ (b) $1 - \frac{RTV}{a}$

(c) $1 + \frac{RTV}{a}$ (d) $1 - \frac{a}{RTV}$

52. The compressibility of a gas is less than unity as STP. Therefore,

(a) $V_m > 22.4$ L (b) $V_m < 22.4$ L

(c) $V_m = 11.2$ L (d) $V_m = 44.8$ L

53. The Joule-Thomson coefficient is zero at

(a) absolute temperature (b) critical temperature

(c) inversion temperature (d) below 0°C

Liquid State

54. The magnitude of surface tension of liquid depends on the attractive forces between the molecules, Arrange the following in increasing order of surface tension water, alcohol (C_2H_5OH) and hexane $[CH_3(CH_2)_4CH_3]$ **[NCERT]**

(a) water < alcohol < hexane

(b) hexane < alcohol < water

(c) alcohol < water < hexane

(d) hexane < water < alcohol

55. Clausius-Clapeyron equation is

(a) $\frac{d \log p}{dT} = \frac{\Delta H_{vap}}{2.303\ RT^2}$

(b) $\log p = \log A - \frac{\Delta H_{vap}}{2.303\ RT}$

(c) Both (a) and (b)

(d) None of the above

56. Following properties will decrease with increase in temperature except
(a) surface tension (b) viscosity
(c) density (d) vapour pressure

57. Which is true statement?
(a) All liquids have concave meniscus
(b) All liquids have convex meniscus
(c) Mercury has convex and other liquids have concave meniscus
(d) Mercury has concave and other liquids have convex meniscus

58. Surface tension of water is 73 dyne cm^{-1} at 20°C. If surface area is increased by 0.10 m^2, work done is
(a) 7.3 erg (b) 7.3×10^4 erg
(c) 73 J (d) 0.73 J

59. What is SI unit of viscosity coefficient (η)? **[NCERT Exemplar]**
(a) Pascal (b) Nsm^{-2} (c) km^{-2} s (d) Nm^{-2}

60. Which of the following property of water can be used to explain the spherical shape of rain droplets? **[NCERT Exemplar]**
(a) Viscosity (b) Surface tension
(c) Critical phenomena (d) Pressure

61. Evaporation and boiling differs
(a) evaporation is spontaneous at all temperatures while boiling is at constant temperature
(b) boiling is spontaneous at all temperatures while evaporation takes place at constant temperature
(c) both are spontaneous at all temperatures
(d) evaporation is exothermic while boiling is endothermic

62. If latent heat of vaporisation is L at boiling point T(K) then entropy of vaporisation is
(a) LT (b) LT^{-1}
(c) TL^{-1} (d) None of these

63. Select the correct statement(s).
(a) The standard boiling temperature is the temperature at which the vapour pressure of the substance is 1 bar
(b) The normal boiling temperature is the temperature at which the vapour pressure of the substance is 1 atm
(c) Substances for which $T > T_c$ and $p > p_c$ are called super critical fluids
(d) All of the above are correct statements

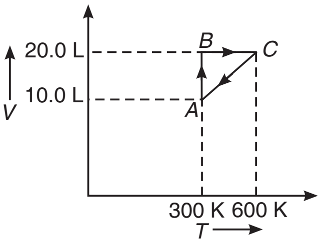
64. Select the incorrect statement.
(a) The properties of liquid crystals are intermediate between liquids and solids
(b) Surface tension of a liquid is maximum at critical temperature
(c) Viscosity decreases with increase in temperature
(d) CO_2 and H_2O show the unusual properties of supercritical fluids

Round II (Mixed Bag)

Only One Correct Option

1. The drain cleaner, Drainex contains small bits of aluminium which react with caustic soda to produce dihydrogen. What volume of dihydrogen at 20° C and 1 bar will be released when 0.15 g of aluminium reacts? **[NCERT]**
(a) 22400 mL (b) 203 mL
(c) 0.203 mL (d) 1120 mL

2. This graph expresses the various steps of the system containing 1 mole of gas. Which type of process, system has when it moves from C to A?



(a) Isochoric (b) Isobaric
(c) Isothermal (d) Cyclic

3.

Gas	CO	CH_4	HCl	SO_2
Critical temp, T_c (K)	134	190	324	430

In the context of given values of critical temperature, the greater ease of liquefication is of
(a) SO_2 (b) HCl
(c) CH_4 (d) CO

4. In two vessels of 1 L each at the same temperature, 1 g of H_2 and 1 g of CH_4 are taken. For these
(a) V_{rms} values will be same
(b) kinetic energy per mol will be same
(c) total kinetic energy will be same
(d) pressure will be same

5. Which one of the following volume (V)-temperature (T) plots represents the behaviour of one mole of an ideal gas at one atmospheric pressure?

(a) 
(b) 
(c) 
(d) 
6. The temperature at which nitrogen under 1.00 atm pressure has the same root mean square speed as that of carbon dioxide at STP, is

(a) 0°C (b) 27°C
(c) −99°C (d) −200°C

7. The molecular mass of each N_2 and CO is 28. If 0.5 L of N_2 at 27°C and 700 mm pressure contains n molecules, the number of molecules in 1.0 L of CO under identical conditions will be

(a) $\frac{n}{2}$ (b) n
(c) $2n$ (d) None of these

8. Gases X, Y, Z, P and Q have the van der Waals' constants a and b (in CGS units) as shown below.

	X	Y	Z	P	Q
a	6	6	20	0.05	30
b	0.025	0.15	0.1	0.02	0.2

The gas with the higher critical temperature is

(a) P (b) Q
(c) Y (d) X

9. Gases possess characteristic critical temperature which depends upon the magnitude of intermolecular forces between the particles. Following are the critical temperatures of some gases.

Gases	H_2	He	O_2	N_2
Critical temperature in Kelvin	33.2	5.3	154.3	126

From the above data what would be the order of liquefaction of these gases?

(Start writing the order from the gas liquefying first)

[NCERT Exemplar]

(a) H_2, He, O_2, N_2
(b) He, O_2, H_2, N_2
(c) N_2, O_2, He, H_2
(d) O_2, N_2, H_2, He

10. Pay load is defined as the difference between the mass of displaced air and the mass of the balloon. Calculate the pay load when a balloon of radius 10 m and mass 100 kg is filled with helium at 1.66 bar at 27°C. (Density of air = 1.2 kg m^{-3} and R = 0.083 bar dm^3 K^{-1} mol^{-1}) **[NCERT]**

(a) 1117.6 kg (b) 1217.46 kg
(c) 5028.57 kg (d) 3811.11 kg

11. A student forgot to add the reaction mixture to the round bottomed flask at 27°C but instead he/she placed the flask on the flame. After a lapse of time, he realized his mistake, and using a pyrometer he found the temperature of the flask was 477°C. What fraction of air would have been expelled out? **[NCERT]**

(a) 0.4 (b) 0.6
(c) 0.8 (d) 0.1

12. Which of the given sets of temperature and pressure will cause a gas to exhibit the greatest deviation from ideal gas behaviour?

(a) 100°C and 4 atm (b) 100°C and 2 atm
(c) −100°C and 4 atm (d) 0°C and 2 atm

13. By what ratio the average velocity of the molecule in a gas change when the temperature is raised from 50 to 200°C?

(a) $\frac{1.21}{1}$ (b) $\frac{1.46}{1}$
(c) $\frac{1.14}{1}$ (d) $\frac{4}{1}$

14. A spherical balloon of 21 cm diameter is to be filled with hydrogen at STP from a cylinder containing the gas at 20 atm and 27°C. If the cylinder can hold 2.82 L of water, the number of balloons that can be filled up is

(a) 5 (b) 2
(c) 10 (d) 12

15. Calculate the total pressure in a 10.0 L cylinder which contains 0.4 g helium, 1.6 g oxygen and 1.4 g nitrogen at 27°C.

(a) 0.492 atm (b) 49.2 atm
(c) 4.92 atm (d) 0.0492 atm

16. The rate of effusion doesn't depend on

(a) the area of cross section of hole
(b) number of molecules per unit volume
(c) the average molecular speed
(d) size of the molecule

17. Which has maximum vapour pressure at a given temperature?

(a) $CH_3CH_2CH_2OH$ (b) 
(c) $CH_3—O—CH_3$ (d) CH_3COOH

18. A gas is heated in such a way so that its pressure and volume both becomes double. Again by lowering temperature, one fourth of initial number of moles of air has been taken in, to maintain the double volume and pressure. By what fraction, the temperature must have been raised finally?

(a) $\frac{1}{5}$ times (b) $\frac{4}{5}$ times
(c) $\frac{16}{5}$ times (d) $\frac{8}{5}$ times

19. Match the following gas laws in column I with the equation representing them in column II.

[NCERT Exemplar]

	Column I		Column II
(i)	Boyle's law	(A)	$V \propto n$ at constant T and p
(ii)	Charles' law	(B)	$p_{\text{Total}} = p_1 + p_2 + p_3 + ...$ at constant T, V
(iii)	Dalton's law	(C)	$\frac{pV}{T}$ = constant
(iv)	Avogadro's law	(D)	$V \propto T$ at constant n and p
		(E)	$p \propto \frac{1}{V}$ at constant n and T

Codes

(a) (i) E (ii) D (iii) B (iv) A (b) (i) A (ii) B (iii) C (iv) D
(c) (i) D (ii) C (iii) B (iv) A (d) (i) A (ii) E (iii) B (iv) D

20. Match the graphs between the following variables with their names. **[NCERT Exemplar]**

Graphs		Names	
(i)	Pressure *vs* temperature graph at constant molar volume.	(A)	Isotherms
(ii)	Pressure *vs* volume graph at constant temperature.	(B)	Constant temperature curve
(iii)	Volume *vs* temperature graph at constant pressure.	(C)	Isochores
		(D)	Isobars

Codes

(a) (i) D (ii) A (iii) C (b) (i) A (ii) D (iii) C
(c) (i) C (ii) A (iii) D (d) (i) A (ii) C (iii) D

21. Match the following graphs of ideal gas with their coordinates **[NCERT Exemplar]**

Graphical representation *x* and *y* coordinates

(i)  (*A*) pV *vs* V

(ii)  (*B*) p *vs* V

(iii)  (*C*) p *vs* $\frac{1}{V}$

Codes

(a) (i) *A* (ii) *B* (iii) *C* (b) (i) *C* (ii) *B* (iii) *A*
(c) (i) *B* (ii) *A* (iii) *C* (d) (i) *B* (ii) *C* (iii) *A*

More than One Correct Option

22. If 1 g of each of the following gases are taken at STP, which of the gases will occupy (a) greatest volume and (b) smallest volume? **[NCERT Exemplar]**

(a) CO (b) H_2O (c) CH_4 (d) NO

23. Which of the following changes decrease the vapour pressure of water kept in a sealed vessel? **[NCERT Exemplar]**

(a) Decreasing the quantity of water
(b) Adding salt to water
(c) Decreasing the volume of the vessel to one-half
(d) Decreasing the temperature of water

24. With regard to the gaseous state of matter which of the following statements are correct? **[NCERT Exemplar]**

(a) Complete order of molecules
(b) Complete disorder of molecules
(c) Random motion of molecules
(d) Fixed position of molecules

25. Under which of the following two conditions applied together, a gas deviates most from the ideal behaviour? **[NCERT Exemplar]**

(a) Low pressure (b) High pressure
(c) Low temperature (d) High temperature

26. If the rms velocities of nitrogen and oxygen molecules are same at two different temperatures and same pressure then

(a) most probable velocity of molecules is also equal
(b) average speed of molecules is also same
(c) number of moles of each gas is also equal
(d) density of nitrogen and oxygen is also equal

27. Boyle's law may be expressed as

(a) $\left(\frac{dp}{dV}\right)_T = \frac{K}{V}$ (b) $\left(\frac{dp}{dV}\right)_T = -\frac{K}{V^2}$
(c) $\left(\frac{dp}{dV}\right)_T = \frac{K^2}{V}$ (d) $V \propto \frac{1}{p}$

28. Which of the following is/are true?

(a) Higher the value of a, weaker is intermolecular force of attraction

(b) At low pressure, $Z = 1 - \frac{a}{V_m RT}$, for ideal gas

(c) $\frac{V_1}{V_2} = \left(\frac{T_2}{T_1}\right)^{3/2}$, for reversible adiabatic expansion

(d) A gas can be liquefied below critical temperature at high pressure

Assertion and Reason

Directions (Q. Nos. 29 to 33) *Each of these questions contains two statements : Statement* I (*Assertion*) *and Statement* II (*Reason*)*. Each of these questions also has four alternative choices, only one of which is the correct answer. You have to select one of the codes* (*a*), (*b*), (*c*), (*d*) *given below*

(a) Statement I is true; Statement II is true; Statement II is a correct explanation for Statement I.

(b) Statement I is true; Statement II is true; Statement II is not a correct explanation for Statement I.

(c) Statement I is true; Statement II is false.

(d) Statement I is false; Statement II is true.

29. **Statement I** Three states of matter are the result of balance between intermolecular forces and thermal energy of the molecules.

Statement II Intermolecular forces tend to keep the molecules together but thermal energy of molecules tends to keep them apart. [NCERT Exemplar]

30. **Statement I** At constant temperature, pV vs V plot for real gases is not a straight line.

Statement II At high pressure all gases have $Z > 1$ but at intermediate pressure most gases have $Z < 1$.

[NCERT Exemplar]

31. **Statement I** At critical temperature liquid passes into gaseous state imperceptibly and continuously.

Statement II The density of liquid and gaseous phase is equal at critical temperture. [NCERT Exemplar]

32. **Statement I** Liquids tend to have maximum number of molecules at their surface.

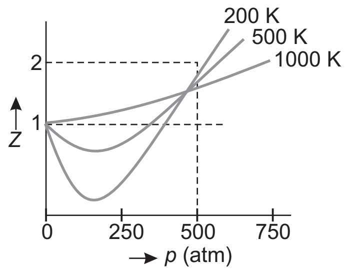
Statement II Small liquid drops have spherical shape. [NCERT Exemplar]

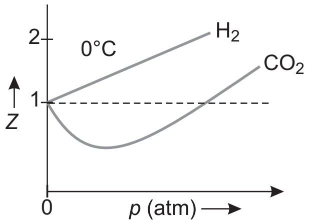
33. **Statement I** In van der Waals' equation of gases, the kinetic equation of gas is modified.

Statement II This modification is carried out with respect to actual volume of molecules and attractive forces between the gaseous molecules.

Comprehension Based Questions

Directions (Q. Nos. 34 to 36) Sketch shows the plot of Z *vs* p for a hypothetical gas for one mole at three distinct temperature.





Boyle's temperature is the temperature at which a gas shows ideal behaviour over a pressure range in the low pressure region.

Boyle's temperature (T_b) $= \frac{a}{Rb}$.

If a plot is obtained at temperature below Boyle's temperature then the curve will show negative deviation in low pressure region and positive deviation in the high pressure region. Near critical temperature, the curve is more likely as CO_2 and at the temperature above critical temperature, the curve is more like H_2 at 0°C.

34. For 500 K plot value of Z changes from 2 to 2.2 if pressure is varied from 1000 atm to 1200 atm (high pressure) then the value of $\frac{b}{RT}$ will be

(a) 10^{-4} atm^{-1}

(b) 10^{-3} atm^{-1}

(c) 10^{-5} atm^{-1}

(d) 0.10 atm^{-1}

35. As shown in the figure at 200 K and 500 atm, value of compressibility factor is 2. Then volume of the gas at this point will be

(a) 0.065 L

(b) 0.045 L

(c) 0.032 L

(d) 1.096 L

36. Which of the following is correct?

(a) $\frac{a}{b} = 1$ kcal mol^{-1}

(b) $\frac{a}{b} < 0.4$ kcal mol^{-1}

(c) $\frac{a}{b} > 0.4$ kcal mol^{-1}

(d) 2 kcal mol$^{-1} > \frac{a}{b} > 0.4$ kcal mol^{-1}

Directions (Q. Nos. 37 to 39) The pressure-volume relationship for gases helps to explain the mechanics of breathing. When we breathe in, the diaphragm is lowered and the chest wall is expanded, increasing the volume of the chest cavity. Boyle's law tells us that the pressure inside the cavity must decrease as outside air enters the lungs because it is at a higher pressure than the air in the chest cavity. When we breathe out, the diaphragm rises and the chest will contract decreasing the volume of chest cavity.

37. A 15.0 L cylinder of Ar gas is connected to an evacuated 235.0 L tank. If the final pressure is 750 mm Hg, what have been the original gas pressure in the cylinder?

(a) 76 atm (b) 12.56 atm

(c) 16.45 atm (d) 23 atm

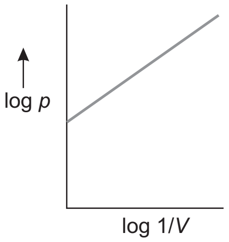
38. A balloon indoors where the temperature is 27°C has a volume of 2.00 L. What will be the volume of outdoors where the temperature is –23°C? Assuming pressure remains constant.

(a) 1.67 L (b) 2.23 L

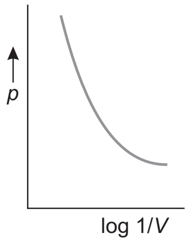
(c) 0.53 L (d) 1.26 L

39. Which of the following graphs is not according to Boyle's law?

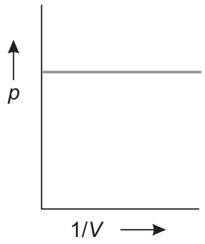
(a)



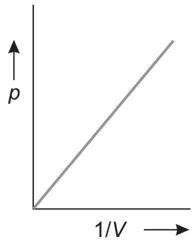
(b)



(c)



(d)



Previous Years' Questions

40. The molecular velocity of any gas is **[AIEEE 2011]**

(a) inversely proportional to the square root of temperature

(b) inversely proportional to absolute temperature

(c) directly proportional to square of temperature

(d) directly proportional to square root of temperature

41. a and b are van der Waals' constants for gases. Chlorine is more easily liquefied than ethane because **[AIEEE 2011]**

(a) a and b for Cl_2 > a and b for C_2H_6

(b) a and b for Cl_2 < a and b for C_2H_6

(c) a for Cl_2 > a for C_2H_6 but b for Cl_2 > b for C_2H_6

(d) a for Cl_2 > a for C_2H_6 but b for Cl_2 < b for C_2H_6

42. When r, p and M represent rate of diffusion, pressure and molecular mass, respectively, then the ratio of the rates of diffusion (r_A/r_B) of two gases A and B, is given as **[AIEEE 2011]**

(a) $(p_A/p_B)^{1/2}(M_A/M_B)$ (b) $(p_A/p_B)(M_B/M_A)^{1/2}$

(c) $(p_A/p_B)^{1/2}(M_B/M_A)$ (d) $(p_A/p_B)(M_A/M_B)^{1/2}$

43. If 10^{-4} dm^3 of water is introduced into a 1 dm^3 flask at 300 K, how many moles of water are in the vapour phase when equilibrium is established (Given vapour pressure of H_2O at 300K is 3170 Pa; $R = 8.314$ JK^{-1} mol^{-1}) **[AIEEE 2010]**

(a) 5.56×10^{-6} mol

(b) 1.53×10^{-2} mol

(c) 4.46×10^{-2} mol

(d) 1.27×10^{-3} mol

44. Equal masses of methane and oxygen are mixed in an empty container at 25°C. The fraction of the total pressure exerted by oxygen is **[AIEEE 2007]**

(a) $\frac{2}{3}$ (b) $\frac{1}{3} \times \frac{273}{298}$

(c) $\frac{1}{3}$ (d) $\frac{1}{2}$

the Guidance

Round I

1. In different physical states, chemical composition of a substance remains the same *i.e.*, H_2O.

3.
$$p \propto \frac{1}{V} \propto T$$

Thus, $p_4 > p_3 > p_2 > p_1$

5.
$$pV = \frac{w}{M} RT$$
$$M = \frac{wRT}{pV}$$
$$= \frac{0.455 \times 0.0821 \times 300 \times 760 \times 1000}{800 \times 380}$$
$$= 28.0 \text{ g}$$

6. Dalton's law of partial pressure is not applicable to gases which react chemically and produce different number of moles of products than the reactants. Some gases which do not obey this law are
$SO_2 + Cl_2, CO + Cl_2, NO + O_2, NH_3 + HCl$ and $H_2 + Cl_2$

7. We know that density
$$d = \frac{pM}{RT}$$
$$d \propto \frac{1}{T}$$
and $$d \propto p$$
Thus, density of neon is maximum at 0°C and 2 atm.

9. We know that
$$p = n\frac{RT}{V} = \frac{w}{M}\,\frac{RT}{V}$$
As the M increases, partial pressure decreases. Thus, H_2O has the highest partial pressure.

10. Rate of diffusion is inversely proportional to the molecular weight *i.e.*,
$$r \propto \sqrt{\frac{1}{M}}$$
So, the order of rate of diffusion is
$$CO_2 > SO_2 > SO_3 > PCl_3$$

11. Partial pressure of O_2 = mole fraction of $O_2 \times$ total p
$$= \frac{4}{1+4} \times 1$$
$$= 0.8 \text{ atm} = 8 \times 10^4 \text{ Nm}^{-2}$$

12. Ideal gas equation
$$pV = nRT$$
$$pV = \frac{w}{M}RT = \frac{8}{32}RT$$
$$pV = \frac{RT}{4}$$

13. Density, $d = \frac{Mp}{RT}$

When T and d are same and R is constant,

then $p_1 M_1$ (gaseous oxide) $= p_2 M_2$ (nitrogen).

$2 \text{ bar} \times M_1 = 5 \text{ bar} \times 28 \text{ u}$

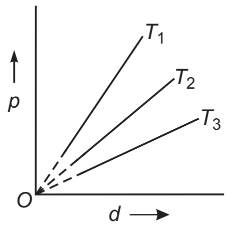
(Molar mass of $N_2 = 28$ u)

Molecular mass of unknown oxide,

$$M_1 = \frac{5 \text{ bar} \times 28}{2 \text{ bar}} = 70 \text{ u}$$

14. Every gas has 22.4 L molar volume at 273.15 K and 1 atm pressure (STP).

15. At constant temperature, density of a gas is directly proportional to its pressure and inversely proportional to its volume.



$T_3 > T_2 > T_1$

16.
$$\frac{d}{p} = \frac{M}{RT}$$

Let density of gas $B = d$

So, density of gas $A = 2d$

and molecular weight of $A = M$

So, molecular weight of $B = 3M$

Since R is a constant and T is same, so

$$p_A = \frac{d_A RT}{M_A} \text{ and } p_B = \frac{d_B RT}{M_B}$$

$$\frac{p_B}{p_A} = \frac{d_B}{d_A} \times \frac{M_A}{M_B} = \frac{d}{2d} \times \frac{M}{3M} = \frac{1}{6}$$

17. At constant temperature and pressure, the masses of two gases in a mixture are same, so

$$M_{N_2} = M_{O_2}$$

18.
$$pV = nRT$$

Moles of $H_2, n_{H_2} = \frac{pV}{RT} = \frac{0.8 \times 0.5}{RT} = \frac{0.40}{RT}$

Similarly, moles of O_2, $n_{O_2} = \frac{pV}{RT} = \frac{0.7 \times 2}{RT} = \frac{1.4}{RT}$

Total number of moles $= \frac{0.40}{RT} + \frac{1.4}{RT} = \frac{1.8}{RT}$

Total pressure, $p_{\text{total}} = \frac{nRT}{V} = \frac{1.8 \times RT}{RT \times 1} = 1.8$ atm

19.
$$pV = nRT$$

$$pV = \frac{\omega RT}{M}$$

Unknown gas; H_2 gas

$$p_1 V_1 = \frac{\omega_1 R T_1}{M_1};\ p_2 V_2 = \frac{\omega_2 R T_2}{M_2}$$

$$p_1 V_1 = p_2 V_2$$

Hence,
$$\frac{\omega_1 R T_1}{M_1} = \frac{\omega_2 R T_2}{M_2}$$

$$\frac{2.9 \text{ g} \times R \times 368 \text{ K}}{M_1} = \frac{0.184 \text{ g} \times R \times 290 \text{ K}}{2 \text{ g mol}^{-1}}$$

Molar mass of unknown gas,

$$M_1 = \frac{2.9 \text{ g} \times 368 \text{ K} \times 2 \text{ g mol}^{-1}}{0.184 \text{ g} \times 290 \text{ K}} = 40 \text{ g mol}^{-1}$$

20.
$$\frac{n'_{He}}{n'_{CH_4}} = \frac{1}{2}\sqrt{\frac{16}{4}} = \frac{1}{1}$$

$$\frac{n'_{He}}{n'_{SO_2}} = \frac{1}{3}\sqrt{\frac{64}{4}} = \frac{4}{3}$$

So, $n'_{He} : n'_{CH_4} : n'_{SO_2} = 4 : 4 : 3.$

21. According to Gay Lussac's law

$$\frac{p_1}{T_1} = \frac{p_2}{T_2}$$

If $\frac{3}{8}^{\text{th}}$ of the air is expelled out then remaining air $= \frac{5}{8}$

$$T_2 = \frac{(273 + 27) \times 8}{5} = \frac{2400}{5} = 480 \text{ K}$$

$$= 480 - 273 = 207° \text{ C}$$

22. According to Graham's law of diffusion,

$$r \propto \sqrt{\frac{1}{M}}$$

The rate of diffusion of ammonia ($M = 17$) is more than the HCl ($M = 36.5$), thus white ring forms near the hydrogen chloride bottle.

23.
$$\frac{p_1}{T_1} + \frac{p_1}{T_1} = \frac{p}{T_1} + \frac{p}{T_2}$$

$$\frac{2p_1}{T_1} = p\left(\frac{T_1 + T_2}{T_1 T_2}\right)$$

or
$$p = \frac{2p_1 T_2}{T_1 + T_2}$$

24. A gas cannot be liquefied above critical temperature. So, gas 'A' is below its critical temperature whereas gas 'B' is above its critical temperature.

25. $\frac{p_1}{d_1} = \frac{p_2}{d_2}$ (at a constant temperature)

This is the Boyle's law.

So, the case — "Air at sea level is dense" is studied under Boyle's law.

26. From the total pressure and the vapour pressure of water, we can calculate the partial pressure of O_2.

$$p_{O_2} = p_T - p_{H_2O} = 760 - 22.4 = 737.6 \text{ mm Hg}$$

From the ideal gas equation we write

$$\omega = \frac{pVM}{RT} = \frac{0.974 \times 0.128 \times 32.0}{0.0821 \times 297} = 0.163 \text{ g}$$

27. At constant temperature, for ideal gas,

$$p_1V_1 = p_2V_2$$

For the given sample,

$$15 \times 76 = 60 \times 20.5$$

$$\therefore \qquad p_1V_1 \neq p_2V_2$$

$\therefore$ The gas behaves non-ideally. However, the gas neither undergo dimerisation nor adsorbed into the vessel walls.

28. Moles of $A, n_A = \frac{p_AV_A}{RT} = \frac{8 \times 12}{RT} = \frac{96}{RT}$

Moles of $B, n_B = \frac{p_BV_B}{RT} = \frac{8 \times 5}{RT} = \frac{40}{RT}$

Total pressure $\times$ total volume $= (n_A + n_B) \times RT$

$$p \times (12 + 8) = \frac{1}{RT}(96 + 40)\,RT$$

$$p = 6.8$$

$\therefore$ Partial pressure of $A = p \times$ mole fraction of A

$$= 6.8 \times \left(\frac{96}{RT} \Big/ \frac{96 + 40}{RT}\right) = 4.8 \text{ atm}$$

$\therefore$ Partial pressure of $B = p \times$ mole fraction of B

$$= 6.8 \times \left(\frac{40}{RT} \Big/ \frac{96 + 40}{RT}\right) = 2 \text{ atm.}$$

30. On the basis of kinetic theory of gases

$$pV = \frac{1}{2} N_A m\bar{v}^2$$

and $$\frac{1}{2} m\bar{v}^2 = \frac{3}{2} KT$$

$$p = \frac{1}{3}\left(\frac{N}{V}\right) m\bar{v}^2$$

or $$p = \frac{2}{3}\left(\frac{N}{V}\right)\frac{1}{2} m\bar{v}^2$$

$$= \frac{2}{3}\left(\frac{N}{V}\right)\left(\frac{3}{2}\right) KT$$

or $$pV = nKT$$

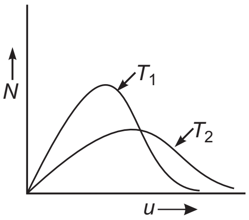
32. Average kinetic energy per molecule

$$= \frac{3}{2} KT$$

$$= \frac{3}{2} \times 1.38 \times 10^{-23} \times 300 \text{ J}$$

$$= 6.21 \times 10^{-21} \text{ J}$$

33. Distribution of molecules (N) with velocity (u) at two temperatures T_1 and $T_2 (T_2 > T_1)$ is shown below :



At both temperatures, distribution velocity first increases, reaches a maximum value and the decreases.

34. $\left(p + \frac{n^2a}{V^2}\right)(V - nb) = nRT$

$$p = \frac{nRT}{(V - nb)} - \frac{an^2}{V^2}$$

$$= \frac{2 \times 0.082 \times 300}{5 - 2 \times 0.03711} - \frac{4.17 \times 4}{25}$$

$$= 9.33 \text{ atm}$$

35. $\text{KE} = \frac{3}{2} RT$ for 1 mole of a gas

$$\Delta\text{KE} = \frac{3}{2} \times 8.314 \times (50 - 0)$$

$$= \frac{3}{2} \times 8.314 \times 50 = 623.55 \text{ J}$$

36. Gases for which intermolecular forces of attraction are small such as N_2, O_2 etc., have low value of T_c, thus liquefied above critical temperature.

37. van der Waals' equation (at low pressure),

$$\left[p + \frac{a}{V^2}\right](V - b) = RT$$

$$(V - b) \approx V$$

or $$pV = RT - \frac{a}{V}$$

or $$\frac{pV_m}{RT} = 1 - \frac{a}{RT} = Z$$

38. $$v_{H_2} = v_{O_2}$$

So, $$\sqrt{M_{O_2}T_{H_2}} = \sqrt{M_{H_2}T_{O_2}}$$

$$32 \times T_{H_2} = 2 \times 1600$$

$$T_{H_2} = \frac{2 \times 1600}{32} = 100 \text{ K}$$

40. $$u_{av} = \sqrt{\frac{8RT}{\pi M}} \quad \text{So, } u_{av\,(O_2)} = \sqrt{\frac{8RT}{\pi \times 32}}$$

$$u_{rms} = \sqrt{\frac{3RT}{M}} \quad \text{so} \quad u_{rms\,(N_2)} = \sqrt{\frac{3RT}{28}}$$

$$\frac{u_{av\,(O_2)}}{v_{rms\,(N_2)}} = \sqrt{\frac{8 \times 28}{\pi \times 32 \times 3}} = \sqrt{\frac{7}{3\pi}} = \left[\frac{7}{3\pi}\right]^{1/2}$$

41. We know that

$$u_{rms} = \sqrt{\frac{3RT}{M}}$$

$\because$ u_{rms} of hydrogen is more than the u_{rms} of nitrogen, thus its temperature is also greater than nitrogen.

45. $$200 = \sqrt{\frac{2RT}{2 \times 10^{-3}}} \text{ or } RT = 40$$

Average kinetic energy $= \frac{3}{2}nRT = \frac{3}{2} \times \frac{8}{2} \times 40 = 240$ J

46. Second member of alkyne series is C_3H_4. ($M = 40$)

$$\begin{array}{ccc} C_3H_4 & & SO_2 \\ \sqrt{\frac{2RT_1}{M_1}} & = & \sqrt{\frac{2RT_2}{M_2}} \end{array}$$

$$T_1 = T_2\left(\frac{M_1}{M_2}\right) = 800\left(\frac{40}{64}\right) \text{ K}$$

$$= 500 \text{ K } = 227°\text{C}$$

47. Kinetic energy $\left(= \frac{3}{2}RT\right)$ does not depends upon the atomic mass of the gases.

48. If $Z > 1$, the gas is less compressible than expected from ideal behaviour and shows positive deviation usually at high pressure, *i.e.*, $pV > RT$

49. We know that, $v_{\text{rms}} = \sqrt{\frac{3RT}{M}}$

So, as the molecular mass increases, rms speed decreases. Thus, the correct order of root mean square speed is

$$H_2 > N_2 > O_2 > HBr$$

50. $$u_1 = \sqrt{\frac{3p}{d}}$$

$$\therefore \quad \Delta u_{\text{rms}} = \sqrt{\frac{3}{d}} \times (\sqrt{p_2} - \sqrt{p_1})$$

$$= \sqrt{\frac{3}{0.75}} \times (300 - 200) = \sqrt{4} \times 100 = 200$$

51. $$\left[p + \frac{a}{V^2}\right]V = RT$$

$$pV + \frac{a}{V} = RT$$

$$\frac{pV}{RT} + \frac{a}{VRT} = 1$$

$$\frac{pV}{RT} = \left(1 - \frac{a}{VRT}\right) = Z.$$

52. The compressibility factor

$$Z = \frac{p \times 22.4}{RT} = 1 \qquad \text{(for ideal gas)}$$

$$Z = \frac{p \times Vm}{RT} < 1$$

$$\therefore \quad \frac{22.4}{V_m} > 1$$

$$\text{or} \quad V_m < 22.4$$

53. Joule-Thomson coefficient (μ) is zero at inversion temperature.

$$\text{Mathematically, } \mu = \left(\frac{\partial T}{\partial p}\right)_H$$

When, $\mu = 0$, the gas neither gets cooled down nor gets heated upon expansion.

54. In hexane, there are only London forces between the molecules. These forces are very weak. H—bonding is stronger in H_2O in comparison to C_2H_5OH. Hence, the increasing order of surface tension is

Hexane > alcohol > water

56. On increasing temperature, vaporisation increases. Hence, vapour pressure increases.

58. Work done = surface tension × increase in area

$$= 73 \times 0.10 = 73 \times 0.10 \times 10^4 = 7.3 \times 10^4 \text{ erg}$$

59. The SI unit of $\eta = \text{Nsm}^{-2}$

62. $$\Delta S = \frac{L}{T} = LT^{-1}$$

Round II

1. $$\underset{\substack{2 \times 27 \text{ g} \\ 0.15 \text{ g}}}{2\text{Al}} + 2\text{NaOH} + 2H_2O \longrightarrow 2\text{NaAlO}_2 + \underset{\substack{3 \text{ mol} \\ \frac{0.15 \times 3}{2 \times 27} = 0.00833 \text{ mol}}}{3H_2}$$

$$pV = nRT$$

$$V_{H_2} = \frac{0.00833 \text{ mol} \times 0.0821 \text{dm}^3 \text{ atm K}^{-1} \text{ mol}^{-1} \times 293 \text{ K}}{1 \times 0.987 \text{ atm}}$$

$$(1\text{bar} = 0.987 \text{ atm})$$

$$V_{H_2} = 0.203 \text{ dm}^3$$

$$V_{H_2} = 203 \text{ mL}$$

Note Temperature must be in kelvin. If it is given in °C, convert it into K.

2. **At *A*** → temperature $= T$, volume $= V$, pressure $= p_1$

At C → temperature $= 2T$ volume $= 2V$, pressure $= p_2$

$$\frac{p_1V}{T} = \frac{p_2 \times 2V}{2T}$$

$p_1 = p_2$, *i.e.*, system is isobaric

3. Higher the critical temperature, greater will be the ease of liquefication.

4. $$\text{KE} = \frac{3}{2}kT$$

where, k is constant.

$$\text{KE} \propto T$$

Here, the temperature is same. Hence, for 1 g of H_2 and 1 g of CH_4 which are taken in two vessels of 1 L each at same temperature, the kinetic energy per mol will be the same.

5. *V-T* plot represents the behaviour of 1 mole of an ideal gas at 1 atm pressure.

Given, $T_1 = 273\text{ K},\ T_2 = 373\text{ K}$

According to Charles' law,

$$V \propto T$$

$$\frac{V_1}{V_2} = \frac{T_1}{T_2} = \frac{273}{373} = 0.73$$

When, $V_1 = 22.4, V_2 = 30.6$, because $\frac{V_1}{V_2} = 0.73.$

6. Let rms speed of nitrogen at *T*K be *u* and is equal to that of CO_2 at STP

$$u_{\text{rms}} = \sqrt{\frac{3RT}{28}} = \sqrt{\frac{3R \times 273}{44}}$$

$$T = \frac{273 \times 28}{44} = 173.73\text{ K} = -99.27^\circ\text{ C}$$

7. Molecular mass of $N_2 = 28, CO = 28$

Number of molecules of N_2

$(V = 0.5\text{ L}, T = 27^\circ\text{ C}, p = 700\text{ mm}) = n$

Number of molecules of N_2

$(V = 1\text{ L}, T = 27^\circ\text{ C}, p = 700\text{ mm}) = 2n$

8. Critical temperature, $T_c = \frac{8a}{27Rb}$

Greater is the value of $\left(\frac{a}{b}\right)$, more is the critical temperature of gas.

For, gas *X* $\frac{a}{b} = \frac{6}{0.025} = 240$

gas *Y*, $\frac{a}{b} = \frac{6}{0.150} = 40$

gas *Z*, $\frac{a}{b} = \frac{20}{0.1} = 200$

gas *P*, $\frac{a}{b} = \frac{0.05}{0.02} = 2.5$

gas *Q*, $\frac{a}{b} = \frac{30}{0.2} = 150$

Therefore, gas *X* will have the highest critical temperature.

9. A gas with higher critical temperature liquify first.

10. Radius, $R_{\text{balloon}} = 10\text{m}$

$$V_{\text{balloon}} = \frac{4}{3}\pi r^3 = \frac{4}{3} \times \frac{22}{7} \times (10)^3 = 4190.476\text{ m}^3$$

$$V_{\text{balloon}} = V_{\text{displaced air(by balloon)}}$$

$\therefore$ Mass of displaced air $= V_{\text{displaced air}} \times$ density of air

$$m_{\text{displaced air}} = 4190.476\text{ m}^3 \times 1.2\text{ kg m}^{-3}$$

$$m = 5028.57\text{ kg}$$

Mass of He filled in balloon, $w_{\text{He}} = \frac{pVM}{RT}$ $\left(pV = \frac{wRT}{M}\right)$

$$w_{\text{He}} = \frac{1.66\text{ bar} \times 4190.476 \times 10^3\text{ dm}^3 \times 4 \times 10^{-3}\text{ kg mol}^{-1}}{0.083\text{ bar dm}^3\text{ K}^{-1}\text{mol}^{-1} \times 300\text{ K}}$$

$$w_{\text{He}} = 1117.46\text{ kg}$$

Total mass of filled balloon, w_{balloon}

= mass of balloon + mass of He filled in the balloon

$$w_{\text{ balloon}} = 100\text{ kg} + 1117.46\text{ kg} = 1217.46\text{ kg}$$

Pay load = mass of displaced air – mass of balloon

= 5028.57 kg – 1217.46 kg = 3811.11 kg

11. Suppose volume of the air in flask $= V\text{ cm}^3$ at 27°C or300 K

$$V_1 = V\text{ cm}^3, V_2 = ?, T_1 = 300\text{ K}, T_2 = 750\text{ K}$$

$$\frac{V_1}{T_1} = \frac{V_2}{T_2}$$

$$\frac{V}{300} = \frac{V_2}{750} \text{ or } 300\ V_2 = 750\ V$$

$$V_2 = 2.5\ V$$

Volume expelled $= 2.5\ V - V = 1.5\ V$ (final volume)

Fraction of air expelled $= \frac{1.5\ V}{2.5\ V} = 0.6$

Alternatively, using $pV = nRT$

$$n \propto \frac{1}{T}$$

$$\frac{n_2}{n_1} = \frac{T_1}{T_2} = \frac{300}{750} \Rightarrow \frac{n_2}{n_1} = 0.4$$

$\therefore$ Fraction of air expelled = 0.6

12. Greatest deviation from ideal behaviour is exhibited by real gases at low temperature and high pressure.

13.

$$\frac{(v_{\text{av}})_1}{(v_{\text{av}})_2} = \sqrt{\frac{T_1}{T_2}}$$

Given, $T_1 = 150 + 273 = 423\text{K}$

$T_2 = 50 + 273 = 323\text{K}$

$$\therefore \quad \frac{(v_{\text{av}})_1}{(v_{\text{av}})_2} = \sqrt{\frac{T_1}{T_2}} = \sqrt{\frac{423}{323}} = \frac{1.14}{1}$$

14. Volume of balloon $= \frac{4}{3}\pi r^3$

$$= \frac{4}{3} \times \frac{22}{7} \times \left(\frac{21}{2}\right)^3 = 4851\text{ mL}$$

Volume of the cylinder containing gas

= 2.82 L = 2820 mL

Volume at STP, $= V_1 = \frac{p_2 V_2 T_1}{T_2 p_1} = 2820 \times \frac{273 \times 20}{300 \times 1}$

= 51324 mL

Volume of the gas that will remain in the cylinder after filling balloons is equal to the volume of cylinder, *i.e.,* 2820 mL.

Available hydrogen for filling = 51324 − 2820

= 48504 mL

Number of balloons $= \dfrac{48504}{4851} \approx 10$

15. Number of moles of helium $= \dfrac{0.4}{4} = 0.1$

Number of moles of oxygen $= \dfrac{1.6}{32} = 0.05$

Number of moles of nitrogen $= \dfrac{1.4}{28} = 0.05$

Total moles in the 10.0 L cylinder at 27°C

$= (0.1 + 0.05 + 0.05) = 0.2$ mol

$$p_T = \frac{nRT}{V} = \frac{0.2 \times 0.082 \times 300}{10} = 0.492 \text{ atm}$$

16. Effusion does not depend on size of the molecule.

17. CH_3OCH_3 lacks H-bonding, hence, it is most volatile, so it has maximum vapour pressure.

18. $p_1 = p; \quad V_1 = V; \quad p_2 = 2p; \quad V_2 = 2V$

$$\frac{p_1V_1}{T_1} = \frac{p_2V_2}{T_2}$$

$$\frac{pV}{T_1} = \frac{2p \times 2V}{T_2} \Rightarrow T_2 = 4T_1$$

When air has been taken in and p, V remain constant,

$$n_1 \cdot 4T_1 = n_2 \cdot T_2$$

$$n_1 = n \text{ and } n_2 = n + \frac{1}{4}n = \frac{5}{4}n$$

$$\therefore \qquad n \cdot 4T_1 = \frac{5}{4}n \cdot T_2 \Rightarrow T_2 = \frac{16}{5}T_1$$

19. Boyle's law, $p \propto \dfrac{1}{V}$ at constant T and n

Charles' law, $V \propto T$ at constant p and n

Dalton's law, $p_{\text{Total}} = p_1 + p_2 + p_3 + \ldots\ldots$ at constant T, V

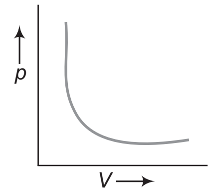
Avogadro's law, $V \propto n$ at constant T and p

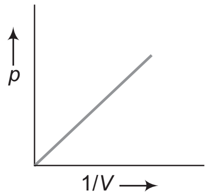
20. When molar volume is constant, the $p-T$ graph is called isochore.

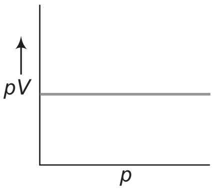
When temperature is constant, the p-V graph is called isotherm.

When pressure is constant, V-T graph is called isobar.

21.







22. Volume of 1mole of the gas = 22.4 L at STP

Volume occupied by 28 g CO (1mol CO) = 22.4L at STP

($\because$ Molar mass of CO $= 12 + 16 = 28 \text{ g mol}^{-1}$)

$\therefore$ Volume occupied by 1 g CO $= \dfrac{22.4}{28}$ L at STP

Similarly, volume occupied by 1 g $H_2O = \dfrac{22.4}{18}$ L at STP

($\because$ Molar mass of $H_2O = (2 \times 1) + 16 = 18 \text{ g mol}^{-1}$)

Volume occupied by 1 g $CH_4 = \dfrac{22.4}{16}$ L at STP

($\because$ Molar mass of $CH_4 = 12 + (4 \times 1) = 16 \text{ g mol}^{-1}$)

Volume occupied by 1 g NO $= \dfrac{22.4}{30}$ L at STP

($\because$ Molar mass of NO $= 14 + 16 = 30 \text{ g mol}^{-1}$)

Thus, 1 g CH_4 will occupy maximum volume and 1 g of NO will occupy minimum volume at STP.

23. When salt is added, less surface area is available for the solvent to vaporise and hence, solvent experience less pressure by vapours. Thus, vapour pressure decreases. Moreover, vapour pressure also decreases with decrease in temperature because kinetic energy of the molecules decreases.

24. In gaseous state, molecules are in a state of random motion *i.e.,* it is the state with higher disorder.

25. At high pressure and low temperature, a gas deviates most from the ideal behaviour.

26.

$$(v_{\text{rms}})_{N_2} = (v_{\text{rms}})_{O_2}$$

$$\sqrt{\frac{3RT_{N_2}}{M_{N_2}}} = \sqrt{\frac{3RT_{O_2}}{M_{O_2}}}$$

$$\frac{T_{N_2}}{M_{N_2}} = \frac{T_{O_2}}{M_{O_2}}$$

Then $v_{\text{av}} \left(\sqrt{\dfrac{8RT}{\pi m}}\right)$ and $v_{\text{mps}} \left(\sqrt{\dfrac{2RT}{M}}\right)$ is also same.

$$d_{N_2} = \frac{p_{N_2}M_{N_2}}{RT_{N_2}} \text{ and } d_{O_2} = \frac{p_{O_2}M_{N_2}}{RT_{O_2}}$$

if $\qquad p_{N_2} = p_{O_2}$ then $d_{N_2} = d_{O_2}$

27. According to Boyle's law

$$V \propto \frac{1}{p} \quad \text{or} \quad p \propto \frac{1}{V}$$

$$p = \frac{K}{V} \qquad \ldots\text{(i)}$$

Differentiating Eq. (i) w.r.t. V at constant T

$$\left(\frac{dp}{dV}\right)_T = -\frac{K}{V^2}$$

28. $\frac{V_1}{V_2} = \left(\frac{T_2}{T_1}\right)^{3/2}$ for reversible adiabatic expansion.

According to van der Waals' equation

$$\left(p + \frac{a}{V_m^2}\right)(V_m - b) = RT$$

At low pressure V_m is high so 'b' can be neglected.

$$pV_m + \frac{a}{V_m} = RT, \frac{pV_m}{RT} + \frac{a}{V_m RT} = 1$$

$$Z + \frac{a}{V_m RT} = 1$$

$$Z = 1 - \frac{a}{V_m RT}$$

29. Intermolecular forces and thermal energy decide the state of matter because the former kept the molecules together but later keep them apart.

30. At constant temperature, pV *vs* plot for real gases is not a straight line because molecular interaction and volume of molecules are not negligible.

31. Statement II is the correct explanation of statement I as at critical temperature, density of liquid and gaseous phase becomes equal. Due to which liquid passes into gaseous state imperceptibly and continuously.

32. Liquids tend to reduce no. of molecules or surface tension at there surface, that's why small liquid drops have spherical shape.

33. In the van der Waals' equation, 'a' refers to the attractive forces between the molecules and 'b' is the volume correction.

34. We know that

In the high pressure region $Z = 1 + \frac{pb}{RT}$

$$2 = 1 + \frac{1000b}{RT} \quad \text{...(i)}$$

$$2.2 = 1 + \frac{1200b}{RT} \quad \text{...(ii)}$$

Solving both the equation we get, $\frac{b}{RT} = 10^{-3}$ atm^{-1}

35. $Z = \frac{pV_m}{RT}$ or $V_m = \frac{ZRT}{p}$,

$R = 0.0821$ atm mol^{-1} K^{-1}, $p = 500$ atm,

$T = 200$ K, $Z = 2$

$$\therefore \quad V_m = \frac{2 \times 0.0821 \times 200}{500} = 0.0656 \text{ L}$$

36.

$$200 < T_B < 1000$$

$$200 < \frac{a}{Rb} < 1000$$

$$400 \text{ cal} < \frac{a}{b} < 2000 \text{ cal} \qquad (\because R = 2 \text{ cal mol}^{-1} \text{ T}^{-1})$$

37. From Boyle's law $p_1V_1 = p_2V_2$

$$p_1 = \frac{p_2V_2}{V_1} = \frac{750 \times 250}{15} \quad [V = 235 + 15 = 250 \text{ L}]$$

$$= 12500 \text{ mm Hg} = 16.45 \text{ atm}$$

38. From Charles' law,

$$\frac{V_1}{T_1} = \frac{V_2}{T_2}$$

$$V_2 = \frac{V_1T_2}{T_1} = \frac{2 \times 250}{300} = 1.67 \text{ L}$$

39. According to Boyle's law, $p \propto \frac{1}{V}$

therefore, graph between p and $\frac{1}{V}$ cannot be a straight line parallel to x-axis.

40. Molecular velocity can be average velocity $= \sqrt{\frac{8RT}{M}}$

root mean square velocity $= \sqrt{\frac{3RT}{M}}$

most probable velocity $= \sqrt{\frac{2RT}{M}}$

In all cases molecular velocity $\propto \sqrt{T}$

41. van der Waals' constant a is due to force of attraction and b due to finite size of molecules.

Thus, greater the value of a and smaller the value of b, larger the liquefaction.

Thus, $a(Cl_2) > a(C_2H_6)$ and $b(Cl_2) < b(C_2H_2)$

42. Rate of diffusion, $r \propto p$

$$r \propto \frac{1}{\sqrt{M}} \quad \therefore \quad r \propto \frac{p}{\sqrt{M}}$$

For gas A, $\quad r_A \propto \frac{p_A}{\sqrt{M_A}} \quad$ ...(i)

For gas B, $\quad r_B \propto \frac{p_B}{\sqrt{M_B}} \quad$ ...(ii)

Eqs. (i)/(ii), we get $\quad \frac{r_A}{r_B} = \frac{p_A}{p_B}\sqrt{\frac{M_B}{M_A}} = \frac{p_A}{p_B}\left(\frac{M_B}{M_A}\right)^{½}$

43. $n = \frac{pV}{RT} = \frac{3170 \times 10^{-3}}{8.314 \times 300} = 1.27 \times 10^{-3}$ mol

Thus, both average kinetic energy and root mean square velocity increase but not significantly when temperature is increased from 10° C to 20°C.

44. Suppose the mass of methane as well as oxygen $= w = 1$g

$$\text{Mole fraction of oxygen} = \frac{\frac{w}{32}}{\frac{w}{32} + \frac{w}{16}} = \frac{\frac{1}{32}}{\frac{3}{32}} = \frac{1}{3}$$

Let the total pressure $= p$

Pressure exerted by oxygen $= \chi_{O_2} \times p_{\text{total}} = p \times \frac{1}{3}$

3.1 Subatomic Particles

A large number of subatomic particles have been discovered hithrtho but only electron, proton and neutron are of great importance among them and hence, are called **fundamental particles.**

Various experiments that lead to the discovery of fundamental particles are as follows

Production of Cathode Rays (Discovery of Electron)

To study the phenomenon of discharge through rarefied gases, a discharge tube with disc shaped aluminium electrode is used and a steady high potential is maintained. At atmospheric pressure, no discharge is observed. If the pressure is reduced to about 10^{-6} atmosphere, the emission of light by air disappears but a fluorescent glow appears. The systematic study of this glow by Thomson, Millikan, Crookes and others proved that its presence is due to a stream of rapidly moving negatively charged particles, called the **cathode rays**.

The discovery of radioactivity, Faraday's law of electrolysis and other observations provided sufficient evidence to prove that atom is not indivisible, but can further be broken down into certain constituents or subatomic particles, such as electron, proton, neutron, meson, neutrino etc. However, it still is the smallest substance that takes part in chemical reactions.

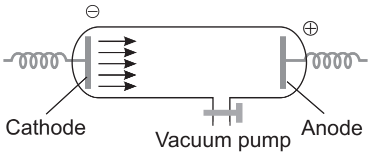

Fig. 3.1 Production of cathode rays

Some of the characteristics exhibited by cathode rays are given below:

1. Cathode rays travel in straight line path away from the cathode and cast shadows of metallic objects placed in their path.
2. Cathode rays can penetrate through thin layers of matter.
3. They produce fluorescence when they strike the glass wall of the discharge tube.
4. Cathode rays cause mechanical motion of a small pin wheel placed in their path. Thus, they possess kinetic energy and must be material particles.

5. Cathode rays are deflected by electric and magnetic field both.
6. Cathode rays produce X-rays when they strike a metallic target.
7. Cathode rays can produce chemical changes and thus, affect photographic plate.
8. The nature of the cathode rays is independent of
   (i) the nature of the cathode and
   (ii) the gas in the discharge tube.

In 1897, **J J Thomson** determined the e/m value (Charge/mass) of the cathode rays particles by studying the deflections of cathode rays in electric and magnetic fields.

He gave the following relation to calculate charge/mass ratio

$$\frac{e}{m} = \frac{E}{rB^2}$$

where, the terms have usual significance.

$$\frac{e}{m} = -1.7588 \times 10^{11}\ \text{C kg}^{-1}$$

In an electric field, the path of a cathode ray particle is parabolic , which is given as

$$y = \frac{eE}{2mv^2} x^2$$

where, y = deflection in the path of cathode ray particle in y-direction

e = charge on cathode ray particle

E = intensity of applied electric field

m = mass of cathode ray particle

v = velocity of cathode ray particle

x = distance between two parallel electric plates within which cathode ray particle is moving.

The path of a cathode ray particle in a magnetic field is circular with radius 'r' and can be given as

$$r = \frac{mv}{eB}$$

where, m = mass of cathode ray particle

v = velocity of cathode ray particle

e = charge on cathode ray particle

B = intensity of applied magnetic field

The radius of the path is proportional to momentum.

By performing a series of experiments, *Thomson proved that whatever gas be taken in the discharge tube and whatever be the material of the electrodes, the value of e/m is always the same. Cathode rays particles are thus common universal constituents of all atoms.*

Charge on Cathode Rays Particles

The first precise measurement of the charge on the electron was made by **Robert A. Millikan** in 1909 by oil drop experiment by measuring the terminal velocity of a charged spherical oil-drop which is made stationary between two electrodes on which a very high potential is applied.

$$\text{Charge on an electron '}q\text{'} = \frac{6\pi\eta r}{E}(v_1 + v_2)$$

where, η = coefficient of viscosity of the gas medium

v_1, v_2 = terminal velocities

E = field strength

r = radius of the oil drop $= \sqrt{\dfrac{9\eta v_1}{2(f-\sigma)g}}$

(f = density of oil; σ = density of gas: g = gravitational force)

By oil drop experiment, the charge (e) on cathode rays particles was determined to be -1.602×10^{-19}C or -4.803×10^{10} esu. *Since an electron has the smallest charge known, it was, thus, termed as unit negative charge.*

Mass of Cathode Rays Particles

The mass of cathode rays particles can thus, be derived by

$$m = \frac{e}{e/m} : \frac{-1.602 \times 10^{-19}}{-1.76 \times 10^{11}} = 9.108 \times 10^{-31}\text{kg}$$

This is termed as the rest mass of the cathode rays particle *i.e.*, mass of the cathode rays particle when moving with low speed. The mass of a moving cathode rays particle may be calculated by applying the following formula

Mass of moving cathode rays particle

$$= \frac{\text{rest mass of cathode rays particle}}{\sqrt{1 - \left(\dfrac{v}{c}\right)^2}}$$

where, v is the velocity of the cathode rays particle and c is the velocity of light. When v becomes equal to c, mass of the moving cathode rays particle becomes infinity and when the velocity of the cathode rays particle becomes greater than c, mass of the cathode rays particle becomes imaginary.

Mass of the Electron Relative to that of Hydrogen Atom

Mass of hydrogen atom =1.008 u

$$= 1.008 \times 1.66 \times 10^{-24}\ \ (\text{since } 1\text{u} = 1.66 \times 10^{-24}\ \text{g})$$

$$= 1.673 \times 10^{-24}\text{g}$$

$$\frac{\text{Mass of hydrogen atom}}{\text{Mass of the electron}} = \frac{1.673 \times 10^{-24}}{9.1096 \times 10^{-28}} = 1837$$

$$\text{Thus, mass of an electron} = \frac{1}{1837} x \text{ mass of hydrogen atom}$$

$$= \frac{1.008}{1837} = 0.000549\ \text{u}$$

Lorentz considered them as subatomic particle *i.e.*, a fundamental constituent of all matter having a mass of 9.108×10^{-31} kg and charge equal to -1.602×10^{-19} C.

These particles (cathode rays particles) *were named as electrons by Stoney.*

Electrons can also be produced by the action of ultraviolet light of X-rays on metal and from heated filaments. $\beta-$particles emitted by radioactive materials are also electrons.

Remember that all electrons carry the same charge. If they did not, they would be deflected by different amounts on passing through electric or magnetic fields.

Positive Rays (Discovery of Proton)

In 1886, **Eugen Goldstein** used a discharge tube with a hole in the cathode. He observed that while cathode rays were streaming away from the cathode, there were coloured rays produced simultaneously which passed through the perforated cathode and caused a glow on the wall opposite to the anode. Thomson observed that these rays consisted of positively charged particles and named them as positive rays. These rays are also known as **canal rays** or **anode rays.**

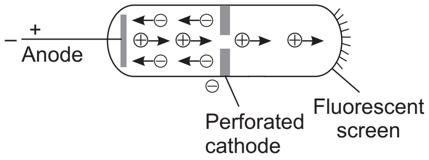

Fig. 3.2 Production of positive rays

Some of the characteristics exhibited by positive rays are as given below

1. These rays travel in straight lines and cast a shadow of the object placed in their path.
2. They possess mass many times the mass of an electron.
3. Like cathode rays, these rays also rotate the wheel placed in their path. Thus, these also possess kinetic energy.
4. The rays produce flashes of light on zinc sulphide screen.
5. The rays are deflected by electric and magnetic fields in a direction opposite to that of cathode rays.

The specific charge (e/m) of positive rays particles was found to vary with nature of gas and was maximum if H_2 is used.

Positive rays particles were thus, called positively charged gaseous atoms left after the removal of electron. Thus, a subatomic particle, *i.e.,* a fundamental constituent of all matter having a mass 1.673×10^{-27} kg and charge $+1.602 \times 10^{-19}$ C was called a **proton.**

Sample **Problem 1** *The ratio of specific charge of a proton and an* α*-particle is*

(*a*) 2 : 1 (*b*) 1 : 1
(*c*) 1 : 4 (*d*) 1 : 2

Interpret (*a*) Before solving this problem, remember that α-particles are actually helium nuclei (He^{2+} ion). Thus, it carries two unit positive charge and 4 u (6.67×10^{-27} kg) mass. Thus,

$$\frac{(e/m)_p}{(e/m)_a} = \frac{+1/1}{2/4} = 2:1$$

Discovery of Neutrons

Chadwick (1932) bombarded beryllium (Be) or boron (B) sheet with high speed alpha (α) particles and noticed the emission of neutral particles, *i.e.,* neutrons of mass nearly equal to protons and with no charge.

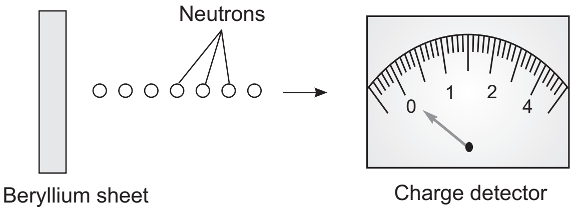

Fig. 3.3 Ejection of neutron (Chadwick experiment)

Neutron is, therefore, having a mass 1.675×10^{-27} kg and no net charge, usually represented as ${}_0n^1$.

$$_4\text{Be}^9 + {}_2\text{He}^4 \longrightarrow {}_6\text{C}^{12} + \underset{\text{Neutron}}{{}_0n^1}$$

Table 3.1 **Properties of Fundamental Particles**

Particles	Mass in			Charge in		Charge in units	Symbol	Discoverer	Location
	CGS	SI (kg)	amu (u)	esu	SI (Coulomb)				
Electron	9.1×10^{-28}	9.1×10^{-31}	0.000549	4.8×10^{-10}	1.602×10^{-19}	−1	${}_{-1}e^0$	JJ Thomson	Outside the nucleus
Proton	1.6×10^{-24}	1.672×10^{-27}	1.00727	—	1.6×10^{-19}	+1	${}_{+1}p^1$ or ${}_{+1}H^1$	Rutherford	In the nucleus
Neutron	1.6×10^{-24}	1.674×10^{-27}	1.00867	0	0	0	${}_0n^1$	Chadwick	In the nucleus

Other Sub-Atomic Particles

Particles other than the fundamental particles may also be present in atom but their existence is not certain.

Some of them are given below

(a) **Positron** $({}_{+1}e^0)$ It was discovered by CD Anderson in 1932. its bears a unit positive charge, and mass equal to mass of an electron. It merges with an electron and emits electromagnetic radiations.

(b) **Meson** (π) In 1935, Yukawa discovered this particle. Different types of meson particles *i.e.*, positive, negative or neutral meson can be found in an atom.

(c) **Neutrino** $({}_0e^0)$ Pauling discovered this particle in 1927. It does not bear any charge, *i.e.,* it is an electroneutral particle.

(d) **Antiproton** This particle was discovered by Segre in 1956. It bears a unit negative charge, and its mass is equal to that of a proton.

Major Problems after the Discovery of Fundamental Particles

When the fundamental particles were discovered, scientists faced other major problems, which were

1. How are these particles arranged in an atom?
2. Why does one element differ from another?
3. How do electromagnetic radiation originate and what is their nature?

To find the answer of these questions, various models were proposed. These models were called atomic models.

3.2 Thomson Atomic Model

JJ Thomson (who discovered electron) proposed a model in 1898, according to which an atom consists of a uniform sphere (radius approximately 10^{-10} m) of positive charge with electrons embedded in such a way so as to give most stable electrostatic arrangement, *i.e.,* he visualised atom as a pudding or cake of positive charge with electrons embedded into it. This model is often called **raisin pudding model** (raisin = electrons) or **plum pudding** or **water melon model.**

This model of atom could account for the electrical neutrality of atom but it could not explain the results of gold foil scattering experiments of Rutherford.

3.3 Rutherford Atomic Model

Rutherford along with Marsden gave the model which was based upon his famous **alpha particle scattering experiment.**

Alpha Particle Scattering Experiment

In this experiment, Rutherford bombarded the gold foil (thickness ≈ 100 nm) with high energy positively charged helium ions (charge +2, mass 4u). The gold foil had a circular fluorescent ZnS screen around it. Whenever an α-particle struck the screen, a tiny flash of light was produced at that point.

Rutherford knew that α-particles had enough energy to pass directly through such atom (having evenly distributed mass spread over the entire atom) and expected the particles to slow down and change direction only by a small angle as they passed through the foil.

The results of such an experiment were, however, quite unexpected as he observed that

1. Most of the α-particles passed through undeflected.

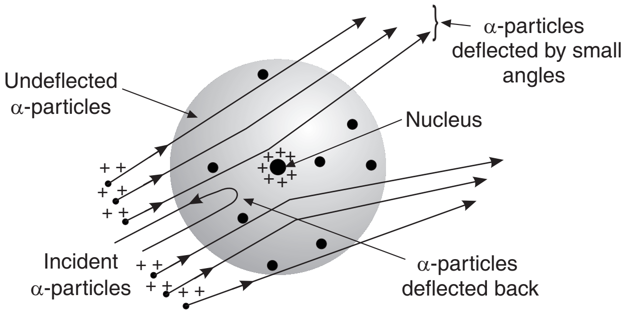

Fig. 3.4 Scattering of α-particles by a dense, positively charged nucleus

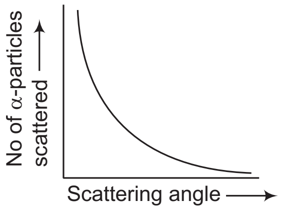
2. A small fraction of α-particles was deflected by small angles.
3. A very few α-particles (1 in 20000 approximate) bounced back, *i.e.,* were deflected by nearly 180°.

On the basis of observations, Rutherford concluded that

1. Atom consists of a heavy and positively charged part at its centre, called the **nucleus** (diameter = 10^{-14} m).
2. The entire mass of an atom resides in its nucleus and is equal to the sum of masses of protons and neutrons, since the mass of electron is negligible.
3. The volume occupied by nucleus is very less as compared to the total volume of atom.
4. The atom consists of lot of empty space around nucleus.
5. Electrons revolve around the nucleus in closed orbits (like planets around the sun) and almost all the space around nucleus is occupied by revolving electrons (in the diameter of about 10^{-10} m).

The graph between angle of scattering and the number of α-particles scattering in the corresponding direction is as shown in the figure.



Informations of Rutherford's scattering equation can be memorised by the following relations

(a) Kinetic energy of α-particles

$$N = K_1 / [(1/2)mv^2]^2$$

(b) Scattering angle 'θ':

$$N = K_2 / [\sin^4(\theta/2)]$$

(c) Nuclear charge

$$N = K_3(Ze)^2$$

Here, N = Number of α-particles striking the screen and K_1, K_2 and K_3 are the constants.

Dissimilarities between Nuclear Atomic Model and Solar System

(i) The sun and the planets are very big bodies and uncharged while the nucleus and electrons are very small objects and charged.

(ii) The revolution of the planets in the solar system is governed by gravitational forces, while the revolution of electrons around the nucleus is governed by electrostatic forces.

(iii) In the solar system, there is only one planet which revolves in any particular orbit, but in the nuclear atomic model more than one electron may rotate in any particular orbit.

Drawbacks of Rutherford Model

1. According to classical theory of electromagnetism, if a charged particle revolves around oppositely charged particle, the former one will radiate energy resulting to decrease in its speed. The circular orbit becomes spiral gradually due to such release of energy and electron finally falls on nucleus. But this does not happen.

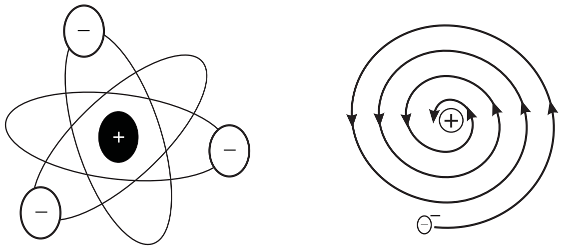


Fig. 3.5 (a) Rutherford's model of atom; electrons orbiting around nucleus

(b) Orbiting electron would radiate energy and spiral into the nucleus

2. If the electron lose energy continuously, the observed spectrum should be continuous but the actual observed spectrum consists of well defined lines of definite frequencies. Hence, the loss of energy by the electrons is non-continuous in an atom.
3. The most important drawback is that this model tells nothing about the electronic structure of atom. In other words, it does not tell about the distribution of electrons around the nucleus.

Sample **Problem 2** *If Rutherford performed his experiment using β-rays, what would have been his observations?*

(a) *Most part of β-particles would have passed undeflected.*

(b) *A sharply defined pencil of β-rays, produced by passing the rays through pinhole, would had become more focussed (contracted) after passing through metal foil.*

(c) *A very few β-particles would had been completely absorbed.*

(d) *All of the above*

Interpret (*d*) In case of β-rays all the given observations are true because β-rays are infact negatively charged and hence, attracted towards nucleus.

Sample **Problem 3** *In Rutherford's experiment, generally the thin foil of heavy atoms, like gold, platinum, etc., have been used to be bombarded by the α-particles. If the thin foil of light atoms like aluminium, etc., is used, what difference would be observed from the above results?* **[NCERT]**

(a) *All the α-particles pass through without the much effect*

(b) *The number of α-particles deflected back becomes half*

(c) *The number of α-particles deflected increases*

(d) *The results are same in both the case*

Interpret (a) Heavy atoms such as gold, platinum have heavy nucleus. Heavy nucleus contains large amount of positive charge. When a beam of α-particles is shot at a thin gold foil, most of them pass through without much effect. Some however, are deflected back or by small angles due to enormous repulsive force of heavy nucleus. If light aluminium foil is used, the number of α-particles deflected back or those deflected by small angles will be negligible.

3.4 Representation of Atom

An atom is generally represented by the following symbol

$${}_{Z}X^{A}$$

In this symbol, Z represents the atomic number (which is generally equal to the number of protons). A represents mass number. It is the sum of number of protons and number of neutrons in an atom.

Mass number = number of protons + number of neutrons

In case of neutral atom, number of protons and number of electrons are equal.

Sample Problem 4 *An element with mass number 81contains 31.7% more neutrons as compared to protons. Assign the atomic symbol* **[NCERT]**

(a) $^{81}_{35}\text{Br}$ (b) $^{81}_{34}\text{Se}$

(c) $^{82}_{35}\text{Br}$ (d) $^{81}_{36}\text{Kr}$

Interpret (*a*) We know that mass number of the element. $A = p + n = 81$ ...(i)

Let the number of protons, $p = x$

Then, number of neutrons, $n = x + \frac{31.7}{100}x = 1.317x$

(as number of neutrons are 31.7% more than the protons).

Hence, from Eq. (i) $x + 1\ .317x = 81$

$$2.317x = 81$$

or $$x = \frac{81}{2.317} = 34.958 \approx 35$$

Therefore, number of protons = 35 and the symbol is $^{81}_{35}\text{Br}$

(Remember number of protons = Atomic number)

Types of Atomic Species

Atomic species are of following types

(a) Isotopes

These are the atoms that have same atomic number (Z) but different mass number (A). *e.g.*, $_1H^1$, $_1H^2$, $_1H^3$ are three isotopes of hydrogen.

(b) Isobars

These are the atoms of different elements that have same mass number (A) but different atomic number, *e.g.*,, $_{18}Ar^{40}$, $_{19}K^{40}$.

(c) Isoelectronic

These species have same number of electrons, *e.g.*, Na^+ ,Mg^{2+} both have 10 electrons.

(d) Isotones

These are the species in which atomic number as well as mass number are different but number of neutrons are same, *e.g.*, $_1H^3$ and $_2He^4$ both have 2 neutrons.

(e) Isodiaphers

These species have same isotopic number, which is obtained by subtracting double of atomic number from atomic mass (or mass number), *i.e.*, Isotopic number = mass number − 2 × atomic number. $_{19}K^{39}$ and $_9F^{19}$ are isodiaphers.

Sample Problem 5

Assertion (A) *All isotopes of a given element show the same type of chemical behaviour.*

Reason (R) *The chemical properties of an atom are controlled by the number of electrons in the atom.* **[NCERT Exemplar]**

(a) *Both A and R are true and R is the correct explanation of A.*

(b) *Both A and R are true but R is not the correct explanation of A.*

(c) *A is true but R is false.*

(d) *Both A and R are false.*

Interpret (a) Isotopes have the same atomic number, *i.e.*, same number of electrons which are responsible for their chemical behaviour. Hence, these exhibit similar chemical properties.

3.5 Developments Leading to the Bohr's Model of Atom

Nature of electromagnetic radiations and spectrum play an important role in the development of Bohr's model.

Wave Nature of Electromagnetic Radiations

Light, X-rays and γ-rays are examples of radiant energy. Indeed, radiation is a mode of transference of energy of different forms.

Clark Maxwell in 1856 showed that radiant energy has wave properties and called them **electromagnetic waves** or **electromagnetic radiations**. All these radiations travel with the speed of light and do not require any medium for their propagation or transmission.

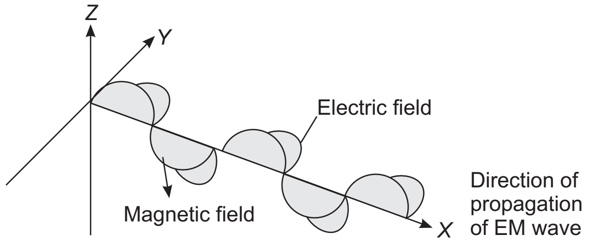

Fig. 3.6 Electric and magnetic fields associated with an electromagnetic wave

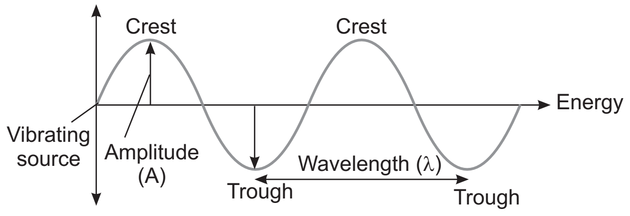
A wave is a periodic disturbance in space or in a medium that involves elastic displacement of material particles or a periodic change in some physical quantities such as temperature, pressure, electric potential, electromagnetic field. Thus, wave motion represents propagation of a periodic disturbance carrying energy.



Light wave

Characteristics of Wave

(a) Wavelength

It is defined as the distance between two successive crests or troughs of a wave *i.e.,* distance between successive points of equal phase. It is denoted by the Greek letter 'λ'. It is expressed in centimetres, metres or in angstrom units.

$$\begin{aligned} 1\,\text{Å} &= 10^{-8}\ \text{cm} \\ &= 10^{-10}\ \text{m} \\ 1\ \text{nm} &= 10^{-9}\ \text{m} \end{aligned}$$

(b) Frequency

The frequency is the number of waves which pass through a given point in one second or it is the number of cycles or oscillations or vibrations of a wave motion in unit time. It is denoted by the letter 'ν' (nu) and is expressed in hertz (Hz) or cycles per second (cps).

$$\boxed{\nu = \frac{\text{velocity}}{\text{wavelength}}}$$

(c) Velocity

It is defined as the distance covered in one second by the waves. It is denoted by the letter 'c'. All the electromagnetic waves travel with the same velocity, *i.e.,* 3×10^{10} cm/s.

(d) Wave Number

Another quantity used to characterise radiation is the wave number. This is inverse of the wavelength and is given by symbol '$\bar{\nu}$' (nu bar).

$$\boxed{\bar{\nu} = \frac{1}{\lambda}}$$

The wave number is the number of wavelength per unit of length covered. Its unit is cm^{-1} or m^{-1}.

(e) Amplitude

It is defined as the height of the crest or depth of the trough of a wave. It is denoted by the letter 'a'. It determines the intensity of the radiation.

(f) Time Period

Time taken by the wave for one complete cycle or vibration is called time period. It is denoted by T. It is expressed in second per cycle.

$$T = \frac{1}{\nu}$$

Electromagnetic radiations are of various types depending upon their wavelength (λ) or frequency (ν). These radiations constitute the electromagnetic spectrum. The various regions of electromagnetic radiations are identified by different names.

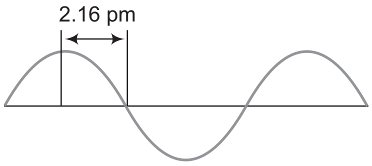
These names alongwith important characteristics of that region are summarised in the following table

Table 3.2 **Characteristics of Various Electromagnetic Radiations**

S. No.	Name	Wavelength (Å)	Frequency (Hz)	Source	Uses
1.	Radiowave	$3 \times 10^{14} - 3 \times 10^{7}$	$1 \times 10^{5} - 1 \times 10^{9}$	Alternating current of high frequency	Signal transmission
2.	Microwave	$3 \times 10^{7} - 6 \times 10^{6}$	$1 \times 10^{9} - 5 \times 10^{11}$	Klystron tube	Cooking radar
3.	Infrared (IR) waves	$6 \times 10^{6} - 7600$	$5 \times 10^{11} - 3.95 \times 10^{14}$	Incandescent objects	Heating
4.	Visible	7600 – 3800	$3.95 \times 10^{14} - 7.9 \times 10^{14}$	Electric bulb, sun rays	Illumination
5.	Ultraviolet wave (UV)	3800 – 150	$7.9 \times 10^{14} - 2 \times 10^{16}$	Sun rays, mercury vapour	Germisidal lamps
6.	X-rays	150 – 0.1	$2 \times 10^{16} - 3 \times 10^{19}$	Cathode rays striking metal plate	Medical pictures, material testing
7.	γ-rays	0.1 – 0.01	$3 \times 10^{19} - 3 \times 10^{20}$	Radioactive decay	Cancer treatment
8.	Cosmic rays	0.01 – zero	3×10^{20} – infinity	Outer space	

Sample **Problem 6** *A hypothetical electromagnetic wave is shown in the figure. Find out the wavelength of the radiation.*

[**NCERT** Exemplar]



(*a*) 2.16 (*b*) 4.32
(*c*) 6.48 (*d*) 8.64

Interpret (*d*) Wavelength is the distance between two successive peaks or two successive troughs of a wave.

Therefore, $\lambda = 4 \times 2.16 \text{ pm} = 8.64 \text{ pm}$

Particle Nature of Electromagnatic Radition

The phenomenon like diffraction, interference can, however, be well explained by wave nature of EMR but it fails to explain the other phenomenon like black body radiation, photoelectric effect etc.

Black Body Radiation and Planck's Quantum Theory

The ideal body, which emits and absorbs all possible frequencies is called a **black body** and the radiation emitted by this body are called **black body radiation.**

In 1900, *Max Planck provided an explanation to this behaviour, according to which*

1. **Atoms** and **molecules** could emit or absorb energy in discrete quantities only, which are called **quantum.**
2. The energy of a **quantum** is proportional to its frequency as $E = h\nu$
   where, h is the proportionality constant, called the Planck's constant with the value 6.626×10^{-34} Js.
3. Energy is always emitted in integral multiples of $h\nu$ as $2h\nu$, $3h\nu$ etc. In other words, energy is quantised.
   Planck was unable to explain that why energies are quantized in this manner. However, **Einstein** explained the quantized nature of light while explaining the phenomenon of photoelectric effect.

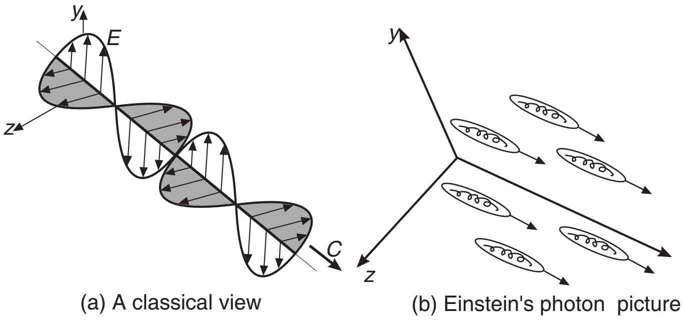
Caution Point *An electron coming to a lower orbit always emits photons of higher energy (shorter wavelength) than the photons emitted when electron comes to higher orbit irrespective of the original orbit number of electron.*

Photoelectric Effect

When a light of certain frequency strikes the surface of a metal, electrons are ejected or given out from the metal surface. This phenomenon of ejection of the electrons from the metal surface under the influence of incident radiation is called *photoelectric effect*. The electrons ejected from a substance in this manner are called *photoelectrons*.

The photoelectric effect is only shown by a few metals under the influence of visible light. However, most of the metals exhibit this effect under the influence of more energetic ultraviolet light.

According to wave theory of light, both the number of electrons ejected and their energies should depend upon the intensity of incident light, however in practice, it is found that only the number of ejected electrons depends upon incident light intensity while their energies do not. Einstein suggested that light consists of streams of particles, called *photons* which move with the speed of light.



(a) A classical view (b) Einstein's photon picture

Fig. 3.7 Picture of a travelling light wave

Using Planck's quantum theory of radiation as a starting point, he deduced that each photon possess energy, E which is equal to

$$\boxed{E = h\nu = \frac{hc}{\lambda}} \qquad \left(\because \ \nu = \frac{c}{\lambda}\right)$$

$$= hc\bar{\nu}$$

where, ν = frequency of light.

Thus, shooting a beam of light on a metal surface means shooting a beam of photons. An electron is ejected when a photon strikes that electron and transfers all of its energy to electron.

There is a characteristic minimum frequency for each metal, called **threshold frequency** (ν_0) below which the 'photoelectric effect' does not occur. We can calculate, minimum amount of energy required to remove an electron from the metal surface, with the help of this frequency as

$$E = h\nu_0$$

This is also called **work function** (W) of metal.

Since, the striking photons have energy equal to $h\nu$ and the minimum energy required to eject an electron is $h\nu_0$, then $h\nu - h\nu_0$ will be transformed as KE of photoelectron, *i.e.,* $\frac{1}{2} m_e v^2$, and as the total energy has to be conserved,

We can write Einstein equation as

$$\frac{1}{2} m_e v^2 = h\nu - h\nu_0$$

$$\boxed{\frac{1}{2} m_e v^2 = h(\nu - \nu_0)}$$

Caution Point *The maximum kinetic energy* (KE_{max}) *of photoelectrons is directly proportional to the frequency of incident light and is independent of its intensity.*

Sample Problem 7 *Neon gas is generally used in sign boards. If it emits strongly at 616 nm, calculate*

(*i*) *the frequency of emission and*

(*ii*) *number of quanta present if produces 2 J of energy respectively* **[NCERT]**

(a) $4.9 \times 10^{14} s^{-1}, 4.2 \times 10^{18}$

(*b*) $8.2 \times 10^{14} s^{-1}, 5.3 \times 10^{18}$

(*c*) $2.6 \times 10^{14} s^{-1}, 42 \times 10^{18}$

(*d*) $4.9 \times 10^{14}\ s^{-1}\ 6.2 \times 10^{18}$

Interpret (*d*) (i) Frequency, $\nu = \frac{c}{\lambda}$

$$\lambda = 616 \text{ nm} = 616 \times 10^{-9} \text{m}$$

$$\nu = \frac{3.0 \times 10^8 \text{ ms}^{-1}}{616 \times 10^{-9} \text{m}} = 4.870 \times 10^{14} \text{s}^{-1}$$

(ii) Energy of quantum (or photon),

$$E = h\nu = 6.626 \times 10^{-34} \text{ Js} \times 4.870 \times 10^{14} \text{s}^{-1}$$

$$= 32.268 \times 10^{-20} \text{ J} = 32.27 \times 10^{-20} \text{J}$$

$$\text{Number of quanta present} = \frac{\text{Total energy produced}}{\text{Energy of 1 quanta}}$$

$$= \frac{2\text{J}}{32.27 \times 10^{-20} \text{J}} = 6.197 \times 10^{18} \approx 6.2 \times 10^{18} \text{ quanta}$$

Sample Problem 8 *Threshold frequency* ν_0 *is the minimum frequency which a photon must possess to eject an electron from a metal. It is different for different metals. When a photon of frequency* $1.0 \times 10^{15} \text{s}^{-1}$ *was allowed to hit a metal surface, an electron having* 1.988×10^{-19} *J of kinetic energy was emitted. If a photon with a wavelength equal to 600 nm hits the metal surface,* **[NCERT Exemplar]**

(a) *the electrons will be ejected*

(*b*) *no electron will be emitted*

(*c*) *four electrons will be emitted*

(*d*) *cannot say anything*

Interpret (*b*) We know that $h\nu = h\nu_0 + \text{KE}$ or $h\nu - \text{KE} = h\nu_0 = (6.626 \times 10^{-34} \text{Js} \times 1 \times 10^{15} \text{s}^{-1}) - 1.988 \times 10^{-19} \text{J}$

$$h\nu_0 = 6.626 \times 10^{-19} - 1.988 \times 10^{-19} \text{J}$$

$$h\nu_0 = 4.638 \times 10^{-19} \text{ J}$$

$$\nu_0 = \frac{4.638 \times 10^{-19} \text{J}}{6.626 \times 10^{-34} \text{Js}}$$

$$= 0.669 \times 10^{15} \text{ s}^{-1}$$

when, $\lambda = 600 \text{nm} = 600 \times 10^{-9} \text{m}$

$$\nu = \frac{c}{\lambda} = \frac{3.0 \times 10^8 \text{ms}^{-1}}{6.0 \times 10^{-7} \text{m}}$$

$$= 0.5 \times 10^{15} \text{s}^{-1}$$

Thus, $\nu < \nu_0$.

Hence, no electron will be emitted.

Spectrum

A spectrum can be defined as "pictorial representation of arrangement of radiations in increasing order of wavelength or decreasing order of frequency". The spectrum may be emission or absorption spectrum on the basis of energy absorbed or emitted.

Atom, molecule and **ions** emit radiations after being excited, *i.e.,* after absorbing energy. The spectrum of such emitted radiations is called **emission spectra.**

An **absorption spectra** is like the photographic negative of an emission spectra. Here a continum of radiations is passed through a sample which absorbs the radiations of certain wavelengths. The missing wavelengths (which correspond to radiations absorbed), leave dark spaces in bright continuous spectrum. Such a spectrum is called **absorption spectrum.**

Both type of spectra, further may be continuous (*i.e.,* one radiation merges with other at its boundary, or., when there is no sharp boundary between the radiations) or discontinuous (*i.e.,* have sharp boundaries).

The emission spectrum of atoms in gaseous phase do not show a continuous spread of wavelengths, here they emit radiation only at specific wavelengths. Such an spectra which contains bright lines with sharp boundaries is called **line spectra** or **discontinuous spectra.**

Hot Spot 1

ATOMIC Spectrum of Hydrogen

It is an important topic for JEE Main examination. The questions are generally numerical type and their level may vary from average to difficult. However, a regular practice help you to solve out problems based on this topic.

The atomic spectrum of hydrogen was proved quite helpful in the development of atomic structure. It can be obtained by passing the light, being emitted from the discharge tube containing hydrogen at low temperature, through spectrograph. Actually the electric discharge dissociates H_2 molecules and energetically excited hydrogen atoms are produced. These hydrogen atoms emit electromagnetic radiations of discrete frequencies.

The spectrum obtained consists of large number of sharp lines each of which corresponds to a particular frequency. These lines are present in UV, visible and infra-red regions of electromagnetic spectrum.

The lines in emission spectrum of hydrogen are classified into six series as follows

1. Lyman series]—UV region
2. **Balmer series**]—Visible region
3. **Paschen series**
4. **Brackett series** } — IR region
5. Pfund series
6. Humphery series - Far IR region

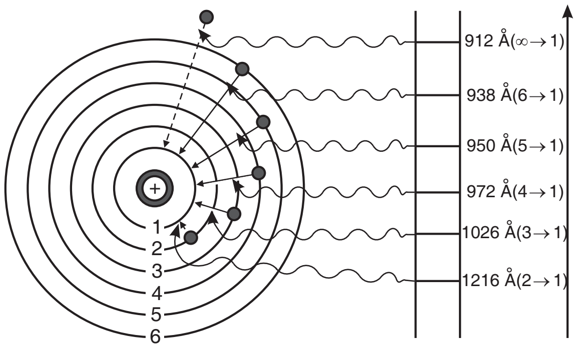


Fig. 3.8 Jump of hydrogen electron (shown by black circle) from higher energy level to 1st energy level to produce spectral lines of Lyman series. The electronic jumps have been shown in brackets. The electronic jump from $n_2 = \infty$ to $n_1 = 1(\infty \rightarrow 1$ jump) has been shown by a dotted arrow.

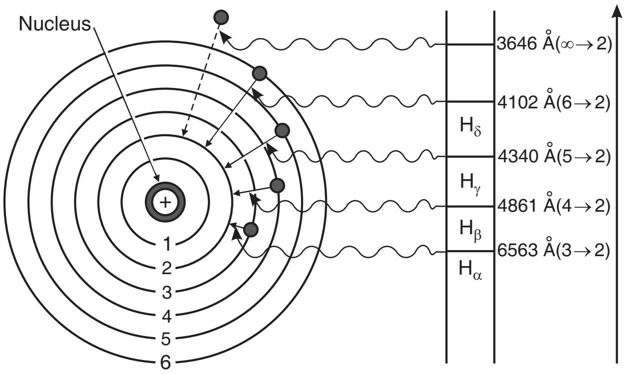

Fig. 3.9 Jump of hydrogen electron (shown by black circle) from higher energy levels to 2nd energy level to produce spectral lines of Balmer series. The electronic jumps have been shown in brackets. The electronic jump from $n_2 = \infty$ to $n_1 = 2(\infty \rightarrow 2$ jump) has been shown by a dotted arrow.

Balmer, in 1885 showed that if spectral lines are expressed in terms of wave number $\bar{\nu}$, then the visible lines of hydrogen spectrum obey the following formula

$$\text{Wave number, } \bar{\nu} = 109{,}677\left(\frac{1}{2^2} - \frac{1}{n^2}\right)\text{cm}^{-1}$$

here, n = an integer equal to or greater than 3.

Swedish spectroscopist **Rydberg** gave above formula in more generalised form which is applicable to all the series of hydrogen spectrum and can be written as

$$\bar{\nu}_H(\text{cm}^{-1}) = R_H\left(\frac{1}{n_1^2} - \frac{1}{n_2^2}\right) \qquad \text{here, } R_H = 1{,}09{,}677 \text{ cm}^{-1}$$

The n_1 and n_2 are integers where $n_2 > n_1$.

For a particular series n_1 is constant.

The values of n_1 and n_2 for different series of hydrogen spectrum will be

(i) Lyman series, $n_1 = 1, \; n_2 = 2, 3, 4, \ldots$
(ii) Balmer series, $n_1 = 2, \; n_2 = 3, 4, 5, \ldots$
(iii) Paschen series, $n_1 = 3, \; n_2 = 4, 5, 6, \ldots$
(iv) Brackett series, $n_1 = 4, \; n_2 = 5, 6, 7, \ldots$
(v) Pfund series, $n_1 = 5, \; n_2 = 6, 7, 8, \ldots$
(vi) Humphery series, $n_1 = 6, \; n_2 = 7, 8, 9 \ldots$

For elements *except hydrogen*, the formula is written as

$$\text{wave number,} \qquad \bar{\nu} = R_H \cdot Z^2\left[\frac{1}{n_1^2} - \frac{1}{n_2^2}\right]$$

where, $R_H = 109677 \text{ cm}^{-1}$, Z = atomic number of element

The Balmer series of lines is the only series which appears in the visible region of EM spectrum.

Always keep in mind, while solving problems based on this topic.

Inter-relate the quantity you have to calculate with the formula you know or divide the question in two steps. For example see the sample problem given below.

Sample **Problem 9** *Find the wavelengths of the first line of* He$^+$ *ion spectral series whose interval between extreme lines is* $\dfrac{1}{\lambda_1} - \dfrac{1}{\lambda_2} = 2.7451 \times 10^4 \text{ cm}^{-1}$

[$R_H = 109677.76 \text{ cm}^{-1}$]

(*a*) 8968 Å
(*b*) 4689 Å
(*c*) 9378 Å
(*d*) 2345 Å

Interpret (*b*) Extreme lines means first and last.

$$\frac{1}{\lambda_1}-\frac{1}{\lambda_2}=R_HZ^2\left[\frac{1}{n_1^2}-\frac{1}{\infty^2}\right]-R_HZ^2\left[\frac{1}{n_1^2}-\frac{1}{(n_1+1)^2}\right]=\frac{RZ^2}{(n_1+1)^2}$$

$$2.7451\times10^4=\frac{109677.76\times2^2}{(n_1+1)^2}$$

$$(n_1+1)=4$$

$$n_1=3$$

Wavelength of first line

$$\frac{1}{\lambda}=109677.76\times2^2\times\left[\frac{1}{3^2}-\frac{1}{4^2}\right]$$

$$\lambda=4689\times10^{-8}\text{cm}=\ 4689\ \text{Å}$$

Sample **Problem10** *The wave number of the first line in the Lyman series in hydrogen spectrum is*

(*a*) 72755.5 *cm*$^{-1}$ (*b*) 109678 *cm*$^{-1}$

(*c*) 82258.5 *cm*$^{-1}$ (*d*) 65473.6 *cm*$^{-1}$

Interpret (*c*) Applying Rydberg formula,

$$\frac{1}{\lambda}=R_H\left[\frac{1}{n_1^2}-\frac{1}{n_2^2}\right]\text{cm}^{-1}$$

For the first line in Lyman series, $n_1=1$ and $n_2=2$

So, $$\frac{1}{\lambda}=109678\left[\frac{1}{1^2}-\frac{1}{2^2}\right]$$

$$=\frac{109678\times3}{4}=82258.5\ \text{cm}^{-1}$$

$\lambda\propto\frac{1}{n}$ and $E\propto\frac{1}{\lambda}$

Thus, for shortest wavelength or maximum energy or maximum frequency, *n* has to be maximum and for maximum wavelength or minimum energy or minimum frequency, *n* has to be minimum. This can be best understood by sample problem14.

Sample **Problem 11** *The series limits of wavelengths in the Paschen series of* He$^+$ *ion is*

(*a*) 250 – 468.7 *nm* (*b*) 468 . 7 – 350 *nm*

(*c*) 760 – 380 *nm* (*d*) 380 – 150 *nm*

Interpret (*a*) For He$^+$ion, $Z=2$ and the modified Rydberg's formula applicable to Paschen's series is

$$\frac{1}{\lambda}=R_HZ^2\left[\frac{1}{9}-\frac{1}{n^2}\right]\text{where, }n=4,5,6,\ldots\infty$$

For, shortest wavelength, *n* = has to be maximum *i.e.*,

$$\therefore\quad\frac{1}{\lambda_{\min}}=\frac{4}{9}R_H$$

or $$\lambda_{\min}=\frac{9}{4R_H}=205\times10^{-9}\text{m}=205\text{nm}$$

For maximum λ, *n* has to be minimum, 4 in the present case.

$$\frac{1}{\lambda_{\max}}=4R_H\left[\frac{1}{9}-\frac{1}{16}\right]=\frac{7R_H}{36}$$

$$\frac{1}{\lambda_{\max}}=\frac{36}{7R_H}=468.7\times10^{-9}\text{m}\ =468.7\text{nm}$$

⇒ Hence, the required series limit is $\{\lambda:250-468.7\text{nm}\}$

Sample **Problem 12** *Calculate the energy and frequency of the radiation emitted when an electron jumps from n = 3 to n = 2 in a hydrogen atom.*

[NCERT Exemplar]

(*a*) 3.028×10^{-9}, 4.57×10^{12}

(*b*) 3.028×10^{-19}, 2.89×10^{14}

(*c*) 3.028×10^{-19}, 4.57×10^{14}

(*d*) 2.128×10^{-19}, 4.57×10^{12}

Interpret (*c*) Here we divide the question into two parts (i) we calculate wavelength or wave number (ii) with the help of wavelength or wave number we calculate energy and frequency.

Wave number , $\bar{\nu}=109677\text{cm}^{-1}\left(\frac{1}{2^2}-\frac{1}{3^2}\right)$

$$\bar{\nu}=109677\times\frac{5}{36}=15232.9\ \text{cm}^{-1}$$

$$\bar{\nu}\ =\frac{1}{\lambda}\text{ or }\lambda=\frac{1}{\bar{\nu}}=\frac{1}{15232.9}=6.564\times10^{-5}\ \text{cm}$$

Wavelength, $\lambda=6.564\times10^{-7}\text{m}$

Energy, $E=\frac{hc}{\lambda}$

$$=\frac{6.626\times10^{-34}\text{Js}\ \times3.0\times10^8\text{ms}^{-1}}{6.564\times10^{-7}\text{m}}=3.028\times10^{-19}\ \text{J}$$

Frequency, $$\nu=\frac{c}{\lambda}=\frac{3.0\times10^8\text{ms}^{-1}}{6.564\times10^{-7}\text{m}}=0.457\times10^{15}\ \text{s}^{-1}$$

$$\nu=4.57\times10^{14}\ s^{-1}$$

Alternate We first inter-relate the two formulae and then put the values: *e.g.,*

$$\bar{\nu}=\frac{1}{\lambda}=R_H\left(\frac{1}{n_1^2}-\frac{1}{n_2^2}\right)$$

$$=\frac{c}{\lambda}=R_Hc\left(\frac{1}{n_1^2}-\frac{1}{n_2^2}\right)=\nu\text{ (frequency)}$$

Now by putting the value, we directly calculate the frequency. Similarly,

$$\nu=\frac{c}{\lambda}=R_Hc\left(\frac{1}{n_1^2}-\frac{1}{n_2^2}\right)=\frac{hc}{\lambda}=R_Hhc\left(\frac{1}{n_1^2}-\frac{1}{n_2^2}\right)$$

$$\therefore\qquad E=R_Hhc\left(\frac{1}{n_1^2}-\frac{1}{n_2^2}\right)$$

By putting the values in the above formula, you can calculate *E* directly.

You have to remember the value of *n*, for different series. (There is no need to remember the value of n_2 because $n_2>n_1$). For example see sample problem 13.

Caution Point *When an electron returns from n_2 to n_1 state, the number of lines in the spectrum will be equal to*

$$\frac{(n_2 - n_1)(n_2 - n_1 + 1)}{2}$$

3.6 Bohr's Model

The weaknesses of Rutherford's model was removed by **Neils Bohr,** who proposed an improved form of Rutherford's model, *according to which*

1. Electrons revolve around the nucleus in specific circular orbits having angular momentum integral multiple of $\frac{h}{2\pi}$ *i.e.,* $mvr = \frac{nh}{2\pi}$ (situated at definite distance from the nucleus) with a definite velocity.

   Number of revolution per second by an electron in a shell

   $$= \frac{\text{velocity}}{\text{circumference}} = \frac{v}{2\pi r}$$

2. As long as electron remains in a particular orbit, it neither emits (loose), nor gains (absorb) energy. This simply means that in a particular orbit, the energy of a particular electron remains stationary or constant. The orbits of such a constant energy are called stationary orbits or stationary energy levels or simply energy levels.
3. Each stationary orbit is associated with a definite amount of energy. The greater is distance of the orbit from the nucleus , more shall be the energy associated with it. These orbits are also called *energy levels* and are numbered as 1, 2, 3, 4, ... or *K, L, M, N,* ... from nucleus outwards.

   i.e., $$E_1 < E_2 < E_3 < E_4 \ldots$$
   $$(E_2 - E_1) > (E_3 - E_2) > (E_4 - E_3) \ldots\ldots$$

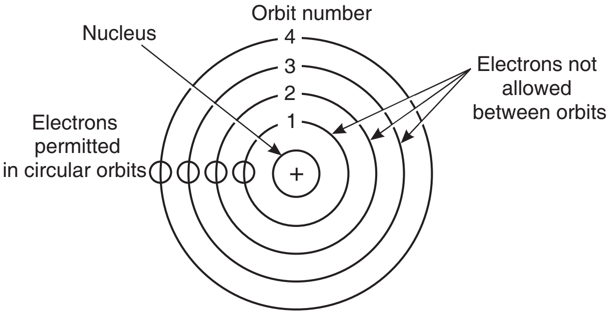

Fig 3.10 Circular electron orbits or stationary levels in an atom

4. An electron can move from one energy level to another through quantum or photon jumps only. When it resides in an orbit with lowest energy, it is said to be in **ground state.** It can jump from its lower energy level to higher energy level after absorbing energy. Here, at higher energy level, it is said to be in **excited state.**

   So, an electron can move only from its ground state to its excited state (after absorbing energy) or from its excited state to ground state (after releasing energy).
5. During transition between two stationary states of different energy, the frequency of radiation absorbed or emitted,

   $$\nu = \frac{E_2 - E_1}{h}$$

   This expression is called **Bohr's frequency rule.**

Bohr Calculations

(a) Radii of Various Orbits

Consider an electron of mass '*m*' and charge '*e*' revolving around the nucleus of charge *Ze* (*Z* = atomic number). Let '*v*' be the tangential velocity of the revolving electron and '*r*' the radius of the orbit. The electrostatic force of attraction between the nucleus and electron (applying Coulomb's law)

$$F = \frac{KZe \times e}{r^2} = \frac{KZe^2}{r^2}$$

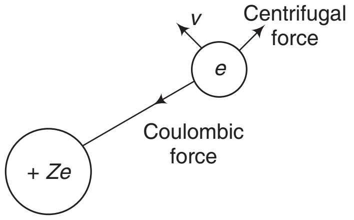

Fig 3.11 Revolution of electron around the nucleus

where, $K = \frac{1}{4\pi\varepsilon_0}$ (where ε_0 is permitivity of free space)

$$K = 9 \times 10^9 \text{ Nm}^2\text{C}^{-2}$$

In CGS units, value of K =1 dyne cm^2 (esu)$^{-2}$

The centrifugal force acting on the electron is $\frac{mv^2}{r}$

Since the electrostatic force balance the centrifugal force, for the stable electron orbit.

$$\frac{mv^2}{r} = \frac{KZe^2}{r^2} \qquad \ldots \text{(i)}$$

or

$$v^2 = \frac{KZe^2}{mr} \qquad \ldots \text{(ii)}$$

According to Bohr's postulate of angular momentum quantization, we have

$$mvr = \frac{nh}{2\pi}$$

$$\therefore \qquad v = \frac{nh}{2\pi mr}$$

$$v^2 = \frac{n^2h^2}{4\pi^2m^2r^2} \qquad \text{...(iii)}$$

Equating (ii) and (iii)

$$\frac{KZe^2}{mr} = \frac{n^2h^2}{4\pi^2m^2r^2}$$

Solving for r we get $\qquad r = \dfrac{n^2h^2}{4\pi^2mkZe^2}$

where $\qquad n = 1,2,3, \dots \infty$

Hence, only certain orbits whose radii are given by the above equation are available for the electron. The greater the value of n, *i.e.,* farther the level from the nucleus, the greater is the radius. The radius of the smallest orbit ($n = 1$) for hydrogen atom ($Z = 1$) is r_0.

$$r_0 = \frac{n^2h^2}{4\pi^2me^2K}$$

$$= \frac{1^2 \times (6.626 \times 10^{-34})^2}{4 \times (3.14)^2 \times 9.1 \times 10^{-31} \times (1.6 \times 10^{-19})^2 \times 9 \times 10^9}$$

$$= 5.29 \times 10^{-11}\text{m} \qquad r_0 = 0.529\text{Å}$$

Radius of nth orbit for an atom with atomic number Z is simply written as

$$\boxed{r_n = r_0 \frac{n^2}{Z} = 0.529 \times \frac{n^2}{Z}\text{ Å}}$$

Sample Problem 13 *The radius of hydrogen atom in the ground state is 0.53 Å. The radius of $_3Li^{2+}$ in the similar state is*

(a) 1.06 Å
(b) 0.53 Å
(c) 0.265 Å
(d) 0.17 Å

Interpret (d) $r_{Li} = \dfrac{r_H \times n^2}{Z}$

($n = 1$, because state is same as hydrogen, *i.e.*, ground state for Li, $Z = 3$)

$$r_{Li} = \frac{0.53 \times (1)^2}{3} = 0.17\text{ Å}$$

(b) Energy Level of Hydrogen Atom

The total energy, E of the electron is the sum of kinetic energy and potential energy. Kinetic energy of the electron $= 1/2\, mv^2$

$$\text{Potential energy} = \frac{-KZe^2}{r}$$

$$\text{Total energy} = \frac{1}{2}mv^2 - \frac{KZe^2}{r} \qquad \text{...(iv)}$$

From Eq. (i) we know that

$$\frac{mv^2}{r} = \frac{KZe^2}{r^2}$$

$$\therefore \qquad \frac{1}{2}mv^2 = \frac{KZe^2}{2r}$$

Substituting this in Eq. (iv)

$$\text{Total energy} \quad (E) = \frac{KZe^2}{2r} - \frac{KZe^2}{r} = -\frac{KZe^2}{2r}$$

$$\text{KE} = -\frac{1}{2}\text{PE}, \text{KE} = -\text{TE}$$

Substituting for r, gives us $E = -\dfrac{2\pi^2mZ^2e^4K^2}{n^2h^2}$

where $n = 1,2,3,\dots$

This expression shows that only certain energies are allowed to the electron. Since this energy expression consists so many fundamental constant, we are giving you the following simplified expressions.

$$\boxed{\begin{aligned} E &= -21.8 \times 10^{-12} \times \frac{Z^2}{n^2}\text{ erg/atom} \\ &= -21.8 \times 10^{-19} \times \frac{Z^2}{n^2}\text{ J/atom} \end{aligned}}$$

$$E_n = -13.6 \times 10^{-19} \times \frac{Z^2}{n^2}\text{ eV/atom}$$

$$[\because 1\text{eV} = 3.83 \times 10^{-23}\text{ kcal} = 1.602 \times 10^{-12}\text{erg} = 1.602 \times 10^{-19}\text{J}]$$

$$E = -313.6 \times \frac{Z^2}{n^2}\text{ kcal/ mol} \quad (\therefore 1\text{ cal} = 4.18\text{ J})$$

The energies are negative since the energy of the electron in the atom is less than the energy of a free electron (*i.e.*, the electron is at infinite distance from the nucleus), which is taken as zero. The lowest energy level of the atom corresponds to $n = 1$ and as the quantum number increase, E becomes less negative.

When $n = \infty, E = 0$ which corresponds to an ionized atom *i.e.*, the electron and nucleus are infinitely separated.

$$\text{H} \longrightarrow \text{H}^+ + e^- \qquad \text{(ionization)}$$

Sample Problem 14 *The ratio of the difference between 1st and 2nd Bohr's orbits energy to that between 2nd and 3rd orbit energy is*

(a) $\frac{1}{2}$
(b) $\frac{1}{3}$
(c) $\frac{27}{5}$
(d) $\frac{5}{27}$

Interpret (c) $\Delta E_{1,2} = E_2 - E_1$

$$= \frac{E_H}{(n_2)^2} - \frac{E_H}{(n_1)^2}$$

$$= E_H\left(\frac{1}{(2)^2} - \frac{1}{(1)^2}\right) = -\frac{E_H \times 3}{4}$$

$$\Delta E_{2,3} = E_3 - E_2 = -E_H \times \frac{5}{36}$$

$$\frac{\Delta E_{1,2}}{\Delta E_{2,3}} = E_H \times \frac{3}{4} \times \frac{36}{E_H \times 5} = \frac{27}{5}$$

Sample **Problem 15** *How far from the nucleus is the electron in a hydrogen atom if it has energy of -0.850 eV?*

(a) 2.39 Å (b) 5.69 Å

(c) 8.46 Å (d) 9.38 Å

Interpret (c) $E_n = -\frac{Z^2}{n^2}\times 21.8\times 10^{-19}$

$$\therefore \qquad -\frac{Z^2}{n^2}\times 21.8\times 10^{-19} = -\,0.85\times 1.6\times 10^{-19}$$

$$\text{Or} \qquad n = 4 \qquad (\because Z = 1)$$

$$r = \frac{n^2}{Z}\times 0.529 = \frac{16}{1}\times 0.529 = 8.46\text{Å}$$

(c) Bohr Velocity or Velocity of Electron

We know that, $mvr = \frac{nh}{2\pi}$; $v = \frac{nh}{2\pi mr}$

By substituting for r we are getting

$$v = \frac{2\pi KZe^2}{nh}$$

where excepting n and Z all are constant $v = 2.18\times 10^8\,\frac{Z}{n}$ cm/s.

Thus, the velocity of an electron in nth orbit of H-atom,

$$V_n = \frac{2\pi e^2}{nh} = \frac{2.1847\times 10^8}{n}\ \text{cm s}^{-1}$$

For H-like atom

$$V_{n\,(\text{H-like atom})} = V_{n\,(\text{H-atom})}\times Z$$

$$\text{Also,} \qquad \boxed{V_n = \frac{2.1\times 10^8\times Z}{n}\ \text{cm s}^{-1}}$$

Sample **Problem 16** *Determine the number of revolutions made by electron in one second in the 2^{nd} Bohr orbit of hydrogen atom.*

(a) 6. 29 $\times 10^{12}$ (b) 5.29 $\times 10^{13}$

(c) 2.39 $\times 10^{15}$ (d) 8.23 $\times 10^{14}$

Interpret (d) If V is the speed of moving electron in the said Bohr orbit then the number of revolutions made by electron in one second would be

$$rps = \frac{v}{2\pi r}$$

$$\text{Also} \qquad v = \frac{nh}{2\pi mr}$$

$$\Rightarrow \qquad rps = \frac{nh}{4\pi^2 mr^2}$$

$$= \frac{nh}{4\pi^2 m\left(\frac{a_0 n^2}{Z}\right)^2}$$

$$= \frac{h\cdot Z^2}{4\pi^2 m a_0^2 n^3}$$

$$= \frac{6.626\times 10^{-34}\times (1)^2}{4\times (3.14)^2\times 9.1\times 10^{-31}\times (0.53\times 10^{-10})^2\times (2)^3}$$

$$= 8.23\times 10^{14}\ \text{Revolution/s}$$

Caution Point *The Bohr's model is applicable only to hydrogen atom and like species i.e., to the one-electron system e.g.,* He^+, Li^{2+}, Be^{3+}, B^{4+} *etc.*

Limitations of Bohr's Model

Bohr left the following facts unexplained

1. Fine structure of atom,
2. Spectrum of multi-electron system,
3. **Zeeman effect** (effect of magnetic field on an excited atom) and **Stark effect** (effect of electric field on an excited atom). Split (resolution) of spectral lines occur in both the effects,
4. Three dimensional existence of atom,
5. Dual nature of electron.

3.7 Bohr Sommerfeld Model

Sommerfeld (1915) suggested the existence of elliptical orbits alongwith circular orbits (with situation of nuclei at one of the foci of ellipse) to explain the fine structure in hydrogen spectrum.

Due to the presence of such orbits the tangential velocity of an electron at any instance can be resolved into two components, *i.e.,* the **radial velocity** (one along the radius vector) and the **transverse** or **angular velocity** (one perpendicular to the radius vector). These two velocities give rise to **radial** and **angular** or **azimuthal momentum** as

$$\text{Radial momentum} = n_r\times\frac{h}{2\pi}$$

$$\text{Azimuthal momentum} = n_\phi\times\frac{h}{2\pi}$$

here, n_r = radial quantum number

n_ϕ = azimuthal quantum number

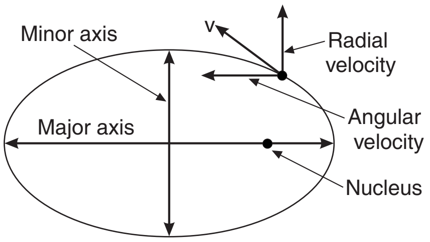

Fig. 3.12 An ellipse with electron showing radial and angular velocities

These n_r and n_ϕ are related to principal quantum number of Bohr (n) as

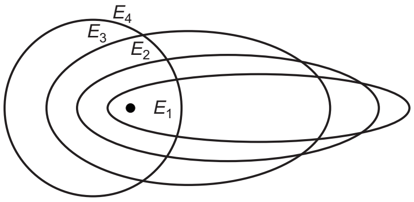
$$n = n_r + n_\phi$$

$$\frac{n}{n_\phi} = \frac{n_r + n_\phi}{n_\phi} = \frac{\text{length of major axis}}{\text{length of minor axis}}$$

Always remember that

1. **The value of n_ϕ can never be zero,** because if $n_\phi = 0$, that means the minor axis of ellipse will also be zero, *i.e.*, the electron is moving in a straight line which is impossible.
2. **n_ϕ cannot be greater than n** because in such cases the path will not be elliptical as minor axis of ellipse exceeds its major axis.
3. **n_ϕ equal to n is possible** but in that case the orbit will be circular (circular orbit is the special case of ellipse, where major axis equals the minor axis).
4. **n_ϕ smaller than n is possible** and in all such cases the orbit will remain elliptical.

If $n = 4$, four values of n_ϕ are possible as 1, 2, 3, 4 (shown as E_1, E_2, E_3 and E_4 in the following figure)



$n = 4$
$n_\phi = E_1, E_2, E_3, E_4$

Sommerfeld also modified the expression of energy of moving electron in elliptical orbit for hydrogen as

$$E_n = -\frac{2\pi^2 me^4}{(n_\phi + n_r)^2 h^2}$$

Drawbacks of Sommerfeld Model

The weak points of Bohr-Sommerfeld model are

(i) Experimental and theoretical observations based on wave mechanics show different values of n_ϕ (azimuthal quantum number) as 0, 1, 2, 3, … till $(n - 1)$, in the place of 1, 2, 3, ... till n as given by *Sommerfeld.*

(ii) This new quantum number beginning with zero and ending at $(n - 1)$ has been represented by l (to avoid the confusion with n_ϕ). This l is related to n as

$$l = \text{zero to } (n - 1)$$

(iii) This theory cannot give the exact idea of number of lines observed in fine spectrum, alongwith the information about the relative intensities of these lines.

(iv) The exact definition of position and momentum of electron can be given by this theory which is contrary to Heisenberg's uncertainty principle.

Check Point 1

1. What did Rutherford's alpha particle scattering experiment prove?
2. Which experiment neglected Thomson's model of the atom as an intimate mixture of negative and positive particles?
3. Why does the charge to mass ratio of positive rays depend on the residual gas in the discharge tube? Why is the charge to mass ratio of all cathode rays same?
4. Write wave number for the longest and the shortest wavelength of visible light.
5. Light of wavelength, λ strikes on a metal surface with intensity X, and the metal emits Y electrons per second of average, Z. What will happen to Y and Z, if X is doubled?

3.8 Modern Structure of Atom

Dual Nature of Matter: de-Broglie Equation

The French physicist **Lewis de-Broglie,** in 1924, proposed that matter like radiation also possesses dual nature, *i.e.,* has wave nature as well as particle nature. In other words, he said that electrons have momentum as well as wavelength just like photons. He examined the consequences of combining two of the more powerful equations in all of physics, the energy equation of Planck's and Einstein. A highly simplified version of what he did has been illustrated here

For an electron moving in an orbit, the energy expression, according to Planck's theory is

$$E = h\nu = \frac{hc}{\lambda} \qquad \text{...(i)}$$

Also, for energy of electron of mass m moving with speed c, the Einstein equation gives

$$E = mc^2 \qquad \text{...(ii)}$$

For the same electron, the two energy values must be identical. Therefore, by equating the right sides of the above two Eqs. (i) and (ii) we get

$$mc = \frac{h}{\lambda}$$

$$\boxed{\lambda = \frac{h}{mc} = \frac{h}{P}} \quad \text{where, } P = mc \text{ (momentum)} \qquad \text{... (iii)}$$

The above relation between wavelength (λ) and momentum (p) correlates the wave–matter duality of electron and known as **de-Broglie equation**. Putting real numbers into the de-Broglie equation shows that for any object in the normal world that the de-Broglie wavelength is too small to detect. However, when we enter the realm of atoms and the electrons, the dimensions of the waves become significant. Infact, the electron's wave is about the size of the atom.

In case kinetic energy, E of the particle is given, the de-Broglie wavelength can be calculated by the

$$\lambda = \frac{h}{\sqrt{2mE}} \qquad [\because P = \sqrt{2mE}]$$

Davisson and **Germer** made the following modification in de-Broglie equation

Let a charged particle say an electron be accelerated with a potential of V then kinetic energy may be given as

$$\frac{1}{2}mv^2 = eV$$

$$m^2v^2 = 2eVm$$

$$mv = \sqrt{2eVm} = P$$

$$\boxed{\lambda = \frac{h}{\sqrt{2eVm}}}$$

$\lambda = \frac{h}{\sqrt{2qVm}}$ for charged particles of charge q. de-Broglie waves are not radiated into space, *i.e.,* they are always associated with electron. Thus, for various sub-atomic particles the value of λ can be give by the following expressions

(i) **For electron**

$$\lambda = \frac{12.27}{\sqrt{V}} \text{Å}$$

(ii) **For proton**

$$\lambda = \frac{0.268}{\sqrt{V}} \text{Å}$$

(iii) **For α –particles** $\lambda = \frac{0.101}{\sqrt{V}} \text{Å}$

where, V = accelerating potential of these particles,

(iv) **For neutrons** $\lambda = \frac{h}{\sqrt{2Em}}$

$$= \frac{6.62 \times 10^{-34}}{\sqrt{2 \times 1.67 \times 10^{-27} \times E}}$$

$$= \frac{0.286}{\sqrt{E(eV)}} \text{Å}$$

(v) **For gas molecules**

$$\lambda = \frac{h}{m \times v_{\text{rms}}} \text{Å} = \frac{h}{\sqrt{3mkT}}$$

where, k = Boltzmann constant,

Bohr Theory *vs* de-Broglie Equation

As de-Broglie realized, the simplest way to introduce quantum ideas into an atomic model was to ascribe wave properties to the electron. A standing wave must have integral wavelengths with no possibility of fractional wavelengths with this superposition; the number of de-Broglie wavelengths in a given Bohr's orbit is always equal to the orbit number as

$$mvr = \frac{nh}{2\pi} \Rightarrow \boxed{2\pi r = \frac{nh}{mv} = n\lambda}$$

Sample **Problem 17** *The velocity associated with a proton moving in a potential difference of* 1000 *V is* $4.37 \times 10^5\ ms^{-1}$. *If the hockey ball of mass* 0.1 *kg is moving with this velocity, calculate the wavelength associated with this velocity.* **[NCERT]**

(a) 1.2×10^{-37} m (b) 1.9×10^{-39}
(c) 1.5×10^{-38} m (d) 2.6×10^{-38} m

Interpret (c) Wavelength associated with the velocity of hockey ball

$$\lambda = \frac{h}{mv} = \frac{6.626 \times 10^{-34}\ \text{kg m}^2\text{s}^{-1}}{0.1\ \text{kg} \times 4.37 \times 10^5\ \text{m s}^{-1}}$$

$$= 15.16 \times 10^{-39}\ \text{m} = 1.516 \times 10^{-38}\ \text{m}$$

Sample **Problem 18** *Determine the de-Broglie wavelength (Å) associated with* He *atom at* 500*K*.

(a) 0.565 (b) 0.435
(c) 0.223 (d) 0.195

Interpret (a) For a gaseous atom, a measure of its average speed is the root mean square speed (rms) as

$$V_{\text{rms}} = \sqrt{\frac{3RT}{M}}$$

$$= \sqrt{\frac{3 \times 8.314 \times 500}{4 \times 10^{-3}}} = 1766\ \text{ms}^{-1}$$

$$\text{Mass of a He atom} = \frac{4 \times 10^{-3}}{6.023 \times 10^{23}} = 6.64 \times 10^{-27}\ \text{kg}$$

$$\therefore \text{ de-Broglie wavelength } (\lambda) = \frac{h}{mv} = \frac{6.626 \times 10^{-34}}{6.64 \times 10^{-27} \times 1766}$$

$$= 5.65 \times 10^{-11}\ \text{m} = 0.565 \text{Å}$$

Heisenberg's Uncertainty Principle

Werner Heisenberg of Germany, gave the principle of uncertainty in which he stated that *the exact position and exact velocity* (or momentum) *of a sub- atomic particle can not be measured simultaneously.* This principle was exactly opposite to Bohr's theory with regard to the fixed position of electron and definite energy of orbits. The principle can be expressed mathematically as

$$\boxed{\Delta P \cdot \Delta x \geq \frac{h}{4\pi}}$$

here, ΔP = uncertainty in momentum,
Δx = uncertainty in position,
h = Planck's constant

Now since, $P = mv$; hence, $\Delta P = m\Delta v$

By putting the value of ΔP in the above expression, we get

$$m \cdot \Delta v \times \Delta x \geq \frac{h}{4\pi}$$

or $$\boxed{\Delta v \times \Delta x \geq \frac{h}{4\pi \times m}}$$

The above expression means that the position and velocity of an object cannot be simultaneously known with certainty.

Uncertainty in velocity or position varies inversely with mass, thus is negligible for macroscopic objects.

Suppose, we locate the position of an electron with uncertainty, $\Delta x = 10^{-2}$ m. Substituting the value in Heisenberg's formula

$$\Delta P_x = \frac{h}{4\pi\Delta x} = \frac{6.626 \times 10^{-34}}{4 \times 3.14 \times 10^{-12}}$$
$$= 5.27 \times 10^{-23} \text{ kg ms}^{-1}$$

The above uncertainty in momentum would be quite negligible in a macroscopic system but it is far from negligible for systems containing electrons and like microparticles, since we are then dealing with masses of the order of 10^{-30} kg. So far our concept of microscopic and macroscopic system is based on the size of the particle, thus microscopic particle cannot have a definite position and a definite momentum simultaneously.

Therefore, we cannot draw a trajectory of a microparticles in contrast to a macroparticle and hence, in light of the Heisenberg's principle, the Bohr's concept of the orbit of an electron becomes untenable.

For precise measurement of position one need to use radiations of very short wavelengths *e.g.*, gamma-rays and alternatively for preciseness in measurement of momentum, radiations of longer wavelength would be needed.

For other canonical conjugates of motion, the equation for Heisenberg uncertainty principle may be given as

$$\text{Momentum} = \text{mass} \times \text{velocity}$$
$$= \text{mass} \times \frac{\text{velocity}}{\text{time}} \times \text{time}$$
$$= \text{force} \times \text{time}$$
$$\text{Momentum} \times \text{Distance} = \text{force} \times \text{distance} \times \text{time}$$
$$= \text{energy} \times \text{time}$$
$$\Delta P \Delta x = \Delta E \Delta t$$
$$\Delta E\, \Delta t \geq \frac{h}{4\pi} \quad \text{(for energy and time)}$$

Similarly, $$\Delta\phi\, \Delta\theta \geq \frac{h}{4\pi} \quad \text{(for angular motion)}$$

On the basis of this principle, therefore, Bohr picture of an electron in an atom, which gives a fixed position in a fixed orbit and definite velocity to an electron, is no longer tenable. The best we can think of in terms of probability of locating an electron with a probable velocity in a given region of space at a given time. The space or a three–dimensional region around the nucleus where there is maximum probability of finding an electron of a specific energy is called an **atomic orbital**.

Caution Point *Heisenberg's uncertainty principle is applicable only when the location and momentum are along the same axis, i.e., if Δx is uncertainty in position along the z-axis then ΔP must also be uncertainty in momentum along the z-axis.*

Sample Problem 19 *If uncertainty in the measurement of position and momentum are equal then uncertainty in the measurement of velocity is equal to*

(a) $\frac{1}{2m}\sqrt{\frac{2h}{\pi}}$
(b) $\frac{1}{2m}\sqrt{\frac{h}{\pi}}$
(c) $\frac{1}{4m}\sqrt{\frac{h}{\pi}}$
(d) $\frac{1}{2m}\sqrt{\frac{h}{2\pi}}$

Interpret (*b*) By Heisenberg's uncertainty principle for minimum uncertainty,

$$\Delta x \cdot \Delta P = \frac{h}{4\pi}$$

Given, $$\Delta x = \Delta P$$

So, $$(\Delta P)^2 = (\Delta x)^2 = \frac{h}{4\pi}$$

$\therefore$ $$\Delta P = \sqrt{\frac{h}{4\pi}}$$

or $$m\Delta v = \frac{1}{2}\sqrt{\frac{h}{\pi}}$$
$$\Delta v = \frac{1}{2m}\sqrt{\frac{h}{\pi}}$$

3.9 Quantum Mechanical Model

In Bohr model, an electron is regarded as a charged particle moving in well defined circular orbits about the nucleus. An orbit can completely be defined only if both the position and the velocity of the electron are known exactly at the same time. This is not possible according to the Heisenberg's uncertainty principle. Further more, the wave character of the electron is not considered in Bohr model.

Therefore, concept of movement of an electron in an orbit was replaced by the concept of probability of finding electron in an orbital due to de-Broglie concept of dual nature of electron and Heisenberg's uncertainty principle. The changed model is called quantum mechanical model of the atom.

On the basis of dual nature of matter and Heisenberg uncertainty principle, **Erwin Schrodinger,** an Austrian physicist, in 1926 developed a new branch of science, called the **quantum mechanics** or **wave mechanics** and gave a model for atom, called **'wave mechanical model'** of atom. In his model he visualised electron as a three dimensional 'wave in the electronic field' of a positively charged nucleus inside the atom.

The quantum mechanical study of any system consists of

(i) Writing Schrodinger equation for the system.

(ii) Solving Schrodinger equation for the meaningful solutions of the wave functions and corresponding energies. The meaningful solutions of wave function must follow the conditions, *i.e.,* they have to be single valued, continuous and finite.

(iii) Calculation of all the observable properties of the system from wave function.

Schrodinger Equation

Schrodinger derived an equation for an electron which describes the wave motion of an electron wave along any of three axis, *i.e., x, y* and *z*. This equation is

$$\frac{\partial^2\psi}{\partial x^2}+\frac{\partial^2\psi}{\partial y^2}+\frac{\partial^2\psi}{\partial z^2}+\frac{8\pi^2 m}{h^2}(E-V)\psi=0$$

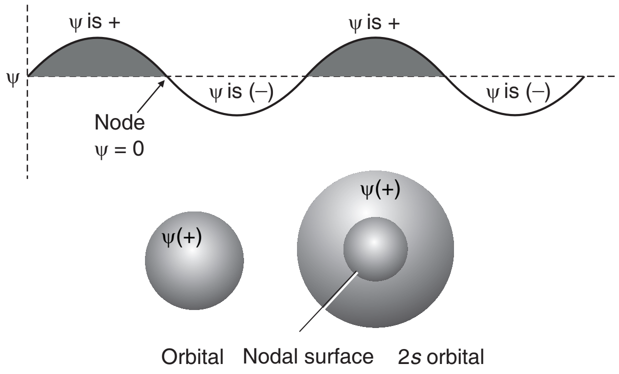
here, ψ = wave function,

h = Planck's constant

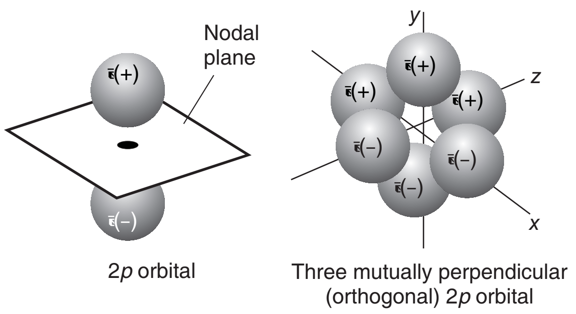
E = total energy of electron, *i.e.,* KE + PE for electron

V = potential energy of electron.

The wave function, ψ (psi) may be regarded as the amplitude function expressed in terms of coordinates *x, y* and *z*. The wave function values may be positive or negative depending upon the values of coordinates. Its comparison with a wave is given below



(a) In *s* orbital



(b) In *p* orbital

Fig. 3.13 The visualisation of wave function in orbitals as compared with a wave

The Schrodinger wave equation can also be written as

$$\nabla^2\psi+\frac{8\pi^2 m}{h^2}(E-V)\psi=0$$

here, $$\nabla^2=\frac{\partial^2}{\partial x^2}+\frac{\partial^2}{\partial y^2}+\frac{\partial^2}{\partial z^2}$$

i.e., the differential (Laplacian) operator. The acceptable solutions of Schrodinger wave equation are called **eigen function.**

Infact, Schrodinger gave a generalised equation, for a system, such as, an atom or a molecule, whose energy does not change with time (time independent) which is written as

$$\hat{H}\psi=E\psi$$

here, $\hat{H}$ is the total energy operator for electron, called **hamiltonian.** (In quantum mechanics, there is an operator corresponding to every observable property. It is like a mathematical command which act on a mathematical function.)

The hamiltonian is the sum of kinetic energy operator $\hat{T}$ and potential energy operator $\hat{V}$, *i.e.,*

$$\hat{H}=\hat{T}+\hat{V}$$

Thus, above equation can be written as

$$(\hat{T} + \hat{V})\psi = E\psi$$

here, E = total energy of the system.

Schrödinger equation for electron wave is the differential equation of second order, hence has several solutions (eigen function) for ψ, many of which are imaginary and not valid.

Only those values of ψ are valid which satisfy following conditions

(i) The wave function must be finite and continuous.

(ii) The solution must be single valued, *i.e.,* at a given point there can never be more than one value for amplitude ψ.

(iii) $\frac{\partial\psi}{\partial x}, \frac{\partial\psi}{\partial y}$ and $\frac{\partial\psi}{\partial z}$ must be continuous functions of x, y and z respectively.

(iv) The probability of finding the electron over all spaces from plus infinity to minus infinity must be equal to one.

The Schrodinger wave equation when fully solved with the help of advanced mathematics gives the same expression as given by Bohr for the energy of an electron. Infact, this equation in polar coordinates is solved for hydrogen atom and its solution gave possible energy states and their corresponding wave functions. For several wave functions, *e.g.,* $\psi_1, \psi_2, \psi_3, \ldots$ several corresponding energies are given as $E_1, E_2, E_3, \ldots$ **Each of these wave functions is called an 'orbital' by analogy** (functional similarity) **with Bohr's orbit.** ***e.g.,*** in the hydrogen atom, the single electron occupies the lowest of the energy levels E_1 and the corresponding wave function ψ_1 describes the orbital, *i.e.,* the volume in space where there is a high probability of finding an electron.

Thus, orbitals can be visualised as diffused negatively charged clouds of different shapes, sizes and orientations around the nucleus.

Concept of Atomic Orbitals as One Electron Wave Functions

A hydrogen atom is the simplest chemical system consisting of one proton and one electron. Assuming that the electron moves at a distance r around the stationary nucleus, the nucleus can be taken as the origin of a coordinate system.

The Schrodinger equation for the hydrogen atom can be written in terms of the Cartesian coordinates (x, y, z) or in terms of the spherical polar coordinates (r, θ, φ) of the electron with respect to the nucleus. Since an atom has spherical symmetry, it is more convenient to write Schrodinger equation in terms of polar coordinates. The relationships between the two coordinate systems are shown below in the Fig. 3.14.

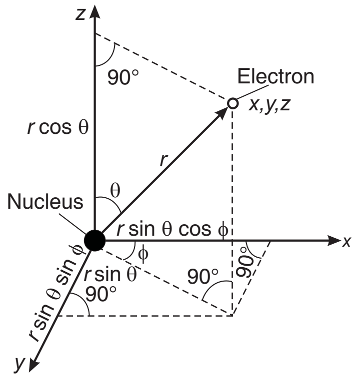


Fig. 3.14 Relationship between cartesian (x, y, z) and polar coordinates (r, θ, φ)

The coordinates x, y, and z of the electron with respect to nucleus in terms of polar coordinates are given by

$$x = r\sin\theta\cos\varphi$$
$$y = r\sin\theta\sin\varphi$$
$$z = r\cos\theta$$
$$x^2 + y^2 + z^2 = r^2$$

When the Schrodinger equation in polar coordinates is solved for the hydrogen atom, it gives the possible energy states and the corresponding wave function $[\psi(r, \theta, \varphi)]$ (called atomic orbitals or hydrogenic orbitals, which are in fact the mathematical function of the coordinates of the electron associated with each energy state). An atomic orbital is a mathematical function of the three coordinates (r, θ and ϕ) and can be factorised into three separate parts, each of which is a function of only one coordinate.

$$\psi(r, \theta, \phi) = R(r)\ominus(\theta)\ \phi(\phi)$$

Here, $R(r)$ = radial function and gives the dependence of orbital upon distance r of electron from the nucleus

$\ominus(\theta)$ and $\phi(\phi)$ = angular functions giving the angular dependence of orbital on θ and ϕ respectively.

The radial function depends upon quantum numbers n and l whereas angular functions depend upon quantum numbers l and m, *i.e.,* these are independent of n. The total wave function may, therefore, be written as :

$$\psi(r, \theta, \phi) = \underset{\text{(radial part)}}{r_{n.l}}\ \underset{\text{(angular part)}}{\theta_{l.m}\ \phi_n}$$

The probability of finding an electron in a given volume of element can be represented by two types of probability distribution curves which are

(i) Radial probability distribution curve,

(ii) Angular probability distribution curve.

The radial probability distribution curves tell, *how the probability of finding an electron varies with its radial distance from the nucleus without any reference to its direction from the nucleus*. Since, the atoms have spherical symmetry, it is more useful to discuss the probability of finding the electron in a spherical shell between the spheres of radius $(r + dr)$ and r as shown in the figure below.

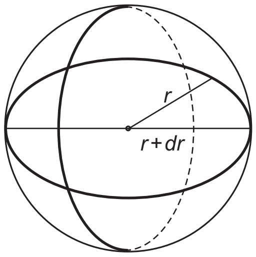

Fig. 3.15 Spherical shell of thickness *dr*

The volume of the shell is equal to

$$\frac{4}{3}\pi(r + dr)^3 - \frac{4}{3}\pi r^3 = 4\pi r^2 dr$$

and the radial probability function $(R) = 4\pi r^2 dr\psi^2$

This can be defined as *"the probability of finding the electron at a distance r from the nucleus regardless of direction."*

Significance of ψ

The wave function may be regarded as the amplitude function expressed in terms of coordinates *x, y,* and *z*. The wave function may have positive or negative values depending upon the values of coordinates.

The main aim of Schrodinger equation is to give a solution for the probability approach. When the equation is solved, it is observed that for some regions of space, the value of ψ is positive and for other regions, the value of ψ is negative. But the probability must be always positive and cannot be negative. It is, thus proper to use ψ^2 in favour of ψ.

Significance of ψ^2

ψ^2 is a probability factor. It describes the probability of finding an electron within a small space. The space in which there is maximum probability of finding an electron is termed as orbital.

The solution of the wave equation is beyond the scope of this book. The important point of the solution of this equation is that it provides a set of numbers, called **quantum numbers,** which describe energies of the electrons in atoms, information about the shapes and orientations of the most probable distribution of electrons around the nucleus.

Variation of ψ and ψ^2 with *'r'*

Wave function ψ can be plotted against distance '*r*' from the nucleus as

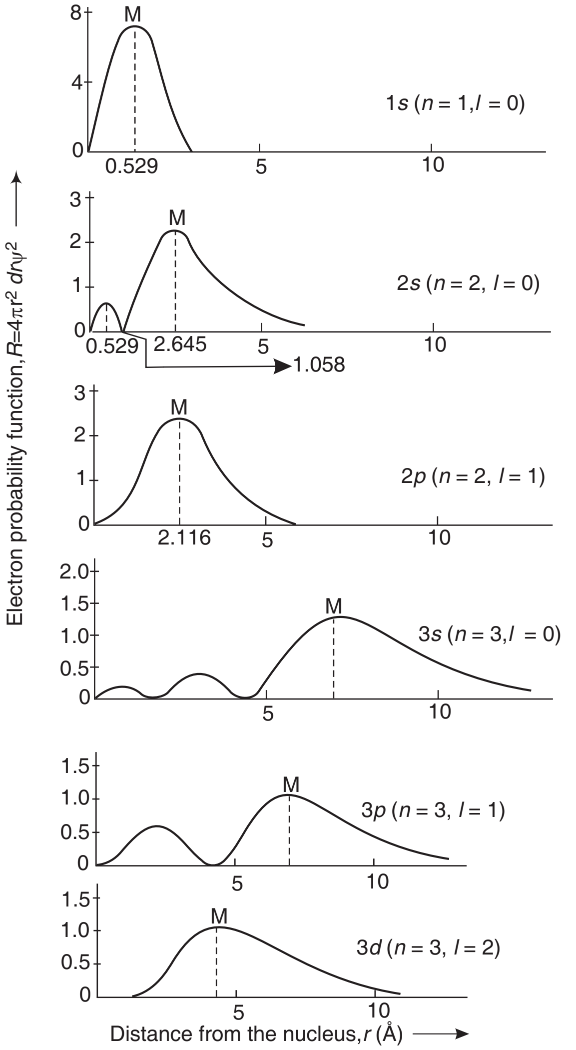

Fig. 3.16 Radial probability distribution curves for 1*s*, 2*s*, 2*p*, 3*s*, 3*p* and 3*d* orbitals. The point M in each curve represents the maximum electron density

These curves (radial distribution) tells us about following

(i) In each case, the probability of finding the electrons at the origin (nucleus) is zero, *i.e.*, **electron will never be found at the nucleus.**

(ii) The distance for maximum probability in an orbital increases with the value of *n* (principal quantum number). *e.g.*, This distance for 1*s*, 2*s* and 3*s* is in the order 1*s* < 2*s* < 3*s*.

(iii) The total number of peaks appearing in the curves for *s, p* and *d* orbitals is equal to n, $(n-1)$ and $(n-2)$ respectively, where, n = principal quantum number.

(iv) From the curve of 1*s* electron, the value of R is zero at nucleus where r is also zero. It then increases as r increases passes through a maximum (peak) at $r = 0.529$ Å, which is equal to the radius of Bohr's first orbit and then falls to zero as r tends to infinity. Thus, for 1*s* electron $R = 0$ at $r = 0$ and R = maximum at $r = 0.529$ Å.

(v) For 2*s* electron, the value of R is zero at $r = 0$. The value of R increases as r increases, passes through a maximum at $r = 0.529$ Å and falls to zero again at $r = 1.058$ Å. R reaches second highest at $r = 5 \times 0.529$ Å and then finally approaches zero as r tends to infinity. *The distance i.e.,* 1.058 Å *at which the probability of finding electron is zero is called node or nodal plane or nodal surface*. Thus, with in the orbital (where probability of finding an electron is maximum), there is a space, called node surrounding nucleus where probability of finding electron is zero.

For an *s* orbital, number of nodes = $(n-1)$, *i.e.*, 1*s* orbital contains no node, 2*s* orbital contains one node, 3*s* orbital contains 2 nodes and so on.

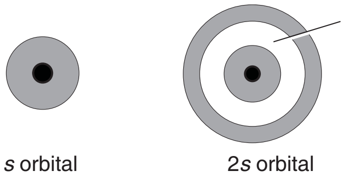

Fig. 3.17 Spherical *s* orbital, symmetrically disposed about the nucleus

Similarly, for a *p* orbital, number of nodes = $(n-2)$. In both the above cases n = principal quantum number.

(vi) For a hydrogen atom wave function, of principal quantum number n, there are
  (1) $(n-l-1)$ radial nodes (or spherical nodes)
  (2) l angular nodes (or non-spherical nodes)
  (3) $(n-1)$ total nodes.

Sample **Problem 20** *Calculate the total number of angular nodes and radial nodes present in 3p-orbital.*

[NCERT Exemplar]

(a) 1, 1	(b) 2, 1
(c) 2, 2	(d) 1, 2

Interpret (a) For 3*p*-orbital, principal quantum number, $n = 3$ and azimuthal quantum number, $l = 1$

Number of angular nodes = $l = 1$

Number of radial nodes = $n - l - 1 = 3 - 1 - 1 = 1$

Structure of Atom on the Basis of Wave Mechanical Model

According to wave mechanical model, the structure of atom can be summarised as

1. The electron in an atom are arranged in shells or different energy levels which are indicated by numbers, 1, 2, 3, ... or letters *K, L, M,* ...
2. With in each shell, there are subshells or sub levels which are designated as *s, p, d* and *f.*
3. Electrons of different energy levels are present in discrete volumes of different shapes, sizes and orientations in the sub-levels around the nucleus.
4. **Each of such discrete volume is called an orbital** which has the maximum probability of finding a particular electron of a particular energy level.
5. Each orbital may hold up two electrons of exactly equal energy provided they have opposite spins.
6. There are in all four quantum numbers to define an electron in an atom. Out of these four, three, *i.e., n, m* and *l* are needed to define the **orbital** and the 4th one defines the spin of electron in it.

Check Point 2

1. Why does Heisenberg's uncertainty principle has no significance in case of macroscopic objects?
2. In what ways do the spatial distributions of the orbitals in given pair differ from each other (2*s* and 2*p*)?
3. Draw a representation of a 3*p* orbital, including in your sketch the information that it has the planar node characteristic of *p* orbitals but in addition has a spherical node.

3.10 Quantum Numbers

The term quantum number is used to identify the various energy levels that are available to an electron. The word quantum is used to signify that all the energy levels which are available to an electron are governed by the laws of quantum mechanics. Four quantum numbers are necessary to characterise completely particular electrons in a particular orbit. These are discussed below

Principal Quantum Number (n)

It defines the principal shell in which the electron is revolving around the nucleus. It designates the average distance of the electron from the nucleus. Hence, this quantum number represents the size of the electron orbits.

In a polyelectron atom or ion, the electron that has a higher principal quantum number is at a higher energy level. An electron with $n = 1$ has the lowest energy and is bound most firmly to the nucleus. There is a limited number of electrons in an atom which can have the same principal quantum number and is given by $2n^2$, where n is the principal quantum number concerned. Thus,

Principal quantum number	$(n) \longrightarrow$	1	2	3	4
Letter designation	$\longrightarrow$	K	L	M	N
Maximum number of electrons $(2n^2)$	$\longrightarrow$	2	8	18	32

Wave Mechanical Aspects of '*n*'

According to modern quantum theory, the behaviour of an electron is described as that of standing wave and the value of '*n*' tells how many peaks of amplitude (antinodes) exist in that particular standing wave pattern; *the more peaks there are, the higher these energies of the state.*

Azimuthal Quantum Number (*l*)

It is also known as the second, subsidiary, lesser or the orbital quantum number. '*l*' describes the name of subshell and the shape of orbital present in it. It is related to orbital angular momentum by the following relation

$$\text{Orbital angular momentum, } mvr = \frac{h}{2\pi}\sqrt{[l(l+1)]}$$

l can have values ranging from 0 to $(n - 1)$.

(i) When $l = 0$, the subshell is s and orbital is spherical in shape.

(ii) When $l = 1$, the subshell is p and orbital is dumb-bell shaped.

(iii) When $l = 2$, the subshell is d and orbital is double dumb-bell shaped.

(iv) When $l = 3$, the subshell is f and orbital is complicated in shape.

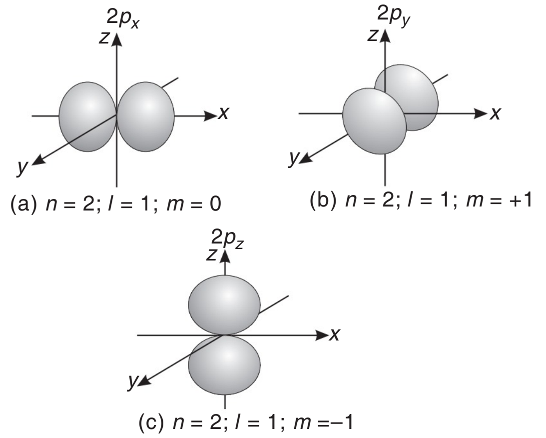
Caution Point *Energy of an electron in an orbit depends on the principal quantum number (n) for systems with only one electron. For multielectron systems, energy depends both on principal quantum number (n) and azimuthal quantum number (l).*

Magnetic Quantum Number (*m*)

This quantum number was introduced to describe the Zeeman effect (*i.e.,* splitting of spectral lines under the influence of an applied magnetic field). The magnetic quantum number is also called **orientation quantum number** because it gives the orientation or distribution of the electron cloud. For each value of azimuthal quantum number, the magnetic quantum number, may assume all the integral values between $+l$ to $-l$ through zero. *e.g.,*

(i) When $l = 0$, m has only one value, *i.e.,* 0; hence, there occur only one spherical orbital for each value of n.

(ii) When $l = 1$, m has 3 values, *i.e.,* +1, 0 and −1; hence, there occur 3 orbitals in p subshell namely p_x, p_y and p_z along the x-axis, y-axis and z-axis respectively.

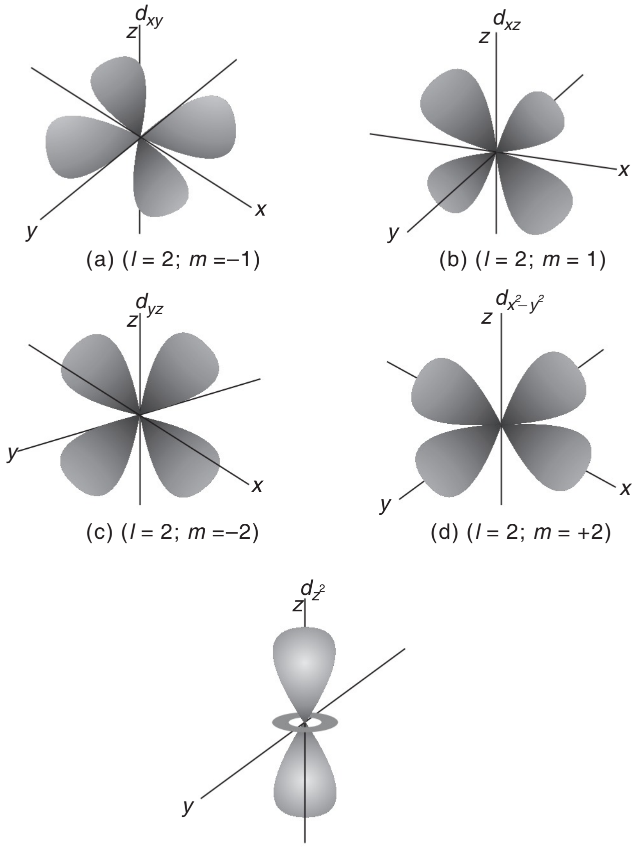


(a) $n = 2$; $l = 1$; $m = 0$ (b) $n = 2$; $l = 1$; $m = +1$ (c) $n = 2$; $l = 1$; $m = -1$

Fig. 3.18 Orientation of p-orbitals along x, y and z axis

These orbitals of a subshell are identical in energy, shape and size and differ only in their direction in space. **Orbitals with identical energy are called degenerate orbitals.**

(iii) For $l = 2$, *i.e.,* d subshell, m has 5 values namely +2, +1, 0, −1, −2 representing 5 such orbitals namely d_{xy}, d_{yz}, d_{zx}, $d_{x^2-y^2}$, d_{z^2}. Out of these only d_{xy} and $d_{x^2-y^2}$ lie in xy plane.



(a) ($l = 2$; $m = -1$) (b) ($l = 2$; $m = 1$) (c) ($l = 2$; $m = -2$) (d) ($l = 2$; $m = +2$) (e) ($l = 2$; $m = 0$)

Fig. 3.19 Orientation of d-orbitals

(iv) For l = 3, *i.e.,* *f* subshell, *m* has 7 values namely +3, +2, +1, 0, −1, −2, −3. These orbitals have representation difficulties that's why we consider their shape as "diffused" in generalised way. There is no unique way of representing all the seven orbitals. According to one opinion these orbitals can be represented as f_{z^3}, f_{xz^2}, f_{yz^2}, f_{xyz}, $f_{x(x^2-3y^2)}$, $f_{y(3x^2-y^2)}$ and $f_{z(x^2-y^2)}$, while according to another view these can be represented as f_{x^3}, f_{y^3}, f_{z^3}, $f_{x(z^2-y^2)}$, $f_{y(z^2-x^2)}$, $f_{z(x^2-y^2)}$ and f_{xyz}.

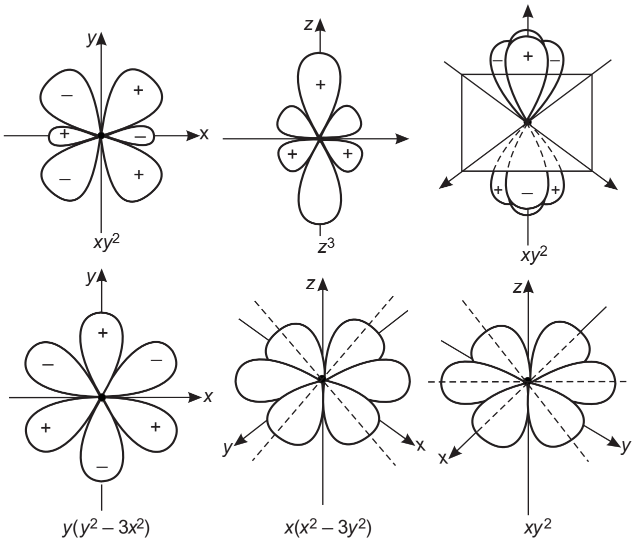


Fig. 3.20 Orientation of *f*-orbitals

Total value of *m* for a given value of $n = n^2$
Total value of *m* for a given value of $l = (2l + 1)$

Spin Quantum Number (*s*)

Spin quantum number arises from the spectral evidence that an electron in its motion around the nucleus in an orbit also rotates or spins about its own axis. The electron can spin clockwise or anti-clockwise. These spinning produces spin angular momentum (*s*) equal to $\sqrt{s(s+1)}\,\frac{h}{2\pi}$. The spin quantum number is either equal to $+\frac{1}{2}$ or $-\frac{1}{2}$.

The positive value of m_l describes orbital angular momentum component which are in the direction of applied magnetic field and the negative value of m_l are for those components which are oriented in direction opposite to that of applied field.

The spin quantum number gives rise to magnetic properties of materials. If there are two electrons in any orbital with opposite spin, their magnetic moments will be cancelled. Presence of magnetic properties indicates the presence of one or more unpaired electrons.

Magnetic moment (μ) can be calculated by the formula $\mu = \sqrt{n(n+2)}$ BM

where, *n* = number of unpaired electrons.

Sample Problem 21 *Which of the following orbitals are degenerate?* [**NCERT Exemplar**]

$$3d_{xy}, 4d_{xy}, 3d_{z^2}, 3d_{yz}, 4d_{z^2},$$

(a) $3d_{xy}$, $3d_{z^2}$, $4d_{xy}$
(b) $4d_{xy}$, $3d_{z^2}$, $4d_{z^2}$,
(c) $3d_{z^2}$, $4d_{z^2}$,
(d) $3d_{xy}$, $3d_{z^2}$, $3d_{yz}$

Interpret (*d*) The orbitals which belongs to same subshell and same shell are called degenerate orbitals. ($3d_{xy}$, $3d_{z^2}$, $3d_{yz}$,) and ($4d_{xy}$, $4d_{yz}$, $4d_{z^2}$) are the two sets of degenerate orbitals.

Hot Spot 2

FINDING QUANTUM Numbers

Many a times questions based on quantum numbers have been seen JEE Main previously AIEEE examination. Which reveals the importance of the topic for the examination. The level of the questions is generally easy.

In order to find all the four quantum number for an electrons follow the following steps

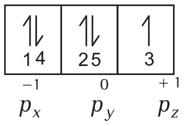
Step I First find the value of n (principal quantum number) for the given, electron from the electronic configuration of the element. *e.g.*. For 17th electron of Cl, configuration is $1s^2, 2s^2, 2p^6, 3s^2, 3p^5$. The 17 electron enters in $3p$ orbital, so $n = 3$

Step II Values of l never be greater than n and possible values of l for a given value of n is 0 to $n - 1$. Thus, possible values of l for $3p$ electrons $= 0, 1, 2$, not 3 ($\because n > l$).

Moreover, value of l is 0, 1, 2 and 3 respectively for s, p, d and f orbitals. Since in case of 17th electron, the orbital is p, so the value of $l = 1$

Step III Values of m varies from $- l$ to $+ l$ including 0.

Thus, for $l = 1$, $m = -1, 0, +1$



Since the fifth electron enters in p_y, $m = 0$

Step IV Value of s may be $+\frac{1}{2}$ or $-\frac{1}{2}$

For 17th electron $s = -\frac{1}{2}$

Thus, the correct set of quantum numbers for 17th electron is

$$n = 3, l = 1, m = 0 \text{ and } s - \frac{1}{2}.$$

Sample **Problem 22** *Which of the following sets of quantum numbers is not possible?*

(*a*) $n = 4, l = 1, m = 0, s = +\frac{1}{2}$

(*b*) $n = 4, l = 3, m = -3, s = -\frac{1}{2}$

(*c*) $n = 4, l = 0, m = 0, s = -\frac{1}{2}$

(*d*) $n = 4, l = 1, m = +2, s = -\frac{1}{2}$

Interpret (*d*) m has values $-l$ to $+l$ including 0. Thus, if $l = 1$, the possible values of $m = -1, 0, +1$ but not $+2$ as given in set (d). Thus, set (d) is not possible.

Sample **Problem 23** *Correct set of four quantum numbers for the valence (outermost) electron of rubidium ($z = 37$) is*

(*a*) $5, 0, 0, +\frac{1}{2}$

(*b*) $5, 1, 0, +\frac{1}{2}$

(*c*) $5, !, 1, . +\frac{1}{2}$

(*d*) $6, 0, 0, +\frac{1}{2}$

Interpret (*a*) The electronic conrfiguration of Rb is [Kr] $5s^1$

Thus, its valence electron enters in 5s orbital.
For 5s orbital, $n = 5$
$l = 0$ (as orbital is s)
$m = -l$ to $+l$ including zero $= 0$, $s = +\frac{1}{2}$

Thus, the correct set of quantum numbers for the valence electron of rubidium is 5, 0, 0, $+\frac{1}{2}$.

3.11 Rules for Filling of Electrons in Orbitals

Following rules have to be followed while filling electrons in orbitals

Aufbau Principle

Aufbau is a German word meaning "building up". The principle related to this word gives us an idea about the filling of orbitals by electrons. The rule states that *orbitals are filled up according to the increase in their energy.'*

The order of increase of energy can be calculated from $(n + l)$ rule which states that

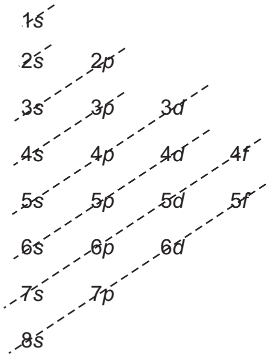
(i) The lower the value of $(n + l)$ for an orbital, the lower is its energy. *e.g.*, between $3d$ and $4s$, the $4s (4 + 0 = 4)$ will be filled before $3d (3 + 2 = 5)$.

Similarly between $4f$ and $6s$, the $6s (6 + 0 = 6)$ will be filled first than $4f (4 + 3 = 7)$.

(ii) If two orbitals have same value of $(n + l)$, the orbital with lower value of n will be filled first. *e.g.*, between $2p$ and $3s$, $2p (2 + 1 = 3)$ will be filled first than $3s (3 + 0 = 3)$.

The order in which electrons are filled in the orbitals, according to this rule is

$$1s < 2s < 2p < 3s < 3p < 4s < 3d < 4p < 5s < 4d < 5p < 6s < 4f < 5d < 6p < 7s < 5f < 6d < 7p$$



Sample **Problem 24** *Which of the following set of quantum numbers belongs to the highest energy?*

(a) $n = 4, l = 1, m = 1, s = +\frac{1}{2}$

(b) $n = 4, l = 0, m = 0, s = +\frac{1}{2}$

(c) $n = 3, l = 2, m = 1, s = +\frac{1}{2}$

(d) $n = 3, l = 1, m = 0, s = +\frac{1}{2}$

Interpret (a) Higher the value of $(n + l)$, higher is the energy.

(a) $(n + l) = (4 + 1) = 5$

(b) $(n + l) = (4 + 0) = 4$

(c) $(n + l) = (3 + 2) = 5$

(d) $(n + l) = (3 + 1) = 4$

Thus, energy is highest for the electron having $n = 4, l = 1$ quantum numbers.

Pauli Exclusion Principle

Pauli, in 1925 proposed that *no two electrons in an atom can be represented by same values of all the four quantum numbers, i.e.*, an orbital can accommodate a maximum of 2 electrons with opposite spin. These two electrons have same values of principal (n), azimuthal (l) and magnetic quantum numbers (m) but the value of spin quantum number will be different in them always.

For example In oxygen (atomic number 8) : $1s^2, 2s^2, 2p^4$

	$1s$	$2s$	$2p_x$	$2p_y$	$2p_z$
Principal Q.N.	1	2	2	2	2
Azimuthal Q.N.	0	0	1	1	1
Magnetic Q.N.	0	0	+1	−1	0
Spin Q.N.	$+\frac{1}{2} - \frac{1}{2}$	$+\frac{1}{2} - \frac{1}{2}$	$+\frac{1}{2} - \frac{1}{2}$	$+\frac{1}{2}$	$+\frac{1}{2}$

Hund's Rule of Maximum Multiplicity

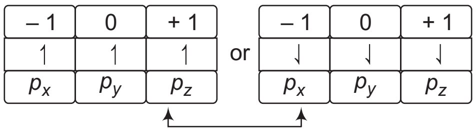
The rule states that *pairing of electrons in the orbitals of a particular sub-shell (p, d, or f) does not take place until all the orbitals of a sub-shell are singly occupied.* Moreover, the singly occupied orbitals must have the electrons with parallel spin.

The basis of this rule is that two electrons in a particular orbital feel greater repulsion and hence, while filling orbitals of equal energy, pairing of electrons is avoided as long as it is possible.

An Illustration of Electron Filling in a Degenerate *p*-Orbital

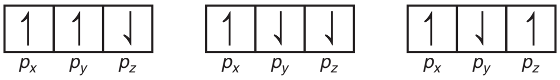
Let us suppose there are three electrons to be filled in a *p*-orbital.

They must obey Hund's rule.



Both are correct electronic representations since both obey the Hund's rule

Other representations are like



All of these are violating Hund's rule of maximum multiplicity *i.e.*, if the orbitals are only singly occupied, all electrons must have same spin quantum number (spinning in the same direction).

3.12 Electronic Configuration of Elements

The arrangement of electrons in various shells, sub-shells and orbitals in an atom is termed as electronic configuration. It is written in terms of nl^x where, n indicates the order of shell, l indicates the subshell and x the number of electrons present in the subshell. Here with the electronic configurations of some elements are given.

Table 3.3 **Electronic Configuration of Some Elements**

Element	Complete electronic configuration	Electronic configuration using inert gas symbol
H (1)	$1s^1$	$1s^1$
He (2)	$1s^2$	$1s^2$
Li (3)	$1s^2, 2s^1$	$[He]\,2s^1$
Be (4)	$1s^2, 2s^2$	$[He]\,2s^2$
B (5)	$1s^2, 2s^2, 2p^1$	$[He]\,2s^2, 2p^1$
C (6)	$1s^2, 2s^2, 2p^2$	$[He]\,2s^2, 2p^2$
N (7)	$1s^2, 2s^2, 2p^3$	$[He]\,2s^2, 2p^3$
O (8)	$1s^2, 2s^2, 2p^4$	$[He]\,2s^2, 2p^4$
F (9)	$1s^2, 2s^2, 2p^5$	$[He]\,2s^2, 2p^5$
Ne (10)	$1s^2, 2s^2, 2p^6$	$[He]\,2s^2, 2p^6$
Na (11)	$1s^2, 2s^2, 2p^6, 3s^1$	$[Ne]\,3s^1$
Cr* (24)	$1s^2, 2s^2, 2p^6, 3s^2, 3p^6, 4s^1, 3d^5$	$[Ar]\,3d^5, 4s^1$
Cu* (29)	$1s^2, 2s^2, 2p^6, 3s^2, 3p^6, 4s^1, 3d^{10}$	$[Ar]\,3s^{10}, 4s^1$
Mo* (42)	$1s^2, 2s^2, 2p^6, 3s^2, 3p^6,$ $4s^2, 3d^{10}, 4p^{6,}\ 5s^1, 4d^5$	$[Kr]\,5s^1, 4d^5$
Pd* (46)	$1s^2, 2s^2, 2p^6, 3s^2, 3p^6,$ $4s^2, 3d^{10}, 4p^6, 4d^{10}, 5s^0$	$[Kr]\,4d^{10}, 5s^0$

*The electronic configuration of these elements are exceptional due to half or completely filled orbitals.

3.13 Extra Stability of Completely Filled and Half-Filled Orbitals

The ground state electronic configuration of atom corresponds to the lowest energy state and gives higher stability. The electronic configuration of most of the atoms follows the basic rules. However, certain elements such as Cr or Cu do not follow the rules.

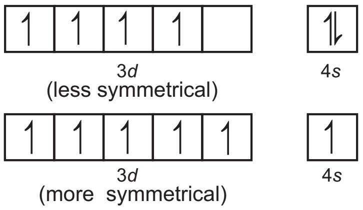
In such elements, the two sub-shells 4*s* and 3*s* slightly differ in energy. *i.e.,* 4*s* is slightly lower in energy than 3*d* orbital. In such case, the electron from lower energy sub-shell may jump to higher energy sub-shell provided such a shift results in all orbitals of the sub-shell of higher energy getting either completely filled or half-filled.

1. **Cr** atomic number 24 — $1s^2, 2\,s^2, 2p^6, 3\,s^2, 3p^6, 3d^5, 4s^1$
2. **Cu** atomic number 29 — $1s^2, 2s^2, 2p^6, 3s^2, 3p^6, 3\,d^{10}, 4s^1$
3. **Nb** atomic number 41 — $1s^2, 2s^2, 2p^6, 3s^2, 3\,p^6, 3\,d^{10}$ $4s^2, 4p^6, 4d^4, 5s^1$
4. **Mo** atomic number 42 — $1s^2, 2s^2, 2p^6, 3s^2, 3\,p^6, 3\,d^{10}$ $4s^2, 4p^6, 4d^5, 5s^1$
5. **Ru** atomic number 44 — $1s^2, 2s^2, 2p^6, 3s^2, 3p^6, 3\,d^{10}$ $4s^2, 4\,p^6, 4\,d^7, 5\,s^1$

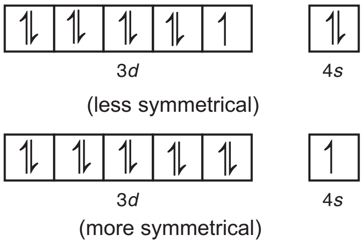
The extra stability of half-filled and fully filled electronic configuration can be explained in terms of symmetry and exchange energy.

Symmetrical Distribution of Electrons

The electronic configurations in which all the orbitals of the same sub-shell are either completely filled or half filled have relatively more symmetrical distribution of electrons. Consequently, their shielding of one another is relatively small and the electrons are more strongly attracted by the nucleus. This leads to more stability of the atom. *e.g.,* the expected configuration of Cr is $3d^4\,4s^2$. But shifting of one electron from 4*s* to 3*d* orbital makes the configuration more symmetrical and hence, more stable.

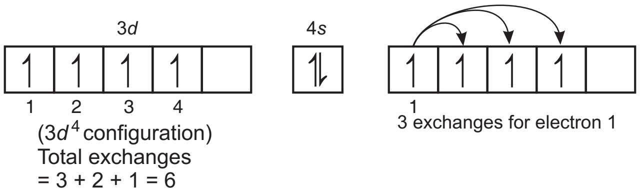


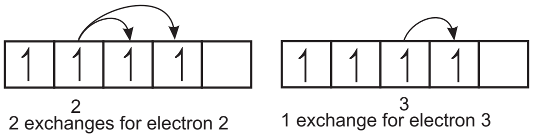
Similarly in copper, shifting of one electron from 4*s* to 3*d* makes the configuration more stable.



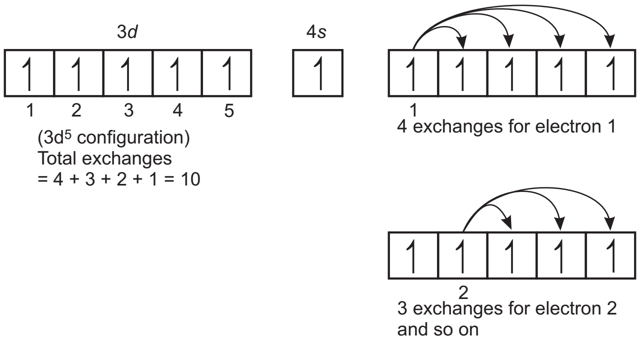
Exchange Energy

For the practical evaluation of this rule, the term "maximum multiplicity" is added in the rule. This term is used to explain the extra stability of half-filled or fully-filled orbitals due to exchange energies. The exchange energy means hypothetical energy evolved on shifting of electrons from one orbital to another within the same sub-shell. Let us compare the number of exchanges in $3d^4 4s^2$ (expected electronic configuration of Cr) and $3d^5 4s^1$ (actual electronic configuration of Cr)





In the above arrangement electron exchanges are six which implies that there are 6 arrangements possible with parallel spin in $3d^4 4s^2$ configuration.



Here, total 10 exchanges are possible, thus it involves more exchange energy and hence, is more stable.

Check Point 3

1. An *f*-orbital can accommodate how many electrons?
2. Hund's rule said that pairing of electrons takes place only when each orbital in a sub-shell is singly occupied. Explain, why?
3. Write down the electronic configuration of Cr in its ground state. (At. no. of Cr = 24)
4. Which properties of elements depend upon the electronic configuration and which do not?

WORKED **OUT** *Examples*

Example 1 *An ion with mass number 56 contains 3 units of positive charge and 30.4% more neutrons than the electrons. Assign the symbol to this ion.* **[NCERT]**

(a) $^{56}_{25}\text{Mn}$ (b) $^{56}_{26}\text{Fe}^{2+}$

(c) $^{56}_{26}\text{Fe}^{3+}$ (d) $^{56}_{25}\text{Mn}^{3+}$

Solution (c) Let the number of electrons in the ion = x

$$\therefore \quad \text{Number of neutrons} = x + \frac{30.4}{100}x = 1.304\,x$$

($\because$ Number of neutrons are 30.4% more than the number of electrons). In the neutral atom, number of electrons $= x + 3$ ($\because$ The ion carries $+3$ charge.)

So, number of protons $= x + 3$

We know that, mass number $= n + p = 1.304\,x + x + 3 = 56$

$$2.304\,x = 53,\ x = \frac{53}{2.304} = 23.003 \approx 23$$

$\therefore$ Number of protons $= 23 + 3 = 26$ = atomic number.

Therefore, the symbol of the ion is $^{56}_{26}\text{Fe}^{3+}$.

Example 2 *The atomic weight of an element is double of its atomic number. If there are four electrons in 2p orbital, the element is isotonic with*

(a) $_{20}\text{Ca}^{40}$ (b) $_{7}\text{N}^{15}$

(c) $_{7}\text{N}^{14}$ (d) $_{8}\text{O}^{17}$

Solution (b) Since, there are four electrons in $2p$ orbital, the outer configuration of the element is $2s^2, 2p^4$. The complete configuration of the element is $1s^2, 2s^2, 2p^4$.

The element contains total 8 electrons, so its atomic number is 8.

Then, the number of neutrons $= 16 - 8 = 8$

It is isotonic with $_{7}\text{N}^{15}$ (as it also contains 8 neutrons).

Example 3 *The radius of first Bohr orbit is x, then de-Broglie wavelength of electron in 3rd orbit is nearly*

(a) $2\pi x$ (b) $6\pi x$

(c) $9x$ (d) $\frac{x}{3}$

Solution (b) The radius of an orbit, $r_n \propto n^2$

Where, n = principal quantum number

$$\Rightarrow \quad \frac{r_1}{r_3} = \frac{1}{3^2}$$

If $\quad r_1 = x$ then $r_3 = 9x$

For third shell, $\quad 2\pi r_3 = 3\lambda$

$$\lambda = \frac{2\pi r_3}{3} = \frac{2\pi 9x}{3} = 6\pi x$$

Example 4 *Photoelectrons are liberated by ultraviolet light of wavelength 3000 Å from a metallic surface for which the photoelectric threshold is 4000 Å. The de-Broglie wavelength of electron emitted with maximum kinetic energy is*

(a) 1.2×10^{-9} m (b) 5.49×10^{-25} m

(c) 7.28×10^{-7} m (d) 1.65×10^{-19} m

Solution (a) KE = quantum energy – threshold energy

$$= \frac{6.626 \times 10^{-34} \times 3 \times 10^8}{3000 \times 10^{-10}} - \frac{6.626 \times 10^{-34} \times 3 \times 10^8}{4000 \times 10^{-10}}$$

$$= 6.626 \times 10^{-19} - 4.9695 \times 10^{-19}$$

$$= 1.6565 \times 10^{-19}\ \text{J}$$

$$\text{KE} = 1.6565 \times 10^{-19} = \frac{1}{2}mv^2$$

$$\therefore \quad m^2v^2 = 2 \times 1.6565 \times 10^{-19} \times 9.1 \times 10^{-31}$$

$$mv = 5.49 \times 10^{-25}$$

$$\text{de-Broglie wavelength, } \lambda = \frac{h}{mv} = \frac{6.626 \times 10^{-34}}{5.49 \times 10^{-25}}$$

$$= 1.2 \times 10^{-9}\ \text{m}$$

Example 5 *Two hydrogen atoms collide head-on and end up with zero kinetic energy. Each then emits a photon with a wavelength 121.6 nm. The transition that leads to this wavelength and the velocity of hydrogen atoms travelling before the collision are, respectively*

(Given, $R_H = 1.097 \times 10^7\ m^{-1}$ and $m_H = 1.67 \times 10^{-27}$ kg)

(a) $n_2 \to n_1;\ 4.43 \times 10^4$ (b) $n_4 \to n_3;\ 4.43 \times 10^4$

(c) $n_3 \to n_2;\ 2.63 \times 10^7$ (d) $n_2 \to n_3;\ 4.43 \times 10^4$

Solution (a) Wavelength is in UV region, thus n_1 will be 1.

$$\frac{1}{121.6 \times 10^{-9}} = 1.097 \times 10^7 \times 1^2 \times \left(\frac{1}{1^2} - \frac{1}{n_2^2}\right)$$

On solving, $n_2 \approx 2$

$$\frac{1}{2} mv^2 = \frac{hc}{\lambda}$$

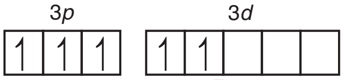
$$\frac{1}{2} \times 1.67 \times 10^{-27} \times v^2 = \frac{6.626 \times 10^{-34} \times 3 \times 10^8}{121.6 \times 10^{-9}}$$

$$v = 4.43 \times 10^4 \text{ m s}^{-1}$$

Example 6 *Maximum value of* $(n + l + m)$ *for unpaired electrons in second excited state of chlorine* $_{17}\text{Cl}$ *is*

(a) 28 (b) 25 (c) 20 (d) 18

Solution (b) Configuration in second excited state is written as



n	3	3	3	3	3
l	1	1	1	2	2
m	−1	0	+1	+2	+1

Total $n + l + m = 25$

Example 7 *What is the degeneracy of the nth level of hydrogen atom that has the energy* $\left(-\frac{R_H}{16}\right)$?

(a) 4 (b) 9 (c) 16 (d) 12

Solution (c) Energy of electron in the nth orbit in terms of R_H is

$$E_n = \frac{-R_H Z^2}{n^2}$$

For hydrogen atoms $Z = 1$, thus

$$E_n = -\frac{R_H}{n^2}$$

On comparing the above equation with the given equation, we get

$$n^2 = 16$$

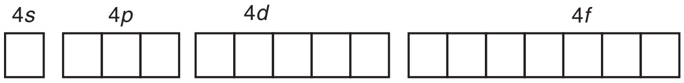
$$n = 4$$

For, $n = 4$ $l = 0(s)$ $m = 0$

$l = 1(p)$ $m = -1, 0, +1$

$l = 2(d)$ $m = -2, -1, 0, +1, +2$

$l = 3(f)$ $m = -3, -2, -1, 0, +1, +2, +3$



Degeneracy = total number of orbitals = 16

Example 8 *The four quantum numbers of the* 19*th electron in* $\text{Ti}(Z = 22)$ *are*

(a) $n = 4, l = 1, m = 0, s = +\frac{1}{2}$

(b) $n = 4, l = 0, m = 0, s = +\frac{1}{2}$

(c) $n = 3, l = 2, m = +2, s = +\frac{1}{2}$

(d) $n = 4, l = 2, m = -1, s = +\frac{1}{2}$

Solution (b) Electronic configuration of $\text{Ti}(Z = 22)$ is

$$1s^2, 2s^2, 2p^6, 3s^2, 3p^6, 4s^2, 3d^2$$

19th is in $4s$, therefore,

Hence, $n = 4, l = 0, m = 0, s = +\frac{1}{2}$

Example 9 *The relationship between the* n^{th} *Bohr radius of hydrogen atom and* Li^{2+} *ion is*

(a) $r(\text{H}) = 2r\ (\text{Li}^{3+})$

(b) $r(\text{H}) = 3r\ (\text{Li})^{2+}$

(c) $r(\text{Li}^{2+}) = 3r\ (\text{H})$

(d) $r(\text{Li}^{2+}) = 2r\ (\text{H})$

Solution (b) For hydrogen atom

$$r(\text{H}) = \frac{a_0 n^2}{Z} = a_0 n^2 \qquad (\because Z = 1)$$

For Li^{2+}; $$r(\text{Li}^{2+}) = \frac{a_0 n^2}{Z} = \frac{a_0 n^2}{3} \qquad (\because Z = 3)$$

Now $$\frac{r(\text{H})}{r(\text{Li}^{2+})} = 3$$

$$\Rightarrow \quad r(\text{H}) = 3r(\text{Li}^{2+})$$

Example 10 *A compound of vanadium has a magnetic moment of 1.73 BM. The electronic configuration of the vanadium ion in the compound is*

(a) $1s^2, 2s^2 2p^6, 3s^2 3p^6, 3d^1$

(b) $1s^2, 2s^2 2p^6, 3s^2 3p^6\ 3d^1, 4s^2$

(c) $1s^2, 2s^2 2p^6, 3s^2 3p^6\ 3d^2$

(d) $1s^2, 2s^2 2p^6, 3s^2 3p^6\ 3d^1, 4s^1$

Solution (a) Magnetic moment = $\sqrt{n(n+2)}$

where, n is the number of unpaired electrons.

$$1.73 = \sqrt{n(n+2)}$$

$$\therefore \quad n = 1$$

$\therefore$ Vanadium atom must have one unpaired electron, hence its configuration is $_{23}V^{4+} = 1s^2, 2s^2p^6, 3s^2p^6, 3d^1$

Example 11 *Which of the following has non-spherical shell of electron?*

(a) He (b) B (c) Be (d) Li

Solution (b) The electronic configuration of the given atoms are as

He — $1s^2$

B — $1s^2, 2s^2, 2p^1$

Be — $1s^2, 2s^2$

Li — $1s^2, 2s^1$

Among these atoms, only B has p sub-shell which is a non-spherical shell.

Start Practice for JEE Main

Round I (Topically Divided Problems)

Sub-atomic Particles, Previous Models and Atomic Species

1. Which of the following statements about the electron is incorrect? **[NCERT Exemplar]**

(a) It is a negatively charged particle

(b) The mass of electron is equal to the mass of neutron

(c) It is a basic constituent of all atoms

(d) It is a constituent of cathode rays

2. Which of the following will not show deflection from the path on passing through an electric field? **[NCERT Exemplar]**

(a) Proton (b) Cathode rays

(c) Electron (d) Neutron

3. Which of the following conclusions could not be derived from Rutherford's α-particle scattering experiment? **[NCERT Exemplar]**

(a) Most of the space in the atom is empty

(b) The radius of the atom is about 10^{-10} m while that of nucleus is 10^{-15} m

(c) Electrons move in a circular path of fixed energy, called orbits

(d) Electrons and the nucleus are held together by electrostatic forces of attraction

4. Which of the following statements is incorrect?

(a) The charge on electron and proton are equal and opposite

(b) Neutrons have no charge

(c) The mass of proton and electron are nearly the same

(d) None of the above

5. Find the total mass of neutrons (in kg) in 7 mg of ^{14}C. (Assume that mass of a neutron = 1.675×10^{-27} kg. **[NCERT]**

(a) 2.40×10^{-8} (b) 4.37×10^{-6}

(c) 1.25×10^{-9} (d) 5.36×10^{-7}

6. Find the total number of protons in 34 mg of NH_3 at STP. (Mass of 1 $p = 1.6726 \times 10^{-27}$ kg). **[NCERT]**

(a) 12.044×10^{23} (b) 12.044×10^{22}

(c) 12.044×10^{21} (d) 12.044×10^{20}

7. The diameter of zinc atom is 2.6 Å. Calculate the number of atoms present in a length of 1.6 cm if the zinc atoms are arranged side by side lengthwise. **[NCERT Exemplar]**

(a) 6.023×10^{23} (b) 6.15×10^{7}

(c) 1.62×10^{19} (d) 6.15×10^{12}

8. Two atoms are said to be isobars if **[NCERT Exemplar]**

(a) they have same atomic number but different mass number

(b) they have same number of electrons but different number of neutrons

(c) they have same number of neutrons but different number of electrons

(d) sum of the number of protons and neutrons is same but the number of protons is different

9. Which of the following is isoelectronic with carbon atom?

(a) N^+ (b) O^{2-}

(c) Na^+ (d) Al^{3+}

10. Rutherford scattering formula fails for very small scattering angles because

(a) the kinetic energy of α-particles is larger

(b) the gold foil is very thin

(c) the full nuclear charge of the target atom is partially screened by its electron

(d) All of the above

11. Choose the arrangement which shows the increasing value of e/m for e, p, n and α-particles.

(a) $n < \alpha < p < e$ (b) $e < p < \alpha < n$

(c) $n < p < e < \alpha$ (d) $p < n < \alpha < e$

12. Which of the following pairs have identical values of e/m?

(a) A proton and a neutron
(b) A proton and deuterium
(c) Deuterium and an α-particle
(d) An electron and γ-rays

Nature of EMR and Spectra of Hydrogen

13. Emission transitions in the Paschen series end at orbit $n = 3$ and start from orbit n and can be represented as $\nu = 3.29 \times 10^{15}\ (\text{Hz}) \left[\frac{1}{3^2} - \frac{1}{n^2}\right]$.

Calculate the value of n if the transition is observed at 1285 nm. Find the region of the spectrum. **[NCERT]**

(a) 4, Infra-red (b) 5, Infra-red
(c) 6, Visible (d) 3, Infra-red

14. Yellow light emitted from a sodium lamp has a wavelength (λ) of 580 nm. Calculate the frequency (ν) and wave number $(\bar{\nu})$ of the yellow light. **[NCERT]**

(a) $5.17 \times 10^{14}\ \text{s}^{-1}$, $1.724 \times 10^{4}\ \text{cm}^{-1}$
(b) $4.27 \times 10^{14}\ \text{s}^{-1}$, $3.245 \times 10^{4}\ \text{cm}^{-1}$
(c) $1.26 \times 10^{15}\ \text{s}^{-1}$, $8.37 \times 10^{3}\ \text{cm}^{-1}$
(d) $51.7 \times 10^{14}\ \text{s}^{-1}$, $1.724 \times 10^{5}\ \text{cm}^{-1}$

15. What is the number of photons of light with a wavelength of 4000 pm that provide 1 J of energy? **[NCERT]**

(a) 4.9695×10^{17} (b) 4.9695×10^{8}
(c) 2.0122×10^{15} (d) 2.0122×10^{16}

16. Arrange the following type of radiations in increasing order of frequency. **[NCERT]**

(i) Radiation from microwave oven
(ii) Amber light from traffic signal
(iii) Radiation from FM radio
(iv) Cosmic rays from outer space and
(v) X-rays

The correct order is

(a) (i) < (iii) < (ii) < (iv) < v)
(b) (iii) < (i) < (v) < (ii) < (iv)
(c) (iii) < (i) < (ii) < (v) < (iv)
(d) (iii) < (v) < (i) < (ii) < (iv)

17. A 25 watt bulb emits monochromatic yellow light of wavelength 0.57 μm. The rate of emission of quanta per second is **[NCERT]**

(a) 7.169×10^{20} photon/s
(b) 8.29×10^{19} photon/s
(c) 7.289×10^{21} photon/s
(d) 7.169×10^{19} photon/s

18. Which of the following transitions are not allowed in the normal electronic emission spectrum of an atom?

(a) $2s \rightarrow 1s$ (b) $2p \rightarrow 1s$
(c) $3d \rightarrow 4p$ (d) $5p \rightarrow 3s$

19. The line spectra of two elements are not identical because

(a) the elements do not have the same number of neutrons
(b) they have different mass numbers
(c) their outermost electrons are at different energy levels
(d) All of the above

20. The maximum kinetic energy of the photoelectrons is found to be 6.63×10^{-19} J. When the metal is irradiated with a radiation of frequency 2×10^{15} Hz, the threshold frequency of the metal is about

(a) $2 \times 10^{15}\ \text{s}^{-1}$ (b) $1 \times 10^{15}\ \text{s}^{-1}$
(c) $2.5 \times 10^{15}\ \text{s}^{-1}$ (d) $4 \times 10^{15}\ \text{s}^{-1}$

21. What is the minimum energy that photons must possess in order to produce photoelectric effect with platinum metal? The threshold frequency for platinum is $1.3 \times 10^{15}\ \text{s}^{-1}$

(a) 3.6×10^{-13} erg (b) 8.2×10^{-13} erg
(c) 8.2×10^{-14} erg (d) 8.6×10^{-12} erg

22. An emission transition starts from the orbit having radius 1.3225 nm and ends at 211.6 pm. Name the series to which this transition belongs and the region of the spectrum. **[NCERT]**

(a) Lyman, UV (b) Balmer, visible
(c) Paschen, IR (d) Brackett, IR

23. Which of the following electron transition in hydrogen atom will require largest amount of energy?

(a) From $n = 1$ to $n = 2$ (b) From $n = 2$ to $n = 3$
(c) From $n = \infty$ to $n = 1$ (d) From $n = 3$ to $n = 5$

Bohr and Sommerfeld Models

24. Bohr's theory is applicable to

(a) He (b) Li^{2+}
(c) He^{2+} (d) None of these

25. According to Bohr's model of hydrogen atom

(a) total energy of the electron is quantised
(b) angular momentum of electron is quantised
(c) Both (a) and (b)
(d) None of the above

26. The radius of which of the following orbit is same as that of the first Bohr's orbit of hydrogen atom?

(a) $\text{Li}^{2+}(n = 2)$ (b) $\text{Li}^{2+}(n = 3)$
(c) $\text{Be}^{3+}(n = 2)$ (d) $\text{He}^{+}(n = 2)$

27. According to Bohr's theory, the angular momentum for an electron of 3rd orbit is

(a) $3\ \hbar$ (b) $1.5\hbar$ (c) $9\hbar$ (d) $2\ \dfrac{h}{\pi}$

28. The energy associated with the first orbit in the hydrogen atom is -2.18×10^{-18} J atom^{-1}. What is the energy associated with the fifth orbit? **[NCERT]**

(a) 0.43×10^{-18} J (b) 0.087×10^{-18} J

(c) 2.18×10^{-18} J (d) 3.16×10^{-15} J

29. Electromagnetic radiation of wavelength 242 nm is just sufficient to ionise the sodium atom. Calculate the ionisation energy of sodium in kJ mol^{-1}. **[NCERT]**

(a) 4.945×10^{5} kJ / mol (b) 4.945×10^{4} kJ / mol

(c) 4.945×10^{2} kJ / mol (d) 4.945×10^{3} kJ / mol

30. What is the maximum number of emission lines when the excited electron of a H-atom in $n = 6$ drops to the ground state? **[NCERT]**

(a) 2 (b) 10 (c) 15 (d) 20

31. The potential energy of an electron present in the ground state of Li^{2+} ion is

(a) $+\dfrac{3e^2}{4\pi\varepsilon_0 r}$ (b) $-\dfrac{3e}{4\pi\varepsilon_0 r}$

(c) $-\dfrac{3e^2}{4\pi\varepsilon_0 r}$ (d) $-\dfrac{3e^2}{4\pi\varepsilon_0 r^2}$

32. The velocity of an electron placed in 3rd orbit of H atom, will be

(a) 2.79×10^{7} cm/s (b) 9.27×10^{27} cm/s

(c) 7.29×10^{7} cm/s (d) 92.7×10^{7} cm/s

Modern Structure of Atom
(de-Broglie and Heisenberg's Principle)

33. The wave nature of electron is verified by

(a) de-Broglie (b) Davisson and Germer

(c) Rutherford (d) All of these

34. Table-Tennis ball has a mass 10 g and a speed of 90 m/s. If speed can be measured within an accuracy of 4%, what will be the uncertainty in position? **[NCERT Exemplar]**

(a) 3.6×10^{-23} m (b) 1.46×10^{-33} m

(c) 2.8×10^{-30} m (d) 1.00×10^{-34} m

35. Similar to electron diffraction, neutron diffraction microscope is also used for the determination of the structure of molecules. If the wavelength used here is 800 pm, calculate the characteristics velocity associated with the neutron (mass of neutron $= 1.675\times10^{-27}$ kg). **[NCERT]**

(a) 4.92×10^{2} (b) 2.46×10^{3}

(c) 9.84×10^{2} (d) 0.246×10^{3}

36. According to de-Broglie, matter should exhibit dual behaviour, that is both particle and wave like properties. However, a cricket ball of mass 100 g does not move like a wave when it is thrown by a bowler at a speed of 100 km/h. Calculate the wavelength of the ball. **[NCERT Exemplar]**

(a) 2.385×10^{-36} m (b) 23.85×10^{-36} m

(c) 238.5×10^{-36} m (d) 2385×10^{-36} m

37. Out of electron, proton, neutron and α-particle which one will have a higher velocity to produce matter wave of the same wavelength? **[NCERT Exemplar]**

(a) Electron (b) Proton

(c) Neutron (d) α-particle

38. Which of the following particles moving with same velocity would be associated with smallest de-Broglie wavelength?

(a) Helium molecule (b) Oxygen molecule

(c) Hydrogen molecule (d) Carbon molecule

39. The mass of an electron is m, its charge is e and it is accelerated from rest through a potential difference, V. The velocity of electron will be calculated by formula

(a) $\sqrt{\dfrac{V}{m}}$ (b) $\sqrt{\dfrac{eV}{m}}$

(c) $\sqrt{\left(\dfrac{2eV}{m}\right)}$ (d) None of these

40. What is the wavelength of an α-particle having mass 6.6×10^{-27} kg moving with a speed of 10^{5} cm s^{-1}? ($h = 6.6\times10^{-34}$ kg m^{2}- s)

(a) 2×10^{-12} m (b) 3×10^{-10} m

(c) 1×10^{-10} m (d) 2×10^{-10} m

41. The de-Broglie wavelength relates to applied voltage for α-particles as

(a) $\lambda = \dfrac{12.3\ \text{Å}}{\sqrt{V}}$ (b) $\lambda = \dfrac{0.286}{\sqrt{V}}\ \text{Å}$

(c) $\lambda = \dfrac{0.101}{\sqrt{V}}\ \text{Å}$ (d) $\lambda = \dfrac{0.856}{\sqrt{V}}\ \text{Å}$

42. The uncertainty in momentum of an electron is 1×10^{-5} kg m / s. The uncertainty in its position will be ($h = 6.62\times10^{-34}$ kg m^{2} / s)

(a) 2.36×10^{-28} m (b) 5.25×10^{-28} m

(c) 2.27×10^{-30} m (d) 5.27×10^{-30} m

43. If the kinetic energy of an electron is increased four times, the wavelength of the de-Broglie wave associated with it would becomes

(a) half times (b) $\dfrac{1}{4}$ times

(c) four times (d) two times

Wave Mechanical Model and Quantum Numbers

44. The two electrons in K-subshell will differ in
(a) principal quantum number
(b) azimuthal quantum number
(c) magnetic quantum number
(d) spin quantum number

45. Which of the following arrangement of orbitals is in the increasing order of energy? **[NCERT Exemplar]**
(a) $1s, 2s, 2p, 3s$ (b) $4s, 3s, 3p, 4d$
(c) $5p, 4d, 5d, 4f, 6s$ (d) $5f, 6d, 7s, 7p$

46. What is the lowest value of n that allows g orbitals to exist? **[NCERT]**
(a) 3 (b) 4
(c) 5 (d) 6

47. The number of spherical nodes in $3p$ orbital is
(a) 0 (b) 1
(c) 2 (d) 3

48. Which of the following sets of quantum numbers are not possible? **[NCERT]**

I. $n = 0, l = 0, m_l = 0, m_s = +\frac{1}{2}$
II. $n = 1, l = 0, m_l = 0, m_s = -\frac{1}{2}$
III. $n = 1, l = 1, m_l = 0, m_s = +\frac{1}{2}$
IV. $n = 2, l = 1, m_l = 0, m_s = -\frac{1}{2}$
V. $n = 3, l = 3, m_l = -3, m_s = +\frac{1}{2}$
VI. $n = 3, l = 1, m_l = 0, m_s = +\frac{1}{2}$

(a) I, II and III (b) I, III and V
(c) I, IV and VI (d) I, II, III and V

49. Total number of orbitals associated with third shell will be **[NCERT Exemplar]**
(a) 2 (b) 4
(c) 9 (d) 3

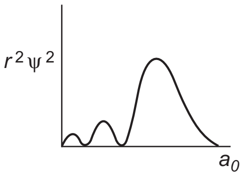
50. Number of angular nodes for $4d$ orbital is **[NCERT Exemplar]**
(a) 4 (b) 3
(c) 2 (d) 1

51. The Z-component of angular momentum of an electron in an atomic orbital is governed by the
(a) magnetic quantum number
(b) azimuthal quantum number
(c) spin quantum number
(d) principal quantum number

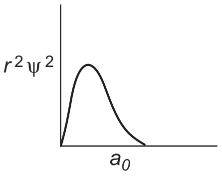
52. Which of the following statements regarding an orbital is correct?
(a) An orbital is a definite trajectory around the nucleus in which electron can move
(b) An orbital always has spherical trajectory
(c) An orbital is the region around the nucleus where there is a 90 – 95% probability of finding all the electrons of an atom
(d) An orbital is characterised by 4 quantum numbers n, l, m and s

53. Which of the following radial distribution graphs correspond to $n = 3, l = 2$ for an atom?

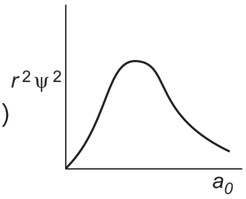
(a)



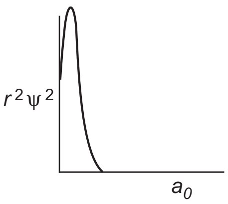
(b)



(c)



(d)



54. For a particular value of azimuthal quantum number, the total number of magnetic quantum number values are given by
(a) $l = \frac{m+1}{2}$ (b) $l = \frac{m-1}{2}$
(c) $l = \frac{2m+1}{2}$ (d) $m = \frac{2l+1}{2}$

55. Among the following sets of quantum numbers, which one is incorrect for $4d$-electron?
(a) $4, 3, 2, +\frac{1}{2}$ (b) $4, 2, 1, +\frac{1}{2}$
(c) $4, 2, -2, +\frac{1}{2}$ (d) $4, 2, 1, -\frac{1}{2}$

56. The quantum numbers $+\frac{1}{2}$ and $-\frac{1}{2}$ for an electron represent
(a) rotation of electron in clockwise and anticlockwise direction respectively
(b) rotation of electron in anticlockwise and clockwise direction respectively
(c) magnetic moment of electron pointing up and down respectively
(d) two quantum mechanical spin states which have no classical analogue

57. For an electron in a hydrogen atom, the wave function ψ is proportional to $\exp^{-t/a_0}$, where a_0 is the Bohr's radius. What is the ratio of the probability of finding the electron at the nucleus to the probability of finding it at a_0?

(a) e (b) e^2 (c) $\frac{1}{e^2}$ (d) Zero

58. Consider the following statements.

1. Electron density in xy plane in $3d_{x^2-y^2}$ orbital is zero
2. Electron density in xy plane in $3d_{z^2}$ orbital is zero
3. 2s orbital has only one spherical node
4. For $2p_z$ orbital yz is the nodal plane

The correct statements are

(a) 2 and 3 (b) 1, 2, 3, 4

(c) Only 2 (d) 1 and 3

Filling of Electrons in Orbitals and Related Principles

59. The distribution of electrons in oxygen atom (atomic number 8) is shown by **[NCERT Exemplar]**

(a)

(b)

(c)

(d) All of these

60. For the electrons of oxygen atom, which of the following statements is correct? **[NCERT Exemplar]**

(a) Z_{eff} for an electron in a 2 s orbital is the same as Z_{eff} for an electron in a 2p orbital

(b) An electron in the 2s orbital has the same energy as an electron in the 2p orbital

(c) Z_{eff} for an electron in 1s orbital is the same as Z_{eff} for an electron in a 2s orbital

(d) The two electrons present in the 2s orbital have spin quantum numbers m_s but of opposite sign

61. The pair of ions having same electronic configuration is **[NCERT Exemplar]**

(a) Cr^{3+}, Fe^{3+} (b) Fe^{3+}, Mn^{2+}

(c) Fe^{3+}, Co^{3+} (d) Sc^{3+}, Cr^{3+}

62. Find the electronic configuration of the O^{2-} ion **[NCERT]**

(a) $1s^2, 2s^2, 2p^4$ (b) $1s^2, 2s^2, 2p^6$

(c) $1s^2, 2s^2, 2p^5$ (d) $1s^2, 2s^2$

63. Which of the following options does not represent ground state electronic configuration of an atom? **[NCERT Exemplar]**

(a) $1s^2 2s^2 2p^6, 3s^2 3p^6, 3d^8, 4s^2$

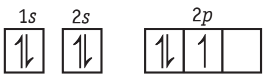
(b) $1s^2 2s^2 2p^6, 3s^2 3p^6 3d^9, 4s^2$

(c) $1s^2 2s^2 2p^6, 3s^2 3p^6 3d^{10}, 4s^1$

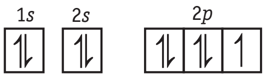
(d) $1s^2 2s^2 2p^6, 3s^2 3p^6 3d^5, 4s^1$

64. Which of the following will violates aufbau principle as well as Pauli's exclusion principle?

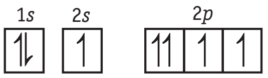
(a)



(b)



(c)



(d) None of the above

65. The atomic number of an element is 35 and its mass is 81. The number of electrons in its outermost shell is

(a) 3 (b) 5 (c) 7 (d) 9

66. How many unpaired electrons are present in Ni^{2+} cation? (At. no. = 28)

(a) 0 (b) 2 (c) 4 (d) 6

67. The electronic configuration with maximum exchange energy will be

(a) $3d^1_{xy}, 3d^1_{yz}, 3d^1_{zx}, 4s^1$

(b) $3d^1_{xy}, 3d^1_{yz}, 3d^1_{zx}, 3d^1_{x^2-y^2}, 3d^1_{z^2}, 4s^1$

(c) $3d^2_{xy}, 3d^2_{yz}, 3d^2_{zx}, 3d^2_{x^2-y^2}, 3d^1_{z^2}, 4s^1$

(d) $3d^2_{xy}, 3d^2_{yz}, 3d^2_{zx}, 3d^2_{x^2-y^2}, 3d^2_{z^2}, 4s^1$

68. A Mo atom in its ground state has $4d^5, 5s^1$ configuration and a Ag atom has $4d^{10}, 5s^1$ configuration. This is because a shell which is half-filled or completely filled is particularly

(a) strongly exchange stabilised

(b) weakly exchange stabilised

(c) weakly exchange destabilised

(d) strongly exchange destabilised

69. In a set of degenerate orbitals, the electrons distribute themselves to retain like spins as far as possible. This statement belongs to

(a) Pauli's exclusion principle

(b) Aufbau principle

(c) Hund's rule of maximum multiplicity

(d) Slater's rule

70. An f-shell containing 6 unpaired electrons can exchange

(a) 6 electrons (b) 9 electrons

(c) 12 electrons (d) 15 electrons

Round II (Mixed Bag)

Only One Correct Option

1. The work function (ϕ) of some metals is listed below. The number of metals which will show photoelectric effect when light of 300 nm wavelength falls on the metal is

Metal	Li	Na	K	Mg	Cu	Ag	Fe	Pt	W
ϕ (eV)	2.4	2.3	2.2	3.7	4.8	4.3	4.7	6.3	4.75

(a) 2 (b) 4 (c) 6 (d) 8

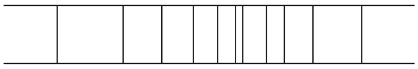
2. Which transition in the hydrogen atomic spectrum will have the same wavelength as the Balmer transition, $n = 4$ to $n = 2$ of He^+ spectrum? [**NCERT**]

(a) $n = 4$ to $n = 3$
(b) $n = 3$ to $n = 2$
(c) $n = 4$ to $n = 2$
(d) $n = 2$ to $n = 1$

3. Which diagram best represents the appearance of the line spectrum of atomic hydrogen in the visible region?

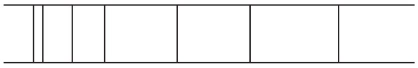
Increasing wavelength

(a)

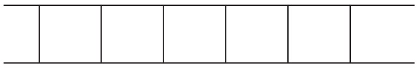


(b)

(c)



(d)



4. The electronic configuration of the oxide ion is much most similar to the electronic configuration of the

(a) sulphide ion
(b) nitride ion
(c) oxygen atom
(d) nitrogen atom

5. The number of photons emitted per second by a 60 W source of monochromatic light of wavelength 663 nm is ($h = 6.63 \times 10^{-34}$ Js).

(a) 4×10^{-20}
(b) 1.54×10^{20}
(c) 3×10^{-20}
(d) 2×10^{20}

6. The work function for caesium atom is 1.9 eV. If the caesium element is irradiated with a wavelength 500nm, the velocity of the ejected photoelectron is [**NCERT**]

(a) 4.527×10^5
(b) 3.258×10^5
(c) 1.892×10^6
(d) 2.329×10^5

7. The ejection of the photoelectron from the silver metal in the photoelectric effect experiment can be stopped by applying the voltage of 0.35 V when the radiation 256.7 nm is used. Calculate the work function for silver metal. [**NCERT**]

(a) 4.83 eV
(b) 4.48 eV
(c) 4.45 eV
(d) 4.34 eV

8. The quantum numbers of six electrons are given below. Arrange them in the order of increasing energies.

I. $n = 4, l = 2, m_l = -2, m_s = -\frac{1}{2}$
II. $n = 3, l = 2, m_l = 1, m_s = +\frac{1}{2}$
III. $n = 4, l = 1, m_l = 0, m_s = +\frac{1}{2}$
IV. $n = 3, l = 2, m_l = -2, m_s = -\frac{1}{2}$
V. $n = 3, l = 1, m_l = -1, m_s = +\frac{1}{2}$
VI. $n = 4, l = 1, m_l = 0, m_s = +\frac{1}{2}$ [**NCERT**]

(a) $1 < 2 = 4 < 3 = 6 < 5$
(b) $5 < 2 = 6 < 3 = 4 < 1$
(c) $5 < 3 = 6 < 2 = 4 < 1$
(d) $5 < 2 = 4 < 3 = 6 < 1$

9. An electron, a proton and an alpha particle have KE of $16E$, $4E$ and E respectively. What is the qualitative order of their de-Broglie wavelengths?

(a) $\lambda_e > \lambda_p > \lambda_\alpha$
(b) $\lambda_p = \lambda_\alpha > \lambda_e$
(c) $\lambda_p < \lambda_e < \lambda_\alpha$
(d) $\lambda_\alpha < \lambda_e \approx \lambda_p$

10. Suppose 10^{-17} J of light energy is needed by the interior of a human eye to see an object. Calculate the number of photons of green light ($\lambda = 550$ nm) needed to generate this minimum amount of energy.

(a) 26 (b) 27 (c) 28 (d) 29

11. The incorrect statement about Bohr's orbit of hydrogen atom is

(a) $r = n^2 \dfrac{h^2}{4\pi^2 m \left(\dfrac{e^2}{4\pi\varepsilon_0}\right)}$

(b) KE of electron = PE of electron

(c) $E = -\dfrac{1}{n^2} \dfrac{2\pi^2 m \left(\dfrac{e^2}{4\pi\varepsilon_0}\right)^2}{h^2}$

(d) None of the above is incorrect

12. If the photon of the wavelength 150 pm strikes an atom and one of its inner bound electrons is ejected out with a velocity of 1.5×10^7 ms^{-1}, the energy with which it is bound to the nucleus is **[NCERT]**

(a) 1.222×10^{-16} J (b) 7.63×10^{3} eV
(c) 1.22×10^{-19} kJ (d) All of these

13. An electron beam is accelerated through a potential difference of 10,000 volt. The de-Broglie wavelength of the electron beam is

(a) 0.123 Å (b) 0.356 Å
(c) 0.186 Å (d) 0.258 Å

14. I_2 molecule dissociates into atoms after absorbing light of 4500 Å. If one quantum of energy is absorbed by each molecule, the KE of iodine atoms will be (BE of I_2 = 240 kJ/mol)

(a) 240×10^{-19} J
(b) 0.216×10^{-19} J
(c) 2.16×10^{-19} J
(d) 2.40×10^{-19} J

15. A particle A moving with a certain velocity has the de-Broglie wavelength of 1 Å. For particle B with mass 25% of A and velocity 75% of A, calculate the de-Broglie wavelength.

(a) 3 Å (b) 5.33 Å
(c) 6.88 Å (d) 0.48 Å

16. Lifetimes of the molecules in the excited states are often measured by using pulsed radiation source of duration nearly in the nanosecond range. If the radiation source has the duration of 2*ns* and the number of photons emitted during the pulse source is 2.5×10^{15}, calculate the energy of the source. **[NCERT]**

(a) 8.28×10^{-10} J (b) 8.28×10^{-10} kJ
(c) 8.28×10^{-10} eV (d) All of these

17. If the shortest wavelength of H-atom in Lyman series is x, the longest wavelength in Balmer series of He^+ is

(a) $\frac{36x}{5}$ (b) $\frac{5x}{9}$
(c) $\frac{x}{4}$ (d) $\frac{9x}{5}$

18. If uncertainties in the measurement of position and momentum of an electron are equal, the uncertainty in the measurement of velocity is

(a) 8.0×10^{12} ms^{-1}
(b) 4.2×10^{10} ms^{-1}
(c) 8.5×10^{10} ms^{-1}
(d) 6.2×10^{10} ms^{-1}

19. An ion with mass number 37 possesses one unit of negative charge. If the ion contains 11.1% more neutrons than the electrons, find the symbol of the ion. **[NCERT]**

(a) $^{35}_{17}Cl$ (b) $^{37}_{17}Cl^-$
(c) $^{37}_{19}K^+$ (d) None of these

20. Chlorophyll present in green leaves of plants absorbs light at 4.620×10^{14} Hz. Which part of the electromagnetic spectrum does it belong to? **[NCERT Exemplar]**

(a) UV (b) IR (c) Far IR (d) Visible

21. Some energy is required to ionize a H-atom if the electron occupies $n = 5$ orbit. The ratio of the ionization enthalpy of H-atom (energy required to remove the electron from $n = 1$ orbit) with the energy required to ionise H-atom if electron occupies $n = 5$ orbit is **[NCERT]**

(a) 1 : 25 (b) 25 : 1 (c) 1 : 5 (d) 5 : 1

22. What is the colour of light emitted when the electron in a hydrogen atom undergoes transition from an energy level with $n = 4$ to an energy level with $n = 2$? **[NCERT]**

(a) Blue (b) White (c) Green (d) Red

23. Which of the following is correctly matched?

(a) Momentum of H- atom when electrons return from $n = 2$ to $n = 1$: $\frac{3Rh}{4}$
(b) Momentum of photon : Independent of wavelength of light
(c) e/m ratio of anode rays : Independent of gas in the discharge tube
(d) Radius of nucleus : $(\text{Mass no.})^{1/2}$

24. Which among the following is correct for $_5B$ in normal state?

(a) 
: Against Hund's rule

(b) : Against Aufbau principle as well as Hund's rule

(c) 
: Violation of Pauli's exclusion principle and not Hund's rule

(d) : Against Aufbau principle

25. The uncertainty in position for a dust particle ($m = 10^{-11}$ g; diameter = 10^{-4} cm and velocity = 10^{-4} cm/s) will be (The error in measurement of velocity is 1%)

(a) 5.27×10^{-4} cm (b) 5.27×10^{-5} cm
(c) 5.27×10^{-6} cm (d) 5.27×10^{-7} cm

26. If an electron has spin quantum number of $+\frac{1}{2}$ and a magnetic quantum number of -1, it cannot be represented in an

(a) s-orbital
(b) p-orbital
(c) d-orbital
(d) f-orbital

27. How many electrons in an atom may have the following quantum number? **[NCERT]**

(i) $n = 4, m_s = \frac{1}{2}$ (ii) $n = 3, l = 0$

(a) 32 and 2 respectively
(b) 16 and 2 respectively
(c) 16 and 1 respectively
(d) 32 and 1 respectively

28. In the ground state of Cu^+, the number of shell occupied, sub-shells occupied, filled orbitals and unpaired electrons respectively are

(a) 4, 8, 15, 0
(b) 3, 6, 15, 1
(c) 3, 6, 14, 0
(d) 4, 7, 14, 2

29. Following results are observed when sodium metal is irradiated with different wavelengths. Calculate threshold wavelength **[NCERT]**

λ (nm)	500	450	400
$v \times 10^5$ (ms^{-1})	2.55	4.35	5.20

(a) 4.28×10^{-6} m
(b) 5.31×10^{-7} m
(c) 3.29×10^{-9} m
(d) 2.48×10^{-7} m

30. Match the following species with their corresponding ground state electronic configuration.

	Atom/Ion		Electronic configuration
A.	Cu	1.	$1s^2, 2s^2 2p^6, 3s^2 3p^6 3d^{10}$
B.	Cu^{2+}	2.	$1s^2, 2s^2 2p^6, 3s^2 3p^6 3d^{10}, 4s^2$
C.	Zn^{2+}	3.	$1s^2, 2s^2 2p^6, 3s^2 3p^6 3d^{10}, 4s^1$
D.	Cr^{3+}	4.	$1s^2, 2s^2 2p^6, 3s^2 3p^6 3d^9$
		5.	$1s^2, 2s^2 2p^6, 3s^2 3p^6 3d^3$

Codes **[NCERT Exemplar]**

	A	B	C	D
(a)	1	2	3	4
(b)	2	3	4	5
(c)	3	4	2	5
(d)	3	4	1	5

31. The frequency of revolution of an electron in the second Bohr orbit in hydrogen atom is

(a) 8.18×10^{14} Hz
(b) 2.39×10^{15} Hz
(c) 3.29×10^{16} Hz
(d) 9.25×10^{14} Hz

32. Determine the Bohr orbit of Li^{2+} ion in which electron is moving at speed equal to the speed of electron in the first Bohr orbit of H-atom.

(a) 1
(b) 2
(c) 3
(d) 4

33. A mixture contains atoms of fluorine and chlorine. The removal of an electron from each atom of sample absorbs 284 kJ while the addition of an electron to each atom of mixture releases 68.89 kJ. Determine the percentage composition of the F in the mixture, given that the ionization energies of F and Cl are 27.91×10^{-22} and 20.77×10^{-22} kJ, respectively, and electron affinities are 5.53×10^{-22} and 5.78×10^{-22} kJ respectively.

(a) 62.19%
(b) 37.8%
(c) 12.1%
(d) 40.2%

More than One Correct Option

34. Which of the following statements concerning the quantum numbers are correct? **[NCERT Exemplar]**

(a) Angular quantum number determines the three dimensional shape of the orbital
(b) The principal quantum number determines the orientation and energy of the orbital
(c) Magnetic quantum number determines the size of the orbital
(d) Spin quantum number of an electron determines the orientation of the spin of electron relative to the chosen axis

35. Which of the following statement/s is/are correct?

(a) The oxidation state of nitrogen in HN_3 is 3
(b) The electronic configuration of Cr is $3d^5 4s^1$
(c) In silver atom, 23 electrons have a spin of one type and 24 of the opposite type (At. no. 47)
(d) The magnetic quantum number may have negative values

36. Which of the following sets of quantum numbers are correct? **[NCERT Exemplar]**

	n	l	m_l		n	l	m_l
(a)	1	1	+ 2	(b)	2	1	+1
(c)	3	2	− 2	(d)	3	4	− 2

37. In which of the following pairs, the ions are iso-electronic? **[NCERT Exemplar]**

(a) Na^+, Mg^{2+}
(b) Al^{3+}, O^-
(c) Na^+, O^{2-}
(d) N^{3-}, Cl^-

38. Out of the following pairs of electrons, identify the pairs of electrons present in degenerate orbitals : **[NCERT Exemplar]**

(a) (i) $n = 3, l = 2, m_l = -2, m_s = -\frac{1}{2}$

(ii) $n = 3, l = 2, m_l = -1, m_s = -\frac{1}{2}$

(b) (i) $n = 3, l = 1, m_l = 1, m_s = +\frac{1}{2}$

(ii) $n = 3, l = 2, m_l = 1, m_s = +\frac{1}{2}$

(c) (i) $n = 4, l = 1, m_l = 1, m_s = +\frac{1}{2}$

(ii) $n = 3, l = 2, m_l = 1, m_s = +\frac{1}{2}$

(d) (i) $n = 3, l = 2, m_l = +2, m_s = -\frac{1}{2}$

(ii) $n = 3, l = 2, m_l = +2, m_s = +\frac{1}{2}$

Assertion and Reason

Directions (Q. No. 39 to 43) *Each of these questions contains two statements : Statement* I (*Assertion*) *and Statement* II (*Reason*). *Each of these questions also has four alternative choices, only one of which is the correct answer. You have to select one of the codes* (*a*), (*b*), (*c*), (*d*) *given below :*

(a) Statement I is true; Statement II is true; Statement II is a correct explanation for Statement I.
(b) Statement I is true; Statement II is true; Statement II is not a correct explanation for Statement I.
(c) Statement I is true; Statement II is false.
(d) Statement I is false; Statement II is true.

39. **Statement I** The charge to mass ratio of the particles in anode rays depends on nature of the gas taken in the discharge tube.

Statement II The particles in anode rays carry positive charge.

40. **Statement I** It is impossible to determine the exact position and exact momentum of an electron simultaneously.

Statement II The path of an electron in an atom is clearly defined. **[NCERT Exemplar]**

41. **Statement I** Black body is an ideal body that emits and absorbs radiations of all frequencies.

Statement II The frequency of radiation emitted by a body goes from a lower frequency to higher frequency with an increase in temperature. **[NCERT Exemplar]**

42. **Statement I** The radius of second orbit of He^+ is equal to that of first orbit of hydrogen.

Statement II The radius of an orbit in hydrogen like species is directly proportional to n^2 and inversely proportional to Z.

43. **Statement I** Only principal quantum number determines the energy of an electron in an orbital in sodium atom.

Statement II For one electron system, the expression of energy is the same as that obtained in Bohr's theory.

Comprehension Based Questions

Directions (Q. Nos. 44 and 45) For a single electron atom or ion the wave number of radiation emitted during the transition of electron from a higher energy state ($n = n_2$) to a lower energy state ($n = n_1$) is given by the expression

$$\bar{\nu} = \frac{1}{\lambda} = R_H \cdot Z^2 \left\{\frac{1}{n_1^2} - \frac{1}{n_2^2}\right\} \quad \text{... (i)}$$

where $R_H = \frac{2\pi^2\, m\, k^2\, e^4}{h^3 C}$ = Rydberg constant for H-atom

where the terms have their usual meanings.

For Lyman series $n_1 = 1$ (fixed for all the lines) while $n_2 = 2, 3, 4, \ldots$ for successive lines *i.e.*, Ist, 2nd, 3rd ... lines, respectively. For Balmer series : $n_1 = 2$ (fixed for all the lines) while $n_2 = 3, 4, 5 \ldots$ for successive lines.

44. The ratio of the wave numbers for the highest energy transition of electron in Lyman and Balmer series of H-atom is

(a) 4:1 (b) 6:1 (c) 9:1 (d) 3:1

45. If proton in H-nucleus be replaced by positron having the same mass as that of proton but same charge as that of proton, then considering the nuclear motion, the wavenumber of the lowest energy transition of He^+ ion in Lyman series will be equal to

(a) $2\,R_H$ (b) $3\,R_H$
(c) $4\,R_H$ (d) R_H

Directions (Q. Nos. 46 to 48) According to the uncertainty principle, it is impossible to know simultaneously both the conjugate properties accurately. Both the position and the momentum of the particle at any instant can't be determined with absolute exactness or certainty. The uncertainty in measurement of position, Δx and the uncertainty of determination of momentum, ΔP are related by Heisenberg's relationship as

$$\Delta x \times \Delta P \geq \frac{h}{4\pi}$$

or

$$\Delta x \times m\Delta v \geq \frac{h}{4\pi}$$

If position is known quite accurately *i.e.,* Δx is very small, the uncertainty regarding velocity, Δv becomes immensely large and *vice-versa*. It is therefore, very clear that the uncertainty principle is only important in considering measurements of small particles comprising an atomic system.

46. If uncertainty in the position of electron is zero, the uncertainty in its momentum would be

(a) $< \frac{h}{4\pi}$ (b) $\geq \frac{h}{4\pi}$
(c) zero (d) infinite

47. The uncertainty in position of an electron ($m = 9.1 \times 10^{-28}$ g) moving with a velocity 3×10^4 cm/s accurate upto 0.001% will be

(a) 3.84 cm
(b) 1.92 cm
(c) 7.68 cm
(d) 5.76 cm

48. If the light of wavelength, λ is used to observe an electron then uncertainty in position of the electron would be

(a) less than λ
(b) more than λ
(c) equal to λ
(d) equal to or greater than λ

Previous Years' Questions

49. The electrons identified by quantum numbers n and l

(1) $n = 4, l = 1$
(2) $n = 4, l = 0$
(3) $n = 3, l = 2$
(4) $n = 3, l = 1$

can be placed in the order of increasing energy as **[AIEEE 2012]**

(a) $3 < 4 < 2 < 1$
(b) $4 < 2 < 3 < 1$
(c) $2 < 4 < 1 < 3$
(d) $1 < 3 < 2 < 4$

50. A gas absorbs photon of 355 nm and emits at two wavelengths. If one of the emission is at 680 nm, the other is at **[AIEEE 2011]**

(a) 1035 nm
(b) 325 nm
(c) 743 nm
(d) 518 nm

51. The frequency of light emitted for the transition $n = 4$ to $n = 2$ of He^+ is equal to the transition in H atom corresponding to which of the follwing? **[AIEEE 2011]**

(a) $n = 3$ to $n = 1$
(b) $n = 2$ to $n = 1$
(c) $n = 3$ to $n = 2$
(d) $n = 4$ to $n = 3$

52. The energy required to break one mole of Cl — Cl bonds in Cl_2 is 242 kJ mol^{-1}. The longest wavelength of light capable of breaking a single Cl — Cl bond is **[AIEEE 2010]**

(a) 594 nm
(b) 640 nm
(c) 700 nm
(d) 494 nm

53. Ionisation energy of He^+ is 19.6×10^{-18} J atom^{-1}. The energy of the first stationary state ($n = 1$) of Li^{2+} is **[AIEEE 2010]**

(a) 4.41×10^{-16} J atom^{-1}
(b) -4.41×10^{-17} J atom^{-1}
(c) -2.2×10^{-15} J atom^{-1}
(d) 8.82×10^{-17} J atom^{-1}

54. Calculate the wavelength (in nanometer) associated with a proton moving at 1.0×10^3 ms^{-1} (mass of proton = 1.67×10^{-27} kg and $h = 6.63 \times 10^{-34}$ Js) **[AIEEE 2009]**

(a) 0.032 nm
(b) 0.40 nm
(c) 2.5 nm
(d) 14.0 nm

55. In an atom, an electron is moving with a speed of 600 m/s with an accuracy of 0.005%. Certainity with which the position of the electron can be located is ($h = 6.6 \times 10^{-34}$ kg m^2 s^{-1}, mass of electron, $e_m = 9.1 \times 10^{-31}$ kg) **[AIEEE 2009]**

(a) 1.52×10^{-4} m
(b) 5.10×10^{-3} m
(c) 1.92×10^{-3} m
(d) 3.84×10^{-3} m

56. The ionisation enthalpy of hydrogen atom is 1.312×10^6 J mol^{-1}. The energy required to excite the electron in the atom from $n = 1$ to $n = 2$ is **[AIEEE 2008]**

(a) 8.51×10^5 J mol^{-1}
(b) 6.56×10^5 J mol^{-1}
(c) 7.56×10^5 J mol^{-1}
(d) 9.84×10^5 J mol^{-1}

57. Which of the following sets of quantum numbers represents the highest energy of an atom? **[AIEEE 2007]**

(a) $n = 3, l = 1, m = 1, s = +1/2$
(b) $n = 3, l = 2, m = 1, s = +1/2$
(c) $n = 4, l = 0, m = 0, s = +1/2$
(d) $n = 3, l = 0, m = 0, s = +1/2$

58. Which one of the following sets of ions represents a collection of isoelectronic species? **[AIEEE 2006]**

(a) K^+, Cl^-, Ca^{2+}, Sc^{3+}
(b) Ba^{2+}, Sr^{2+}, K^+, S^{2-}
(c) N^{3-}, O^{2-}, F^-, S^{2-}
(d) Li^+, Na^+, Mg^{2+}, Ca^{2+}

59. According to Bohr's theory, the angular momentum of an electron in 5th orbit is **[AIEEE 2006]**

(a) $25\frac{h}{\pi}$
(b) $1.0\frac{h}{\pi}$
(c) $10\frac{h}{\pi}$
(d) $2.5\frac{h}{\pi}$

60. Which one of the following statements in relation to the hydrogen atom is correct? **[AIEEE 2005]**

(a) 3s, 3p and 3d orbitals all have the same energy
(b) 3s and 3p orbitals are of lower energy than 3d orbital
(c) 3p orbital is lower in energy than 3d orbital
(d) 3s orbital is lower in energy than 3p orbital

Answers

the Guidance

Round I

1. Mass of electron = 9.1×10^{-31} kg

Mass of neutron = 1.67×10^{-27} kg

2. Neutron being neutral will not show deflection from the path on passing through an electric field.

5. 1 mol^{14} C $= 14$ g $= 6.022 \times 10^{23}$ carbon atoms

Number of neutrons in 1 carbon atom

$$= \text{mass number} - \text{atomic number} = 14 - 6 = 8 \text{ neutrons}$$

$\because 6.023 \times 10^{23}$ carbon atoms will contain $6.023 \times 10^{23} \times 8$ neutrons

$\therefore$ 14 g carbon-14 have $6.023 \times 10^{23} \times 8$ neutrons

and 7 mg or 7×10^{-3} g carbon-14 will have

$$\frac{7 \times 10^{-3} \times 6.023 \times 10^{23} \times 8}{14} \text{ neutrons}$$

$$= 24.092 \times 10^{20} \text{ neutrons} = 2.4092 \times 10^{21} \text{ neutrons}$$

Mass of 1 neutron $= 1.675 \times 10^{-27}$ kg

Mass of 2.4092×10^{21} neutrons

$$= 2.4092 \times 10^{21} \times 1.675 \times 10^{-27} \text{ kg}$$

$$= 4.0347 \times 10^{-6} \text{ kg}$$

6. 1 mole of NH_3 contains protons $= 7 + 3 = 10$ moles of protons (7 in N and 1 in each H atom) $= 6.023 \times 10^{23} \times 10$ protons

$= 6.023 \times 10^{24}$ protons 34 mg or 34×10^{-3} g NH_3 will contain

$$\frac{34 \times 10^{-3} \times 6.023 \times 10^{24}}{17} = 12.046 \times 10^{21} \text{ protons}$$

7. Diameter of Zn atom $= 2.6$ Å $= 2.6 \times 10^{-10}$ m

Given, length $= 1.6$ cm $= 1.6 \times 10^{-2}$ m

Number of Zn atoms in 1.6×10^{-2} m

$$= \frac{1.6 \times 10^{-2} \text{ m}}{2.6 \times 10^{-10} \text{ m}} = 0.6154 \times 10^{8} \text{ atoms}$$

$$= 6.154 \times 10^{7} \text{ atoms}$$

8. Isobars have the same mass number (*i.e.*, sum of protons and neutrons) but different atomic number (*i.e.*, number of protons).

10. According to Rutherford

$$\text{Scattering angle} \propto \frac{1}{\sin^4 (\theta/2)}$$

It fails for very small scattering angles because the full nuclear charge of the target atom is partially screened by its electron.

11. Mass of electron $= 9.1 \times 10^{-31}$ kg,

Mass of proton $= 1.67 \times 10^{-27}$ kg

Mass of neutron $= 1.675 \times 10^{-27}$ kg

Mass of α-particle $= 6.67 \times 10^{-27}$ kg

So, increasing order of e/m for e, p, n and α-particle is $e > p > \alpha > n$ (∵ neutron has no charge).

12. $$\frac{\frac{e}{m_d}}{\frac{2e}{m_{\alpha-p}}} = \frac{4m_{\alpha-p}}{4m_d} = 1$$

So, deuterium and an α-particle have identical value of e/m.

13. Given, frequency $\nu = \dfrac{c}{\lambda} = 3.29 \times 10^{15}\,\text{Hz}\left(\dfrac{1}{3^2} - \dfrac{1}{n^2}\right)$

$$\nu = \frac{3.0 \times 10^8 \text{ms}^{-1}}{1285 \times 10^{-9}\,\text{m}} = 3.29 \times 10^{15}\,\text{Hz}\left(\frac{1}{9} - \frac{1}{n^2}\right)$$

$$\frac{3.0 \times 10^8 \text{ms}^{-1}}{1285 \times 10^{-9}\,\text{m} \times 3.29 \times 10^{15}\,\text{Hz}} = \left(\frac{1}{9} - \frac{1}{n^2}\right)$$

$$0.0709 = 0.1111 - \frac{1}{n^2}$$

$$\frac{1}{n^2} = 0.1111 - 0.0709 = 0.0402 \approx 0.04 = \frac{1}{25}$$

$$n^2 = 25 \text{ or } n = 5$$

∴ The electron jumps from $n = 5$ to $n = 3$ *i.e.*, the transition occurs in Paschen series and lies in infrared region.

Note The radiation 1285 nm lies in the infrared region.

14. Frequency, $\nu = \dfrac{c}{\lambda}$

$$[1 \text{ nm} = 10^{-9} \text{ m}]$$

$580 \text{ nm} = 580 \times 10^{-9}\,\text{m} = 580 \times 10^{-7}$ cm

$$\nu = \frac{3.0 \times 10^8 \text{ ms}^{-1}}{580 \times 10^{-9}\,\text{m}} = 5.17 \times 10^{14}\,\text{s}^{-1}$$

(∴ Velocity of light $= 3 \times 10^8 \text{ ms}^{-1}$)

Wave number, $\bar{\nu} = \dfrac{1}{\lambda} = \dfrac{1}{580 \times 10^{-7}\text{ cm}}$

$$= 1.724 \times 10^4 \text{ cm}^{-1}$$

15. Energy of one photon,

$$E = \frac{hc}{\lambda} = \frac{6.626 \times 10^{-34}\text{Js} \times 3.0 \times 10^8 \text{ ms}^{-1}}{4000 \times 10^{-12}\,\text{m}}$$

$$(1\text{pm} = 10^{-12} \text{ m})$$

$$= 4.9695 \times 10^{-17}\text{J}$$

Number of photons,

$$N = \frac{1\text{J}}{4.9695 \times 10^{-17}\text{J}} = 2.0122 \times 10^{16} \text{ photons}$$

16. The order of frequency is radiation from FM radio < microwaves < amber colour < X-rays < cosmic rays.

17. 25 watt $= 25 \text{ Js}^{-1}$ $\quad (1 \text{watt} = 1 \text{Js}^{-1})$

Wavelength, $\lambda = 0.57\,\mu\text{m} = 0.57 \times 10^{-6}$ m $\quad (1\mu\text{m} = 10^{-6}\,\text{m})$

Energy of one photon,

$$E = \frac{hc}{\lambda} = \frac{6.626 \times 10^{-34}\text{Js} \times 3.0 \times 10^8 \text{ ms}^{-1}}{0.57 \times 10^{-6} \text{ m}}$$

$$E = 34.87 \times 10^{-20} \text{ J}$$

Number of photons emitted per second

$$= \frac{\text{Total energy per second}}{\text{Energy of photon}}$$

$$= \frac{25 \text{ Js}^{-1}}{34.87 \times 10^{-20}} = 0.7169 \times 10^{20} \text{ photons per second}$$

$$= 7.169 \times 10^{19} \text{ photon per second}$$

18. Atoms corresponds to different transitions from higher energy levels to lower energy levels.

20. Kinetic energy $= h(\nu - \nu_0)$

$$\text{KE} = h\nu - h\nu_0$$

$$\nu_0 = \nu - \frac{\text{KE}}{h} = 2 \times 10^{15} - \frac{6.63 \times 10^{-19}}{6.63 \times 10^{-34}}$$

$$= 1 \times 10^{15} \text{ s}^{-1}$$

21. The threshold frequency (ν_0) is the lowest frequency that photons may possess to produce the photoelectric effect. The energy corresponding to this frequency is the minimum energy (E).

$$E = h\nu_0$$

$$= (6.626 \times 10^{-27} \text{ erg-}s)\,(1.3 \times 10^{15} \text{ s}^{-1})$$

$$= 8.6 \times 10^{-12} \text{ erg}$$

22. Radius of nth orbit of H like species,

$$r_n = \frac{52.9\,(n^2)}{Z}\,\text{pm}$$

$$r_1 = 1.3225\,\text{nm} = 1322.5\,\text{pm} = \frac{52.9\,n_1^2}{Z}$$

$$r_2 = 211.6 \text{ pm} = \frac{52.9\,n_2^2}{Z}$$

$$\frac{r_1}{r_2} = \frac{1322.5}{211.6} = \frac{n_1^2}{n_2^2}$$

$$\frac{n_1^2}{n_2^2} = 6.25 \text{ or } \frac{n_1}{n_2} = 2.5$$

If $n_1 = 5$, $n = 2$, so, the transition (emission transition) is from 5th orbit to 2nd orbit and it belongs to Balmer series.

$$\bar{\nu} = \frac{1}{\lambda} = 1.09677 \times 10^7 \left[\frac{1}{n_1^2} - \frac{1}{n_2^2}\right] \text{m}^{-1}$$

$$\frac{1}{\lambda} = 1.09677 \times 10^7 \left[\frac{1}{2^2} - \frac{1}{5^2}\right] \text{m}^{-1}$$

$$\frac{1}{\lambda} = 1.09677\times 10^{7} \times \frac{21}{100} = 2.303\times 10^{6}\ \text{m}^{-1}$$

$$\lambda = 0.434\times 10^{-6}\text{m} = 434\times 10^{-9}\text{m} = 434\,\text{nm}$$

It belongs to visible region.

Note In the above Rydberg formula if $n_1 = 1, 2\ldots$ then $n_2 = n_1 + 1$, $n_1 + 2\ldots$ For Balmer series, spectral region is visible.

23. $E \propto \left(\frac{1}{n_1^2} - \frac{1}{n_2^2}\right)$ or $E \propto \frac{1}{n^2}$

26. $r_{\text{H}} = 0.529$ Å

$$r_n = r_{\text{H}} \times \frac{n^2}{Z}$$

For Li^{2+} $(n = 2)$,

$$r_{\text{Li}^{2+}} = r_{\text{H}} \times \frac{(2)^2}{3} = \frac{r_{\text{H}} \times 4}{9}$$

For $\text{Li}^{2+} (n = 3)$,

$$r_{\text{Li}^{2+}} = r_{\text{H}} \times \frac{(3)^3}{3} = 3r_{\text{H}}$$

For $\text{Be}^{3+} (n = 2)$

$$r_{\text{Be}^{3+}} = r_{\text{H}} \times \frac{(2)^2}{4} = r_{\text{H}}$$

For $\text{He}^{+} (n = 2)$

$$r_{\text{He}^{+}} = r_{\text{H}} \times \frac{(2)^2}{2} = 2r_{\text{H}}$$

Thus, $\text{Be}^{3+} (n = 2)$ has same radius as that of the first Bohr's orbit of H-atom.

27. Angular momentum, $mvr = \frac{nh}{2\pi} = \frac{3\times h}{2\pi} = \frac{1.5h}{\pi}$

$$= 3\hbar \qquad \left[\because\ \hbar = \frac{h}{2\pi}\right]$$

28. Energy in nth orbit, $E_n = \frac{-2.18\times 10^{-18}}{n^2}$ J

Energy in fifth orbit, $E_5 = \frac{-2.18\times 10^{-18}}{5^2}\text{ J} = -0.0872\times 10^{-18}\text{ J}$

29. Given, wavelength, $\lambda = 242\,\text{nm} = 242\times 10^{-9}$ m

Energy, $E = h\nu = \frac{hc}{\lambda} = \frac{6.626\times 10^{-34}\,\text{Js}\times 3.0\times 10^{8}\ \text{ms}^{-1}}{242\times 10^{-9}\ \text{m}}$

$$E = 0.0821\times 10^{-17}\ \text{J/atom}$$

This energy is sufficient for ionization of one Na atom, so it is the ionization energy of Na.

$$E = 6.02\times 10^{23}\times 0.0821\times 10^{-17}\ \text{J/mol}$$

$$E = 4.945\times 10^{5}\ \text{J/mol} = 4.945\times 10^{2}\ \text{kJ/mol}$$

30. Number of lines produced when electron from nth shell drops to ground state $= \frac{n(n-1)}{2}$

When $n = 6$, number of lines produced

$$= \frac{6(6-1)}{2} = \frac{6\times 5}{2} = 15$$

31. $E = \frac{1}{4\lambda\varepsilon_0}\frac{Ze^2}{r}$

For Li^{2+}, $Z = 3$ so $E = \frac{3e^2}{4\lambda\varepsilon_0 r}$

32. $v = \frac{2.18\times 10^{8}\times Z}{n}$ cm s^{-1}

For H atom, $Z = 1$ and third orbit, $n = 3$,

$$v_3 = \frac{2.18\times 10^{8}\times 1}{3}$$

$$= 7.26\times 10^{7}\ \text{cm s}^{-1}$$

34. $m = 10\,\text{g} = 10\times 10^{-3}$ kg

Uncertainty in speed $(\Delta\nu)$ = 4% of 90 ms^{-1} $= \frac{4\times 90}{100}$

$$= 3.6\ \text{ms}^{-1}$$

From Heisenberg uncertainty principle,

$$\Delta x\cdot\Delta\nu = \frac{h}{4\pi m} \text{ or } \Delta x = \frac{h}{4\pi m\Delta\nu}$$

Uncertainty in position,

$$\Delta x = \frac{6.626\times 10^{-34}\ \text{kg m}^2\text{s}^{-1}}{4\times 3.14\times 10\times 10^{-3}\ \text{kg}\times 3.6\,\text{ms}^{-1}}$$

$$= 1.46\times 10^{-33}\ \text{m}$$

35. Wavelength, $\lambda = \frac{h}{mv}$

Mass of neutron, $m = 1.675\times 10^{-27}$kg

$$\lambda = 800\ \text{pm} = 800\times 10^{-12}\text{m} = \frac{6.626\times 10^{-34}\ \text{kg m}^2\ \text{s}^{-1}}{1.675\times 10^{-27}\ \text{kg}\times v}$$

$$v = \frac{6.626\times 10^{-34}\,\text{kg m}^2\ \text{s}^{-1}}{1.675\times 10^{-27}\ \text{kg}\times 800\times 10^{-12}\text{m}}$$

$$= 0.494\times 10^{3}\ \text{ms}^{-1} = 4.94\times 10^{2}\text{ms}^{-1}$$

36. Given, $m = 100\,\text{g} = 0.1\text{kg}$

$$v = 100\text{km/h} = \frac{100\times 1000}{60\times 60} = \frac{1000}{36}\ \text{ms}^{-1}$$

From de-Broglie equation, wavelength, $\lambda = \frac{h}{mv}$

$$\lambda = \frac{6.626\times 10^{-34}\ \text{kg m}^2\ \text{s}^{-1}}{0.1\ \text{kg}\times\frac{1000}{36}\ \text{ms}^{-1}} = 238.5\times 10^{-36}\ \text{m}$$

(As the wavelength is very small so wave nature cannot be detected)

37. From de-Broglie equation, wavelength, $\lambda = \frac{h}{mv}$

For same wavelength of different particles, *i.e.,* electron, proton, neutron and α-particle, $m_1v_1 = m_2v_2$ as (h is constant). Lesser the mass of the particle, greater will be the velocity. Hence, electron will have higher velocity.

38. de-Broglie wavelength,

$$\lambda = \frac{h}{mv}$$

or $$\lambda \propto \frac{1}{m} \qquad \text{If } v = \text{constant (same)}$$

39. We know that kinetic energy = eV

or $$= \frac{1}{2} mv^2$$

So, $$\frac{1}{2} mv^2 = eV$$

$$v^2 = \frac{2eV}{m}$$

$$\therefore \qquad v = \sqrt{\frac{2eV}{m}}$$

40. $\lambda = \dfrac{h}{mv} = \dfrac{6.6 \times 10^{-34} \text{ kg m}^2 \text{ s}^{-1}}{6.6 \times 10^{-27} \text{ kg} \times 10^3 \text{ ms}^{-1}} = 1 \times 10^{-10} \text{ m}$

41. The de-Broglie wavelength associated with the charged particles as

For electron, $\lambda = \dfrac{12.27}{\sqrt{V}}$ Å

For proton, $\lambda = \dfrac{0.286}{\sqrt{V}}$ Å

For α-particles, $\lambda = \dfrac{0.101}{\sqrt{V}}$ Å

42. $\Delta x \cdot \Delta P = \dfrac{h}{4\pi}$

$$\Delta x = \frac{6.63 \times 10^{-34}}{4 \times 3.14 \times 10^{-5}}$$

$$= \frac{5.27 \times 10^{-35}}{1 \times 10^{-5}}$$

$$= 5.27 \times 10^{-30} \text{ m}$$

43. $\lambda = \dfrac{h}{\sqrt{2Em}}$

When kinetic energy of electron becomes four times, the de-Broglie wavelength will become half.

45. The arrangement of orbitals is based upon $(n + l)$ rule. According to which,lower the value of $(n + l)$, lower is the energy. For the orbitals having similar value of $(n + l)$ lower the value of n, lower is the energy. Thus, the correct order of arrangement are

(a) $1s < 2s < 2p < 3s$
(b) $3s < 3p < 4s < 4d$
(c) $4d < 5p < 6s < 4f < 5d$
(d) $7s < 5f < 6d < 7p$

46. For g subshell $l = 4$ and to have $l = 4$ minimum value of $n = 5$ [because the value of $l = 0$ to $(n - 1)$]

47. Number of spherical nodes in $3p$ orbital

$$= n - l - 1 = 3 - 1 - 1 = 1$$

48. (I) is not possible as $n \neq 0$

(II) is possible ($1s$)
(III) is not possible because if $n = 1, l = 0$ only $l \neq 1$
(VI) is possible ($2p$)
(V) is not possible because if $n = 3, l = 0\ 1$ and $2\ (l \neq 3)$
(VI) is possible ($3p$)

49. Total number of orbitals associated with nth shell = n^2

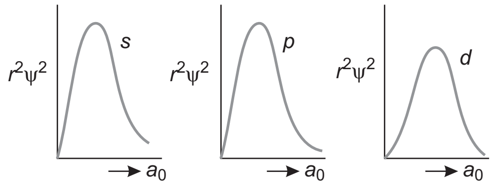
∴ Total number of orbitals associated with 3rd shell = $(3)^2 = 9$

50. Number of angular nodes = l

For 4th orbital, $(n = 4)$ and $l = 2$ for d orbital

∴ Number of angular nodes = 2

53. The electron density is directly proportional to ψ^2. The larger the electron density, the larger the value of ψ^2 and more is the probability of finding the electrons.



54. For a particular value of azimuthal quantum number, the total number of magnetic quantum number,

$$m = 2l + 1 \quad \text{or} \quad 2l = m - 1$$

$$l = \frac{m - 1}{2}$$

55. For $4d$ electron,

$$n = 4, l = 2, m = -2, -1, 0, +1, +2$$

$$s = +\frac{1}{2} \text{ or } -\frac{1}{2}$$

56. $+\dfrac{1}{2}$ and $-\dfrac{1}{2}$ spinning produces angular momentum equal to Z-component of angular momentum which is given as $m_s(h/2\pi)$.

57. Higher values of ψ^2 means greater probability for finding electron and a zero value of ψ^2 means the probability for finding the electron is zero (at nucleus).

58. The four lobes of $d_{x^2 - y^2}$ orbital are lying along x and y axes, while the two lobes of d_{z^2} orbital are lying along z-axis, and contain a ring of negative charge surrounding the nucleus in xy plane.

$2s$ orbital has only one spherical node, where electron density is zero.

p-orbital have directional character.

$$\text{orbital} \longrightarrow \; p_z \quad p_x \quad p_y$$
$$m \longrightarrow \; 0 \quad \pm 1 \quad \pm 1$$
$$\text{Nodal plane} \longrightarrow \; xy \quad yz \quad zx$$

59. $_8O = 1s^2 \quad 2s^2 \quad 2p^4$

60. (a) Z_{eff} of $2s >$ Z_{eff} of $2p$

(b) energy of $2s$ orbital $<$ energy of $2p$ orbital

(c) Z_{eff} of $1s \neq$ Z_{eff} of $2s$

(d) For the two electrons of $2s$ orbital,

the value of m_s is $+\frac{1}{2}$ and $-\frac{1}{2}$

61. $Cr_{24} = [Ar]3d^5, 4s^1$

$Cr^{3+} = [Ar]3d^3$

$Fe_{26} = [Ar]3d^6, 4s^2$

$Fe^{3+} = [Ar]3d^5$

$Mn_{25} = [Ar]3d^5, 4s^2$

$Mn^{2+} = [Ar]3d^5$

$Co_{27} = [Ar]3d^7, 4s^2$

$Co^{3+} = [Ar]3d^6$

$Sc_{21} = [Ar]3d^1, 4s^2$

$Sc^{3+} = [Ar]$

Thus, Fe^{3+} and Mn^{2+} have the same electronic configuration.

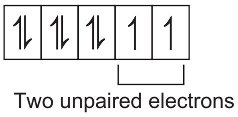
62. (i) (c) $_8O = 1s^2, 2s^2, 2p^4$; $O^{2-} = 1s^2, 2s^2, 2p^6$

65. $35 = 1s^2, 2s^2, 2p^6, 3s^2, 3p^6, 4s^2, 3d^{10}, 4p^5$

Thus, it contains 7 electrons in 4th or outermost shell.

66. $_{28}Ni = 1s^2, 2s^2, 2p^6, 3s^2, 3p^6, 4s^2, 3d^8$

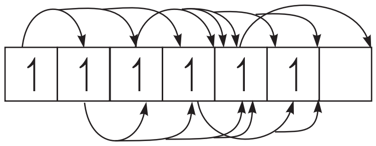
$Ni^{2+} = 1s^2, 2s^2, 2p^6, 3s^2, 3p^6, 3d^8$



67. The energy of electrons in the same orbital is the same. For $3d$ orbitals, $3d_{xy}, 3d_{yz}, 3d_{zx}, 3d_{z_2^2}, 3d_{x^2-y^2}$, are at the same level of energy, irrespective of their orientation. The electronic configuration $3d^2_{xy}, 3d^2_{yz}, 3d^2_{zx}, 3d^2_{x^2-y^2}, 3d^2_{z^2}, 4s^1$ has maximum exchange energy.

68. A subshell having nearly half-filled or nearly completely filled configurations tends to acquire exactly half-filled or exactly completely filled nature to have lower energy level in order to attain extra stability.

70.



$5 + 4 + 3 + 2 + 1 = 15$

Round II

1. Energy of photon $= \frac{hc}{\lambda}\text{J} = \frac{hc}{e\lambda}\text{eV}$

$$= \frac{6.626 \times 10^{-34} \times 3 \times 10^{8}}{300 \times 10^{-9} \times 1.602 \times 10^{-19}}$$

$$= 4.14 \text{ eV}$$

For photoelectric effect to occur, energy of incident photons must be greater than work functions of metal and only Li, Na, K and Mg have work functions less than 4.14 V.

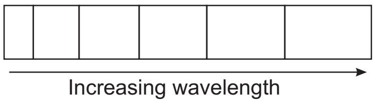
2. $\frac{1}{\lambda} = Z^2 \cdot R_H \left(\frac{1}{n_1^2} - \frac{1}{n_2^2} \right)$

For He^+, $\frac{1}{\lambda} = 2^2 \cdot R_H \left[\frac{1}{2^2} - \frac{1}{4^2} \right] = 4 \times \frac{3}{16} = \frac{3}{4}$

For $H, \frac{1}{\lambda} = 1^2 \cdot R_H \left[\frac{1}{1^2} - \frac{1}{2^2} \right] = \frac{3}{4}$

Hence, for hydrogen the given transition corresponds to $n = 2$ to $n = 1$ transition,

3. Line spectrum of atomic hydrogen in the visible region is as



4. Species having the same number of electrons as in oxide ion, has the same electronic configuration as oxide ion. O^{2-} or N^{3-} both species have same number of electrons (10 electrons).

5. Energy, $E = \frac{nhc}{\lambda}$

$$\Rightarrow \quad 60 \times 1\text{Js} = \frac{n \times 6.63 \times 10^{-34} \text{ Js} \times 3 \times 10^{8} \text{ m}}{663 \times 10^{-9} \text{m}}$$

$$\left[\because \text{Power} = \frac{\text{energy}}{\text{time}} \right]$$

$$\because \quad n = \frac{60 \times 1 \times 663 \times 10^{-9}}{6.63 \times 10^{-34} \times 3 \times 10^{8}} = 2 \times 10^{20}$$

6. Work function $W_0 = h\nu_0$

$$W_0 = 1.9 \text{ eV} = 1.9 \times 1.602 \times 10^{-19} \text{ J}$$

Threshold frequency,

$$\nu_0 = \frac{W_0}{h} = \frac{1.9 \times 1.602 \times 10^{-19} \text{ J}}{6.626 \times 10^{-34} \text{ Js}}$$

$$\nu_0 = 4.59 \times 10^{14} \text{ s}^{-1}$$

KE of ejected photoelectron $= h(\nu - \nu_0)$

λ of striking radiation $= 500 \text{ nm} = 500 \times 10^{-9}$ m

$$\nu = \frac{c}{\lambda} = \frac{3.0\times 10^{8}\ \text{ms}^{-1}}{500\times 10^{-9}\ \text{m}} = 6.0\times 10^{14}\ \text{s}^{-1}$$

$$\text{KE} = 6.626\times 10^{-34}\ \text{Js}\ (6.0\times 10^{14}\ \text{s}^{-1} - 4.59\times 10^{14}\ \text{s}^{-1})$$

$$= 9.34\times 10^{-20}\ \text{J}$$

$$\text{KE} = \frac{1}{2}mv^2\ (\text{Mass of an electron} = 9.11\times 10^{-31}\ \text{kg})$$

$$9.34\times 10^{-20}\ \text{J} = \frac{1}{2}\times 9.11\times 10^{-31}\ \text{kg}\times v^2$$

$$\therefore \quad v^2 = 2.050\times 10^{11}\ \text{m}^2\text{s}^{-2} \qquad (\because 1\,\text{J} = 1\,\text{kg m}^2\text{s}^{-2})$$

$$\text{or} \quad v = \sqrt{20.50\times 10^{10}}\ \text{m}^2\text{s}^{-2}$$

$$\text{or} \quad v = 4.527\times 10^{5}\ \text{ms}^{-1}$$

Note Minimum energy required to eject an electron is also known as work function, W_0 ($W_0 = h\nu_0$).

7. Energy of incident radiation, $h\nu = h\nu_0 + \text{KE}$

$$E = h\nu = \frac{hc}{\lambda} = \frac{6.626\times 10^{-34}\ \text{Js}\times 3.0\times 10^{8}\ \text{ms}^{-1}}{256.7\times 10^{-9}\ \text{m}}$$

$$= 7.74\times 10^{-19}\ \text{J} = \frac{7.74\times 10^{-19}\ \text{eV}}{1.602\times 10^{-19}} = 4.83\ \text{eV}$$

Applied potential gives the kinetic energy to electron, *i.e.*,

$$\text{eV}_0 = \frac{1}{2}mv_{\text{max}}^2 = \text{KE}$$

$$= \frac{1}{2}mv_{\text{max}}^2 = 1.6\times 10^{-19}\times 0.35 = 0.56\times 10^{19}\ \text{J}$$

$$= \frac{0.56\times 10^{-19}}{1.6\times 10^{-19}}\ \text{eV} = 0.35\ \text{eV}$$

$$\therefore \quad \text{KE} = 0.35\ \text{eV}$$

Work function, W_0 or $h\nu_0 = h\nu - \text{KE}$

$$= 4.83\ \text{eV} - 0.35\ \text{eV} = 4.48\ \text{eV}$$

8.

	Subshell notation	***n* + *l***
1. $n = 4, l = 2, m_l = -2, m_s = -\frac{1}{2}$	$4d$	$4 + 2 = 6$
2. $n = 3, l = 2, m_l = 1, m_s = +\frac{1}{2}$	$3d$	$3 + 2 = 5$
3. $n = 4, l = 1, m_l = 0, m_s = +\frac{1}{2}$	$4p$	$4 + 1 = 5$
4. $n = 3, l = 2, m_l = -2, m_s = -\frac{1}{2}$	$3d$	$3 + 2 = 5$
5. $n = 3, l = 1, m_l = -1, m_s = +\frac{1}{2}$	$3p$	$3 + 1 = 4$
6. $n = 4, l = 1, m_l = 0, m_s = +\frac{1}{2}$	$4p$	$4 + 1 = 5$

$$5 < 2 = 4 < 3 = 6 < 1$$

$$3p < 3d = 3d < 4p = 4p < 4d$$

(Arrangement of orbitals in order of their increasing energies.)

9. $\lambda = \frac{h}{mv}$, *i.e.*, $\lambda \propto \frac{1}{\sqrt{mE}}$ and $m >>> E$

Thus, correct order is $\lambda_e > \lambda_p > \lambda_\alpha$.

10. Energy of one photon, $E = \frac{hc}{\lambda}$

$$= \frac{6.626\times 10^{-34}\times 3\times 10^{8}}{550\times 10^{-9}\ \text{m}} = 3.61\times 10^{-19}\ \text{J}$$

$$\therefore \quad \text{Number of photons} = \frac{\text{energy required}}{\text{energy of one photon}}$$

$$= \frac{10^{-17}}{3.61\times 10^{-19}} = 27.67 \approx 28$$

11. In Bohr orbit,

$$\text{KE of} \quad e^- = \frac{1}{2}\frac{Zke^2}{r_n}$$

$$\text{PE of} \quad e^- = \frac{Zke^2}{r_n}$$

$$\text{Thus,} \quad \text{KE} = -\frac{1}{2}\ \text{PE}$$

12. Energy of incident radiation, $h\nu = h\nu_0 + \frac{1}{2}mv^2$

$$E = h\nu = \frac{hc}{\lambda} = \frac{6.626\times 10^{-34}\ \text{Js}\times 3.0\times 10^{8}\ \text{ms}^{-1}}{150\times 10^{-12}\ \text{m}}$$

$$(1\ \text{pm} = 10^{-12}\ \text{m})$$

$$E = 13.25\times 10^{-16}\ \text{J}$$

$$\text{KE of ejected electron} = \frac{1}{2}mv^2$$

$$= \frac{1}{2}\times 9.11\times 10^{-31}\ \text{kg}\ \times (1.5\times 10^{7}\ \text{ms}^{-1})^2$$

$$= 1.025\times 10^{-16}\ \text{J}$$

$$W_0 = h\nu_0 = h\nu - \frac{1}{2}mv^2$$

$$= 13.25\times 10^{-16}\ \text{J} - 1.025\times 10^{-16}\ \text{J}$$

$$= 12.225\times 10^{-16}\ \text{J}$$

$$= \frac{12.225\times 10^{-16}}{1.602\times 10^{-19}}\ \text{eV} = 7.63\times 10^{3}\ \text{eV}$$

Note Energy with which the electron was bound to the nucleus = work function for the metal.

13. $\lambda = \frac{h}{\sqrt{2eVm_e}}$

$$e = 1.6\times 10^{-19}\ \text{C}, V = 10{,}000\ \text{V}, m_e = 9.1\times 10^{-31}\ \text{kg}$$

$$\lambda = \frac{6.63\times 10^{-34}}{\sqrt{2\times 1.6\times 10^{-19}\times 10{,}000\times 9.1\times 10^{-31}}} = 0.123\ \text{Å}$$

14. Energy given to I_2 molecule $= \frac{hc}{\lambda}$

$$= \frac{6.626\times 10^{-34}\times 3\times 10^{8}}{4500\times 10^{-10}} = 4.4\times 10^{-19}\ \text{J}$$

Energy of I_2 molecule $= 240\times 10^{3}$ J/mol

$$= \frac{240\times 10^{3}}{6.023\times 10^{23}}\ \text{J/atom} = 3.98\times 10^{-19}\ \text{J/atom}$$

$$\text{KE} = (4.4\times 10^{-19}) - (3.98\times 10^{-19}) = 0.42\times 10^{-19}\ \text{J/atom}$$

$$\text{KE of I atoms} \quad = \frac{0.42}{2}\times 10^{-19} = 0.21\times 10^{-19}$$

15. $\lambda_A = \dfrac{h}{m_A v_A}$ and $\lambda_B = \dfrac{h}{m_B v_B}$

$$\frac{\lambda_A}{\lambda_B} = \frac{m_B v_B}{m_A v_A}$$

$$\frac{1\times10^{-10}}{\lambda_B} = \frac{m_A \times 3v_A}{m_A \times 4 \times v_A \times 4}$$

$$\lambda_B = \frac{16\times10^{-10}}{3} = 5.33\ \text{Å}$$

16. Frequency, $\nu = \dfrac{1}{\text{period}} = \dfrac{1}{2ns} = \dfrac{1}{2\times 10^{-9}\text{s}} = 0.5\times 10^{-9}\ \text{s}^{-1}$

Energy of the source = Energy of 1 photon × number of photons produced

$$E_{\text{source}} = h\nu \times N$$

$$= 6.626\times 10^{-34}\ \text{Js}\times 0.5\times 10^{9}\ \text{s}^{-1}\times 2.5\times 10^{15}$$

$$= 8.28\times 10^{-10}\ \text{J}$$

17. $\bar{\nu} = \dfrac{1}{\lambda} = R' Z^2 \left[\dfrac{1}{n_1^2} - \dfrac{1}{n_2^2}\right]$

For shortest wavelength (maximum energy) in Lyman series of hydrogen $Z = 1, n_1 = 1, n_2 \to \infty$ and

$$\lambda = x$$

$$\frac{1}{x} = R'$$

For longest wavelength (minimum energy) in Balmer series of He^+, $Z = 2$ and $n_1 = 2, n_2 = 3$.

$$\frac{1}{\lambda} = R' 2^2 \left[\frac{1}{2^2} - \frac{1}{3^2}\right]$$

$$\frac{1}{\lambda} = \frac{4}{x}\left[\frac{1}{4} - \frac{1}{9}\right]$$

$$\frac{1}{\lambda} = \frac{4}{x}\,\frac{5}{36}$$

$$\lambda = \frac{9x}{5}$$

18. Given, $\Delta x = \Delta P$ or $\Delta x = m\cdot\Delta v$

From Heisenberg's uncertainty principle,

$$\Delta x \cdot m \cdot \Delta v = \frac{h}{4\pi}$$

$$m\cdot\Delta v\cdot m\Delta v = \frac{h}{4\pi}$$

$$(\Delta v)^2 = \frac{h}{4\pi m^2}$$

$$\Delta v = \frac{1}{2m}\sqrt{\frac{h}{\pi}}$$

$$= \frac{1}{2\times 9.1\times 10^{-31}}\sqrt{\frac{6.63\times 10^{-34}}{3.14}}$$

$$= 7.98\times 10^{12}\ \text{ms}^{-1} \approx 8\times 10^{12}\ \text{ms}^{-1}$$

19. Let the number of electrons in an ion = x

$\therefore$ Number of neutrons, $n = x + \dfrac{11.1}{100}x = 1.111x$

(As the number of neutrons are 11.1% more than the number of electrons.)

In the neutral atom, number of electrons, $e^- = x - 1$

(as the ion carries – 1 charge)

Similarly, number of protons, $p = x - 1$

we know that, mass number = $n + p = 37$

or $1.111x + x - 1 = 37$

$$2.111x = 37 + 1 = 38$$

$$x = \frac{38}{2.111} = 18.0009 \approx 18$$

Number of protons = atomic number = 18 − 1 = 17

Therefore, the symbol of the ion is ${}^{37}_{17}\text{Cl}^-$.

20. $\lambda = \dfrac{c}{\nu} = \dfrac{3.0\times 10^8 \text{ms}^{-1}}{4.620\times 10^{14}\ \text{Hz}} = 0.6494\times10^{-6}\ \text{m} = 649.4\ \text{nm};$

Thus, it belongs to visible region.

21. Energy change, $\Delta E = E_f - E_i$

$$\Delta E = 2.18\times10^{-18}\ \text{J}\left(\frac{1}{n_i^2} - \frac{1}{n_f^2}\right)$$

When $n_i = 5$ and $n_f = \infty$,
Energy change,

$$\Delta E = 2.18\times 10^{-18}\ \text{J}\left(\frac{1}{5^2} - \frac{1}{\infty}\right) = 0.0872\times 10^{-18}\ \text{J}$$

When $n_i = 1$ and $n_f = \infty$, energy change,

$$\Delta E' = 2.18\times 10^{-18}\ \text{J}\left(\frac{1}{1^2} - \frac{1}{\infty}\right)$$

$$\Delta E' = 2.18\times 10^{-18}\ \text{J}$$

$$\frac{\Delta E'}{\Delta E} = \frac{2.18\times 10^{-18}}{0.0872\times 10^{-18}} = 25$$

Hence, energy required to remove an electron from first orbit is 25 times than that required to remove an electron from fifth orbit.

22. Wave number, $\bar{\nu} = \dfrac{1}{\lambda} = R\left(\dfrac{1}{n_1^2} - \dfrac{1}{n_2^2}\right)$

(Rydberg constant, $R = 109677\ \text{cm}^{-1}$)

$$\frac{1}{\lambda} = 109677\left(\frac{1}{2^2} - \frac{1}{4^2}\right)\ \text{cm}^{-1}$$

$$\frac{1}{\lambda} = 109677\left(\frac{3}{16}\right)\ \text{cm}^{-1}$$

$$\frac{1}{\lambda} = 20564.4\ \text{cm}^{-1}$$

$$\lambda = \frac{1}{20564.4}\ \text{cm} = 486\times 10^{-7}\ \text{cm}$$

$$= 486\times 10^{-9}\ \text{m} = 486\ \text{nm}$$

The colour corresponding to this wavelength is blue.

23. $\frac{1}{\lambda}=R\left[\frac{1}{1^2}-\frac{1}{2^2}\right]=\frac{3R}{4}$

$$\lambda=\frac{h}{P}$$

$$P=\frac{h}{\lambda}=h\times\frac{3R}{4}=\frac{3Rh}{4}$$

24. Option (c) is correct as in it Pauli's exclusion principle is violated but Hund's rule does not.

25. Use, $\Delta v\times\Delta x=\frac{h}{4\pi m}$ or $\Delta x=\frac{h}{4\pi m\cdot\Delta v}$

26. $m=-1$ is not possible for s-orbital ($l=0$).

27. (a) Total electrons if $n=4=2n^2=2\times4^2=32$

Half of the total electrons, *i.e.*, 16 electrons have $m_s=-\frac{1}{2}$

(b) $n=3, l=0$ it is 3s-orbital and it can have two electrons.

28. ${}_{29}\text{Cu}=1s^2, 2s^2, 2p^6, 3s^2, 3p^6, 4s^1, 3d^{10}$

$\text{Cu}^+=1s^2, 2s^2, 2p^6, 3s^2, 3p^6, 3d^{10}, 4s^0$

Total number of shells occupied = 3

Number of sub-shells occupied = 6

Number of orbitals filled = 14

Number of unpaired electrons = 0

29. Kinetic energy, KE $=h(\nu-\nu_0)=\frac{1}{2}mv^2$

On substituting the given results of the three experiments, we get

For Ist experiment, $\lambda=500\text{ nm}=500\times10^{-9}\text{ m}$;

$$\nu=\frac{c}{\lambda}=\frac{3.0\times10^8\text{ ms}^{-1}}{500\times10^{-9}\text{ m}}=6\times10^{14}\text{ s}^{-1}$$

$$h(6\times10^{14}\text{ s}^{-1}-\nu_0)=\frac{1}{2}m(2.55\times10^5\text{ ms}^{-1})^2 \quad \text{...(i)}$$

For 2nd experiment, $\lambda=450\text{ nm}=450\times10^{-9}\text{ m}$;

$$\nu=\frac{c}{\lambda}=\frac{3.0\times10^8\text{ ms}^{-1}}{450\times10^{-9}\text{ m}}=6.67\times10^{14}\text{ s}^{-1}$$

$$h(6.67\times10^{14}\text{s}^{-1}-\nu_0)=\frac{1}{2}\text{m}(4.35\times10^5\text{ ms}^{-1})^2 \quad \text{...(ii)}$$

For 3rd experiment, $\lambda=400\text{ nm}=400\times10^{-9}\text{ m}$;

$$v=\frac{c}{\lambda}=\frac{3.0\times10^8\text{ ms}^{-1}}{400\times10^{-9}\text{ m}}=7.5\times10^{14}\text{ s}^{-1}$$

$$h(7.5\times10^{14}\text{ s}^{-1}-\nu_0)=\frac{1}{2}m(5.20\times10^5\text{ ms}^{-1})^2 \quad \text{...(iii)}$$

On dividing Eq. (ii) by Eq. (i), we get

$$\frac{h(6.67\times10^{14}\text{s}^{-1}-\nu_0)=\frac{1}{2}m(4.35\times10^5\text{ ms}^{-1})^2}{h(6\times10^{14}\text{ s}^{-1}-\nu_0)=\frac{1}{2}m(2.55\times10^5\text{ ms}^{-1})^2}$$

$$\frac{6.67\times10^{14}\text{ s}^{-1}-\nu_0}{6\times10^{14}\text{ s}^{-1}-\nu_0}=\frac{(4.35)^2}{(2.55)^2}=2.91$$

$$6.67\times10^{14}\text{ s}^{-1}-\nu_0=17.46\times10^{14}\text{s}^{-1}-2.91\,\nu_0$$

$$2.91\nu_0-\nu_0=17.46\times10^{14}\text{ s}^{-1}-6.67\times10^{14}\text{ s}^{-1}$$

$$1.91\nu_0=10.79\times10^{14}\text{s}^{-1}$$

$$\nu_0=\frac{10.79\times10^{14}\text{s}^{-1}}{1.91}=5.649\times10^{14}\text{ s}^{-1}$$

$$\lambda_0=\frac{c}{\nu_0}=\frac{3.0\times10^8\text{ ms}^{-1}}{5.649\times10^{14}\text{ s}^{-1}}=5.31\times10^{-7}\text{ m}$$

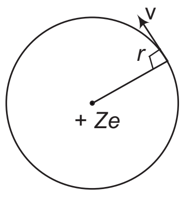
30. $\text{Cu}_{29}=1s^2, 2s^2, 2p^6, 3s^2, 3p^6, 3d^{10}, 4s^1$

$\text{Cu}^{2+}=1s^2, 2s^2, 2p^6, 3s^2, 3p^6, 3d^9$

$\text{Zn}^{2+}=1s^2, 2s^2, 2p^6, 3s^2, 3p^6, 3d^{10}$

$\text{Cr}^{3+}=1s^2, 2s^2, 2p^6, 3s^2, 3p^6, 3d^3$

31. The frequency of revolution of an electron is given by



$$\text{Frequency}=\frac{1}{\text{Time period}}$$

$$\text{Time period}=\frac{\text{Total distance covered in one revolution}}{\text{Velocity}}$$

$$=\frac{2\pi r}{v}$$

$$\therefore\quad \text{Frequency}=\frac{v}{2\pi r}$$

Calculate the velocity (v_2) and radius (r_2) of the electron in the second Bohr orbit in H atom

$Z=1$ for H atom

Using $r_n=0.529\frac{n^2}{Z}$ Å

We get,

$$r_2=0.529\times10^{-10}\frac{(2)^2}{1}\text{ m}=2.12\times10^{-10}\text{m}$$

$$v_n=2.18\times10^6\,(1/n)\text{ m s}^{-1}$$

$$v^2=2.18\times10^6(1/2)=1.09\times10^6\text{ m s}^{-1}$$

$$\therefore\quad \text{Frequency}=\frac{v_2}{2\pi r_2}=\frac{1.09\times10^6}{2(\pi)(2.12\times10^{-10})}$$

$$v=8.18\times10^{14}\text{Hz}$$

Note Frequency of revolution $(f)=\frac{1}{T}$

where $T=\frac{2\pi r}{v}\propto\frac{n^3}{Z^2}$ $\left[\because r\propto\frac{n^2}{Z}\text{ and } v\propto\frac{Z}{n}\right]$

32. In the 1st Bohr orbit of H

$$v=2.18\times10^6\text{ ms}^{-1}$$

Now, let us consider that in Li^{2+} the electron is in nth orbit. Speed of electron in nth Bohr orbit of Li^{2+} is

$$v\,(\text{Li}^{2+}) = 2.18\times 10^{6}\times\frac{3}{n}$$

Now, applying the condition of equal speed

$$2.18\times 10^{6}\times\frac{3}{n} = 2.18\times 10^{6}$$

$$\Rightarrow \qquad n = 3$$

33. Let atoms of chlorine and fluorine in the mixture be x and y respectively

∴ Energy absorbed 284 kJ

$$= (x)\times 20.77\times 10^{-22} + (y)\times 27.91\times 10^{-22} \qquad \ldots\text{(i)}$$

Energy released

$$= 68.8\text{ kJ} = (x)\times 5.78\times 10^{-22} + (y)\times 5.53\times 10^{-22} \qquad \ldots\text{(ii)}$$

On solving equation (i) and (ii) we can get the values of x and y respectively.

% of Cl = 62.19

% of F = 37.81

34. Angular quantum number determines the three dimensional shape of the orbital.

Principal quantum number shows the energy of orbital but not orientation, which is shown by magnetic quantum number.

Spin quantum number is related with the spinning of electrons.

35. The choice (a) is incorrect as the oxidation state of nitrogen in HN_3 is $-\frac{1}{3}$ and not –3.

36. When $n = 1 \;\; l \neq 1 \;\; (\because l < n)$

When $n = 3 \;\; l \neq 4 \;\; (\because l < n)$

37.

$$\text{Na}^{+} = 11 - 1 = 10$$

$$\text{Mg}^{2+} = 12 - 2 = 10$$

$$\text{Al}^{3+} = 13 - 3 = 10$$

$$\text{O}^{-} = 8 + 1 = 9$$

$$\text{O}^{2-} = 8 + 2 = 10$$

$$\text{N}^{3-} = 7 + 3 = 10$$

$$\text{Cl}^{-} = 17 + 1 = 18$$

Thus, Na^{+} is isoelectronic with Mg^{2+} and O^{2-}.

38. The orbitals of same energy are called degenerate orbitals.

(a) (i) $3d_{xy}$ (ii) $3d_{yz}$

(b) (i) $3p_x$ (ii) $3d_{xy}$

(c) (i) $4s$ (ii) $3d_{xy}$

(d) (i) $3d_{x^2-y^2}$ (ii) $3d_{x^2-y^2}$

Thus, $3d_{xy}$ and $3d_{yz}$, $3d_{x^2-y^2}$ and $3d_{x^2-y^2}$ represent pair of degenerate orbitals.

39. The particles in anode rays are positive ions formed by loss of one or more electrons by atoms of the gas in the discharge tube.

40. According to Heisenberg's uncertainty principle, the exact position and exact momentum of an electron cannot be determined simultaneously. Thus, the path of electron in an atom is not clearly defined.

41. A body which absorbs and emits all radiations falling on it is called perfect black body. With rise in temperature, frequency increases.

42. The radius of second orbit of He^{+} is twice that of the first orbit of hydrogen. Bohr expression for radius of the electron in a particular orbit in hydrogen and hydrogen like species is

$$r_n = \frac{n^2h^2}{4\pi^2 kmZe^2}$$

43. In a multi-electron atom such as sodium atom energy of the electron is determined by both n and l.

44. For highest energy transition,

$$\bar{v} = R_H\left(\frac{1}{n_1^2} - \frac{1}{n_2^2}\right)$$

here, for Lyman series $n_1 = 1$ and $n_2 = \infty$

For Balmer series, $n = 2$ and $n_2 = \infty$

$$\frac{\bar{v}_{\text{Lyman}}}{\bar{v}_{\text{Balmer}}} = \frac{1\times(2)^2}{(1)^2\times 1} = 4:1$$

45. For lowest energy transition in Lyman series,

$$n_1 = 1, n_2 = 2$$

$$\bar{v} = R_H Z^2\left[\frac{1}{(1)^2} - \frac{1}{(2)^2}\right]$$

$$= R_H(2)^2\left[\frac{1}{1} - \frac{1}{4}\right]$$

$$= R_H\frac{4\times 3}{4} = 3R_H$$

46. $\Delta x\cdot\Delta P \geq \frac{h}{2\pi}$

when, $\Delta x = 0$ ΔP becomes infinite.

47. Uncertainty in velocity $= 3\times 10^{4}\times\frac{0.001}{100} = 0.3$ cm/s

$$\Delta x\cdot\Delta v = \frac{h}{4\pi m} = \frac{6.6\times 10^{-27}}{4\times 3.14\times 9.1\times 10^{-28}}$$

$$\Delta x = \frac{6.6\times 10^{-27}}{4\times 3.14\times 9.1\times 10^{-28}\times 0.3}$$

$$= 1.92 \text{ cm}$$

48. The uncertainty in the position of electron would be less than λ.

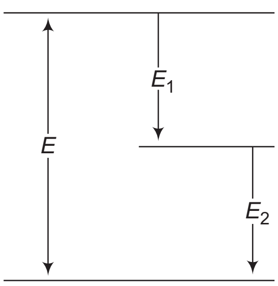
49.

	n	l	nl (suborbit)	$n+l$
(a)	4	1	$4p$	5
(b)	4	0	$4s$	4
(c)	3	2	$3d$	5
(d)	3	1	$3p$	4

Higher the value of $(n+l)$, higher the energy. If for two electrons the value of $(n+l)$ is same, suborbit with lower value of n has lower energy, Thus

$$3p < 4s < 3d < 4p$$
$$4 < 2 < 3 < 1$$

50. Energy values are always additive.



$$E_{\text{total}} = E_1 + E_2$$
$$\frac{hc}{\lambda} = \frac{hc}{\lambda_1} + \frac{hc}{\lambda_2}$$
$$\frac{1}{\lambda} = \frac{1}{\lambda_1} + \frac{1}{\lambda_2}$$
$$\frac{1}{355} = \frac{1}{680} + \frac{1}{\lambda_2}$$
$$\lambda_2 = 742.77 \text{ nm} \approx 743 \text{ nm}$$

51. $\Delta E = hv = \dfrac{2\pi^2 mZ^2e^4k^2}{h^2}\left[\dfrac{1}{n_1^2} - \dfrac{1}{n_2^2}\right]$

If electron falls from n_2 level to n_1 level.

$\therefore$ In He$^+$ for the $n_2 = 4$ to $n_1 = 2$ transition

$$v(\text{He}^+) = \text{constant }(4)\left[\frac{1}{2^2} - \frac{1}{4^2}\right] \qquad [\because Z_{\text{He}^+} = 2]$$
$$= \text{constant} \times 4\left[\frac{3}{16}\right] = \frac{3}{4}\text{ constant}$$
$$v(\text{H}) = \text{constant }(1)^2\left[\frac{1}{n_1^2} - \frac{1}{n_2^2}\right]$$
$$= \text{constant} \times \left[\frac{1}{n_1^2} - \frac{1}{n_2^2}\right]$$

(a) For $n_2 = 3$ and $n_1 = 1$

$$v(\text{H}) = \text{constant}\left[\frac{1}{1} - \frac{1}{9}\right]$$
$$= \frac{8}{9}\text{ constant}$$
$$\neq \frac{3}{4} \times \text{constant}$$

(b) For $n_2 = 2$ and $n_1 = 1$

$$v(\text{H}) = \text{constant} \times \left[\frac{1}{1} - \frac{1}{4}\right]$$
$$= \frac{3}{4} \times \text{constant}$$
$$= v(\text{He}^+)$$

52. Energy required for 1 Cl_2 molecule $= \dfrac{242 \times 10^3}{N_A}$ J

$$E = \frac{hc}{\lambda}$$

or $$\lambda = \frac{hc}{E} = \frac{6.626 \times 10^{-34} \times 3 \times 10^8 \times 6.02 \times 10^{23}}{242 \times 10^3}$$
$$= 494 \times 10^{-9} \text{ m} = 494 \text{ nm}$$

53. IE $= -E_1$

$$E_1 \text{ for He}^+ = -19.6 \times 10^{-18} \text{ J atom}^{-1}$$
$$\frac{(E_1)_{\text{He}^+}}{(E_1)_{\text{Li}^{2+}}} = \frac{(Z_{\text{He}^+})^2}{(Z_{\text{Li}^{2+}})^2}$$
$$\frac{-19.6 \times 10^{-18}}{(E_1)_{\text{Li}^{2+}}} = \frac{4}{9}$$

or $$E_1(\text{Li}^{2+}) = \frac{-19.6 \times 9 \times 10^{-18}}{4} = -4.41 \times 10^{-17} \text{ J atom}^{-1}$$

54. $\lambda = \dfrac{h}{mv} = \dfrac{6.63 \times 10^{-34}}{1.67 \times 10^{-27} \times 1 \times 10^3}$

$$= 3.97 \times 10^{-10} \text{m} \sim 0.40 \text{ nm}$$

55. By Heisenberg's uncertainty principle,

$$\Delta x \cdot m\Delta v = \frac{h}{4\pi}$$
$$\Delta v = 0.005\% \text{ of } 600 \text{ m/s} = \frac{600 \times 0.005}{100} = 0.03$$
$$\Delta x \times 9.1 \times 10^{-31} \times 0.03 = \frac{6.6 \times 10^{-34}}{4 \times 3.14}$$

Hence, $$\Delta x = \frac{6.6 \times 10^{-34}}{4 \times 3.14 \times 0.03 \times 9.1 \times 10^{-31}}$$
$$= 1.92 \times 10^{-3} \text{ m}$$

56. Ionisation enthalpy of hydrogen at 1.312×10^6 J mol^{-1}. It suggests that the enegy of electron in the ground state (first orbit) is -1.312×10^6 J mol^{-1}

$$\Delta E = E_2 - E_1$$
$$= \frac{1.312 \times 10^6}{2^2} - \left(\frac{-1.312 \times 10^6}{1}\right)$$
$$= -9.84 \times 10^5 \text{ J mol}^{-1}$$

57. $n + l = 5$ (maximum), thus has the highest energy.

58. Isoelectronic means having same number of electrons.

K$^+$, Cl$^-$, Ca^{2+}, Sc^{3+} (all are having 18 electrons).

59. Angular momentum of an electron

$$mvr = \frac{nh}{2\pi} \text{ (n is orbit number)}$$

$$\text{In 5th orbit} = \frac{5h}{2\pi} = \frac{2.5h}{\pi}$$

60. Hydrogen atom is in $1s^1$ and the $3s$, $3p$ and $3d$ orbitals will have the same energy.

4.1 Bond

"A bond is a kind of inter-atomic, inter-molecular, or inter-ionic attraction which holds two or more constituents (atoms, molecules or ions) *together*." The combining capacity of different constituents is called their **valency**. In case of elements of I A and II A group it is equal to their group number *i.e.*, + 1 and + 2 respectively.

For other elements it varies from group number to group number – 8 *i.e.*,

Valency = group number to (group number – 8)

(Here, group number are in accordance with modern Periodic Table). *e.g.*, Nitrogen, an element of group V A, has valency from + 5 to – 3 (= 5 – 8).

Depending upon the nature of combining constituents (atoms, ions), the bonds can be of following two types.

"Chemical bonding is the phenomenon of union of two or more atoms by redistribution of electrons, so that each atom involved in bonding acquires stable configuration to gain stability or to achieve a state of lower energy".

1. Chemical Bonds

These involves redistribution of electrons *i.e.,* the electrons are either transferred or shared to achieve a state of lower energy. Here, the lowering of energy exceed 40 kJ mol^{-1}.

A chemical bond is further classified into following types

(a) Electrovalent or ionic bond
(b) Covalent bond
(c) Coordinate bond

2. Physical Bonds

In this case, the atoms within molecules are held together by chemical bonds, but various molecules attract each other by physical forces like hydrogen bonding, van der Waals' forces. These bonds are weaker than chemical bonds. Here, lowering of energy is less than 40 kJ mol^{-1}.

Lewis Symbols

The simple notations that represent the valence electrons in an atom is called Lewis symbol *e.g.,*

$$\underset{(2\text{ valence }e^-)}{\cdot\text{Be}\cdot}\ ,\quad \underset{(3\text{ valence }e^-)}{\cdot\dot{\text{B}}\cdot}\ ,\quad \underset{(5\text{ valence }e^-)}{\cdot\ddot{\text{N}}:}$$

Lewis dot structure can also be written for molecules also. *General steps that you have to follow to write the Lewis structure are*

(i) Calculate the total number of valence electrons of all the atoms.

(ii) If species is charged, add or subtract the number of electrons equal to negative or positive charge of the ion.

(iii) Select the central atom (which is generally the least electronegative atom) and draw the skeletal structure by making an intelligent guess to indicate which atom is linked to which atom.

For example in CO

Number of valence electrons = 4 (C) + 6 (O) = 10

In skeletal structure of CO the octet of C can be completed by sharing two more electron pairs from oxygen.

$$:\text{C}\,\vdots\vdots\,\text{O}: \quad \text{or} \quad :\text{C}\equiv\text{O}:$$

[In Lewis dot structure, the electrons may be represented by dot, cross or any other symbol]

In Lewis representation number of bonds = $\dfrac{n_1 - n_2}{2}$

where, n_1 = number of atoms (other than H) $\times 8$ + no. of H atoms $\times 2$

n_2 = number of valence electrons of all isolated atom + (negative charge) − (positive charge)

e.g., In N_2, $n_1 = 2 \times 8 + 0 = 16$; $n_2 = 5 \times 2 + 0 - 0 = 10$

$$\text{Number of bonds} = \frac{n_1 - n_2}{2} = \frac{16 - 10}{2} = 3$$

$$\therefore \qquad N_2 = \ddot{\text{N}} \equiv \ddot{\text{N}}$$

4.2 Theories of Chemical Bonding

As formation of chemical compounds takes place as a result of combination of atoms of various elements in different way, it raises many questions like why do atoms combine? Why are only certain combinations possible? etc. In order to answer such questions different theories and concepts have been put forward from time to time, out of which two important are as follows

Kossel-Lewis Approach (Octet Rule)

In 1961, Kossel and Lewis proposed a concept on the basis of electronic configuration of elements. Thus, this concept was called **electronic concept of valency** or **octet rule.** Langmuir later on, extended it.

The main points of this concepts are as

1. The outer most shell of an atom is called the **valence shell** and the electrons present in it are called **valence electrons**.
2. It was assumed that inert gases (rare gases) are stable or chemically inert due to their stable configuration, *i.e.,* due to the presence of eight electrons (except He) in their valence shell. On this basis, Kossel and Lewis proposed that elements having eight electrons (except H which has 2 electrons in their valence shell) *i.e.,* having complete octet, are chemically inert.
3. Elements that do not have complete octet (or 8 electrons in their valence shell) have a high tendency to attain this configuration either by losing or gaining or sharing electrons to the atoms of same or other elements.

Violation of Octet Rule

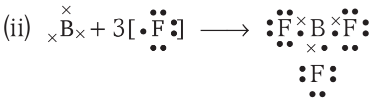
However, the octet rule is violated in a significant number of cases.
These are

1. Be and B have less than 4 valence electrons, hence their octet cannot be completed even if they bind with their full strength *e.g.,*

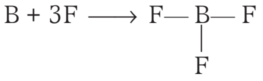
(i) $_\times\text{Be}_\times + 2[\cdot\ddot{\underset{\cdot\cdot}{\text{F}}}:] \longrightarrow :\ddot{\underset{\cdot\cdot}{\text{F}}}\overset{\times}{\cdot}\ \text{Be}\ \overset{\times}{\cdot}\ddot{\underset{\cdot\cdot}{\text{F}}}:$

or $\quad \text{Be} + 2\text{F} \longrightarrow \text{BeF}_2$

(Total 4 electrons in octet)

(ii)


$_\times\overset{\times}{\text{B}}_\times + 3[\cdot\ddot{\underset{\cdot\cdot}{\text{F}}}:] \longrightarrow :\ddot{\underset{\cdot\cdot}{\text{F}}}\overset{\times}{\cdot}\underset{:\ddot{\text{F}}:}{\text{B}}\overset{\times}{\cdot}\ddot{\underset{\cdot\cdot}{\text{F}}}:$

or


$\text{B} + 3\text{F} \longrightarrow \text{F—}\underset{\substack{|\\ \text{F}}}{\text{B}}\text{— F}$

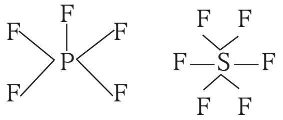
(Total 6 electrons in octet)

2. In molecules with an odd number of electrons, the octet rule is not satisfied for all the atoms, *e.g.,* in molecules like NO, NO_2, ClO_2^- etc., as they have $2c-3e^-$ bond (2 centre three electron bond)

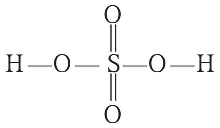
$$\ddot{\underset{\cdot}{\text{N}}}{=}\overset{\times\times}{\underset{\times\times}{\text{O}}} \qquad \ddot{\underset{\cdot\cdot}{\text{O}}}{=}\overset{\cdot+}{\text{N}}{-}\ddot{\underset{\cdot\cdot}{\text{O}}}:^{-}$$

(Total 7 electrons in nitrogen octet)

3. In a number of compounds there are more than 8 valence electrons present in the central atom. This is termed as **expanded octet.** This tendency is seen in elements beyond the 3rd period of the Periodic Table as they have vacant *d*-orbitals for bonding. Obviously octet rule is not applicable in such cases. Some of the examples of such compounds are PF_5, SF_6, H_2SO_4, etc.

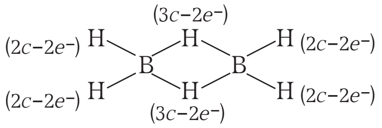


10 electrons in valence shell of P, 12 electrons in valence shell of S



12 electrons in valence shell of S

4. It also does not explain the formation of $3c-2e^-$ bonds as found in B_2H_6.



The other drawbacks of octet rule include

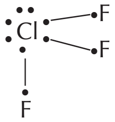
1. The shape of the molecule is not clear
2. It is totally silent about the energy of the molecule *i.e.*, relative stability.

Sample Problem 1 *Which of the following compounds does not follow octet rule?*

(*a*) ICl (*b*) ClF_3

(*c*) PCl_3 (*d*) CO_2

Interpret (*b*)



In this molecule, Cl has 10 electrons, thus it does not follow octet rule.

Modern Theory

The cause or basis of attractive forces or chemical bond, can be easily understood if we look at structure of an atom having positive nucleus and negative electrons. When two atoms come closer to combine, the attractive and repulsive forces begin to operate between them as

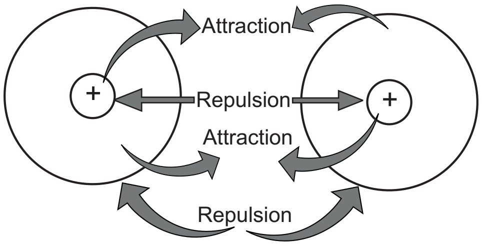


Fig 4.1 Attractive and repulsive forces between two atoms

The net result of these forces may be either attraction or repulsion between the atoms. A bond is formed if the net result of interaction is in the form of attraction. Now the agency *i.e.*, basis for a chemical bond is same in all cases thatswhy these attractive forces are called by different names? Here, the answer lies in one sentence and that is *"the different names to bonds are assigned due to difference in the intensities of these forces"*. These difference are summarized in the following table.

Table 4.1 **Various Attractive Electric Forces**

S. No.	Electric force	Relative strength	Type	Example
1.	Cation-anion (in a crystal) or ionic bond	Very strong	+ −	Lithium fluoride crystal lattice
2.	Covalent bonds	Strong (140-523 kJ mol^{-1})	Shared electron pairs δ + δ −	H—H (435 kJ mol^{-1}) $CH_3—CH_3$ (370 kJ mol^{-1}) I — I (150 kJ mol^{-1})
3.	Coordinate bond	Moderate	Shared electrons but given by one atom	$NH_3 \longrightarrow BH_3$
4.	Ion-dipole	Moderate	δ + δ − + δ − δ +	Na^+ in water
5.	Dipole-dipole (including hydrogen bonds)	Moderate to weak (4-38 kJ mol^{-1})	$\overset{\delta-}{—Z:}\ldots\overset{\delta+}{H}—$	 and $\overset{\delta+}{CH_3}—\overset{\delta-}{Cl}\ \overset{\delta+}{CH_3}—\overset{\delta-}{Cl}$

4.3 Ionic Bonding or Electrovalent Bonding

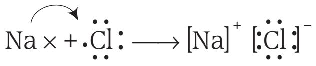
The attractive forces of ionic bond (*i.e.*, electrostatic force of attraction) are developed between an electropositive atom (*i.e.,* an atom with tendency to loose electron and convert into a cation) and an electronegative atom (*i.e.,* an atom with tendency to gain electron and convert into an anion) due to complete transfer of electrons from former to later. It is generally formed between the atoms having large difference in their electronegativity.

e.g., (i) Consider the formation of the compound "NaCl"

$$\underset{(1s^2, 2s^2, 2p^6, 3s^1)}{\text{Na}} \longrightarrow \underset{(1s^2, 2s^2, 2p^6)}{\text{Na}^+} \qquad \text{(cation formation)}$$

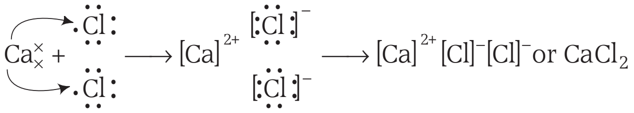
$$\underset{(1s^2, 2s^2, 2p^6, 3s^2, 3p^5)}{\text{Cl}} + e^- \longrightarrow \underset{(1s^2, 2s^2, 2p^6, 3s^2, 3p^6)}{\text{Cl}^-} \qquad \text{(anion formation)}$$

$$\text{Na}^+ + \text{Cl}^- \longrightarrow \text{NaCl} \qquad \text{(molecule formation)}$$



$$\text{Na}\times + \cdot\ddot{\underset{\cdot\cdot}{\text{Cl}}}: \longrightarrow [\text{Na}]^+ [:\ddot{\underset{\cdot\cdot}{\text{Cl}}}:]^-$$ (Lewis diagram)

e.g., (ii) Formation of "$CaCl_2$"



$$\text{Ca}^{\times}_{\times} + 2\,\cdot\ddot{\underset{\cdot\cdot}{\text{Cl}}}: \longrightarrow [\text{Ca}]^{2+} \, 2[:\ddot{\underset{\cdot\cdot}{\text{Cl}}}:]^- \longrightarrow [\text{Ca}]^{2+}[\text{Cl}]^-[\text{Cl}]^- \text{or } \text{CaCl}_2$$

Transfer of electron is not the necessary condition for this type of bonding, rather it is considered as a generalized condition. Such attractive forces can be seen between any two oppositely charged atoms or ions even from different sources, *e.g.,*

$$\text{H}^+\text{Cl}^-(l) + \text{Na}^+\text{OH}^-(l) \longrightarrow \text{Na}^+\text{Cl}^- + \text{H}_2\text{O}$$

In the above reaction Cl^- was formed after gaining an electron from H^+ and Na^+ is formed after losing an electron to OH^-.

If the difference between electronegativity is around 1.9 and more the bond is generally ionic, meaning that one atom has gained complete control of the electron pair in the bond.

Electrovalency

The number of electrons lost (or gained) by an atom during the formation of ionic bond is called the electrovalency of that atom.

For most of the atoms, its value is fixed and depends upon the number of valence electrons. However, certain elements (metals) show more than one electrovalency in their electrovalent compounds. The atoms of these elements lose different number of electrons under different conditions, thereby showing variable electrovalency. The following are two reasons for variable electrovalency.

(a) Instability of the Core

The residue configuration left after the loss of valency electrons (electrons present in the outermost energy level) is called the **core** or **kernel**. In case of transition elements, ions formed after the loss of valency electrons do not possess a stable core as the configuration of outermost shell is not ns^2np^6, but $ns^2np^6d^{1\text{ to }10}$. The outer shell generally loses one or more electrons giving rise to metal ions of higher valencies *e.g.,* Iron

$$\text{Fe }(26) = 2, 8, 8, 6, 2 \quad 3s^2 \quad 3p^6 \quad 3d^6, \quad 4s^2$$
$$\text{Fe}^{2+} (24) = 2, 8, 8, 6 \quad 3s^2 \quad 3p^6 \quad 3d^6 \quad \text{(Not stable)}$$
$$\text{Fe}^{3+} (23) = 2, 8, 8, 5 \quad 3s^2 \quad 3p^6 \quad 3d^5 \quad \text{(Stable)}$$

Thus, iron exhibits + 2 and + 3 valencies. *The compounds of* Fe^{3+} (ferric ion) *are more stable than the compounds of* Fe^{2+} (ferrous ion).

The only electron present in the outermost shell of copper atom is lost by it to get converted into Cu^+ (cuprous) ion.

$$\text{Cu}(29) = 2, 8, 18, 1 \quad 3s^23p^63d^{10}, 4s^1$$
$$\text{Cu}^+(28) = 2, 8, 18 \quad 3s^23p^63d^{10}$$

The $s^2p^6d^{10}$ configuration is not as stable as s^2p^6 configuration and the nuclear charge is not sufficiently strong to hold all the electrons intact in their positions. Thus, Cu^+ ion loses one more electron to form Cu^{2+} (cupric) ion. The Cu^{2+} ion is quite stable as the nuclear charge is sufficient to hold 27 electrons intact.

$$\text{Cu}^{2+} = 2, 8, 17 \text{ or } 3s^2 \ 3p^6 \ 3d^9$$

Thus, cupric (Cu^{2+}) *compounds are more stable than cuprous* (Cu^+) *compounds.*

The above two explanations fail to account why

(i) Co^{2+} ion cannot be easily converted into Co^{3+} ion like Fe^{2+} ion.

(ii) Zn^{2+} ion does not lose one more electron as its configuration ($3s^2\ 3p^6\ 3d^{10}$) is similar to Cu^+ ion.

In general, we can say that whenever the core is unstable, it loses one or more electrons to show higher valency and if the core is comparatively stable it always resists the loss of more electrons.

The cores of Co^{2+} ion and Zn^{2+} ion are comparatively stable as the nuclear charges are sufficient to hold all the electrons intact in their positions. Co^{2+} ion changes into Co^{3+} ion in the presence of an oxidising agent, but cobaltous compounds are comparatively more stable than cobaltic compounds.

(b) Inert Pair Effect

In case of heavier p-block elements, the outer ns^2 electrons penetrate to some extent to penultimate orbit consisting 18 electrons thereby attracted strongly towards nucleus. Due to this they (ns^2 electrons) do not take part in bond formation. *"The reluctance of s-electrons to take part in bond formation is called inert pair effect". e.g.,*

Pb	(IV group)	2,8,18,32,18, $6s^2 6p^2$	
Pb^{2+}		2,8,18,32,18, $6s^2$	Only $6p$ electrons are lost
Bi	(V group)	2,8,18,32,18, $6s^2 6p^3$	
Bi^{3+}		2,8,18,32,16, $6s^2$	Only $6p$ electrons are lost

When sufficient energy is available, the s-electrons also enter into bond formation and higher valencies are observed *e.g.,* Pb^{4+} = 2, 8, 18, 32, 18. This tendency to show higher valencies is less in the case of Tl, Pb and Bi but more in the case of comparatively lighter elements such as In, Sn, Sb, etc.

Factors Affecting the Formation of Ionic Bonds

The formation of an ionic bond is related to the ease of formation of cations and anions, which depends upon the ionisation energy of metal atom and electron affinity of non-metallic atom. Thus, these two also affects the formation of ionic bond.

For the formation of ionic bond

1. The ionisation energy of the electropositive element should be low *i.e.,* the metal atoms form a low charged positive ion easily.
2. The quantitative value of electron affinity of electronegative element should be high *i.e.,* the non-metal atom is small and give rise to low charged negative ion easily.
3. Lattice enthalpy should be high.

Lattice Enthalpy

The energy given off when gaseous positive and negative ions come together to form 1 mole of the solid ionic compound is called **lattice enthalpy** (U). *e.g.,*

$$Na^+(g) + Cl^-(g) \longrightarrow NaCl(s), \qquad \Delta H = -U$$

For the reverse process,

$$NaCl(s) \longrightarrow Na^+(g) + Cl^-(g), \qquad \Delta H = +U$$

Lattice enthalpy varies directly with the charge of ions and inversely with the size of ions. Thus,

$$\text{Lattice enthalpy} \propto \text{charge of ions}$$
$$\propto \frac{1}{\text{size of ions}}$$

Lattice energy can be calculated using Born-Haber cycle.

Sample Problem 2 *Which shows the highest lattice energy?*

(a) RbF (b) CsF (c) NaF (d) KF

Interpret (c) In all the given molecules, anion (*i.e.,* F^-) is common, thus lattice energy depends upon the size of cations. The order of size is

$$Na^+ < K^+ < Rb^+ < Cs^+$$

$$\text{Lattice energy} \propto \frac{1}{\text{size of ion}}$$

Thus, the order of lattice energy is

$$NaF > KF > RbF > CsF$$

Born-Haber Cycle

The fundamental of this cycle is based upon the fact that the formation of an ionic crystal may occur either by direct combination of the elements or by an alternate process in which

(i) The reactants are vaporized to convert into gaseous state.

(ii) The gaseous atoms are converted into ions.

(iii) The gaseous ions are combined to form ionic lattice of molecules.

e.g., $$M(s) + \frac{1}{2}X_2(g) \longrightarrow MX(s), \qquad \Delta H_1 = Q$$

Alternatively

(i) $M(s) \longrightarrow M(g), \qquad \Delta H = S$

(ii) $M(g) \longrightarrow M^+(g) + e^-, \qquad \Delta H = I$

(iii) $\frac{1}{2}X_2(g) \longrightarrow X(g), \qquad \Delta H = \frac{D}{2}$

(iv) $X(g) + e^- \longrightarrow X^-(g), \qquad \Delta H = -E$

(v) $M^+(g) + X^-(g) \longrightarrow MX(s), \qquad \Delta H = -U$

$$\Delta H_2 = S + I + \frac{D}{2} - E - U$$

where, S = heat of sublimation
I = ionisation energy
D = dissociation energy
E = electron affinity

ΔH_1 and ΔH_2 represent the enthalpy change for same chemical change. Hence,

$$\Delta H_1 = \Delta H_2$$

$$\therefore \quad Q = S + I + \frac{D}{2} - E - U$$

$$\therefore \quad U = S + I + \frac{D}{2} - E - Q$$

Sample Problem 3 *Calculate the lattice energy (in kJ mol $^{-1}$) of the salt MX(s) from the following data*

Heat of formation of $MX(\Delta H) = -550\ kJ\ mol^{-1}$

Heat of sublimation of metal, $M = 80\ kJ\ mol^{-1}$

Heat of dissociation of $X_2 = 155\ kJ\ mol^{-1}$

Ionisation energy of $M = 374\ kJ\ mol^{-1}$

Electron affinity of $X = -343\ kJ\ mol^{-1}$

(a) 738.5 (b) −324.5 (c) −816 (d) 402

Interpret (a) $U = S + I + \frac{D}{2} - E - Q$

$$= 80 + 374 + \frac{155}{2} - 343 - (-550) = +\ 738.5$$

Sample Problem 4 *If the ionisation potential of* Na *is* 495.8 *kJ mol* $^{-1}$*, the electron affinity of* Cl *is* 349.4 *kJ mol* $^{-1}$ *and lattice energy is* 776 *kJ mol* $^{-1}$*, the true statement for the formation of ionic bond in* NaCl *is*

(a) *total energy released per mole of* NaCl *formed is* 628.6 *kJ*
(b) *the ionic bond formed is unstable*
(c) *the total energy absorbed per mole of* NaCl *formed is* 1125.4 *kJ*
(d) *net energy released in this process is* 629.6 *kJ*

Interpret (d) $Na(g) + 495.8 \longrightarrow Na^+(g) + e^-$ ...(i)

$$Cl(g) + e^- \longrightarrow Cl^-(g) + 349.4$$

$$Na^+(g) + Cl^-(g) \longrightarrow NaCl(s) + 776\ kJ\ mol^{-1}$$

Total energy released per mole of NaCl formed

$$= 776 + 349.4 = 1125.4\ kJ$$

Total energy absorbed in step (i) = 495.8 kJ

Net energy released = 629.6 kJ

Thus, a stable ionic bond is formed between NaCl.

Lattice enthalpy (or lattice energy) **play an important role in deciding the solubility of ionic solids.** *It affects the solubility in the following manner*

1. If the anion and the cation are of comparable size, the cationic radius will influence the lattice energy. Since, lattice energy decreases much more than the hydration energy with increasing ionic size, solubility will increase as we go down the group.
2. If the anion is large compared to the cation, the lattice energy will remain almost constant within a particular group. Since, the hydration energies decrease down a group, solubility will decrease as found for alkaline earth metal carbonates and sulphates.

Characteristics of Ionic Compounds

The main characteristics of ionic compounds are as follows

1. These are usually crystalline in structure. Thus, at normal temperature and pressure, these are solids with **low volatility, high stability** and **high density.**
2. Due to strong forces of attraction, these possess high melting and boiling points.
3. These are **very hard** and **brittle** as the crystal planes can be separated very easily.
4. These are soluble in polar solvents like water because polar solvent molecules interact very strongly with the ions of crystal (solvation or hydration) and the high solvation or hydration energy released, is sufficient to break the lattice structure. In addition, ions in solution acquire greater degree of motion.

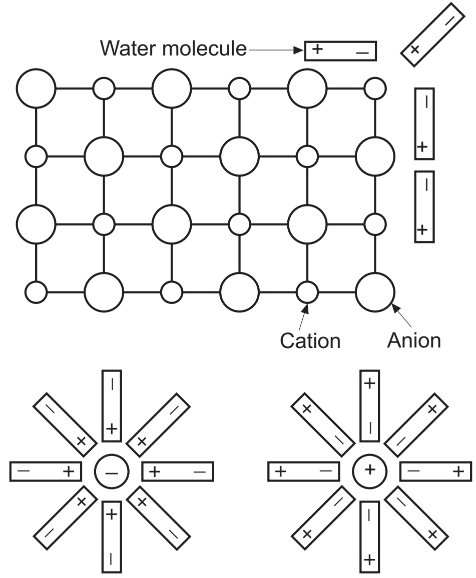


Fig 4.2 Solubility of ionic compounds in polar solvent

Note for dissolution solvation energy > lattice energy and dissolution is also favoured by high dielectric constant of solvent, *e.g.,*

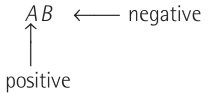
Solvent	H_2O	CH_3OH	C_2H_5OH	CH_3COCH_3	CH_3OCH_3
Dielectric constant	81	35	27	21	4.1

—capacity for dissolving ions decreases ⟶

5. Ionic compounds do not conduct electricity in solid state but these are very good conductors when fused or dissolved in a solvent of high dielectric constant due to the presence of mobile ions.
6. Compounds with same electronic configuration are isomorphous to each other. (Isomorphous = structurally same).
7. Ionic compounds undergo very fast reactions in solution which are of simple ion exchange type. The reactions are so fast because ions of the ionic compound maintain their indivisibility, thus easily separated from each other in the presence of polar molecules like water as polar molecules interfere with the attractive forces between the ions.
8. The ionic bond power is never saturated in a crystal, therefore, ionic bonds are always **non-rigid** and **non-directional,** and thus, do not exhibit space isomerism.

Steps to be Followed While Writing Formula of an Ionic Compound

***Step* 1.** Write the symbols of the ions side by side in such a manner so that the positive ion is at the left and negative ion is at the right as

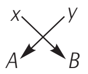


***Step* 2.** Write their electrovalencies in figure on the top of each symbol as

$A^x B^y$.

***Step* 3.** Divide their valencies by HCF

***Step* 4.** Now apply cross-cross rule as



Thus, the formula is $A_y B_x$.

4.4 Covalent Bonding

A "covalent bond" is formed between atoms of comparable electronegativity. The attractive forces are developed due to the sharing of electron pair with each atom contributing one electron to the pair.

Example (Lewis structure)

(i) $H\bullet + \bullet H \longrightarrow H:H\ [H—H]$

(ii)

$\ddot{\underset{\cdot\cdot}{O}}: + :\ddot{\underset{\cdot\cdot}{O}} \longrightarrow \ddot{\underset{\cdot\cdot}{O}}::\ddot{\underset{\cdot\cdot}{O}}\ [O{=}O]$

(iii)

$\bullet\dot{\underset{\bullet}{C}}\bullet + 2\,\ddot{\underset{\cdot\cdot}{O}}: \longrightarrow \ddot{\underset{\cdot\cdot}{O}}::C::\ddot{\underset{\cdot\cdot}{O}}\ [O{=}C{=}O]$

(iv)

$2[H\bullet] + 2[\bullet\dot{\underset{\bullet}{C}}\bullet] \longrightarrow H:C\underset{\cdot\cdot}{\vdots}C:H\ [H—C\equiv C—H]$

Formal Charge (FC)

The atoms of a molecule or ion are usually neutral, *i.e.*, carry no charge but for some purposes, such as to find reaction mechanisms, assigning of formal charge of atoms in a molecule or ion is important. Formal charge (FC) is calculated as

$$FC = V - \left[lp + \frac{1}{2}bp\right]$$

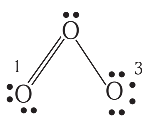
where,

V = total number of valence electrons in the free atom

lp = total number of non-bonding electrons or lone pairs

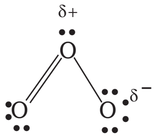
bp = total number of bondpair of electrons

e.g., formal charge of O atoms in ozone molecule is calculated as



$$\text{FC of } O^1 = 6 - \left(4 + \frac{1}{2} \times 4\right)$$
$$= 6 - 6 = 0$$
$$\text{FC of } O^2 = 6 - \left(2 + \frac{1}{2} \times 6\right)$$
$$= 6 - 5 = +1$$
$$\text{FC of } O^3 = 6 - \left(6 + \frac{1}{2} \times 2\right)$$
$$= 6 - 7 = -1$$

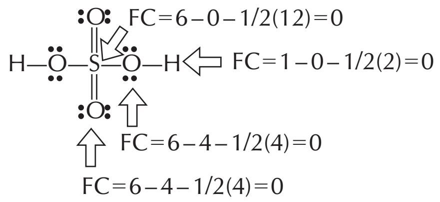
Thus, the correct representation of ozone molecule is



Sample **Problem 5** *The formal charge of each atom in sulphuric acid is equal to*

(*a*) 0 (*b*) 1 (*c*) 2 (*d*) 3

Interpret (*a*)



Types of Covalent Bonds

The covalent bond can be of following two types

(a) Non-polar Covalent Bond

If the covalent bond is formed between two homonuclear atoms, *i.e.*, between atoms of exactly equal electronegativity, the electron pair is equally shared between them. Such a bond is called non-polar covalent bond, *e.g.*, H_2, Cl_2, F_2, Br_2, etc.

(b) Polar Covalent Bond

If the bond forming entities are dissimilar *i.e.*, heteronuclear or with different electronegativity, the bond formed has partial ionic character as the electron pair is attracted by more electronegative entity. Such a bond is called polar covalent bond. *e.g.*,

$$\overset{\delta+}{H}\cdots\overset{\delta-}{O}\cdots\overset{\delta+}{H} \quad \overset{\delta+}{H}\cdots\overset{\delta-}{Cl}$$

The greater the difference in electronegativity, higher is the polar nature. The relative order of electronegativity of some important elements is

	F	> O	> Cl ≈ N	> Br	> S ≈ C ≈ I	> H
Max. of all the elements known	4.0	3.5	3.0	2.8	2.5	2.1

The ionic character in a polar bond can be calculated by the following methods

1. Pauling gave the following equation to calculate the percentage ionic character of a polar bond by using electronegativity difference $(x_A - x_B)$

Amount of ionic character in $A-B$ bond

$$= [1 - e^{0.25(x_A - x_B)}]\%$$

or $$[18(x_A - x_B)^{1.4}]\%$$

With the help of this equation, **Pauling** established the following relation

$(x_A - x_B)$	—	0.6	1.0	1.4	1.7	2.0	2.4	3.0	3.2
% ionic character	—	9	22	39	51	63	76	91	92

↑ At about midway between covalent and ionic character

2. **Hannary** and **Smith** also used the electronegativity difference $(x_A - x_B)$ to find the percentage ionic character by the following expression.

Ionic character in $A-B$ bond

$$= [16(x_A - x_B) + 3.5\,(x_A - x_B)^2]\%$$

3. There is an another method also which is based upon dipole moment.

Dipole Moment

The polarity of covalent bonds results in the formation of electric dipole possessing a permanent dipole moment, μ which is defined as the product of net charge and the distance between the two charged ends (bond length).

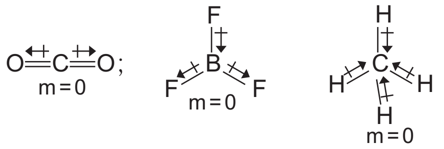
$$\mu = \text{charge}\,(e) \times \text{bond length}\,(d)$$

The units of dipole moment in CGS system is **debye** (*D*) and in SI system is **coulomb-metre.**

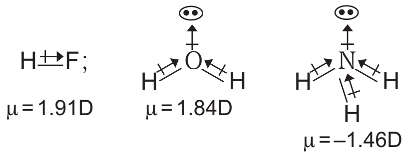
Dipole moment is a vector quantity, thus indicated by the symbol (⟶) pointing towards the negative end. *e.g.,*

$$\overset{\delta+}{\mathrm{H}} \overset{\longmapsto}{—} \overset{\delta-}{\mathrm{Cl}}$$

For symmetrical molecules, dipole moment is zero but unsymmetrical molecules have some dipole moment. *e.g.,* CO_2, BF_3, CH_4 etc. Being symmetrical have zero dipole moment.



However, unsymmetrical molecules like HF, H_2O, NH_3 have some dipole moment as



By using dipole moment, the percentage ionic character of a polar bond $(A-B)$ can be calculated as,

$$\text{Percentage ionic character} = \frac{\mu_{\text{exp}}}{\mu_{\text{cal}}} \times 100 = \frac{\mu_{\text{exp}}}{d_{A-B} \times e} \times 100$$

here, μ_{exp} = experimental (or observed) value of dipole moment of *AB* molecule,

$(\mu_{\text{cal}})_{\text{ionic}}$ = calculated (theoretical) value of dipole moment of *AB* molecule when molecule was assumed to be completely ionic. This value can be calculated as

$d \times e$, *i.e.,* bond length × charge

Sample **Problem 6** *Polarity in a molecule and hence, the dipole moment depends primarily on electronegativity of the constituent atoms and shape of a molecule. Which of the following has the highest dipole moment?* **[NCERT Exemplar]**

(a) CO_2	(b) HI
(c) H_2O	(d) SO_2

Interpret (c) CO_2 being symmetrical has zero dipole moment.

Among HI, SO_2 and H_2O, dipole moment is highest for H_2O as in it the central atom contains 2 lone pairs.

Sample **Problem 7** *The bond length of* HCl *bond is* 2.29×10^{-10} *m. The percentage ionic character of* HCl*, if measured dipole moment is* 6.226×10^{-30} *C-m, is*

(a) 8%	(b) 20%
(c) 17%	(d) 50%

Interpret (c) $\mu_{\text{cal}} = e \times d$

$$= 1.6 \times 10^{-19} \times 2.29 \times 10^{-10}$$
$$= 3.664 \times 10^{-29}\ \text{C - m}$$

$$\%\ \text{ionic character} = \frac{\mu_{\text{exp}}}{\mu_{\text{cal}}} \times 100$$

$$= \frac{6.226 \times 10^{-30}}{3.664 \times 10^{-29}} \times 100 = 17\%$$

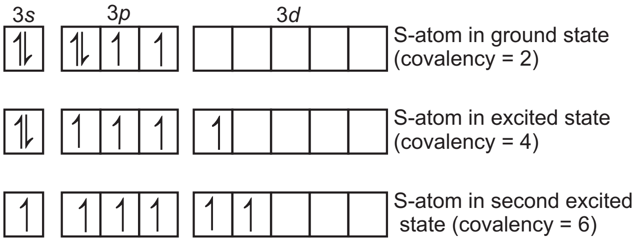
Covalency

The number of electrons contributed by an atom for sharing with other atoms to achieve inert gas configuration is called its **covalency. The usual covalency of an atom** (except hydrogen-covalency 1) **is equal to 8– number of the group to which element belongs. This is applicable for non-metals of *p*-block only.**

Generally, the covalency of an element is equal to the total number of unpaired electrons present in *s* and *p*-orbitals. The elements having vacant *d*-orbitals in their valence shell (*e.g.,* P, S, Cl, As, Sn etc) show variable covalency by increasing the number of unpaired electrons during excited conditions. The maximum covalency of the elements in different periods is

1. 4 for the elements of second period,
2. 6 for the elements of 3rd and 4th period,
3. 8 for the elements of 5th period onwards.

Such a variation in maximum covalency can be explained on the basis of absence of vacant *d*-orbitals in 2nd period elements and their availability in 3rd and subsequent period elements. *e.g.,* in case of sulphur



On this basis we can explain why compounds like OF_6, NCl_5 or ion like CF_6^{2-}, NF_6^{3-} do not exist and compounds like ICl, ICl_3, IF_5, IF_7 or ion like SiF_6^{3-}, PF_6^{3-} can be formed.

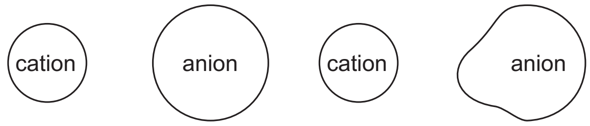
Characteristics of Covalent Compounds

The main characteristics of covalent compounds are as

1. Normal covalent compounds are **gases** or **liquids** under ordinary conditions of temperature and pressure. Some of the compounds are soft solids also if molecular weights are high. *e.g.,* Cl_2 (mol. wt. = 71) is a gas, Br_2 (mol. wt. = 160) is a liquid, I_2 (mol. wt. = 254) is a volatile solid.
2. With a few exceptions (like diamond, carborundum, silica) covalent compounds have relatively low values of their melting and boiling points.
3. In solid state crystals of covalent compounds are of three types mainly
   - (i) Soft, easily fusible, volatile crystals in which molecules are held by weak van der Waals' forces. *e.g.,* crystals of organic compounds, sulphur, iodine etc.
   - (ii) Very hard crystals in which every atom is bonded with the other atoms resulting in the formation of a **giant molecule.** *e.g.,* diamond crystal.
   - (iii) The crystals which consists of separate **lattice layers.** *e.g.,* graphite. These crystals are very soft and of lubricating nature.
4. The covalent bond is rigid and directional hence, different spatial arrangements of atoms are possible. Thus, these compounds exhibit structural as well as space isomerism.
5. In general, covalent compounds are bad conductors of electricity in fused as well as in solid state. However, graphite can conduct electricity as it possess free electrons in its layers.
6. In general, covalent compounds are insoluble in polar solvents like water but dissolve in non-polar solvents like benzene, CCl_4, ether etc. However, some of them like alcohols are miscible with water due to intermolecular H-bonding.
7. The reaction of covalent compounds are slow and complex as these involve fission of older bonds and formation of new bonds.

Fajan's Rule

When two oppositely charged ions of unequal size approach each other closely, the ion smaller in size attracts outermost electrons of the other ion and repel its nuclear charge. The net result of this is distortion or polarisation of the bigger ion which is generally the anion. This distortion is usually done by the cation as its size is smalller than the anion. The electron cloud of anion no longer remains symmetrical but is elongated towards the cation. The ability of a cation to polarize the nearby anion is called its **polarizing power** and the tendency of an anion to get distorted or deformed or polarized by the cation is called its **polarisability**. Due to polarization, sharing of electrons occur between two ions to some extent and the bond show some covalent character.



(a) No polarisation (b) Polarised anion

Fig 4.3 Representation of polarisation

Fajan gave the following rules to decide the magnitude of polarisation or covalent character in an ionic bond

(a) Higher Charge on Cation or Anion

As the charge on the cation increases, its tendency to polarise the anion increases. This brings more and more covalent nature in the electrovalent compound *e.g.,* in case of NaCl, $MgCl_2$ and $AlCl_3$, the polarisation increases from NaCl to $AlCl_3$, thereby covalent character becomes more and more as the charge on the cation increases. (Na^+, Mg^{2+}, Al^{3+})

A larger anion is polarised more and thus, also result in increased covalent character. *e.g.,* $CaSO_4$ is more covalent than $Ca(NO_3)_2$.

(b) Smaller Size of Cations

The charge possessed by a small cation will be more concentrated, thus causing more polarisation of anion. Hence, we can say that ionic compounds having smaller cations show more covalent nature.

(c) Larger Size of Anions

In such anions, the outer electrons will be at a greater distance from the nucleus, hence, more easily influenced by the attractive forces of cation. As a result larger anions will be more easily polarised in comparison to smaller anions.

(d) Non-inert Gas Configuration

The polarising power of those cations which don't have inert gas configuration will be more in comparison to cations having inert gas configuration. *e.g.,* polarising power of Cu^+ ion (electronic configuration 2, 8, 18) is more in comparison with polarising power of Na^+ ion (electronic configuration 2, 8).

Generally, electrovalent compound having high values of polarisation (more covalent character) are found to be less soluble in water but more soluble in organic solvents. This can be seen in the following examples

(i) Sulphides are less soluble in water than oxides of the same metal.
(ii) Lithium salts are soluble in organic solvents.
(iii) Beryllium compounds are less soluble than corresponding other alkaline earth metal compounds.
(iv) The solubility of aluminium halides decreases from AlF_3 to AlI_3.

Sample **Problem 8** *Which compound is most covalent?*

(*a*) LiF (*b*) LiCl
(*c*) LiBr (*d*) LiI

Interpret (*d*) Covalent character ∝ size of anion

[∵ In the given compounds, same cation, Li^+ is present.]

The order of size of anions is

$$F^- < Cl^- < Br^- < I^-$$

Thus, the order of covalent character is

$$LiF < LiCl < LiBr < LiI$$

Variation of Polarising Power/Polarisability in the Periodic Table

(i) On moving down a group, the polarising power of the cations decreases.
(ii) Polarising power of the cations increase on moving from left to right in a period.
(iii) The polarisability of the anions by a given cation decreases on moving from left to right in a period.
(iv) The polarisability of the anions by a given cation increases on moving down a group.

Valence Shell Electron Pair Repulsion Theory (VSEPR Theory)

This theory was given by "**Gillespie** and **Nyholm**" and is helpful in predicting the geometric arrangement of atoms in molecules. It includes all molecules which may or may not obey octet rule.

The main postulates of this theory are

1. The shape of the molecule is determined by repulsions between all the electrons pairs present in the valence shell.
2. A lone pair of electrons takes up more space around the central atom than a bond pair, since the lone pair is attracted to only one nucleus whilst the bond pair is shared by two nuclei. It follows that repulsion between two lone pair is greater than repulsion between a lone pair and a bond pair, which in turn is greater than, the repulsion between two bond pairs. Thus, the presence of lone pairs on the central atom causes slight distortion of the bond angles from the ideal shape calculated from hybridization.

   Thus, repulsion among pairs increases as

   $$bp - bp < bp - lp < lp - lp.$$
3. The magnitude of repulsions between bonding pairs of electrons depends on the electronegativity difference between the central atom and the other atoms.
4. Double bonds cause more repulsion than single bonds and triple bonds cause more repulsion than double bonds.

A brief summary of molecular shapes resulting from different configurations of electrons pairs is presented below

Table 4.2 **Geometry of Molecules According to VSEPR Theory**

S. No.	Molecule type	No. of bonding pairs	No. of lone pairs	Arrangement of electron pairs	Shape (Geometry)	Examples
1.	AB_2	2	0	B—A—B	Linear	BeF_2
2.	AB_3	3	0		Trigonal planar	BF_3
3.	AB_2E	2	1	 Trigonal planar	Bent	SO_2,O_3
4.	AB_4	4	0		Tetrahedral	CH_4,
5.	AB_3E	3	1	 Tetrahedral	Trigonal pyramidal	NH_3
6.	AB_2E_2	2	2	 Tetrahedral	Bent or V-shape	H_2O
7.	AB_5	5	0		Trigonal bipyramidal	PF_5
8.	AB_4E	4	1	 Trigonal bipyramidal	See-saw	SF_4
9.	AB_3E_2	3	2	 Trigonal bipyramidal	T-shaped	ClF_3
10.	AB_6	6	0		Octahedral	SF_6
11.	AB_5E	5	1	 Octahedral	Square pyramid	BrF_5
12.	AB_4E_2	4	2	 Octahedral	Square planar	XeF_4
13.	AB_7	7	0		Pentagonal bipyramidal	IF_7

Note With very few exceptions, the predictions based on the VSEPR theory have been shown to be correct.

Hot Spot 1

FINDING Shapes of Molecules

It is very important topic for JEE Main examination as questions are frequently asked from this topic. By following some simple steps, the geometry of a molecule can be obtained easily.

To find the shape of a molecule, follow the steps given below.

Step I *Identify the central atom and count the number of valence electrons. e.g.,* In PCl_3, P being less electronegative is the central atom.
No. of valence electrons of P = 5

Step II *Find the number of electron pairs shared.*
e.g., In PCl_3, there are 3Cl atoms, so total no. of shared electrons $= \underset{\text{from P}}{3} + \underset{\text{from Cl}}{3} = 6e^-$

$$\text{Use, No. of bond pairs} = \frac{\text{total no. of shared electrons}}{2}$$

$$\text{and No. of lone pairs} = \frac{\text{Valence } e^- - \text{bond pair}}{2}$$

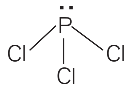
$$\therefore \text{No. of bond pairs} = \frac{6}{2} = 3$$

$$\text{and No. of lone pairs} = \frac{5-3}{2} = \frac{2}{2} = 1$$

Step III *While counting the number of electron pairs for ion, value of negative charge is added and positive charge is subtracted* (with/from the valence e^- of central atom). In PCl_3, no charge is there, so we left this step.

Step IV *On the basis of total number of electron pairs (bond pairs + lone pairs) predict the geometry of the molecule with the help of the above table.*

Note Learn the table mainly *lp*, *bp* and geometry for examination
e.g., The shape of PCl_3 with 3*bp* + 1*lp* is pyramidal.



Sample Problem 9 *The shape of* BrF_5 *is* **[NCERT]**

(*a*) *octahedral* (*b*) *pentagonal bipyramidal*
(*c*) *trigonal bipyramidal* (*d*) *square pyramidal*

Interpret (*d*) In BrF_5^-, Br being less electronegative is the central atom.

In Br, no. of valence $e^- = 7$

5 F atoms shaped with 5 Br atoms.

So, no. of electrons shared = 5 + 5 = 10

$$\therefore \text{No. of bond pairs} = \frac{10}{2} = 5$$

$$\text{No. of lone pairs} = \frac{7-5}{2} = 1$$

Thus, the shape of BrF_5 with 5 *bp* and 1 *lp* is square pyramidal.

Sample Problem 10 *In* NO_3^- *ion, the number of bond pairs and lone pairs of electrons on nitrogen atom are* **[NCERT Exemplar]**

(*a*) 2,2 (*b*) 3,1 (*c*) 1,3 (*d*) 3,0

Interpret (*d*) In N atom,
No. of valence electrons = 5
Due to the presence of one negative charge
No. of valence electrons = 5 + 1 = 6
One O atom forms two bond (═ bond), thus, each O atom shared with two e^-s of N atom.
Thus, 3 O atoms shared with 6 e^-s of N atom.
$\therefore$ No. of bond pairs (or shared pairs) = 3
No. of lone pairs = 0

Important Characteristics of Covalent Bonds

Covalent bonds are characterised by the some parameters which are as follows

(a) **Bond Length**

The average distance between the centre of nuclei of the two bonded atoms in a molecule is known as bond length. It depends upon the size of atoms, hybridization, steric effect, resonance etc.

Usually bond length of polar bond is smaller as compared to a non-polar bond. Bond length increases as the size of atom or orbital increases.

(b) **Bond Enthalpy**

Bond enthalpy is the amount of energy required to break a particular bond in one mole of gaseous molecule.

$$\text{Bond enthalpy} \propto \text{electronegativity}$$
$$\propto \frac{1}{\text{size of atoms}}$$
$$\propto \frac{1}{\text{number of lone pair of electrons}}$$

(c) Bond Order

It is the number of covalent bonds present between the two atoms in a molecule.

$$\text{Bond order} \propto \text{Bond enthalpy} \propto \frac{1}{\text{bond length}}$$

(d) Bond Angles

It is the angle between the bonded orbitals. Presence of lone pair of electrons greatly affects the bond angle.

Some examples are given below.

1. As the number of lone pairs of electrons increased, bond angle decreased, *e.g.,* The bond angle order for CH_4, NH_3 and H_2O is

   $CH_4 > NH_3 > H_2O$, *i.e.,* 109°28′, 106°51′ and 104°31′ respectively.

2. Bond angle increases as the electronegativity of the central atom increases. *e.g.*,

   in hydrides of oxygen family, order of bond angle is.

   $$\underset{(104.5)}{H_2O} > \underset{(92)}{H_2S} > \underset{(91)}{H_2Se} > \underset{(89)}{H_2Te}$$

   However, in molecule having same central atom, bond angle increases as the electronegativity of surrounding atoms decreases, *e.g.,* the order of bond angle for PI_3, PBr_3 and PCl_3 is as

   $$\underset{(102)}{PI_3} > \underset{(101.5)}{PBr_3} > \underset{(100)}{PCl_3}$$

   ∵ The order of electronegativity is Cl > Br > I

   Similarly, NF_3 and NH_3 both have structure based on a tetrahedron with one corner occupied by a lone pair. The high electronegativity of F push the bonding electrons further away from N than in NH_3. Hence, the lone pair in NF_3 causes a greater distortion from tetrahedral and gives a F — N — F bond angle of 102°30′ as compared with 107°48′ in NH_3. The same effect is found in H_2O (bond angle 104°27′) and F_2O (bond angle 102°).

3. pi (π) bonds do not affect the stereochemistry of a molecule. However, multiple bond orbitals repel other orbitals more strongly than single bond orbital, thus the bond angle will increase.

   (i)    $H_2C{=}O$, $\angle H—C—H \Rightarrow 116°$ and $\angle H—C{=}O \Rightarrow 122°$.

   (ii)    $F_2C{=}O$, $\angle F—C—F \Rightarrow 108°$ and $\angle F—C{=}O \Rightarrow 126°$

   (iii)    $(H_2N)_2C{=}O$, $\angle N—C—N \Rightarrow 118°$ and $\angle N—C—O \Rightarrow 121°$

4. A lone pair and double bond repulsion is much greater than a lone electron and double bond repulsion.

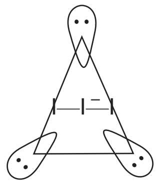
   
   Bond angle = 180° (No lone pair) Bond angle = 134° (A lone electron) Bond angle = 115° (A lone pair)

5. The bond angle of $PF_3 > PCl_3$. The PF_3 molecule has lone pair of electrons on F atom and P has vacant *d*-orbitals. The small size of F-atom leads to *pπ-dπ* bonding in PF_3 as shown below

   
   The double bond formation increases bond pair-bond pair repulsion to result in an increase in bond angle in PF_3. In PCl_3, the Cl-atom being larger in size does not show *pπ-dπ* bonding. Similarly, bond angle in arsenic halides are:

   $$\underset{102°}{AsF_3} > \underset{98.4°}{AsCl_3}$$

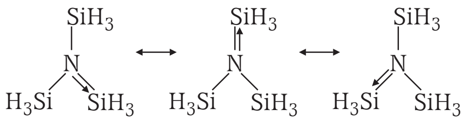
6. The lone pairs always occupy the equatorial positions (in an triangle), rather than the axial positions (up and down). Thus in I_3^- ion, the central I atom has five electron pairs in the outer shell, made of two bond pairs and three lone pairs. The lone pairs occupy all the three equatorial positions and the two I atoms occupy the top, and bottom positions in the bipyramid, thus giving a linear arrangement with a bond angle of exactly 180°.

7. The interaction between an empty orbital and lone pair of electrons known as **back bonding.**

   e.g., the nitrogen in trimethyl amine and trisilyl amine has a lone pair of electrons at nitrogen but nitrogen in trimethyl amine has pyramidal shape while in trisilyl amine nitrogen has planar shape because in trimethyl amine there is repulsion between lone pair and bond pair that's why the shape becomes pyramidal.

   
   In trisilyl amine, there is vacant *d*-orbital at silicon which overlaps with lone pair of nitrogen, called *pπ – dπ* back bonding, hence geometry becomes planar.

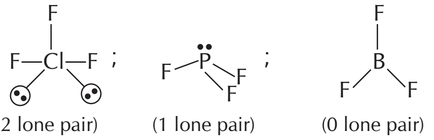
   


Sample **Problem 11** *The correct increasing bond angle among* BF_3, PF_3 *and* ClF_3 *follows the order*

(*a*) $BF_3 > PF_3 > ClF_3$ (*b*) $PF_3 < BF_3 < ClF_3$

(*c*) $BF_3 = PF_3 = ClF_3$ (*d*) $ClF_3 < PF_3 < BF_3$

Interpret (*d*) Bond angle $\propto \dfrac{1}{\text{number of lone pairs}}$

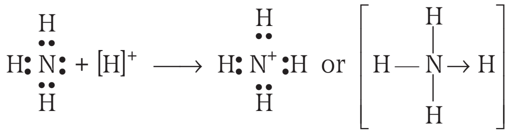


Thus, the order of bond angle is $ClF_3 < PF_3 < BF_3$.

4.5 Coordinate Bonding

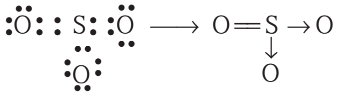
Coordinate covalent bond or **dative bond** is a special type of covalent bond, which involves sharing of a pair of electrons. The speciality in this bonding is that the shared electron pair is donated by one atom (called donor) and shared by both the atoms (the other atom being called acceptor) *e.g.,*

(i) **Formation of** NH_4^+

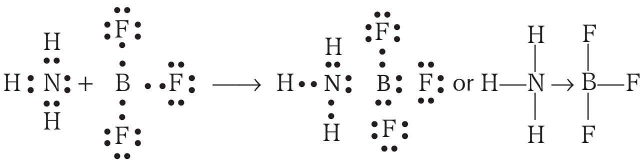


(ii) **Formation of** SO_2

(iii) **Formation of** SO_3



(iv) **Formation of** $NH_3 \rightarrow BF_3$



Characteristics of Dative Bond or Coordination Compounds

The important characteristics of dative compounds are as follows

1. The compounds exist in all the three states *i.e.,* solids, liquids and gases under ordinary conditions.
2. The melting and boiling points of these compounds are higher as compared to covalent compounds but lower than those of ionic compounds.
3. Like covalent compounds these are also poor conductors of electricity in solid as well as in fused state.
4. These compounds are sparingly soluble in polar solvents like water, however, these are readily soluble in organic solvents.
5. These compounds are generally as stable as covalent compounds. The addition compounds are not very stable.
6. **Coordinate linkage is rigid and directional, thus they exhibit isomerism.** Due to its directional nature the coordinate bond is shown as (under classical approach)

   Donor atom $\longrightarrow$ Acceptor atom

   But under modern approach, this bond can also be shown as

   Donor atom $\overset{+\;-}{\longrightarrow}$ Acceptor atom
7. Dative compounds show molecular reactions just like covalent compounds.
8. The dielectric constants for these compounds are higher.

Check Point 1

1. Why does a molecule is more stable in terms of energy than the uncombined atoms?
2. Why are zero group elements chemically inert?
3. Cu and Fe exhibits variable electrovalency, explain, why?
4. Sodium chloride does not conduct electricity in solid state but does so in molten and liquid state. Give reason.
5. Which out of NH_3 and NF_3 has the higher dipole moment and why?
6. Why the repulsion between non-bonding orbitals are greater than between the bonded orbitals?
7. Bond angle in ammonia is 107° 28′ while that in water is 104° 20′, however both are sp^3 hybridised. Explain, why?

4.6 Quantum Mechanical Approach to Covalent Bonding

Electronic theory of covalent bonding was not capable to explain correct shape of molecules, nature of bonds, and formation of bonds. Thus, new theories, called collectively the quantum mechanical theory have been proposed, which includes dual nature of electrons. Electronic theory however gives an impression that electrons are located very precisely in a molecule.

Two theories based on quantum mechanical treatment are

1. Valence bond theory
2. Molecular orbital theory

4.7 Valence Bond Theory (VBT)

It was put forward by **Heitler** and **London** in 1927 and was extended by **Pauling** and **Slater** in 1931.

According to this theory, atoms with unpaired electrons tend to combine with other atoms which also have unpaired electrons. In this way the unpaired electrons are paired up, and the atoms involved, all attain a stable electronic arrangement. This is usually a full shell of electrons (*i.e.,* a noble gas configuration). **Two electrons shared between two atoms constitute a bond**. The number of bonds formed by an atom is usually the same as the number of unpaired electrons in the ground state, *i.e.,* the lowest energy state.

However, in some cases the atoms may form more bonds than this. This occurs by excitation of the atom (*i.e.,* providing it with energy) when electrons, which were paired in the ground state, are unpaired and promoted into suitable empty orbitals. This increases the number of unpaired electrons and hence, increase the number of bonds which can be formed.

The theory can be summarised as

1. A covalent bond is formed when the orbital of one atom overlaps with the orbital of another atom, each of the orbital containing one unpaired electron.
2. The two atomic orbital in such a case, merge to form a single **bond orbital** or **a localized molecular orbital,** which is occupied by both the electrons.
3. The two electrons occupying the bond orbital must have opposite spins. **(Pauli principle)**
4. Each electron may be considered to belong to both the atomic nuclei.
5. As a result of overlapping, there is maximum electron density somewhere between the two atoms. The electrostatic attraction between the nuclei and the accumulated electron clouds between them provides a large part of the binding force of covalent bond.
6. The neutralization of spin magnetic moments of the two electrons taking part in the bond formation also contributes to the binding force.

The modifications suggested by Pauling and Slater were

1. The strength of chemical bond is proportional to the extent of overlapping between the atomic orbital.
2. Overlapping will take place only between those atomic orbitals, electrons of which take part in chemical bonding.
3. Between two orbital of the same stability, the one with more directionally concentrated cloud would form a stronger bond, *e.g., p*-orbital will form stronger bonds than *s*-orbital.
4. A spherically symmertical orbital, *e.g., s*-orbital, will not show any preference in direction whereas, non-spherical orbital, *e.g., p*-or *d*-orbital will tend to form a bond in their direction of maximum electron density.

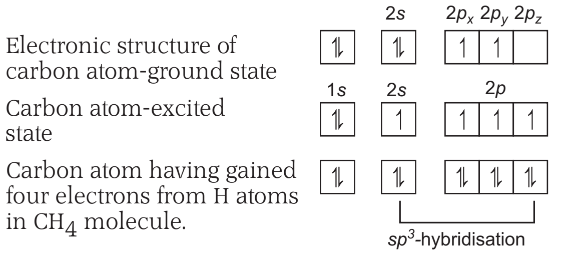
For example

(i) In HF, H has a singly occupied *s*-orbital that overlaps with a singly filled 2*p* orbital for F.

(ii) In H_2O, the O atom has two singly filled 2*p* orbitals, each of which overlaps with a single occupied *s*-orbital from two H atoms.

(iii) In NH_3, there are three singly occupied *p* orbitals on N which overlap with *s* orbitals from three H atoms.

(iv) In CH_4, the C atom in its ground state has the electronic configuration $1s^2, 2s^2, 2p_x^1, 2p_y^1$ and only has two unpaired electrons and so can form only two bonds. If the C atom is excited, then the 2*s* electrons may be unpaired, giving $1s^2, 2s^1, 2p_x^1, 2p_y^1, 2p_z^1$ configuration. There are now four unpaired electrons which overlap with singly occupied *s* orbitals on four H atoms.



CH_4 molecule uses its three *p*-orbitals p_x, p_y and p_z, which are mutually at right angles to each other, and the *s* orbital is spherically symmetrical. Hence, they form tetrahedral structure.

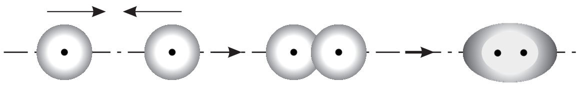
CH_4 $\quad$ H—C—H = 109°28′

Overlapping of Orbitals

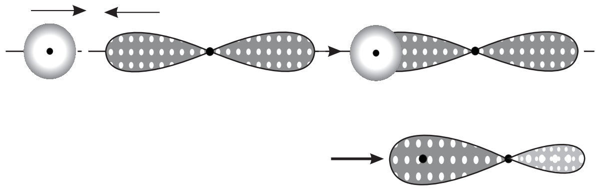
The overlapping of orbitals may be of two types

1. **End to end overlapping or axial overlapping or head on overlapping resulting** to σ-bond (sigma bond). Here, the electron density is concentrated in between the two atoms. The main examples of σ-bond include

(a) ***s-s* overlapping**



(b) ***s-p* overlapping**



(c) ***p-p* overlapping**

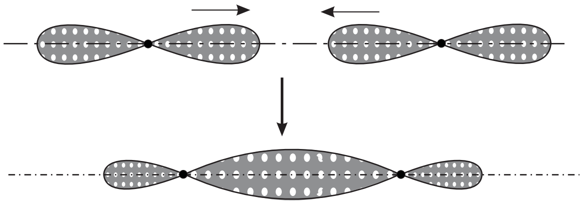


Fig 4.4 Different cases tend to end or axial overlapping

2. **Sidewise overlapping or parallel overlapping** which is seen normally after atleast one axial overlapping between orbitals of same atom and results to a π-bond (pi bond). Here, also the electron density concentrates between the atoms but on either side of line of joining nuclei as

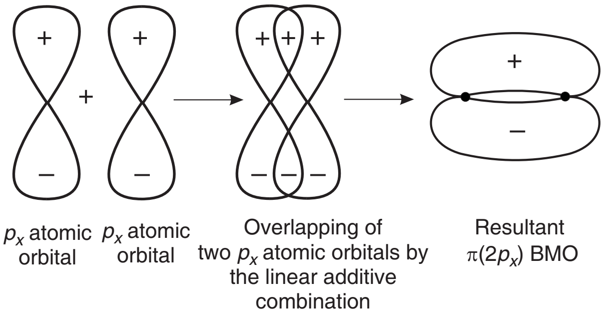

Fig 4.5 Sidewise overlapping Overlapping of two p_x atomic orbitals by linear additive combination to give $\pi 2p_x$ bonding molecular orbitals (BMO).

From the above, *it is concluded, single bond* (—) *contains only one* σ*-bond and no* π*-bond, double bond* (=) *contains one* σ *and one* π*-bond and triple bond* (≡) *contains one* σ *and two* π*-bonds.*

4.8 Hybridisation

The process of hybridisation involves the mixing of orbitals of almost similar energy belonging to same atom, to form the same number of orbitals of exactly equal energy. The new orbitals formed are called **hybrid orbitals.** The phenomenon in actual sense involves redistribution of energy.

Salient Features of the Phenomenon of Hybridisation (Rules of Hybridisation)

1. Only the valence shell atomic orbitals of an atom or ion mix together to give the hybrid orbitals.
2. *The atomic orbitals of the atom of a given molecule or ion which participate in the formation of* π*-bonds remain excluded from the hybridisation process.* For example in CO_2 molecule (O=C=O), the singly-filled $2s$ and $2p_x$-orbitals of C-atom mix together to form two *sp* hybrid orbitals while the singly-filled $2p_y$ and $2p_z$-orbitals remain excluded from the hybridisation process, since these orbitals make two (C—O) π-bonds.
3. *Atomic orbitals having lone pairs of electrons* (completely-filled orbitals) *are also involved in the hybridisation,* if the central atom of the given molecule or ion also has one or more lone pairs of electrons.
4. In a few cases, *empty atomic orbitals are also involved in hybridisation.*
5. A hybrid orbital, like an atomic orbital, can accommodate a maximum of two electrons with opposite spins.
6. The number of hybrid orbitals formed is exactly equal to the number of orbitals taking part in the process.
7. *The electronic charge in hybrid orbitals is concentrated more in one direction.* This property make the hybrid orbitals to overlap with the atomic orbitals to a greater extent and hence, give stronger bonds.
8. The hybridised orbitals have equivalent energies and identical size and shape, *i.e.,* **hybrid orbitals are degenerate.** The sum of the energies of all the hybrid orbitals is equal to the sum of the energies of orbitals which participated in the process *i.e., the process of hybridisation does not involve any loss or gain of energy.* Here, only redistribution of energy occurs.
9. Atomic orbitals can mix together effectively to give hybrid orbitals only when they are of almost same energy and same symmetry.
10. Same atom can assume different hybrid states under different situations.

11. The shapes of hybrid orbitals are different from those of the atomic orbitals which are taking part in the process of hybridisation.
12. The energy released (decrease in energy) in the formation of σ-bonds by the hybrid orbitals is more than that which is released in the formation of σ-bonds by the pure atomic orbitals. σ-bonds formed by the use of hybrid orbitals of the atom are, therefore stronger and hence, more stable than those which are formed by the use of pure atomic orbitals only.

Types of Hybridisation

The hybridisation can be of following types

(a) sp (b) sp^2 (c) sp^3 or dsp^2

(d) sp^3d (e) sp^3d^2 and (f) sp^3d^3.

Out of these the former three are described here in detail.

(a) *sp*-Hybridisation (Linear Hybridisation)

In this hybridisation, one *s* and one *p*-orbital (if axis is supposed to be the molecular *x*-axis, *p*-orbital will p_x-orbital) of the valence shell of atom combine together and give rise to the formation of a set of two equivalent hybrid orbitals, which are called *sp*-hybrid orbitals. Since, the lobes of a *p*-orbital can combine with an *s*-orbital in two different ways as shown in figure below, two *sp*-hybrid orbitals are obtained.

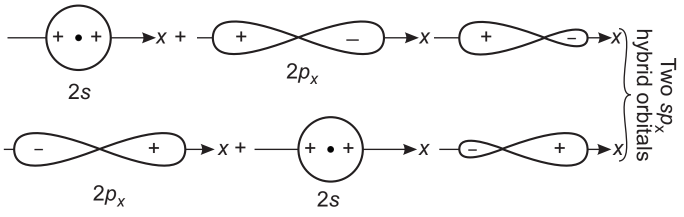

Fig 4.6 Formation of two sp_x hybrid orbitals

Characteristics of *sp*-hybrid orbitals include

1. *sp*-hybrid orbitals are equivalent and symmetrical.
2. These have same shape and same energy.
3. These are collinear, *i.e.,* they lie in one axis in a straight line and hence, the angle between them is 180° and their spatial arrangement is linear, *i.e.,* they are directed in a straight line in opposite directions.
4. *s*-orbital is spherical and *p* is pear-shaped but *sp*-hybrid orbital which results from the mixing of one *s* and one *p*-orbital is oval-shaped due to the presence of 50% *s*-character and 50% *p*-character in it.

An example of *sp*-hybridised molecule is $BeCl_2$ molecule.

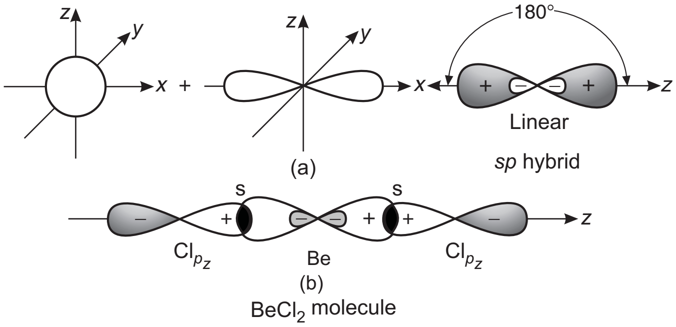

Fig 4.7 (a) Formation of *sp* hybrids formal *s* and *p* orbits; (b) Formation of the linear $BeCl_2$ molecule.

(b) sp^2-Hybridisation
(Trigonal Planar Hybridisation)

In this hybridisation, one *s* and any two *p*-orbitals of the valence shell of the atom combine together and give a set of three equivalent hybrid orbitals which are called sp^2 or trigonal hybrid orbitals.

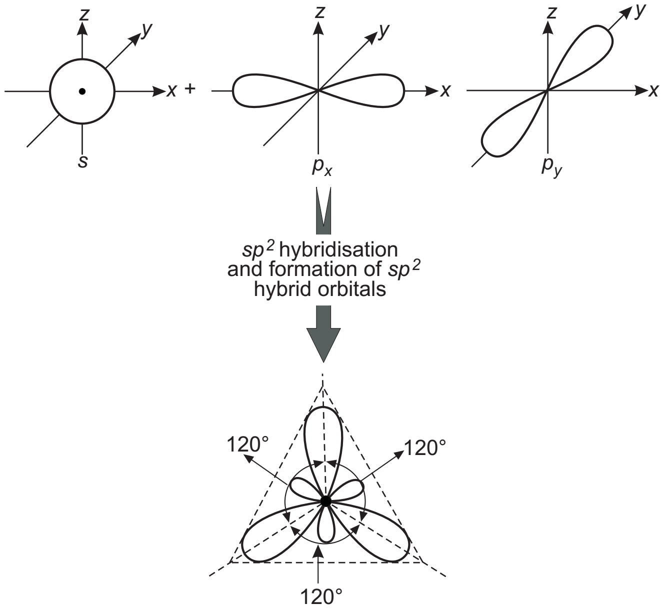

Fig. 4.8 Showing sp^2-hybridisation with angle and arrangement of orbitals

Characteristics of sp^2-hybrid orbitals include

1. They have the same shape and energy.
2. They lie in one plane.
3. They are directed towards the corners of an equilateral triangle and hence, the angle between each pair of them is 120°. Thus, in other words, we can say that the spatial arrangement of the three sp^2-hybrid orbitals is trigonal.
4. The sp^2 hybrid orbitals which result from the combination of one *s* and two *p*-orbitals are less oval than the *sp*-hybrid orbitals because the contribution of the two pear-shaped *p*-orbitals to the

formation of sp^2-hybrid orbitals is greater. The shape of sp^2-hybrid orbitals, therefore, tends more towards a pear. Here, the *s*-character is 33% and the *p*-character is 67%.

An example of sp^2-hybridised molecule is BCl_3 molecule

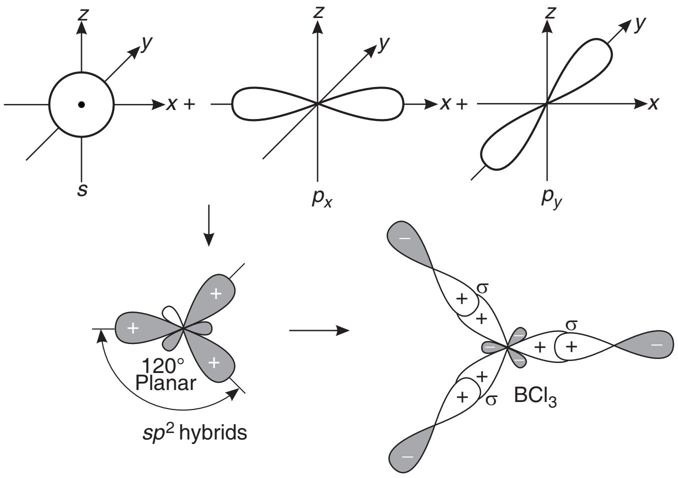

Fig. 4.9 Formation of sp^2 hybrids and the BCl_3 molecule

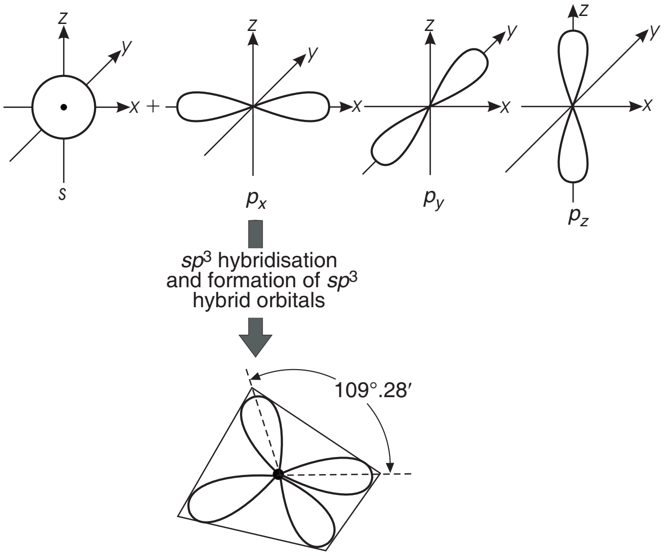
(c) sp^3-Hybridisation (Tetrahedral Hybridisation)

The term sp^3-hybridised means that one *s* and all the three *p*-orbitals (p_x, p_y and p_z orbitals) of the valence shell of the atom combine together and form a set of four hybrid orbitals which are called sp^3 or tetrahedral hybrid orbitals.

Four sp^3-hybrid orbitals can also be regarded as having been formed by adding one atomic *p*-orbitals to three sp^2-hybrid orbitals which, we know, lie in the same plane (co-planar) and are inclined to each other at 120°. Each pair of these sp^3-hybrids is inclined at an angle of 109°28′ approximately.



Showing sp^3 hybridisation with angle and arrangement of orbitals

Characteristics of sp^3-hybrid orbitals include

1. sp^3-hybrid orbitals are equivalent and symmetrical.
2. They are directed towards the four corners of a regular tetrahedron and the angle between each pair of them is 109.5°. This angle is called **tetrahedral angle.**
3. Each of the four sp^3-hybrid orbitals, has one fourth *s*-character and three-fourth *p*-character, *i.e.*, *s*-character = 25% and *p*-character = 75%.
4. In case of sp^3-hybrid orbitals, since the contribution of three *p*-orbitals predominates over the contribution of one *s*-orbital, the shape of sp^3-hybrid orbitals is practically the same as that of the parent *p*-orbitals except for the fact that the lobes in sp^3-hybrid orbitals are somewhat more spread and are somewhat shorter in length than the pure *p*-orbitals.

Table 4.3 **Relationship between Hybridisation, Shape and Bond Angle**

No. of atomic orbitals involved in hybridisation	Type of hybridisation	No. of hybrid orbitals	Shape of molecules	Bond angles	Examples
2	sp ($s + p$)	2	Linear	180°	$BeCl_2$, BeF_2
3	sp^2 ($s + p + p$)	3	Planar triangular	120°	BF_3, BCl_3
4	sp^3 ($s + p + p + p$)	4	Tetrahedral	109° 28′	CH_4, CCl_4
4	dsp^2 one 'd' ($d_{x^2-y^2}$) + one 's' + two 'p'	4	Square planar	90°	$[Ni(CN)_4]^{2-}$, $[PtCl_4]^{2-}$
5	dsp^3 or sp^3d one 's' + three 'p' + one d (d_{z^2})	5	Trigonal bipyramid	120° and 90°	PCl_5
6	d^2sp^3 or sp^3d^2 one 's' + three 'p' + two 'd' ($d_{x^2-y^2}$, d_{z^2})	6	Octahedral	90°	SF_6
7	d^3sp^3 or sp^3d^3 one 's' + three 'p' + two 'd' (d_{xy}, d_{yz}, d_{zx})	7	Pentagonal bipyramid	72° and 90°	IF_7

Hot Spot 2

METHOD FOR IDENTIFICATION
of Hybridisation for Molecule

Finding hybridisation of molecule is also a hot topic for JEE Main. It is a very easy topic, so scoring, if you do some practice. There are several methods that can be used to find the hybridisation of a molecules. These methods are as follows

First Method

1. Write electronic configuration for the outermost orbit or central atom using boxes.
2. Find oxidation state of central atom. Excite the electrons from orbits of higher energy in such a way that total no. of upaired electrons = oxidation state of central atom.

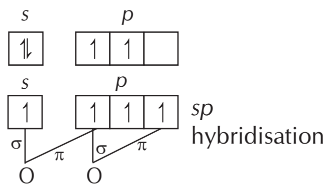
Note π-bonds are excluded from hybridisation calculation.

Sample **Problem 12** *Predict the shape of* CO_2 *molecule.*

(a) *linear*
(b) *trigonal*
(c) *planar*
(d) *tetrahedral*

Interpret (a) CO_2

Electronic configuration of C (ground state)
oxidation state of C = 4
Electronic configuration after excitation add electron to pocket

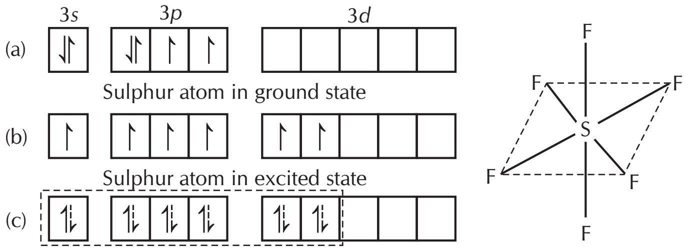


Thus, CO_2 is *sp* hybridised and hence,

Shape of the molecule is linear O═C═O

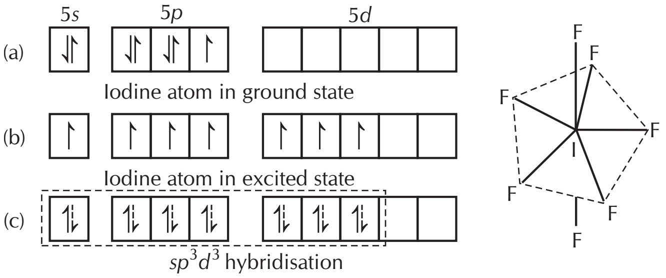
Similarly the hybridisation and shape of SF_6 and IF_7 are described.

(i) SF_6 molecule sp^3d^2 hybridisation



Octahedral geometry of SF_6 molecule resulting from sp^3d^2 hybridisation of the central S atom. Dotted arrows represent electrons supplied by fluorine atoms.

(ii) IF_7 molecule sp^3d^3 hybridisation



Pentagonal bipyramidal geometry of IF_7 molecule resulting from sp^3d^3 hybridisation of the central I atom. Dotted arrows represent electrons supplied by fluorine atoms.

Second Method

The type of hybridisation undergone by the atom/ion in a given molecule or ion depends on the sum of σ-bond pairs and lone pairs surrounding the central atom/ion, *e.g.*, if the sum of σ-*bps* and *lps* is 2 then the central atom/ion undergoes *sp*-hybridisation. Similarly for the sum equal to 3, 4, 5, 6 and 7, the central atom undergoes sp^2, sp^3, sp^3d, sp^3d^2 and sp^3d^3 hybridisation respectively.

Alongwith these, dsp^2 hybridisation is also seen in which 1*d* + 1*s* + 2*p* orbitals combine to hybridise. The shape of the molecule is **square planar** with a bond angle of 90°.

A few examples are being given below

(i) Beryllium chloride ($BeCl_2$)

No. of σ-bonds at Be atom = 2
No. of lone pair of electrons at Be atom = 0
Total = 2 + 0 = 0

Hybridisation is *sp*, *i.e.*, $BeCl_2$ is linear and bond angle is 180°.

(ii) Ammonia (NH_3)

No. of σ-bonds at N atom = 3
No. of lone pair of electrons at N atom = 1
Total = 3 + 1 = 4
Hybridisation is sp^3

Shape is trigonal pyramidal (not tetrahedral) and bond angles are not 109°28′ but 106°45′.

(iii) Water (H_2O)

No. of σ-bonds at O atom = 2

No. of lone pair of electrons at O atom = 2

Total = 2 + 2 = 4

Hybridisation is sp^3

Shape is angular or V-shape (not tetrahedral) and bond angles are not 109°28′ but 104°35′.

Third Method

An alternative way of finding hybridisation is the use of following formula

$$H = \frac{1}{2}[V + Y - C + A]$$

Here, V = valence shell electrons of the cental metal

Y = number of monovalent atom

C = total positive charge

and A = total negative charge on molecule

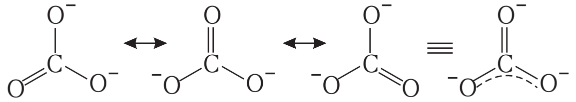
For the 2, 3, 4, 5, 6 and 7 value of H, the hybridisation is respectively sp, sp^2, sp^3, sp^3d, sp^3d^2 and sp^3d^3 *e.g.*,

PF_5	$COCl_2$	NH_4^+	ClO_4^-
$X = \frac{1}{2}[5+5]$ $= 5$	$X = \frac{1}{2}[2+4]$ $= 3$	$X = \frac{1}{2}[4+5-1]$ $= 4$	$X = \frac{1}{2}[0+7+1]$ $= 4$
Hybrid state of P is sp^3d	Hybrid state of C is sp^2	Hybrid state of N is sp^3	Hybrid state of Cl is sp^3
NO_3^-	**IF_5**	**CO_2**	**XeF_4**
$X = \frac{1}{2}[0+5+1]$ $= 3$	$X = \frac{1}{2}[5+7]$ $= 6$	$X = \frac{1}{2}[0+4]$ $= 2$	$X = \frac{1}{2}[4+8]$ $= 6$
sp^2	sp^3d^2	sp	sp^3d^2

Note From the above three method, learn and practice only one method which, you think, is easiest for you.

4.9 Resonance

In some molecules or ions, having double or triple bond, it is difficult to assign which lone pairs are used for forming these multiple bonds. If such a condition exists, all the possible structures of a molecule are called resonance structure or canonical forms and the actual molecule is considered to have a structure equivalent to an average of these structures. *e.g.*, carbonate ion is a resonance hybrid of following canonical forms



From the concept of resonance, the bond order (BO) of a molecule (or ion) is calculated as,

$$BO = \frac{\text{total number of bonds between two atoms in all the structures}}{\text{total number of canonical forms}}$$

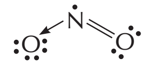
The stability of a resonance structure can be decided by considering the following points

1. A non-polar canonical form is more stable.
2. More the number of covalent bonds, more is the stability.
3. Resonance structure in which negative charge resides on electronegative atom and positive charge on electropositive atom is more stable as compared to that for which opposite is true.

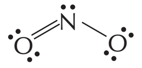
(To know more about resonance see chapter 13)

Sample **Problem 13** *Which of the following is not the correct resonating structure for* NO_2*?* **[NCERT]**

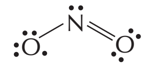
(*a*)



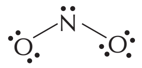
(*b*)



(*c*)



(*d*)



Interpret (*b*) Structure given in option (b) is not possible as in it the octet of O atom, remain incomplete.

Sample **Problem 14** *Which of the following resonating structures is not correct for* CO_2 *?*

(*a*)

(*b*)

(*c*)

(*d*)

Interpret (*c*) Structure given in option (c) is not possible as in this structure, the O-atom, which is bonded to carbon by a triple bond, has 10 electrons in the valence shell. But this situation is impossible as *d*-orbitals are not present in O atoms. So, O cannot expand its valency beyond 8.

Check Point 2

1. σ-bonds are stronger than π bonds. Explain why?
2. Is there any change in hybridisation of atoms involved in the following reactions?
   $BF_3 + NH_3 \longrightarrow F_3B \rightarrow NH_3$
3. In PCl_5 axial Cl atoms are more reactive than equatorial Cl atoms, explain why?
4. Why does C exhibit + 4 oxidation state or forms 4 bonds although it contains only two unpaired electrons?
5. *p*-orbital will form a stronger bond as compared to *s*-orbital, why?

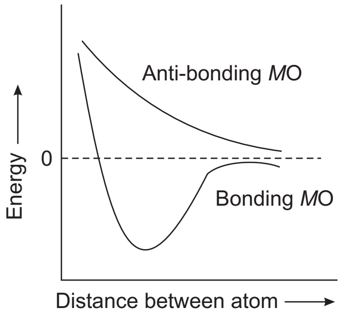
4.10 Molecular Orbital Theory (MOT)

Why He_2 molecule does not exist and why O_2 is paramagnetic? These questions cannot be explained by valence bond theory. In 1932 F. Hund, Huckel and R.S. Mulliken put forward a theory, known as Molecular Orbital Theory, to explain above questions and many others on the basis of **Schrodinger** wave interpretation of electrons.

According to this theory,

1. A molecule is supposed to have orbitals of varying energy levels in the same way as an isolated atom has. These orbitals of molecule are called **molecular orbitals** (MO) .
2. Molecular orbitals are formed by the combination of atomic orbitals of comparable energy and proportional symmerty. While an electron in atomic orbital is influenced by one nucleus, in a molecular orbital, it is influenced by two or more nuclei depending upon the number of atoms in the molecule. Thus, orbitals of atoms loose their individual identity. Hence, **an atomic orbital is monocentric while a molecular orbital is polycentric.**
3. Just as the electron probability distribution around a nucleus in an atom is given by an atomic orbital, the electron probability distribution in molecule is given by molecular orbital.
4. The number of molecular orbitals formed is equal to the number of combining atomic orbitals.
5. When two atomic orbitals combine, two molecular orbitals are formed. One is known as **bonding molecular orbital** (BMO) whereas other is **anti-bonding molecular orbital** (ABMO). BMO has lower energy and hence, greater stability than the corresponding ABMO. First BMO are filled, then ABMO starts filling because BMO has lower energy than that of ABMO.
6. The shapes of molecular orbitals formed depends upon the type of combining atomic orbitals.
7. The filling of molecular orbital obey Aufbau principle, Pauli's exclusion principle and Hund's rule of maximum multiplicity.

Electron density is increased for the bonding MO's in the internuclear region but decreased for anti-bonding MO's. Shielding of the nuclei by increased electron density in bonding MO's reduces internuclear repulsions and thus stabilizes the molecule whereas lower electron density (even as compared to the individual atom in anti-bonding MO's) increases the repulsion and destabilizes the system.



Linear Combination of Atomic Orbitals (LCAO)

The Schrodinger wave equation is very difficult to apply on the system containing more than one electron because here one electron is moving in the field of several nuclei so some approximation method used in the formation of molecular orbitals can be explained on the basis of LCAO. It is very convenient method of approximation.

According to LCAO, the wave function (ψ) of individual atomic orbitals linearly combined and form molecular orbitals, *i.e.,* during the formation of AB molecule ψ of A and ψ of B will linearly combine as

$$\psi_{MO} = \psi_A + \psi_B$$

Case I When two waves are in phase (constructive interference), the waves adds up and amplitude of new wave is

$$\psi_{MO} = \psi_A + \psi_B \qquad \text{(Bonding M.O.)}$$

Case II When two waves are out of phase, the waves are subtracted from each other so that the amplitude of new wave is

$$\psi^*_{MO} = \psi_A - \psi_B \text{ (Antibonding M.O.)}$$

Knowing that probability is given by square of the amplitude, we have

$$\psi^2_{MO} = (\psi_A + \psi_B)^2$$
$$= \psi^2_A + \psi^2_B + 2\psi_A\psi_B$$

and $$(\psi^*_{MO})^2 = (\psi_A - \psi_B)^2$$
$$= \psi^2_A + \psi^2_B - 2\psi_A\psi_B$$

i.e., $$\psi^2_{MO} > \psi^2_A + \psi^2_B$$

whereas $$(\psi^*_{MO})^2 < \psi^2_A + \psi^2_B$$

Thus, by combination of two atomic orbitals, two new molecular orbitals are formed, one by constructive and other by destructive interference of atomic orbitals. These interactions are based upon the fact that when orbitals or lobes of orbitals with same wave function (ψ) combine, the result is **constructive interaction** while when orbitals or lobes of orbitals with opposite wave function (ψ) combine, the result is **destructive interaction.**

Constructive interaction of orbitals give rise to orbitals of lower energy, called **bonding orbitals** or **HOMOs** (highly occupied molecular orbitals) as electrons prefer to stay in these orbitals due to their lower energy as compared to combining atomic orbitals.

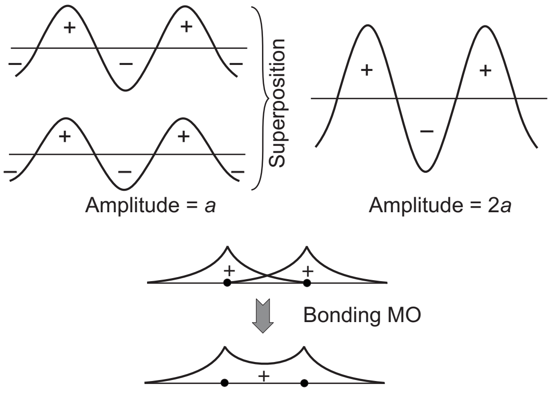


Fig 4.11 Constructive interaction

Destructive interaction, on the other hand, give rise to orbitals of higher energy, called **antibonding orbitals or LUMOs** (lowest unoccupied molecular orbitals) as electrons don't prefer them due to their higher energy as compared to combining atomic orbitals

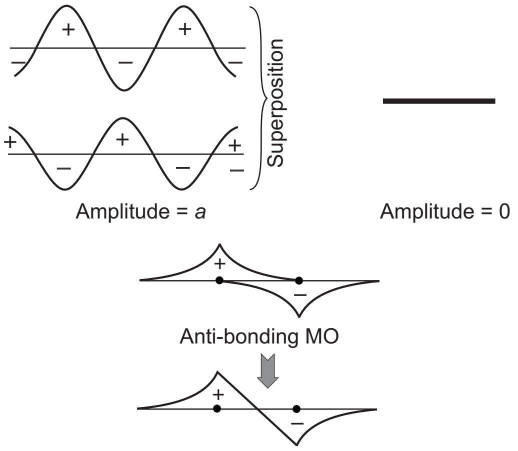

Fig 4.12 Destructive interaction

The condition of lower energy (bonding molecular orbital) is also called attractive state for electrons while condition of higher energy (antibonding molecular orbital) is also called repulsive state for electrons.

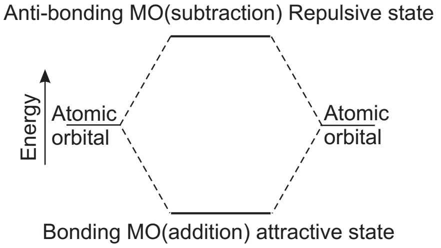

Fig 4.13 Energy level diagram of molecular orbitals

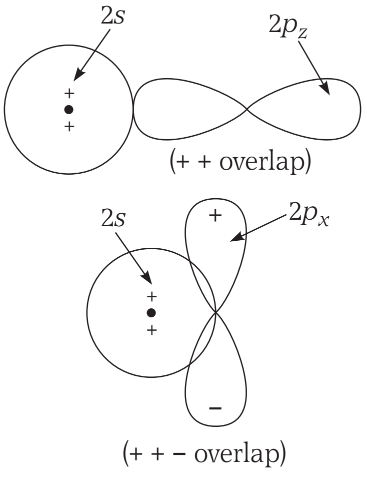
The bonding molecular orbitals are shown as σ or π*ns* or *np* while antibonding molecular orbitals are shown as σ* or π**ns* or *np* accordingly.

The total energy of two molecular orbitals, however, remains the same as that of two original atomic orbitals.

Conditions for Combination of Atomic Orbitals

The combination of the atomic orbitals is based on the following conditions.

1. *The combining atomic orbitals must have comparable energies*. It may be noted that in the homonuclear diatomic molecules of the type A_2 (*e.g.,* H_2, O_2, N_2, F_2 etc.), the participating atomic orbitals must have comparable energies. This means that 1*s* atomic orbital of one atom can combine with 1*s* atomic orbital of the other atom and not with its 2s orbital. However, in heteronuclear molecules *AB* (*e.g.,* HF, HCl etc.) such a combination is permissible.
2. *The extent of overlapping must be large*. The overlapping of the atomic orbitals results in decrease in energy and increase in stability. Thus, greater the extent of the overlapping, more will be the stability of the molecular orbital formed.
3. *The combining atomic orbitals must have same symmetry about internuclear axis*. The atomic orbitals taking part in the overlap must have same orientation or same sign of symmetry.

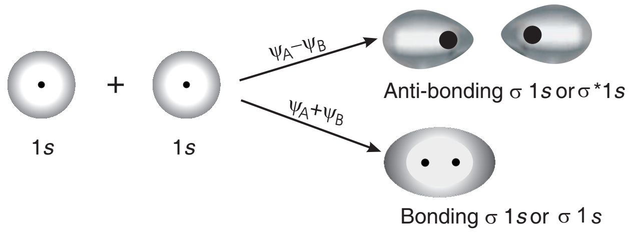


Types of Molecular Orbitals

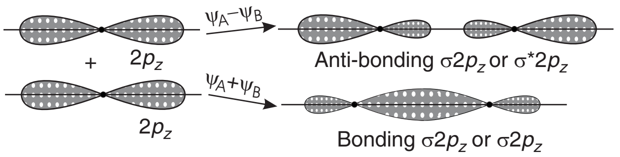
Molecular orbitals of diatomic molecule are designated as σ (sigma means head on overlap), π (pi represent side ways overlap) etc. Sigma (σ) molecular orbitals are symmetrical around the bond axis while pi (π) molecular orbitals are not symmetrical.

Formation of σ and π HOMOs and LUMOs

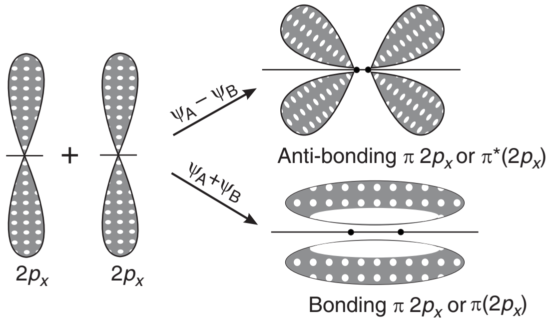
(a) **Combination of *s*-orbitals**



(b) **Head on combination of two *p*-orbitals**



(c) **Sidewise combination of two *p*-orbitals**



[Here *z* axis is considered as internuclear axis]

Hot Spot 3

MOLECULAR ORBITAL
Electronic Configuration

Molecular orbital electronic configuration is an important topic as it is related to the bond order, bond length, bond strength and magnetic nature and questions based on these topics are frequently asked. So do practice to write electronic configuration and finding its relation with these topics.

The energy levels of molecular orbitals have been determined experimentally from spectroscopic data, for homonuclear diatomic molecules of the 2nd row elements of Periodic Table. The increasing order of energies of molecular orbitals for O_2 and F_2 molecules is given as

$$\sigma 1s < \overset{*}{\sigma} 1s < \sigma 2s < \overset{*}{\sigma} 2s < \sigma 2p_z < \pi 2p_x \approx \pi 2p_y < \overset{*}{\pi} 2p_x \approx \overset{*}{\pi} 2p_y < \overset{*}{\sigma} 2p_z$$

However, for remaining molecules *i.e.*, $Li_2, Be_2, B_2, C_2, N_2$ the order is

$$\sigma 1s < \overset{*}{\sigma} 1s < \sigma 2s < \overset{*}{\sigma} 2s < \pi 2p_x \approx \pi 2p_y < \sigma 2p_z < \overset{*}{\sigma} 2p_x \approx \overset{*}{\pi} 2p_y < \overset{*}{\sigma} 2p_z$$

i.e., here the energy of $\pi 2p_x \approx \pi 2p_y$ is less than the energy of $\sigma 2p_z$ molecular orbital.

The molecular orbital energy level diagrams are different because the energy difference between 2*s* and 2*p* atomic energy level is small (except O_2 and F_2) as a result both come together and hence, repulsive forces arises which raise the energy σ2*p* above that of π2*p* molecular orbitals.

Bond Order

The one-half of the difference between the number of electrons present in bonding orbitals and number of electrons present in anti-bonding orbitals is called **bond order** of that molecule, *i.e.*,

$$\text{Bond order} = \frac{N_b - N_a}{2}$$

Here, N_b = Number of electrons in bonding orbitals

N_a = Number of electrons in anti-bonding orbitals

The **stability** of a molecule can be determined by its bond order as

1. A positive bond order means a stable molecule,
2. A negative or zero bond order means an unstable molecule,
3. Bond order values 1, 2 and 3 corresponds to single, double and triple bond respectively.

Bond length varies inversely with bond order *i.e.*, decreases as the bond order increases.

$$\text{Bond order} \propto \frac{1}{\text{Bond length}}$$

Magnetic nature of molecule can also be determined by molecular orbitals as

1. If all orbitals are fully occupied, *substance is diamagnetic.*
2. If one or more molecular orbitals are singly occupied, *substance is paramagnetic.*

Bonding in Some Homonuclear Diatomic Molecules

(i) **H_2 molecule**

Electronic configuration : $\sigma 1s^2$

$$\text{Bond order} = \frac{2-0}{2} = 1$$

Conclusion Stable molecule, with single bond between 2H atoms, diamagnetic.

(ii) **He_2 molecule**

Electronic configuration : $\sigma 1s^2, \overset{*}{\sigma} 1s^2$

$$\text{Bond order} = \frac{2-2}{2} = 0$$

Conclusion Unstable molecule, does not exist.

Similarly, Be_2 molecule with electronic configuration $\sigma 1s^2 \overset{*}{\sigma} 1s^2 \sigma 2s^2 \overset{*}{\sigma} 2s^2$ does not exist.

(iii) **Li_2 molecule**

Electronic configuration : $\sigma 1s^2, \sigma * 1s^2, \sigma 2s^2$

$$\text{Bond order} = \frac{4-2}{2} = 1$$

Conclusion Stable (known in vapour phase) with single bond between 2 Li atoms, **diamagnetic.**

(iv) **C_2 molecule**

Electronic configuration

$$\sigma 1s^2, \sigma * 1s^2, \sigma 2s^2, \overset{*}{\sigma} 2s^2, \pi 2p_x^2 \approx \pi 2p_y^2$$

$$\text{Bond order} = \frac{8-4}{2} = 2$$

Conclusion Stable (detected in vapour phase), with 2π-bonds between two C-atoms instead of 1σ and 1π, diamagnetic.

(v) **O_2 molecule**

Electronic configuration

$$\sigma 1s^2, \overset{*}{\sigma} 1s^2, \sigma 2s^2, \overset{*}{\sigma} 2s^2, \sigma 2p_z^2, \pi 2p_x^2 \approx \pi 2p_y^2, \overset{*}{\pi} 2p_x^1 \approx \overset{*}{\pi} 2p_y^1$$

$$\text{Bond order} = \frac{10-6}{2} = 2$$

Conclusion Stable, with double bond between two oxygen atoms, paramagnetic.

(vi) **F_2 molecule**

Electronic configuration : $\sigma 1s^2, \overset{*}{\sigma} 1s^2, \sigma 2s^2, \overset{*}{\sigma} 2s^2$

$$\sigma 2p_z^2, \pi 2p_x^2 \approx \pi 2p_y^2, \overset{*}{\pi} 2p_x^2 \approx \overset{*}{\pi} 2p_y^2$$

$$\text{Bond order} = \frac{10-8}{2} = 1$$

Conclusion Stable, with one σ bond between two F atoms, diamagnetic.

Note $\pi 2p_x$ and $\pi 2p_y$ have one nodal plane while $\overset{*}{\pi} 2p_x$ and $\overset{*}{\pi} 2p_y$ have two nodal planes.

Sample Problem 15 *Which of the following options represents the correct bond order ?* **[NCERT Exemplar]**

(a) $O_2^- > O_2 > O_2^+$
(b) $O_2^- < O_2 < O_2^+$
(c) $O_2^- > O_2 < O_2^+$
(d) $O_2^- < O_2 > O_2^+$

Interpret (*b*) E.C. of O_2 (16 electrons)

$$= \sigma 1s^2, \overset{*}{\sigma} 1s^2, \sigma 2s^2, \overset{*}{\sigma} 2s^2, \sigma 2p_z^2, \pi 2p_x^2 \approx \pi 2p_y^2, \overset{*}{\pi} 2p_x^1 \approx \overset{*}{\pi} 2p_y^1$$

$$\text{Bond order} = \frac{1}{2}(N_b - N_a) = \frac{1}{2}(10-6) = 2$$

E.C. of O_2^+ (15 electrons)

$$= \sigma 1s^2, \overset{*}{\sigma} 1s^2, \sigma 2s^2, \overset{*}{\sigma} 2s^2, \sigma 2p_z^2, \pi 2p_x^2 \approx \pi 2p_y^2, \overset{*}{\pi} 2p_x^1 \approx \overset{*}{\pi} 2p_y$$

$$\text{Bond order} = \frac{1}{2}(N_b - N_a) = \frac{1}{2}(10-5) = 2.5$$

E.C. of O_2^- (17 electrons)

$$= \sigma 1s^2, \overset{*}{\sigma} 1s^2, \sigma 2s^2, \overset{*}{\sigma} 2s^2, \sigma 2p_z^2, \pi 2p_x^2 \approx \pi 2p_y^2, \overset{*}{\pi} 2p_x^2 \approx \overset{*}{\pi} 2p_y^1$$

$$\text{Bond order} = \frac{1}{2}(N_b - N_a) = \frac{1}{2}(10-7) = 1.5$$

Thus, the order of bond order is $O_2^- < O_2 < O_2^+$

Sample Problem 16 *The relative stabilities of* H_2, H_2^+ *and* H_2^- *are in the order of*

(a) $H_2^+ > H_2^- < H_2$
(b) $H_2^- < H_2^+ < H_2$
(c) $H_2^+ < H_2 < H_2^-$
(d) $H_2 < H_2^- < H_2^+$

Interpret (*b*) Stability ∝ Bond order

$H_2 = \sigma 1s^2$, $\quad \text{BO} = \frac{2-0}{2} = 1$

$H_2^+ = \sigma 1s^1$ $\quad \text{BO} = \frac{1-0}{2} = \frac{1}{2}$

$H_2^- = \sigma 1s^2, \overset{*}{\sigma} 1s^1$ $\quad \text{BO} = \frac{2-1}{2} = \frac{1}{2}$

Antibonding orbitals destabilises the molecule, then, correct stability order is $H_2^- < H_2^+ < H_2$

Sample Problem 17 *Which of the following molecule is paramagnetic?*

(a) *Fluorine* (b) *Oxygen* (c) *Nitrogen* (d) *Hydrogen*

Interpret (*b*)

(a) $F_2 (9 + 9 = 18) = \sigma 1s^2, \overset{*}{\sigma} 1s^2, \sigma 2s^2, \overset{*}{\sigma} 2s^2, \sigma 2p_z^2, \pi 2p_x^2 \approx \pi 2p_y^2, \overset{*}{\pi} 2p_x^2 \approx \overset{*}{\pi} 2p_y^2.$

All the electrons are paired, so F_2 is diamagnetic.

(b) $O_2 (8 + 8 = 16) = \sigma 1s^2, \overset{*}{\sigma} 1s^2, \sigma 2s^2, \overset{*}{\sigma} 2s^2, \sigma 2p_z^2, \pi 2p_x^2 \approx \pi 2p_y^2, \overset{*}{\pi} 2p_x^1 \approx \overset{*}{\pi} 2p_y^1$

Due to the presence of two unpaired electrons, O_2 is paramagnetic.

(c) $N_2 (7 + 7 = 14) = \sigma 1s^2, \overset{*}{\sigma} 1s^2, \sigma 2s^2, \overset{*}{\sigma} 2s^2, \pi 2p_x^2 \approx \pi 2p_y^2, \sigma 2p_z^2.$

Since all the electrons are paired, N_2 is diamagnetic.

(d) $H_2 (1 + 1 = 2) = \sigma 1s^2$

Since, all the electrons are paired, H_2 is also diamagnetic.

4.11 Metallic Bonding

The peculiar type of bonding which holds the metal atoms together in a metal crystal is called **metallic bonding.** Different models have been proposed to explain the nature of metallic bonding, the two important of them are as

Electron Sea Model

According to this model, a metal is regarded as a group of positive metal ions packed together as closely as possible in a regular geometric pattern and immersed in a sea of electron which move about freely in the vacant valence orbitals.

The attractive force that binds the metal ions to the mobile electrons is called **metallic bond.** The positive metal ions, here are called **positive cores** or **kernels** and mobile electrons are **electron pool** or **electron gas.**

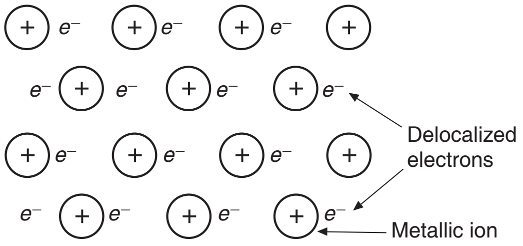


Fig 4.14 Electron sea model

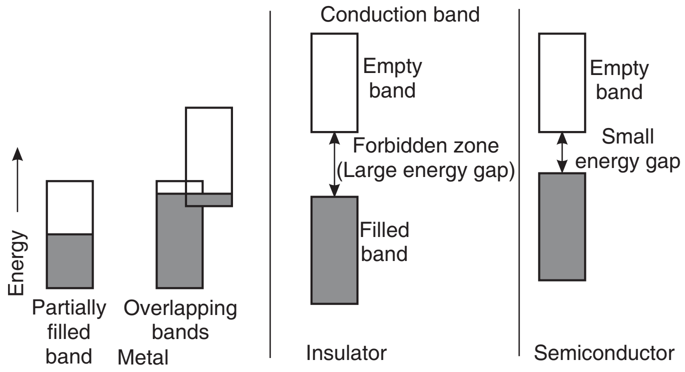
Band Model

This model is based upon molecular orbital theory. According to this theory, a metal lattice has an extremely large number of atoms. The atomic orbitals of these atoms overlap together due to similar symmetry and similar energy resulting to the formation of energy bands. The arrangement of electrons in the different energy bands determines the characteristic of a metal.



(In each case, an unshaded area represents a conduction band)

Fig 4.15 Distinction among metals, insulators and semiconductors.

The highest occupied energy band is called the **valence band** while the lowest unoccupied energy band is called **conduction band.** The properties of various elemental solids can be explained by the gap present between the top of valence band and the bottom of conduction band, called **energy gap** (E_g). In the case of metals, semimetals and non-metals the valence and conduction bands can be seen as

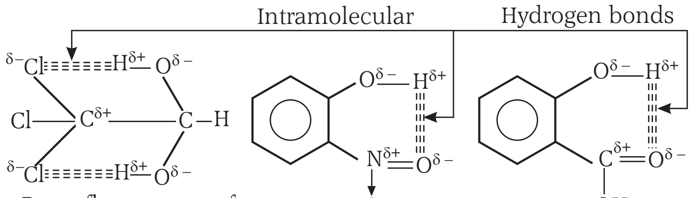
4.12 Hydrogen Bonding

The attractive electrostatic force between a hydrogen atom (which is already covalently attached to a strong electronegative atom *i.e.,* any of F, O and N) and an electronegative atom (any out of F, O and N) is known as hydrogen bond.

Hydrogen bonding is of two types

1. Intramolecular H-bonding

It is seen in a single molecule and when this type of H-bonding leads to linking of two groups in such a way that a ring like structure is formed, the effect is also called **chelation,** *e.g.,*



Butterfly structure of chloral hydrate ($CCl_3CH(OH_2)$) in which 2–OH groups are attached in stable

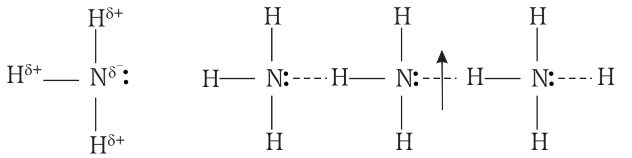
o-nitrophenol

Salicylic acid (*ortho*-hydroxy benzoic acid)

Molecules with intramolecular H-bonding are known to have lower boiling point and melting point.

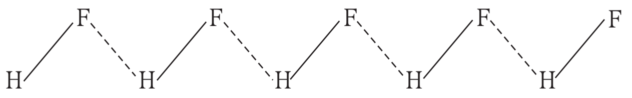
2. Intermolecular H-bonding

It occurs between two or more molecules of similar or different compounds, *e.g.,*



Ammonia molecule

Intermolecular H-bonding in NH_3



Hydrogen fluoride molecule showing intermolecular H-bonding

The intermolecular H-bonding is found to be responsible for high mp and bp of compounds in which it is seen.

Certain organic compounds like alcohols show miscibility with polar solvents like water. It is also attributed to intermolecular H-bonding between alcohol and water molecules.

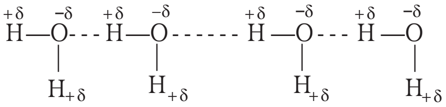
Nature and Importance of H-bonding

1. H-bond is simply dipole-dipole attraction within oppositely partially charged ends.
2. H-bond never involves more than two atoms.
3. Bond energy of H-bond is of the order of 3–10 kcal mol^{-1}, *i.e.,* about 1/10 of covalent bond.
4. As the electronegativity difference of H and other atom to which it is covalently bonded increases, the strength of H-bond increases.
   $H-$ bond order : $H-F > H-O > H > N-H > Cl$
5. All the three atoms X–H---X lie in one plane.

Effects of H-Bonding

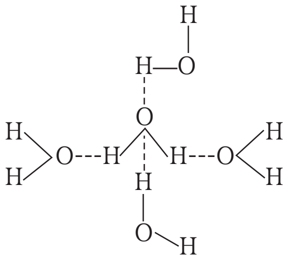
(a) High Boiling Point of Water

Due to polar nature of H_2O, there is association of water molecules giving a liquid state of abnormally high boiling point.



$\overset{+\delta}{H}-\underset{\underset{H_{+\delta}}{|}}{\overset{-\delta}{O}}\cdots\overset{+\delta}{H}-\underset{\underset{H_{+\delta}}{|}}{\overset{-\delta}{O}}\cdots\cdots\overset{+\delta}{H}-\underset{\underset{H_{+\delta}}{|}}{\overset{-\delta}{O}}\cdots\overset{+\delta}{H}-\underset{\underset{H_{+\delta}}{|}}{\overset{-\delta}{O}}$

Actually, in water, one water molecule is joined to four water molecules (two with H-atom and other two with O-atoms.) *Thus, coordination number of water molecule in water is four.*

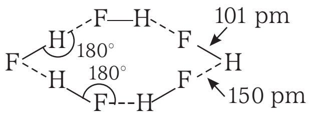


(b) Low Density of Ice as Compared to Water

When ice is formed from liquid water, some air gap is formed (in tetrahedral packing of water molecules). Due to this, volume of ice is greater than liquid water and thus, ice is lighter than water. In another word, we can say that density decreases when ice is formed. Reversely when ice melts, density increases but only upto 4°C, after this intermolecular H-bonding between water molecules breaks, hence volume increases and hence, density decreases. *Thus, water has maximum density at* 4°*C.*

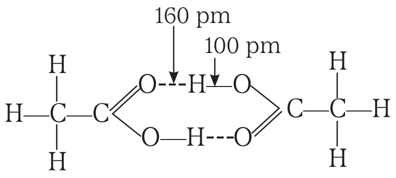
(c) Pentagonal Arrangement of HF

In the gaseous state, several polymeric forms of HF molecules exist in which the monomers are held together through H-bonding. A pentagonal arrangement of H–F molecules is shown below



(d) Dimerisation of Carboxylic Acids

Carboxylic acid dimerises in gaseous state due to H-bonding.



Check Point 3

1. The bonding σ 2*s* orbital has a higher energy than the antibonding $\overset{*}{\sigma}$ 1*s* orbital. Why is the former a bonding orbital while the latter is antibonding?
2. Explain, why N_2 has a greater dissociation energy than N_2^+, whereas O_2 has a lower dissociation energy than O_2^+.
3. Though the electronegativity of N and Cl both are same, NH_3 exists as liquid whereas, HCl as gas, Explain why?
4. Usually solids have high density as compared to liquid but density of ice is less than that of water, Explain.
5. Is hydrogen bond weaker or stronger than the van der Waals' forces?

WORKED OUT
Examples

Example 1 *Which of the following substances has the highest melting point?*

(a) BaO (b) MgO (c) KCl (d) NaCl

Solution (*b*) Melting point depends upon lattice energy. NaCl and KCl have unit charge on their ions while MgO and BaO have two units of charge, therefore, lattice energies of MgO and BaO are expected to be larger than those of NaCl and KCl.

Since, Mg^{2+} is smaller than Ba^{2+}, therefore, MgO has the highest lattice energy and hence, has the highest melting point.

Example 2 *Consider two elements with atomic no. 37 and 53, the bond between their atoms would be*

(a) *covalent* (b) *Ionic*
(c) *coordinate* (d) *metallic*

Solution (*b*) $37 = 1s^2, 2s^2, 2p^6, 3s^2, 3p^6, 4s^2, 3d^{10}, 4p^6, 5s^1$

Thus, the element belongs to IA group and has valency +1.
$53 = 1s^2, 2s^2, 2p^6, 3s^2, 3p^6, 4s^2, 3d^{10}, 4p^6, 5s^2, 4d^{10}, 5p^5$

Since, there are 7 electrons in the valence shell, thus this element requires one electron to complete its octet, *i.e.,* has valency –1.

Hence, element with atomic number 37 transfers its electron to the element having atomic number 53 and results in the formation of an ionic bond.

Example 3 *The molecule ML_x is planar with six pairs of electrons around M in the valence shell. The value of x is*

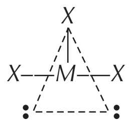
(a) 6 (b) 2 (c) 4 (d) 3

Solution (*c*) Since, the molecule has six pairs, it should have octahedral geometry. But the structure is planar, therefore it should have two lone pairs and four bond pairs. Therefore, value of *x* in ML_x is 4.

Example 4 *A σ bonded molecule MX_3 is T-shaped. The number of non-bonding pairs of electron is*

(a) 0
(b) 2
(c) 1
(d) *can be predicted only if atomic number of M is known*

Solution (*b*) The formula of MX_3 shows the presence of 3σ bonds. Since, it has *T*-shape geometry, it must contain 2 lone pair as



Example 5 *Each carbon in carbon suboxide is*

(a) *sp^2-hybridised*
(b) *sp^3-hybridised*
(c) *sp-hybridised*
(d) *sp^2-hybridised but linked with one coordinate bond.*

Solution (c) The structure of carbon suboxide is

$$:\ddot{\mathrm{O}}\underset{1\pi}{\overset{1\sigma}{=}}\mathrm{C}\underset{1\pi}{\overset{1\sigma}{=}}\mathrm{C}\underset{1\pi}{\overset{1\sigma}{=}}\mathrm{C}\underset{1\pi}{\overset{1\sigma}{=}}\ddot{\mathrm{O}}:$$

Number of hybrid orbitals of carbon = no. of bonds + no. of *lps*
= 2 + 0 = 2

Thus, each carbon is *sp*-hybridised.

Example 6 *Which of the following has least covalent* P—H *bond?*

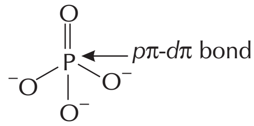
(a) PH_3 (b) P_2H_6 (c) P_2H_5 (d) PH_6^+

Solution (*d*) Due to the presence of positive charge on P, it attracts the electrons of the P—H bond towards itself. Consequently, the bond has some ionic character. In other words, the P—H bond in PH_6^+ is least covalent.

Example 7 *Among the following ions, the pπ - dπ overlapping could be present in*

(a) PO_4^{3-} (b) NO_2^- (c) NO_3^- (d) CO_3^{2-}

Solution (*a*) In PO_4^{3-}, P is sp^3 hybridised, it forms four P—O σ bonds by overlap of sp^3-orbitals of P with *p*-orbitals of O. The bond is, however, formed by overlap of *p*-orbitals of O and *d*-orbitals of P.



N and C, on the other hand, can't form pπ - dπ bond, since they do not have *d*-orbitals.

Example 8 *Which of the following liquids is not deflected by a non-uniform electrostatic field?*

(a) H_2O (b) $CHCl_3$ (c) C_6H_{14} (d) $C_6H_5NO_2$

Solution (c) C_6H_{14} has symmetrical geometry, thus its dipole moment is zero and it is not deflected by a non-uniform electrostatic field.

Example 9 *Which of the following species has the lowest ionization potential?*

(a) O (b) O_2 (c) O_2^+ (d) O_2^-

Solution (*d*) O_2^- has three electrons in the anti-bonding orbitals and hence, has the highest energy of least ionization potential.

Start **Practice** *for* JEE Main

Round I (Topically Divided Problems)

Octet Rule and Ionic Bonding

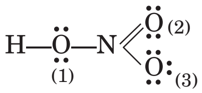
1. Which of the following compounds does not follow the octet rule for electron distribution?
(a) H_2O (b) PH_3
(c) PCl_3 (d) PCl_5

2. Which of the following has an electrovalent linkage?
(a) CH_4 (b) $SiCl_4$
(c) $MgCl_2$ (d) BF_3

3. As compared to covalent compounds, electrovalent compounds generally have
(a) low melting points and low boiling points
(b) high melting points and high boiling points
(c) low melting points and high boiling points
(d) high melting points and low boiling points

4. Arrange the bonds in order of increasing ionic character in the molecules; LiF, K_2O, N_2, SO_2 and ClF_3. **[NCERT]**
(a) $N_2 < ClF_3 < SO_2 < LiF < K_2O$
(b) $N_2 < SO_2 < ClF_3 < K_2O < LiF$
(c) $N_2 < ClF_3 < SO_2 < K_2O < LiF$
(d) $N_2 < SO_2 < ClF_3 < Lif < K_2O$

5. In the following Lewis structure of HNO_3, the formal charge on O_3 atom is **[NCERT]**



(a) 0 (b) −1
(c) −2 (d) +1

6. Arrange the following bonds in order of increasing ionic character N—H, F—H, C—H and O—H **[NCERT]**
(a) F—H < O—H < C—H < N—H
(b) N—H < O—H < C—H < F—H
(c) C—H < N—H < O—H < F—H
(d) F—H < C—H < O—H < N—H

7. X, Y and Z elements have 4, 5 and 7 valence electrons. Among the given the correct formula is **[NCERT]**
(a) XH_3 (b) YH_4
(c) HZ (d) YH_5

8. If the electronegativity difference between two atoms A and B is 2.0, then the percentage of covalent character in the molecule is
(a) 54% (b) 46%
(c) 23% (d) 72%

9. Among the following isostructural compounds, identify the compound which has the highest lattice energy.
(a) LiF (b) LiCl
(c) NaCl (d) MgO

10. A pair of compounds which have odd electrons in the group NO, CO, ClO_2, N_2O_5, SO_2 and O_3 are
(a) NO and ClO_2 (b) CO and SO_2
(c) ClO_2 and CO (d) SO_2 and O_3

11. CaO and NaCl have the same crystal structure and approximately the same ionic radii. If U is the lattice energy of NaCl, the approximate lattice energy of CaO is
(a) $\frac{U}{2}$ (b) U
(c) $2U$ (d) $4U$

12. An atom X has three valence electrons and atom Y has six valence electrons. The compound formed between them will have the formula
(a) X_2Y_6 (b) XY_2
(c) X_2Y_3 (d) X_3Y_2

Covalent Bonding and Coordinate Bonding

13. The order of resultant dipole moment in CO_2, NF_3 and $CHCl_3$ is **[NCERT]**

(a) $NF_3 < CO_2 < CHCl_3$
(b) $CHCl_3 < CO_2 < NF_3$
(c) $CO_2 < NF_3 < CHCl_3$
(d) $CO_2 < CHCl_3 < NF_3$

14. Which of the following does not have a coordinate bond?

(a) SO_2 (b) H_2SO_3
(c) HNO_2 (d) HNO_3

15. Which is the most covalent?

(a) C—F (b) C—O
(c) C—S (d) C—Br

16. The number of electrons involved in the bond formation of N_2 molecule is

(a) 2 (b) 4
(c) 6 (d) 10

17. Which has maximum covalent character?

(a) $SiCl_4$ (b) $MgCl_2$
(c) NaCl (d) $AlCl_3$

18. Why BeH_2 molecule has a zero dipole moment although the Be—H bonds are polar? **[NCERT]**

(a) Because of its linear geometry
(b) Because of two opposite and equal dipoles
(c) Both (a) and (b)
(d) None of the above

19. Although both CO_2 and H_2O are triatomic molecules, the shape of the H_2O molecule is bent while that of CO_2 is linear. This is because **[NCERT]**

(a) C is less electronegative than H
(b) C is more electronegative than H
(c) lone pairs are present on O atom of H_2O but not in O atom of CO_2
(d) lone pairs carrying O is the central atom in H_2O but not in CO_2

20. The types of bonds present in $CuSO_4 \cdot 5H_2O$ are only

(a) electrovalent and covalent
(b) electrovalent and coordinate
(c) electrovalent, covalent and coordinate covalent
(d) covalent and coordinate covalent.

21. Isostructural species are those which have the same shape and hybridisation. Among the given species identify the isostructural pairs. **[NCERT Exemplar]**

(a) NF_3 and BF_3 (b) BF_4^- and NH_4^+
(c) BCl_3 and $BrCl_3$ (d) NH_3 and NO_3^-

22. N_2 is less reactive than CN^- due to

(a) difference in spin quantum number
(b) presence of more electrons in orbitals
(c) absence of dipole moment
(d) None of the above

23. Which of the following has a bond order of 1.75?

(a) ClO_3^- (b) ClO_4^-
(c) NO_3^- (d) CO_3^{2-}

24. Amongst LiCl, RbCl, $BeCl_2$ and $MgCl_2$, the compounds with the greatest and the least ionic character, respectively are

(a) LiCl and RbCl (b) RbCl and $MgCl_2$
(c) RbCl and $BeCl_2$ (d) $MgCl_2$ and $BeCl_2$

25. The correct order of decreasing polarity is

(a) $HF > SO_2 > H_2O > NH_3$
(b) $HF > H_2O > SO_2 > NH_3$
(c) $HF > NH_3 > SO_2 > H_2O$
(d) $H_2O > NH_3 > SO_2 > HF$

26. Which one of the following compounds has bond angle as nearly 90°?

(a) NH_3 (b) H_2S
(c) H_2O (d) CH_4

27. The bond angles of NH_3, NH_4^+ and NH_2^- are in the order

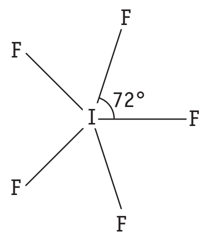
(a) $NH_2^- > NH_3 > NH_4^+$ (b) $NH_4^+ > NH_3 > NH_2^-$
(c) $NH_3 > NH_2^- > NH_4^+$ (d) $NH > NH_4^+ > NH_2^-$

28. In the electronic structure of H_2SO_4, the total number of unshared electrons is

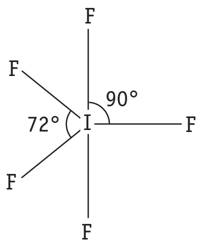
(a) 20 (b) 16
(c) 12 (d) 8

29. The structure of IF_5 can be best described as

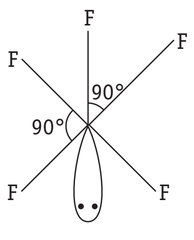
(a)



(b)



(c)



(d) None of these

30. The correct order in which the O—O bond length increases in the following is

(a) $O_2 < O_3 < H_2O_2$ (b) $H_2O_2 < O_3 < O_2$
(c) $O_3 < O_2 < H_2O_2$ (d) $O_2 < H_2O_2 < O_3$

31. Although geometries of NH_3 and H_2O molecules are distorted tetrahedral, bond angle in water is less than that of ammonia. This is due to **[NCERT]**

(a) *lp-lp* repulsion in NH_3 and *lp bp* repulsion in H_2O
(b) *lp-lp* repulsion in H_2O and *lp-bp* repulsion in NH_3
(c) *bp-bp* repulsion in NH_3 and *lp-bp* repulsion in H_2O
(d) None of the above

32. In which of the following molecule/ion all the bonds are not equal? **[NCERT Exemplar]**

(a) XeF_4 (b) BF_4^- (c) C_2H_4 (d) SiF_4

33. Apart from tetrahedral geometry, another possible geometry for CH_4 is square planar with the four H-atoms at the corners of the square and the C atom at its centre. But CH_4 does not have square planar geometry because of **[NCERT]**

(a) the absence of *d* orbital
(b) the smaller size of C atom
(c) the smaller size of H atom
(d) All of the above

34. Which of the following species has tetrahedral geometry? **[NCERT Exemplar]**

(a) BH_4^- (b) NH_2^-
(c) CO_3^{2-} (d) H_3O^+

35. The correct order towards bond angle is

(a) $sp^3 < sp^2 < sp$ (b) $sp < sp^2 < sp^3$
(c) $sp < sp^3 < sp^2$ (d) $sp^2 < sp^3 < sp$

36. Which molecule is linear ?

(a) H_2S (b) NO_2 (c) ClO_2 (d) CO_2

37. Which of the following pair has same structure?

(a) PCl_5 and SF_6 (b) SO_2 and NH_3
(c) PH_3 and BCl_3 (d) NH_4^+ and SO_4^{2-}

38. In a polar molecule, the ionic charge is 4.8×10^{-10} esu. If the interionic distance is 1 Å unit, then the dipole moment is

(a) 0.48 debye (b) 4.18 debye
(c) 4.8 debye (d) 41.8 debye

VBT, Resonance, Hybridisation

39. The *d*-orbital involved in sp^3d hybridisation is

(a) $d_{x^2-y^2}$ (b) d_{xy}
(c) d_{z^2} (d) d_{zx}

40. In which molecule are all atoms coplanar?

(a) PF_3 (b) NH_3
(c) BF_3 (d) CH_4

41. Resonance structures can be written for

(a) O_3 (b) NH_3
(c) CH_4 (d) H_2O

42. Which of the following statements is not correct?

(a) Hybridisation is the mixing of atomic orbitals prior to their combining into molecular orbitals
(b) sp^2 hybrid orbitals are formed from two *p*-atomic orbitals and one *s*-orbital
(c) d^2sp^3 hybrid orbitals are directed towards the corners of a regular octahedron
(d) dsp^3 hybrid orbitals are all at 90° to one another

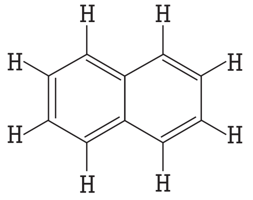
43. The bond in the formation of fluorine molecule will be

(a) due to *s-s* overlapping
(b) due to *s-p* overlapping
(c) due to *p-p* overlapping
(d) due to hybridisation

44. Which of the following angle corresponds to sp^2 hybridisation? **[NCERT Exemplar]**

(a) 90° (b) 120°
(c) 180° (d) 109°

45. Number of π bonds and σ bonds in the following structure is



(a) 6, 19 (b) 4, 20
(c) 5, 19 (d) 5, 20

46. Which orbital is used by oxygen atom to form a sigma bond with other oxygen atom in O_2 molecule?

(a) pure *p*-orbital
(b) sp^2-hybrid orbital
(c) sp^3-hybrid orbital
(d) *sp*-hybrid orbital

47. Two hybrid orbitals have a bond angle of 120°. The percentage of *s* character in the hybrid orbital is nearly

(a) 25% (b) 33%
(c) 50% (d) 66%

48. The hybrid state of S in SO_3 is similar to that of

(a) C in C_2H_2 (b) C in C_2H_4
(c) C in CH_4 (d) C in CO_2

49. Which of the following will provide the most efficient overlap?

(a) s-s
(b) s-p
(c) sp^2-sp^2
(d) sp-sp

50. Considering x-axis as the internuclear axis, which out of the following will not form a sigma bond ? **[NCERT]**

(a) $1s$ and $1s$
(b) $1s$ and $2p_x$
(c) $2p_y$ and $2p_y$
(d) $1s$ and $2s$

51. The types of hybrid orbitals of nitrogen in NO_2^+, NO_3^- and NH_4^+ respectively are expected to be **[NCERT Exemplar, AIEEE 2011]**

(a) sp, sp^3 and sp^2
(b) sp, sp^2 and sp^3
(c) sp^2, sp and sp^3
(d) sp^2, sp^3 and sp

52. In which of the following the carbon atoms marked with star is sp hybridised?

(a) $\overset{*}{C}H_2{=}CH{-}\overset{\overset{O}{\|}}{C^*}{-}O{-}H$

(b) $CH_3{-}\overset{*}{C}H_2{-}OH$

(c) $\overset{*}{C}H_3{-}CH_2{-}\overset{\overset{O}{\|}}{C^*}{-}H$

(d) $CH_3{-}\overset{*}{C}{\equiv}CH$

53. The possible number of resonance structures for NO_3^- is. **[NCERT]**

(a) 2
(b) 3
(c) 4
(d) 5

Molecular Orbital Theory (MOT)

54. Molecular orbital theory was developed mainly by

(a) Pauling
(b) Mulliken
(c) Thomson
(d) Pauling and Slater

55. Which one is paramagnetic and has the bond order half (0.5)?

(a) F_2
(b) N_2
(c) O_2
(d) H_2^+

56. Which of the following molecular orbitals has two nodal planes?

(a) $\sigma 2p_x$
(b) $\pi 2p_y$
(c) $\pi^* 2p_y$
(d) $\sigma^* 2p_x$

57. In which of the following diatomic molecules/ions is the bond order of each molecule/ion = 2.5?

(a) O_2^+, NO, CN^-
(b) CN^-, N_2^+, N_2
(c) N_2^+, NO, O_2^+
(d) O_2^+, CN^-, N_2^+

58. Bond energies in NO, NO^+ and NO^- are such as

(a) $NO^- > NO > NO^+$
(b) $NO^+ > NO^- > NO$
(c) $NO > NO^- > NO^+$
(d) $NO^+ > NO > NO^-$

59. The bond length of species O_2, O_2^+ and O_2^- are in the order of

(a) $O_2^+ > O_2 > O_2^-$
(b) $O_2^- > O_2 > O_2^+$
(c) $O_2 > O_2^+ > O_2^-$
(d) $O_2 > O_2^- > O_2^+$

60. In which of the following pairs molecules have bond order three and are isoelectronic?

(a) CN^-, CO
(b) CO, O_2^+
(c) NO^+, CO^+
(d) CN^-, O_2^+

61. In the formation of NO^+ from NO, the electron is removed from

(a) a σ orbital
(b) a π orbital
(c) a σ^* orbital
(d) a π^* orbital

62. Which among the following molecules/ions is diamagnetic?

(a) Super oxide ion
(b) Oxygen
(c) Carbon molecule
(d) Unipositive ion of N_2 molecule

63. If Z-axis is the molecular axis, then π-molecular orbitals are formed by the overlap of

(a) $s + p_z$
(b) $p_x + p_y$
(c) $p_z + p_z$
(d) $p_x + p_x$

64. N_2 and O_2 are converted into monocations, N_2^+ and O_2^+ respectively. Which of the following is wrong?

(a) In N_2^+, N—N bond weakens
(b) In O_2^+, the O—O bond order increases
(c) In O_2^+, paramagnetism decreases
(d) N_2^+ becomes diamagentic

65. Which of the following diatomic molecules would be stabilized by the removal of an electron?

(a) C_2
(b) CN
(c) N_2
(d) O_2

Metallic and Hydrogen Bonding

66. In the following, which bond will be responsible for maximum value of hydrogen bond?

(a) N—H
(b) O—H
(c) F—H
(d) S—H

67. Two ice cubes are pressed over each other until they unite to form one block. Which one of the following forces dominates for holding them together?

(a) Dipole-dipole interaction
(b) van der Waals' forces
(c) Hydrogen bond formation
(d) Covalent attraction

68. Which of the following does not apply to metallic bond?
(a) Overlapping valence orbitals
(b) Mobile valence electrons
(c) Delocalized electrons
(d) Highly directed bonds

69. The maximum possible number of hydrogen bonds in a H_2O molecule that can participate is
(a) 1 (b) 2 (c) 3 (d) 4

70. Hydrogen bonds are formed in many compounds *e.g.*, H_2O, HF, NH_3. The boiling point of such compounds depends to a large extent on the strength of hydrogen bond and the number of hydrogen bonds. The correct decreasing order of the boiling points of above compounds is **[NCERT Exemplar]**
(a) $HF > H_2O > NH_3$ (b) $H_2O > HF > NH_3$
(c) $NH_3 > HF > H_2O$ (d) $NH_3 > H_2O > HF$

Round II (Mixed Bag)

Only One Correct Option

1. The electronic configuration of four elements *L*, *P*, *Q* and *R* are given in brackets $L(1s^2, 2s^2, 2p^4)$, $P(1s^2, 2s^2, 2p^6, 3s^1)$, $Q(1s^2, 2s^2, 2p^6, 3s^2, 3p^5)$, $R(1s^2, 2s^2, 2p^6, 3s^2)$. The formula of ionic compounds that can be formed between these elements are
(a) L_2P, RL, PQ and R_2Q (b) LP, RL, PQ and RQ
(c) P_2L, RL, PQ and RQ_2 (d) LP, R_2L, P_2Q, and RQ

2. With which of the given pairs CO_2 resembles?
(a) $HgCl_2, C_2H_2$ (b) C_2H_2, NO_2
(c) $HgCl_2, SnCl_4$ (d) N_2O, NO_2

3. Which of the following has maximum dipole moment?
(a) NCl_3 (b) NBr_3
(c) NH_3 (d) NI_3

4. Carbon suboxide (C_3O_2) has recently been shown as a component of the atmosphere of Venus. Which of the following formulation represents the correct ground state Lewis structure for carbon suboxide?
(a) :O: C::C :C: O:
(b) : O ::C::C: C ::O:
(c) $:\ddot{\text{O}}::\text{C}::\text{C}::\text{C}::\ddot{\text{O}}:$
(d) : O: C: C: C: O:

5. Among the species: $CO_2, CH_3COO^-, CO, CO_3^{2-}$, HCHO which has the weakest C—O bond?
(a) CO (b) CO_2
(c) CO_3^{2-} (d) CH_3COO^-

6. In which one of the following cases breaking of covalent bond takes place?
(a) Boiling of H_2O (b) Melting of KCN
(c) Boiling of CF_4 (d) Melting of SiO_2

7. Which of the following does not contain coordinate bond?
(a) BH_4^- (b) NH_4^+ (c) CO_3^{2-} (d) H_3O^+

8. The species C_2
(a) has one σ bond and one π bond
(b) has both π bonds
(c) has both σ bonds
(d) does not exist

9. The AsF_5 molecule is trigonal bipyramidal. The hybrid orbitals used by the As atoms for bonding are
(a) $d_{x^2-y^2}, d_{z^2}, s, p_x, p_y$ (b) d_{xy}, s, p_x, p_y, p_z
(c) $s, p_x, p_y, p_z, d_{z^2}$ (d) $d_{x^2-y^2}, s, p_x, p_y$

10. The bond angle between two hybrid orbitals is 105°. The percentage of *s*-character of hybrid orbital is between
(a) 50–55% (b) 9–12%
(c) 22–23% (d) 11–12%

11. The true statements from the following are
1. PH_5 and $BiCl_5$ do not exist
2. $p\pi$-$d\pi$ bond is present in SO_2
3. Electrons travel at the speed of light
4. SeF_4 and CH_4 have same shape
5. I_3^+ has bent geometry

(a) 1, 3 (b) 1, 2, 5
(c) 1, 3, 5 (d) 1, 2, 4

12. The HOMO in CO is
(a) π-bonding (b) π-antibonding
(c) σ-antibonding (d) σ-bonding

13. Which of the following hydrogen bonds are strongest in vapour phase?
(a) HF---HF (b) HF---HCl
(c) HCl---HCl (d) HF---HI

14. Which combination is best explained by the coordinate covalent bond?
(a) $H^+ + H_2O$ (b) Cl + Cl
(c) $Mg + \frac{1}{2} O_2$ (d) $H_2 + I_2$

15. The species having pyramidal shape is

(a) SO_3 (b) BrF_3

(c) SiO_3^{2-} (d) OSF_2

16. Assuming that Hund's rule is violated, the bond order and magnetic nature of the diatomic molecule B_2 is

(a) 1 and diamagnetic

(b) 0 and diamagnetic

(c) 1 and paramagnetic

(d) 0 and paramagnetic

17. Peroxide ion

(i) has five completely filled antibonding molecular orbitals

(ii) is diamagnetic

(iii) has bond order one

(iv) is isoelectronic with neon

Which of these are correct?

(a) (ii) and (iii) (b) (i), (ii) and (iv)

(c) (i), (iii) and (iii) (d) (i) and (iv)

18. Which one of the following conversions involve change in both hybridisation and shape?

(a) $CH_4 \longrightarrow C_2H_6$ (b) $NH_3 \longrightarrow NH_4^+$

(c) $BF_3 \longrightarrow BF_4^-$ (d) $H_2O \longrightarrow H_3O^+$

19. Which is the correct statement about σ and π molecular orbitals? Statements are

(i) π-bonding orbitals are ungerade

(ii) π-antibonding orbitals are ungerade

(iii) σ-antibonding orbitals are gerade

(a) (i) only (b) (ii) and (iii) only

(c) (iii) only (d) (ii) only

20. Two types of F*X* F angles are present in which of the following molecules? ($X =$ S, Xe, C)

(a) SF_4 (b) XeF_4

(c) SF_6 (d) CF_4

21. Which of the following statements is not correct from the view point of molecular orbital therory? **[NCERT Exemplar]**

(a) Be_2 is not a stable molecule

(b) He_2 is not stable but He_2^+ is expected to exist

(c) Bond strength of N_2 is maximum amongst the homonuclear diatomic molecules belonging to the second period

(d) The order of energies of molecular orbitals in N_2 molecule is

$$\sigma 2s < \sigma^* 2s < \sigma 2p_z < (\pi 2p_x \approx \pi 2p_y) < (\pi^* 2p_x \approx \pi^* 2p_y) < \sigma^* 2p_z$$

22. Match the species in Column I with the geometry/shape in Column II. **[NCERT Exemplar]**

Column I		Column II	
A.	H_3O^+	1.	Linear
B.	$HC \equiv CH$	2.	Angular
C.	ClO_2^-	3.	Tetrahedral
D.	NH_4^+	4.	Trigonal bipyramidal
		5.	Pyramidal

Codes

	A	B	C	D
(a)	1	2	3	4
(b)	5	1	2	3
(c)	1	2	5	3
(d)	3	2	4	1

23. Match the species in Column I with the bond order in Column II. **[NCERT Exemplar]**

Column I		Column II	
A.	NO	1.	1.5
B.	CO	2.	2.0
C.	O_2^-	3.	2.5
D.	O_2	4.	3.0

Codes

	A	B	C	D
(a)	3	4	1	2
(b)	1	2	3	4
(c)	2	4	3	1
(d)	3	1	2	4

More than One Correct Option

24. Which of the following have identical bond order? **[NCERT Exemplar]**

(a) CN^- (b) NO^+

(c) O_2^- (d) O_2^{2-}

25. Which of the following attain the linear structure? **[NCERT Exemplar]**

(a) $BeCl_2$ (b) NCO^+

(c) NO_2 (d) CS_2

26. Which of the following statements are correct about CO_3^{2-}? **[NCERT Exemplar]**

(a) The hybridisation of central atom is sp^3

(b) Its resonance structure has one C—O single bond and two C ═O double bonds

(c) The average formal charge on each oxygen atom is 0.67 units

(d) All C—O bond lengths are equal

27. Which of the following statements are not correct? **[NCERT Exemplar]**

(a) NaCl being an ionic compound is a good conductor of electricity in the solid state

(b) In canonical structures there is a difference in the arrangement of atoms

(c) Hybrid orbitals form stronger bonds than pure orbitals

(d) VSEPR theory can explain the square planar geometry of XeF_4

28. Which of the following pairs contain same number of electrons but their shapes are different?

(a) BF_3, BCl_3 (b) CH_4, NH_3

(c) NH_3, H_2O (d) $BeCl_2, BeF_2$

Assertion and Reason

Directions (Q. Nos. 29 to 32) *Each of these questions contains two statements : Statement* I (*Assertion*) *and Statement* II (*Reason*). *Each of these questions also has four alternative choices, only one of which is the correct answer. You have to select one of the codes* (*a*), (*b*), (*c*), (*d*) *given below*

(a) Statement I is true; Statement II is true; Statement II is a correct explanation for Statement I.

(b) Statement I is true; Statement II is true; Statement II is not a correct explanation for Statement I.

(c) Statement I is true; Statement II is false.

(d) Statement I is false; Statement II is true.

29. **Statement I** F—F bond has low bond dissociation energy.

Statement II The fluorine has low reactivity.

30. **Statement I** CO_2 molecules are linear.

Statement II The value of dipole moment of CO_2 is zero.

31. **Statement I** Sodium chloride formed by the action of chlorine gas on sodium metal is a stable compound.

Statement II This is because sodium and chloride ions acquire octet in sodium chloride formation. **[NCERT Exemplar]**

32. **Statement I** Though the central atom of both NH_3 and H_2O molecules are sp^3 hybridised, yet H—N—H bond angle is greater than that of H—O—H.

Statement II This is because nitrogen atom has one lone pair and oxygen atom has two lone pairs. **[NCERT Exemplar]**

33. **Statement I** Among the two O—H bonds in H_2O molecule, the energy required to break the first O—H bond and the other O—H bond is the same.

Statement II This is because the electronic environment around oxygen is the same even after breakage of one O—H bond. **[NCERT Exemplar]**

Comprehension Based Questions

Directions (Q. Nos. 34 to 36) The electronic configurations of three elements, A, B and C are given below.
Answer the questions 34 to 36 on the basis of these configurations. **[NCERT Exemplar]**

A	$1s^2$	$2s^2$	$2p^6$		
B	$1s^2$	$2s^2$	$2p^6$	$3s^2$	$3p^3$
C	$1s^2$	$2s^2$	$2p^6$	$3s^2$	$3p^5$

34. Stable form of A may be represented by the formula

(a) A (b) A_2

(c) A_3 (d) A_4

35. The molecular formula of the compound formed from B and C will be

(a) BC (b) B_2C

(c) BC_2 (d) BC_3

36. The bond between B and C will be

(a) ionic (b) covalent

(c) hydrogen (d) coordinate

Directions (Q. Nos. 37 to 39) According to the concept of resonance, whenever a single Lewis structure can't describe a molecule accurately, then a number of structures called resonating structures, with similar energy, same relative position of all nuclei and with same number of paired and unpaired electrons are drawn.
The molecule as such has a single definite structure which is the resonance hybrid of the resonating structures and can't as such be depicted by a single Lewis structure. As a result of resonance, the bond order may change in many molecules or ions and is given by formula.

$$\text{Bond order} = \frac{\text{Total number of bonds between two atom in all the structures}}{\text{Total number of resonating structures}}$$

37. Which of the following molecule contains one pair of non-bonding electrons?

(a) H_2O

(b) HF

(c) NH_3

(d) CH_4

38. What is the bond order of benzene?

(a) 2 (b) 1.5

(c) 2.5 (d) 3.0

39. Bond order of N—O bonds in nitrate ion is

(a) 1.25

(b) 2.00

(c) 1.45

(d) 1.33

Previous Years' Questions

40. In which of the following pairs, the two species are not isostructural? [AIEEE 2012]

(a) CO_3^{2-} and NO_3^- (b) PCl_4^+ and $SiCl_4$

(c) PF_5 and BrF_5 (d) AlF_6^{3-} and SF_6

41. Among the following the maximum covalent character is shown by the compound [AIEEE 2011]

(a) $FeCl_2$ (b) $SnCl_2$

(c) $AlCl_3$ (d) $MgCl_2$

42. The structure of IF_7 is [AIEEE 2011]

(a) square pyramid (b) trigonal bipyramid

(c) octahedral (d) pentagonal bipyramid

43. Which of the following has maximum number of lone pairs associated with Xe? [AIEEE 2011]

(a) XeO_3 (b) XeF_4

(c) XeF_6 (d) XeF_2

44. The number and types of bonds between two carbon atoms in calcium carbide is [AIEEE 2011, 2005]

(a) one sigma, two pi (b) one sigma, one pi

(c) two sigma, one pi (d) two sigma, two pi

45. Using MO theory predict which of following species has the shortest bond length? [AIEEE 2009]

(a) O_2^+ (b) O_2^{2+}

(c) O_2^- (d) O_2^{2-}

46. Which one of the following constitutes a group of the isoelectronic species? [AIEEE 2008]

(a) C_2^{2-}, O_2^-, CO, NO (b) $NO^+, C_2^{2-}, CN^-, N_2$

(c) $CN^-, N_2, O_2^{2-}, CO_2^{2-}$ (d) N_2, O_2^-, NO^+, CO

47. Which of the following molecules/ions does not contain unpaired electrons? [AIEEE 2006]

(a) O_2^{2-} (b) B_2 (c) N_2^+ (d) O_2

48. In which of the following molecules/ions all the bonds are not equal? [AIEEE 2006]

(a) SF_4 (b) SiF_4 (c) XeF_4 (d) BF_4

49. Of the following sets which one does not contain isoelectric species? [AIEEE 2005]

(a) $BO_3^{3-}, CO_3^{2-}, NO_3^-$ (b) $SO_3^{2-}, CO_3^{2-}, NO_3^-$

(c) CN^-, N_2, C_2^{2-} (d) $PO_4^{3-}, SO_4^{2-}, ClO_4^-$

50. The molecular shapes of SF_4, CF_4 and XeF_4 are [AIEEE 2005]

(a) different with 1, 0 and 2 lone pairs of electrons on the central atom, respectively

(b) different with 0, 1 and 2 lone pairs of electrons on the central atom, respectively

(c) the same with 1, 1 and 1 lone pair of electrons on the central atoms, respectively

(d) the same with 2, 0 and 1 lone pairs of electrons on the central atom, respectively

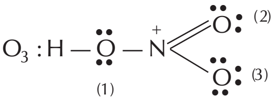
the Guidance

Round I

4. $N_2 < SO_2 < ClF_3 < K_2O < LiF$

5. HNO_3 :



Formal charge on an atom in a Lewis structure

$$= [\text{total number of valence electrons in free atom}] - [\text{total number of non-bonding (lone pairs) electrons}] - \frac{1}{2}[\text{total number of bonding or shared electrons}]$$

Formal charge on $H = 1 - 0 - \frac{1}{2} \times 2 = 0$

Formal charge on $N = 5 - 0 - \frac{1}{2} \times 8 = 1$

Formal charge on $O(1) = 6 - 4 - \frac{1}{2} \times 4 = 0$

Formal charge on $O(2) = 6 - 4 - \frac{1}{2} \times 4 = 0$

Formal charge on $O(3) = 6 - 6 - \frac{1}{2} \times 2 = -1$

6. Greater is the electronegativity difference between the two bonded atoms, greater is the ionic character.

	N—H	F—H	C—H and	O—H
Electronegativity	(3.0 − 2.1) =	(4.0 − 2.1) =	(2.5 − 2.1) =	(3.5 − 2.1)
difference	0.9	1.9	0.4	= 1.4

Therefore, increasing order of ionic character of the given bonds is as follow

$$C—H < N—H < O—H < F—H$$

7. In order to complete their octet *X* requires 4, *Y* requires 3 and *Z* requires only one electron.

Thus, valency of X, Y and Z are respectively 4,3,1.

Thus, the formulae of their hydrides are XH_4, YH_3 and YH_5, $Z—H$.

Thus, YH_5 is the correct formula.

8. % ionic character $= 16(x_A - x_B) + 3.5(x_A - x_B)^2$

$$= 16 \times 2 + 3.5 \times (2^2)$$

$$= 46\ \%$$

$\therefore$ The % covalent character $= 100 - 46 = 54\ \%$

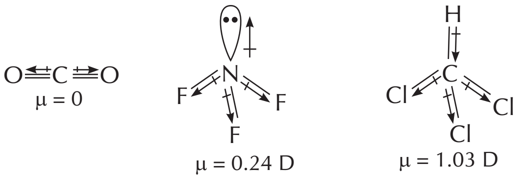
9. Lattice energy $\propto$ charge of ions $\propto \frac{1}{\text{size of ions}}$

11. Lattice energy, $U = \frac{q_1 q_2}{r^2}$

Since, interionic distances in CaO and NaCl are similar, (larger cation has smaller anion and *vice -versa*) *r* is almost the same. Therefore, lattice energy depends only on charge.

Since, the magnitude of charge on Na^+ and Cl^- ions is same *i.e.*, unity and that on Ca^{2+} and O^{2-} ions is 2 each, therefore, the lattice energy of CaO is four times the lattice energy of NaCl, *i.e.*, 4U.

13.

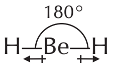


Order of dipole moment

$$CO_2 < NF_3 < CHCl_3$$

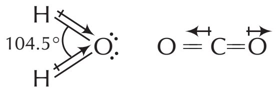
17. $SiCl_4$ because covalent character α charge of cation.

18. BeH_2 molecule is linear. The two equal bond dipoles point in opposite directions and cancel the effect of each other. That's why its dipole moment is zero.



BeH_2 molecule, $\mu = 0$

19. The net dipole moment of CO_2 is zero. This is because the two equal bond dipoles ($\overset{\delta^+}{C}—\overset{\delta^-}{O}$) point in opposite directions and cancel the effect of each other. Hence, CO_2 is linear. On the other hand, H_2O molecule is found to have a net dipole moment (1.84 D) which suggests that the two O—H dipoles are not in a straight line opposing each other, *i.e.*, H_2O does not have linear structure, but they (O—H) must be inclined to each other at certain angle. Thus, H_2O molecule has a bent structure in which the two O—H bonds are oriented at an angle of 104.5°.



21. (a) $NF_3 \Rightarrow 3\,bp + 1\,lp \Rightarrow$ pyramidal

$BF_3 \Rightarrow 3\,bp + 0\,lp \Rightarrow$ trigonal planar

(b) $BF^- \Rightarrow 4\,bp + 0\,lp \Rightarrow$ tetrahedral

$NH_4^+ \Rightarrow 4\,bp + 0\,lp \Rightarrow$ tetrahedral

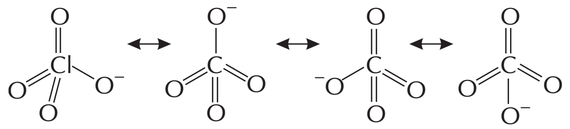
(c) $BCl_3 \Rightarrow 3\,bp + 0\,lp \Rightarrow$ trigonal planar

$BrCl_3 \Rightarrow 3\,bp + 2\,lp \Rightarrow$ T-shape

(d) $NH_3 \Rightarrow 3bp + 1\,lp \Rightarrow$ pyramidal

$NO_3^- \Rightarrow 3\,bp + 0\,lp \Rightarrow$ trigonal planar

23. The resonating structures of ClO_4^- are as



$$\text{Bond order} = \frac{\text{Total number of bonds between Cl and O}}{\text{Total number of resonating structures}}$$

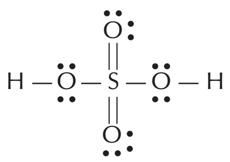
$$= \frac{7}{4} = 1.75$$

24. According to Fajan's rule, largest cation and smallest anion form ionic bond.

27. As the number of lone pairs of electrons increases, bond angle decreases. Thus, the order of bond angle is

$$\underset{(\text{no } lp)}{NH_4^+} > \underset{(1\,lp)}{NH_3} > \underset{(2\,lp)}{NH_2^-}$$

28.

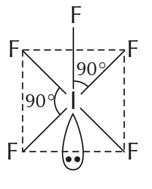


Total number of unshared electrons $= 4 \times 4 = 16$.

29. Number of hybrid orbitals = no. of bp + no. of lp

$$= 5 + 1 = 6$$

Thus, hybridisation is sp^3d^2 but geometry, due to the presence of one lone pair, is square pyramidal, *i.e.,*

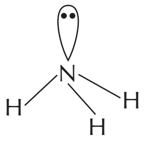


30. H—O—O—H, O ← O═O, O═O

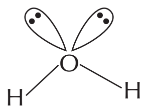
Due to resonance, in O_3, the O—O bond length will be in between O═O and O—O.

O—O being a single bond is larger than the O═O.

31.



NH_3
$bp = 3$
$lp = 1$



H_2O
$bp = 2$
$lp = 2$

In H_2O molecule, there is lone pair-lone pair repulsion due to the presence of two lone pairs of electrons while in NH_3 molecule there found only lone pair-bond pair repulsion. According to VSEPR theory, the former one is more stronger and hence, the bond angle in water is less than that of ammonia (NH_3).

32. $XeF_4 \Rightarrow 4bp + 2\,lp \Rightarrow$ square planar $\Rightarrow$ all bonds equal

$BF_4^- \Rightarrow 4bp + 0\,lp \Rightarrow$ tetrahedral (all bonds equal)

$C_2H_4 \Rightarrow$  $\Rightarrow$ C ═ C bond is not equal to C—H bond

$SiF_4 \Rightarrow 4\,bp + 0\,lp \Rightarrow$ tetrahedral (all bonds equal)

Thus, in C_2H_4 all the bonds are not equal.

33. Electronic configuration of carbon

In ground state : ${}_6C — 1s^2, 2s^2, 2p_x^1, 2p_y^1$

In excited state : $1s^2, \underbrace{2s^1, 2p_x^1, 2p_y^1, 2p_z^1}_{sp^3 \text{ hybridised}}$

In CH_4 molecule, carbon is sp^3 hybridised, so it is tetrahedral in shape. For square planar, dsp^2 hybridisation is required which is not possible in carbon due to absence of d-orbitals. Furthermore according to VSEPR theory, the four bonded electron pairs around carbon atom arranged themselves in a regular tetrahedron geometry. For tetrahedral structure, the bond angle is 109°28′ while in square planar structure, the bond angle is 90°.Therefore, in tetrahedral structure repulsions between bonded electron pairs is less than that of the square planar.

34. $BH_4^- \Rightarrow 4\,bd + 0\,lp \Rightarrow sp^3$ hybridised = tetrahedral geomety

38. Given, ionic charge $= 4.8 \times 10^{-10}$ esu

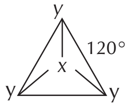
and, ionic distance $= 1$ Å $= 10^{-8}$ cm

We know that

Dipole moment = ionic charge × ionic distance

$$= 4.8 \times 10^{-10} \times 10^{-8}$$
$$= 4.8 \times 10^{-18} \text{ esu cm}^{-1}$$
$$= 4.8 \text{ debye}$$

44. For sp^2 hybridisation, the geometry is generally triangular planar.



Thus, bond angle is 120°.

45. A single bond $= 1\sigma$ bond

Double bond $= 1\sigma$ and 1π bonds

Triple bond $= 1\sigma$ and 2π bonds

Thus, the given molecule contains 19σ and 5π bonds.

47. Since bond angle is 120°, orbital is sp^2 hybridised. In sp^2 hybridised orbital, % of s-character $= \frac{1}{1+2} \times 100 = 33\%$

50. Only (c) will not form a σ-bond. Because on taking x-axis as the internuclear axis, $2p_y$ and $2p_y$ orbitals overlap sideway (lateral overlapping) resulting in the formation of a π-bond.

51. $NO_2^+ = 2bp + 0lp$ = linear = sp hybridised

$NO_3^- = 3\ bp + 0\ lp \Rightarrow sp^2$ hybridised

$NH_4^+ \Rightarrow 4\ bp + 0\ lp \Rightarrow sp^3$ hybridised

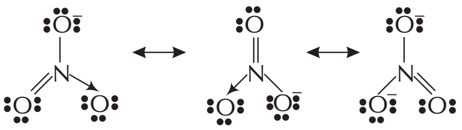
52. (a) 
$\underset{\substack{sp^2\\(3\sigma)}}{\dot{C}H_2}=CH-\underset{\substack{sp^2\\(3\sigma)}}{\overset{\overset{\displaystyle O}{\|}}{C^{\bullet}}}-O-H$

(b) 
$CH_3\underset{\substack{sp^3\\(4\sigma)}}{\dot{C}}H_2OH$

(c) 
$CH_3-CH_2-\underset{\substack{sp^2\\(3\sigma)}}{\overset{\overset{\displaystyle O}{\|}}{C^{\bullet}}}-H$

(d) 
$CH_3-\underset{\substack{sp\\(2\sigma)}}{\dot{C}}\equiv CH$

53. Nitrate ion, NO_3^-



55. $H_2^+ (1+1-1=1) = \sigma 1s^1$

$$BO = \frac{1-0}{2} = 0.5$$

Since one unpaired electron is peresent, it is a paramagnetic species.

58. $NO^+ (7+8-1=14)$

$= \sigma 1s^2, \overset{*}{\sigma} 1s^2, \sigma 2s^2, \overset{*}{\sigma} 2s^2, \pi 2p_x^2 \approx 2p_y^2, \sigma 2p_z^2, \overset{*}{\pi} 2p_x^0 \approx \overset{*}{\pi} 2p_y^0$

$$BO = \frac{10-4}{2} = 3$$

$NO (7+8=15)$ $\quad BO = \frac{10-5}{2} = 2.5$

$NO^- (7+8+1=16)$

$$BO = \frac{10-6}{2} = 2$$

Since, bond length $\propto \frac{1}{BO}$

So, the order of bond length is

$$NO^- < NO < NO^+$$

59. Find BO for each species from MO configuration (BO of $O_2^+ = 2.5, O_2 = 2\ O_2^- = 1.5$). So, the order of bond length is $O_2^- > O_2 > O_2^+$.

60. For BO 3, there should be 14 electrons which are present in CN^- and CO.

61. $NO (7+8=15) = \sigma 1s^2 \overset{*}{\sigma} 1s^2, \sigma 2s^2, \overset{*}{\sigma} 2s^2, \sigma 2p_z^2, \pi 2p_x^2$

$$\approx \pi 2p_y^2, \overset{*}{\pi} 2p_x^1$$

$NO^+ (7+8-1=14) = \sigma 1s^2, \overset{*}{\sigma} 1s^2, \sigma 2s^2, \overset{*}{\sigma} 2s^2, \sigma 2p_z^2, \pi 2p_x^2$

$$\approx \pi 2p_y^2$$

Thus, electron is removed from $\overset{*}{\pi}$ orbital.

62. $C_2 (6+6=12)\ \sigma 1s^2, \overset{*}{\sigma} 1s^2, \sigma 2s^2, \overset{*}{\sigma} 2s^2, \pi 2p_x^2 \approx \pi 2p_y^2$

64. $N_2 (7+7=14) = \sigma 1s^2 \overset{*}{\sigma} 1s^2, \sigma 2s^2, \overset{*}{\sigma} 2s^2, \pi 2p_x^2 \approx \pi 2p_y^2, \sigma 2p_z^2$

$$BO = \frac{10-4}{2} = 3$$

$N_2^+ (7+7-1=13) = \sigma 1s^2 \overset{*}{\sigma} 1s^2, \sigma 2s^2, \overset{*}{\sigma} 2s^2, \pi 2p_x^2 \approx \pi 2p_y^2, \sigma 2p_z^1$ (paramagnetic)

$$BO = \frac{9-4}{2} = 2.5$$

$O_2 (8+8=16) = \sigma 1s^2, \overset{*}{\sigma} 1s^2, \sigma 2s^2, \overset{*}{\sigma} 2s^2, \sigma 2p_z^2,$

$$\pi 2p_z^2 \approx \pi 2p_y^2, \overset{*}{\pi} 2p_x^1 \approx \overset{*}{\pi} 2p_y^1$$

$$BO = \frac{10-6}{2} = 2$$

$O_2^+ (8+8-1=15)$

$$BO = \frac{10-5}{2} = 2.5$$

Thus, $N_2 > N_2^+$ and $O_2^+ > O_2$ (stability order)

N_2^+ is paramagnetic.

65. In O_2, there are two electrons in antibonding orbitals. Removal of one electron from the O_2 molecule gives O_2^+ in which the number of antibonding electrons is one less and hence, BO increases. Thus, removal of one electron from O_2 stabilizes the molecule.

66. Hydrogen bonding $\propto$ electronegativity.

69. In case of water, five water molecules are attached together through four hydrogen bonding.

70. Although F forms stronger H bonding, but H_2O has higher boiling point due to more number of H_2O molecules that bonded together by H bonds.

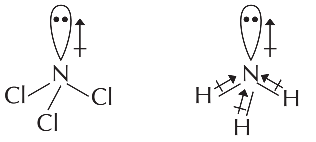
Round II

1. Valencies of *L, Q, P* and *R* is –2, –1, +1, and +2 respectively. So, they will form P_2L, *RL PQ*, and RQ_2.

2. All have linear structure.

$$O{=}C{=}O,\ Cl{-}Hg{-}Cl,\ H{-}C{\equiv}C{-}H$$

3. Electronegativity difference between N (3.0) and Cl (3.0) is zero and hence, N—Cl bonds are non-polar. As a result, the overall dipole moment of NCl_3 molecule and its direction is just the dipole moment of the lone pair of electrons.



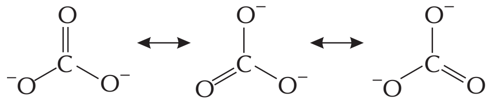
On the other hand, N—Br, (3.0 – 2.8), N—I (3.0 – 2.5) and N—H (3.0 – 2.1) bonds are polar and hence, contribute towards the overall dipole moment of the respective molecules. Since, the EN difference is higher in case of N—H bonds, therefore, NH_3 has the higher dipole moment.

4. In structure (c), all the atoms have complete octet. Thus, it is the correct representation of carbon suboxide.

5. Among the given species, the bond dissociation energy of C—O bond is minimum in case of CO_3^{2-} by which C—O bond become more weaker in CO_3^{2-} or the bond order of CO_3^{2-}(1.33) is minimum so, the bond become weaker.

6. During melting of SiO_2, the giant network structure held by covalent bonds breaks to give individual molecules of SiO_2. In contrast, during boiling of H_2O only change of state occurs from liquid to gaseous; during melting of KCN, electrostatic attraction between K^+ and CN^- ions is overcome; during boiling of CF_4, van der Waals' forces of attraction breaks.

7. CO_3^{2-} has the following structure



It contains only covalent bonds.

8. In C_2 only 2π bonds are present.

9. AsF_5 has sp^3d hybridisation. In sp^3d hybridisation, it is d_{z^2} orbitals which takes part.

10. *s*-character ∝ bond angle

For 25% *s* character (as in sp^3 hybrid orbital), bond angle is 109.5°, for 33.3% *s* character (as in sp^2 hybrid orbital), bond angle is 120° and for 50% *s* character (as in *sp* hybrid orbital), bond angle is 180°.

Similarly, when the bond angle decreases below 109.5°, the *s*-character will decrease accordingly.

$$\text{Decrease in bond angle} = 120° - 109.5° = 10.5°$$

$$\therefore\ \text{Decrease in } s\text{-character} = 33.3 - 25 = 8.3$$

$$\text{Actual decrease in bond angle} = 109.5° - 105° = 4.5°$$

$$\therefore\ \text{Expected decrease in } s\text{-character} = \frac{8.3}{10.5} \times 4.5 = 3.56\%$$

Thus, the *s*-character should decrease by about 3.56%, *i.e.*, *s*-character = 25 – 3.56 = 21.44%

11. SeF_4 has distorted tetrahedral geometry while, CH_4 has tetrahedral geometry.

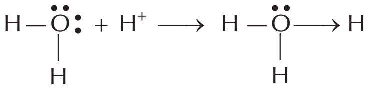
Speed of electron ≠ speed of light

12. HOMO, means highest occupied molecular orbital and in CO (14 electron ion), σ bonding molecular orbital is HOMO.

$$CO = \sigma 1s^2, \overset{*}{\sigma} 1s^2, \sigma 2s^2, \overset{*}{\sigma} 2s^2, \pi 2p_x^2 \approx \pi 2p_y^2, \sigma 2p_z^2$$

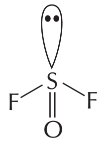
13. A compound having maximum electronegative element will form strong hydrogen bond.

14.



$$H{-}\ddot{O}{:}(H) + H^+ \longrightarrow H{-}\ddot{O}(H){\longrightarrow}H$$

15. OSF_2 has pyramidal shape.



16. B_2 : Total electrons = 10

Configuration: $\sigma 1s^2, \overset{*}{\sigma} 2s^2, \sigma 2s^2, \overset{*}{\sigma} 2s^2, \pi 2p_x^1 \approx \pi 2p_y^1$

If Hund's rule is violated, then

$$\sigma 1s^2, \overset{*}{\sigma} 1s^2, \sigma 2s^2, \overset{*}{\sigma} 2s^2, \pi 2p_x^2 \approx \pi 2p_y^0$$

So, diamagnetic,

$$\text{Bond order} = \frac{6-4}{2} = 1$$

17. Peroxide ion is O_2^{2-}

$$O_2^{2-}(18) = \sigma 1s^2, \overset{*}{\sigma} 1s^2, \sigma 2s^2, \overset{*}{\sigma} 2s^2, \sigma 2p_z^2$$

$$\pi 2p_x^2 \approx \pi 2p_y^2, \overset{*}{\pi} 2p_x^2 \approx \overset{*}{\pi} 2p_y^2$$

$$\text{Bond order} = \frac{N_b - N_a}{2} = \frac{10-8}{2} = 1$$

It contains four completely filled antibonding molecular orbitals. Since, all the electrons are paired, O_2^{2-} is diamagnetic.

Peroxide ion is isoelectronic with argon, not with neon.

18. (a)

	CH_4	$\longrightarrow$	$CH_3{-}CH_3$	
	$4bp + 0\,lp$		$4bp$	$4bp$
Hybridisation	sp^3		sp^3	sp^3
Structure	Tetrahedral		Tetrahedral	

(b)

	NH_3	$\longrightarrow$	NH_4^+
	$3bp + 1\,lp$		$4bp$
Hybridisation	sp^3		sp^3
Structure	Pyramidal		Tetrahedral

(c) $\underset{3bp}{BF_3} \longrightarrow \underset{4bp}{BF_4^-}$

Hybridisation sp^2 sp^3

Structure Trigonal planar Tetrahedral

(d) $\underset{2bp\,+\,2lp}{H_2O} \longrightarrow \underset{3bp\,+\,1\,lp}{H_3O^+}$

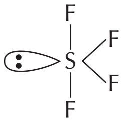
Hybridisation sp^3 sp^3

Structure angular pyramidal

Thus, conversion of BF_3 into BF_4^- involves change in both hybridisation and shape.

19. According to molecular orbital theory, π-bonding orbitals an ungerade.

20. FXF angles of two types are present in sp^3d hybrid orbitals. Since, SF_4 shows sp^3d hybridisation as follows, therefore, it exhibits two different FXF angles.



21. (a) $Be_2\ (4 + 4 = 8) = \sigma 1s^2, \overset{*}{\sigma}1s^2, \sigma 2s^2, \overset{*}{\sigma}2s^2$

$$BO = \frac{4-4}{2} = 0$$

Thus, it does not exist.

(b) $He_2\ (2 + 2 = 4) = \sigma 1s^2, \overset{*}{\sigma}1s^2, BO = \frac{2-2}{2} = 0$

Hence, it also does not exist.

$He_2^+\ (2 + 2 - 1 = 3) = \sigma 1s^2, \overset{*}{\sigma}1s^1, BO = \frac{2-1}{2} = 0.5$

Since the bond order is not zero, this molecule is expected to exist.

(c) $N_2\ (7+7=14) = \sigma 1s^2, \overset{*}{\sigma}1s^2, \sigma 2s^2, \overset{*}{\sigma}2s^2, \pi 2p_x^2 \approx \pi 2p_y^2, \sigma 2p_z^2$

$$BO = \frac{10-4}{2} = 3$$

(d) It is incorrect

22. (a) $H_3O^+ = 3bp + 1lp \Rightarrow$ pyramidal

(b) $HC \equiv CH$ = linear as sp hybridised

(c) $ClO_2^- \Rightarrow 2bp + 2lp \Rightarrow$ angular

(d) $NH_4^+ \Rightarrow 4bp + 0lp \Rightarrow$ tetrahedral

23. $NO\ (7 + 8 = 15) = \sigma 1s^2, \overset{*}{\sigma}1s^2, \sigma 2s^2, \overset{*}{\sigma}2s^2, \sigma 2p_z^2,$

$$\pi 2p_x^2 \approx \pi 2p_y^2, \overset{*}{\pi}2p_x^1$$

$$BO = \frac{10-5}{2} = 2.5$$

$CO\ (6 + 8 = 14)$

$$BO = \frac{10-4}{2} = 3$$

$O_2^-\ (8 + 8 + 1 = 17) = \sigma 1s^2, \overset{*}{\sigma}1s^2, \sigma 2s^2, \overset{*}{\sigma}2s^2, \sigma 2p_z^2,$

$$\pi 2p_x^2 \approx \pi 2p_y^2, \overset{*}{\pi}2p_x^2 \approx \overset{*}{\pi}2p_y^1$$

$$BO = \frac{10-7}{2} = 1.5$$

$O_2\ (8 + 8 = 16),\ BO = \frac{10-6}{2} = 2$

24. $CN^-\ (6 + 7 + 1 = 14)$

$NO^+\ (7 + 8 - 1 = 14)$

$O_2^-\ (8 + 8 + 1 = 17)$

$O_2^{2-}\ (8 + 8 + 2 = 18)$

Thus, CN^- and NO^+ because of the presence of same number of electrons have same bond order.

25. Cl—Be—Cl

linear

non -linear

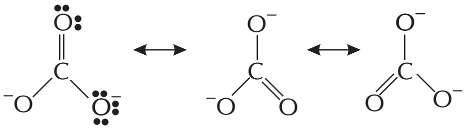
non-linear

S═C═S

linear

26. $CO_3^{2-} \Rightarrow 3bp + 0lp \Rightarrow$ trigonal planar

$\Rightarrow sp^2$ hybridised



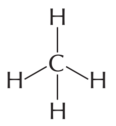
Due to resonance all C—O bond lengths are equal.

Average FC over O = 0.67

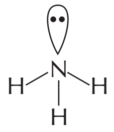
27. (a) NaCl is a bad conductor of electricity in solid state due to the absence of free ions.

(b) Canonical structures differ in the arrangement of electrons, not in the arrangement of atoms.

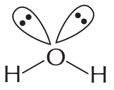
28. The central atom in each of three molecules CH_4, NH_3 and H_2O undergoes sp^3 hybridisation. In CH_4 no lone pair is present. In NH_3 one lone pair is present while in water two lone pairs are present.



tetrahedral (109°28′)



pyramidal structure (106.5°)



V-structure (104.5°)

29. Fluorine is highly reactive because F—F bond has low bond dissociation energy.

30. The values of dipole moments provide valuable information about the structure of molecules.

31. $\underset{(2,8,1)}{\text{Na}} + \underset{(2,8,7)}{\text{Cl}} \longrightarrow \underset{(2,8)\ (2,8,8)}{\text{NaCl}}$

Thus, statement (II) is the correct explanation for statement (I).

32.

Thus, statement (II) is the correct explanation for statement (I).

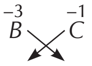
33.

The O—H bond energy is same for both the bonds. After the cleavage of one O—H bond, the electronic environment get changed. Hence, statement II is incorrect.

34. Since the outer shell of *A* is completely filled it exists as monovalent atom, *i.e.*, as *A*.

35. Valency of $B = -3$

Valency of $C = -1$

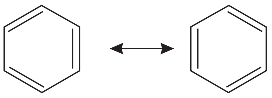


or BC_3

36. Since both *B* and *C* are electronegative atom, *i.e.*, non-metals, the bond formed between them is covalent.

37. In NH_3, nitrogen has one lone pair of electrons.

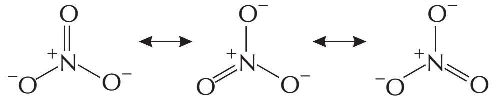
38.



$$80 = \frac{\text{Total number of bonds between two atoms in all structure}}{\text{Total number of resonating structures}}$$

$$= \frac{2+1}{2} = 1.5$$

39. Nitrate ion has the following three resonating structures.



As it evident, three O-atoms are attached to the N-atom by four bonds, therefore, bond order of N—O bond is $\frac{4}{3} = 1.33$.

40. (a) CO_3^{2-}, NO_3^-; triangular planar

(b) $PCl_4^+, SiCl_4$; tetrahedral

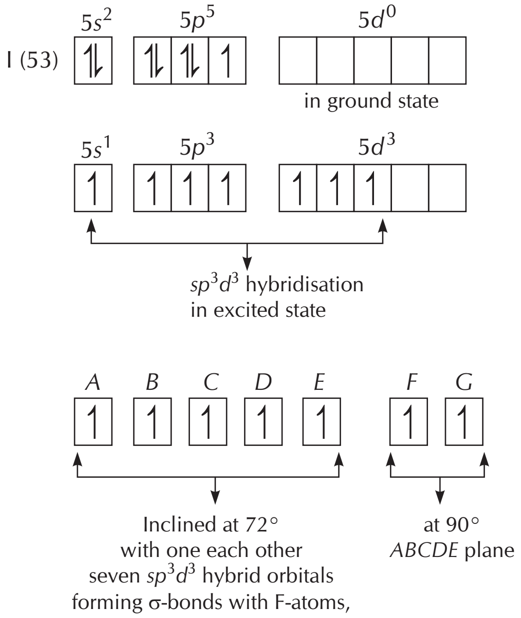
(c) PF_5; trigonal bipyramidal

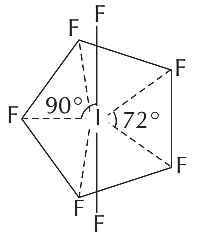
BrF_5; square pyramidal

(d) AlF_6^{3-}, SF_6; octahedral

41. In all the given compounds, anion is same (Cl^-), hence polarising power is decided by size and charge of cation. Al^{3+} with maximum charge and smallest size has maximum polarising power hence, $AlCl_3$ is maximum covalent.

42. IF_7





Pentagonal bipyramidal structure

43.

	Species	Hybridisation of Xe	Lone pair of Xe	Bonding pairs
(a)	XeO_3	sp^3	1	3
(b)	XeF_4	sp^3d^2	2	4
(c)	XeF_6	sp^3d^3	1	6
(d)	XeF_2	sp^3d	3 (Max.)	2

44. $CaC_2 \rightleftharpoons Ca^{2+} + \underset{\text{carbide ion}}{C_2^{2-}}$

In carbide ion, two carbon atoms are joined by triple bond (It is isoelectronic with N_2)

$$—C{\equiv}C—$$

with two π and one σ-bonds.

45. Higher the bond order shorter the bond length. Therefore O_2^{2+} has the shortest bond length (BO = 3)

Bond order of remaining species are

$O_2^{+}(2.5)$, $O_2^{-}(1.5)$ and $O_2^{2-}(1)$

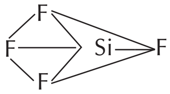
46. Isoelectronic species have same number of electrons, NO^+ C_2^{2-}, CN^- and N_2 all have 14 electrons.

47. O_2^{2-} (Total number of electrons = 18)

$$\sigma 1s^2, \overset{*}{\sigma} 1s^2, \sigma 2s^2, \overset{*}{\sigma} 2s^2, \sigma 2p_z^2, \pi 2p_x^2 \approx \pi 2p_y^2, \overset{*}{\pi} 2p_x^2 \approx \overset{*}{\pi} 2p_y^2$$

48. SF_4 has trigonal bipyramidal geometry, lone pair of electrons repels the axial bond pair and decrease the bond angle to 73°.

SiF_4



regular tetrahedral

XeF_4

5.1 Fundamentals of Thermodynamics

Several terms used in thermodynamics are described below.

System, Surroundings and Boundary

A **system** is the specific portion which is under thermodynamic studies. Besides system, the rest of the universe, *i.e.*, **all other matter that can interact** with the system is called **surroundings.**

The real or imaginary surfaces or lines separating two or more systems or a system from its surroundings is called **boundary**. The boundary may be diathermic (*i.e.*, allow passage of heat) or adiabatic (*i.e.*, does not allow passage of heat).

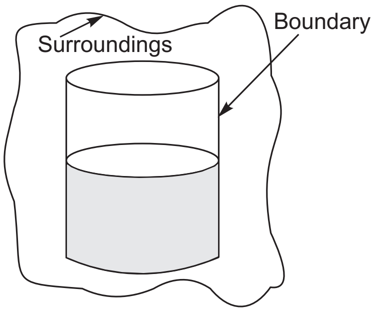

Fig. 5.1 Representation of system surrounding and boundary

The study of heat or any other form of energy into or out of a system, due to physical or chemical transformations is called **thermodynamics**. *It is concerned with energy changes only and not with the total energy of a body.*

Types of System

Depending upon the nature of boundary, the system can be of the following types :

(a) Open System

An open system can exchange matter as well as energy with its surroundings. The boundary here is not sealed and non-insulated thermally, *e. g.*, all living systems, car engines, etc. For such a system, $\Delta m \neq 0$, $\Delta E \neq 0$.

(b) Close System

A *closed system* does not exchange matter with its surroundings but can exchange energy in the form of heat, work or radiations *i.e.*, the boundary is sealed but not insulated. *e.g.,* hot water kept in a closed container. For such a system, $\Delta m = 0$, $\Delta E \neq 0$.

(c) Isolated System

An *isolated system* neither exchange matter nor energy with its surroundings *i.e.,* the boundary is sealed as well as insulated, *e.g.,* thermosflask. For such a system, $\Delta m = 0$, $\Delta E = 0$.

Besides above written types, the system may be **homogeneous** (with identical properties and chemical composition throughout *i.e.*, with one phase only) or **heterogeneous** (consisting of two or more phases).

Caution Point *A phase may be defined as the physically distinct and mechanically separable part of the system from the other parts.*

Macroscopic Properties

The physical quantities used to define the state of a system are called properties. Thermodynamics deals with matter in bulk (*i.e.*, in large excess) and the properties that arises because of bulk behaviour of matter are called **macroscopic properties** or **bulk properties of the system.**

These are further of two types

(a) Intensive Properties

The properties which do not depend upon the quantity of matter are called **intensive properties**, *e.g.*, pressure, temperature, density, concentration, surface tension, viscosity, refractive index etc.

(b) Extensive Properties

The properties which depend upon the quantity of matter are called **extensive properties,** *e.g.*, volume, number of moles, enthalpy, entropy, mass, work etc.

The above properties can be best understood by the following example : If at a certain temperature, a solution is taken in a beaker and a partition is inserted in the beaker in such a way that it divides the solution into two halves, the volume of the solution becomes half while temperature of each part remains the same. It is obvious, temperature is an intensive property while volume is an extensive property.

It may be noted that the **ratio of the two extensive properties becomes intensive in nature**. *e.g.,* mass and volume are extensive properties, but the ratio of mass and volume *i.e.,* density is intensive, it is independent of quantity of matter. Similarly, heat capacity is extensive, but molar heat capacity is intensive. In general, if x is any extensive property of n moles of system, the molar property of the system x_m is intensive because it refers to the property of 1 mole of the system and is independent of the quantity of matter $x_m = x/n$.

Intensive properties cannot be added or subtracted directly. Only extensive properties can be added or subtracted.

State Variables

A thermodynamic system is said to be in certain state when all of its properties are fixed *i.e.,* its measurable properties have a definite value. If any of such properties changes, then the state of system also changes. The measurable properties here are called **state variables,** *e.g.* temperature, pressure, volume, composition, number of moles, internal energy, entropy, enthalpy, free energy, etc.

State and Path Functions

The property of a system whose value depends only upon the state of the system (*i.e.*, initial and final state) and is independent of the path or manner by which the state is reached is called the **state function**. Thus, most of the common variables are infact state functions.

Examples of state functions are pressure, volume, temperature, internal energy, enthalpy, entropy etc.

If $z = f(x, y)$ and $\frac{\partial}{\partial y}\left(\frac{\partial z}{\partial x}\right) = \frac{\partial}{\partial x}\left(\frac{\partial z}{\partial y}\right)$, then z is called exact differentiable function. The above condition is also representing that z should be state function and hence, we may say that **state functions are exact differentials.**

The functions that depend upon the path followed are called **path functions** *e.g.,* work done, heat etc.

Types of Processes

The state of a variable can be changed *via* a thermodynamic process.

These processes are of the following types

(a) Adiabatic Process

In adiabatic process, the system does not exchange heat with its surroundings *i.e.,* no heat can flow in or out of the system. For an adiabatic process,

$$dq = 0$$

(b) Isothermal Process

The isothermal process is carried out at constant temperature *i.e.,* it is the process in which temperature remains fixed. For an isothermal process,

$$dT = 0 \text{ and thus, } \Delta E = 0$$

(c) Isobaric Process

In isobaric process, change of state is brought about at constant pressure *i.e.*,

$$dp = 0$$

(d) Isochoric Process

In an isochoric process, volumes of the system remains constant *i.e.,*

$$dV = 0$$

The above four basic thermodynamic processes can be represented in a graph as

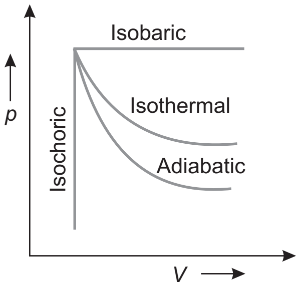

Fig. 5.2 *pV* graph for various thermodynamic processes

(e) Cyclic Process

When a system is undergone a number of different states and finally returns to its initial state, the process is called **cyclic**. For such a process, change in internal energy and enthalpy is zero *i.e.,*

$$dE \text{ or } dU = 0$$

and $$dH = 0$$

e.g., in a process shown below, the system returns to the original state *A* after successive changes.

$$A(p_1, V_1, T_1) \longrightarrow B(p_2, V_2, T_1) \longrightarrow C(p_2, V_3, T_2) \longrightarrow A(p_1, V_1, T_1)$$

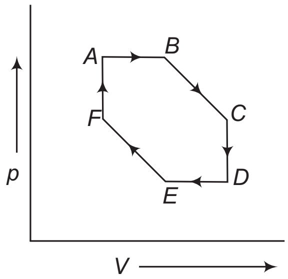
(f) Reversible Process

A reversible system is defined as a system where change takes place infinitesimally slow and the direction of which at any point can be reversed by infinitesimal change in the state of the system. Reversible process is an ideal process and here every intermediate state is in equilibrium with others, if any.

(g) Irreversible Process

An irreversible process is one, the direction of which cannot be reversed by small change in variables. All natural processes are generally irreversible and the net work done in an irreversible process is somewhat less than that in reversible process, *i.e.*, $W_{\text{irr}} < W_{\text{rev}}$.

Sample **Problem 1** *Identify the adiabatic steps in the following cyclic process.*



Temperature at A, B and F is T_1 and at C, D and E is T_2. Given $T_1 > T_2$

(a) $F \rightarrow A$; $D \rightarrow E$ (b) $B \rightarrow C$; $E \rightarrow F$
(c) $B \rightarrow C$; $C \rightarrow D$ (d) $A \rightarrow B$; $E \rightarrow E$

Interpret (*b*) (i) $A \rightarrow B$ (Temperature and pressure are constant).

∴ It is isothermal and isobaric process.

(ii) $B \rightarrow C$ It is adiabatic expansion in which temperature falls from T_1 and T_2.

(iii) $C \rightarrow D$ (Temperature and volume are constant)

∴ This process is isothermal and isochoric.

(iv) $D \rightarrow E$ (Temperature and pressure are constant)

∴ It is isothermal and isobaric contraction.

(v) $E \rightarrow F$ (It is adiabatic compression in which temperature increases from T_2 to T_1).

(vi) $F \rightarrow A$ (Temperature and volume are constant).

∴ It is isothermal and isochoric process.

Thermodynamic Equilibrium

It is an equilibrium that involves following three equilibria

(i) Mechanical equilibrium, *i.e.,* when no work is done on the system or by the system.

(ii) Thermal equilibrium, *i.e.,* temperature remains constant throughout the system including the surroundings.

(iii) Chemical equilibrium, *i.e.,* composition of the system remains constant and definite.

5.2 Work

If an object is displaced through a distance *dx* by a force *F*, the amount of work done is given by

$$W = F \times dx$$

i. e., it is the product of two factors

(i) Intensity factor, *F*

(ii) Capacity factor, *dx*

Work done is a path function, not a state function, as depends upon the path followed. Work done on the system increases the energy of the system and is taken as negative while work done by the system is taken as positive.

i.e., work done by the system = – ve
work done on the system = + ve

Different Types of Work

Work can be defined in the following ways

(a) Gravitational Work, W_g

$$W_g = mgh$$

where, mg = intensity factor, h = capacity factor

(b) Electrical Work, W_e

$$W_e = VQ \text{ (potential difference)}$$

where, V = intensity factor (quantity of electricity)
Q = capacity factor

(c) Mechanical Work or Pressure-volume Work, W

Let a system expands by which the position moves by a very little distance dx. Then the small work done by the system,

$$dW = -F_{\text{ext}} \cdot dx = -p_{\text{ext}} \cdot A \cdot dx = -p_{\text{ext}} \cdot dV$$

where, A = cross sectional area of piston.
p = pressure (intensity factor)
ΔV = change in volume (capacity factor)

Work Done in Isothermal Irreversible Expansion or Compression

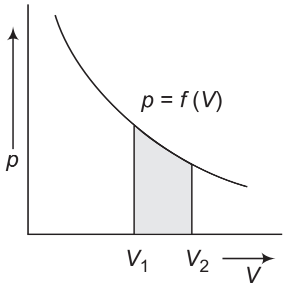


Fig. 5.3 Irreversible work done

In an isothermal irreversible expansion, the total work done by the system can be obtained by integrating $-pdV$ when its volume changes from V_1 to V_2 at constant external pressure, *i.e.*,

$$W = -\int_{V_1}^{V_2} p_{\text{ext}} \cdot dV$$

Geometrically, the magnitude of work done represents the area bounded between the curve $p = f(V)$ and volume axis from V_1 to V_2.

The mechanical work is considered as expansion (if $\Delta V > 0$) or contraction (if $\Delta V < 0$). Thus, $W_{\text{exp}ansion}$ is negative and $W_{\text{contraction}}$ is positive.

Work Done in Isothermal Reversible Expansion or Compression of an Ideal Gas

In reference to the above example, we know that $W = -p \cdot \Delta V$. If the external pressure is not constant and changes in finite number of steps in going from volume V_1 to V_2 then the net work done is the summation of $-p \cdot \Delta V$ terms over all the steps as shown in the Fig. 5.4 and is represented as

$$W = -\Sigma p \cdot \Delta V$$

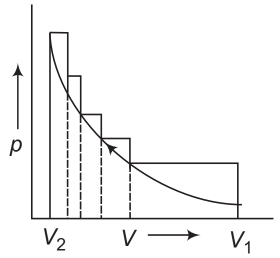

Fig. 5.4 *pV* plot when pressure changes in finite steps during compression from initial volume V_1 to final volume V_2

Further assume that the pressure is not constant but changes during the process in such a manner so that it is always infinitesimally greater than the pressure of the gas, then at each stage of compression the volume decreases by an infinitesimal amount, dV. In such a condition, the work done on the gas can be calculated by the relation

$$W = -\int_{V_1}^{V_2} p_{\text{ex}}\, dV$$

Here, p_{ex} at each state is equal to $(p_{\text{in}} + dp)$ in case of compression. In an expansion process under similar conditions, the external pressure is always less than the pressure of the system *i.e.*, $p_{\text{ex}} = (p_{\text{in}} \pm dp)$. Such processes are called reversible processes.

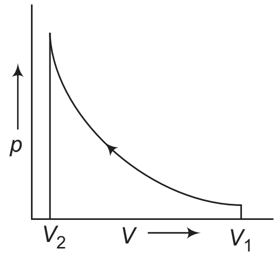

Fig. 5.5 *pV* plot when pressure changes in infinite steps (reversible conditions) during compression from initial volume V_1 to final volume V_2

Thus, the work can be related to internal pressure of the system under reversible conditions as

$$W_{\text{rev}} = -\int_{V_1}^{V_2} p_{\text{ex}}\, dV = -\int_{V_1}^{V_2} (p_{\text{in}} \pm dp) dV$$

Since $dp \times dV$ is very small,

$$W_{\text{rev}} = -\int_{V_1}^{V_2} p_{\text{in}}\, dV$$

Now, the pressure of the gas (p_{in} or p) can be expressed in terms of its volume through gas equation. For n mole of an ideal gas, *i.e.*, $pV = nRT$. $\Rightarrow$ $p = \frac{nRT}{V}$

Therefore, at constant temperature (isothermal process).

$$W_{\text{rev}} = -\int_{V_1}^{V_2} nRT \frac{dV}{V} = -nRT \ln \frac{V_2}{V_1}$$

$$= -2.303 nRT \log \frac{V_2}{V_1} \text{ or } -2.303 nRT \log \frac{p_1}{p_2}$$

W_{rev} is Maximum Work

Work done during isothermal expansion of an ideal gas is given by the equation

$$W = -p_{\text{ex}}\, \Delta V$$

Now, for a given change of volume (ΔV), W can be maximum if p_{ex} is maximum. But for expansion p_{ex} has to be smaller than p_{in}. This means that for getting maximum work, the external pressure has to be infinitesimally smaller than the internal pressure of the gas. These conditions are nearly close to reversibility. Thus, for a given change of volume

$$W_{\text{rev}} = W_{\max}$$

Free Expansion

Expansion of a gas in vacuum ($p_{\text{ex}} = 0$) is called free expansion. No work is done during free expansion (*i.e.*, $W = 0$) of an ideal gas whether the process is reversible or irreversible.

Caution Points

- *(i) The magnitude of work in isothermal irreversible expansion increases as the number of step involved increases.*
- *(ii) The magnitude of work will be more in isothermal irreversible compression than isothermal reversible compression, for the same change in volume. The magnitude of work decreases as the number of steps involved increases.*
- *(iii) The magnitude of work will be more in isothermal reversible expansion of an ideal gas than real gas.*

Work Done in Adiabatic Expansion or Compression Processes

In adiabatic expansion, no heat is allowed to enter or leave the system, hence $q = 0$.

$\therefore$ From first law of thermodynamics $\Delta E = W$. The molar heat capacity at constant volume of an ideal gas is given by $C_V = \left(\frac{dE}{dT}\right)_V$

or $$dE = C_V \cdot dT$$

and for finite changes, $\Delta E = C_V \times \Delta T = W$

(a) Work Done in Reversible Adiabatic Expansion

Let p be the external pressure and ΔV be the increase in volume then work done by the system is $W = -p\Delta V$ and if ΔT is the fall in temperature, then $C_V \Delta T = -p\Delta V$

For very small change in a reversible process and for one mole of a gas,

$$C_V dT = -p\, dV = \frac{-RT}{V} dV \text{ or } C_V \frac{dT}{T} = -R\frac{dV}{V}$$

For a process in which the volume of a gas is V_1 at temperature T_1 and the new volume is V_2 at a temperature T_2,

$$C_V \int_{T_1}^{T_2} \frac{dT}{T} = R \int_{V_1}^{V_2} \frac{dV}{V}$$

On taking log, we get

$$\log \frac{T_1}{T_1} = \frac{R}{C_V} \log \frac{V_1}{V_2}$$

We know that $C_p - C_V = R$ dividing by C_V

$$\frac{C_p}{C_V} - 1 = \frac{R}{C_V}; \gamma - 1 = \frac{R}{C_V} \qquad \left[\frac{C_p}{C_V} = \gamma\right]$$

$$\log \frac{T_2}{T_1} = (\gamma - 1) \log \frac{V_1}{V_2} = \log \left(\frac{V_1}{V_2}\right)^{\gamma - 1}$$

$$\frac{T_2}{T_1} = \left(\frac{V_1}{V_2}\right)^{\gamma - 1}$$

$$T_1 V_1^{\gamma - 1} = T_2 V_2^{\gamma - 1}$$

$$\boxed{TV^{\gamma - 1} = k = \text{constant}}$$

Further, $$\frac{p_1 V_1}{p_2 V_2} = \left(\frac{V_2}{V_1}\right)^{\gamma - 1}$$

or $$\boxed{pV^{\gamma} = \text{constant}}$$

$$p_1 V_1^{\gamma} = p_2 V_2^{\gamma}$$

$$\boxed{\text{Work done} = C_V \times \Delta T = C_V \times (T_2 - T_1) = \frac{R}{\gamma - 1}(T_2 - T_1)}$$

(b) Work Done in Irreversible Adiabatic Expansion

In free expansion, the external pressure is zero, *i.e.*, work done is zero.

$$\therefore \qquad \Delta E = W = 0$$

In intermediate expansion, suppose the pressure is suddenly released to 1 atm and the gas expands adiabatically against the constant pressure. Since this is not a reversible expansion, above equation cannot be used.

Since, $q = 0, \Delta E = W$

$$W = C_V (T_2 - T_1)$$

Let the volume changes from V_1 to V_2 against external pressure, p_{ext},

$$W = - p_{\text{ext}} (V_2 - V_1)$$

$$= - p_{\text{ext}} \left(\frac{RT_2}{p_2} - \frac{RT_1}{p_1} \right)$$

$\therefore$ Work done, $W = - Rp_{\text{ext}} \left(\dfrac{T_2 p_1 - T_1 p_2}{p_1 p_2} \right)$

Caution Points

(*i*) *The temperature of gas decreases in adiabatic expansion i.e., cooling occurs and increases in adiabatic compression (i.e., the system gets warmed).*

(ii) *In any adiabatic process (expansion or compression), the final temperature of the gas in reversible process is lower than that in irreversible process.*

(*iii*) *Isobaric process* $W = - p_{\text{ext}} (V_2 - V_1)$

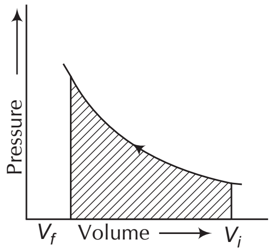
(*iv*) *Isochoric expansion* $W = 0$

Sample **Problem 2** *The pressure-volume work for an ideal gas can be calculated by using the expression* $W = -\int_{V_i}^{V_f} p_{ex} dV$. *The work can also be calculated from the pV –plot by using the area under the curve within the specified limits. When an ideal gas is compressed (a) reversibly and (b) irreversibly from volume* V_i *to* V_f, *choose the correct option.* **[NCERT Exemplar]**

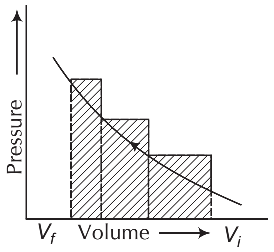
(*a*) W (reversible) = W (irreversible)
(*b*) W (reversible) $<$ W (irreversible)
(*c*) W (reversible) $>$ W (irreversible)
(*d*) W (reversible) = W (irreversible) + $p_{ex} \cdot \Delta V$

Interpret (*b*) W (reversible) $<$ W (irreversible)

This is because area under the curve is always more in irreversible compression as can be seen from Fig. (a) and (b).

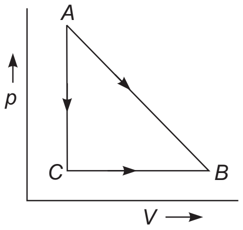


(a) Reversible compression



(b) Irreversible compression

Sample **Problem 3** *Consider the modes of transformations of a gas from state A to state B as shown in the given p-V diagram. Which one of the following is not true?*



(*a*) $\Delta H = q$ along $A \to C$
(*b*) ΔS is same along both $A \to B$ and $A \to C \to B$
(*c*) W is same along both $A \to B$ and $A \to C \to B$
(*d*) $W > 0$ along $A \to B$

Interpret (*c*) Work (W) is a path function, so depends upon the path followed, not only on the initial and final state of the system.

Sample **Problem 4** *A system consisting of 1 mole of an ideal gas undergoes an isothermal expansion at 25°C from 1.0 bar to a lower pressure while generating 100 J of work. What is the final pressure of the system if the external pressure is constant at 0.1 bar?*

(*a*) 1.23 *bar*	(*b*) 0.712 *bar*
(*c*) 0.958 *bar*	(*d*) 0.664 *bar*

Interpret (*b*) $W = - p_{\text{ext}} (V_2 - V_1)$

$$= - p_{\text{ext}} \left(\frac{nRT}{p_2} - \frac{nRT}{p_1} \right)$$

$$= - nRTp_{\text{ext}} \left(\frac{1}{p_2} - \frac{1}{p_1} \right)$$

or, $$-100 = -1 \times 8.314 \times 298 \times 0.1 \left(\frac{1}{p_2} - \frac{1}{1} \right)$$

$\therefore$ $p_2 = 0.712$ bar

Sample **Problem 5** *During an adiabatic expansion, a gas obeys* VT^3 = *constant. The gas must be*

(*a*) *monoatomic*
(*b*) *diatomic*
(*c*) *polyatomic*
(*d*) *either of the above*

Interpret (*c*) VT^3 = constant,

Also $V^{\gamma - 1} T$ = constant for adiabatic expansion.

$$VT^{\frac{1}{\gamma - 1}} = \text{constant or } \frac{1}{\gamma - 1} = 3$$

$\gamma = \dfrac{4}{3}$, *i.e.*, the gas is polyatomic.

5.3 Heat

Heat is defined as the quantity of energy, which flows between system and surroundings on account of temperature difference. It is also a path function, *i.e.,* depends upon the path followed. It is given as

$$H = ms\Delta t$$

where, m = mass of substance, s = specific heat

Δt = temperature difference

Heat flowing into the system is taken as **positive** and heat flowing out of the system is taken as **negative.**

Difference between Heat and Work

When heat is supplied to a gas in a system, the molecules start moving faster with greater randomness in different directions. However, when work is done on the system then initially the molecules start moving down in the direction of the piston. Thus, work is an organised form of energy while heat is a random form of energy.

5.4 Zeroth Law of Thermodynamics

This law was put forward much after the establishment of the first and second laws of thermodynamics. It is placed before the first and second laws as it provides a logical basis for the concept of temperature of a system.

According to this laws, "When two objects (maintained at different temperatures) are brought in thermal contact, they exchange heat with each other until they reach a state of thermal equilibrium". *The heat flows always from the object of higher temperature to the object of lower temperature*. At thermal equilibrium, the temperature of both of them became same.

This idea of thermal equilibrium is called *zeroth law of thermodynamics or law of temperature* or *law of thermal equilibrium*.

This law is also applicable for more than two objects. In such a condition, it states "if each of the two objects is in thermal equilibrium with a third object then they are also in thermal equilibrium with each other."

Check Point 1

1. When an ideal gas expands in vacuum, there is neither absorption nor evolution of heat. Explain, why?
2. Neither heat nor work is a state function but their sum, *i.e.*, $q + W$ is a state function. Explain why?
3. Why does the change in internal energy zero during an isothermal process?
4. Why does work done during a reversible isothermal expansion is more than that in intermediate expansion?

5.5 Internal Energy

Every system is associated with a definite amount of energy, called the internal energy of the system. It is the sum of all forms of **kinetic** and **potential energies** that it can have under specified conditions *i.e.,* translational, vibrational, rotational, chemical bond energy, etc. The **gravitational energy** is usually neglected.

Internal energy is a state function , *i.e.,* depends only upon the state of the system (*i.e.,* conditions of temperature, pressure, etc.) and is independent of the method by which state has been attained. The absolute value of internal energy can't be determined. However, change in internal energy (difference between the internal energies of the products E_f or E_p and that of reactants, E_i or E_R can be determined experimentally using a bomb calorimeter.

$$\Delta E = E_f - E_i$$

Internal energy of a system depends upon the quantity of substance contained in the system. Hence, it is an extensive property.

The internal energy of ideal gases is a function of temperature only. Hence in isothermal processes, as the temperature remains constant, there is no change in internal energy, *i.e.,*

$$\Delta E = 0$$

Caution Point *By convention the internal energy of an element, in most stable form, is zero.*

Units of *E* The units of energy are ergs (CGS units) or joules (SI units).

$$1 \text{ cal} = 4.184 \text{ J}$$

$$1 \text{ cal} = 4.184 \times 10^7 \text{ erg}$$

$$1 \text{ J} = 0.2390 \text{ cal}$$

$$1 \text{ J} = 10^7 \text{ erg}$$

$$1 \text{ J} = 1 \text{ N m (newton-metre)},$$

$$1 \text{ L atm} = 101.3 \text{J}$$

$$= 24.206 \text{ cal},$$

thus, $1 \text{ cal} > 1 \text{ joule} > 1 \text{ erg}$

The change in internal energy can be brought about in two ways:

(i) Either by allowing the heat to flow into the system (absorption) or out of the system (evolution).

(ii) By doing work on the system or the work done by the system.

5.6 First Law of Thermodynamics

The *first law of thermodynamics* given by Helmholtz and Robert Mayer is similar to the *law of conservation of energy*. The law states

1. Energy can neither be created nor destroyed although it can be changed from one form to another.
2. It is impossible to construct a perpetual motion machine which could produce work without consuming energy.
3. The total energy of an isolated system remains constant though it may change from one form to another.
4. Whenever a quantity of one kind of energy disappears, an exactly equivalent quantity of energy in some other form must appear.

Mathematical Expression of First Law of Thermodynamics

Suppose a system consumes heat (q) and work (W) is done on the system. In this process, the internal energy changes from E_1 to E_2 then

$$\Delta E = q + W \quad \text{where, } \Delta E = (E_2 - E_1) = \Delta U$$

It is the mathematical expression of first law of thermodynamics.

(i) *When a system undergoes isothermal change* $\Delta E = 0$, *i.e.,* there is no increase or decrease in the internal energy of the system, then the first law of thermodynamics reduces to

$$0 = q + W$$

or $\quad q = -W$

i.e., heat absorbed from surroundings = Work done by the system

or $\quad W = -q$

Heat given to the surroundings = work done on the system

(ii) *If no work is done*, $W = 0$ and the first law reduces to

$$\Delta E = q$$

i.e., increase in internal energy of the system is equal to the heat absorbed by the system or decrease in internal energy of the system is equal to heat lost by the system.

(iii) *If there is no exchange of heat between the system and surroundings,* $q = 0$, the first law reduces to

$$\Delta E = W$$

i.e., work is done at the expense of internal energy.

(iv) *In case of gaseous system*, if a gas expands against the constant external pressure, p, let the volume change be ΔV, the mechanical work done by the gas is equal to $-p \times \Delta V$

Substituting this value in $\Delta E = q + W$

$$\Delta E = q - p\Delta V$$

when, $\quad \Delta V = 0,$

$$\Delta E = q \text{ or } q_v$$

The symbol q_v indicates the heat change at constant volume.

Caution Point *According to old conventions* $\Delta E = q - W$ *, but according to latest convention, by first law of thermodynamics* $\Delta E = q + W$ (*Work done on the system is taken as positive*)

Sample Problem 6 *Expansion of a gas in vacuum is called free expansion. Calculate the work done and the change in internal energy when 1 L of ideal gas expands isothermally into vacuum until its total volume is 5 L?* **[NCERT Exemplar]**

(a) 0, 4
(b) 0, 0
(c) 0, −5
(d) −5, 0

Interpret (b) $(-W) = p_{\text{ext}}(V_2 - V_1) = 0 \times (5 - 1) = 0$

For isothermal expansion, $q = 0$

By first law of thermodynamics

$$q = \Delta E + (-W)$$

$$\Rightarrow \quad 0 = \Delta E + 0 \quad \text{so} \quad \Delta E = 0$$

Sample Problem 7 *A system undergoes a certain change in state by path I and the corresponding heat absorbed and work done are 10 kcal and 0 erg, respectively. For the same change in state by path II, the respective quantities are 11 kcal and 0.5* W_{max}*, where* W_{max} *represents the work done if the change were reversibly carried out. Find the magnitude of* W_{max} *in erg.*

(a) 2
(b) 8.4×10^7
(c) 8.4×10^{10}
(d) 8.4×10^{-7}

Interpret (c) As internal energy is a state function, its change is independent from path and hence,

$$\Delta U_{\text{I}} = \Delta U_{\text{II}}$$

or, $\quad q_1 + W_1 = q_{\text{II}} + W_{\text{II}}$

or, $\quad 10 + 0 = 11 + 0.5W_{\text{max}}$

$\therefore \quad |W_{\text{max}}| = 2 \text{ kcal} = 2 \times 1000 \times 4.2 \times 10^7$

$$= 8.4 \times 10^{10} \text{ erg}$$

Hot Spot 1

ENTHALPY

Analysis of last year AIEEE or JEE Main examination shown that it is a very important topic. Questions based on the relationship of ΔE and ΔH are frequently asked. Here, the main point is "finding the value of Δn_g.

The total heat content of a system at constant pressure is called the **enthalpy of the system**. Indeed, it is the sum of internal energy and the product of pressure-volume work. It is an extensive quantity and represented by the symbol H.

$$\therefore \qquad H = E + p\Delta V \qquad \text{...(i)}$$

Its units are kcal or kJ/mol.

Suppose a system absorbs heat, q_p and its volume changes from V_1 to V_2 against a constant pressure, p, the work done by the system,

$$(W) = -p\,(V_2 - V_1)$$
$$= -p\Delta V$$

Now applying the first law of thermodynamics,

$$\Delta E = q_p - p\,(V_2 - V_1)$$

i.e.,
$$(E_2 - E_1) = q_p - p\,(V_2 - V_1)$$

or
$$(E_2 + pV_2) - (E_1 + pV_1) = q_p \qquad \text{...(ii)}$$

We know that,

$$E + pV = H \qquad (\textit{i.e.}, \text{ enthalpy of the system})$$

Thus
$$(E_2 + pV_2) = H_2 \text{ and } (E_1 + pV_1) = H_1$$

By putting these values in Eq. (ii), we get

$$H_2 - H_1 = q_p \text{ or } \Delta H = q_p$$

Now in the equation $\Delta E + p\Delta V = \Delta H$

If $\Delta V = 0$, so $\qquad \Delta H = \Delta E$

and as $\qquad \Delta H = q_v$

Hence, $\qquad \Delta E = q_v$

Here, q_v = heat supplied at constant volume

Thus, we can say that **"heat supplied at constant pressure is the measure of enthalpy change, while the heat supplied at constant volume is the measure of internal energy change."**

In other words, the enthalpy change of a reaction can be defined as the amount of heat absorbed or evolved at constant pressure when the quantities of substance indicated by thermochemical equation have completely reacted *e.g.,* in the reaction,

$$CH_4(g) + 2O_2(g) \longrightarrow CO_2(g) + 2H_2O(g); \qquad \Delta H = -890.3 \text{ kJ}$$

Thus, heat of reaction for the above reaction is –890.3 kJ or in other words if 1 mole of CH_4 combines with 2 moles of O_2 in gaseous state, 890.3 kJ of energy is liberated.

Relationship Between ΔH and ΔE

The difference in ΔH and ΔE is insignificant for solids and liquids, however in the case of gases, if pressure and temperature remain constant, then for a given thermochemical equation, (*i.e.*, the chemical reactions in which heat of the reaction and state of the substance taking part are mentioned) change in number of moles,

$$\Delta n_g = n_2 - n_1$$

So, the above equation *i.e.,*

$$\Delta H = \Delta E + p\Delta V$$

can be converted to

$$\Delta H = \Delta E + \Delta n_g RT \qquad (\because\ p\Delta V = \Delta n_g RT)$$

If,

Case I : $\Delta n_g = 0$ then $\Delta H = \Delta E$

Case II : $\Delta n_g < 0$ then $\Delta H < \Delta E$

Case III : $\Delta n_g > 0$ then $\Delta H > \Delta E$

If ΔH is positive, the process will be endothermic, *i.e.,* accompany with the evolution of heat [or the heat content of the products (H_p) is lesser than that of the reactants (H_R)] or product is more stable than reactant. If ΔH is negative, the process will be exothermic, *i.e.,* proceeds with the absorption of heat[or $H_P > H_R$].

Ways of Solving Problems

In order to solve out ΔE and ΔH based problems if

(i) **Pressure and volume are given use the formula**

$$\Delta H = \Delta E + p\Delta V$$

Sample **Problem 8** *The enthalpy change for the reaction of 50 mL of ethylene with 50 mL of* H_2 *at 1.5 atm pressure is –0.31 kJ. The value of ΔE is*

(a) –0.5640 kJ (b) –0.2350 kJ
(c) –0.2835 kJ (d) –0.5032 kJ

Interpret (b) $C_2H_2(g) + H_2(g) \longrightarrow C_2H_4(g)$

$$\Delta H = -0.31 \text{ kJ mol}^{-1}$$
$$p = 1.5 \text{ atm}$$
$$(V_2 - V_1) = (50 - 100)$$
$$\Delta V = -50 \text{ mL} = -0.050 \text{ L}$$
$$\Delta H = \Delta E + p\Delta V$$
$$\Delta E = \Delta H - p\Delta V$$
$$= -0.31 \text{ kJ mol}^{-1} - 1.5 \times (-0.050)$$
$$= -0.235 \text{ kJ}$$

(ii) **Pressure and volume are not given** Calculate Δn_g (or Δn) from balanced equation and then use the formula

$$\Delta H = \Delta E + \Delta n_g RT$$

Sample Problem 9 *The reaction of cyanamide, $NH_2CN(s)$, with dioxygen was carried out in a bomb calorimeter, and ΔU was found to be $-742.7\ kJ\ mol^{-1}$ at 298 K. Calculate the enthalpy change for the reaction at 298 K ($R = 8.314 \times 10^{-3}\ kJ\ K^{-1}\ mol^{-1}$)*

$$NH_2CN(s) + \frac{3}{2}O_2(g) \longrightarrow N_2(g) + CO_2(g) + H_2O(l)$$

[NCERT]

(a) −741.46 (b) −743.9
(c) +741.46 (d) + 743.9

Interpret (a) Use the following steps to solve out such problems.

Step I Write the balanced equation

$$NH_2CN(s) + \frac{3}{2}O_2(g) \longrightarrow N_2(g) + CO_2(g) + H_2O(l)$$

Step II Calculate Δn_g

Difference of moles of gaseous products and reactants,

$$\Delta n_g = n_p - n_r = 2 - \frac{3}{2} = \frac{1}{2} = 0.5 \text{ mol}$$

Step III Calculate ΔH by using the formula $\Delta H = \Delta U + \Delta n_g RT$

$$\Delta H = \Delta U + \Delta n_g RT$$

$$\Delta H = -742.7 \text{ kJ mol}^{-1} + (0.5 \text{ mol} \times 8.314 \times 10^{-3} \text{ kJ mol}^{-1} \times 298 \text{ K})$$

$$\Delta H = (-742.7 \text{ kJ} + 1238.786 \times 10^{-3} \text{ kJ}) \text{ mol}^{-1}$$

$$= -741.46 \text{ kJ mol}^{-1}$$

During calculation always remember the units of different quantities, *i.e.*, ΔH, ΔU and R must be the same.

Caution Point *In the laboratory most of the reactions are carried out at constant pressure, so ΔH is more significant than ΔE.*

Enthalpy Change of a Reaction ($\Delta_r H$)

The heat change during a chemical reaction (when moles of reactants and products being same as indicated by balanced chemical equation) is called **enthalpy** or **heat of reaction.**

$\Delta_r H$ = sum of enthalpies of products − sum of enthalpies of reactants

$$\Delta_r H = \sum_i x_i H_p - \sum_i y_i H_R$$

where, x_i and y_i = stoichiometric coefficients of products and reactants respectively in a balanced equation.

H_p = enthalpy of formation of products

H_R = enthalpy of formation of reactants

e.g., For the reaction,

$$CH_4 + 2O_2 \longrightarrow CO_2 + 2H_2O$$

$\Delta_r H$ is written as

$$\Delta_r H = [H_{(CO_2,\,g)} + 2 \times H_{(H_2O,\,l)}] - [H_{(CH_4,\,g)} + 2 \times H_{(O_2,\,g)}]$$

Sample Problem 10 *Enthalpies of formation of CO(g), $CO_2(g)$, $N_2O(g)$ and $N_2O_4(g)$ are −110, −393, 81 and 9.7 kJ mol^{-1} respectively. Find the value of $\Delta_r H$ for the reaction,*

$$N_2O_4(g) + 3CO(g) \longrightarrow N_2O(g) + 3CO_2(g)$$

[NCERT]

(a) −776.4 kJ (b) −778 kJ (c) −777.7 kJ (d) − 760 kJ

Interpret (b) Heat of reaction,

$$\Delta_r H^\circ = \Sigma \Delta_f H^\circ_{\text{products}} - \Sigma \Delta_f H^\circ_{\text{reactants}}$$

$$= [\Delta_f H^\circ (N_2O) + 3\Delta_f H^\circ (CO_2)] - [\Delta_f H^\circ (N_2O_4) + 3\Delta_f H^\circ (CO)]$$

$$= [81 + (3 \times -393)] - [9.7 + (3 \times -110)] \text{ kJ}$$

$$= -777.7 \text{ kJ} \approx 778 \text{ kJ}.$$

Factors Affecting Enthalpy of Reaction

The heat or enthalpy of reaction depends upon the following factors

(i) Physical state of reactants and products
(ii) Allotropic forms of elements involved
(iii) Chemical composition of reactants and products
(iv) Amount of reactants
(v) Temperature
(vi) Medium of reaction

The variation of enthalpy of reaction with temperature is given by **Kirchhoff's equation.**

Consider a process

$$A \longrightarrow B$$

E_A and H_A are the internal energy and enthalpy of A, respectively whereas E_B and H_B are the internal energy and enthalpy of B, respectively.

Hence,

$$\Delta H = H_B - H_A$$

Since enthalpy is a function of temperature and pressure. The above equation can be differentiated *w.r.t.* temperature at constant pressure, *i.e.*,

$$\left[\frac{\delta(\Delta H)}{dT}\right]_p = \left[\frac{\delta(H_B)}{dT}\right]_p - \left[\frac{\delta(H_A)}{dT}\right]_p$$

$$= (C_p)_B - (C_p)_A = \Delta C_p$$

where, ΔC_p = difference in the heat capacity between reactants and products

or $$d(\Delta H) = \Delta C_p \cdot dT$$

Case I **When ΔC_p is constant between two temperature T_1 and T_2.**

$$\therefore \qquad \int_{H_1}^{H_2} d(\Delta H) = \int_{T_1}^{T_2} \Delta C_p \cdot dT$$

or

$$[\Delta H]_{H_1}^{H_2} = \Delta C_p (T)_{T_1}^{T_2}$$

$$\Delta H_2 - \Delta H_1 = \Delta C_p (T_2 - T_1) \qquad \text{...(i)}$$

Similarly, we can write,

$$\Delta U_2 - \Delta U_1 = \Delta C_V \cdot (T_2 - T_1) \qquad \text{...(ii)}$$

Eqs. (i) and (ii) are known as **Kirchhoff's equations.**

Case II **ΔC_p varies with temperature**

$$\int d(\Delta H) = \Delta C_p \cdot dT$$

or

$$\Delta H = \int \Delta C_p dT + K$$

where, K is the integration constant,

When $T = 0$, then $\Delta H_0 = K$

$$\therefore \qquad \Delta H = \Delta H_0 + \int \Delta C_p \, dT \qquad \text{...(iii)}$$

where, ΔH_0 refers to the enthalpy change at absolute zero.

or

$$\Delta H = \Delta H_0 + \alpha T + \beta \frac{T^2}{2} + \gamma \frac{T^3}{3} \qquad \text{...(iv)}$$

Eqs. (iii) and (iv) are another forms of Kirchhoff's equation.

Sample **Problem 11** *One mole of an ideal gas with $C_y = 3/2\,R$ is heated at a constant pressure of 1 atm from 25°C to 100°C. The ΔE and ΔH are respectively.*

(*a*) 300, 225 (*b*) 225, 375

(c) 375, 225 (*d*) 225, 300

Interpret (*b*) For ideal gas,

$$\Delta E = n \cdot C_V \cdot \Delta T = 1 \times \left(\frac{3}{2} \times 2\right) \times (100 - 25) = \mathbf{225\ cal}$$

Now,
$$C_p = C_V + R = \frac{3}{2} R + R = \frac{5}{2} R$$

Now,
$$\Delta H = n \cdot C_p \Delta T = 1 \times \left(\frac{5}{2} \times 2\right) \times (100 - 25) = \mathbf{375\ cal}$$

Calculation of Enthalpy of the Reaction

Calorimeter is the apparatus which is used to measure the heat of the reaction experimentally. If we know water equivalent of the calorimeter (W), mass (m) and specific heat (s) of liquid and initial and final temperature of the calorimeter, the heat of the reaction is calculated as

$$Q = (W + m) \times s \times (T_2 - T_1)$$

Two common types of calorimeters are **water calorimeter** and **bomb calorimeter**.

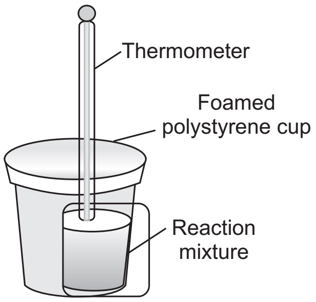


Fig. 5.6 Calorimeter for measuring heat changes at constant pressure (atmospheric pressure)

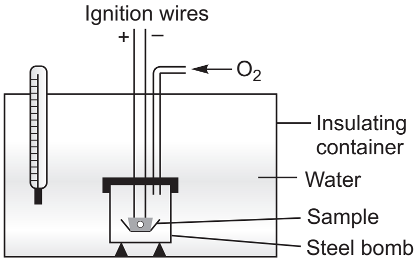

Fig. 5.7 Bomb calorimeter

In **water calorimeter** pressure remains constant, thus it gives the heat at constant pressure, *i.e.*, ΔH. In **bomb calorimeter**, the volume remains constant, thus the heat, measured by it, is called the heat at constant volume (*i.e.*, q_V) or ΔE.

$$\Delta E = \frac{(W + m)\,(T_2 - T_1) \times s}{w_1} \times M \text{ kcal}$$

Here, w_1 = mass of substance taken

and M = molecular mass of the substance

or
$$\Delta E = \frac{C \times \Delta T \times M}{w_1}$$

where, C = thermal capacity of calorimeter

Sample **Problem 12** *0.16 g of methane is subjected to combustion at 27°C in bomb calorimeter system. The temperature of the calorimeter system (including water) was found to rise by 0.5°C. Calculate the heat of combustion of methane (in kJ mol^{-1}) at constant volume. The thermal capacity of the calorimeter system is 17.7 kJ K^{-1}.*

(*a*) –695 (*b*) –1703

(*c*) –890 (*d*) –885

Interpret (*d*) For bomb calorimeter, $\Delta E = \dfrac{C \times \Delta T \times M}{m}$

($\because$ In bomb calorimeter V remains constant)

$$= \frac{17.7 \times 0.5 \times 16}{0.16} = 885 \text{ kJ/mol}$$

Thus, the heat produced is q_V *i.e.*, $q_V = -885$ kJ

Standard Enthalpy of Reaction

A substance is in its **standard state** at 1 atm pressure and 298 K. Hence, when the reaction is carried out at standard conditions, its enthalpy change is called standard enthalpy of the reaction and is denoted by $\Delta_r H^\circ$.

The sign of $\Delta_r H^\circ$ gets reversed on reversing a chemical equation.

Enthalpy of Formation

The enthalpy change when one mole of a compound is formed from its elements in their most stable state of aggregation, is called **enthalpy of formation** and is denoted by $\Delta_f H$ *e.g.,*

$$\text{C(graphite)} + 2H_2(g) \longrightarrow CH_4(g); \quad \Delta_f H = -74.8 \text{ kJ}$$

The above enthalpy change under standard conditions (1 atm and 298 K) is called **standard heat of formation** and is denoted by $\Delta_f H^\circ$.

Enthalpy of formation of an element at standard state (or in its most stable state) by convention is taken as zero, *e.g.,* enthalpy of formation of Mg, Al, Na, H_2, O_2, F_2, etc. is taken as zero.

Sample **Problem 13** *Given,*

$$N_2(g) + 3H_2(g) \longrightarrow 2NH_3(g); \ \Delta_r H^\circ = -92.4 \text{ kJ mol}^{-1}$$

The standard enthalpy of formation of NH_3 *gas is*

[NCERT]

(*a*) $+92.4$ kJ mol^{-1}
(*b*) -92.4 kJ mol^{-1}
(*c*) -46.2 kJ mol^{-1}
(*d*) $+46.2$ kJ mol^{-1}

Interpret (*c*) Given, $N_2(g) + 3H_2(g) \longrightarrow 2NH_3(g)$

$$\Delta_r H^\circ = -92.4 \text{ kJ mol}^{-1}$$

Chemical reaction for the enthalpy of formation of $NH_3(g)$ is as follows

$$\frac{1}{2} N_2(g) + \frac{3}{2} H_2(g) \longrightarrow NH_3(g)$$

Therefore, $$\Delta_f H^\circ = \frac{-92.4}{2} = -46.2 \text{ kJ mol}^{-1}$$

Enthalpy Change During Phase Transformation

The enthalpy change when one mole of a substance changes from its one state or phase to another, is called enthalpy change during phase transformation.

It can be of following types

(a) Enthalpy of Fusion

The enthalpy change when one mole of a solid substance is converted into its liquid state at its melting point is called the **enthalpy of fusion** ($\Delta_{\text{fus}} H$). Ionic solids have high values of $\Delta_{\text{fus}} H$ as compared to molecular solids.

(b) Enthalpy of Vaporisation

The enthalpy change that accompanies vaporisation of one mole of a liquid at its boiling point is called the *enthalpy of vaporisation* ($\Delta_{\text{vap}} H$). High value of enthalpy of vaporisation shows the presence of stronger forces of attraction.

(c) Enthalpy of Sublimation

It is defined as the enthalpy change when one mole of a solid sublimes (*i.e.,* converts directly into gaseous state) at a temperature below its melting point. It is represented by $\Delta_{\text{sub}} H$.

$$\Delta_{\text{sub}} H = \Delta_{\text{fus}} H + \Delta_{\text{vap}} H$$

Enthalpies for Different Types of Reactions

(a) Enthalpy of Combustion

The amount of heat evolved or absorbed when one mole of the substance is completely burnt in oxygen or air, is called *enthalpy of combustion*. It is denoted by $\Delta_c H$, *e.g.,*

$$CH_4(g) + 2O_2(g) \longrightarrow CO_2(g) + 2H_2O(l); \quad \Delta_c H = -192 \text{ kcal}$$

The value of $\Delta_c H$ *is always negative. This is because heat is evolved during combustion.*

The grading of food articles and various fuels can be done on the basis of the values of enthalpies of combustion If heat of combustion is measured in kcal/g or kJ/g (*i.e.*, calculated for one gram of a substance), it is called the **calorific value.** In other words, *the amount of heat produced in calorie or joule when one gram of a substance (food or fuel) is completely burnt or oxidised,* is called calorific value.

Mathematically,

$$\text{Calorific value} = \frac{\Delta_c H}{\text{mass}}$$

Table 5.1 **Calorific Value of Important Food Stuffs and Fuels**

Fuel	Calorific value (kJ/g)	Food	Calorific value (kJ/g)
Wood	17	Milk	3.1
Charcoal	33	Egg	6.7
Kerosine	48	Rice	16.7
Methane	55	Sugar	17.3
LPG	55	Butter	30.4
Hydrogen	150	Ghee	37.6

Out of the fuels listed, hydrogen has the highest calorific value. However, it is not used as domestic or industrial fuel due to some technical problems. Of the various constituents of our food, fats and carbohydrates serve as the main sources of energy. The calorific value of proteins is quite low.

On combustion, C, H and S of a compounds are oxidised to CO_2, H_2O and SO_2 respectively.

Sample Problem 14 *ΔH for combustion of ethane and ethyne are –341.1 and –310.0 kcal respectively. Which is better gas welder?*

(a) *Ethane* (b) *Ethyne*
(c) *Both have equal capacity* (d) *Data insufficient*

Interpret (*b*) Calorific value = heat produced by 1 g of fuel.

Given, $\Delta_C H$ for $C_2H_6 = -341.1$ kcal

$$\therefore \quad \text{Calorific value} = \frac{-341.1}{30} = -11.37 \text{ kcal/g}$$

Given, $\Delta_C H$ for $C_2H_2 = -310.0$ kcal

$$\therefore \quad \text{Calorific value} = \frac{-310.0}{26} = -11.92 \text{ kcal/g}$$

As the calorific value of C_2H_2 is high as compared to C_2H_6, therefore C_2H_2 is a better gas welder.

(b) Enthalpy of Neutralisation

The enthalpy change when one equivalent of an acid is neutralized by one equivalent of a base in a fairly dilute solution is called the *heat or enthalpy of neutralization*. It is denoted by $\Delta_n H$ *e.g.*,

$$HCl(aq) + NaOH(aq) \longrightarrow NaCl(aq) + H_2O; \quad \Delta_n H = -13.7 \text{ kcal}$$

The heat of neutralisation of a strong acid against a strong base is always constant i.e., 13.7 kcal/equivalent or **57.1 kJ.** This is because it is infact heat of formation of water in case of dilute solution *i.e.*,

$$H^+ + OH^- \longrightarrow H_2O; \quad \Delta H = -13.7 \text{ kcal}$$

For a weak acid against a strong base or a strong acid against a weak base or a weak acid against a weak base, its numerical value is always less than 13.7 kcal due to the fact that here some heat is used up in the ionisation of acid or base. However, **for HF, $\Delta_n H$ is higher due to high heat of hydration of fluoride ion**.

Neutralisation reactions are always exothermic, thus, it always have a negative value.

The heat of neutralisation of an acid or base can be easily determined in the laboratory with the help of polythene or polystyrene bottle. Bottle is fitted with rubber cork through which a thermometer and a stirrer are fitted as shown in the fig. 5.8. 100 mL each of acid and alkali of equal normality are taken in separate bottles. The temperature of each solution is regularly recorded. When constant temperature is attained, the alkali solution is added to the acid solution. The mixture is quickly stirred and the maximum temperature attained is noted.

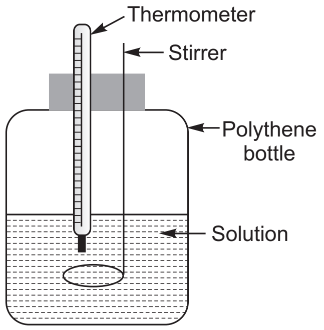

Fig. 5.8 Determination of heat of neutralisation

Calculations

Suppose, the initial temperature of acid and base $= T_1$

Final temperature of solution after mixing $= T_2$

$$\text{Rise in temperature} = T_2 - T_1$$

For the purpose of simplicity, the heat capacity of the bottle may be neglected as it is very small in comparison to that of solution. The specific heat capacity of the solution is assumed to be the same as that of water.

Q = Heat change in reaction

= Mass of solution × sp. heat × $(T_2 - T_1)$

Q is the heat evolved by the neutralisation.

$$\text{Therefore, the enthalpy of neutralisation} = \frac{Q}{100} \times 1000 \times \frac{1}{x}$$

where, x = normality of the acid or base.

Sample Problem 15 *When 50 mL of 1 M HCl (aq) with 50 mL of 1 M NaOH (aq), the enthalpy of neutralisation will be*

(a) *+57.1 kJ* (b) *114.2 kJ*
(c) *–57.1 kJ* (d) *2.9 kJ*

Interpret (*d*)

$$\underset{\substack{(50/1000)\times 1 \\ 0.05\text{ mol/L}}}{HCl} + \underset{\substack{(50/1000)\times 1 \\ 0.05\text{ mol/L}}}{NaOH} \longrightarrow NaCl + H_2O$$

∵ When 1 mole HCl is neutralised by 1 mole NaOH, the enthalpy of neutralisation = –57.1 kJ

∴ When 0.05 mole HCl is neutralised by 0.05 mol NaOH,

$$\Delta_n H = -57.1 \times 0.05$$
$$= 2.85 \approx 2.9 \text{ kJ}$$

(c) Enthalpy of Solution

The enthalpy change when one mole of solute is dissolved completely in excess of solvent is called **enthalpy** or **heat**

of solution. The solvent used here is usually water. It is denoted by $\Delta_{sol}H$, e.g.,

$$NH_4Cl(s) + H_2O(l) \longrightarrow NH_4Cl(aq);$$
$$\Delta_{sol}H = +\ 3.90 \text{ kcal}$$
$$\Delta_{sol}H = \text{hydration energy} - \text{lattice energy}$$

(About lattice energy, you have read in chemical bonding).

(d) Enthalpy of Hydration

The enthalpy change can be defined as **enthalpy** or **heat of hydration** when one mole of anhydrous or partially hydrated salt combines with required number of moles of water to form a specific hydrate. Its symbol is $\Delta_{hyd}H$, e.g.,

$$CuSO_4(s) + 5H_2O(l) \longrightarrow CuSO_4 \cdot 5\ H_2O(s);$$
$$\Delta_{hyd}H = 78.22 \text{ kJ}$$

In general cases, hydration is an exothermic process but there are some cases also where hydration is an endothermic process.

Sample **Problem 16** *At 298 K, the enthalpy of solution of solid magnesium sulphate is* -91.21 *kJ mol*$^{-1}$ *and that of hydrated magnesium sulphate is* 13.81 *kJ mol*$^{-1}$*. The heat of hydration of solid magnesium sulphate is*

(*a*) -91.21 (*b*) -105.02

(*c*) $+105.02$ (*d*) $+91.21$

Interpret (*b*) Given

$$\text{(i) } MgSO_4(s) + 7H_2O \xrightarrow{\text{Excess}} MgSO_4 \cdot 7H_2O(aq)$$
$$\Delta_{sol}H_1 = -91.21 \text{ kJ mol}^{-1}$$
$$\text{(ii) } MgSO_4 \cdot 7H_2O(s) + H_2O \text{ (excess)} \longrightarrow MgSO_4 \cdot 7H_2O(aq)$$
$$\Delta_{sol}H_2 = 13.81 \text{ kJ mol}^{-1}$$

Eq. (i) is infact, involves the following two steps :

$$MgSO_4(s) + 7H_2O \longrightarrow MgSO_4 \cdot 7H_2O(s);$$
$$\Delta_{hyd}H_3 = ?$$
$$MgSO_4 \cdot 7H_2O(s) + H_2O(\text{excess}) \longrightarrow MgSO_4 \cdot 7H_2O(aq);$$
$$\Delta_{sol}H_2 = 13.81 \text{ kJ mol}^{-1}$$

Thus, $\Delta_{sol}H_1 = \Delta_{sol}H_2 + \Delta_{hyd}H_3$

or
$$\begin{aligned}\Delta_{hyd}H_3 &= \Delta_{sol}H_1 - \Delta_{sol}H_2\\ &= -91.21 - 13.81\\ &= -105.02 \text{ kJ mol}^{-1}\end{aligned}$$

(e) Enthalpy of Dilution

The enthalpy change when the solution containing one mole of a substance is diluted from one concentration to another is called **enthalpy** or **heat of dilution.** e.g.,

$$KCl\ (200H_2O) \longrightarrow KCl(300\ H_2O);\ \Delta_{dil}H = x \text{ kJ}$$

If integral heat of solution of the hydrated and anhydrous salt is known, the heat of hydration is obtained by subtracting $\Delta_{hyd}H$ (hydrated salt) from $\Delta_{hyd}H$ (anhydrous salt), e.g.,

$$CuSO_4(\text{anhydrous}) + a\ H_2O(l) \longrightarrow CuSO_4 \cdot a\ H_2O$$
$$\Delta_{hyd}H_{(\text{anhy})} = -66.50 \text{ kJ}$$
$$CuSO_4 \cdot 5H_2O + (a-5)\ H_2O(l) \longrightarrow CuSO_4 \cdot a\ H_2O$$
$$\Delta_{hyd}H_{(\text{Hydrated})} = 11.71 \text{ kJ}$$

Thus, $\Delta_{hyd}H$ of solution $= \Delta_{hyd}H(\text{anhy.}) - \Delta_{hyd}H\ (\text{hydrated})$

(f) Enthalpy of Ionisation

The enthalpy change when one mole of a weak acid or a weak base is completely ionised into its constituents, is called the **enthalpy** or **heat of ionisation.** It is represented by $\Delta_{ion}H$, e.g.,

$$CH_3COOH(aq) \rightleftharpoons CH_3COO^-(aq) + H^+(aq);$$
$$\Delta_{ions}H = -55.43 \text{ kJ mol}^{-1}$$

Heat of ionisation can also be obtained by subtracting the heat of neutralisation of weak acid or a weak base from the heat of neutralisation of strong acid and strong base (*i.e.,* -13.7 kcal or -57.32 kJ)

Since, *heat is required for ionisation process, the enthalpy of ionisation is usually negative.*

(g) Enthalpy of Transition

The enthalpy change when one mole of a substance changes from its one allotropic form into another is called **enthalpy of transition.** It is represented by $\Delta_{transition}H$ or Δ_tH, e.g.,

$$S_{(\text{rhombic})} \longrightarrow S_{(\text{monoclinic})};\qquad \Delta_tH = -13.14 \text{ kJ}$$

(h) Enthalpy of Atomisation

The enthalpy change that accompanies the total separation of all atoms in a chemical substance (either element or molecule or compound) is called the **enthalpy of atomisation.** It is denoted by Δ_aH. e.g.,

$$\text{(i) } CH_4(g) \longrightarrow C(g) + 4H(g);\qquad \Delta_aH = 1665 \text{ kJ mol}^{-1}$$
$$\text{(ii) } Na(s) \longrightarrow Na(g);\qquad \Delta_aH = 108.4 \text{ kJ mol}^{-1}$$

(In this case, enthalpy of atomisation is same as that of sublimation.)

$$\text{(iii) } H_2(g) \longrightarrow 2\ H(g);\qquad \Delta_aH = 435.0 \text{ kJ mol}^{-1}$$

(Here, enthalpy of atomisation is same as the bond dissociation enthalpy.)

Hence, *it can be concluded that in case of diatomic molecule,* ΔH_a = *bond dissociation enthalpy and in case of monoatomic metal, it is equal to sublimation enthalpy.*

Bond Energy and Bond Dissociation Energy

When a bond is formed between two atoms in gaseous state to form a molecule, some heat is always evolved which is called **bond energy** or **bond formation energy.** Infact two terms **bond energy** and **bond dissociation energy** are always confused with each other, but these terms are shown to have different usage. *Bond dissociation energy is the amount of energy required to break/dissociate bond of a particular type present in one molecule of the compound while bond energy is taken as the average value of dissociation energies of same type of bonds present in one mole.*

In case of diatomic molecules, bond energy is equal to the enthalpy of bond dissociation.

$$\text{H—Cl}(g) \longrightarrow \text{H}(g) + \text{Cl}(g);\ \Delta H = +431\ \text{kJ mol}^{-1}$$

However, in case of polyatomic molecules, as

$$\text{CH}_4(g) \longrightarrow \text{C}(g) + 4\text{H}(g); \quad \Delta H = 1664\ \text{kJ mol}^{-1}$$

$$\text{C—H bond energy} = \frac{1}{4}\ \text{of bond dissociation energy}$$

(as there are four C—H bonds in CH_4)

$$= \frac{1664}{4} = 416\ \text{kJ mol}^{-1}$$

As a chemical reaction involves the breaking of old bonds in reactants and formation of new bonds in products, the enthalpy change of a reaction can also be calculated by, the following formula.

$$\Delta_r H = \text{sum of BE of reactants} - \text{sum of BE of products}$$

Sample **Problem 17** *Bond energy of* H—H *bond is* 430 *kJ mol*$^{-1}$ *and that of* Cl—Cl *bond is* 242 *kJ mol*$^{-1}$. *If the heat of formation of* HCl *is* –91 *kJ mol*$^{-1}$, *the bond energy of* H—Cl *is*

(a) 427 *kJ mol*$^{-1}$ (b) 490 *kJ mol*$^{-1}$

(c) 245 *kJ mol*$^{-1}$ (d) 290 *kJ mol*$^{-1}$

Interpret (a) Given, $H_2 + Cl_2 \longrightarrow 2HCl \quad \Delta_f H = -91\ \text{kJ mol}^{-1}$

∵ In this reaction, two moles of HCl are produced,

$$\Delta_r H = 2 \times \Delta_f H = 2 \times -91 = -182\ \text{kJ mol}^{-1}$$

Let the bond energy of H—Cl bond is x.

∴ The bond energy for 2 moles of HCl = $2x$.

For the reaction,

$$\text{H—H} + \text{Cl—Cl} \longrightarrow 2\text{H—Cl}$$

$$\Delta_r H = \Sigma\,\text{BE}_{(\text{reactants})} - \Sigma\,\text{BE}_{(\text{products})}$$

$$-182 = 430 + 242 - 2x$$

$$-182 = 672 - 2x$$

$$\therefore \quad x = \frac{854}{2} = 427\ \text{kJ mol}^{-1}$$

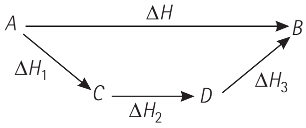
Hot Spot 2

HESS'S LAW of Constant Heat Summation

Analysis of previous years' JEE Main & AIEEE examination reveal that the topic is very important. Many a times questions were see from this topic. The questions are generally numerical type and their level varies from easy to average.

"The total heat change (ΔH) accompanying a chemical reaction is the same whether the reaction takes place in one or more steps" or "Enthalpy change in a particular reaction is always constant and is independent of the path in which the reaction takes place." The above statements are called **Hess's law of constant heat summation.**

Suppose, enthalpy change for direct conversion $A \longrightarrow B$ is ΔH. B can also be prepared from A through intermediates C and D, for which enthalpy changes are ΔH_1, ΔH_2 and ΔH_3 respectively as shown.



Then according to Hess's law

$$\Delta H = \Delta H_1 + \Delta H_2 + \Delta H_3$$

e.g., for the formation of CO_2 directly as

$$\text{C} + \text{O}_2(g) \longrightarrow \text{CO}_2(g); \quad \Delta H = -393.5\ \text{kJ}$$

CO_2 can also be prepared as

$$\text{C} + \frac{1}{2}\text{O}_2(g) \longrightarrow \text{CO}(g); \quad \Delta H_1 = -110.5\ \text{kJ}$$

$$\text{CO} + \frac{1}{2}\text{O}_2(g) \longrightarrow \text{CO}_2(g); \quad \Delta H_2 = -283.0\ \text{kJ}$$

Thus, total heat $\Delta H = \Delta H_1 + \Delta H_2$

$$= -110.5 - 283.0 = -393.5\ \text{kJ}$$

Hence, it is clear from the above that ΔH direct and ΔH obtained indirectly are same.

It clearly indicates that when chemical equations are added, subtracted or multiplied, the heat changes can also be added, subtracted or multiplied correspondingly.

Applications of Hess's Law

1. For the determination of enthalpies of formation of compounds.
2. For the determination of enthalpies of extremely slow reactions.
3. For the determination of enthalpies of transformation of one allotropic form into another.
4. For the determination of bond energies.

   $\Delta H_{\text{reaction}} = \Sigma$ Bond energies of reactants − Σ Bond energies of products

   Note In case of atomic species, bond energy is replaced by heat of atomization.
5. For the determination of resonance energy.

When a compound shows resonance, there is considerable difference between the heat of formation as calculated from bond energies and that determined experimentally.

$\therefore$ Resonance energy = Experimental or actual heat of formation − Calculated heat of formation.

Thermochemical Calculations

For making thermochemical calculations, the following points are to be kept in mind :

(i) Write down the required thermochemical equation. For example, if heat of formation of methane is to be determined, write down the following equation :

$$C(s) + 2H_2(g) \longrightarrow CH_4(g); \;\; \Delta H = ?$$

(ii) Try to obtain the required equation from the given data.

There are two ways for doing this.

First way By adding, subtracting and multiplying various the rmochemical equation.

Second way Enthalpy of reaction = Σ enthalpies of products − Σ enthaplies of reactants.

Sample Problem 18 *Calculate the standard enthalpy of formation of* $CH_3OH(l)$ *from the following data :*

[NCERT]

$$CH_3OH(l) + \frac{3}{2}O_2(g) \longrightarrow CO_2(g) + 2H_2O(l);$$

$$\Delta_r H^\circ = -726 \text{ kJ mol}^{-1}$$

$$C_{\text{graphite}} + O_2(g) \longrightarrow CO_2(g); \;\; \Delta_c H^\circ = -393 \text{ kJ mol}^{-1}$$

$$H_2(g) + \frac{1}{2}O_2(g) \longrightarrow H_2O(l); \;\; \Delta_f H^\circ = -286 \text{ kJ mol}^{-1}$$

(a) −2339 (b) +239

(c) +119.5 (d) −119.5

Interpret (a) Firstly we write the required chemical equation for the formation of 1 mole of methanol (l) and then calculate $\Delta_f H^\circ$ for the formation of methanol by adding all the equation in such a way so that it give the required equation (*i.e.*, apply Hess's law)

Required reaction for the formation of methanol is as follows

$$C(s) + 2H_2(g) + \frac{1}{2}O_2(g) \longrightarrow CH_3OH(l); \quad \Delta_f H^\circ = ?$$

Given, enthalpy for the combustion of methanol

$$\text{(i)}\;\; CH_3OH(l) + \frac{3}{2}O_2(g) \longrightarrow CO_2(g) + 2H_2O(l);$$

$$\Delta_r H^\circ = -726 \text{ kJ mol}^{-1}$$

Enthalpy for the formation of 1 mole of $CO_2(g)$;

$$\text{(ii)}\;\; C(s) + O_2(g) \longrightarrow CO_2(g); \quad \Delta_f H^\circ = -393 \text{ kJ mol}^{-1}$$

Enthalpy for the formation of 1 mole of $H_2O(l)$;

$$\text{(iii)}\;\; H_2(g) + \frac{1}{2}O_2(g) \longrightarrow H_2O(l); \quad \Delta_f H^\circ = -286 \text{ kJ mol}^{-1}$$

Multiplying Eq. (iii) by 2 [because 2 moles $H_2O(l)$ are formed in Eq. (i)] we get,

$$\text{(iv)}\;\; 2H_2(g) + O_2(g) \longrightarrow 2H_2O(l); \quad \Delta_f H^\circ = -572 \text{ kJ mol}^{-1}$$

Summing up the Eqs. (ii) and (iv), we get

$$\text{(v)}\;\; C(s) + 2H_2(g) + 2O_2(g) \longrightarrow CO_2(g) + 2H_2O(l);$$
$$\Delta_f H^\circ = -965 \text{ kJ mol}^{-1}$$

Reversing Eq.(i) we get

$$\text{(vi)}\;\; CO_2(g) + 2H_2O(l) \longrightarrow CH_3OH(l) + \frac{3}{2}O_2(g);$$

$$\Delta_f H^\circ = +726 \text{ kJ mol}^{-1}$$

Adding Eqs. (v) and (vi) we get required equation

$$C(s) + 2H_2(g) + \frac{1}{2}O_2(g) \longrightarrow CH_3OH(l);$$

$$\Delta_f H^\circ = -239 \text{ kJ mol}^{-1}$$

Sample Problem 19 *Given,*

$$CCl_4(g) \longrightarrow C(g) + 4Cl(g)$$

Calculate the bond enthalpy of C—Cl *in* $CCl_4(g)$.

$$\Delta_{\text{vap}} H^\circ (CCl_4) = 30.5 \text{ kJ mol}^{-1}$$

$$\Delta_f H^\circ (CCl_4) = -135.5 \text{ kJ mol}^{-1}$$

$$\Delta_a H^\circ (C) = 715.0 \text{ kJ mol}^{-1},$$

where, $\Delta_a H^\circ$ is enthalpy of atomisation, $\Delta_a H^\circ (Cl_2) = 242 \text{ kJ mol}^{-1}$.

[NCERT]

(a) + 1304 (b) −1304

(c) −326 (d) + 326

Interpret (d) ***Step I*** Write the balanced equation for all the enthalpy changes.

$$\text{(i)}\;\; CCl_4(l) \longrightarrow CCl_4(g); \quad \Delta_{\text{vap}} H^\circ = +30.5 \text{ kJ mol}^{-1}$$

$$\text{(ii)}\;\; C(s) + 2Cl_2(g) \longrightarrow CCl_4(l); \quad \Delta_f H^\circ = -135.5 \text{ kJ mol}^{-1}$$

$$\text{(iii)}\;\; C(s) \longrightarrow C(g); \quad \Delta_a H^\circ = 715.0 \text{ kJ mol}^{-1}$$

$$\text{(iv)}\;\; Cl_2(g) \longrightarrow 2Cl(g); \quad \Delta_a H^\circ = 242 \text{ kJ mol}^{-1}$$

Step II Apply Hess's law to obtain the ΔH for the equation

$$CCl_4(g) \longrightarrow C(g) + 4Cl(g)$$

Multiply Eq. (iv) by 2

(v) $2Cl_2(g) \longrightarrow 4Cl(g)$; $\quad \Delta_a H^\circ = 484.0 \text{ kJ mol}^{-1}$

Add Eqs. (iii) and (v),

(vi) $C(s) + 2Cl_2(g) \longrightarrow C(g) + 4Cl(g)$; $\quad \Delta H = 1199 \text{ kJ mol}^{-1}$

Reverse Eqs. (i) and (ii),

(vii) $CCl_4(g) \longrightarrow CCl_4(l)$; $\quad \Delta H = -30.5 \text{ kJ mol}^{-1}$

(viii) $CCl_4(l) \longrightarrow C(s) + 2Cl_2(g)$; $\quad \Delta H = +135.5 \text{ kJ mol}^{-1}$

Add Eqs. (vi), (vii) and (viii), we get

$$CCl_4(g) \longrightarrow C(g) + 4Cl(g);\ \Delta H = 1304 \text{ kJ mol}^{-1}$$

Step III Since bond enthalpy is average of all the bonds.

$$\text{Bond enthalpy of C—Cl bond in } CCl_4 = \frac{1304}{4} = 326 \text{ kJ mol}^{-1}$$

(∵ There are four C—Cl bonds in CCl_4,  $\mathrm{Cl{-}\overset{\displaystyle Cl}{\underset{\displaystyle Cl}{C}}{-}Cl}$.)

5.7 Heat Capacity

The quantity of heat required to raise the temperature of system by one degree is called heat capacity of that system. This is denoted by C_V (when volume is constant) and by C_p (when pressure is constant).

Thus, in general we can say

$$\text{Heat capacity} = \frac{dq}{dT}$$

The magnitude of heat capacity depends upon the size, composition and nature of the system. Heat capacity varies directly with the amount of substance. It also affects temperature. If the magnitude of heat capacity is large, there is only a small rise in temperature by a given amount of heat, *e.g.*, Heat capacity of H_2O is large, thus a large amount of heat is required to raise its temperature.

In chemical calculations we often use specific heat capacity and molar heat capacities. **Specific heat** is defined as "the heat required to raise the temperature of one unit mass by 1 degree (either celsius or kelvin)". When the definition is given in terms of mole, it is considered as **molar heat capacity**, *i.e.*, the heat capacity of one mole of a substance.

The specific heat capacity is denoted by c and can be calculated with the help of following formula

$$q = c \times m \times \Delta T$$

where, q = heat required to raise the temperature by 1°C

c = specific heat capacity

m = mass

Δt = temperature change (in °C)

If C is the heat capacity of n mol of the system, then its molar heat capacity C_m is given by $C_m = C/n$.

Relation Between C_p and C_V

Enthalpy of the system

$$H = E + pV$$

From ideal gas equation.

$$pV = nRT$$

where, $n = 1$

$$pV = RT \quad \text{or} \quad H = E + RT$$

On differentiating with respect to T

$$\therefore \qquad \frac{dH}{dT} = \frac{dE}{dT} + R$$

$$\text{or} \qquad C_p = C_V + R$$

$$\text{or} \qquad (C_p - C_V) = R = 1.99 \text{ cal K}^{-1} \text{ mol}^{-1} = 8.314 \text{ JK}^{-1} \text{ mol}^{-1}$$

The difference between C_p and C_V is equal to the work done by 1 mole of a gas in expansion when heated through 1°C.

C_p is Always Greater than C_V

When gas is heated at constant volume, the pressure of a gas has to increase. As the gas is not allowed to expand, therefore in case of C_V heat is required for raising the temperature of one mole of a gas through one degree.

When gas is heated at constant pressure it expands. The gas has done some work against external pressure. More heat is, therefore, supplied to raise its temperature through one degree. Thus, C_p is heat required for the purpose of

(i) increasing temperatures of one mole of gas through one degree.

(ii) for increasing the volume of the gas against external pressure.

C_p/C_V Ratio

The ratio of molar heat capacities at constant pressure to that at constant volume is represented by γ. The value of γ gives information about the atomicity of gases.

$$\frac{C_p}{C_V} = \gamma$$

From the ratio of C_P and C_V, we get idea of atomicity of a gas.

1. For **monoatomic gas,** $C_p = 5$ cal; $C_V = 3$ cal

   hence, $\qquad \gamma = \dfrac{C_p}{C_V} = \dfrac{5}{3} = 1.67$

2. For **diatomic gas,** $C_p = 7$ cal; $C_V = 5$ cal

   hence, $$\gamma = \frac{C_p}{C_V} = \frac{7}{5} = 1.40$$

3. For **triatomic gas,** $C_p = 8$ cal, $C_V = 6$ cal

   hence, $$\gamma = \frac{8}{6} = 1.33$$

4. For any hypothetical process, if type of gas is given (*i.e.*, monoatomic, diatomic etc.) then specific heat can be calculated by the expression :

   $$C = \frac{R}{\gamma - 1} + \frac{R}{1 - x}$$

   provided gas follows $pV^{\gamma} = \text{constant}$

***Sample* Problem 20** *4 moles of an ideal gas having* $\gamma = 1.67$ *are mixed with 2 moles of another ideal gas having* $\gamma = 1.40$. *Find the equivalent values of* γ *for the mixture*.

(*a*) 1.33 (*b*) 1.54 (*c*) 1.67 (*d*) 1.23

Interpret (*b*) $$\gamma_{\text{mix}} = \frac{C_{P_{\text{mix}}}}{C_{V_{\text{mix}}}} = \frac{\left(\dfrac{n_1 C_{p_1} + n_2 C_{p_2}}{n_1 + n_2}\right)}{\left(\dfrac{n_1 C_{V_1} + n_2 C_{V_2}}{n_1 + n_2}\right)}$$

$$= \frac{n_1 \cdot \dfrac{R \cdot \gamma_1}{\gamma_1 - 1} + n_2 \cdot \dfrac{R \cdot \gamma_2}{\gamma_2 - 1}}{n_1 \cdot \dfrac{R}{\gamma_1 - 1} + n_2 \cdot \dfrac{R}{\gamma_2 - 1}}$$

$$= \frac{n_1 \gamma_1 (\gamma_2 - 1) + n_2 \gamma_2 (\gamma_1 - 1)}{n_1 (\gamma_2 - 1) + n_2 (\gamma_1 - 1)}$$

$$= \frac{4 \times 1.67 \times (1.40 - 1) + 2 \times 1.40 \times (1.67 - 1)}{4 \times (1.40 - 1) + 2 \times (1.67 - 1)}$$

$$= 1.547$$

Alternate Method γ_{mix} may also be determined by first calculating $C_{V_{\text{mix}}}$. Try yourself.

Check Point 2

1. Why does the enthalpy of combustion is always negative?
2. Why is the heat of neutralisation between an weak acid and strong base less than 13.7 kcal?
3. HF is a weak acid but its enthalpy of neutralisation is greater than 57.1 kJ. Explain, why?
4. Calculation ΔH is more significant than $\Delta E°$, in laboratories, why?
5. Although the calorific values of hydrogen is very high, yet it is not used as domestic fuel. Explain, why?
6. Why is a large amount of heat required to raise the temperature of water?

5.8 Spontaneous and Non-spontaneous Processes

A physical or chemical change that occurs by its own *i.e.*, without the help of an external source, is called **spontaneous process** or **natural process** or **feasible process or probable** process. For example rolling ball, heat flow, gas flow, etc. There are also some processes which require some initiation before they proceed spontaneously. These processes are also considered as spontaneous processes. Thus, we can say that spontaneous processses are of two types :

1. Spontaneous processes which does not require initiation *e.g.,* sugar dissolution in water, water evaporation from river, ponds, etc.
2. Spontaneous processes where initiation is required, for example,

   $$2H_2(g) + O_2(g) \xrightarrow[\text{spark}]{\text{Electric}} 2H_2O(l)$$

   Here, the reaction is initiated by electric spark, and then proceeds spontaneously.

   $$CH_4(g) + 2O_2(g) \longrightarrow CO_2(g) + 2H_2O(g)$$

   Here, CH_4 burns spontaneously when ignited initially.

Rest of the other processes which require a continuous supply of energy from outside the system are called **non-spontaneous processes.**

The spontaneity of the process can be explained on the basis of change in energy. A spontaneous process generally proceeds with decrease in energy, but it is not the case with all process *e.g.*, melting of ice is an endothermic process.

Besides energy decrease, increase in randomness is another factor which determines the spontaneity of a process. Thus, there are two factors which govern the spontaneity of a process :

(i) Tendency to attain minimum energy state, *i.e.*, tendency to become more and more stabilised.

(ii) Tendency to attain maximum randomness or disorderness.

Both of these factors are equally responsible for spontaneity and both of them are independent of each other. Spontaneous changes are always unidirectional and in case of reversible reactions proceed till equilibrium is achieved.

5.9 Entropy

The extent of randomness in a system may be expressed in terms of entropy, which is defined as, the property of a system which measures the degree of randomness in a system. It is generally denoted by S and is a state function, *i.e.*, change in entropy (ΔS) depends only on the initial and final states of the system.

Thus,

$$\Delta S = S_{\text{final}} - S_{\text{initial}}$$

Units of entropy are **joule per kelvin per mole.**

For a given substance, the crystalline solid state is most ordered and therefore, has the lowest entropy while gaseous state is most disordered, therefore, has the highest entropy. The liquid state is the intermediate between two. Thus, the order of randomness and thus, the entropy is

$$\text{gas} > \text{liquid} > \text{solid}$$

Some examples in which entropy either increases or decreases are

1. A molecule if kept in a larger volume container will have higher entropy.
2. Decomposition of a compound increases entropy while combination results to decrease in entropy.
3. In case of atoms or molecules belonging to different elements, the one with higher mass have greater entropy, *i.e.*, for inert gases :

   $$S_{\text{He}} < S_{\text{Ne}} < S_{\text{Ar}} < S_{\text{Kr}} < S_{\text{Xe}} < S_{\text{Rn}}$$

   Similarly, for halogens

   $$S_{\text{F}_2} < S_{\text{Cl}_2} < S_{\text{Br}_2} < S_{\text{I}_2}$$
4. The molecules with more atoms of given type or with greater number of chemical bonds or greater capacity to take up energy means greater thermal disorder thus, have greater entropy, *e.g.,*

   $$S_{\text{acetylene}} < S_{\text{ethylene}} < S_{\text{ethane}}$$
5. Vaporisation and fusion results to entropy increase while crystallisation results to decrease in entropy.
6. At absolute zero, entropy of all pure elements and compounds is zero because kinetic energy of constituent atoms is zero.
7. Stretching of rubber band results in increase in entropy while in case of boiling of egg, entropy decreases.

Entropy is also a measure of unavailable energy, the energy which cannot be converted into work by the system. The unavailable energy of any system is given as a product of change in entropy at the temperature at which system absorbs heat, and the temperature at which system loses heat.

Unavailable energy = Change in entropy × temperature

Entropy Change in Reversible Process

Consider an isothermal reversible process. In this process, let the system absorbs q amount of heat from surroundings at temperature T. The increase in the entropy of the system will be

$$\Delta S_{\text{system}} = +\frac{q}{T}$$

On the other hand, surroundings lose the same amount of heat at the same temperature. The decrease in the entropy of the surroundings will be

$$\Delta S_{\text{surroundings}} = -\frac{q}{T}$$

Total change in entropy of the process = entropy change in system + entropy of change in surroundings

$$\Delta S_{\text{total}} = \Delta S_{\text{system}} + \Delta S_{\text{surroundings}} = \frac{q}{T} - \frac{q}{T} = 0$$

When the reversible process is adiabatic, there will be no heat exchange between system and surroundings, *i.e.*, $q = 0$

$$\therefore \quad \Delta S_{\text{system}} = 0,$$

$$\Delta S_{\text{surroundings}} = 0$$

$$\Delta S_{\text{total}} = \Delta S_{\text{system}} + \Delta S_{\text{surroundings}} = 0$$

Entropy Change in Irreversible Processes

Consider a system at higher temperature T_1 and its surroundings at lower temperature T_2. 'q' amount of heat goes irreversibly from system to surroundings.

$$\therefore \quad \Delta S_{\text{system}} = -\frac{q}{T_1}$$

$$\Delta S_{\text{surroundings}} = +\frac{q}{T_2}$$

$$\Delta S_{\text{process}} = \Delta S_{\text{system}} + \Delta S_{\text{surroundings}}$$

$$= -\frac{q}{T_1} + \frac{q}{T_2} = q\left[\frac{T_1 - T_2}{T_1 T_2}\right]$$

But $\quad T_1 > T_2$

$$\therefore \quad T_1 - T_2 = +\text{ve} \text{ or } \Delta S_{\text{process}} > 0$$

Hence, entropy increases in an irreversible process.

Caution Points

(*i*) *A thermodynamically irreversible process is always accompanied by increase in entropy of the universe while in case of reversible process, entropy remains constant.*

(*ii*) *Most of the natural phenomenon are irreversible in nature.*

Entropy and Spontaneity

Positive and negative values of ΔS shows the spontaneous and non-spontaneous processes respectively. For equilibrium when an isolated system is in equilibrium, the entropy is maximum. The mathematical condition for entropy (S) to be maximum is that the change in entropy (ΔS) is zero, *i.e.*, $\Delta S = 0$ (at equilibrium for an isolated system)

Entropy Change During Phase Transition

The change of matter from one state to another is called **phase transition**. The entropy changes at the time of phase change can be summarised as

$$\Delta S_{\text{melting}} = \frac{\Delta H_{\text{fusion}}}{T_m}$$

where, T_m = melting point of substance.

$$\Delta S_{\text{vaporisation}} = \frac{\Delta H_{\text{vaporisation}}}{T_b}$$

where, T_b = boiling point of substance

Similarly, $$\Delta S_{\text{sublimation}} = \frac{\Delta H_{\text{sublimation}}}{T_{\text{sub}}}$$

where, T_{sub} = sublimation temperature

Entropy Change for Ideal Gases

Change in entropy for an ideal gas under different conditions may be calculated as

(i) When the gas changes from initial state (1) to final state (2)

$$\Delta S = 2.303 nC_V \log\left(\frac{T_2}{T_1}\right) + 2.303\, nR\log\left(\frac{V_2}{V_1}\right)$$

(when T and V are variables)

$$\Delta S = 2.303 nC_p \log\left(\frac{T_2}{T_1}\right) + 2.303 nR\log\left(\frac{p_1}{p_2}\right)$$

(when T and p are variables)

(ii) For isothermal process, $\Delta S = nR\ln\frac{V_2}{V_1} = nR\ln\frac{p_2}{p_1}$ $(\because \Delta T = 0)$

(iii) For isobaric process, $\Delta S = nC_p \ln\frac{T_2}{T_1}$ $(\because p_1 = p_2)$

(iv) For isochoric process, $\Delta S = nC_V \ln\frac{T_2}{T_1}$ $(\because V_1 = V_2)$

(v) **Entropy change in mixing of ideal gases** Let n_1 mole of gas A and n_2 mole of gas B are mixed; then total entropy change can be calculated as

$$\Delta S = -2.303\, R[n_1 \log x_1 + n_2 \log x_2]$$

x_1, x_2 are mole fractions of gases A and B,

i.e., $x_1 = \frac{n_1}{n_1 + n_2}$; $x_2 = \frac{n_2}{n_1 + n_2}$

$$\Delta S/\text{mol} = -2.303 R\left[\frac{n_1}{n_1 + n_2}\log x_1 + \frac{n_2}{n_1 + n_2}\log x_2\right]$$

$$\Delta S/\text{mol} = -2.303 R[x_1 \log x_1 + x_2 \log x_2]$$

(vi) Entropy change in adiabatic expansion will be zero, $\Delta S = 0$.

Standard and Molar Entropy Change

If entropy change is measured under standard conditions, it is called **standard entropy change** (ΔS°). Once, we know the entropies of a variety of substances participating in a reaction, we can calculate the standard entropy change, ΔS° as

ΔS° = sum of ΔS° of products − sum of ΔS° of reactants

e. g., in a general reaction,

$$aA + bB \longrightarrow xX + yY$$

$$\Delta S^\circ = [xS^\circ \text{ for } X + yS^\circ \text{ for } Y] - [aS^\circ \text{ for } A + bS^\circ \text{ for } B]$$

The standard entropy of a substance can be calculated with the help of following formula

$$S^\circ = 2.303\, C_p \log T$$

If entropy is defined per unit amount of substance, it is called **molar entropy** (S_m).

Sample Problem 21 *The entropy change can be calculated by using the expression $\Delta S = \frac{q_{rev}}{T}$. When water freezes in a glass beaker, choose the correct statement amongst the following :* **[NCERT Exemplar]**

(a) ΔS (system) decreases but ΔS (surroundings) remains the same

(b) ΔS (system) increases but ΔS (surroundings) decreases

(c) ΔS (system) decreases but ΔS (surroundings) increases

(d) ΔS (system) decreases and ΔS (surroundings) also decreases.

Interpret (c) Freezing is exothermic process. The heat released increases the entropy of surroundings.

Sample Problem 22 *When 36 g of liquid water evaporates at 373 K ($\Delta_{vap}H = 40.63$ kJ mol^{-1}), the entropy change is*

(a) 218 JK^{-1} (b) 315 JK^{-1}

(c) 185 JK^{-1} (d) 268 JK^{-1}

Interpret (a) $\Delta_{\text{vap}}H = 40.63 \text{ kJ mol}^{-1}, T_b = 373 \text{ K}$

$$\Delta_{\text{vap}} S = \frac{\Delta_{\text{vap}}H}{T_b} = \frac{40.63 \times 1000 \text{ J mol}^{-1}}{373 \text{ K}}$$

$$= 109 \text{ JK}^{-1}\text{mol}^{-1}$$

Entropy change for evaporation of 36 g of water

$$= \frac{109}{18} \times 36 = 218 \text{ JK}^{-1}$$

5.10 Second and Third Laws of Thermodynamics

Second Law of Thermodynamics

The second law of thermodynamics can be stated as

1. Whenever a spontaneous process takes place, it is always accompanied by an increase in total entropy of the universe.
2. It is impossible to take heat from a hotter reservoir and completely convert into work by a cyclic process without transferring a part of heat to a cooler reservoir. This statement of second law is called **Kelvin's statement**.
3. It is impossible for a cyclic process to transfer heat from a body at lower temperature to one at a higher temperature without converting some work to heat. This statement of the second law of thermodynamics is known as **Clausius statement**.

The above statements (*i.e.*, the second law) in simplified form can be stated as "for a spontaneous process in an isolated system, the change in entropy is positive."

In statement (i) above, the term universe means the system and the surroundings. Thus,

$$\Delta S_{\text{univ}} = \Delta S_{\text{syst}} + \Delta S_{\text{surr}}$$

Conversion of Heat into Work
(Carnot Cycle)

Carnot in 1824 gave an imaginary reversible cycle which demonstrates the maximum conversion of heat into work. He actually proposed a theoretical heat engine to show that its efficiency was based upon the temperatures, between which it operated. Infact, heat engine is a machine which can do work by using heat that flows out spontaneously from a high temperature source to a low temperature sink.

A Carnot cycle comprises four operations or processes:

(i) Isothermal reversible expansion
(ii) Adiabatic reversible expansion
(iii) Isothermal reversible compression
(iv) Adiabatic reversible compression

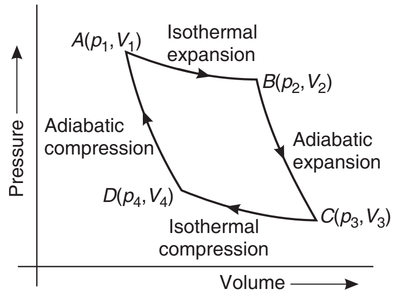


Fig. 5.9 Carnot cycle

(a) Net work done in 1 cycle is

$$W = RT_2 \ln \frac{V_2}{V_1} + RT_1 \ln \frac{V_4}{V_3}$$

(b) Net heat absorbed in the whole cycle is

$$q = R(T_2 - T_1) \ln \frac{V_2}{V_1}$$

The ratio of the work obtained in a cyclic process (W) to the heat taken from a high efficiency reservoir is called the **efficiency of heat engine.** It is denoted by η.

$$\eta = \frac{W}{q_2} = \frac{T_2 - T_1}{T_2} = 1 - \frac{T_1}{T_2}$$

The above relation shows that efficiency depends upon the temperature limits between which the cycle operates. The above relation was stated in the form of **Carnot theorem** by Carnot *i.e.*, **"***Every perfect engine working reversibly between the same temperature limits has the same efficiency, whatever be the working substance.***"**

Sample **Problem 23** *The maximum efficiency of a steam engine operating between* 100°C *and* 25°C *is*

(*a*) 25% (*b*) 22.2% (*c*) 30% (*d*) 20%

Interpret (*d*) $\eta = \frac{T_2 - T_1}{T_2} = \frac{373 - 298}{373} = 0.20$ or 20%

Third Law of Thermodynamics

This law was proposed by German chemist **Walther Nernst.** According to this law, "*The entropy of a perfectly crystalline substance approaches zero as the absolute zero of temperature is approached*"**.** It forms the basis from which entropies at other temperatures can be measured.

$$\lim_{T \to 0} S = 0$$

In case of CO *and* NO *molecules in solid state, there is randomness even at* 0 K *due to their dipole moment hence entropy in such cases is not zero even at* 0 K.

As the temperature is raised, the molecules begin to vibrate. The number of ways in which the vibrational energy can be distributed increases with increase in temperature and the entropy of the solid increases steadily as the temperature increases. At the melting point (mp) of a solid, there is a discontinuous jump in entropy because there are many more ways of arranging the molecules in the liquid than in the solid. An even greater jump in entropy is observed at the boiling point (bp) because molecules in the gas are free to occupy a more larger volume and hence randomness increases.

Check Point 3

1. Why does a real crystal has more entropy than an ideal crystal?
2. Why is entropy of substance taken as zero at absolute zero temperature?
3. How does entropy change when
   (i) temperature increases?
   (ii) pressure decreases?
4. Which of the following will have larger entropy; a mole of ice at 0°C or a mole of water at the same temperature?

Hot Spot 3

GIBBS FREE ENERGY

Analysis of previous years' AIEEE or JEE Main examination papers reveals the importance of Gibbs free energy and its relationship with spontaneity for this examination. The question are generally numerical type and may be direct or indirect.

The maximum amount of energy available to a system, during a process, that can be converted into useful work is called **free energy** or **Gibbs free energy** or **Gibbs energy.** It was called Gibbs free energy in early literature but in accordance with IUPAC recommendations we shall use the term free energy for it.

Gibbs energy is the measure of capacity of a system to do useful work. It is denoted by G and given as

$$G = H - TS$$

where, H = enthalpy of system, S = entropy of system

T = absolute temperature

but we know that, $H = E + pV$

Hence, $G = E + pV - TS$

Similarly, change in free energy is expressed as

$$\Delta G = \Delta E + \Delta(pV) - \Delta(TS)$$

If the process is carried out at constant temperature and pressure, then $\Delta(pV)$ becomes $p\Delta V$ and $\Delta(TS)$ becomes $T\Delta S$.

Hence, $\Delta G = \Delta E + p\Delta V - T\Delta S$ ...(i)

but $\Delta E + p\Delta V = \Delta H$

thus , $\Delta G = \Delta H - T\Delta S$ ...(ii)

The above Eq. (ii) is called **Gibbs Helmholtz equation** and is very useful in predicting the spontaneity of a process.

(i) If ΔG is negative, the process is spontaneous
(ii) If ΔG is positive, the process is non-spontaneous
(iii) If ΔG is zero, the process is in equilibrium state

Gibbs Free Energy as Criteria for Spontaneity

Spontaneity of a process is decided by the value of ΔG. A negative value of ΔG shows a spontaneous process and a positive value shows a non-spontaneous process. Since, the value of ΔG depends upon ΔS and ΔH, these two also play an important role for deciding spontaneity of a process. [$\Delta G = \Delta H - T\Delta S$, Gibbs Helmholtz equation]. For negative value of ΔG, several conditions exist that are mentioned in the table given below :

Table 5.2 **Relationship between ΔG and Spontaneity of a Process**

S. No.	ΔS	ΔH	ΔG	Spontaneous/ Non-spontaneous process
1.	+	–	–ve at all temperatures	Spontaneous at all temperature
2.	–	–	–ve at low temperature but +ve at high temperature	Spontaneous at low temperature but non-spontaneous at high temperature
3.	+	+	+ve at low temperature and –ve at high temperature	Spontaneous at high temperature
4.	+	+	+ve at all temperatures	Non-spontaneous at all temperature

Sample **Problem 24** *For the reaction at 298 K,*

$$2A+B \longrightarrow C$$

$\Delta H = 400$ kJ mol^{-1} and $\Delta S = 0.2$ kJ K^{-1} mol^{-1}

At what temperature will the reaction become spontaneous considering ΔH and ΔS to be constant over the temperature range?

(a) 1000 *K* (b) 1900 *K* (c) 2000 *K* (d) 2200 *K*

Interpret (*d*) In order to solve out such problems following steps are involved.

Step I Write the information that you have.

e.g., In the above question, we have

$$\Delta H = 400 \text{ kJ mol}^{-1}, \Delta S = 0.2 \text{ kJ K}^{-1}\text{mol}^{-1}$$

Process spontaneous, so $\Delta G < 0$

Step II Think which formula you can use for the information given so that you can find spontaneity.

ΔG is helpful in finding spontaneity and is also related to ΔH and ΔS as

$$\Delta G = \Delta H - T\,\Delta S$$

Step III Calculate the value of T by putting the values of ΔH, ΔS and ΔG.

$$0 > \Delta H - T\,\Delta S$$

$$T\,\Delta S > \Delta H, T > \frac{\Delta H}{\Delta S}, T > \frac{400}{0.2}, T > 2000 \text{ K}$$

Sample **Problem 25** *What is the free energy change; ΔG, when 1.0 mole of water at 100°C and 1 atm pressure is converted into steam at 100°C and 1 atm pressure?*

(a) 0 *cal* (b) 10 *cal* (c) 320 *cal* (d) 290 *cal*

Interpret (a) At equilibrium $\Delta G = 0$

Standard Free Energy Change

The free energy change for a process at 298 K and 1 atm pressure in which the reactants in their standard state are converted into products in their standard state, is called **standard free energy change**. It is denoted by $\Delta G°$.

Free energy change when1 mole of the compound is made from its elements in their standard states is called **standard molar free energy of formation of a compound.** For an element, it is taken as zero by convention. Standard free energy for formation of $H^+(aq)$ is zero.

Efficiency of a fuel cell

$$= \frac{\text{total useful work}}{\text{total heat given}} \times 100 = \frac{\Delta G}{\Delta H} \times 100$$

Caution Points

(*i*) *The dependence of free energy on temperature is given by Gibbs-Helmholtz equation :*

$$\Delta G = \Delta H + T \cdot \left[\frac{\partial(\Delta G)}{\partial T}\right]_P$$

(*ii*) *For isothermal expansion or compression of an ideal gas,* $\Delta G = nRT \ln \frac{p_2}{p_1}$

(*iii*) *Process with negative ΔG is called exo-ergonic and positive ΔG, endo-ergonic.*

(*iv*) *$\Delta_f H°$ and $\Delta G°$ of an element is taken as zero but $\Delta S°$ of an element never be equal to zero.*

Relation between Gibbs Free Energy and Equilibrium Constant

$$\Delta G = \Delta G° + RT \ln Q$$

At equilibrium, $\Delta G = 0$ and $Q = K$

on putting the values we get

$$0 = \Delta G° + RT \ln K \text{ or } \Delta G° = RT \ln K$$

Thus the standard free energy $(\Delta G°)$ is related to equilibrium constant K as

$$\Delta G° = -RT \ln K \; i.e., \Delta G° = -2.303\, RT \log K$$

Table 5.3 **Relationship between the Standard Free Energy Change and the Equilibrium Constant**

$\Delta G°$	$\log K$	K	Comment
$\Delta G° = 0$	$\log K = 0$	1	The equilibrium mixture contains comparable amounts of reactants and products ($K = 1$ for 1M concentrations and 1 atm partial pressures)
$\Delta G° < 0$	$\log K > 0$	$K > 1$	The equilibrium mixture is mainly products.
$\Delta G° > 0$	$\log K < 0$	$K < 1$	The equilibrium mixture is mainly reactants.

Relation between Gibbs Free Energy and EMF of the Cell

Any process that occurs spontaneously can be utilised for performance of work. The greater the Gibbs energy change, the greater is the amount of work that can be obtained from the process.

The free energy change (ΔG) is related to the electrical work done in the cell as

$$\Delta G = -nFE_{\text{cell}}$$

where, E = emf of the cell

n = number of moles of electrons involved

F = Faraday's constant *i.e.*, 96500 C

If reactants and products are in their standard state,

$$\Delta G° = -nFE°$$

where, $E°$ = standard cell potential

Check Point 4

1. What is the value of ΔG at melting point of ice?
2. Which one becomes zero at equilibrium from ΔG and $\Delta G°$?
3. An exothermic reaction $A \rightarrow B + C$ is spontaneous in the back direction. What is the sign of ΔS for the forward direction?
4. If for a hypothetical reaction; $A(s) + B(s) \longrightarrow AB(g)$, the heat of the reaction is $+y$, tell under what conditions will the reaction occur spontaneously?

WORKED OUT Examples

Example 1 *56 g of iron reacts with* HCl *in a closed vessel of fixed volume. Again, same amount of* Fe *is made to react in an open beaker at 27°C. The work done (in cal) in both the cases will be respectively*

(a) –600, –600 (b) –600, +600
(c) –300, –600 (d) 0, –600

Solution (*d*) In first case, since the volume is fixed,

$$\Delta V = 0$$
$$W = -p_{ext}\Delta V = 0$$

In second case,

$$W = -p_{ext}\Delta V$$

or $$= -p_{ext} \times \frac{\Delta n_g RT}{p_{ext}} = -\Delta n_g RT \qquad \left(\because \Delta V = \frac{\Delta n_g RT}{p}\right)$$

56 g of Fe = 1 mole of Fe

Thus, $$\underset{1\text{ mol}}{\text{Fe}(s)} + 2\text{HCl}\,(aq) \longrightarrow \text{FeCl}_2(aq) + \underset{1\text{ mol}}{\text{H}_2(g)}$$

$$\Delta n_g = 1 - 0 = 1$$
$$W = -1 \times 2 \times 300 = -600 \text{ cal}$$

Example 2 *Consider a system consisting of one mole of a diatomic gas, contained in a piston. What is the temperature change of the gas, if* $q = 50.0\,J$ *and* $W = -100.0\,J$?

(a) –50 *J* (b) –2.4 *J*
(c) – 5.8 *J* (d) –1.25 *J*

Solution (*b*) According to the first law of thermodynamics,

$$\Delta E = q + W = 50 - 100 = -50 \text{ J}$$

Molar heat capacity at constant volume, $C_V = \left(\frac{\Delta E}{\Delta T}\right)_V$

$$\therefore \qquad \Delta T = \frac{\Delta E}{C_V} = \frac{-50\text{ J}}{\frac{5}{2}R} = \frac{-50}{\frac{5}{2} \times 8.314} = -2.41 \text{ K}$$

Example 3 *1 mole of carbon dioxide gas at 300 K is expanded under adiabatic condition such that its volume becomes 27 times. The work done during the process is (Given,* $\gamma = 1.33$ *and* $C_V = 6$ *cal* mol^{-1} *for* CO_2)

(a) 1200 *cal*
(b) 600 *cal*
(c) 1800 *cal*
(d) –600 *cal*

Solution (*a*) For adiabatic condition, $\frac{T_2}{T_1} = \left(\frac{V_1}{V_2}\right)^{\gamma - 1}$

or $$\frac{T_2}{T_1} = \left(\frac{1}{27}\right)^{1.33-1} = \left(\frac{1}{27}\right)^{0.33}$$

$$= \left(\frac{1}{27}\right)^{1/3} = \frac{1}{3}$$

or $$T_2 = \frac{1}{3} \times T_1$$

$$T_2 = \frac{1}{3} \times 300 = 100 \text{ K}$$

From first law of thermodynamics,

$$\Delta E = q + W$$
$$W = -\Delta E$$

($\because q = 0$ for adiabatic expansion)

$$= -C_V (T_2 - T_1)$$
$$= -6\ (100 - 300) = +1200 \text{ cal}$$

Example 4 *The vapour pressure of benzene is* 0.153×10^5 Nm^{-2} *at 303 K and* 0.520×10^5 Nm^{-2} *at 333 K. The mean latent heat of evaporation of benzene over this temperature range is*

(a) 48.5 *kJ* mol^{-1} (b) 31.8 *kJ* mol^{-1}
(c) 40.5 *kJ* mol^{-1} (d) 34.2 *kJ* mol^{-1}

Solution (*d*) From Clausius-Clapeyron equation,

$$\Delta H_V = \frac{2.303\, RT_1T_2}{(T_2 - T_1)} \log \frac{p_2}{p_1}$$

$$= \frac{2.303 \times 8.314 \times 303 \times 333}{(333 - 303)} \log \frac{0.520 \times 10^5}{0.153 \times 10^5}$$

$$= 34.2 \times 10^3 \text{ J} = 34.2 \text{ kJ mol}^{-1}$$

Example 5 *The heat liberated from the combustion of* 0.5 g *of carbon raised the temperature of* 2000 g *of water from* 24°C *to* 26°C*. The heat of the combustion of carbon is*

(a) –4 *kcal* (b) –8 *kcal*
(c) –62 *kcal* (d) –96 *kcal*

Solution (*d*) The amount of heat liberated by 0.05 g of *C*

$$= ms\Delta t$$
$$= 2000 \times 1 \times (26 - 24)$$
$$= 4000 \text{ cal} = 4 \text{ kcal}$$

$$\text{Calorific value} = \frac{4\text{ kcal}\times 1}{0.5} = 8\text{ kcal per g}$$

∴ Heat of combustion = $-8\times 12 = -96$ kcal per mole

Example 6 *The specific heat of silver is* 0.0565 *cal/g°C. Assuming no heat loss, the final temperature, when* 100 g *of* Ag *at* 40.0°*C is immersed in* 60.0 g *of water at* 10.0°*C, is*

(*a*) 10.15 (*b*) 12.58
(*c*) 40.00 (*d*) 19.16

Solution (*b*) Suppose final temperature is t and $Q = ms\Delta t$

$$\text{Heat lost by silver} = 100\times 0.0565\times(40-t)$$
$$\text{Heat gained by water} = 60\times 1\times(t-10)$$
$$\text{Heat lost by silver} = \text{heat gained by water}$$
$$5.65\times(40-t) = 60\,(t-10)$$
$$\therefore\quad t = 12.58°\text{ C}$$

Example 7 *Standard enthalpy of formation of* $C_3H_7NO_2(g)$, $CO_2(g)$ *and* $H_2O(l)$ *are* −133.57, −94.05 *and* −68.32 *kcal/mol respectively. Standard enthalpy of combustion of* CH_4 *at* 25°*C is* −212.8 *kcal/mol.*

Calculate ΔE *for combustion of* $C_3H_7NO_2(s)$.

(*a*) −372.69 (*b*) −387.70
(*c*) −370.89 (*d*) −372.16

Solution (*b*) $C_3H_7NO_2(s) + \frac{11}{2}O_2(g) \longrightarrow 3CO_2(g) + \frac{1}{2}N_2(g) + \frac{7}{2}H_2O(g)$

$$\Delta H_{\text{comb}} = 3\Delta H_f^\circ(CO_2) + 0 + \frac{7}{2}\Delta H_f^\circ(H_2O) - \Delta H_f^\circ(C_3H_7NO_2) - 0$$
$$= 3(-94.05) + \frac{7}{2}(-68.32) - (-133.57)$$
$$= -387.70\text{ kcal/mol}$$

Example 8 *Find* ΔH *of the following reaction,*

$$OF_2(g) + H_2O(g) \longrightarrow O_2(g) + 2HF(g);$$

Average bond energies of O—F, O—H, O═O, H—F *are* 44, 111, 118 *and* 135 *kcal/mol respectively.*

(*a*) 310 (*b*) −698
(*c*) −78 (*d*) −388

Solution (c) Energy used in bond breaking, *i.e.*, ΔH_1

$$F-O-F \longrightarrow O(g) + 2F(g);\qquad \Delta H = +2\times 44$$
$$H-O-H \longrightarrow O(g) + 2H(g);\qquad \Delta H = +2\times 111$$
$$\therefore\quad \Delta H_1 = 2\times 44 + 2\times 111 = +310\text{ kcal}$$

Energy released in bond formation, *i.e.*, ΔH_2

$$O + O \longrightarrow O_2;\qquad \Delta H = -118$$
$$2[H + F \longrightarrow H-F];\qquad \Delta H = -2\times 135$$
$$\therefore\quad \Delta H_2 = -118 + (-2\times 135) = -388\text{ kcal}$$

Using Hess's Law; $\Delta_r H = H_1 + H_2$

$$= 310 + (-388) = -78\text{ kcal.}$$

Example 9 *Calculate the standard free energy change for the formation of methane at 298 K. The value of* $\Delta_r H^\circ$ *for* $CH_4(g)$ *is* −74.81 *kJ mol*$^{-1}$ *and S values for* C(*graph*), $H_2(g)$ *and* $CH_4(g)$ *are* 5.70, 130.7 *and* 186.3 JK^{-1} mol^{-1} *respectively.*

(*a*) −80.8 (*b*) −98.91
(*c*) −50.74 (*d*) −40.4

Solution (c) For the reaction; $C + 2H_2 \longrightarrow CH_4$

Given, $\Delta H^\circ = -74.81\text{ kJ mol}^{-1}$

ΔS_m° can be calculated as

$$\Delta S_m^\circ = S^\circ_{m\,(\text{product})} - S^\circ_{m\,(\text{reactant})}$$
$$= S_m^\circ CH_4(g) - [S_m^\circ C_{(\text{graph})} + 2S_m^\circ H_2(g)]$$
$$= [186.3 - (5.70 + 2\times 130.7)]\text{ JK}^{-1}\text{ mol}^{-1}$$
$$= -80.8\text{ JK}^{-1}\text{ mol}^{-1}$$
$$= -80.8\times 10^{-3}\text{ JK}^{-1}\text{ mol}^{-1}$$

Since, $\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ$

$$= -74.81 - [(298)\times(-80.8\times 10^{-3})]$$
$$= -74.81 + 24.07\text{ kJ mol}^{-1}$$
$$= -50.74\text{ kJ mol}^{-1}$$

Example 10 *What is the equilibrium constant, K for the following reaction at 400 K?*

$$2NOCl(g) \rightleftharpoons 2NO(g) + Cl_2(g)$$

$\Delta H = 77.2$ kJ mol^{-1} *and* $\Delta S = 122$ JK^{-1} mol^{-1} *at* 400 *K*.

(*a*) −3.708 (*b*) 1.95×10^{-4}
(*c*) 2.8×10^4 (*d*) 1.67×10^{-5}

Solution (*b*) $\Delta G = \Delta H - T\Delta S$

$$= 77.2 - 400\times 122\times 10^{-3}$$
$$= +28.4\text{ kJ mol}^{-1} = 28400\text{ J mol}^{-1}$$

Further, $\Delta G = -2.303\,RT\log K$

or $28400 = -2.303\times 8.314\times 400\times\log K$

$$\log K = -\frac{28400}{2.303\times 8.314\times 400}$$
$$\log K = -3.708$$
$$K = \text{Antilog}\,(-3.708) = 1.95\times 10^{-4}$$

Start Practice for JEE Main

Round I (Topically Divided Problems)

Fundamentals of Thermodynamics

1. Identify the intensive quantity from the following.

(a) Enthalpy and temperature
(b) Volume and temperature
(c) Enthalpy and volume
(d) Temperature and refractive index

2. If a refrigerator's door is opened then, we get

(a) room heated
(b) room cooled
(c) more amount of heat is passed out
(d) no effect on room

3. In ... process, work is done at the expense of internal energy.

(a) isothermal (b) isochoric
(c) adiabatic (d) isobaric

4. Choose the correct answer. A thermodynamic state function is a quantity **[NCERT]**

(a) used to determine heat changes
(b) whose value is independent of path
(c) used to determine pressure-volume work
(d) whose value depends on temperature only.

5. Thermodynamics is not concerned about...... . **[NCERT Exemplar]**

(a) energy changes involved in a chemical reaction
(b) the extent to which a chemical reaction proceeds
(c) the rate at which a reaction proceeds
(d) the feasibility of a chemical reaction

6. Which of the following statements is correct? **[NCERT Exemplar]**

(a) The presence of reacting species in a covered beaker is an example of open system
(b) There is an exchange of energy as well as matter between the system and the surroundings in a closed system
(c) The presence of reactants in a closed vessel made up of copper is an example of a closed system
(d) The presence of reactants in a thermos flask or any other closed insulated vessel is an example of a closed system

Work, Heat and First Law of Thermodynamics

7. Which of the following expressions represents the first law of thermodyamics?

(a) $\Delta E = -q + W$ (b) $\Delta E = q - W$
(c) $\Delta E = q + W$ (d) $\Delta E = -q - W$

8. If a gas at constant temperature and pressure expands then its

(a) internal energy increases and then decreases
(b) internal energy increases
(c) internal energy remains the same
(d) internal energy decreases

9. At 27° C, one mole of an ideal gas is compressed isothermally and reversibly form a pressure of 2 atm to 10 atm. The values of ΔE and q are $(R = 2)$

(a) 0, −965.84 cal
(b) −965.84 cal, −865.58 cal
(c) +865.58 cal, −865.58 cal
(d) −865.58 cal, −865.58 cal

10. In a process, 701 J of heat is absorbed by a system and 394 J of work is done by the system. What is the change in internal energy for the process? **[NCERT]**

(a) −464 J (b) + 464 J
(c) +307 J (d) −307 J

11. The change in internal energy for an isolated system at constant volume is **[NCERT Exemplar]**

(a) zero (b) − 2.18 erg
(c) +4.27 erg (d) +2.78 erg

12. In an adiabatic process, no transfer of heat takes place between system and surroundings. Choose the correct option for free expansion of an ideal gas under adiabatic condition form the following. **[NCERT Exemplar]**

(a) $q = 0$, $\Delta T \neq 0$, $W = 0$ (b) $q \neq 0$, $\Delta T = 0$, $W = 0$

(c) $q = 0$, $\Delta T = 0$, $W = 0$ (d) $q = 0$, $\Delta T = 0$, $W \neq 0$

13. In a closed insulated container, a liquid is stirred with a paddle to increase its temperature. In this process, which of the following is true?

(a) $\Delta E = W \neq 0, Q = 0$ (b) $\Delta E \neq 0, Q = W = 0$

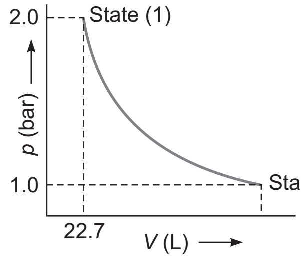
(c) $\Delta E = W = Q = 0$ (d) $\Delta E = 0, Q \neq 0, W = 0$

14. How many joules of heat are absorbed when 70.0 g of water is completely vaporised at its boiling point?

(a) 23352 J (b) 7000 J

(c) 15813 J (d) 158200 J

15. 1.0 mole of a monoatomic idea gas is expanded from state (1) to state (2) as shown in the figure. Calculate the work done for the expansion of gas from state (1) to state (2) at 298 K **[NCERT Exemplar]**



(a) −1717.46 J (b) +1717.46 J

(c) −1908.2 J (d) +1908.2 J

16. An ideal gas is allowed to expand against a constant pressure of 2 bar from 10 L to 50 L in one step. The amount of work done by the gas is *x*. If the same expansion were carried out reversibly, will the work done be higher or lower than the earlier case? **[NCERT Exemplar]**

(a) Lower (b) Higher

(c) Same as before (d) Can't anything

Enthalpy $\Delta_f H$ and $\Delta_r H$

17. The enthalpy of reaction for the reaction :

$2H_2(g) + O_2(g) \longrightarrow 2H_2O(l)$ is $\Delta_r H^\ominus = -572 \text{kJ mol}^{-1}$

What will be the standard enthalpy for the of formation of $H_2O(l)$? **[NCERT Exemplar]**

(a) -572 kJ mol^{-1}

(b) + 57 kJ mol^{-1}

(c) +286 kJ mol^{-1}

(d) -286 kJ mol^{-1}

18. Which of the following equations correctly represents the standard heat of formation (ΔH_f°) of methane?

(a) C(diamond) + $2H_2 \longrightarrow CH_4(g)$

(b) C(graphite) + $2H_2(g) \longrightarrow CH_4(l)$

(c) C(graphite) + $2H_2(g) \longrightarrow CH_4(g)$

(d) C(graphite) + $4H \longrightarrow CH_4(g)$

19. ΔU° of combustion of methane is $-X$ kJ mol^{-1}. The value of ΔH° is **[NCERT]**

(a) $= \Delta U^\circ$ (b) $> \Delta U^\circ$

(c) $< \Delta U^\circ$ (d) $= 0$

20. For the reactions $A \to B$; $\Delta H = +24$ kJ/mol and $B \to C$; $\Delta H = -18$ kJ/mol, the decreasing order of enthalpy of *A*, *B* and *C* follows the order

(a) *A, B, C* (b) *B, C, A*

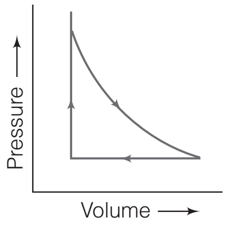
(c) *C, B, A* (d) *C, A, B*

21. If the combustion of 1 g of graphite produces 20.7 kJ of heat, what will be the molar enthalpy change? **[NCERT Exemplar]**

(a) -2.48 kJ mol^{-1} (b) -248 kJ mol^{-1}

(c) -2.48 J mol^{-1} (d) -248 J mol^{-1}

22. A sample of 1.0 mole of a monoatomic ideal gas is taken through a process of expansion and compression as shown in the figure. What will be the value of ΔH for the process as a whole? **[NCERT Exemplar]**



(a) −3.150 (b) −2.303

(c) +2.303 (d) 0

23. The enthalpies of the elements in their standard states are assumed to be

(a) zero at 298 K

(b) unit at 298 K

(c) zero at all temperatures

(d) zero at 273 K

24. For the reaction $N_2 + 3H_2 \rightleftharpoons 2NH_3$; ΔH is

(a) $\Delta E - 2RT$ (b) $\Delta E - RT$

(c) $\Delta E + RT$ (d) $\Delta E + 2RT$

25. What is Δn_g for the combustion of 1 mole of benzene, when both the reactants and products are gas at 298 K?

(a) 0 (b) 1

(c) 0.5 (d) 1.5

26. The ΔH_f° of O_3, CO_2, NH_3 and HI are 142.2, –393.3, –46.2 and + 25.9 kJ per mol respectively. The order of their increasing stabilities will be

(a) O_3, CO_2, NH_3, HI (b) CO_2, NH_3, HI, O_3
(c) O_3, HI, NH_3, CO_2 (d) NH_3, HI, CO_2, O_3

27. Two moles of an ideal gas is expanded isothermally and reversibly from 1 L to 10 L at 300 K. The enthalpy change (in kJ) for the process is

(a) 11.4 (b) –11.4 (c) 0 (d) 4.8

Different Enthalpies, Hess's Law and Bond Energy

28. 50 mL of water takes 5 min to evaporate from a vessel on a heater connected to an electric source which delivers 400 W. The enthalpy of vaporisation of water is

(a) 40.3 kJ per mol (b) 43.2 kJ per mol
(c) 16.7 kJ per mol (d) 180.4 kJ per mol

29. Hess's law is applicable for the determination of heat of

(a) reaction (b) formation
(c) transition (d) All of these

30. Enthalpy of combustion of carbon to CO_2 is $-393.5\text{ kJ mol}^{-1}$. Calculate the heat released upon the formation of 35.2 g of CO_2 from carbon and dioxygen gas. (Molar mass of $CO_2 = 44\text{ g mol}^{-1}$). [NCERT]

(a) 13.851 kJ (b) 138.5 kJ
(c) 31.48 J (d) 314.8 kJ

31. Consider the reaction given below. On the basis of these reactions find out which of the algebric relations given in options (a) to (d) is correct?

(I) $C(g) + 4H(g) \longrightarrow CH_4(g); \Delta_r H = x\text{ kJmol}^{-1}$

(II) $C\text{ (graphite, s)} + 2H_2(g) \longrightarrow CH_4(g);$

$\Delta_r H = y\text{ kJ mol}^{-1}$ [NCERT Exemplar]

(a) $x = y$ (b) $x = 2y$
(c) $x > y$ (d) $x < y$

32. What would be the heat released when an aqueous solution containing 0.5 mole of HNO_3 is mixed with 0.3 mole of OH^-? (Enthalpy of neutralization is –57.1 kJ)

(a) 28.5 kJ (b) 17.1 kJ
(c) 45.7 kJ (d) 1.7 kJ

33. $C_{\text{diamond}} + O_2 \longrightarrow CO_2;$ $\Delta H = -395.3\text{ kJ/ mol}$

$C_{\text{graphite}} + O_2 \longrightarrow CO_2;$ $\Delta H = -393.4\text{ kJ / mol}$

$C_{\text{graphite}} \longrightarrow C_{\text{diamond;}}$ $\Delta H = ?$

(a) –3.8 (b) –1.9
(c) +3.8 (d) +1.9

34. Given,

(i) $S + O_2 \longrightarrow SO_2,$ $\Delta H = -298.2\text{ kJ}$

(ii) $SO_2 + \frac{1}{2}O_2 \longrightarrow SO_3,$ $\Delta H = -98.7\text{ kJ}$

(iii) $SO_3 + H_2O \longrightarrow H_2SO_4,$ $\Delta H = -130.2\text{ kJ}$

(iv) $H_2 + \frac{1}{2}O_2 \longrightarrow H_2O,$ $\Delta H = -287.3\text{ kJ}$

The enthalpy of formation of H_2SO_4 is

(a) –715.4 kJ (b) –814.4 kJ
(c) –554 kJ (d) –455.3 kJ

35. Enthalpy of sublimation of a substance is equal to [NCERT Exemplar]

(a) enthalpy of fusion + enthalpy of vaporisation
(b) enthalpy of fusion
(c) enthalpy of vaporisation
(d) twice the enthalpy of vaporisation

36. The net enthalpy change of a reaction is the amount of energy required to break all the bonds in reactant molecules minus amount of energy required to form all the bonds in the product molecules. What will be the enthalpy change for the following reaction?

$$H_2(g) + Br_2(g) \longrightarrow 2HBr(g)$$

Given that bond energy of H_2, Br_2 and HBr is $435\text{ kJmol}^{-1}, 192\text{ kJmol}^{-1}$ and 368 kJmol^{-1} respectively.

(a) $+109\text{ kJ mol}^{-1}$ (b) -109 kJ mol^{-1}
(c) $+493\text{ kJ mol}^{-1}$ (d) -493 kJ mol^{-1}

37. The enthalpy of vaporisation of CCl_4 is 30.5 kJ mol^{-1}. Calculate the heat required for the vaporisation of 284 g of CCl_4 at constant pressure. (Molar mass of $CCl_4 = 154\text{g mol}^{-1}$). [NCERT Exemplar]

(a) 56.2 kJ (b) 52.5 kJ
(c) 18.4 kJ (d) 30.5 kJ

38. In a calorimeter, the temperature of the calorimeter increases by 6.12 K, the heat capacity of the system is 1.23 kJ/g/deg. What is the molar heat of decomposition for NH_4NO_3?

(a) –7.53 kJ/mol
(b) –398.1 kJ/mol
(c) –16.1 kJ/mol
(d) –602 kJ/mol

39. Which is the best definition of heat of neutralization?

(a) The heat absorbed when one gram molecule of an acid is neutralized by one gram molecule of a base in dilute solution at a stated temperature
(b) The heat set free or absorbed when one gram atom of an acid is neutralized by one gram atom of a base at a stated temperature

(c) The heat set free or absorbed when a normal solution containing one gram-equivalent of an acid is neutralized by a normal solution containing one gram-equivalent of a base at a stated temperature

(d) The heat set free when one gram-equivalent of an acid is neutralized by one gram-equivalent of a base in dilute solution at a stated temperature

40. 18.0 g water completely vaporises at 100°C and 1 bar pressure and the enthalpy change in the process is 40.79 kJ mol^{-1}. What will be the enthalpy change for vaporising two moles of water under the same conditions and what is the standard enthalpy of vaporisation for water? **[NCERT Exemplar]**

(a) 81.58 kJ, 81.58 kJ (b) 40.79kJ, 40.79 kJ
(c) 40.79 kJ,81.58 kJ (d) 81.58kJ, 40.79 kJ

41. The absolute enthalpy of neutralisation of the reaction

$\text{MgO}(s) + 2\text{HCl}(aq) \longrightarrow \text{MgCl}_2(aq) + \text{H}_2\text{O}(l)$ will be

(a) greater than -57.33 kJ mol^{-1}
(b) 57.33 kJ mol^{-1}
(c) less than -57.33 kJ mol^{-1}
(d) -57.33 kJ mol^{-1}

42. The heat of formations of $\text{CO}(g)$ and $\text{CO}_2(g)$ are –26.4 kcal and –94.0 kcal respectively. The heat of combustion of carbon monoxide will be

(a) –67.6 kcal (b) 36.5 kcal
(c) –36.5 kcal (d) –46.5 kcal

43. Enthalpy of solution of NaOH (solid) in water is – 41.6 kJ mol^{-1}. When NaOH is dissolved in water, the temperature of water

(a) increases (b) decreases
(c) does not change (d) fluctuates indefinitely

44. The enthalpy of dissolution of $\text{BaCl}_2(s)$ and $\text{BaCl}_2 \cdot 2\text{H}_2\text{O}(s)$ are –20.6 and 8.8 kJ per mol respectively. The enthalpy of hydration for

$\text{BaCl}_2(s) + 2\text{H}_2\text{O} \longrightarrow \text{BaCl}_2 \cdot 2\text{H}_2\text{O}(s)$ is

(a) 29.4 kJ (b) –29.4 kJ
(c) –11.8 kJ (d) 38.2 kJ

45. Given that, $\text{C}(g) + 4\text{H}(g) \longrightarrow \text{CH}_4(g)$; $\Delta H = -166$ kJ. The bond energy C—H will be

(a) –416 kJ/mol (b) –41.6 kJ/mol
(c) 832 kJ/mol (d) None of these

46. If enthalpies of methane and ethane are respectively 320 and 360 cal then the bond energy of C—C bond is

(a) 80 cal (b) 40 cal (c) 60 cal (d) 120 cal

47. The heat of atomisation of $\text{PH}_3(g)$ is 228 kcal per mol and that of $\text{P}_2\text{H}_4(g)$ is 335 kcal per mol. The energy of P—P bond is

(a) 102 kcal/mol (b) 31 kcal/mol
(c) 26 kcal/mol (d) 204 kcal/mol

48. The heat evolved in the combustion of methane is given by the following equation

$$\text{CH}_4(g) + 2\text{O}_2(g) \longrightarrow \text{CO}_2(g) + 2\text{H}_2\text{O}(l); \quad \Delta H = -890.3 \text{ kJ}$$

How many gram of methane would be required to produce 445.15 kJ of heat of combustion?

(a) 4 g (b) 8 g (c) 12 g (d) 16 g

49. Diborane is a potential rocket fuel which undergoes combustion according to the equation

$$\text{B}_2\text{H}_6(g) + 3\text{O}_2(g) \longrightarrow \text{B}_2\text{O}_3(g) + 3\text{H}_2\text{O}(g)$$

Calculate the enthalpy change for the combustion of diborane.

Given

(i) $2\text{B}(s) + \frac{3}{2}\text{O}_2(g) \longrightarrow \text{B}_2\text{O}_3(s); \Delta H = -1273$ kJ/mol
(ii) $\text{H}_2(g) + \frac{1}{2}\text{O}_2(g) \longrightarrow \text{H}_2\text{O}(l); \Delta H = -286$ kJ/mol
(iii) $\text{H}_2\text{O}(l) \longrightarrow \text{H}_2\text{O}(g); \quad \Delta H = 44$ kJ/mol
(iv) $2\text{B}(s) + 3\text{H}_2(g) \longrightarrow \text{B}_2\text{H}_6(g); \Delta H = 36$ kJ/mol

(a) +2035 kJ/mol (b) –2035 kJ/mol
(c) +2167 kJ/mol (d) –2167 kJ/mol

50. The standard molar heat of formation of ethane, CO_2 and water (l) are respectively –21.1, –94.1 and – 68.3 kcal. The standard molar heat of combustion of ethane will be

(a) –372 kcal (b) 162 kcal (c) –240 kcal (d) 183.5 kcal

51. Combustion of glucose takes place according to the equation

$$\text{C}_6\text{H}_{12}\text{O}_6 + 6\text{CO}_2 \longrightarrow 6\text{CO}_2 + 6\text{H}_2\text{O}; \ \Delta H = -72 \text{ kcal}$$

How much energy will be required for the production of 1.6 g of glucose? (Molecular mass of glucose = 180)

(a) 0.064 kcal (b) 0.64 kcal (c) 6.4 kcal (d) 64 kcal

Heat Capacity, Entropy, Second and Third Law of Thermodynamics

52. The enthalpy of vaporisation of a substance is 840 J/mol and its boiling point is –173K. Its entropy of vaporisation is

(a) 4.8 J/mol/K (b) 12 J/mol/K
(c) 210/mol/K (d) 49 J/mol/K

53. Maximum entropy will be in which of the following?

(a) Ice (b) Liquid water
(c) Snow (d) Water vapour

54. The molar heat capacity of water at constant pressure is 75 JK^{-1} mol^{-1}. When 1.0 kJ of heat is supplied to 100 g of water which is free to expand the increase in temperature of water is

(a) 2.4 K (b) 3.6 K (c) 4.8 K (d) 1.2 K

55. For an isolated system, $\Delta U = 0$, what will be ΔS ? **[NCERT]**

(a) 0 (b) > 0
(c) < 0 (d) ≥ 0

56. For the reaction, $2Cl(g) \longrightarrow Cl_2(g)$, what are the signs of ΔH and ΔS ? **[NCERT]**

(a) +,+ (b) +, –
(c) –, – (d) –, +

57. The entropy change in surroundings when 1.00 mole of $H_2O(l)$ is formed under standard conditions is

$$\Delta_f H^\circ = -286 \text{ kJ mol}^{-1}.$$ **[NCERT]**

(a) 856.5 JK^{-1} mol^{-1} (b) 765 JK^{-1} mol^{-1}
(c) 1050 JK^{-1} mol^{-1} (d) 959.7 JK^{-1} mol^{-1}

58. The standard molar entropy of $H_2O(l)$ is 70 JK^{-1} mol^{-1}. Standard molar entropy of $H_2O(s)$ is **[NCERT Exemplar]**

(a) more than 70 JK^{-1} mol^{-1}
(b) less than 70 JK^{-1} mol^{-1}
(c) equal to 70 JK^{-1} mol^{-1}
(d) None of the above

59. Heat capacity (C_p) is an extensive property but specific heat (C) is an intensive property. What will be the relation between C_p and C for 1 mole of water? **[NCERT Exemplar]**

(a) + 4.18 JK^{-1} (b) – 4.18 JK^{-1}
(c) – 75.3 JK^{-1} (d) + 75.3 JK^{-1}

60. Which one of the following has ΔS° greater than zero?

(a) $CaO + CO_2(g) \rightleftharpoons CaCO_3(s)$
(b) $NaCl(aq) \rightleftharpoons NaCl(s)$
(c) $NaNO_3(s) \rightleftharpoons Na^+(aq) + NO_3^-(aq)$
(d) $N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$

61. Mark the correct statement.

(a) For a chemical reaction to be feasible, ΔG should be zero
(b) Entropy is a measure of order in a system
(c) For a chemical reaction to be feasible, ΔG should be positive
(d) The total energy of an isolated system is constant

62. The entropy values (in JK^{-1} mol^{-1}) of $H_2(g)$ = 130.6 $Cl_2(g)$ = 223.0 and $HCl(g)$ = 186.7 J mol^{-1} K^{-1} at 298 K and 1 atm pressure, then entropy change for the reaction

$$H_2(g) + Cl_2(g) \longrightarrow 2HCl(g) \text{ is}$$

(a) +540.3
(b) +727.3
(c) −166.9
(d) +19.8

63. A container has hydrogen and oxygen mixture in the ratio of 1 : 1 by weight, then

(a) internal energy of the mixture decreases
(b) internal energy of the mixture increases
(c) entropy of the mixture increases
(d) entropy of the mixture decreases

64. Equal volumes of monoatomic and diatomic gases at same initial temperature and pressure are mixed. The ratio of specific heats of the mixture (C_p/C_V) will be

(a) 1 (b) 2
(c) 1.67 (d) 1.2

65. If a gas has 2 atm and 5 atm pressure at 30°C and 27°C respectively. Then it will

(a) cool on expansion
(b) warm on expansion
(c) no change on expansion
(d) None of the above

Gibbs Free Energy and Spontaneity

66. The free energy change for a reversible reaction at equilibrium is

(a) large, positive (b) small, negative
(c) small, positive (d) zero

67. In which of the following conditions a chemical reaction cannot occur?

(a) ΔH and ΔS increase and $T\Delta S > \Delta H$
(b) ΔH and ΔS decrease and $\Delta H > T\Delta S$
(c) ΔH increases and ΔS decreases
(d) ΔH decreases and ΔS increases

68. The equilibrium constant for a reaction is 10. What will be the value of ΔG°? $R = 8.314$ JK^{-1} mol^{-1}, $T = 300$ K. **[NCERT]**

(a) −574.414 J mol^{-1} (b) 5744.14 J mol^{-1}
(c) −57.4414 J mol^{-1} (d) 57441.4 J mol^{-1}

69. Calculate the free energy change of

$$2CuO(s) \longrightarrow Cu_2O(s) + \frac{1}{2} O_2(g)$$

Given, ΔH = 145.6 kJ per mol

ΔS = 116 J per mol per K

(a) 113.8 kJ per mol
(b) 221.5 kJ per mol
(c) 55.4 kJ per mol
(d) 145.6 kJ per mol

70. For a reaction at 25°C, enthalpy and entropy changes are -11.7×10^3 J mol^{-1} and -105 J mol^{-1} K^{-1} respectively. What is the Gibbs free energy?

(a) 15.05 kJ (b) 19.59 kJ
(c) 2.55 kJ (d) 22.55 kJ

Round II (Mixed Bag)

Only One Correct Option

1. When one mole of monoatomic ideal gas at T temperature undergoes adiabatic change under a constant external pressure of 1 atm, change in volume is from 1 L to 2 L. The final temperature in kelvin would be

(a) $\frac{T}{2^{(2/3)}}$ (b) $T + \frac{2}{3 \times 0.0821}$

(c) T (d) $T - \frac{2}{3 \times 0.0821}$

2. If 900 J/g of heat is exchanged at boiling point of water then increase in entropy is

(a) 43.4 J/mol (b) 87.2 J/mol

(c) 900 J/mol (d) zero

3. Calculate the enthalpy change on freezing of 1.0 mole of water at 10.0°C to ice at – 10.0° C.

$$\Delta_{\text{fus}}H = 6.03 \text{ kJ mol}^{-1} \text{ at } 0°\text{C}.$$
$$C_p[H_2O(l)] = 75.3 \text{ J mol}^{-1} \text{ K}^{-1}$$
$$C_p[H_2O(s)] = 36.8 \text{ J mol}^{-1} \text{ K}^{-1}$$

[NCERT]

(a) -753 J mol^{-1} (b) -368 J mol^{-1}

(c) $-7.151 \text{ kJ mol}^{-1}$ (d) $-6.03 \text{ kJ mol}^{-1}$

4. Given that $dE = TdS - pdV$ and $H = E + pV$. Which one of the following relations is true?

(a) $dH = TdS - Vdp$ (b) $dH = SdT + Vdp$

(c) $dH = -SdT - Vdp$ (d) $dH = dE - pdV$

5. The free energy change for the following reactions are given below.

$$C_2H_2(g) + \frac{5}{2}O_2(g) \longrightarrow 2CO_2(g) + H_2O(l); \quad \Delta G° = -1234 \text{ kJ}$$
$$C(s) + O_2(g) \longrightarrow CO_2(g)\,; \quad \Delta G° = -394 \text{ kJ}$$
$$H_2(g) + \frac{1}{2}O_2(g) \longrightarrow H_2O(l)\,; \quad \Delta G° = -237 \text{ kJ}$$

What is the standard free energy change for the reaction?

$$H_2(g) + 2C(s) \longrightarrow C_2H_2(g)$$

(a) – 209 kJ (b) – 2259 kJ

(c) + 2259 kJ (d) 209 kJ

6. The value of $\log_{10} K$ for a reaction $A \rightleftharpoons B$ is (Given, $\Delta_r H°_{298\text{ K}} = -54.07 \text{ kJ mol}^{-1}$, $\Delta_r S°_{298\text{ K}} = 10 \text{ kJ}^{-1} \text{ mol}^{-1}$ and $R = 8.314 \text{ JK}^{-1} \text{ mol}^{-1}$,

(a) 5 (b) 10

(c) 95 (d) 100

7. In an isobaric process, the ratio of heat supplied to the system $(d\theta)$ and work done by the system (dW) for diatomic gas is

(a) 1 : 1 (b) 7 : 2

(c) 7 : 5 (d) 5 : 7

8. A cylinder of gas is assumed to contain 11.2 kg of butane (C_4H_{10}). If a normal family needs 20000 kJ of energy per day, the cylinder will last in (Given that ΔH for combustion of butane is –2658 kJ)

(a) 20 days (b) 25 days

(c) 26 days (d) 24 days

9. The direct conversion of A to B is difficult, hence it is carried out by the following shown path

$$\begin{tikzcd} C \arrow[r] & D \arrow[d] \\ A \arrow[u] & B \end{tikzcd}$$

Given,
$$\Delta S_{(A \to C)} = 50 \text{ eu}$$
$$\Delta S_{(C \to D)} = 30 \text{ eu}$$
$$\Delta S_{(D \to B)} = 20 \text{ eu}$$

where eu is entropy unit, then $\Delta S_{(A \to B)}$ is

(a) +100 eu (b) +60 eu

(c) –100 eu (d) –60 eu

10. For the reaction $CO(g) + \frac{1}{2}O_2(g) \longrightarrow CO_2(g)$, ΔH, and ΔS are –283 kJ and -87 JK^{-1}, respectively. It was intended to carry out this reaction at 1000, 1500, 3000 and 3500 K. At which of these temperatures would this reaction be thermodynamically spontaneous?

(a) 1500 and 3500 K

(b) 3000 and 3500 K

(c) 1000, 1500 and 3000 K

(d) 1500,3000 and 3500 K

11. The heat of neutralisation of a strong acid and a strong alkali is 57.0 kJ mol^{-1}. The heat released when 0.5 mole of HNO_3 solution is mixed with 0.2 mole of KOH is

(a) 57.0 kJ (b) 11.4 kJ

(c) 28.5 kJ (d) 34.9 kJ

12. The enthalpy of combustion of H_2, cyclohexene (C_6H_{10}) and cyclohexane (C_6H_{12}) are –241, –3800 and –3920 kJ per mol respectively. Heat of hydrogenation of cyclohexene is

(a) 121 kJ/mol (b) –121 kJ/mol

(c) +242 kJ/mol (d) –242 kJ/mol

13. Heat of dissociation of benzene to elements is 5335 kJ/ mol. The bond enthalpies of $-\overset{|}{\underset{|}{C}}-\overset{|}{\underset{|}{C}}-$; $\overset{|}{\underset{|}{C}}=\overset{|}{\underset{|}{C}}$ and $-\overset{|}{\underset{|}{C}}-H$ bonds are 347.3, 615 and 412.2 kJ respectively. Resonance energy of benzene is
- (a) 1.15 kJ
- (b) 15.1 kJ
- (c) 974.2 kJ
- (d) 1511 kJ

More than One Correct Option

14. Which of the following statements is/are correct?
- (a) Heat, like work is a way of transferring energy
- (b) Heat is not a property of the system, whereas the temperature is a property of the system
- (c) Heat is manifested only at the boundary of system and surroundings
- (d) None of the above

15. Thermodynamics mainly deals with **[NCERT Exemplar]**
- (a) interrelation of various forms of energy and their transformation from one form to another
- (b) energy changes in the processes which depend only on initial and final states of the microscopic systems containing a few molecules
- (c) how and at what rate these energy transformations are carried out
- (d) the system in equilibrium state or moving from one equilibrium state to another equilibrium state

16. The spontaneity means, having the potential to proceed without the assistance of external agency. The processes which occur spontaneously are **[NCERT Exemplar]**
- (a) flow of heat from colder to warmer body
- (b) gas in a container contracting into one corner
- (c) gas expanding to fill the available volume
- (d) burning carbon in oxygen to give carbon dioxide

17. A sample containing 1.0 mole of an ideal gas is expanded isothermally and reversibly to ten times of its original volume, in two separate experiments. The expansion is carried out at 300 K and at 600 K respectively. Choose the correct option. **[NCERT Exemplar]**
- (a) Work done at 600 K is 20 times the work done at 300 K
- (b) Work done at 300 K is twice the work done at 600 K
- (c) Work done at 600 K is twice the work done at 300 K
- (d) $\Delta E = 0$ in both cases

18. Consider the following reaction between zinc and oxygen and choose the correct options out of the options given beolw : **[NCERT Exemplar]**

$$2\,\text{Zn}(s) + \text{O}_2(g) \longrightarrow 2\,\text{ZnO}(s); \quad \Delta H = -693.8 \text{ kJ mol}^{-1}$$

- (a) The enthalpy of two moles of ZnO is less than the total enthalpy of two moles of Zn and one mole of oxygen by 693.8 kJ
- (b) The enthalpy of two moles of ZnO is more than the total enthalpy of two moles of Zn and one mole of oxygen by 693.8 kJ
- (c) 693.8 kJ mol^{-1} energy is evolved in the reaction
- (d) 693.8 kJ mol^{-1} energy is absorbed in the reaction

Assertion and Reason

Directions (Q. Nos. 19 to 23) *Each of these questions contains two statements : Statement* I (*Assertion*) *and Statement* II (*Reason*). *Each of these questions also has four alternative choices, only one of which is the correct answer. You have to select one of the codes* (*a*), (*b*), (*c*), (*d*) *given below :*
- (a) Statement I is true; Statement II is true; Statement II is a correct explanation for Statement I.
- (b) Statement I is true; Statement II is true; Statement II is not a correct explanation for Statement I.
- (c) Statement I is true; Statement II is false.
- (d) Statement I is false; Statement II is true.

19. **Statement I** Absolute values of internal energy of substance can't be determined.

Statement II It is impossible to determine exact values of constituent energies of the substances.

20. **Statement I** The mass and volume of a substance are the extensive properties and are proportional to each other.

Statement II The ratio of mass of a sample to its volume is an intensive property.

21. **Statement I** Zeroth law can also be termed as law of thermal equilibrium.

Statement II Two objects in thermal equilibrium with the third one, are in thermal equilibrium with each other.

22. **Statement I** Combustion of all organic compounds is an exothermic reaction.

Statement II The enthalpies of all elements in their standard state are zero. **[NCERT Exemplar]**

23. **Statement I** A liquid crystallises into a solid and is accompanied by decrease in entropy.

Statement II In crystals, molecules organise in an ordered manner. **[NCERT Exemplar]**

Comprehension Based Questions

Directions (Q. Nos. 24 to 26) The first law of thermodynamics was given as $Q = \Delta E + (-W)$; where Q is the heat given to a system and ΔE represents increase in internal energy and $-W$ is work done by the system. Various processes such as isothermal, adiabatic, cyclic, isobaric and isochoric process in terms of first law of thermodynamics leads for important results. The molar heat capacity for 1 mole of monoatomic gas is $3/2R$ at constant volume and $5/2R$ at constant pressure.

24. Which of the following statements are correct?

(1) Both work and heat appears at the boundaries of system.

(2) Heat given to a system is given positive sign.

(3) Heat given to a system is equal to increase in internal energy under isothermal conditions.

(4) Heat given to a system is used to increase internal energy under isochoric conditions.

(5) Both work and heat are not state functions but their sum $(q + W)$ is a state function.

(a) 1, 2, 4, 5
(b) 1, 3, 4, 5
(c) 1, 2, 3, 4
(d) 2, 3, 4, 5

25. A system is allowed to move from state A to B following path ACB by absorbing 80 J of heat energy. The work done by the system is 30 J. The work done by the system in reaching state B from A is 10 J through path ADB. Which statements are correct?

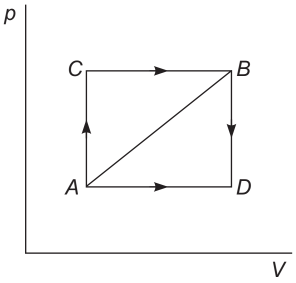
(1) Increase in internal energy from state A to state B is 50 J.

(2) If path ADB is followed to reach state B, $\Delta E = 50$ J.

(3) If work done by the system in path AB is 20 J, the heat absorbed during path $AB = 70$ J.

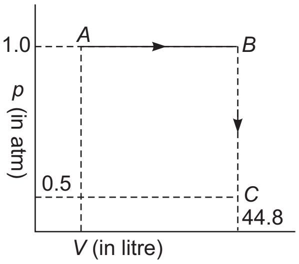
(4) The value $E_C - E_A$ is equal to $E_D - E_B$.

(5) Heat absorbed by the system to reach B from A through path ADB is 60 J.



(a) 1,5 (b) 1, 3, 5
(c) 1, 2, 3, 5 (d) 1, 4, 5

26. 1 mole of a monoatomic gas is expanded through path ABC as shown in the figure.



Select the correct statements.

(1) If specific heat of gas are 0.125 and 0.075 cal/g, the mol. wt. of gas = 40.

(2) Temperature at point A, B, C are 273, 546 and 273 K respectively.

(3) ΔE for the process A to B is 2.27 kJ.

(4) ΔE for the process B to C is 3.44 kJ.

(5) ΔE for the overall cycle $A \rightarrow B \rightarrow C \rightarrow A$ is 3.4 kJ.

(a) 1, 2, 3, 4 (b) 3, 4, 5
(c) 1, 3, 4 (d) 1, 2, 5

Directions (Q. Nos. 27 and 28) The bond dissociation energy of a diatomic molecule is also called bond energy. However, the bond dissociation energy depends upon the nature of bond and also the molecule in which the bond is present.

The bond energy of N—H bond in NH_3 is equal to one-third of the energy of dissociation of NH_3 because there are three N—H bonds and those of C—H bond in CH_4 is equal to one-fourth of the energy of dissociation of CH_4.

Heat of a reaction = Bond energy of reactants − Bond energy of products

27. The enthalpy changes for the reaction

$$H_2O(g) \longrightarrow H(g) + OH(g)$$

and

$$OH(g) \longrightarrow O(g) + H(g)$$

are 501.87 kJ mol^{-1} and 423.38 kJ mol^{-1}. The bond enthalpy of O—H bond is

(a) −462.625 kJ mol^{-1} (b) 462.625 kJ mol^{-1}
(c) −713.54 kJ mol^{-1} (d) 713.54 kJ

28. Find the bond enthalpy of S—S bond from the following data.

C_2H_5—S—$C_2H_5(g)$ $\Delta H_f^\circ = -147.23$ kJ mol^{-1}

C_2H_5—S—S—$C_2H_5(g)$ $\Delta H_f^\circ = -201.92$ kJ mol^{-1}

S$(g)\Delta H_f^\circ = -222.80$ kJ mol^{-1}

(a) − 227.49 kJ mol^{-1} (b) 277.49 kJ mol^{-1}
(c) −349.15 kJ mol^{-1} (d) 349.15 kJ mol^{-1}

Directions (Q. Nos. 29 to 31) In a fuel cell (device used for producing electricity directly from a chemical reaction), methanol is used as a fuel and oxygen gas is used an an oxidizer. The standard enthalpy of combustion of methanol is $-726\ \text{kJ mol}^{-1}$. The standard free energies of formation of $CH_3OH(l), CO_2(g)$ and $H_2O(l)$ are –166.3, –394.4 and $-237.1\ \text{kJ mol}^{-1}$ respectively.

29. The standard free energy change of the reaction will be

(a) $-597.8\ \text{kJ mol}^{-1}$ (b) $-298.9\ \text{kJ mol}^{-1}$

(c) $-465.2\ \text{kJ mol}^{-1}$ (d) $-702.3\ \text{kJ mol}^{-1}$

30. The efficiency of the fuel cell will be

(a) 96.7% (b) 66.2%

(c) 41.3% (d) 85.1%

31. The standard internal energy change of the cell reaction will be

(a) $-727.24\ \text{kJ mol}^{-1}$

(b) $-724.76\ \text{kJ mol}^{-1}$

(c) $-728.48\ \text{kJ mol}^{-1}$

(d) $-723.42\ \text{kJ mol}^{-1}$

Previous Years' Questions

32. The incorrect expression among the following is **[AIEEE 2012]**

(a) $\dfrac{\Delta G_{\text{system}}}{\Delta S_{\text{total}}} = -T$

(b) In isothermal process, $W_{\text{reversible}} = -nRT \ln \dfrac{V_f}{V_i}$

(c) $\ln K = \dfrac{\Delta H^\circ - T\Delta S^\circ}{RT}$

(d) $K = e^{-\Delta G^\circ/RT}$

33. The entropy change involved in the isothermal reversible expansion of 2 moles of an ideal gas from a volume of $10\ \text{dm}^3$ to volume of $100\ \text{dm}^3$ at 27°C is **[AIEEE 2011]**

(a) $38.3\ \text{J mol}^{-1}\text{K}^{-1}$ (b) $35.8\ \text{J mol}^{-1}\text{K}^{-1}$

(c) $32.3\ \text{J mol}^{-1}\text{K}^{-1}$ (d) $42.3\ \text{J mol}^{-1}\text{K}^{-1}$

34. The value of enthalpy change (ΔH) for the reaction

$C_2H_5OH(l) + 3O_2(g) \longrightarrow 2CO_2(g) + 3H_2O(l)$; at 27° C is $-1366.5\ \text{kJ mol}^{-1}$. The value of internal energy change for the above reaction at this temperature will be **[AIEEE 2011]**

(a) –1371.5 kJ (b) –1369.0 kJ

(c) –1364.0 kJ (d) –1361.5 kJ

35. Consider the reaction,

$4NO_2(g) + O_2(g) \longrightarrow 2N_2O_5(g)$; $\Delta_r H = -111$ kJ. If $N_2O_5(s)$ is formed instead of $N_2O_5(g)$ in the above reaction, the $\Delta_r H$ value will be

(Given, ΔH of sublimation for N_2O_5 is $54\ \text{kJ mol}^{-1}$) **[AIEEE 2011]**

(a) –165 kJ

(b) + 54 kJ

(c) + 219 kJ

(d) –219 kJ

36. The standard enthalpy of formation of NH_3 is $-46.0\ \text{kJ mol}^{-1}$. If the enthalpy of formation of H_2 from its atoms is $-436\ \text{kJ mol}^{-1}$ and that of N_2 is $-712\ \text{kJ mol}^{-1}$, the average bond enthalpy of N—H bond in NH_3 is **[AIEEE 2010]**

(a) $-964\ \text{kJ mol}^{-1}$ (b) $+352\ \text{kJ mol}^{-1}$

(c) $+1056\ \text{kJ mol}^{-1}$ (d) $-1102\ \text{kJ mol}^{-1}$

37. For a particular reversible reaction at temperature T, ΔH and ΔS were found to be both positive. If T_e is the temperature at equilibrium, the reaction would be spontaneous when **[AIEEE 2010]**

(a) $T_e > T$ (b) $T > T_e$

(c) T_e is 5 times T (d) $T = T_e$

38. On the basis of the following thermochemical data $[\Delta_f G^\circ\ H^+(aq) = 0]$

$$H_2O(l) \longrightarrow H^+(aq) + OH^-(aq);\ \Delta H = 57.32\ \text{kJ}$$

$$H_2(g) + \frac{1}{2}O_2(g) \longrightarrow H_2O(l);\Delta H = -286.02\ \text{kJ}$$

The value of enthalpy of formation of OH^- ion at 25° C is

(a) –22.88 kJ (b) –228.88 kJ

(c) +228.88 kJ (d) –343.52 kJ

39. Standard entropy of X_2, Y_2 and XY_3 are 60, 40 and $50\ \text{JK}^{-1}\text{mol}^{-1}$, respectively. For the reaction, $\frac{1}{2}X_2 + \frac{3}{2}Y_2 \longrightarrow XY_3$, $\Delta H = -30$ kJ, to be at equilibrium, the temperature will be **[AIEEE 2008]**

(a) 1250 K (b) 500 K (c) 750 K (d) 1000 K

40. Assuming that water vapour is an ideal gas, the internal energy change (ΔE) when 1 mole of water is vaporised at 1 bar pressure and 100° C, (Given, molar enthalpy of vaporisation of water at 1 bar and $373\ \text{K} = 41\ \text{kJ mol}^{-1}$ and $R = 8.3\ \text{J mol}^{-1}\ \text{K}^{-1}$) will be **[AIEEE 2007]**

(a) $4.100\ \text{kJ mol}^{-1}$ (b) $3.7904\ \text{kJ mol}^{-1}$

(c) $37.904\ \text{kJ mol}^{-1}$ (d) $41.00\ \text{kJ mol}^{-1}$

41. Identify the correct statement regarding a spontaneous process. **[AIEEE 2007]**

(a) For a spontaneous process in an isolated system, the change in entropy is positive
(b) Endothermic processes are never spontaneous
(c) Exothermic processes are always spontaneous
(d) Lowering of energy in the reaction process is the only criterion for spontaneity

42. In conversion of limestone to lime, $CaCO_3(s) \longrightarrow CaO(s) + CO_2(g)$ the values of ΔH° and ΔS° are $+179.1$ kJ mol^{-1} and 160.2 J/K respectively at 298 K and 1 bar. Assuming that ΔH° and ΔS° do not change with temperature, temperature above which conversion of limestone to lime will be spontaneous is **[AIEEE 2007]**

(a) 1008 K
(b) 1200 K
(c) 845 K
(d) 1118 K

43. An ideal gas is allowed to expand both reversibly and irreversibly in an isolated system. If T_i is the initial temperature and T_f is the final temperature, which of the following statements is correct? **[AIEEE 2006]**

(a) $(T_f)_{\text{irrev}} > (T_f)_{\text{rev}}$
(b) $T_f > T_i$ for reversible process but $T_f = T_i$ for irreversible process
(c) $(T_f)_{\text{rev}} = (T_f)_{\text{irrev}}$
(d) $T_f = T_i$ for both reversible and irreversible processes

44. The enthalpy changes for the following processes are listed below :

$$Cl_2(g) \longrightarrow 2Cl(g), 242.3 \text{ kJ mol}^{-1}$$
$$I_2(g) \longrightarrow 2I(g), 151.0 \text{ kJ mol}^{-1}$$
$$ICl(g) \longrightarrow I(g) + Cl(g), 211.3 \text{ kJ mol}^{-1}$$
$$I_2(s) \longrightarrow I_2(g), 62.76 \text{ kJ mol}^{-1}$$

Given that the standard states for iodine and chlorine are $I_2(s)$ and $Cl_2(g)$, the standard enthalpy for the formation of $ICl(g)$ is **[AIEEE 2006]**

(a) -14.6 kJ mol^{-1}
(b) -16.8 kJ mol^{-1}
(c) $+16.8$ kJ mol^{-1}
(d) $+244.8$ kJ mol^{-1}

45. The standard enthalpy of formation (ΔH_f°) at 298 K for methane, $CH_4(g)$ is -74.8 kJ mol^{-1}. The addition information required to determine the average energy for C—H bond formation would be **[AIEEE 2006]**

(a) the dissociation energy of H_2 and enthalpy of sublimation of carbon
(b) latent heat of vaporisation of methane
(c) the first four ionisation energies of carbon and electron gain enthalpy of hydrogen
(d) the dissociation energy of hydrogen molecule, H_2

46. An ideal gas expands in volume from 1×10^{-3} m^3 to 1×10^{-2} m^3 at 300 K against a constant pressure of 1×10^5 Nm^{-2}. The work done is **[AIEEE 2004]**

(a) -900 J
(b) -900 kJ
(c) 270 kJ
(d) 900 kJ

47. The internal energy change when a system goes from state A to B is 40 kJ/mol. If the system goes from A to B by a reversible path and returns to state A by an irreversible path, what would be the net change in internal energy? **[AIEEE 2003]**

(a) 40 kJ
(b) > 40 kJ
(c) < 40 kJ
(d) Zero

48. If at 298 K the bond energies of C—H, C—C, C=C and H — H bonds are respectively 414, 347, 615 and 435 kJ mol^{-1}, the value of enthalpy change for the reaction,

$H_2C{=}CH_2(g) + H_2(g) \longrightarrow H_3C - CH_3(g)$ at 298 K will be **[AIEEE 2003]**

(a) + 250 kJ
(b) -250kJ
(c) + 125 kJ
(d) -125 kJ

49. In an irreversible process taking place at constant T and p and in which only pressure-volume work is being done, the change in Gibbs free energy (dG) and change in entropy (dS), satisfy the criteria **[AIEEE 2003]**

(a) $(dS)_{V,E} < 0, (dG)_{T,p} < 0$
(b) $(dS)_{V,E} > 0, (dG)_{T,p} < 0$
(c) $(dS)_{V,E} = 0, (dG)_{T,p} = 0$
(d) $(dS)_{V,E} = 0, (dG)_{T,p} > 0$

50. Heat required to raise the temperature of 1 mole of a substance by 1° is called **[AIEEE 2002]**

(a) specific heat
(b) molar heat capacity
(c) water equivalent
(d) specific gravity

the Guidance

Round I

1. When a gas undergoes adiabatic expansion, $dq = 0$, it gets cooled due to loss of kinetic energy.

2. In such a condition, the compressor has to run for longer time, releasing more heat to the surroundings.

3. We know that $\Delta E = q + W$

If heat supplied from the surrounding, $q = 0$

$\therefore \quad \Delta E = W$

i.e., work is done at the expense of only internal energy and $q = 0$ for adiabatic process.

4. A thermodynamic state function is a quantity whose value is independent of path. Its value depends only upon the state of the system.

5. Thermodynamics deals with the energy changes, feasibility and extent of a reaction, but not with the rate and mechanism of a process.

6. Presence of reaction species in a covered beaker-Closed system. Exchange of matter as well as energy - Open system

Presence of reactant in a closed vessel - Closed system

Presence of reactants in thermos flask - Isolated system.

8. We know that internal energy of a gas depends upon its pressure and temperature. Thus, if a gas expands at constant temperature and pressure then its internal energy remains same.

9. $W = 2.303 nRT \log \frac{p_2}{p_1} = 2.303 \times 1 \times 2 \times 300 \log \frac{10}{2} = 965.84$

At constant temperature, $\Delta E = 0$

$$\Delta E = q + W;$$
$$q = -W = -965.84 \text{ cal}$$

10. Given, $q = +701 \text{ J}$ (heat is absorbed, hence q is positive)

$W = -394 \text{ J}$ (work is done by the system, hence W is negative)

By first law of thermodynamics,

Internal energy change, $\Delta E = q + W$

$= +701 \text{ J} + (-394 \text{ J}) = +307 \text{ J}.$

Hence, internal energy of the system increases by 307 J.

11. For isolated system there is no transfer of energy as heat or work so according to the first law of thermodynamics,

$$\Delta U = q + W$$
$$\Delta U = 0 + 0 = 0$$

12. Free expansion $W = 0$

Adiabatic process, $q = 0$

$\Delta U = q + W = 0$, this means that internal energy remains constant. Therefore, $\Delta T = 0$

In ideal gas there is no intermolecular attraction. Hence, when such a gas expands under adiabatic conditions into a vacuum, no heat is absorbed or evolved since no external work is done to separate the molecules.

13. As the system is closed and insulated, no heat enter or leave the system, *i.e.,* $q = 0$

$$\Delta E = q + W = W$$

and $\quad \Delta E \neq 0$ as ΔT is not zero.

14. Since the process involves phase change, heat absorbed,

$Q = \text{mass} \times \text{latent heat of vaporisation}$

Given, $\quad \text{mass} = 70.0 \text{ g} = 0.07 \text{ kg}$

$L_y = 2260 \text{ kJ/kg}$

$\therefore \quad Q = 0.07 \times 2260 \text{ kJ} = 158.2 \text{ kJ} = 158200 \text{ J}$

15. It is clear from the figure that the process has been carried out in infinite steps, hence it is isothermal reversible expansion.

$$W = -2.303nRT \log \frac{V_2}{V_1}$$

But, $\quad p_1V_1 = p_2V_2$

$\Rightarrow \quad \frac{V_2}{V_1} = \frac{p_1}{p_2} = \frac{2}{1} = 2$

$\therefore \quad W = -2.303nRT \log \frac{p_1}{p_2}$

$$= -2.303 \times 1 \text{ mol} \times 8.314 \text{ J mol}^{-1}\text{K}^{-1} \times 298\text{K} \times \log 2$$

$$= -2.303 \times 8.314 \times 298 \times 0.3010 \text{ J} = -1717.46 \text{ J}$$

16. $W = -p_{ex}(V_f - V_t) = -2 \times 40 = -80 \text{ L bar} = -8 \text{ kJ}$

The negative sign shows that work is done by the system on the surrounding. Work done will be more in the reversible expansion because internal pressure and external pressure are almost same at every step.

17. According to the definition of standard enthalpy of formation, the enthalpy change for the following reaction will be standard enthalpy of formation of $H_2O(l)$.

$$H_2O(g) + \frac{1}{2}O_2(g) \longrightarrow H_2O(l).$$

or the standard enthalpy of formation of $H_2O(l)$ will be half of the enthalpy of the given equation *i.e.*, $\Delta_r H^\ominus$ is also halved.

$$\Delta_f H^\ominus_{H_2O}(l) = \frac{1}{2} \times \Delta_r H^\ominus = \frac{-572 \text{ kJ mol}^{-1}}{2}$$

$$= -286 \text{ kJ/mol}.$$

18. Standard heat of formation of methane is represented by C(graphite) + $2H_2(g) \longrightarrow CH_4(g)$ because the elements taken are in their standard state.

19. $CH_4(g) + 2O_2(g) \longrightarrow CO_2(g) + 2H_2O(l)$

$$\Delta n_g = (n_p - n_r) = 1 - 3 = -2$$
$$\Delta H^\circ = \Delta U^\circ + \Delta n_g RT$$
$$\Delta H^\circ = -X - 2RT$$

Hence, $\quad \Delta H^\circ < \Delta U^\circ$

20. $A \longrightarrow B, \Delta H = +24 \text{ kJ/mol}$

$\Rightarrow \quad H_B - H_A = +24 \quad \ldots$(i)

$BC, \; \Delta H = -18 \text{ kJ/mol}$

$\Rightarrow \quad H_C - H_B = -18 \quad \ldots$(ii)

or $\quad H_B - H_C = +18$

From Eqs. (i) and (ii), we have

$$H_C - H_A = 6$$

$\therefore \quad H_B > H_C > H_A$

21. Molar enthalpy change for the combustion of graphite, ΔH = enthalpy of combustion of 1g graphite × molar mass

$$\Delta H = -20.7 \text{ kJ g}^{-1} \times 12 \text{ g mol}^{-1}$$

$$\Delta H = -2.48 \times 10^2 \text{ kJ mol}^{-1}$$

Negative sign in the value of ΔH indicates that the reaction is exothermic.

22. The net enthalpy change, ΔH for a cyclic process is zero as enthalpy change is a state function.

24. $\Delta H = \Delta E + \Delta n_g RT$

Since, $\quad \Delta n_2 = 2 - 4 = -2$

Therefore, $\quad \Delta H = \Delta E - 2RT$

25. $C_6H_6(g) + \frac{15}{2}O_2(g) \longrightarrow 6CO_2(g) + 3H_2O(g)$

$$\Delta n = 6 + 3 - 1 - \frac{15}{2} = +0.5$$

26. Energy absorbed $\propto \frac{1}{\text{stability of compound}}$

Energy released $\propto$ stability of compound

Thus, the order of stability is

$$142.2 > 25.9 > -46.2 > -393.2$$

i.e., $\quad O_3 > HI > NH_3 > CO_2$

27. $\Delta H = nC_P \Delta T$

The process is isothermal therefore,

$$\Delta H = 0.$$

28. Work done in 1 s = 400 J

Hence, work in 5 min (300 s)

$$= 400 \times 300 = 120 \text{ kJ}$$

$$\Delta H^\circ_{vap} = \frac{120 \text{ kJ}}{50/18} = 43.2 \text{ kJ/mol}$$

30. The reaction for the combustion of carbon into CO_2 is

$$\underset{44 \text{ g}}{C(s) + O_2(g) \longrightarrow CO_2(g)}; \quad \Delta H = -393.5 \text{ kJ mol}^{-1}$$

Heat released in the formation of 44g CO_2 = 393.5kJ

Heat released in the formation of 35.2g CO_2

$$= \frac{393.5 \text{ kJ} \times 35.2 \text{ g}}{44 \text{ g}} = 314.8 \text{ kJ}$$

32. 0.5 mol $HNO_3 \equiv$ 0.5 mol H^+ and 0.3 mol OH^-

$$0.5\, H^+(aq) + 0.3 OH^-(aq) \longrightarrow 0.5\, H_2O(l)$$

$$\Delta H = 0.3 \times 57.1$$
$$= 17.13 \text{ kJ}$$

33. By (ii) – (i) C(graphite) $\longrightarrow$ C(diamond);

$$\Delta H = -393.4 - (-395.3) = +1.9$$

34. For the equation,

$$H_2 + S + 2O_2 \longrightarrow H_2SO_4$$

Eqs. (i) + (ii) + (iii) + (iv)

$$\Delta H = -287.3 + (-298.2) + (-98.7) + (-130.2)$$
$$= -814.4 \text{ kJ}$$

36. $\Delta_r H^\ominus$ = Bond energy of H_2 + Bond energy of $Br_2 - 2 \times$ Bond energy of HBr $= 435 + 192 - (2 \times 368)$ kJ mol^{-1}

$$\Rightarrow \qquad \Delta_r H^\ominus = -109 \text{ kJ mol}^{-1}$$

37. $q_p = \Delta H = -30.5 \text{ kJ mol}^{-1}$

$\therefore$ Heat required for vaporisation of 284 g of

$$CCl_4 = \frac{284 \text{ g}}{154 \text{ g mol}^{-1}} \times 30.5 \text{ kJ mol}^{-1}$$

$$= 56.2 \text{ kJ}$$

38. Molecular weight of NH_4NO_3 = 80 g mol^{-1}

$\therefore$ Molar heat of decomposition,

$$H = ms\Delta t = 80 \times 1.23 \times 6.12$$

$$= 602 \text{ kJ/mol}$$

40. $18.0 \text{ g } H_2O = 1 \text{ mol } H_2O$

Enthalpy change for vaporising 1 mole of H_2O = 40.79 kJ

$\therefore$ Enthalpy change for vaporising 2 moles of

$$H_2O = 2 \times 40.79 \text{ kJ} = 81.58 \text{ kJ}$$

Standard enthalpy of vaporisation at 100° C and 1 bar pressure,

$$\Delta_{vap} H^\circ = +\, 40.79 \text{ kJ mol}^{-1}$$

41. Heat of neutralisation will be less than −57.33 kJ/mol because some amount of this energy will be required for the dissociation of weak base (MgO).

42. $C(s) + \frac{1}{2} O_2(g) \longrightarrow CO(g); \ \Delta H_1 = -26.4$ ...(i)

$C(s) + O_2(g) \longrightarrow CO_2(g); \ \Delta H_2 = -94.0$ ...(ii)

We have to find ΔH for the reaction

$$CO + \frac{1}{2} O_2 \longrightarrow CO_2; \qquad \Delta H_1 = ?$$

Eqs. (ii) − (i), we get

$$\Delta H = -94 - (-26.4) = -67.6 \text{ kcal}$$

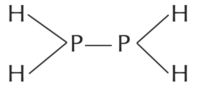
43. Since, process is exothermic, heat is evolved, due to this temperature of water increases.

45. Bond energy of C—H bond $= \frac{-166}{4} = -\ 41.5$ kJ / mol

47. ***Step I*** P—H bond energy from bond dissociation energy of $PH_3(g)$ containing 3 such P—H bonds

$$= \frac{228}{3} = 76 \text{ kcal/mol}$$

Step II The structure of P_2H_4 is



i.e., it contains four P—H bonds and one P—P bond, so P—P bond energy can be calculated by $4 \times$ P — H + P — P = bond dissociation energy of P_2H_4.

$\therefore$ P—P bond energy = 335 − 4(76)

= 31 kcal per mol

48. CH_4 required $= \frac{445.15 \times 16}{890.3} = 8$ g

49. For the equation

$$B_2H_6(g) + 3O_2(g) \longrightarrow B_2O_3(g) + 3H_2O(g)$$

Eqs. (i) + 3(ii) + 3(iii) − (iv)

$$\Delta H = -1273 + 3(-286) + 3(44) - 36$$

$$= -1273 - 858 + 132 - 36$$

= −2035 kJ/mol

50. Given, (i) $2C + 3H_2 \longrightarrow C_2H_6; \qquad \Delta H = -21.1$

(ii) $C + O_2 \longrightarrow CO_2; \qquad \Delta H = -94.1$

(iii) $H_2 + \frac{1}{2} O_2 \longrightarrow H_2O; \qquad \Delta H = -68.3$

Eqs. 2 (ii) + 3 (iii) − (i)

$$C_2H_6 + \frac{3}{2} O_2 \longrightarrow 2CO_2 + 3H_2O$$

$$\Delta x = 2(-94.1) + 3(-68.3) - (-21.1)$$

$$= -\ 372 \text{ kcal}$$

51. ΔH per 1.6 g $= \frac{72 \times 1.6}{180} = 0.64$ kcal

52. Entropy of vaporisation $= \frac{\Delta H_{vap}}{\text{boling point}} = \frac{840}{173} = 4.8$ J/mol/K

54. Heat capacity of water per gram $= \frac{75}{18} = 4.17$ J

$$Q = mst = 100 \times 4.17 \times t = 1000$$

$$t = \frac{1000}{100 \times 4.17} = 2.4 \text{ K}$$

55. For an isolated system, $\Delta U = 0$ and for a spontaneous process, total entropy change must be positive.

Moreover $\Delta S = \frac{q_{rev}}{T} = \frac{\Delta H}{T} = \frac{\Delta U + p\Delta V}{T} = \frac{p\Delta V}{T} \quad (\because \Delta U = 0)$

i.e., $T\Delta S$ or $\Delta S > 0$

56. In the given reaction, a molecule of Cl_2 is formed from its two gaseous atoms and the energy is released with the formation of bond. Hence, ΔH is negative In this reaction, randomness (entropy) also decreases because 2 moles atoms of Cl have more randomness than one mole molecules of chlorine. Hence, ΔS is negative.

57. Enthalpy change for the formation of 1 mole of $H_2O(l)$.

$$H_2(g) + \frac{1}{2} O_2(g) \longrightarrow H_2O(l); \qquad \Delta_f H^\circ = -286 \text{ kJ mol}^{-1}$$

Energy released in the above reaction is absorbed by the surroundings. It means $q_{surr} = +286 \text{ kJ mol}^{-1}$

$$\Delta S = \frac{q_{surr}}{T} = +\frac{286 \text{ kJ mol}^{-1}}{298 \text{ K}}$$

$$= 0.9597 \text{ kJ K}^{-1} \text{mol}^{-1}$$

$$= 959.7 \text{ JK}^{-1} \text{mol}^{-1}$$

58. Less, because ice is more ordered than $H_2O(l)$.

59. For water, molar heat capacity, $C_p = 18 \times$ specific heat, C

Specific heat, $C = 4.18\ \text{Jg}^{-1}\text{K}^{-1}$ (for water)

Heat capacity, $C_p = 18 \times 4.18\ \text{JK}^{-1} = 75.3\ \text{JK}^{-1}$

62. $\Delta S° = 2S°_{HCl} - (S°_{H_2} + S°_{Cl_2})$

$$= 2 \times 186.7 - (130.6 + 223.0) = 19.8\ \text{JK}^{-1}\text{mol}^{-1}$$

63. Mixing of gases increase the entropy.

64. For monoatomic gas, $\gamma_1 = \dfrac{C_p}{C_v} = 1.67$

For diatomic gas, $\gamma_2 = \dfrac{C_p}{C_v} = 1.40$

$\therefore \quad \gamma_1 : \gamma_2 = \dfrac{1.67}{1.40} = 1.19 : 1$

65. Joule-Thomson coefficient $\mu = \dfrac{dT}{dp} = \dfrac{27 - 30}{5 - 2} = -1$

For all negative values of μ, the gas warms on expansion.

67. If $\Delta H = +$ ve and $\Delta S = -$ ve then the reaction is non-spontaneous.

68. $\Delta G° = -2.303RT \log K_c$

Given, $R = 8.314\ \text{JK}^{-1}\text{mol}^{-1}$, $T = 300\ K, K_c = 10$

$\Delta G° = -2.303 \times 8.314\ \text{JK}^{-1}\text{mol}^{-1} \times 300\ \text{K} \times \log 10\ (\log 10 = 1)$

$$= -5744.14\ \text{J mol}^{-1}$$

69. Use $\Delta G = \Delta H - T\Delta S$

$$\Delta G = 145.6 - 273 \times 0 \cdot 116$$

$$= 113.93\ \text{KJ/mol}$$

70. $\Delta G = \Delta H - T\Delta S$,

$$T = 25 + 273 = 298\ \text{K}$$

$$= -11.7 \times 10^3 - 298 \times (-105)$$

$$= 19590\ \text{J} = 19.59\ \text{kJ}$$

Round II

1. $\dfrac{T}{T_{\text{final}}} = \left(\dfrac{V_2}{V_1}\right)^{\gamma - 1}$

$$\frac{T}{T_{\text{final}}} = \left(\frac{2}{1}\right)^{(5/3 - 1)} = 2^{(2/3)}$$

$$T_{\text{final}} = \frac{T}{2^{(2/3)}}$$

2. $\Delta S_{\text{vap}} = \dfrac{(900 \times 18)}{373} = 43.4\ \text{JK}^{-1}\text{mol}^{-1}$

3. Enthalpy change for the conversion of 1 mole liquid water at 10° C into 1 mole liquid water at 0° C,

$$\Delta H_1 = C_pH_2O(l) \times \Delta T$$

$$= -75.3\ \text{J mol}^{-1}\text{K}^{-1} \times 10\text{K} = -753\ \text{J mol}^{-1}$$

Enthalpy of fusion,

$$\Delta H_2 = \Delta H_{\text{freezing}} = -\Delta H_{\text{fusion}} = -6.03\ \text{kJ mol}^{-1}$$

Enthalpy change for the conversion of 1 mole of ice at 0° C to 1 mole of ice at 10° C,

$$\Delta H_3 = C_pH_2O(s) \times \Delta T = -36.8\ \text{J mol}^{-1}\text{K}^{-1} \times 10\text{K}$$

$$= -368\ \text{J mol}^{-1}$$

$$\Delta H_{\text{total}} = -(0.753 + 6.03 + 0.368)\ \text{kJ mol}^{-1} = -7.151\ \text{kJ mol}^{-1}$$

Note Heat is evolved in the process of cooling (freezing) so such step will have a negative sign with ΔH.

4. Given, $dE = TdS - pdV \quad \ldots\text{(i)}$

$H = E + pV \quad \ldots\text{(ii)}$

Differentiating Eq. (ii)

$dH = dE + pdV + Vdp \quad \ldots\text{(iii)}$

From Eq. (i) and (iii), we get

$$dH = TdS - Vdp$$

5. $C_2H_2(g) + \dfrac{5}{2}O_2(g) \longrightarrow 2CO_2(g) + H_2O(l); \quad \ldots\text{(i)}$

$\Delta G° = -1234\ \text{kJ}$

$C(s) + O_2(g) \longrightarrow CO_2(g); \quad \Delta G° = -394\ \text{kJ} \ldots\text{(ii)}$

$H_2(g) + \dfrac{1}{2}O_2(g) \longrightarrow H_2O(l); \quad \Delta G° = -237\ \text{kJ} \ldots\text{(iii)}$

Eq. 2(ii) + (iii) – (i)

$$2C(s) + H_2(g) \longrightarrow C_2H_2(g)$$

$$\Delta G° = 2(-394) + (-237) - (-1234)$$

$$\Delta G° = 209\ \text{kJ}$$

6. $A \rightleftharpoons B$

$$\Delta G° = \Delta H° - T\Delta S°$$

$$\Delta G° = -2.303\ RT \log k$$

$$\log k = \frac{\Delta H° - T\Delta S°}{-2.303RT}$$

$$= \frac{-54.07 \times 10^3 - 298 \times 10}{-2.303 \times 8.314 \times 298} = 10$$

7. $-\dfrac{dQ}{dW} = \dfrac{dQ}{dQ - dE};$

$[\because\ dE = dW + dQ : -dW = dQ - dE]$

$$= \frac{nC_p\,dT}{nC_pdT - nC_vdT} = \frac{C_p}{(C_p - C_v)}$$

$= \dfrac{7}{2}$ for diatomic gas

8. Cylinder contains 11.2 kg or 193.10 mole butane.

[$\because$ Molecular mass of butane = 58]

$\because$ Energy released by 1 mole of butane = −2658

$\therefore$ Energy released by 193.10 mole of butane

$$= -2658 \times 193.10$$
$$= 5.13 \times 10^5 \text{ kJ}$$

$\therefore$ cylinder will last in $\dfrac{5.13 \times 10^5}{20000} = 25.66$ or 26 days

9. $\Delta S_{A \to B} = \Delta S_{(A \to C)} + \Delta S_{(C \to D)} + \Delta S_{(D \to B)}$

$$= \Delta S_{(A \to C)} + \Delta S_{(C \to D)} - \Delta S_{(B \to D)}$$
$$= 50 + 30 - 20$$
$$= 60 \text{ eu}$$

10. $\because$ $\Delta G = \Delta H - T \cdot \Delta S$

For a spontaneous reaction ΔG should be negative

$$\Delta H = -238 \text{ kJ}, \quad \Delta S = -87 \text{ kJ}^{-1}$$

Hence, reaction will be spontaneous when $\Delta H > T \cdot \Delta S$. Therefore, at 1000, 1500 and 3000 K the reaction would be spontaneous.

11. 0.2 mole will neutralize 0.2 mole of HNO_3

Heat evolved = 57 × 0.2 = 11.4 kJ

12. Given, (i) $H_2 + \frac{1}{2} O_2 \longrightarrow H_2O; \qquad \Delta H = -241$ kJ

(ii) $C_6H_{10} + \frac{17}{2} O_2 \longrightarrow 6CO_2 + 5H_2O; \Delta H = -3800$ kJ

(iii) $C_6H_{12} + 9O_2 \longrightarrow 6CO_2 + 6H_2O; \Delta H = -3920$ kJ

Required reaction is

$$C_6H_{10} + H_2 \longrightarrow C_6H_{12}$$

So, Eq. (i) + (ii) − (iii) gives

$$C_6H_{10} + 9O_2 \longrightarrow C_6H_{12}$$
$$\Delta H = -241 - 3800 - (-3920)$$
$$= -121 \text{kJ mol}^{-1}$$

13. First we calculate the expected bond dissociation energy of benzene molecule as

$3 \times$ C—C + $3 \times$ C═C + $6 \times$ C—H

$\therefore$ Calculated value = 3 (347.3) + 3(615) + 6(412.2)

= 5360.1

Resonance energy = experimental value − calculated value

= 6335 − 5360.1

= 974.2 kJ/mol

14. Heat is not a state function, while temperature is a state function. Heat flowing into the system is positive and heat flowing out of the system is negative.

15. Thermodynamics deals with interrelation of various forms of energy and their transformation into each other. It also deals with thermal or mechanical equilibrium. However, it does not tell anything about the rate of reaction.

16. Flowing of heat from warmer to colder body, expanding of gas and burning of carbon to give carbon dioxide, all are spontaneous process.

17. $$\frac{W_{600\text{K}}}{W_{300\text{K}}} = \frac{1 \times R \times 600\, K \ln \frac{10}{1}}{1 \times R \times 300 K \ln \frac{10}{1}} = \frac{600}{300} = 2$$

For isothermal expansion of ideal gases, $\Delta E = 0$

Since temperature is constant this means there is no change in internal energy. Therefore, $\Delta E = 0$

18. Negative value of ΔH shows that the process is exothermic *i.e.,* proceed with the evolution of heat. For exothermic process,

$$E_{\text{product}} < E_{\text{reactant}}$$

$\therefore$ Enthalpy of two moles of ZnO is then the total enthalpy of two moles of Zn and one mole of O_2 by 693.8 kJ.

19. It is the fact that absolute values of internal energy of substances cannot be determined. It is also true that determination of exact values of constituent energies of the substance is impossible.

20. The mass and volume depend upon the quantity of matter so these are extensive properties while ratio of mass to its volume *i.e.,* density does not depend upon the quantity of matter so this ratio is an intensive property.

21. Zeroth law of temperature can also be summarized as two objects at different temperatures in thermal contact with each other tend to move towards the same temperature.

22. During combustion, energy is released so it is always an exothermic process.

The enthalpy of all the elements in their standard state are zero

23. When a liquid crystallises, entropy decreases because in crystalline form the molecules are more ordered as compared to a liquid.

24. $Q = \Delta E + p\Delta V$ and $\Delta E = Q + W$ = state function

At T = constant $Q = p\Delta V$

25. $ACB = AC + BC$

$ADB = AD + BD$

Heat absorbed 80 J.

Work done by the system = 10 J $\therefore W = -10$ J

$\therefore \qquad W = -30$ Also $W = -10$ J

$\therefore \qquad E_B - E_A = 50$ J $\therefore$ $Q = 50 + 10 = 60$ J

26. $C_p - C_v = \dfrac{R}{M}$

At $A, p = 1$ atm, $V = 22.4$ L

$\therefore \qquad 0.125 - 0.075 = \dfrac{2}{M} \times 273 \qquad [\therefore T = 273 \text{ K}]$

$\therefore \qquad M = 40$

At $B, p = 1$ atm. $V = 44.8$ L

$$\therefore \qquad T = 546\text{ K}$$

At $C, p = 0.5$ atm., $\quad V = 44.8$ L

$$\therefore \qquad T = 273\text{ K}$$

Also at constant V

$$\Delta E = p \times \Delta E \ \Delta U = C_v \times \Delta T$$
$$= 1 \times 22.4\text{ L atm.,}$$
$$= \frac{1 \times 22.4}{0.0821} \times 8.314\text{ J}$$
$$= 0.075 \times 40 \times 4.12$$
$$= 2268.37\text{ J} = 2.27\text{ kJ}$$

27. The enthalpy of dissociation of the O—H bond depends on the molecular species from which H-atom is being separated.

$$H_2O(g) \longrightarrow H(g) + OH(g); \quad \Delta H^\circ = 501.87\text{ kJ mol}^{-1}$$

However to break O—H bond in hydroxyl a different quantity of heat (423.38kJ mol^{-1}) is

$$\text{BE(O–H)} = \frac{501.87\text{ kJmol}^{-1} + 423.38\text{ kJmol}^{-1}}{2}$$
$$= 462.625\text{ kJ mol}^{-1}$$

28. $\text{BE(S – S)} = \Delta H_{\text{vap}}(s) - \Delta H_f^\circ$

$$= \Delta H_{\text{vap}}(s) - \{H_f^\circ(C_2H_5S — SC_2H_5)\} - H_f^\circ(C_2H_5S — C_2H_5)$$
$$= 222.80 - \{-201.92 - (-147.23)\}$$
$$= 277.49\text{ kJ mol}^{-1}$$

29. Reaction for the combustion of methanol is

$$2CH_3OH(l) + 3O_2(g) \longrightarrow 2CO_2(g) + 4H_2O(l)$$

$$\Delta_r G^\circ = \left[2\Delta G^\circ_{CO_2} + 4\Delta G^\circ_{H_2O}\right] - \left[2 \times \Delta G^\circ_{CH_3OH} + 3 \times \Delta G^\circ_{O_2}\right]$$
$$= [-2 \times 394.4 + 4 \times (-237.1)] - [2 \times (-166.3) + 3 \times 0]$$
$$= -1737.2 + 332.6$$
$$= -1404.6$$
$$\Delta_f G^\circ_{CH_3OH} = \frac{-1404.6}{2} = -702.3\text{ kJ mol}^{-1}$$

30. Efficiency of fuel cell $= \dfrac{\Delta G}{\Delta H} \times 100$

$$= \frac{702.3}{726} \times 100 = 96.7\%$$

31. $\Delta n_g = 1 - \dfrac{3}{2} = \dfrac{2-3}{2} = \dfrac{-1}{2} = -0.5$

$$\Delta H = \Delta E + \Delta n_g RT$$
$$-726 = \Delta E - (0.5) \times 8.314 \times 298 \times 10^{-3}$$
$$\Delta E = -726 + 1.24$$
$$= -724.76\text{ kJ mol}^{-1}$$

32. (a) $\Delta G = \Delta H - T\Delta S$

For a system, total entropy change $= \Delta S_{\text{total}}$

$$\Delta H_{\text{total}} = 0$$
$$\therefore \qquad \Delta G_{\text{system}} = -T\Delta S_{\text{total}}$$
$$\frac{\Delta G_{\text{system}}}{\Delta S_{\text{total}}} = -T$$

Thus, (a) is correct.

(b) For isothermal reversible process, $\Delta E = 0$

By first law of thermodynamics

$$\Delta E = Q + W$$
$$\therefore \qquad W_{\text{reversible}} = -Q = -\int_{V_i}^{V_f} p\,dV$$
$$W_{\text{reversible}} = -nRT \ln \frac{V_f}{V_i}$$

Thus, (b) is correct.

(c) $\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ$

$$\Delta G^\circ = -RT \log K$$
$$\therefore \qquad -RT \log K = \Delta H^\circ - T\Delta S^\circ$$
$$\therefore \qquad \log K = -\left(\frac{\Delta H^\circ - T\Delta S^\circ}{RT}\right)$$

Thus, (c) is incorrect.

(d) $\Delta G^\circ = -RT \log K$

$$\therefore \qquad \log K = -\frac{\Delta G^\circ}{RT}$$
$$\therefore \qquad K = e^{-\Delta G^\circ/RT}$$

Thus, (d) is also correct.

33. Entropy change for of isothermal expansion of n moles of an ideal gas from volume V_1 to volume V_2 is

$$\Delta S = 2.303\, nR \log \frac{V_2}{V_1}$$
$$= 2.303 \times 2 \times 8.3143 \log \frac{100}{10}$$
$$= 38.296\text{ J mol}^{-1}\text{ K}^{-1}$$

34. Relation between ΔH (enthalpy change) and ΔE (internal energy change) is

$$\Delta H = \Delta E + \Delta n_g RT$$

where, Δn_g = moles of gaseous products – moles of gaseous reactants

$$= 2 - 3 = -1$$
$$\Rightarrow \qquad -1366.5 = \Delta E - 1 \times 8.314 \times 10^{-3} \times 300$$
$$\therefore \qquad \Delta E = -1364.0\text{ kJ mol}^{-1}$$

35. $4NO_2(g) + O_2(g) \longrightarrow 2N_2O_5(g); \ \Delta_r H = -111\text{ kJ}$

$$2N_2O_5(g) \longrightarrow 2N_2O_5(s), \quad \Delta_s H = (-54 \times 2)\text{ kJ}$$
$$4NO_2(g) + O_2(g) \longrightarrow 2N_2O_5(s),$$
$$\Delta_r H = -219\text{ kJ}$$

Note ΔH_r sublimation of $N_2O_5(s)$ t is 54 kJ mol^{-1}.
Thus, for reverse process, it is –54 kJ mol^{-1}.

36. Given, $\frac{1}{2}N_2(g) + \frac{3}{2}H_2(g) \longrightarrow NH_3(g)$

$$\Delta H_f^\circ = -46.0 \text{ kJ mol}^{-1}$$

$$2H(g) \longrightarrow H_2(g); \quad \Delta H_f^\circ = -436 \text{ kJ mol}^{-1}$$

$$2N(g) \longrightarrow N_2(g); \quad \Delta H_f^\circ = -712 \text{ kJ mol}^{-1}$$

$$-46 = 3\text{N—H} - \left[-\frac{1}{2}\times 712 - \frac{3}{2}436\right]$$

$$= 3\text{N—H} - \left[\frac{-1}{2}\times 712 - \frac{3}{2}436\right]$$

$$= 3\text{N—H} - [-1010]$$

$$3\text{N—H} = 1056 \text{ kJ mol}^{-}$$

$$\text{N—H} = \frac{1056}{3} = 352 \text{ kJ mol}^{-1}$$

37. $\Delta G = \Delta H - T\Delta S$

At equilibrium, $\Delta G = 0$ for a reaction to be spontaneous ΔG should be negative, so T should be greater than T_e.

38. Consider the heat of formation of H_2O

$$H_2(g) + \frac{1}{2}O_2(g) \longrightarrow H_2O(l) \qquad \Delta H = -286.20 \text{ kJ}$$

$$\Delta H_r = \Delta H_f\,(H_2O, l) - \Delta H_f\,(H_2, g) - \frac{1}{2}\Delta H_f\,(O_2, g)$$

$$-286.20 = \Delta H_f\,(H_2O, l) - 0 - 0$$

$$\Delta H_f\,(H_2O, l) = -286.20$$

Now, consider the ionization of H_2O

$$H_2O(l) \longrightarrow H^+(aq) + OH^-(aq); \quad \Delta H = 57.32 \text{ kJ}$$

$$\Delta H_r = \Delta H_f\,(H^+, aq) + \Delta H_f\,(OH^-, aq) - \Delta H_f\,(H_2O, l)$$

$$57.32 = 0 + \Delta H_f\,(OH^-, aq) - (-286.20)$$

Thus, $\Delta H_f\,(OH^- aq) = 57.32 - 286.20$

$$= -228.88 \text{ kJ.}$$

39. $\frac{1}{2}X_2 + \frac{3}{2}Y_2 \longrightarrow XY_3$

$$\Delta S_{\text{reaction}} = S_{\text{products}} - S_{\text{reactants}}$$

$$\Delta S_{\text{reaction}} = 50 - \left(\frac{3}{2}\times 40 + \frac{1}{2}\times 60\right) = -40 \text{ J mol}^{-1}$$

$$\Delta G = \Delta H - T\Delta S$$

At equilibrium as $\Delta G = 0$

$\therefore \qquad \Delta H = T\Delta S$

$\Rightarrow \qquad T = \frac{\Delta H}{\Delta S} = \frac{30\times 10^3}{40} = 750 \text{ K}$

40. $H_2O(l) \longrightarrow H_2O(g)$

$$\Delta n_g = 1 - 0 = 1$$

$$\Delta E = \Delta H - \Delta n_g RT$$

$$= 41 - 1\times 8.3\times 373\times 10^{-3} \qquad (R = 8.3\times 10^{-3})$$

$$= 37.9 \text{ kJ mol}^{-1}$$

41. In an isolated system where either mass and energy are not exchanged with surrounding for the spontaneous process, the change in entropy is positive.

42. We know that, $\Delta S = \frac{\Delta H}{T}$

$$\Delta S = 160.2 \text{ J/K}$$

$$\Delta H = 179.1\times 10^3 \text{ J/mol}$$

$$T = \frac{179.1\times 10^3 \text{ J/mol}}{160.2 \text{ J/K}}$$

$$= 1117.97 \text{ K} \approx 1118 \text{ K}$$

43. $T_{f\,(\text{irreversible})} > T_{f\,(\text{reversible})}$

It is an adiabatic expansion and W (rev) is maximum.

44. $\frac{1}{2}I_2(s) + \frac{1}{2}Cl_2(g) \longrightarrow ICl(g)$

$$\Delta H = \left[\frac{1}{2}\Delta H_{s\to g} + \frac{1}{2}\Delta H_{\text{diss}}(Cl_2) + \frac{1}{2}\Delta H_{\text{diss}}(I_2)\right] - \Delta H_{ICl}$$

$$= \left(\frac{1}{2}\times 62.76 + \frac{1}{2}\times 242.3 + \frac{1}{2}\times 151.0\right) - 211.3$$

$$= 228.03 - 211.3$$

$$\Delta H = 16.73$$

45. Carbon is found in solid state. The state of substance affects the enthalpy change.

$$C(s) \longrightarrow C(g) \text{ sublimation}$$

and $\quad H_2(g) \longrightarrow 2H(g)$ dissociation

are required for C—H bond.

46. Work done due to change in volume against constant pressure is

$$W = -p(V_2 - V_1)$$

$$= -1\times 10^5 \text{ Nm}^{-2}(1\times 10^{-2} - 1\times 10^{-3})\text{m}^3$$

$$= -900 \text{ Nm} = -900 \text{ J} (1 \text{ Nm} = 1 \text{ J})$$

47. $\Delta E = 0$, in a cyclic process.

48. $CH_2{=}CH_2 + H_2 \longrightarrow CH_3{-}CH_3$

$$\Delta H = (BE)_{\text{reactants}} - (BE)_{\text{products}}$$

$$= 4(BE)_{C-H} + (BE)_{C=C} + (BE)_{H-H} - [6(BE)_{C-H} + (BE)_{C-C}]$$

$$= [4\times 414 + 615 + 435] - [6\times 414 + 347]$$

$$= -125 \text{ kJ}$$

49. An irreversible process

$\Rightarrow$ spontaneous process

$\Rightarrow (dS)_{V,E}$ (change in entropy) $= +$ ve > 0

$\Rightarrow (dG)_{T,p}$ (change in Gibbs free energy) $-$ve $\Rightarrow < 0$

50. The amount of heat required to raise the temperature of one mole of a substance through 1° C is called molar heat capacity.

$$C = \frac{q}{T_2 - T_1}$$

6.1 Concept of Dynamic Equilibrium

When the equilibrium is attained in a chemical reaction all the observable properties of the system like concentration, colour etc., become constant.

It leads us to think that the reaction stops altogether at equilibrium. But this is not true. At equilibrium, the rate of forward reaction becomes equal to the rate of backward reaction so that there is no net change in the concentration of various species. In other words, the equilibrium state is a dynamic balance between the forward and the backward reaction.

On carrying chemical reactions in a closed vessel at a particular temperature, initially the reactant concentration keep on decreasing and product concentration keep on increasing. After sometime, a stage is reached at which there is no net reaction. This stage is called ***state of equilibrium.***

When such a stage is achieved between ions and undissociated electrolytes, it is termed as ***ionic equilibrium.***

6.2 Equilibria Involving Physical Processes

The equilibrium which develops between different phases or physical properties is termed as physical equilibria.

Some of such example are

Solid-Liquid Equilibria

On heating a pure solid substance under atmospheric pressure, it gradually starts converting into the liquid. At a certain temperature, these two phases coexist, which is called the normal *melting point* or *freezing point* of the substance *e.g.,*

Ice and water kept in a perfectly insulated thermos flask at 0°C and the atmospheric pressure are in equilibrium state. There is no change in the mass of ice and water, as the rates of transfer of molecules from ice into water and of reverse transfer from water into ice are equal. This represents a dynamic equilibrium between ice and water, *i.e.*,

$$H_2O(s) \rightleftharpoons H_2O(l)$$

or Rate of melting $\rightleftharpoons$ Rate of freezing

Caution Point *During melting of ice, the volume decreases from 1.09 mL to 1.01 mL per gram.*

Liquid-Gas Equilibria

On heating a pure liquid, it starts to convert into its vapours. If the process is carried out in a closed vessel, the vapours get condensed to give liquid. After some time a stage is reached, at which the rate of evaporation becomes equal to the rate of condensation and the volume of liquid water and vapour become constant. Such a condition, represents liquid-gas equilibria.

$$H_2O(l) \rightleftharpoons H_2O(g); \qquad 373\text{ K; 1 atm pressure}$$

Rate of evaporation = Rate of condensation

Caution Point *The temperature at which a pure liquid starts to convert into its vapours is called its boiling point. At this temperature, the vapour pressure of the liquid becomes equal to the atmospheric pressure. That's why this temperature changes with change in altitude.*

Solid-Vapour Equilibria

Such equilibrium exists only in case of sublimates (the substance which on heating directly vapourised without liquefication). *e.g.,* If a sublimate like solid iodine is heated in a closed vessel, after sometime the vessel gets filled up with violet vapour and the intensity of colour increases with time. After sometime, the intensity of colour becomes constant and at this stage the rate of sublimation of solid becomes equal to the rate of condensation of vapour into solid. This stage is referred to the equilibrium state, *i.e.,*

Rate of sublimation $\rightleftharpoons$ Rate of condensation

or $I_2(s) \rightleftharpoons I_2\text{ (vap)}$

Dissolution of Gases into Liquids

(Henry's Law)

Dissolution of a gas into a liquid is governed by Henry's law, which states that *the mass of a gas dissolved in a given mass of a solvent at any temperature is proportional to the pressure of the gas above the solvent.*

$$m \propto p$$

$$m = k_H p$$

where k_H is the proportionality constant, called the Henry's law constant and depends upon the temperature. Thus, on increasing the temperature, the amount of dissolved gas decreases.

General Characteristics of Equilibria Involving Physical Processes

For the physical processes following characteristics are common to the system at equilibrium

1. At equilibrium, at all the measurable properties of the system remain constant.
2. Equilibrium is possible only in a closed system at a given temperature.
3. Equilibrium is dynamic in nature, *i.e.,* the opposing processes do not stop but take place at the same rate.
4. The physical equilibrium is characterised by constant value of one of its parameter at a given temperature. *e.g.,* for the dissolution of CO_2 in water, at equilibrium

$$CO_2(g) \rightleftharpoons CO_2(aq)$$

$\frac{[CO_2(aq)]}{[CO_2(g)]}$ is constant at a given temperature.

This constant is called the equilibrium constant. Greater the value of equilibrium constant, greater is the extent to which CO_2 dissolves in water.

6.3 Equilibria Involving Chemical Processes

Analogous to the physical system, chemical reactions also attain a state of equilibrium. When opposing processes take place in a chemical reaction, the reaction is said to be a reversible reaction. In other words, reactions, which proceed in both the directions and do not reach to completion, are known as **reversible reactions.** It is represented by putting a double headed arrow ($\rightleftharpoons$) between the reactants and the products, one arrow pointing towards the products and the other pointing towards the reactants.

Some examples of such reactions are as follows

(i) $3Fe + 4H_2O \rightleftharpoons Fe_3O_4 + 4H_2$

(ii) $2HI \rightleftharpoons H_2 + I_2$

Caution Point *Any reaction in which one of the product is gas, but carried out in closed container, i.e., leaving no scope for gas to escape out, can be reversible in nature.*

A reversible reaction is called *homogeneous*, if contains only one phase or called *heterogeneous*, if have more than one phase *e.g.,*

$$H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$$

(Homogeneous with only gaseous phase)

$$MgCO_3(s) \rightleftharpoons MgO(s) + CO_2(g)$$

(Heterogeneous with solid and gaseous phase)

Irreversible Reactions

The reactions, which move in one direction only, *i.e.,* the reactants are almost completely converted into products are called **irreversible reactions.**

Some examples of such reactions are

(i) $BaCl_2 + Na_2SO_4 \longrightarrow BaSO_4 \downarrow + 2NaCl$ (Precipitation reactions)

(ii) $2KClO_3 \xrightarrow{\Delta} 2KCl + 3O_2$ (Decomposition reactions)

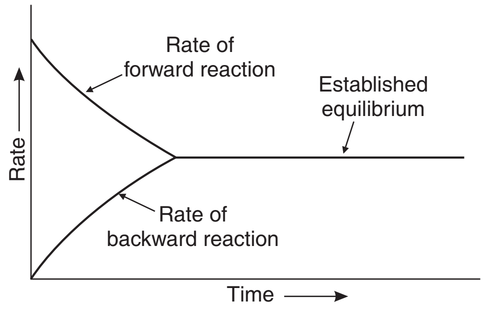
Concept of Chemical Equilibrium

The state of reversible reactions at which the concentration of the reactants and products do not change with time is known as **chemical equilibrium.**

At equilibrium state,

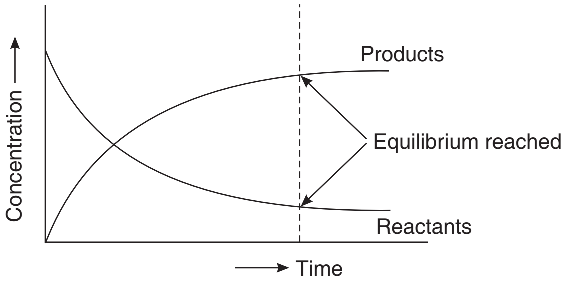
Rate of forward reaction = Rate of backward reaction.

This can be seen in a graphical mode as



Further more, the true equilibrium of a reaction can be attained from both the sides, *i.e.,* the equilibrium concentrations of reactants and products will always be the same whether we begin with the reactants or the products.

The variation of concentration of reactants and products in a reversible reaction can be seen as:



Variation of the concentration of the reactants and products

The equilibrium state is dynamic and not static in nature. It means that the reaction does not stop but both the opposing reactions are going on continuously with same speeds. At this state, the number of moles of substances produced per second in the forward reaction is equal to the number of moles of substances which disappear per second in the backward direction.

Characteristics of Chemical Equilibrium

1. In chemical equilibrium, at a given temperature, the measurable properties like pressure, concentration, density or colour remain constant.
2. Chemical equilibrium can be attained from either side.
3. Chemical equilibrium can be attained in a lesser time by the use of a catalyst, however a catalyst does not change the chemical equilibrium as it affects the rate of both (forward and reverse reaction) to the same extent.
4. Chemical equilibrium is dynamic in nature (*i.e.,* the reaction does not stop but continues in both the directions with same speed).
5. The chemical equilibrium will continue indefinitely if the conditions such as temperature and concentration are not changed.

6.4 Law of Mass Action or Law of Chemical Equilibrium

According to this law, "The rate at which a substance reacts is directly proportional to its active mass and the rate at which a chemical reaction proceeds is proportional to the product of active masses of reacting substances with each concentration term raised to the power of stoichiometric coefficient of that species in the chemical equation".

The term active mass means the molar concentration, *i.e.*, number of moles per litre. It is expressed by enclosing the formula of substance in square brackets as [ ]. Thus, active mass of H_2 can be represented as $[H_2]$.

Sample **Problem 1** *The active mass of* 64 *g of* HI *in a* 2 *L flask would be*

(*a*) 0.25 (*b*) 0.50
(*c*) 25 (*d*) 32

Interpret (*a*) Moles of HI $= \frac{64}{128}$

(Molar mass of HI $= 1 + 127 = 128$ g mol^{-1})

$$\therefore \quad [HI] = \frac{\frac{64}{128}}{2} = 0.25 \text{ mol / L}$$

Caution Point *Active masses of pure solids and liquids are taken as unity because their concentration (or density) remain same throughout the reaction. This is because Gibbs' function for pure solid and liquid are defined at stipulated pressure of* 1.00 *bar and as the p of system changes, Gibbs function remain constant.*

Hot Spot 1

EXPRESSION for Equilibrium Constant from Law of Mass Action

It is an important topic for JEE Main examination. The questions may be based on expression of K or numerical type. The level of question is easy to moderate.

Consider a homogeneous reversible reaction,

$$aA + bB \rightleftharpoons cC + dD$$

According to law of mass action,

Rate of forward reaction,

$$R_f \propto [A]^a[B]^b$$

or $$R_f = k_f[A]^a[B]^b$$

Rate of backward reaction,

$$R_b \propto [C]^c[D]^d$$

or $$R_b = k_b[C]^c[D]^d$$

where, k_f and k_b are the rate constants for forward and backward reactions respectively.

At equilibrium,

rate of forward reaction = rate of backward reaction

i.e., $$k_f[A]^a[B]^b = k_b[C]^c[D]^d$$

or, $$\frac{k_f}{k_b} = \frac{[C]^c[D]^d}{[A]^a[B]^b} \quad \text{or} \quad K_c = \frac{[C]^c[D]^d}{[A]^a[B]^b}$$

where, $K_c = \frac{k_f}{k_b}$ = constant and is known as **equilibrium constant.** It has a definite value for every chemical reaction at a particular temperature regardless of the concentration of reactants.

If K_c is expressed in terms of mole fraction, it is denoted by K_x.

$$K_x = \frac{(\chi_C)^c(\chi_D)^d}{(\chi_A)^a(\chi_B)^b}$$

In terms of partial pressures, equilibrium constants is denoted by K_p.

$$K_p = \frac{p_C^c p_D^d}{p_A^a p_B^b}$$

Sample Problem 2 *Write the expression for the equilibrium constant, K_c for each of the following reactions.*

(i) $2NOCl(g) \rightleftharpoons 2NO(g) + Cl_2(g)$

(ii) $2Cu(NO_3)_2(s) \rightleftharpoons 2CuO(s) + 4NO_2(g) + O_2(g)$

(iii) $CH_3COOC_2H_5(aq) + H_2O(l) \rightleftharpoons CH_3COOH(aq) + C_2H_5OH(aq)$

(iv) $Fe^{3+}(aq) + 3OH^-(aq) \rightleftharpoons Fe(OH)_3(s)$

(v) $I_2(s) + 5F_2 \rightleftharpoons 2IF_5$ **[NCERT]**

Interpret K_c shows the ratio of the product of concentrations of the products to the product of concentrations of the reactants, each raised to the power equal to the corresponding stoichiometric coefficient.

(i) $K_c = \frac{[NO]^2[Cl_2]}{[NOCl]^2}$

(ii) $K_c = [NO_2]^4[O_2]$

(because molar concentrations of pure solids are constant)

(iii) $K_c = \frac{[CH_3COOH(aq)][C_2H_5OH(aq)]}{[CH_3COOC_2H_5(aq)][H_2O(l)]}$

(iv) $K_c = \frac{1}{[Fe^{3+}(aq)]\cdot[OH^-(aq)]^3}$ because $[Fe(OH)_3(s)] = 1$

(v) $K_c = \frac{[IF_5]^2}{[F_2]^5}$ (because $[I_2(s) = 1]$)

Sample Problem 3 *Nitric oxide reacts with* Br_2 *and gives nitrosyl bromide as per reaction given below*

$$2NO(g) + Br_2(g) \rightleftharpoons 2NOBr(g)$$

When 0.087 *mole of* NO *and* 0.0437 *mole of* Br_2 *are mixed in a closed container at constant temperature,* 0.0518 *mole of* NOBr *is obtained at equilibrium. The equilibrium amount of* NO *and* Br_2 *are respectively.* **[NCERT]**

(*a*) 0.0352, 0.0178 (*b*) 0.0872, 0.0259

(*c*) 0.0518, 0.0259 (*d*) 0.0259, 0.0518

Interpret (*a*) In order to solve such problems, following steps are involved

Step I Set up a balance sheet using symbols for the expected equilibirum amounts of reactants and products.

	2NO	+ Br_2	$\longrightarrow$ 2NOBr
Initial moles	0.087	0.0437	0 (as no reaction occur)
At equilibrium moles	$(0.087 - 2x)$	$(0.0437 - x)$	$2x$

[Remember! multiply the value of x with the stoichiometric coefficient of the molecule.]

Step II Compare with the given information

Given equilibrium moles of NOBr = 0.0518

$\therefore$ $$2x = 0.0518$$

and $$x = \frac{0.0518}{2} = 0.0259$$

Step III Put the value of x to obtained equilibrium concentration of other species.

Moles of NO at equilibrium $= (0.087 - 2x)$

$$= 0.087 - 0.0518 = 0.0352 \text{ mol}$$

Moles of Br_2 at equilibrium $= (0.0437 - x)$

$$= 0.0437 - 0.0259 = 0.0178 \text{ mol}$$

Sample Problem 4 *Dihydrogen gas used in Haber's process is produced by reacting methane from natural gas with high temperature steam. The first stage of two stage reaction involves the formation of* CO *and* H_2*. In second stage,* CO *formed in first stage is reacted with more steam in water gas shift reaction,*

$$CO\,(g) + H_2O\,(g) \rightleftharpoons CO_2(g) + H_2(g)$$

If a reaction vessel at 400°C is charged with an equimolar mixture of CO and steam such that $p_{CO} = p_{H_2O} = 4.0$ *bar, what will be the partial pressure of* H_2 *(in bar) at equilibrium?* $K_p = 10.1$ *at 400°C.*

[NCERT]

(a) 12.71
(b) 3.17
(c) 5.32
(d) 3.04

Interpret (*d*) First find the equilibrium concentration in terms of partial pressure and then put these values in K_p expression to find partial pressure of H_2.

	$CO\,(g)$	$+\ H_2O\,(g)$	$\rightleftharpoons\ CO_2(g)$	$+\ H_2(g)$
Initial pressure	4.0 bar	4.0 bar	0	0
At equili.	$(4.0 - p)$	$(4.0 - p)$	p	p

$$K_p = \frac{p_{CO_2} \cdot p_{H_2}}{p_{CO} \cdot p_{H_2O}} = \frac{p \cdot p}{(4-p)\,.\,(4-p)}$$

$$10.1 = \frac{p^2}{(4-p)^2}$$

$$\sqrt{10.1} = \frac{p}{(4-p)}$$

$$3.17 = \frac{p}{(4-p)}$$

$$p = 12.71 - 3.17\,p$$

$$4.17p = 12.71$$

$$p = \frac{12.71}{4.17} = 3.04 \text{ bar}$$

Hence, $p_{H_2} = 3.04$ bar

Relationship Between K_p, K_c and K_x

Consider a gaseous phase reaction,

$$n_1A + n_2B + \ldots\ldots \rightleftharpoons m_1C + m_2D + \ldots\ldots$$

According to law of mass action,

$$K_p = \frac{p_C{}^{m_1} p_D{}^{m_2}}{p_A{}^{n_1} p_B{}^{n_2}} \quad \ldots(\text{i})$$

In terms of molar concentration,

$$K_c = \frac{[C]^{m_1}[D]^{m_2}}{[A]^{n_1}[B]^{n_2}} \quad \ldots(\text{ii})$$

Since for gases, $pV = nRT$

or, $p = \dfrac{n}{V} RT = CRT \quad [C = \text{concentration}]$

$\therefore \quad p_A = C_ART,\ p_B = C_BRT$

$\quad\ \ p_C = C_CRT,\ p_D = C_DRT$

Using these expressions in Eq. (i), we get

$$K_p = \frac{(C_CRT)^{m_1}(C_DRT)^{m_2}}{(C_ART)^{n_1}(C_BRT)^{n_2}}$$

or, $$K_p = \frac{C_C^{m_1} \cdot C_D^{m_2} (RT)^{m_1 + m_2}}{C_A^{n_1} \cdot C_B^{n_2} (RT)^{n_1 + n_2}}$$

or, $$K_p = \frac{C_C^{m_1} C_D^{m_2}}{C_A^{n_1} C_B^{n_2}} (RT)^{(m_1 + m_2) - (n_1 + n_2)}$$

or, $$K_p = \frac{C_C^{m_1} C_D^{m_2}}{C_A^{n_1} C_B^{n_2}} (RT)^{\Delta n_g} \quad \ldots(\text{iii})$$

[$\because\ \Delta n_g = (m_1 + m_2) - (n_1 + n_2)$ or Δn_g = moles of gaseous products − moles of gaseous reactants]

From Eqs. (i) and (iii)

$$\boxed{K_p = K_c (RT)^{\Delta n_g}}$$

We know that partial pressure,

$$p = \text{mole fraction } (\chi) \times \text{total pressure } (p)$$

For the above reaction

$$p_n = \chi_A p,\ p_B = \chi_B p,\ p_c = \chi_C p \text{ and } p_D = \chi_D p$$

So, $$K_p = \frac{p_C^{m_1} \cdot p_D^{m_2}}{p_A^{n_1} \cdot p_B^{n_2}}$$

$$= \frac{(\chi_C p)^{m_1} (\chi_D p)^{m_2}}{(\chi_A p)^{n_1} (\chi_B p)^{n_2}}$$

$$= \frac{\chi_C^{m_1} \cdot \chi_D^{m_2}}{\chi_A^{n_1} \cdot \chi_B^{n_2}} \cdot \frac{p^{(m_1 + m_2)}}{p^{(n_1 + n_2)}}$$

$$= K_x \cdot p^{(m_1 + m_2) - (n_1 + n_2)}$$

$$K_p = K_x p^{\Delta n_g}$$

So, like $$K_p = K_c (RT)^{\Delta n_g}$$

$$K_p = K_x (RT)^{\Delta n_g}$$

If, $\Delta n_g = 0$ then $K_p = K_c$
If, $\Delta n_g = +$ ve then $K_p > K_c$
If, $\Delta n_g = -$ ve then $K_p < K_c$

Sample Problem 5 *The value of* K_c *for each of the following equilibria are respectively.* **[NCERT]**

(i) $2NOCl(g) \rightleftharpoons 2NO(g) + Cl_2(g);\ K_p = 1.8 \times 10^{-2}$ *at 500 K*

(ii) $CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g);\ K_p = 167$ *at 1073 K*

(*a*) $4.38 \times 10^{-4}, 2.89$ (*b*) $4.3 \times 10^{-5}, 2.89$

(*c*) $4.38 \times 10^{-4}, 1.89$ (*d*) $4.3 \times 10^{-5}, 1.89$

Interpret (*c*) (i) $2NOCl(g) \rightleftharpoons 2NO(g) + Cl_2(g);$

$$K_p = 1.8 \times 10^{-2} \text{ at } 500\text{ K}$$

$$\Delta n_g = n_p - n_r = 3 - 2 = 1$$

$$K_c = \frac{K_p}{(RT)^{\Delta n_g}} = \frac{1.8 \times 10^{-2}}{0.0821 \times 500} = 4.38 \times 10^{-4}$$

(ii) $CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g);\ K_p = 167$ at 1073 K

$$\Delta n_g = n_p - n_r = 1$$

$$K_c = \frac{K_p}{(RT)^{\Delta n_g}} = \frac{167}{0.0821 \times 1073} = 1.89$$

Hot Spot 2

CHARACTERISTICS OF Equilibrium Constant

Calculation of equilibrium constant of a reaction from the equilibrium constant(s) of other reaction(s) is also an important topic of this chapter for JEE Main examination. Questions based on this topic are generally easy.

Main characteristics of equilibrium

1. The value of equilibrium constant does not depend on
   - (i) Initial concentrations of reactants
   - (ii) The presence of a catalyst
   - (iii) The direction from which the equilibrium has been attained
   - (iv) Presence of inert materials
   - (v) Nature and number of steps in the reaction as long as stoichiometry is constant.
2. If the equation is divided by a factor '*n*', the new equilibrium constant is n^{th} root of the previous value.
3. If the equation is multiplied by a factor '*n*', the new equilibrium constant is n^{th} power of the previous value. *e.g.,* For the reaction

$$\frac{1}{2}N_2 + \frac{3}{2}H_2 \rightleftharpoons NH_3 \qquad K_c = \frac{1}{5}$$

therefore for the reaction

$$N_2 + 3H_2 \rightleftharpoons 2NH_3$$

$$K_c' = (K_c)^2 = \left(\frac{1}{5}\right)^2 = 0.04$$

4. If the equation representing equilibrium constant is reversed, the new equilibrium constant is inverse of the first value, *e.g.,* For the following equilibrium, $K_c = 6.3 \times 10^{14}$ at 1000 K

$$NO(g) + O_3(g) \rightleftharpoons NO_2(g) + O_2(g)$$

both the forward and reverse reactions in the equilibrium are elementary bimolecular reactions. We have to find the value of K_c for the reverse reaction.

For the reaction, $NO(g) + O_3(g) \rightleftharpoons NO_2(g) + O_2(g);$

$$K_c = 6.3 \times 10^{14} \text{ at } 1000\text{ K}$$

$$K_c = \frac{[NO_2][O_2]}{[NO][O_3]} = 6.3 \times 10^{14} \qquad \text{...(i)}$$

For reverse reaction,

$$NO_2(g) + O_2(g) \rightleftharpoons NO(g) + O_3(g)$$

$$K_c' = \frac{[NO][O_3]}{[NO_2][O_2]} \qquad \text{...(ii)}$$

From Eqs. (i) and (ii), we get

$$K_c' = \frac{1}{K_c} = \frac{1}{6.3 \times 10^{14}} = 1.587 \times 10^{-15}$$

5. If two equations are added, their equilibrium constants are multiplied and if they are subtracted, their equilibrium constants are divided (Always remember, equilibrium constants are never added or subtracted).

Sample **Problem 6** *K_{a_1}, K_{a_2} and K_{a_3} are the respective ionisation constants for the following reactions.*

$$H_2S \rightleftharpoons H^+ + HS^-$$

$$HS^- \rightleftharpoons H^+ + S^{2-}$$

$$H_2S \rightleftharpoons 2H^+ + S^{2-}$$

The correct relationship between K_{a_1}, K_{a_2} and K_{a_3} is

[NCERT Exemplar]

(*a*) $K_{a_3} = K_{a_1} \times K_{a_2}$ (*b*) $K_{a_3} = K_{a_1} + K_{a_2}$

(*c*) $K_{a_3} = K_{a_1} - K_{a_2}$ (*d*) $K_{a_3} = K_{a_1} / K_{a_2}$

Interpret (*a*) For the reaction,

$$H_2S \rightleftharpoons H^+ + HS^-$$

$$K_{a_1} = \frac{[H^+][HS^-]}{[H_2S]}$$

For the reaction,

$$HS^- \rightleftharpoons H^+ + S^{2-}$$

$$K_{a_2} = \frac{[H^+][S^{2-}]}{[HS^-]},$$

When the above two reactions are added,

$$K_{a_3} = \frac{[H^+]^2[S^{2-}]}{[HS^-]} = K_{a_1} \times K_{a_2}$$

∵ When two reactions are added, their equilibrium constants are multiplied.

6. The value of equilibrium constant changes with change of temperature. If K_1 and K_2 be the equilibrium constants of a reaction at absolute temperatures T_1 and T_2 and ΔH is the heat of reaction at constant pressure then

$$\log K_2 - \log K_1 = -\frac{1}{2.303\,R}\left[\frac{1}{T_2} - \frac{1}{T_1}\right]\Delta H$$

or
$$\log \frac{K_2}{K_1} = \frac{\Delta H}{2.303R}\left[\frac{1}{T_1} - \frac{1}{T_2}\right]$$

Case I If $\Delta H = 0$, *i.e.*, neither heat is absorbed nor evolved then $\log K_2 - \log K_1 = 0 \Rightarrow K_2 = K_1$

Thus, **equilibrium constant remains same at all temperatures.**

Case II If $\Delta H > 0$, *i.e.*, the reaction is endothermic.

Let $T_2 > T_1$, then $\frac{1}{T_2} - \frac{1}{T_1} < 0$

or $\log K_2 - \log K_1 > 0$

$\Rightarrow$ $K_2 > K_1$

Hence, **the value of equilibrium constant rises with rise in temperature.**

Case III If $\Delta H < 0$, *i.e.*, the reaction is exothermic.

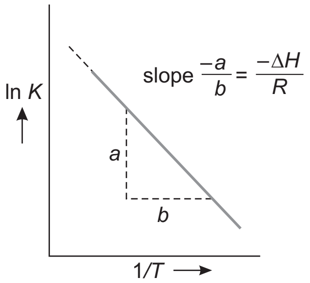
Let $T_2 > T_1$, then $\log K_2 - \log K_1 < 0 \Rightarrow K_2 < K_1$

Therefore, **the value of equilibrium constant is lowered with rise in temperature.**

The other form of the above equation is

$$\ln K = -\frac{\Delta H}{R} \times \frac{1}{T} + \text{constant}$$

(It is the equation of straight line).



Graph of ln K vs $\frac{1}{T}$

The slope of the line allows us to calculate ΔH and the intercept on the ln K axis gives the value of the constant.

The temperature dependence of K_c and K_p can be drawn by **van't Hoff equation** directly as :

(i) $$\frac{\Delta H}{RT^2} = \frac{d(\ln K_p)}{dT}$$

here, ΔH = enthalpy change of reaction at constant pressure

(ii) $$\frac{\Delta E}{RT^2} = \frac{d(\ln K_c)}{dT}$$

here, ΔE = heat of reaction at constant volume.

Sample **Problem 7** *The equilibrium constant for the reaction* $H_2(g) + S(s) \rightleftharpoons H_2S(g)$ *is 18.5 at 925 K and 9.25 at 1000 K respectively. The enthalpy of the reaction is*

(a) 2 kJ mol^{-1} (b) +71 kJ mol^{-1}
(c) −71 kJ mol^{-1} (d) 75 kJ mol^{-1}

Interpret (c) We know that,

$$\log \frac{K_2}{K_1} = \frac{\Delta H}{2.303R}\left[\frac{T_2 - T_1}{T_1 T_2}\right]$$

$$\log \frac{9.25}{18.5} = \frac{\Delta H}{2.303 \times 8.314} \times \frac{75}{925 \times 1000}$$

$$-0.3010 = \frac{\Delta H \times 75}{2.303 \times 8.314 \times 925 \times 1000}$$

or $$\Delta H = -71080.57 \text{ J mol}^{-1}$$

$$= -71.08 \text{ kJ mol}^{-1}$$

Units of K_c and K_p

If number of moles of reactants and products are equal (*i.e.*, $\Delta n_g = 0$) *e.g.*,

$$2NO \rightleftharpoons N_2 + O_2$$

then, K_p as well as K_c have no units.

If a reaction proceeds with increase in number of moles, (*i.e.*, $\Delta n > 0$)

e.g., $$PCl_5 \rightleftharpoons PCl_3 + Cl_2$$
$$N_2O_4 \rightleftharpoons 2NO_2$$

then, unit of K_p is (atmosphere)$^{\Delta n_g}$ and unit of K_c is (mol per litre)$^{\Delta n_g}$.

If the reaction shows a decrease in the number of moles (*i.e.*, $\Delta n_g < 0$).

e.g., $$N_2 + 3H_2 \rightleftharpoons 2NH_3$$

then, unit of K_p is (atmosphere)$^{\Delta n_g}$ and that of K_c is (litre per mol)$^{\Delta n_g}$.

Significance of Equilibrium Constants (K_p and K_c)

1. Greater the value of equilibrium constant, greater will be the tendency of the reaction to go in forward direction.
2. Greater the equilibrium constant of a reaction, greater will be the stability of the products and unstability of the reactants.
3. If the value of K is greater than 10^3, products predominates, if value of K is less than 10^{-3}, reactant predominates, if it is in between 10^3 to 10^{-3}, considerable amount of both is present.

Sample **Problem 8** *Predict which of the following reaction will have appreciable concentration of reactants and products?* **[NCERT]**

(a) $Cl_2(g) \rightleftharpoons 2Cl(g); \quad K_c = 5 \times 10^{-39}$

(b) $Cl_2(g) + 2NO(g) \rightleftharpoons 2NOCl(g); \quad K_c = 3.7 \times 10^8$

(c) $Cl_2(g) + 2NO_2(g) \rightleftharpoons 2NO_2(g); \quad K_c = 1.8$

(d) *All have appreciable concentration of reactants and products.*

Interpret (c) For this reaction, value of K is in between 10^{-3} to 10^3, thus in it considerable amount of both (reactants and products) are present.

Relationship Between *K* and Standard Gibbs Free Energy

Gibbs free energy change and reaction quotient are related as

$$\Delta G = \Delta G^\circ + 2.303RT \log Q_c$$

At equilibrium, $\Delta G = 0$ and $Q_c = K_c$

On putting values,

$$\Delta G^\circ = -2.303\, RT \log K_c$$

or $$\Delta G^\circ = -2.303\, RT \log K_p \quad \text{(for ideal gases)}$$

Significance of ΔG°

(i) If $\Delta G^\circ < 0, \log K > 0, \Rightarrow K > 1$

Hence, forward reaction is spontaneous.

(ii) If $\Delta G^\circ > 0, \log K < 0 \Rightarrow K < 1$

Hence, the backward reaction is favoured.

(iii) If $\Delta G^\circ = 0, \log K = 0 \Rightarrow K = 1$

Hence, it represents equilibrium.

(iv) If ΔG° is large positive number, $K >> 1$, the forward reaction is nearly complete.

(v) If ΔG° is a very small positive number, $K << 1$, the reverse reaction is nearly complete.

Check Point 1

1. The nature of equilibrium state is dynamic. Explain this.
2. Explain why pure liquids and solids can be ignored while writing the equilibrium expression?
3. Write the equilibrium constant expressions for the following reactions
   (i) $Ag_2O(s) + 2HNO_3(aq) \rightleftharpoons 2AgNO_3(aq) + H_2O(l)$
   (ii) $BaCO_3(s) \rightleftharpoons BaO(s) + CO_2(g)$
   (iii) $CH_4(g) + 2O_2(g) \rightleftharpoons CO_2(g) + 2H_2O(g)$
4. Explain why K_p is equal to K_c when Δn_g is zero?
5. Explain how does equilibrium constant affect spontaneity of a chemical reaction?

6.5 Reaction Quotient or Mass Action Ratio

Reaction quotient is the ratio of the molar concentration or partial pressure of the product species to that of reactant species at any stage in the reaction.

For a reaction,

$$A + B \rightleftharpoons C + D$$

$$Q = \frac{[C][D]}{[A][B]}$$

Reaction quotient, Q is denoted as Q_c or Q_p depending upon whether the concentration is taken in terms of moles per litre or partial pressure respectively. With the help of reaction quotient we can predict the direction of reaction.

(i) If $Q = K$, the reaction is in equilibrium.

(ii) If $Q > K$, the reaction moves from right to left, (*i.e.,* in backward direction).

(iii) If $Q < K$, the reaction moves from left to right (*i.e.,* in forward direction).

Sample **Problem 9** *A mixture of* 1.57 *moles of* N_2, 1.92 *moles of* H_2 *and* 8.13 *moles of* NH_3 *is introduced into a* 20 *L reaction vessel at* 500 *K. At this temperature, the equilibrium constant,* K_c *for the reaction,* $N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$ *is* 1.7×10^2. **[NCERT]**

The true statement is

(a) *the reaction is at equilibrium*

(b) *the reaction goes in the direction of reactants*

(c) *the reaction goes in the direction of products*

(d) *None of the above*

Interpret (*b*) $N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$

$$Q_c = \frac{[NH_3]^2}{[N_2][H_2]^3}$$

Given, $[NH_3] = \frac{8.13}{20} M = 0.4065 M$; $[N_2] = \frac{1.57}{20} M = 0.0785 M$

$$[H_2] = \frac{1.92}{20} M = 0.096 M$$

$$Q_c = \frac{[0.4065 M]^2}{[0.0785 M][0.096 M]^3} = 2.379 \times 10^3 M^{-2}$$

$Q_c \neq K_c$, so the reaction mixture is not in equilibrium. $Q_c > K_c$, it indicates that the reaction will proceed in the direction of reactants.

6.6 Relation Between Vapour Density and Degree of Dissociation

Consider the following reversible chemical equation

$$A \rightleftharpoons yB$$

Initial moles : 1 $\quad 0$

At equilibrium $(1 - x)$ $\quad yx$ (x = degree of dissociation)

Number of moles of A and B at equilibrium

$$= 1 - x + yx$$
$$= 1 + x(y - 1)$$

If initial volume of 1 mole of A is V then volume of equilibrium mixture of A and B is $[1 + x(y - 1)]V$.

Now, molar density before dissociation,

$$D = \frac{\text{molecular weight } (m)}{\text{volume } (V)}$$

Molar density after dissociation,

$$d = \frac{m}{[1 + x(y - 1)]V}$$

$$\therefore \quad \frac{D}{d} = [1 + x(y - 1)] \text{ and } x = \frac{D - d}{d(y - 1)}$$

where, y = number of moles of products from one mole of reactant

$\frac{D}{d}$ = van't Hoff factor

Also, $D \times 2$ = molecular weight (theoretical value)

$d \times 2$ = molecular weight of the mixture (abnormal value)

e.g., (i) $PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$

$$y = 2, \text{ and thus, } x = \frac{D - d}{d}$$

(ii) $2NO_2 \rightleftharpoons N_2O_4$

$$y = \frac{1}{2}, \text{ and thus, } x = \frac{2(d - D)}{d}$$

Sample **Problem 10** *Calculate the degree of dissociation, if vapour density of the equilibrium mixture of* NO_2 *and* N_2O_4 *is found to be 40 for the reaction,*

$$N_2O_4 \rightleftharpoons 2NO_2$$

(*a*) 1.25
(*b*) 0.15
(*c*) 1.50
(*d*) 2.50

Interpret (*b*) Theoretical molecular weight $= 2 \times D = 92$

$$D = \frac{92}{2} = 46$$

Hence, $$x = \frac{D - d}{d} = \frac{46 - 40}{40} = 0.15$$

6.7 Le-Chatelier's Principle

In 1884, French chemist **Henry Le-Chatelier** proposed a general principle which applies to all systems in equilibrium. The principle commonly called Le-Chatelier's principle and states that *when a change is brought about on a system in equilibrium, the system tends to adjust itself to reduce the effect of change.*

or

If a system in equilibrium is subjected to a change of concentration, pressure or temperature, the equilibrium shifts in the direction that tends to undo the effect of the change.

Factors Affecting Equilibrium Concentration

Various factors that affect the state of equilibrium are as follows.

(a) Change in Concentration

If concentration of the reactants is increased or product is removed, the equilibrium will shift in the forward direction. On the other hand, if concentration of the products is increased, the equilibrium will shift in the backward direction.

(b) Change in Pressure

If a system in equilibrium consists of gases, the concentration of all the components may be altered by changing the pressure as the pressure at equilibrium is determined by the total number of molecules it contain.

As a general rule, the increase of pressure on a chemical equilibrium shifts it in that direction in which the number of gaseous molecules decreases and *vice-versa*. Thus,

if $\Delta n_g = 0$, no effect on equilibrium due to pressure change.

if $\Delta n_g > 0$, the increase in pressure favours backward reaction.

if $\Delta n_g < 0$, the increase in pressure favours forward reaction.

(c) Change in Temperature

When temperature is raised, the equilibrium is shifted in the direction in which heat is absorbed. Thus, for an exothermic reaction, the increase in temperature favours backward reaction and for an endothermic reaction, the forward reaction is favoured by increase in temperature.

(d) Effect of Catalyst

Catalyst increases (or decreases) both forward and backward reactions equally, therefore equilibrium will be attained in less (or more) time. So, only the time required to reach the equilibrium state is changed by the presence of catalyst. Thus, a catalyst does not affect equilibrium constant.

(e) Effect of Addition of Inert Gas

(i) If keeping pressure of the system constant, an inert gas is added, it will increase the volume of the system. Therefore, the equilibrium will shift in a direction in which there is increase in number of moles of gases.

(ii) If keeping volume of the system constant, an inert gas is added, the relative molar concentration of the substance will not change. Hence, the equilibrium position of the reaction remains unaffected.

Table 6.1 **Effect of Varying Conditions of the Equilibrium, $aA + bB \rightleftharpoons cC + dD, \Delta n_g = (c + d) - (a + b)$**

S. No.	Change imposed on the system in equilibrium	Equilibrium position moves	Equilibrium constant	Any other points
1.	Conc. of *A* and/or *B* increased	To right	No change	No change
2.	Conc. of *C* and/or *D* increased	To left	No change	No change
3.	Pressure increased	To right if $(c + d) < (a + b)$, *i.e.*, $\Delta n_g = -\text{ve}$ To left if $(c + d) > (a + b)$, *i.e.*, $\Delta n_g = +\text{ ve}$ No change if $(c + d) = (a + b)$, *i.e.*, $\Delta n_g = 0$	No change No change No change	Very little effect, if any, on reactions in liquid solution
4.	Temperature increased	To left if $\Delta H = -\text{ve}$ (exothermic) To right if $\Delta H = +\text{ve}$ (endothermic)	Value decreased Value increased	Equilibrium achieved faster
5.	Addition of catalyst	No change	No change	Equilibrium achieved faster
6.	Addition of inert gas			
	(i) At constant *p*	To the direction of increasing gaseous moles	No change	No change
	(ii) At constant *V*	No effect	No change	No change

Applications of Le-Chatelier's Principle

This principle is applicable to physical as well as chemical equilibria.

Some of its applications are mentioned below.

(a) Formation of HI

$$H_2 + I_2 \rightleftharpoons 2HI, \quad \Delta H = -12.4 \text{ kcal}$$

The favourable conditions for forward reaction are

(i) high concentration of H_2 or/and I_2.

(ii) unaffected by pressure change (as $\Delta n_g = 0$)

(iii) low reaction temperature (as the reaction is exothermic).

(iv) no effect of addition of inert gas.

(b) Haber's Process of Synthesis of Ammonia

$$N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g) \quad \Delta H = -22.4 \text{ kcal}$$

The favourable conditions are

(i) high concentration of N_2 or/and H_2

(ii) high pressure (as $\Delta n_g = -2$)

(iii) low temperature (as the reaction is exothermic)

Although the low temperature favour the formation of NH_3, yet an optimum temperature is set, as the rate of reaction is very slow at low temperature. A temperature of 500° C is selected and a pressure of 200 atm is applied in practice. To enhance the rate of reaction, catalyst, finely divided iron containing molybdenum (acts as promoter) is used.

(c) Manufacture of Nitric Acid (Birkeland-Eyde Process)

$$N_2(g) + O_2(g) \rightleftharpoons 2NO(g) \; \Delta H = +\, 43.2 \text{ kcal}$$

The factors favouring formation of NO are

(i) increase in concentration of N_2 and O_2

(ii) unaffected by pressure change (as $\Delta n_g = 0$)

(iii) increase in temperature (as the reaction is endothermic).

(d) Melting of Ice

$$\underset{\substack{1\text{ g}\\1.09\text{ mL}}}{\text{Ice}} \rightleftharpoons \underset{\substack{1\text{ g}\\1.01\text{ mL}}}{\text{Water}} - x\text{ kcal}$$

In the above case, forward change is accompanied with absorption of heat and a decrease in volume.

Hence, on applying Le-Chatelier's principle, the favourable conditions for the melting of ice are high temperature (as forward reaction is endothermic) and high pressure (as forward reaction shows decrease in volume).

(e) Boiling of Water

$$\underset{\text{(low volume)}}{\text{Water}} \rightleftharpoons \underset{\text{(higher volume)}}{\text{Steam}} \quad -x\text{ kcal}$$

The forward change is accompanied with absorption of heat and increase in volume. Hence, according to Le-Chatelier principle, the favourable conditions for vaporisation of water are high temperature and low pressure.

(f) Solubility of Salts

If solubility of a salt is accompanied by absorption of heat. *e.g.*, Consider the solution of NaCl in water, following equilibrium exists

$$\text{NaCl}(s) + H_2O \rightleftharpoons \text{NaCl}(aq); \qquad \Delta H > 0$$

As the dissolution of NaCl proceeds with absorption of heat, it is favoured by high temperature.

If solubility of a salt is accompanied by evolution of heat, *e.g.*, KOH dissolves in water with evolution of heat, the solubility of KOH, thus decreases with increase in temperature.

$$\text{KOH}(s) + H_2O \rightleftharpoons \text{KOH}(aq) \qquad \Delta H < 0$$

Sample **Problem 11** *The exothermic formation of* ClF_3 *is represented by the equation,* $Cl_2(g) + 3F_2(g) \rightleftharpoons 2ClF_3(g)$, $\Delta H_r = -329\,kJ$. *Which of the following will increase the quantity of* ClF_3 *in an equilibrium mixture of* Cl_2, F_2 *and* ClF_3?

(a) *Removing* Cl_2
(b) *Adding* F_2
(c) *Increasing the temperature*
(d) *Increasing the volume of the container*

Interpret (*b*) For the reaction,

$$\Delta n_g = -\text{ve}$$
$$\Delta H = -\text{ve}$$

∴ The reaction will shift in the forward direction on decreasing the volume, decreasing temperature, removing ClF_3 and adding either Cl_2 or F_2.

Check Point 2

1. Explain why high pressure is applied in the synthesis of ammonia?
2. In the presence of Cl_2, dissociation of PCl_5 decreases, why?
3. What is the effect of halving the pressure by doubling the volume of the following system at 500°C?
$$H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$$
4. What is the effect on this equilibrium of halving the volume and doubling the total pressure?
$$N_2 + 3H_2 \rightleftharpoons 2NH_3 + 22\text{kcal}$$
5. When ice (solid) melts into water liquid, volume decreases explain, why?

6.8 Electrolytes and Non-Electrolytes

Electrolytes

The solutes which dissociate into ions when dissolved in water, are called **electrolytes.** These form a solution, which conducts electricity, however, not all the electrolytes ionise to the same extent in solution. Depending upon the extent of ionisation, the electrolytes are divided into two classes

(a) Strong Electrolytes

These are dissociated largely or almost completely in solution and the solution consequently becomes very good conductor of electricity. For example, HCl, H_2SO_4, HNO_3, NaOH, KOH, NaCl, KCl, KNO_3, NH_4Cl etc.

(b) Weak Electrolytes

These get never completely dissociated. In ordinary conditions, weak electrolytes dissociate in solution to a small extent and the solution consequently is poor conductor of electricity. For example, CH_3COOH, H_3PO_4, H_3BO_3, NH_4OH, $(NH_4)_2CO_3$, HCN etc.

Non-Electrolytes

A solution of solute like urea, glucose, etc., does not contain any ion, hence the solution is bad conductor of electricity. Such solutes are termed as **non-electrolytes.**

6.9 Arrhenius Theory of Electrolytic Ionisation

This theory explains the mechanism of electrolysis and abnormal behaviour of electrolytes in dilute solutions.

The main postulates of this theory are

1. In aqueous solution, the molecules of an electrolyte undergo spontaneous dissociation into positive and negative ions. The positively charged ions are called **cations** and the negatively charged ions are called **anions.**
2. When a current of electricity is passed through a solution of an electrolyte, the positively charged ions move towards cathode and negatively charged ions move towards anode and lose their charges and convert into products. This movement of ions constitutes the electric current in the solution.
3. A dynamic equilibrium, called the **ionic equilibrium,** is established between the ions and undissociated molecules.

$$AB \rightleftharpoons A^+ + B^-$$

4. The properties of solutions of electrolytes are essentially the properties of individual ions.
5. The fraction of the total number of molecules undergoing dissociation is called the **"degree of dissociation** (α)". Alternatively, the fraction of the amount of the electrolyte in solution present as free ions is called the degree of dissociation.

$$\alpha = \frac{\text{number of molecules of electrolyte dissociated as ions}}{\text{total number of molecules of electrolyte dissolved}}$$

or $$\alpha = \frac{\text{amount of electrolyte dissociated}}{\text{initial amount}}$$

Degree of dissociation (α) increases with dilution and reaches to maximum limit (unity) at infinite dilution for weak electrolytes.

Factors Affecting Degree of Dissociation

Various factors by which the degree of dissociation gets affected are as follows

(a) Nature of Solute

Strong electrolytes have high value of degree of dissociation while weak electrolytes have lower values.

(b) Nature of Solvent

Degree of dissociation of an electrolyte increases with the polarity of the solvent.

(c) Concentration

The degree of dissociation of an electrolyte decreases with rise in concentration of the electrolyte.

(d) Temperature

In general, the degree of dissociation rises with raise in temperature of the solution.

(e) Addition of Other Species

Addition of another species (solute) having an ion common to that of weak electrolyte shows a decrease in degree of dissociation of weak electrolyte (common ion effect).

Hot Spot 3

OSTWALD'S Dilution Law

It is one of the important topic of the chapter for JEE Main examination. The question is generally numerical type and its level varies from easy to moderate.

Ostwald proposed that the **law of mass action could be applied to the ionic equilibrium** as in the case of chemical equilibrium. This application of law of mass action to dilute solutions is called **Ostwald's dilution law.** Consider a binary electrolyte AB dissociating in solution according to the following equation

$$\begin{array}{lccc} & AB & \rightleftharpoons & A^+ & + & B^- \\ \text{Initially} & C & & 0 & & 0 \\ \text{At equilibrium} & C(1-\alpha) & & C\alpha & & C\alpha \end{array}$$

where, C (mol/L) be the initial concentration of the electrolyte and α be the degree of dissociation. So, dissociation constant may be given as

$$K = \frac{[A^+][B^-]}{[AB]} = \frac{C\alpha \times C\alpha}{C(1-\alpha)} = \frac{C\alpha^2}{1-\alpha} \qquad \text{...(i)}$$

For very weak electrolytes,

$$\alpha <<< 1 \Rightarrow (1-\alpha) \approx 1$$

$$\therefore \qquad K = C\alpha^2$$

$$\text{or} \qquad \alpha = \sqrt{\frac{K}{C}}$$

$$\text{or} \qquad \alpha \propto \frac{1}{\sqrt{C}} \propto \sqrt{V} \qquad \left(\because C \propto \frac{1}{V}\right)$$

$$V = \text{dilution of solution}$$

Thus, *"the degree of dissociation is proportional to the square root of dilution for weak electrolytes." This is the statement of Ostwald Law.* Degree of dissociation increases as dilution increases.

Applications of Ostwald's Dilution Law

This law is used

1. To calculate the value of dissociation constant (K) of the weak acids and weak bases, by determining the degree of dissociation (α) from conductance measurement $\left(\frac{\lambda_V}{\lambda_\infty}\right)$ at any concentration C.
2. To calculate the degree of dissociation, α of weak acids and bases by knowing the value of K.

   For weak acid, put $[A^+] = [H^+]$ and $K = K_a$

   Similarly for weak bases,

   $$[B^-] = [OH^-] \text{ and } K = K_b$$

Limitations of Ostwald's Law

1. This law holds good only in case of weak electrolytes. Even weak electrolytes do not obey this law in concentrated solutions.
2. The value of K can be calculated only in dilute solutions of weak electrolytes.

Caution Point *The approximation* $(1-\alpha) \approx 1$ *can be applied only if* $\alpha < 5\%$. *If on solving a problem by applying the approximate formula;* α *comes out to be* $>5\%$, *the problems may be solved by applying the exact formula and* α *may be calculated applying the solution of the quadratic equation*

$$\alpha = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a} \qquad (\text{for, } a\alpha^2 + b\alpha + c = 0)$$

Sample **Problem 12** *The ionisation constant of* 0.05 M *solution of phenol is* 1.0×10^{-10}. *What will be its degree of ionisation if the solution is also* 0.01 M *in sodium phenolate?*

[NCERT]

(a) 1×10^{-10} (b) 1×10^{-8}

(c) 1×10^{-4} (d) 1×10^{-6}

Interpret (b) Write equation of dissociation as

$$C_6H_5OH \longrightarrow C_6H_5O^- + H^+(H_3O^+)$$

When mixture contains 0.05 M phenol and 0.01 M phenolate ion (from sodium phenolate) then

$$K_a = \frac{[C_6H_5O^-][H_3O^+]}{[C_6H_5OH]}$$

$$1.0 \times 10^{-10} = \frac{[0.01] \times [H_3O^+]}{[0.05]}$$

$$[H_3O^+] = \frac{0.05 \times 1.0 \times 10^{-10}}{0.01}$$

$$= 5 \times 10^{-10} \text{ M}$$

$$[H_3O^+] = C \cdot \alpha = 5 \times 10^{-10}$$

$$\text{or} \qquad \alpha = \frac{5 \times 10^{-10}}{C}$$

$$\alpha = \frac{5 \times 10^{-10}}{0.05} = 1 \times 10^{-8}$$

Sample **Problem 13** *0.16 g N_2H_4 is dissolved in water and the total volume is made upto 500 mL. Calculate the percentage of N_2H_4 that has reacted with water in this solution. K_b for N_2H_4 is 4.0×10^{-6} M.*

(a) 12% (b) 8%
(c) 2% (d) 20%

Interpret (c)

$$\begin{array}{lcccl} N_2H_4 + H_2O & \rightleftharpoons & N_2H_5^+ & + OH^- & \\ 1 & & 0 & 0 & \text{initially} \\ 1-\alpha & & \alpha & \alpha & \text{after dissociation} \end{array}$$

$$K_b = \frac{C\alpha^2}{(1-\alpha)}$$

$$K_b = C\alpha^2 \quad [\text{if } (1-\alpha) \approx 1]$$

$$C = [N_2H_4] = \frac{0.16 \times 1000}{32 \times 500} = 0.01$$

$$K_b = 4 \times 10^{-6}\ M$$

$$\alpha = \sqrt{\frac{4 \times 10^{-6}}{0.01}} = 0.02 \quad \text{or} \quad 2\%$$

6.10 Various Concepts of Acids and Bases

The earlier criteria for acids and bases were the experimentally observed properties of aqueous solutions. An **acid** is that whose aqueous solution tastes sour, turns blue litmus red, neutralises bases and so on. On the other hand, the aqueous solution of a **base** tastes bitter, turns red litmus blue, neutralises acid and so on. Later on some concepts are given to signify acids and bases. These are

Arrhenius Concept

According to this concept, all substances, which give H^+ ions in their aqueous solutions are called **acids,** while those, which furnish OH^- ions in water are called **bases.**

$$HA \rightleftharpoons H^+ + A^- \text{ (acid)}$$

$$BOH \rightleftharpoons B^+ + OH^- \text{ (base)}$$

The strength of the acid or base depends upon its tendency to furnish H^+ or OH^- ions in solution.

Water is amphoteric because it furnish both H^+ *and* OH^- *ions in solution.*

$$H_2O \rightleftharpoons H^+ + OH^-$$

Number of H^+ ions delivered by an acid in its aqueous solution is called **basicity** or **protocity** of the acid. *The acids are referred as monobasic, dibasic, tribasic* etc., according as the number of protons given in aqueous solution are one, two or three.

Similarly, the number of OH^- furnished by the base in its aqueous solution is called its **acidity.**

Limitations of Arrhenius Theory

1. Free H^+ and OH^- ions do not exist in water.
2. The concept is limited to aqueous solutions only.
3. It cannot explain the acidic character of certain salts like, $AlCl_3$, BF_3 and basic character of NH_3, PH_3.
4. It cannot be applied to compounds which do not contain free H^+ or OH^- ions.

Caution Point *$H^{\oplus}$ ion is a bare proton (~10^{-15} m radius) with intense electric field, binds itself with the water molecules at one of the two available lone pairs on it, giving $H_3O^{\oplus}$.*

In aqueous solution, the $H_3O^{\oplus}$ is further hydrated to give species such as $H_5O_2^{\oplus}$, $H_7O_3^{\oplus}$ and $H_9O_4^{\oplus}$, e.g.,

$$H_3O^{\oplus} + H_2O \longrightarrow H_5O_2^{\oplus}$$

$$H_5O_2^{\oplus} + H_2O \longrightarrow H_7O_3^{\oplus}$$

Similarly, the $\overset{\ominus}{O}H$ ion is hydrated to give several ionic species such as $H_3O_2^{\ominus}$, $H_5O_3^{\ominus}$, and $H_7O_4^{\ominus}$.

$$\overset{\ominus}{O}H + H_2O \longrightarrow H_3O_2^{\oplus}$$

Bronsted-Lowry Concept

According to this concept, an **acid** is a substance (molecule or ion) that can donate H^+ to some other substance and a **base** is a substance that can accept a proton from an acid. Thus, an acid is a proton donor **(protogenic)** and a base is proton acceptor **(protophilic).**

Consider the following equilibrium

$$B + H^+ \rightleftharpoons BH^+$$

In the above reaction B is acting as **base.** The compound BH^+ has a tendency to release H^+.

The acid and base, which differ by a proton, are said to form a conjugate acid-base pair.

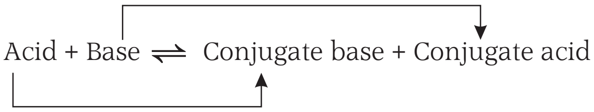
Consider the following reaction

$$CH_3COOH + H_2O \rightleftharpoons H_3O^+ + CH_3COO^-$$

It involves two conjugate pairs,

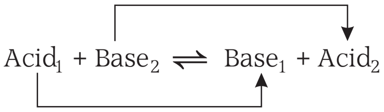
$$CH_3COOH \underset{+H^+}{\overset{-H^+}{\rightleftharpoons}} CH_3COO^- \text{ and } H_2O \underset{-H^+}{\overset{+H^+}{\rightleftharpoons}} H_3O^+$$

Such pairs of substances are known as conjugate acid-base pairs. In symbol, we can write



Acid + Base $\rightleftharpoons$ Conjugate base + Conjugate acid

Or



$Acid_1 + Base_2 \rightleftharpoons Base_1 + Acid_2$

Examples

$$H_2SO_4 + H_2O \rightleftharpoons HSO_4^- + H_3O^+$$

$$H_2O + NH_3 \rightleftharpoons NH_4^+ + OH^-$$

$$HCl + OH^- \rightleftharpoons H_2O + Cl^-$$

$$H_3O^+ + OH^- \rightleftharpoons H_2O + H_2O$$

The strength of the acids/bases depend upon their tendency to donate/accept the proton.

Generally, a strong base has a weak conjugate acid and a weak base has strong conjugate acid. The above reactions, which involve the transfer of proton are called **neutralisation reactions.**

Always remember a substance behaves as an acid only if there is an acceptor of proton furnished by it.

The compounds which have dual character, *i.e.,* they may act as acid as well as base are called **amphoteric** or **amphiprotic**, *e.g.*, NH_3, H_2O, CH_3COOH, etc.

$$H_2O + H_2O \rightleftharpoons H_3O^+ + OH^-$$

$$NH_3 + NH_3 \rightleftharpoons NH_4^+ + NH_2^-$$

$$CH_3COOH + CH_3COOH \rightleftharpoons CH_3CO\overset{+}{O}H_2 + CH_3COO^-$$

All strong acids or bases appear to be equally strong in water, hence water levels the strength of all acids and bases. This is called **levelling effect.** We, therefore, cannot compare the strength of acids or bases in aqueous medium. The strength of an acid depends on the solvent. *e.g.,* The acids $HClO_4$, H_2SO_4, HCl, HNO_3 all appear to have nearly same strength in aqueous solution, but their strength is in order $HClO_4 > H_2SO_4 > HCl > HNO_3$ in acetic acid.

HCl acts as an acid in H_2O, stronger acid in NH_3, weak acid in CH_3COOH, neutral in C_6H_6 and a weak base in HI.

Generalised variation of acidic and basic strengths can be seen as :

1. The acidic strength of hydracids in the same period increases across the period, *e.g.*, in II period,

   $$CH_4 < NH_3 < H_2O < HF$$

   This is due to the stability order of their conjugate base.

   $$CH_3^- < NH_2^- < H^- < F^-$$

2. The hydracids show a regular increase in strength down a group, because *E*—H (where *E* = any element except H) bond length increases which facilitate the removal of proton. *e.g.,*

   $$NH_3 < PH_3 < AsH_3 < SbH_3 < BiH_3$$
   $$H_2O < H_2S < H_2Se < H_2Te$$
   $$HF < HCl < HBr < HI$$

3. The acidic character of oxyacids of same element increases with increase in number of oxygen atoms, *e.g.,*

   $$HClO < HClO_2 < HClO_3 < HClO_4$$
   $$H_2SO_3 < H_2SO_4$$
   $$HNO_2 < HNO_3$$

   However, the rule fails in oxyacids of phosphorus

   $$H_3PO_2 > H_3PO_3 > H_3PO_4$$

4. The acidic character of oxyacids of different elements which are in same oxidation state decreases with increase in atomic number (due to increase in size and decrease in electronegativity).

   $$HClO_4 > HBrO_4 > HIO_4$$
   $$H_2SO_3 > H_2SeO_3$$

Limitations of Bronsted-Lowry Concept

1. The protonic definition cannot be used to explain the reactions occurring in the non-protonic solvents such as $COCl_2$, SO_2, N_2O_4 etc.
2. This concept cannot explain the reactions between some acidic oxides (such as CO_2, SO_2, SO_3) and basic oxides (such as CaO, BaO, MgO) which take place even in the absence of the solvent, *e.g.,*

   $$CaO + SO_3 \longrightarrow CaSO_4$$

3. BF_3, $AlCl_3$ etc., do not have any hydrogen and hence, cannot give a proton but are known to behave as acids.

Caution Points *Solvents can be classified into following four types on the basis of proton interaction.*

(*i*) **Protophilic solvents** *These solvents have a high tendency to accept protons, e.g., water, alcohol, liquid ammonia etc.*

(*ii*) **Protogenic solvents** *These solvents have tendency to produce protons, e.g., water, liquid hydrogen chloride, glacial acetic acid etc.*

(*iii*) **Amphiprotic solvents** *They have tendency to accept as well as donate proton, e.g.,* NH_3 *etc.*

(*iv*) **Aprotic solvents** *These are the solvents which neither donate nor accept protons. These solvents do not influence the acid-base characteristic of solute. e.g., benzene, carbon tetrachloride, carbon disulphide etc.*

Lewis Concept

According to this concept, a **base** is defined as a substance, which can give a pair of electrons to form a co-ordinate bond and the **acid** is the substance which can accept the pair. Thus, *an acid is an electrophile, while a base is a nucleophile.*

According to Lewis, a general acid-base reaction can be expressed as below

$$A + {:}B \longrightarrow A \leftarrow B$$
$$\text{acid} + \text{base} \longrightarrow \text{complex}$$

Example

$$H^+ + {:}OH^- \longrightarrow H \leftarrow OH$$

$$BF_3 + \ddot{N}H_3 \longrightarrow H_3N \rightarrow BF_3$$

Types of Lewis acids include

1. Compounds in which the central atom has incomplete octet, *e.g.,* BF_3, $AlCl_3$, $GaCl_3$, $MgCl_2$, $BeCl_2$ etc.
2. Compounds in which the central atom has available *d*-orbital, *e.g.,* PF_3, PF_5, SF_4, SeF_4, $TeCl_4$, GeX_4, $SnCl_4$ etc.
3. All simple cations like Na^+, Cu^{2+}, Ag^+, Al^{3+}, Fe^{3+}, Ca^{2+}, H^+, etc. *However,* Na^+, K^+, Ca^{2+} *etc., have very little tendency to accept electrons.*
4. Molecules with multiple bonds between dissimilar atoms, *e.g.,* $O{=}C{=}O$, $O{=}S{=}O$, SO_3, etc.
5. Elements with an electron sextet, *e.g.,* O, S, etc.

Types of Lewis bases include

1. All simple anions, like Cl^-, F^-, OH^-, CN^-, etc.
2. Molecules with one or two unshared (lone) pairs, *e.g.,* $H_2\underset{\cdot\cdot}{\ddot{O}}$, $\ddot{N}H_3$, $R\underset{\cdot\cdot}{\ddot{O}}H$, $R_2\underset{\cdot\cdot}{\ddot{O}}$, $R_2\underset{\cdot\cdot}{\ddot{S}}$, pyridine, etc.
3. Multiple bonded compounds which form co-ordination compounds with transition metals, *e.g.,* CO, NO, ethylene, acetylene etc.

Limitations of Lewis Concept

1. The strength of Lewis acids and bases is found to depend on the type of reaction, *it is not possible to arrange them in any order of their relative strength.*
2. It does not explain the behaviour of protonic acids such as HNO_3, HCl, H_2SO_4 etc.
3. Catalytic activity of Lewis acid can't be explained because the catalytic activity of many acids is due to their tendency to furnish H^+. Lewis acid does not do so.

Hard and Soft Acids and Bases (HSAB) Principle

"Hardness" is the property of retaining valence electrons very strongly. It is the basis of this principle.

Hard Acids

These are characterised by small size of electron accepting atom. They have high charge and have no electron which are easily polarised or removed. Examples of hard acids are H^+, Li^+, Na^+, Be^{2+}, Mg^{2+}, Mn^{2+}, Al^{3+}, Cr^{3+}, Co^{3+}, Fe^{3+}, La^{3+}, Ce^{3+}, As^{3+}, BF_3, $AlCl_3$, SO_3 etc.

Soft Acids

In these acceptor atom is large, carries low charge, has electrons which can be easily distorted. Examples of soft acids are Pb^{2+}, Cd^{2+}, Pt^{3+}, Hg^{2+}, Cu^+, Ag^+, Tl^+, Hg^{2+}, $GaCl_3$, B_2H_6, RO^+, I_2, Br_2, metal atoms etc.

Hard Bases

These are the Lewis base that hold electrons strongly, *e.g.,* H_2O, NH_3, OH^-, F^-, Cl^-, CO_3^{2-}, ClO_4^-, NO_3^-, ROH· RO^-, R_2O, RNH_2 etc.

Soft Bases

These are the Lewis base from which electrons can be easily removed, *e.g.,* R_2S, RHS, RS^-, I^-, SCN^-, R_3P, R_3As, CN^-, RNC, CO, C_2H_4, H^-, R^-, etc.

Caution Point *Hard acid prefers hard base, for binding.*

Some rememberable facts are as

1. All organic acids (except those having $—SO_3H$) are weak acids.
2. Oxides of metals are normally basic while oxides of non-metals are normally acidic.
3. The oxides of alkali and alkaline earth metals are strong base and rest all oxides are weak base.

Relative Strengths of Acids and Bases

The extent to which the acidic property is shown by an acid is a measure of its strength. The strength of an acidic solution does not depend upon its concentration but depend upon the number of H^+ ions present. Thus, to measure the relative strength of the two acids, the measurements of their H^+ ions concentration, *i.e.,* the degree of dissociation of their equinormal solutions is used.

$$\frac{\text{Strength of acid I}}{\text{Strength of acid II}}=\frac{\alpha_1}{\alpha_2}=\sqrt{\frac{K_1/C}{K_2/C}}=\sqrt{\frac{K_1}{K_2}}$$

where, K_1 and K_2 are the dissociation constants of two acids at the same concentration, C.

α_1 and α_2 are their degree of dissociation.

Di- and Polybasic Acids and Di- and Polyacidic Bases

Acids which have more than one ionisable proton per molecule of acids are known as polybasic or polyprotic acids, *e.g.,* oxalic acid (HOOC — COOH), H_2SO_4, and H_3PO_4.

The ionisation reactions for a dibasic acid, H_2X are represented as

$$H_2X(aq) \rightleftharpoons H^{\oplus}(aq) + HX^{\ominus}(aq)$$

$$HX^{\ominus}(aq) \rightleftharpoons H^{\oplus}(aq) + X^{2-}(aq)$$

The corresponding equilibrium constants are as

$$K_{a_1}=\frac{[H^{\oplus}][HX^{\ominus}]}{[H_2X]} \text{ and } K_{a_2}=\frac{[H^{\oplus}][X^{2-}]}{[HX^{\ominus}]}$$

(K_{a_1} and K_{a_2} are called first and second ionisation constants, respectively, of the acid H_2X).

Similarly, for tribasic acids such as H_3PO_4, there are three ionisation constants.

It is found that K_{a_1} of polyprotic acid is greater than K_{a_2} or K_{a_3} (*i.e.*, $K_{a_1} > K_{a_2} > K_{a_3}$), because it is more difficult to remove a positively charged proton from a negative ion due to electrostatic forces. Similarly, it is more difficult to remove a proton from a doubly charged anion as compared to single charged anion.

The primary reaction involves the dissociation of H_2X and $H_3O^{\oplus}$ in the solution comes mainly from the first dissociation step.

Sample Problem 14 *K_1 and K_2 for dissociation of H_2S are 4×10^{-3} and 1×10^{-5}. Calculate sulphide ion concentration in 0.1 M H_2S solution.*

(a) 10^{-4} (b) 10^{-8}

(c) 10^{-5} (d) 10^{-6}

Interpret (c) $H_2S \rightleftharpoons H^{\oplus} + HS^{\ominus}$

$$K_1 = \frac{[H^{\oplus}][HS^{\ominus}]}{[H_2S]} = 4\times10^{-3}$$

$$[H^{\oplus}] = C\alpha, [HS^{\ominus}] = C\alpha, \quad [H_2S] = C(1-\alpha)$$

or $$4\times10^{-3} = \frac{C\alpha\cdot C\alpha}{C(1-\alpha)} = \frac{C\alpha^2}{(1-\alpha)}$$

$$4\times10^{-3} = \frac{0.1\times\alpha^2}{(1-\alpha)} \quad (1-\alpha \text{ should not be neglected})$$

or $$\alpha = 0.18,$$

$\therefore$ $$[H^{\oplus}] = C\alpha = 0.1\times0.18 = 0.018\text{ M}$$

$$[HS^{\ominus}] = C\alpha = 0.1\times0.18 = 0.018\text{ M}$$

$$[H_2S] = C(1-\alpha) = 0.1(1-0.18)$$
$$= 0.082\text{ M}$$

Now, $HS^{\ominus}$ further dissociates to $H^{\oplus}$ and S^{2-};

$$C_1 = [HS^{\ominus}] = 0.018\text{ M}$$

$$\begin{array}{ccccc} HS^{\ominus} & \rightleftharpoons & H^{\oplus} & + & S^{2-} \\ 1 & & 0 & & 0 \\ (1-\alpha_1) & & \alpha_1 & & \alpha_1 \end{array}$$

$\therefore$ $$K_2 = 1\times10^{-5} = \frac{[H^{\oplus}][S^{2-}]}{[HS^{\ominus}]}$$

Because $[H^{\oplus}]$ already in solution $= 0.018$ and thus, dissociation of $HS^{\ominus}$ further suppresses due to common ion effect and $1-\alpha \approx 1$.

$\therefore$ $$1\times10^{-5} = \frac{0.018\times C_1\alpha_1}{C_1(1-\alpha_1)}$$
$$= 0.018\times\alpha_1$$

$\therefore$ $$\alpha_1 = \frac{1\times10^{-5}}{0.018} = 5.55\times10^{-4}$$

$\therefore$ $$[S^{2-}] = C_1\alpha_1 = 0.018\times5.55\times10^{-4}$$
$$= 10^{-5}$$

Check Point 3

1. Write the formulae for the conjugate bases of the following acids : HCN, HCO_3^-, C_2H_5OH.
2. Account for the acidic properties of nitrous acid in terms of Bronsted-Lowry theory.
3. Br^- ion is a Lewis as well as Bronsted base. Justify it.
4. Water acts both as an acid and as a base. Explain it.
5. Why K_{a_1} for H_2S is higher than K_{a_2} ?

6.11 Ionisation of Water

Pure water is a weak electrolyte and is ionised according to following equation

$$H_2O(l) + H_2O(l) \rightleftharpoons H_3O^+(aq) + OH^-(aq)$$

Applying law of mass action,

$$K = [H_3O^+][OH^-] / [H_2O]^2$$

Since concentration of water is very high, hence $[H_2O]$ may be taken as constant and we may write a new constant (K_w) in place of $K[H_2O]^2$.

Thus,
$$K_w = [H_3O^+][OH^-]$$

Since, $[H_3O^+] = [H^+]$, we get
$$K_w = [H^+][OH^-]$$

The constant K_w is termed as **ionic product of water.** Its value at 298 K is found to be 1.00×10^{-14} mol^2 L^{-2}.

Since, pure water is neutral.

Therefore, $[H^+] = [OH^-]$, clearly

$$[H^+] = [OH^-] = \sqrt{K_w} = C_\alpha$$
$$= \sqrt{(1.00\times10^{-14})} \text{ at 298 K}$$
$$= 1.00\times10^{-7}\text{ mol L}^{-1}$$

The molarity (*M*) of pure H_2O $$= \frac{\text{Density}}{M}$$
$$= \left(\frac{1000\text{ gL}^{-1}}{18.0\text{ g mol}^{-1}}\right)$$
$$= 55.55\text{ M}$$

$$\alpha = \frac{10^{-7}}{C} = \frac{10^{-7}}{55.6} = 1.8\times10^{-9}$$

or $$\%\text{ dissociation} = 1.8\times10^{-7}$$

Some facts related to ionic product of water are

1. With increase in temperature, the dissociation of water increases, increasing $[H^+]$ and $[OH^-]$ and consequently K_w increases.

2. If some acid or base is added to water then $[H^+] \neq [OH^-]$, however, K_w remains constant at the constant temperature.
3. If an acid is added to water, the concentration of H^+ increases. Consequently, the equilibrium shifts to reverse direction in order to maintain constant K_w, in any case, $[H^+][OH^-] = K_w$

   Therefore, in this case as $[H^+] > [OH^-]$
   $$[H^+] > 1 \times 10^{-7} \text{ mol L}^{-1}$$
   $$[OH^-] < 1 \times 10^{-7} \text{ mol L}^{-1}$$
   Similarly, if a base is added, concentration of OH^- increases and in this case,
   $$[H^+] < [OH^-]$$
   $$\therefore \quad [H^+] < 1 \times 10^{-7} \text{ mol L}^{-1}$$
   $$\text{and} \quad [OH^-] > 1 \times 10^{-7} \text{ mol L}^{-1}$$

Sample **Problem 15** *At 363 K, pure water has* $[H_3O^+] = 10^{-6}$ *M. The value of* K_w *at this temperature will be*

(a) 10^{-6} (b) 10^{-12}
(c) 10^{-13} (d) 10^{-14}

Interpret (b) $[H_3O^+] = [OH^-] = 10^{-6}$ M

From $$K_w = [H_3O^+][OH^-]$$
$$= 10^{-6} \times 10^{-6}$$
$$= 10^{-12} \text{ M}$$

6.12 Relation Between K_a and K_b

K_a and K_b represent the strength of an acid and a base, respectively. The conjugate acid-base pair are related in a manner so that if one is known, the other can be deducted.

For example in case of $\overset{\oplus}{N}H_4$ and NH_3,

$$\overset{\oplus}{N}H_4(aq) + H_2O(l) \rightleftharpoons H_3O^{\oplus}(aq) + NH_3(aq) \quad \text{...(i)}$$

$$K_a = \frac{[H_3O^{\oplus}][NH_3]}{[\overset{\oplus}{N}H_4]} = 5.6 \times 10^{-10}$$

(*K_a represents the strength of* $\overset{\oplus}{N}H_4$ *as an acid*)

$$NH_3(aq) + H_2O(l) \rightleftharpoons \overset{+}{N}H_4(aq) + \overset{\ominus}{O}H(aq) \quad \text{...(ii)}$$

$$K_b = \frac{[\overset{\oplus}{N}H_4][\overset{\ominus}{O}H]}{[NH_3]} = 1.8 \times 10^{-5}$$

(*K_b represents the strength of* NH_3 *as a base*)

Adding Eqs. (i) and (ii), the net equation is

$$2H_2O(l) \rightleftharpoons H_3O^{\oplus}(aq) + \overset{\ominus}{O}H(aq) \quad \text{...(iii)}$$

$$K_w = [H_3O^{\oplus}][\overset{\ominus}{O}H] = 10^{-14} \text{ M}$$

Multiplying K_a and K_b, we get

$$K_a \times K_b = \frac{[H_3O^{\oplus}][NH_3]}{[\overset{\oplus}{N}H_4]} \times \frac{[\overset{\oplus}{N}H_4][\overset{\ominus}{O}H]}{[NH_3]}$$
$$= [H_3O^{\oplus}][\overset{\ominus}{O}H]$$
$$= K_w = 10^{-14}$$

Thus, $$K_a \times K_b = K_w$$
$$(5.6 \times 10^{-10})(1.8 \times 10^{-5}) = 10^{-14} \text{ M}$$

Therefore, it can be generalised that the equilibrium constant for a net reaction obtained after adding two or more reactions equals to the product of the equilibrium constants for individual reactions :

$$\therefore \quad K_{\text{Net}} = K_1 \times K_2 \times \ldots \quad \text{...(iv)}$$

Similarly, in case of a conjugate acid-base pair,

$$K_a \times K_b = K_w \quad \text{...(v)}$$

Taking negative logarithm both side of Eq. (v)

$$-\log(K_a) - \log K_b = -\log K_w$$
$$\therefore \quad pK_a + pK_b = pK_w \quad \text{(at 298 K)} \quad \text{...(vi)}$$

Therefore, from Eqs. (v) and (vi), in case of conjugate acid-base pair, knowing one, the other can be obtained.

$$\therefore \quad K_b = \frac{K_w}{K_a} \quad \text{...(vii)}$$

$$\text{and} \quad K_a = \frac{K_w}{K_b} \quad \text{...(viii)}$$

6.13 pH Scale

The idea of pH scale and the scale was given by **Sorensen**. The pH of a solution is defined as *"the negative logarithm of the concentration* (in mol L^{-1}) *of hydrogen ions which it contains* (or logarithm of the reciprocal of H^+ ion concentration).

Thus, $$pH = -\log[H^+] = \log \frac{1}{[H^+]}$$

Concentration of hydrogen ions can be written as

$$[H^+] = 1 \times 10^{-pH}$$

Caution Point *A decrease of a single pH unit corresponds to ten folds increase in acidic nature.*

pOH Value

Just as pH indicates H^+ ion concentration, pOH represents the OH^- ion concentration,

i.e., $$pOH = -\log[OH^-]$$

Relation between pH and pOH

We know that at 298 K in aqueous solution,

$$[H^+][OH^-] = K_w = 1 \times 10^{-14}$$

$$\therefore \qquad pH + pOH = 14$$

1. In case of pure water as $[H^+] = [OH^-] = 1 \times 10^{-7}$, thus $pH = pOH = 7$ represents neutrality.
2. In case of acidic solution, $[H^+] > [OH^-]$, thus $pH < 7$ and $pOH > 7$.
3. Also, in case of alkaline solution, $[H^+] < [OH^-]$, thus, $pH > 7$ and $pOH < 7$.

The solutions having pH between 0 and 2 are strongly acidic, those with pH between 2 to 4 are moderately acidic, while others having pH between 4 to 7 are weakly acidic.

Similarly, the solutions having pH value between 7 to 10 are weakly basic, those having pH between 10 to 12 are moderately basic whereas others which have pH between 12 to 14 are strongly basic.

pH *range of some common substances are* :

Gastric juice	1.0–3.0	Rain water	6.0
Soft drinks	2.0–4.0	Tears	7.4
Lemon	2.2–2.4	Sea water	8.5
Vinegar	2.4–3.4	Milk of magnesia	10.5
Urine (human)	4.8–8.4	Milk (Cow)	6.3–6.6
Saliva (human)	6.5–7.5	Blood plasma (human)	7.36 –7.42

Caution Point *A change in blood* pH *by* 0.2 *units results in death.*

pH of a Weak Monobasic Acid

pH of such solutions can be calculated as

$$pH = -\log [H_3O^+] = -\log \sqrt{K_a \cdot C}$$

$$= -\frac{1}{2}\log K_a - \frac{1}{2}\log C$$

$$= \frac{1}{2}[pK_a - \log C]$$

pOH of a Weak Monoacidic Base

pH of such solutions can be calculated as

$$pOH = -\log [OH^-] = -\log\sqrt{K_b \cdot C}$$

$$= \frac{1}{2}[pK_b - \log C]$$

$$pH = 14 - pOH = 14 - \frac{1}{2}[pK_b - \log C]$$

Total $[OH^-]$ in a mixture of two weak bases,

$$[OH^-] = \sqrt{K_1C_1 + K_2C_2}$$

Sample Problem 16 *Calculate* pH *of* 0.10 *N acetic acid having* $K_a = 1.8 \times 10^{-5}$.

(*a*) 2.8 (*b*) 5.6
(*c*) 6.8 (*d*) 3.4

Interpret (a) $CH_3COOH \rightleftharpoons CH_3COO^- + H^+$ (weak acid)

$$\begin{array}{cccl} 1 & 0 & 0 & \text{initially} \\ (1-\alpha) & \alpha & \alpha & \text{at equilibrium} \end{array}$$

$$[H^+] = C\alpha \text{ or } C \cdot \sqrt{\frac{K_a}{C}} = \sqrt{K_a \cdot C}$$

$$= \sqrt{1.8 \times 10^{-5} \times 0.1} = 1.34 \times 10^{-3}\ M$$

Thus, $pH = -\log [H^+]$

$$= -\log (1.34 \times 10^{-3})$$

$$= 2.87$$

Sample Problem 17 2 *g of* NaOH *is dissolved in water to make* 1 *L solution. What is the* pH *of solution?*

(*a*) 10.25 (*b*) 8.56
(*c*) 12.69 (*d*) 10.89

Interpret (*c*) Weight of NaOH dissolved = 2 g

$\therefore$ Equivalent of NaOH dissolved $= \frac{2}{40}$

$$\therefore \qquad N_{NaOH} = \frac{2}{40} = 0.05$$

$$\therefore \qquad [OH^-] = 0.05 = 5 \times 10^{-2}$$

or

$$pOH = -\log [OH^-] = -\log (5 \times 10^{-2})$$

$$= 1.3010$$

$$pH + pOH = 14$$

$$\therefore \qquad pH = 14 - pOH$$

$$= 14 - 1.3010 = 12.699$$

pH of Mixtures of Acids and Bases

The rules for determining the pH *of mixtures of acids and bases are as follows*

1. If strong acid or strong base remains unused, calculate the concentration or molarity of $H^{\oplus}$ ions and $\overset{\ominus}{O}H$ ions left in the solution and then calculate the pH or pOH accordingly.
2. If weak acid or weak base is left behind or remains unused, a buffer (acidic or basic) is formed. Calculate the concentration of salt formed (mmoles of salt formed/volume of solution) and the concentration of weak acid or weak base left behind. Use the buffer equation to calculate the pH of the solution.
3. If acids or bases are completely neutralised, then salt is formed. Calculate the concentration of the salt formed and use the hydrolysis equation to calcualte the pH of the solution.

Sample **Problem 18** *What will be the resultant* pH *when* 200 *mL of an aqueous solution of* HCl (pH = 2) *is mixed with* 300 *mL of an aqueous solution of* NaOH (pH = 12)?

(*a*) 2 (*b*) 12
(*c*) 11.3 (*d*) 7

Interpret (*c*) pH of HCl = 2 $\therefore$ $[\text{HCl}] = 10^{-2}$ M

$$\text{pH of NaOH} = 12 \quad \therefore \ [\text{NaOH}] = 10^{-2}\ \text{M}$$

$$\text{HCl} + \text{NaOH} \rightleftharpoons \text{NaCl} + H_2O$$

$$\text{meq after reaction} \quad 0 \qquad 100 \times 10^{-2} = 1$$

$$[\text{OH}^-] \text{ after reaction} = \frac{1}{500} = 2 \times 10^{-3}\ \text{M}$$

$$\text{pOH} = -\log[\text{OH}^-] = -\log(2 \times 10^{-3}) = 2.7$$

$$\therefore \quad \text{pH} = 14 - 2.7 = 11.3$$

Limitations of pH Scale

1. pH values of the solutions do not give us immediate idea of the relative strengths of the solutions.
2. pH value of 1 N solution of strong acid is obtained zero. But in case the concentration is 2 N, 3 N, 10 N etc., the respective pH values are negative.
3. A solution of an acid having very low concentration say 10^{-8} N show pH value less than 7 inspite of 8, as shown by pH formula.

Sample **Problem 19** pH *of* 10^{-8} *M* HCl *is*

(*a*) 8 (*b*) 6.958
(*c*) 6 (*d*) *Cannot be calculated*

Interpret (*b*) $\because$ $\text{pH} = -\log[\text{H}^+]$

$$= -\log 10^{-8} = 8$$

But this is not true because an acidic solution cannot have pH greater than 7. In this condition, $[\text{H}^+]$ of water cannot be neglected.

Therefore, $$[\text{H}^+]_{\text{total}} = [\text{H}^+]_{\text{HCl}} + [\text{H}^+]_{H_2O}$$

$$= 10^{-8} + 10^{-7}$$

$$= 10^{-8}(1 + 10) = 11 \times 10^{-8}$$

Now from, $$\text{pH} = -\log[\text{H}^+]$$

$$= -\log(11 \times 10^{-8})$$

$$= -\log 11 - \log 10^{-8}$$

$$= 6.958$$

6.14 p*K* Value

p stands for negative logarithm. Thus, p*K* is the negative logarithm of dissociation constant.

$$\therefore \quad pK_a = -\log K_a \quad \text{and} \quad pK_b = -\log K_b$$

Weak acids have higher pK_a *values. Similarly weak bases have higher* pK_b *values.*

For any conjugate acid-base pair in aqueous solution, we know that,

$$K_a \times K_b = K_w = 1 \times 10^{-14} \qquad \text{(at 298 K)}$$

Taking logarithm on both sides, we have

$$\log(K_a \times K_b) = \log(1 \times 10^{-14})$$

$$\text{or} \qquad \log K_a + \log K_b = -14$$

$$\text{or} \qquad (-\log K_a) + (-\log K_b) = 14$$

$$\text{or} \qquad pK_a + pK_b = 14 \qquad \text{(at 298 K)}$$

Sample **Problem 20** *The* pH *of* 0.005 *M codeine* ($C_{18}H_{21}NO_3$) *solution is* 9.95. *Its* pK_b *value is* **[NCERT]**

(*a*) 8.92 (*b*) 5.81 (*c*) 3.76 (*d*) 4.29

Interpret (*b*)

$$\text{Codeine} \quad (C_{18}H_{21}NO_3) + H_2O \rightleftharpoons \text{Codeine H}^+ + \text{OH}^-$$

$$\text{pH} = 9.95 \quad \text{or} \quad \text{pOH} = 14 - 9.95 = 4.05$$

$$\text{pOH} = -\log[\text{OH}^-]$$

$$\log[\text{OH}^-] = -4.05 = \bar{5}.95$$

$$[\text{OH}^-] = \text{antilog } \bar{5}.95 = 8.913 \times 10^{-5}$$

$$K_b = \frac{[\text{codeine H}^+][\text{OH}^-]}{[\text{codeine}]} = \frac{[\text{OH}^-]^2}{[\text{codeine}]}$$

(because $[\text{codeine H}^+] = [\text{OH}^-]$)

$$K_b = \frac{(8.913 \times 10^{-5})^2}{0.005} = 1.588 \times 10^{-6}$$

$$pK_b = -\log[K_b] = -\log[1.588 \times 10^{-6}]$$

$$pK_b = 6 + (-0.2009) = 5.7791 \approx 5.80$$

6.15 Common Ion Effect

Let *AB* is a weak electrolyte dissociating as follows

$$AB \rightleftharpoons A^+ + B^-$$

Applying law of mass action,

$$K = [A^+][B^-]/[AB]$$

Now, if another electrolyte furnishing either A^+ or B^- ion be added to the above solution, it will increase the concentration of either A^+ or B^- ions accordingly. In order to keep *K* constant, the concentration of *AB* must increase, *i.e.,* the equilibrium shifts to left side. Thus, *the degree of dissociation of an electrolyte is suppressed here by the addition of another electrolyte containing a common ion. This phenomenon is termed as common ion effect. e.g.,* Consider a saturated solution of AgCl, following equilibrium is established.

$$\text{AgCl}(s) \rightleftharpoons \text{Ag}^+(aq) + \text{Cl}^-(aq)$$

When NaCl is added to the solution, the concentration of Cl^- ions will increase and the equilibrium will shift towards left. Hence, the dissociation of AgCl will decrease.

When a partially soluble ionic solid, for example, AgCl, is dissolved in water, after a certain time, a dynamic equilibrium is established between the solid phase and the cations and anions in solutions.

$$AgCl(s) \rightleftharpoons Ag^+ + Cl^-$$

At equilibrium, the solute dissolves at the same rate at which the ions recombine to crystallise the salt. Such a solution is said to be saturated.

As a result of common ion effect, the concentration of the ions other than the common ion is decreased.
This phenomenon is used in qualitative analysis to adjust concentration of S^{2-} ions in second group and OH^- ion concentration in third group of analysis.

6.16 Salt Hydrolysis

The reaction between an acid and a base to from salt and water is known as **neutralisation.** *e.g.*,

$$HCl(aq) + NaOH\,(aq) \rightleftharpoons NaCl(aq) + H_2O\,(l)$$

Thus, salts are ionic compounds made by a reaction between an acid and a base. The positive part of a salt comes properties of salts in aqueous solutions are the propeerties of ions.

Consider BA is a salt of acid HA and base BOH and gets dissociated in aqueous solution as shown below

$$BA \rightleftharpoons B^+ + A^-$$

The ions A^- and B^+ may break O—H bond of water given by following reactions

$$A^- + H—O—H \rightleftharpoons HA + \bar{O}—H \qquad \text{...(i)}$$

$$B^+ + H—O—H \rightleftharpoons BOH + H^+ \qquad \text{...(ii)}$$

The process of salt hydrolysis is actually the reverse process of neutralisation.

The reaction of an anion or cation with water accompanied by cleavage of O—H *bond, is called hydrolysis*.

In above cases of reactions : (i) is called **anionic hydrolysis,** and the solution becomes slightly basic (pH > 7) and (ii) is called **cationic hydrolysis** and the solution becomes slightly acidic (pH < 7).

The hydrolysis depends on the type of salt being used for the purpose.

Depending upon the nature of acid and base, the salts are classified into following four classes

Salts of Weak Acids and Strong Bases

Salts of sodium and potassium other than halides, sulphates and nitrates fall in this category. Such a salt, BA in aqueous medium exhibits following equilibrium

$$BA \longrightarrow B^+ + A^-$$

$$B^+ + A^- + H_2O \rightleftharpoons HA + OH^- + B^+$$

(BOH being a strong base remains dissociated completely). Thus, for this reaction,

$$\text{Equilibrium constant, } K = \frac{[HA][OH^-]}{[A^-][H_2O]}$$

As K, $[H_2O]$ is regarded as constant, hence we may write a new constant K_h

$$\therefore \qquad K_h = \frac{[HA][OH^-]}{[A^-]}$$

K_h is called **hydrolysis constant.**

(a) Degree of Hydrolysis

It is defined as the fraction of total salt that has undergone hydrolysis on attainment of equilibrum. It is denoted by h. Let C be the concentration of salt and h be its degree of hydrolysis.

$$\underset{C-Ch}{A^{\ominus}} + H_2O \rightleftharpoons \underset{Ch}{\overset{\ominus}{O}H} + \underset{Ch}{HA} \qquad \text{(equation of hydrolysis)}$$

$$K_h = \frac{[\overset{\ominus}{O}H][HA]}{[A^{\ominus}]} = \frac{(Ch)(Ch)}{C-Ch} = \frac{Ch^2}{1-h}$$

$$\Rightarrow \qquad K_h = Ch^2 \;\text{[assuming } h << 1] \Rightarrow h = \sqrt{\frac{K_h}{C}}$$

Now, considering the dissociations of weak acid HA and H_2O.

$$HA \rightleftharpoons H^{\oplus} + A^{\ominus};\; K_a = \frac{[H^{\oplus}]}{[HA]} \qquad \text{...(i)}$$

$$H_2O \rightleftharpoons H^{\oplus} + \overset{\ominus}{O}H:\; K_w = [H^{\oplus}][\overset{\ominus}{O}H] \qquad \text{...(ii)}$$

$\Rightarrow K_h = \dfrac{K_w}{K_a}$ (Subtracting Eqs. (i) from Eqs. (ii), we get the equation of hydrolysis)

Now substituting the value of K_h in expression of h.

$$\Rightarrow \qquad h = \sqrt{\frac{K_w}{K_a C}}$$

Caution Point *Weaker is the acid, greatest is the hydrolysis constant. The degree of hydrolysis increases when C decreases, i.e., with dilution.*

(b) pH of Solution

pH of a basic solution is given as

$$pH = 14 + \log[\overset{\ominus}{O}H] \text{ and } [\overset{\ominus}{O}H] = Ch = \sqrt{K_h C}$$

Substituting for K_h, we get

$$[\overset{\ominus}{O}H] = \sqrt{\frac{K_w C}{K_a}}$$

$$\Rightarrow \qquad \text{pH} = 14 + \log\sqrt{\frac{K_w C}{K_a}}$$

$$\Rightarrow \qquad \text{pH} = \frac{1}{2}(\text{p}K_w + \text{p}K_a + \log C)$$

$$= 7 + \frac{1}{2}(\text{p}K_a + \log C) \text{ at } 25^\circ\text{C}$$

Clearly, pH > 7

Salts of Strong Acids and Weak Bases

Halides, sulphates and nitrates of metals other than sodium, potassium fall in this category. The aqueous solution of such a salt BA, exhibits following equilibrium :

$$BA \longrightarrow B^+ + A^-$$

$$B^+ + A^- + H_2O \rightleftharpoons BOH + H^+ + A^-$$

[As the acid HA is strong].

The hydrolysis constant is given by,

$$K_h = \frac{[H^+][BOH]}{[B^+]}$$

(a) Degree of Hydrolysis

The net reaction of hydrolysis is

$$\underset{C-Ch}{B^{\ominus}} + H_2O \rightleftharpoons \underset{Ch}{BOH(aq)} + \underset{Ch}{H^{\oplus}(aq)}$$

[It is also called cationic hydrolysis.]

$$K_h = \frac{[BOH][H^{\oplus}]}{[B^{\oplus}]} = \frac{(Ch)(Ch)}{C-Ch} = \frac{Ch^2}{1-h} = Ch^2$$

$$(h << 1) \Rightarrow h = \sqrt{\frac{K_h}{C}}$$

Considering ionisation of weak base BOH and H_2O

$$BOH \rightleftharpoons B^{\oplus} + \overset{\ominus}{O}H: \; K_b = \frac{[B^{\oplus}][\overset{\ominus}{O}H]}{[BOH]} \qquad \text{...(ii)}$$

$$H_2O \rightleftharpoons H^{\oplus} + \overset{\ominus}{O}H; \; K_w = [H^{\oplus}][\overset{\ominus}{O}H] \qquad \text{...(i)}$$

Relation between K_w, K_b and K_h can be written as

$$\frac{K_w}{K_b} = K_h$$

Thus, the hydrolysis constant K_h, varies inversely with the dissociation constant, K_b of the weak base.

As in the above case, the degree of dissociation,

$$h = \sqrt{\frac{K_w}{K_b}V} = \sqrt{\frac{K_w}{K_b C}}$$

(b) pH of Solution

Now, $\quad \text{pH} = -\log[H^{\oplus}]$ and $[H^{\oplus}] = Ch = C\sqrt{\frac{K_h}{C}} = \sqrt{K_h C}$

$$\Rightarrow \qquad [H^{\oplus}] = \sqrt{\frac{K_w C}{K_b}} \Rightarrow \text{pH} = -\log\sqrt{\frac{K_w C}{K_b}}$$

$$\Rightarrow \qquad \text{pH} = \frac{1}{2}(\text{p}K_w - \text{p}K_b - \log C)$$

$$= 7 - \frac{1}{2}(\text{p}K_b + \log C) \text{ at } 25^\circ\text{C}$$

Clearly, pH < 7

Salts of Weak Acids and Weak Bases

The salts other than halides, sulphates, nitrates of metals (other than sodium, potassium) fall in this category. In aqueous solution such a salt BA exhibits following equilibrium

$$B^+ + A^- + H_2O \rightleftharpoons BOH + HA$$

The hydrolysis constant is given by, $K_h = \dfrac{[BOH][HA]}{[B^+][A^-]}$

(a) Degree of Hydrolysis

$$\begin{array}{lccccc}
 & B^+ + & A^{\ominus} + H_2O & \rightleftharpoons & \underset{\text{(weak base)}}{BOH(aq)} & + \; \underset{\text{(weak acid)}}{HA(aq)} \\
\text{Initially} & C & C & & 0 & 0 \\
\text{At equilibrium} & C-Ch & C-Ch & & Ch & Ch
\end{array}$$

$$\Rightarrow \qquad K_b = \frac{[BOH][HA]}{[B^{\oplus}][A^{\ominus}]} = \frac{(Ch)(Ch)}{(C-Ch)^2}$$

$\Rightarrow \quad K_b = \dfrac{h^2}{(1-h)^2}$; taking square root on both sides to get

$$h = \frac{\sqrt{K_h}}{1+\sqrt{K_h}} \qquad (\text{Here, } 1-h \neq 1)$$

(Remember that the degree of hydrolysis of such salts is independent of the concentration of salt solution.)

Now considering the dissociation of both weak base and acid.

$$HA \rightleftharpoons H^{\oplus} + A^{\ominus}: \qquad K_a = \frac{[H^{\oplus}][A^{\ominus}]}{[HA]}$$

$$BOH \rightleftharpoons B^{\oplus} + \overset{\ominus}{O}H: \qquad K_b = \frac{[B^{\oplus}][\overset{\ominus}{O}H]}{[BOH]}$$

$$H_2O \rightleftharpoons H^{\oplus} + \overset{\ominus}{O}H; \qquad K_w = [H^{\oplus}][\overset{\ominus}{O}H]$$

Combining K_h, K_b, K_a, and K_w, we have

$$K_b = \frac{K_w}{K_a K_b} \text{ and } h = \frac{\sqrt{K_h}}{1+\sqrt{K_h}}$$

[It is also called cationic-anionic hydrolysis.]

(Observe that $1-h \neq 1$) (if K_h is small, then $h = \sqrt{K_h}$)

(b) pH of Solution

Consider, $K_a = \dfrac{[\mathrm{H}^{\oplus}][A^{\ominus}]}{[\mathrm{H}A]} \Rightarrow [\mathrm{H}^{\oplus}] = K_a \dfrac{[\mathrm{H}A]}{[A^{\ominus}]}$

Since, bases and acids are weaker, hence

$$[B\mathrm{OH}] = [\mathrm{H}A] \Rightarrow [B^{\oplus}] = [A^{\ominus}]$$

$$\Rightarrow \quad K_h = \frac{[B\mathrm{OH}][\mathrm{H}A]}{[B^{\oplus}][A^{\ominus}]} = \frac{[\mathrm{H}A]^2}{[A^{\ominus}]}$$

$$\Rightarrow \quad [\mathrm{H}^{\oplus}] = K_a\sqrt{K_h} = \sqrt{\frac{K_w K_a}{K_b}}$$

$$\mathrm{pH} = -\log[\mathrm{H}^{\oplus}] = -\log\sqrt{\frac{K_w K_a}{K_b}}$$

$$\Rightarrow \quad \mathrm{pH} = \frac{1}{2}(\mathrm{p}K_w + \mathrm{p}K_a - \mathrm{p}K_b) \text{ at } 25°\mathrm{C}$$

$$= 7 + \frac{1}{2}(\mathrm{p}K_a - \mathrm{p}K_b)$$

If $\mathrm{p}K_a = \mathrm{p}K_b$, *i.e.,* the dissociation constants of acid and base are equal, then $\mathrm{pH} = 7$. Thus, the solution will be neutral, despite the fact that hydrolysis has taken place.

***Case* I** If $\mathrm{p}K_a > \mathrm{p}K_b$, or $K_a < K_b$, *i.e.,* **base** is relatively stronger, then $\mathrm{pH} > 7$

***Case* II** If $\mathrm{p}K_a < \mathrm{p}K_b$ or $K_a > K_b$, *i.e.,* **acid** is relatively stronger, then $\mathrm{pH} < 7$.

Salts of Strong Acids and Strong Bases

Halides, sulphates, nitrates of sodium and potassium fall in this category. Following equilibrium will be observed in aqueous solution of such a salt BA

$$B^+ + A^- + \mathrm{H_2O} \rightleftharpoons B^+ + A^- + \mathrm{H_2O}$$

[As the acid as well as base is strong.]

Hence, no hydrolysis takes place in this case and the solution remains neutral.

Hydrolysis of Amphiprotic Anion

(a) Cation is not Hydrolysed

e.g., $\mathrm{NaHCO_3}$, NaHS, etc., can undergo ionisation to form $\mathrm{H^+}$ ion and can undergo hydrolysis to form $\mathrm{OH^-}$ ($\mathrm{Na^+}$ ion is not hydrolysed).

(i) $$\mathrm{HCO_3^- + H_2O \xrightleftharpoons{\text{Ionisation}} \underset{\text{acid}}{CO_3^{2-} + H_3O^+}}$$

$$\mathrm{HCO_3^- + H_2O \xrightleftharpoons{\text{Hydrolysis}} H_2CO_3 + \underset{\text{base}}{OH^-}}$$

Thus, $\mathrm{HCO_3^-}$ is an amphiprotic anion.

$$\mathrm{H_2CO_3 \rightleftharpoons H^+ + HCO_3^-}$$

K_{a_1} = first ionisation constant

$$\mathrm{HCO_3^- \rightleftharpoons H^+ + CO_3^{2-}}$$

K_{a_2} = second ionisation constant

$$\mathrm{pH(HCO_3^-)} = \left(\frac{\mathrm{p}K_{a_1} + \mathrm{p}K_{a_2}}{2}\right)$$

(ii) $$\mathrm{H_3PO_4 \rightleftharpoons H_2PO_4^- + H^+}$$

K_{a_1} = first ionisation constant

$$\mathrm{H_2PO_4^- \rightleftharpoons HPO_4^{2-} + H^+}$$

K_{a_2} = second ionisation constant

$$\mathrm{HPO_4^{2-} \rightleftharpoons PO_4^{3-} + H^+}$$

K_{a_3} = third ionisation constant

$\mathrm{H_2PO_4^-}$ and $\mathrm{HPO_4^{2-}}$ are amphiprotic anions.

$$\mathrm{pH}_{(\mathrm{H_2PO_4^-})} = \frac{\mathrm{p}K_{a_1} + \mathrm{p}K_{a_2}}{2}$$

$$\mathrm{pH}_{(\mathrm{HPO_4^{2-}})} = \left(\frac{\mathrm{p}K_{a_2} + \mathrm{p}K_{a_3}}{2}\right)$$

Since, $\mathrm{H_2PO_4^-}$ is involved between $\mathrm{HPO_4^{2-}}$ (conjugate base) and $\mathrm{H_3PO_4}$ (conjugate acid), hence we use $\mathrm{p}K_{a_1}$ and $\mathrm{p}K_{a_2}$ values in hydrolysis of $\mathrm{H_2PO_4^-}$. In $\mathrm{HPO_4^{2-}}$, we use $\mathrm{p}K_{a_2}$ and $\mathrm{p}K_{a_3}$ values since it is involved between $\mathrm{PO_4^{3-}}$(conjugate base) and $\mathrm{HPO_4^{2-}}$ (conjugate acid).

(b) Cation is also Hydrolysed

$[\mathrm{H_3O^+}]$ in salts like $\mathrm{NH_4^+}$, $\mathrm{HCO_3^-}$, $\mathrm{NH_4^+HS^-}$ (in which $\mathrm{HCO_3^-}$, $\mathrm{HS^-}$ are amphiprotic and $\mathrm{NH_4^+}$ ion is also hydrolysed) is

$$[\mathrm{H_3O^+}] = \sqrt{K_{a_1}\left(\frac{K_w}{K_b} + K_{a_2}\right)}$$

Table 6.2 **Hydrolysis at a Glance**

S. No.	Salt	Nature	Degree of Hydrolysis	pH
1.	NaCl (strong acid + strong base)	Neutral	No hydrolysis	—
2.	$\mathrm{CH_3COONa}$ (weak acid + strong base)	Basic	$h = \sqrt{\dfrac{K_w}{CK_a}}$	$\mathrm{pH} = \dfrac{1}{2}[\mathrm{p}K_w + \mathrm{p}K_a + \log C]$
3.	$\mathrm{NH_4Cl}$ (strong acid + weak base)	Acidic	$h = \sqrt{\dfrac{K_w}{CK_b}}$	$\mathrm{pH} = \dfrac{1}{2}[\mathrm{p}K_w - \mathrm{p}K_b - \log C]$
4.	$\mathrm{CH_3COONH_4}$ (weak acid + weak base)	*	$h = \sqrt{\dfrac{K_w}{K_a \times K_b}}$	$\mathrm{pH} = \dfrac{1}{2}[\mathrm{p}K_w + \mathrm{p}K_a - \mathrm{p}K_b]$

Sample **Problem 21** *A 0.02 M solution of pyridinium hydrochloride has* pH = 3.44. *The ionisation constant of pyridine is* [**NCERT**]

(*a*) 1.84×10^{-7}
(*b*) 2.63×10^{-9}
(*c*) 1.5×10^{-9}
(*d*) 3.62×10^{-7}

Interpret (*c*) Pyridinium hydrochloride is a salt of weak base (pyridine) and strong acid (hydrochloric acid), hence, its pH is given as

$$\mathrm{pH} = 7 - \frac{\mathrm{p}K_b}{2} - \frac{\log C}{2}$$

$$3.44 = 7 - \frac{\mathrm{p}K_b}{2} - \frac{\log 0.02}{2}$$

$$\mathrm{p}K_b = 8.82$$

$$\mathrm{p}K_b = 8.82 = -\log K_b$$

$$\log K_b = -8.82 = \bar{9}.18$$

$$K_b = \text{antilog } \bar{9}.18 = 1.5 \times 10^{-9}$$

Alternatively,

$$C_6H_5N \cdot HCl + H_2O \rightleftharpoons C_6H_5N^+Cl^- + H_3O^+$$

$$K_a = \frac{[C_6H_5N^+Cl^-][H_3O^+]}{[C_6H_5N \cdot HCl]}$$

$$\mathrm{pH} = 3.44 = -\log [H_3O^+]$$

$$\log [H_3O^+] = -3.44 = \bar{4}.56$$

$$[H_3O^+] = \text{ antilog } \bar{4}.56 = 3.63 \times 10^{-4} \text{ M}$$

$$[H_3O^+] = [C_6H_5N^+Cl^-] = 3.63 \times 10^{-4}$$

Hence,
$$K_a = \frac{3.63 \times 10^{-4} \times 3.63 \times 10^{-4}}{0.02} = 6.588 \times 10^{-6}$$

$$\mathrm{p}K_a = -\log K_a = -\log (6.588 \times 10^{-6})$$

$$\mathrm{p}K_a = 6 + (-0.8187) = 5.18$$

$$\mathrm{p}K_a + \mathrm{p}K_b = 14$$

$$\mathrm{p}K_b = 14 - 5.18 = 8.82$$

$$-\log K_b = -8.82$$

$$\log K_b = -8.82 = \bar{9}.18$$

$$K_b = \text{antilog } \bar{9}.18 = 1.5 \times 10^{-9}$$

Sample **Problem 22** *The ionisation constant of nitrous acid is* 4.5×10^{-4}. *The pH of 0.04 M* $NaNO_2$ *solution and its degree of hydrolysis are respectively.*

(*a*) $8.23, 2.36 \times 10^{-4}$
(*b*) $7.98, 2.36 \times 10^{-4}$
(*c*) $7.98, 2.36 \times 10^{-5}$
(*d*) $8.23, 2.36 \times 10^{-5}$

Interpret (*c*) Sodium nitrite is a salt of weak acid and strong base. Hence, to calculate pH of its aqueous solution use the formula

$$\mathrm{pH} = 7 + \frac{\mathrm{p}K_a + \log C}{2},$$

$$\therefore \quad \mathrm{pH} = 7 + \frac{3.35 + \log 0.04}{2} = 7.98$$

$$[\mathrm{p}K_a = -\log K_a = -\log (4.5 \times 10^{-4}) = 3.35]$$

$$\mathrm{pH} = 7.98$$

Degree of hydrolysis,
$$h = \sqrt{\frac{K_w}{K_a C}} = \sqrt{\frac{10^{-14}}{4.5 \times 10^{-4} \times 0.04}}$$

$$h = 2.36 \times 10^{-5}$$

Alternatively, $NO_2^- + H_2O \rightleftharpoons HNO_2 + OH^-$

	NO_2^-	HNO_2	OH^-
Initial conc.	C	0	0
After hydrolysis conc.	$(C - Ch)$	Ch	Ch

$$[OH^-] = Ch = 0.04 \times 2.36 \times 10^{-5}$$

$$[OH^-] = 9.44 \times 10^{-7}$$

$$\mathrm{pOH} = -\log [9.44 \times 10^{-7}]$$

$$\mathrm{pOH} = 7 - 0.9750 = 6.03$$

$$\mathrm{pH} + \mathrm{pOH} = 14 \quad \text{or} \quad \mathrm{pH} = 14 - 6.03 = 7.97$$

Check Point 4

1. pH of an aqueous 10^{-2} M acetic acid solution is not 2.0, why?
2. Explain why pH of 10^{-8} M HCl is not 8?
3. AgCl is more soluble in pure water as compared to salty water. Explain why?
4. The aqueous solution of $FeCl_3$ is acidic while that of sodium acetate is basic. Explain, why?

Hot Spot 4 SOLUBILITY and Solubility Product

It is the most important topic of the chapter for JEE Main examination. The level of question may vary from easy to typical. The question may be numerical based or expression based. A small practice can help you to solve the question and score higher.

The concentration of substance in a saturated solution is defined as its **solubility** (S). It is generally represented as gram of solute in 100 mL of solution or as moles per litre (*i.e.,* molarity). The value of solubility depends on the solvent and the temperature.

Consider saturated solution of sparingly soluble electrolyte, AB.

$$\underset{\text{solid}}{AB} \rightleftharpoons \underset{\substack{\text{unionised}\\ \text{(dissolved)}}}{AB} \rightleftharpoons \underbrace{A^+ + B^-}_{\text{ions}}$$

Applying the law of mass action,

$$K = \frac{[A^+][B^-]}{[AB]}$$

Since, the solution is saturated, the concentration of unionised molecules of the electrolyte will be constant at a particular temperature. *i.e.,*

$$[AB] = \text{constant} = K' \text{ (say)}$$

Hence, $$[A^+][B^-] = KK'$$
$$= K_{sp} \text{ (constant)}$$

This new constant K_{sp} is called **solubility product** and is defined as the product of the concentration of ions in a saturated solution of an electrolyte at a given temperature.

Consider, in general, the electrolyte of the type A_xB_y, which is dissociated as

$$A_xB_y \rightleftharpoons xA^{y+} + yB^{x-}$$
$$K_{sp} = [A^{y+}]^x[B^{x-}]^y$$

Thus, *solubility product may be defined as the product of concentrations of the ions raised to a power equal to the number of times the ions occur in the equation representing the dissociation of the electrolyte at a given temperature when the solution is saturated.*

Caution Point *$K_{sp} = x^x y^y S^{x+y}$ is the general expression for relation between S and K_{sp}. By putting the values of x and y, you can directly obtain it (Here x and y = no. of cation and anion respectively.)*

e.g., For $$As_2S_3 \rightleftharpoons 2As^{3+} + 3S^{2-}$$
$$x = 2$$
and $$y = 3$$
$$K_{sp} = (2)^2 \times (3)^3 \times S^{2+3} = 108S^5$$

Finding Relationship Between S and K_{sp}

In order to find the relation between solubility (S) and solubility product (K_{sp}) follow the following steps

Steps	Example
Step I Dissociate electrolyte into ion as $A_xB_y \rightleftharpoons xA^{y+} + yB^{x-}$	$Ag_2CO_3 \rightleftharpoons 2Ag^+ + CO_3^{2-}$
Step II Write solubility of each ion. (Remember, if solubility of one ion is S, then for x ions, it is xS.) $\underset{S}{A_xB_y} \rightleftharpoons \underset{xS}{xA^{y+}} + \underset{yS}{yB^{x-}}$	$\underset{S}{Ag_2CO_3} \rightleftharpoons \underset{2\times S}{2Ag^+} + \underset{1\times S}{CO_3^{2-}}$
Step III Write the expression of K_{sp} and put the values of solubilities of ions. $K_{sp} = [A^{y+}]^x[B^{x-}]^y$ $= (xS)^x(yS)^y$	$K_{sp} = [Ag^+]^2[CO_3^{2-}]$ $= (2S)^2(S)$
Step IV Solve the equation obtained to get the relation $K_{sp} = x^x y^y S^{x+y}$	$K_{sp} = 4S^2 \cdot S = 4S^3$

Predicting Precipitate Formation From K_{sp}

When two reacting solutions are mixed, we calculate the concentration of each ion in the solution in which precipitate is produced. The ionic product (Q), *i.e.,* the product of concentration of ions is then calculated.

If $Q > K_{sp}$, then precipitation will take place.

If $Q < K_{sp}$, then no precipitation will occur.

If $Q = K_{sp}$, the reaction is at equilibrium.

Sample Problem 23 *The solubility product of* $BaSO_4$ *at* 25°C *is* 1.0×10^{-9}. *What would be the concentration of* H_2SO_4 *necessary to precipitate* $BaSO_4$ *from a solution of* 0.01 *M* Ba^{2+} *ions?*

(a) 10^{-10} (b) 10^{-9}

(c) 10^{-8} (d) 10^{-7}

Interpret (*d*) Precipitation will take place when, ionic product > solubility product

$$\underset{}{BaSO_4} \rightleftharpoons \underset{0.01}{Ba^{2+}} + \underset{s}{SO_4^{2-}}$$

$$\because \quad K_{sp} = [Ba^{2+}][SO_4^{2-}]$$

$$\therefore \quad S = \frac{1.0 \times 10^{-9}}{0.01} = 10^{-7} \text{ mol/L}$$

Sample **Problem 24** *What is the maximum concentration of equimolar solutions of ferrous sulphate and sodium sulphide so that when mixed in equal volumes, there is no precipitation of iron sulphide? (For iron sulphide,* $K_{sp} = 6.3 \times 10^{-18}$*)* **[NCERT]**

(*a*) 2.51×10^{-18}

(*b*) 2.51×10^{-9}

(*c*) 5.02×10^{-18}

(*d*) 5.02×10^{-9}

Interpret (*d*) FeS is at the point of precipitation when

$$[Fe^{2+}][S^{2-}] = K_{sp}$$

$$[Fe^{2+}] = [S^{2-}] = \sqrt{K_{sp}} = \sqrt{6.3 \times 10^{-10}}$$

$$[Fe^{2+}] = [S^{2-}] = 2.51 \times 10^{-9} \text{ M}$$

Since, equimolar solutions are to be mixed, hence on mixing concentration is halved. Thus, in original solution

$$[FeSO_4] = [Na_2S] = 2 \times 2.51 \times 10^{-9} \text{ M}$$
$$= 5.02 \times 10^{-9} \text{ M}$$

Relation between S and K_{sp} in the Presence of Common Ion

Let S is the solubility of silver chromate,

$$Ag_2CrO_4 \rightleftharpoons 2Ag^+ + CrO_4^{2-}$$

The solubility product of Ag_2CrO_4 is

$$K_{sp} = (2s)^2 \times s = 4s^3 \qquad \text{... (i)}$$

Now suppose that x mol/ L of $AgNO_3$ is added and in this solution, the solubility of Ag_2CrO_4 is s' then

$$[Ag^+] = 2s' + x \text{ and } [CrO_4^{2-}] = s'$$

so
$$K_{sp} = (2s' + x)(s') \qquad \text{...(ii)}$$

Eqs. (i) and (ii) can be used to find s'.

If K_{sp} is very small, we may neglect $2s'$ against x in (ii) and it becomes

$$K_{sp} = xs' \qquad \text{...(iii)}$$

Difference between Ionic Product and Solubility Product

Both ionic product and solubility product represent the product of the concentrations of the ions in the solution. Ionic product is applicable to all types of solutions, either unsaturated or saturated and varies accordingly. On the other hand, solubility product is applied only to a saturated solution in which there exists a dynamic equilibrium between the undissolved salt and the ions present in the solution.

Caution Point *When the ionic product is less than the solubility product, the solution is unsaturated and the solution contain only ions and no undissociated salt.*

Applications of Solubility Product

Solubility product found its applications in following respects.

(a) Calculation of Remaining Concentration After Precipitation

Remaining concentration of an ion after precipitation may be calculated as

$$[A^+]_{\text{left}} = \frac{K_{sp}[AB]}{[B^-]}$$

Percentage precipitation of an ion

$$= \left[\frac{\text{initial conc.} - \text{left conc.}}{\text{initial conc.}}\right] \times 100$$

(b) Salting out Action of Soap

Soaps are sodium salts of higher fatty acids. A saturated solution of soap ($RCOONa$) show precipitation of soap on addition of sodium chloride. This is because of the fact that an increase in Na^+ ion concentration helps in crossing over $[Na^+][RCOO^-]$ to their K_{sp} value.

$$\begin{array}{r} RCOONa \rightleftharpoons \boxed{Na^+} + RCOO^- \\ NaCl \rightleftharpoons \boxed{Na^+} + Cl^- \\ \text{common ion} \end{array}$$

(c) Purification of Common Salt

HCl gas is circulated through the saturated solution of common salt (NaCl). Thus, the concentration of Cl^- ions increases considerably in the solution due to ionisation of HCl. Hence, the ionic product $[Na^+][Cl^-]$ exceeds to their K_{sp} value and therefore, pure NaCl precipitates out from the solution.

(d) In Qualitative Analysis

Principle of selective precipitation is used in qualitative analysis of a mixture containing all the common cations. In selective precipitation, the precipitation of only cation is brought about at a time. The cations are divided into different groups for this purpose.

(i) **Group I** contains Ag^+, Pb^{2+} and Hg_2^{2+} which are precipitated as chlorides by adding excess of dil HCl.

K_{sp} of their chlorides is very low and is easily exceeded. The K_{sp} of other chlorides is comparatively high.

(ii) **Group II** contains Hg^{2+}, Cd^{2+}, Bi^{3+}, Cu^{2+} and Sn^{4+}, which are precipitated as sulphides by passing H_2S. K_{sp} of their sulphides is low, thus very small concentration of S^{2-} is needed. *The passage of* H_2S *in acidic medium, due to common ion effect results in low concentration of* S^{2-}, *just sufficient for precipitation of these sulphides.*

$$HCl \rightleftharpoons \boxed{H^+} + Cl^-$$
$$H_2S \rightleftharpoons \boxed{2H^+} + S^{2-}$$

common ion

The ions $Mn^{2+}, Zn^{2+}, Ni^{2+}, Co^{2+}$ (which belong to IV group) may also precipitate as sulphide, but their sulphides have high K_{sp}, hence, not precipitated in this step.

(iii) **Group III** contains Al^{3+}, Fe^{3+}, Cr^{3+} which are precipitated as hydroxide. The K_{sp} values of their hydroxides are extremely low, thus a very small quantity of OH^- ions is needed. **This is obtained by adding NH_4Cl followed by NH_4OH** (common ion effect).

$$NH_4Cl \rightleftharpoons \boxed{NH_4^+} + Cl^-$$
$$NH_4OH \rightleftharpoons \boxed{NH_4^+} + OH^-$$

common ion

The ions like Zn^{2+}, Mn^{2+} (of IV group) and Mg^{2+} (of VI group) have high K_{sp} of their hydroxide hence, these are not precipitated in this step.

(iv) **Group IV** contains Mn^{2+}, Zn^{2+}, Ni^{2+}, Co^{2+} which are precipitated as sulphides. The K_{sp} of these sulphides are high. *The required amount of* S^{2-} *ions are provided by passing* H_2S *in the presence of* NH_4OH. *Here,* H_2S *is dissociated to a larger extent due to alkaline nature of testing solution*

(v) **Group V** contains $Mg^{2+}, Ba^{2+}, Sr^{2+}$ and Ca^{2+} which are precipitated as carbonates by adding an excess of sodium carbonate solution.

(vi) **Group VI** contains Mg^{2+}, Na^+ and K^+, Mg^{2+} is precipitated as its phosphate while remaining ions, if present in the mixture, are identified through individual testing by the flame test.

Simultaneous Solubility

Solubility of two eletrolytes having common ion, when they are dissolved in the same solution, is called **simultaneous solubility.** *e.g.,*

(i) Solubility of AgBr and AgSCN, when dissolved together.

(ii) Solubility of CaF_2 and SrF_2, when dissolved together.

(iii) Solubility of MgF_2 and CaF_2, when dissolved together.

Sample Problem 25 *If* K_{sp} $AgCNS = 1 \times 10^{-12}$ *and* K_{sp} $AgBr = 5 \times 10^{-13}$ *then the value of simultanoeus solubility of* AgCNS *and* AgBr *in a solution of water will be*

(a) $8.16 \times 10^{-7}, 4.08 \times 10^{-7}$ (b) $4.08 \times 10^{-7}, 8.16 \times 10^{-7}$

(c) 8.16, 4.08 (d) $1 \times 10^{-12}, 5 \times 10^{-13}$

Interpret (a) Let the solubility of AgCNS and AgBr in water are x and y respectively.

$$AgCNS \rightleftharpoons \underset{x}{Ag^+} + \underset{x}{CNS^-}$$
$$AgBr \rightleftharpoons \underset{y}{Ag^+} + \underset{y}{Br^-}$$

$\therefore$ $[Ag^+] = (x + y), [CNS^-] = x, [Br^-] = y$

$K_{sp}[AgCNS] = [Ag^+][CNS^-] = x(x + y)$

$\Rightarrow$ $1 \times 10^{-12} = x(x + y)$ ...(i)

and, $K_{sp}[AgBr] = [Ag^+][Br^-] = y(x + y)$

$\Rightarrow$ $5 \times 10^{-13} = y(x + y)$ ...(ii)

On solving Eq. (i) and (ii), we get

$$x = 8.16 \times 10^{-7} \text{ mol/L}$$
$$y = 4.08 \times 10^{-7} \text{ mol/L}$$

6.17 Buffer Solution

The solution, which maintains its pH constant or reserve acidic or basic nature even upon addition of small amounts of acid or base, is called **buffer solution.** The ability of buffer solution to resist changes in pH on addition of acid or base is called **buffer action.**

Characteristics of a Buffer Solution

A buffer solution should exhibit following characteristics

1. Buffer solutions posses a definite pH value.
2. Their pH value remains constant on keeping long or dilution.
3. The pH value is not changed on the addition of a strong acid in acidic buffer and a strong base in basic buffer.

Preparation of Buffer

A buffer solution can be obtained.

1. By mixing an acid salt with a normal salt of a polybasic acid, *e.g.,* $Na_2HPO_4 + Na_3PO_4$ or a salt of weak acid and a weak base, such as CH_3COONH_4 (*natural buffer*).
2. By a solution of ampholyte. The ampholytes or amphoteric electrolytes are the substances which show properties of both an acid and a base. Proteins and amino acids are the examples of such electrolytes.

3. By mixing a weak acid with its salt of strong base. These are called *acidic buffer. e.g.,*
   - (i) $CH_3COOH + CH_3COONa$
   - (ii) Boric acid + Borax
   - (iii) Phthalic acid + Potassium acid phthalate
4. By mixing a weak base with its salt of strong acid. These are called *basic buffer. e.g.,*
   - (i) $NH_4OH + NH_4Cl$
   - (ii) Glycine + Glycine hydrochloride

Acidic Buffer

A buffer solution pH of which is less than 7 is called **acidic buffer.** It contains equimolal quantities of weak acid and its salt with a strong base, *e.g.,* $CH_3COOH + CH_3COONa$; boric acid + borax; phthalic acid + potassium phthalate.

Mechanism of Buffer Action

Consider a solution containing CH_3COOH and CH_3COONa, which dissociate as follows

$$CH_3COOH \rightleftharpoons CH_3COO^- + H^+ \quad \text{(feebly ionised)}$$

$$CH_3COONa \longrightarrow CH_3COO^- + Na^+ \text{(completely ionised)}$$

$$H_2O \rightleftharpoons H^+ + OH^- \quad \text{(very weakly ionised)}$$

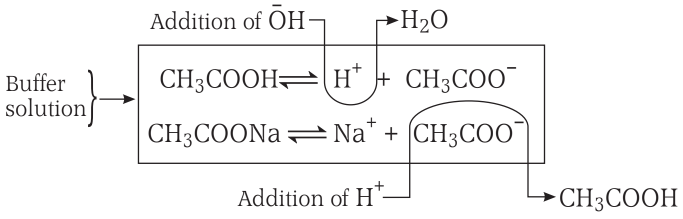
***Case* I** Now suppose we add a drop of conc HCl (a strong electrolyte) to the above solution. HCl immediately ionises as $HCl \rightleftharpoons H^+ + Cl^-$. These H^+ ions combine with CH_3COO^- ions present in the solution to form CH_3COOH, which ionises to a slight extent. This means that CH_3COO^- and H^+ ions cannot exist together in solution to a large extent. Hence, even addition of HCl, a strong electrolyte does not produce any appreciable change in H^+ ion concentration or pH of the solution.

***Case* II** When a drop of NaOH is added to it, the OH^- ions react with undissociated acid to form H_2O molecules.

$$CH_3COOH + OH^- \longrightarrow CH_3COO^- + H_2O$$

Again, pH remains unchanged.

The mechanism of acidic buffer can be summarized as



It is clear from the above mechanism that the reserve acidity is due to the presence of CH_3COOH and reserve alkalinity is due to the presence of CH_3COO^-.

pH of Acidic Buffer

pH of an acidic buffer is given by **Henderson-Hesselbalch equation** or **Henderson equation** which is as

$$pH = pK_a + \log\frac{[salt]}{[acid]}$$

where, K_a is dissociation constant of the acid.

Basic Buffer

A buffer solution having pH more than 7 is called **basic buffer.** It is obtained by mixing equimolal amounts of a weak base and its salt with strong acid, *e.g.,* $NH_4OH + NH_4Cl$, glycine + glycine hydrochloride.

Mechanism of Buffer Action

The buffer action of a basic buffer can be similarly explained by taking a solution of weak base (NH_4OH) and one of its salt (NH_4Cl). The solution contains a very small concentration of OH^- ions in the solution because NH_4OH is slightly ionised. Morever, common NH_4^+ ions from highly ionised NH_4Cl further suppress the ionisation of NH_4OH, a weak electrolyte.

$$NH_4OH \rightleftharpoons NH_4^+ + OH^- \quad \text{(feebly ionised)}$$

$$NH_4Cl \longrightarrow NH_4^+ + Cl^- \text{(completely ionised)}$$

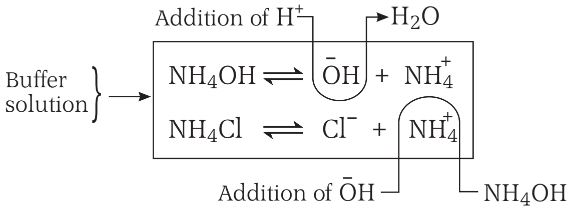
***Case* I** When a drop of NaOH is added to it, the OH^- ions from it, combined with NH_4^+ ions present in the solution to form NH_4OH which ionises to slight extent. Thus, the addition of NaOH, a strong electrolyte, does not produce a marked change in the pH of the solution.

***Case* II** Now suppose we add a drop of conc HCl, a strong electrolyte to the above solution. HCl immediately ionises as $HCl \rightleftharpoons H^+ + Cl^-$. The H^+ ions react with undissociated base to form H_2O molecules.

$$NH_4OH + H^+ \longrightarrow NH_4^+ + H_2O$$

Again, pH remains unchanged.

The mechanism of basic buffer can be summarised as



It is clear from the above mechanism that the reserve acidity is due to the presence of NH_4^+ and reserve alkalinity is due to the presence of NH_4OH.

pH of a Basic Buffer

It is calculated through **Henderson-Hesselbalch equation** or **Henderson equation** and can be given as

$$\text{pOH} = \text{p}K_b + \log\frac{[\text{salt}]}{[\text{base}]} \quad \text{and} \quad \text{pH} = 14 - \text{pOH}$$

Sample Problem 26 *A weak acid* HA *after treatment with* 1.2 *mL of* 0.1*M strong base has a pH of* 5. *At the end point, the volume of same base required is* 26.6 *mL. The value of* K_a *is*

(a) 8.2×10^{-6} (b) 6.4×10^{-6}

(c) 5.3×10^{-5} (d) 2.4×10^{-6}

Interpret (a) For complete neutralisation,

Total millieq. of acid = millieq. of base = $26.6 \times 0.1 = 2.66$

For partial neutralisation

$$\begin{array}{llcll} HA & + \ BOH & \longrightarrow & BA & + \ H_2O \\ 2.66 & 1.2 & & 0 & 0 \quad \text{before reaction} \\ 1.46 & 0 & & 1.2 & 1.2 \quad \text{after reaction} \end{array}$$

The resultant mixture has HA and BA and thus acts as buffer.

$$\because \quad \text{pH} = -\log K_a + \log\frac{[\text{salt}]}{[\text{acid}]}$$

$$5 = -\log K_a + \log\frac{1.2}{1.46} \quad \text{or} \quad K_a = 8.21 \times 10^{-6}$$

Buffer Capacity

Buffer capacity is quantitatively defined as the number of moles of acid or base added in 1 L of solution to change the pH by unity.

Buffer capacity (ϕ)

$$= \frac{\text{no. of moles of acid or base added to 1 L of buffer}}{\text{change in pH}}$$

The ability of buffer mixtures to maintain almost constant pH value is based on the fact that individual components combine with the H^+ or OH^- ions of acids or bases added to the solution (or formed as a result of reactions). This ability however depends on the concentrations of the components in the buffer mixture. For example, if more than 0.1 mole of HCl or NaOH is added to 1 L of 0.1 N ammonium buffer mixture ($NH_4OH + NH_4Cl$ at 0.1 N concentrations), a very large change of pH is obtained in either case.

This is due to the fact that the amount of NH_4OH or NH_4Cl available are not sufficient to combine with the H^+ or OH^- ions. Thus, excess of added strong acid or strong base remains in the solution and hence, causes a sharp change in pH value. Thus, *every buffer mixture maintains a practically constant pH value only up to a certain limiting amount of added acid or alkali, i.e., it has a definite buffer capacity.*

The higher the concentrations of the components of a buffer mixture, the greater will be the buffer capacity.

Buffer capacity is maximum

(i) When [salt] = [acid], *i.e.,* pH = pK_a for acidic buffer.

(ii) When [salt] = [base], *i.e.,* pH = 14 − pK_b or pK_w − pK_b for basic buffer.

Under above conditions the buffer is called **efficient.**

Sample Problem 27 *When* 0.01 *moles of sodium hydroxide are added to a buffer solution, its pH changes from* 4.745 *to* 4.815. *The buffer capacity of the buffer solution is*

(a) 0.14 (b) 0.36 (c) 0.27 (d) 0.04

Interpret (a) Buffer capacity

$$= \frac{\text{no. of moles of acid or base added to 1 L of buffer}}{\text{change in pH}}$$

$$= \frac{0.01}{4.815 - 4.745} = \frac{0.01}{0.07} = 0.14$$

Applications of Buffer Solution

1. Normal blood has pH of 7.4. This pH is maintained by buffer action of following two buffers
   (i) buffer of carbonic acid (H_2CO_3 and $NaHCO_3$)
   (ii) buffer of phosphoric acid ($H_2PO_4^-$, HPO_4^{2-})
2. Buffers are used to determine pH with the help of indicators.
3. Buffers are used for the removal of phosphate ion in the qualitative inorganic analysis after second group. For this purpose $CH_3COOH + CH_3COONa$ buffer is used.
4. $CH_3COOH + CH_3COONa$ is used for the precipitation of lead chromate quantitatively in gravimetric analysis.
5. $NH_4Cl + NH_4OH$ buffer is used for the precipitation of hydroxides of third group of qualitative analysis.
6. Buffers find numerous applications in industrial processes, like manufacture of paper, drugs, dyes, inks, paints etc.
7. Buffer solutions are applied for digestion process of food.
8. These are used as preservatives of foods and fruits.
9. Buffer can be used for preservation of many dairy and agricultural products.

Check Point 5

1. Explain why solubility of AgCl is more in water than in a solution of common salt?
2. Explain why Zn^{2+} is precipitated by passing H_2S in ammoniacal solution but it is not precipitated from acidic solution.
3. Degree of dissociation is more in the presence of polar solvents. Explain, why?
4. A mixture of sodium acetate and acetic acid resists change in its pH value on adding acids or bases. Explain, why?
5. Explain why a solution containing a strong base and its salt does not act as a buffer solution?

WORKED **OUT**
Examples

Example 1 *Following equilibrium is studied by taking 1 mole of* N_2 *and 3 moles of* H_2 *in 1 L flask at a given temperature*

$$N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$$

$NH_3(g)$ *formed at equilibrium is neutralised by* 100 *mL of* 1 *M* HCl. *The value of equilibrium constant,* K_c *will be*

(a) 3.7×10^{-2} (b) 1.22×10^{-2}
(c) 2.25×10^{-3} (d) 4.55×10^{-4}

Solution (d) $NH_3(g) + HCl(aq) \rightleftharpoons NH_4Cl(aq)$

$$\Rightarrow \quad 1 \text{ mole of } NH_3 = 1 \text{ mole of HCl}$$

$$100 \text{ mL of } 1 \text{ M HCl} \equiv 100 \text{ millimole of HCl}$$
$$= 0.1 \text{ mole of HCl}$$
$$= 0.1 \text{ mole of } NH_3$$

$$\begin{array}{cccl} N_2(g) & + \; 3H_2(g) & \rightleftharpoons \; 2NH_3(g) & \\ 1 & 3 & 0 & \text{Initially} \\ 1-x & 3-3x & 2x & \text{At equilibrium} \end{array}$$

$$\Rightarrow \quad 2x = 0.1 \quad i.e., \quad x = \frac{0.1}{2} = 0.05 \text{ mol}$$

and $\quad V = 1 \text{ L}$

Therefore,

$$K_c = \frac{[NH_3]^2}{[N_2][H_2]^3}$$

$$= \frac{\left(\frac{2x}{V}\right)^2}{\left(\frac{1-x}{V}\right)\left(\frac{3-3x}{V}\right)^3}$$

$$= \frac{4x^2V^2}{27(1-x)^4}$$

$$= \frac{4 \times (0.05)^2 \times (1)^2}{27(1-0.05)^4}$$

$$= 4.55 \times 10^{-4}$$

Example 2 *What is the value of* K_c *for the equilibrium,*

$$HA + OH^- \rightleftharpoons H_2O + A^- \, ?$$

Given,

$$HA + H_2O \rightleftharpoons H_3O^+ + A^-, \qquad K_1 = 2 \times 10^{-5}$$

$$H_2O + H_2O \rightleftharpoons H_3O^+ + OH^- \qquad K_2 = 1 \times 10^{-14}$$

(a) 2×10^{-9} (b) 4×10^{-8}
(c) 2×10^{-8} (d) 6×10^{-9}

Solution (a) $HA + H_2O \rightleftharpoons H_3O^+ + A^-; \quad K_1 = 2 \times 10^{-5}$ ...(i)

$$H_2O + H_2O \rightleftharpoons H_3O^+ + OH^-; K_2 = 1 \times 10^{-14} \text{ ...(ii)}$$

$$H_3O^+ + OH^- \rightleftharpoons H_2O + H_2O; \; K_2' = 1 \times 10^{14} \text{ ...(iii)}$$

$$\left(\because \; K_2' = \frac{1}{K_2}\right)$$

On adding Eqs. (i) and (iii), we get

$$HA + OH^- \rightleftharpoons H_2O + A^- \qquad K = K_1K_2' = 2 \times 10^{+9}$$

Example 3 *The degree of dissociation of* I_2 *molecule at* $1000°C$ *and under atmospheric pressure is* 40% *by volume. The total pressure on the gas at equilibrium so that the dissociation is reduced to* 20% *at the same temperature, will be*

(a) 4.57 *atm* (b) 2.83 *atm*
(c) 5.33 *atm* (d) 7.57 *atm*

Solution (c) $I_2(g) \rightleftharpoons 2I(g)$

$$\begin{array}{llll} \text{At } t = 0 & 1 & 0 & \\ \text{At equilibrium} & 1-x & 2x & x = 0.40, p_1 = 1 \text{ atm in case I} \\ & 1-y & 2y & y = 0.20, p_2 = \text{? in case II} \end{array}$$

$$K_p = \frac{p_1^2}{p_{1_2}} = \frac{4x^2p_1}{(1-x)} = \frac{4y^2p_2}{(1-y)}$$

$$\therefore \quad \frac{4 \times 0.16 \times 1}{(1-0.4)} = \frac{4 \times 0.04 \times p_2}{(1-0.2)}$$

$$\Rightarrow \quad p_2 = 5.33 \text{ atm}$$

Example 4 *If* 2.0 *mole each of A and B were allowed to come to equilibrium at* 300 *K for the reaction*

$$A + B \rightleftharpoons C + D, \qquad \Delta G° = 460 \text{ cal}$$

the equilibrium concentration ratio of C to A will be

(a) 1 (b) $\frac{1}{2}$
(c) 0.68 (d) 0.46

Solution (c) We know, $-\Delta G° = 2.303 \, RT \log K$

$$\therefore \quad \log K = \frac{-\Delta G°}{2.303 \, RT}$$

$$= \frac{-460}{2.303 \times 2 \times 300}$$

$$= -0.333$$

$$\therefore \qquad K = 0.464$$

Also, at equilibrium

$$[A] = [B] \quad \text{and} \quad [C] = [D]$$

$$\therefore \qquad K = \frac{[C][D]}{[A][B]} = \frac{[C]^2}{[A]^2} = 0.464$$

$$\Rightarrow \qquad \frac{[C]}{[A]} = 0.681$$

Example 5 *In what manner will increase of pressure affect the equation,* $C(s) + H_2O(g) \rightleftharpoons CO(g) + H_2(g)$ *?*

(a) *Shift in the reverse direction*
(b) *Increase in the yield of* H_2
(c) *Shift in the forward reaction*
(d) *No effect*

Solution (a) Since for the given reaction,

$$n_R = 1$$

$$n_p = 2$$

$$\therefore \qquad \Delta n_g = n_p - n_R = 1$$

Positive value of Δn_g shows shifting of equilibrium in reverse direction on applying pressure.

Example 6 *A solution which is* 10^{-3} *M each in* Mn^{2+}, Fe^{2+}, Zn^{2+} *and* Hg^{2+} *is treated with* 10^{-16} *M sulphide ion. If* K_{sp} *of* MnS, FeS, ZnS *and* HgS *are* 10^{-15}, 10^{-23}, 10^{-20} *and* 10^{-54} *respectively, which one will precipitate first?*

(a) FeS (b) HgS
(c) ZnS (d) MgS

Solution (b) Precipitation will occur only when

$$Q_{ip} > K_{sp}$$

Salt	Q_{ip}	K_{sp}
MnS	$10^{-3} \times 10^{-16} = 10^{-19}$	10^{-15}
FeS	$10^{-3} \times 10^{-16} = 10^{-19}$	10^{-23}
ZnS	$10^{-3} \times 10^{-16} = 10^{-19}$	10^{-20}
HgS	$10^{-3} \times 10^{-16} = 10^{-19}$	10^{-54}

Therefore, HgS will be precipitated first.

Example 7 *The solubility product of* $Ag_2C_2O_4$ *at* 25°C *is* 1.29×10^{-11} *mol*^{3} *L*$^{-3}$. *A solution of* $K_2C_2O_4$ *containing* 0.1520 *mole in* 500 *mL of water is shaken with excess of* Ag_2CO_3 *till the following equilibrium is reached.*

$$Ag_2CO_3 + K_2C_2O_4 \rightleftharpoons Ag_2C_2O_4 + K_2CO_3$$

At equilibrium, the solution contains 0.0358 *mole of* K_2CO_3. *Assuming the degree of dissociation of* $K_2C_2O_4$ *and* K_2CO_3 *to be equal, the solubility product of* Ag_2CO_3 *will be*

(a) 1.96×10^{-12} (b) 8.48×10^{-11}
(c) 1.29×10^{-11} (d) 3.97×10^{-12}

Solution (d) $Ag_2CO_3 + K_2C_2O_4 \rightleftharpoons Ag_2C_2O_4 + K_2CO_3$

	$K_2C_2O_4$	K_2CO_3
At $t = 0$	0.1520 mol	0
At equilibrium	0.1520 – 0.0358 = 0.1162 mol	0.0358 mol
Concentration	2×0.1162 = 0.2324 M	2×0.0358 = 0.0716 M

$$K_{sp}(Ag_2C_2O_4) = [Ag^+]^2[C_2O_4^{2-}]$$

$$\text{or,} \qquad [Ag^+] = \left[\frac{K_{sp}\,(Ag_2C_2O_4)}{[C_2O_4^{2-}]}\right]^{1/2} \qquad \ldots\text{(i)}$$

$$\text{and,} \qquad K_{sp}(Ag_2CO_3) = [Ag^+]^2[CO_3^{2-}]$$

$$\text{or} \qquad [Ag^+] = \left[\frac{K_{sp}\,(Ag_2CO_3)}{[CO_3^{2-}]}\right]^{1/2} \qquad \ldots\text{(ii)}$$

From Eqs. (i) and (ii),

$$\left[\frac{K_{sp}\,(Ag_2C_2O_4)}{[C_2O_4^{2-}]}\right]^{1/2} = \left[\frac{K_{sp}(Ag_2CO_3)}{[CO_3^{2-}]}\right]^{1/2}$$

$$\text{or,} \qquad K_{sp}(Ag_2CO_3) = \frac{K_{sp}\,(Ag_2C_2O_4) \times [CO_3^{2-}]}{[C_2O_4^{2-}]}$$

$$= \frac{K_{sp}\,(Ag_2C_2O_4) \times [K_2CO_3]}{[K_2C_2O_4]}$$

$$= \frac{1.29 \times 10^{-11} \times 0.0716}{0.2324}$$

$$= 3.97 \times 10^{-12}\ \text{mol}^3\ \text{L}^{-3}$$

Example 8 *A solution has* 0.05 *M* Mg^{2+} *ions and* 0.05 *M* NH_3. *Calculate the concentration of* NH_4Cl *required to prevent the formation of* $Mg(OH)_2$ *in this solution.* K_{sp} *of* $Mg(OH)_2 = 9.0 \times 10^{-12}$ *and ionisation constant of* $NH_3 = 1.8 \times 10^{-5}$.

(a) 0.05 *M* (b) 0.067 *M*
(c) 2.0×10^{6} *M* (d) 1.8×10^{-10} *M*

Solution (b) The maximum concentration of OH^- ions that will precipitate $Mg(OH)_2$ is given by

$$K_{sp} = [Mg^{2+}][OH^-]^2$$

$$[OH^-]^2 = \frac{K_{sp}}{[Mg^{2+}]} = \frac{9.0 \times 10^{-12}}{0.05}$$

$$= 1.8 \times 10^{-10}$$

$$\text{or} \qquad [OH^-] = 1.34 \times 10^{-5}\ \text{M}$$

NH_3 is present in solution in the form of NH_4OH

$$\underset{0.05}{NH_3} + H_2O \rightleftharpoons \underset{0.05}{NH_4OH} \rightleftharpoons NH_4^+ + OH^-$$

The ionisation of NH_4OH is suppressed by the addition of strong electrolyte, NH_4Cl.

$$K_{NH_3} = K_{NH_4OH} = \frac{[NH_4^+][OH^-]}{[NH_4OH]}$$

$$[NH_4^+] = \frac{K_{NH_4OH} \times [NH_4OH]}{[OH^-]}$$

$$= \frac{1.8 \times 10^{-5} \times 0.05}{1.34 \times 10^{-5}} = 0.067 \text{ M}$$

i.e., $[NH_4Cl] = 0.067$ M

Example 9 *What volume of 0.10 M sodium formate solution should be added to 50 mL of 0.05 M formic acid to produce a buffer solution of pH 4.0? (pK_a for formic acid is 3.80).*

(*a*) 3.96 *mL* (*b*) 25 *mL*
(*c*) 39.6 *mL* (*d*) 100 *mL*

Solution (*c*) Let *x* mL of 0.10 M sodium formate is added.

Number of moles in *x* mL of 0.10 M sodium formate $= \frac{0.10}{1000} \times x$

Number of moles in 50 mL of 0.05 M formic acid $= \frac{0.05}{1000} \times 50$

$$\therefore \quad \frac{[\text{Sodium formate}]}{[\text{Formic acid}]} = \frac{\frac{0.10 \times x}{1000}}{\frac{0.05 \times 50}{1000}} = 0.04\,x$$

From Henderson's equation,

$$\text{pH} = \text{p}K_a + \log \frac{[\text{salt}]}{[\text{acid}]}$$

$$4.0 = 3.80 + \log 0.04x$$

$$\log 0.04x = 0.2$$

$$\therefore \quad x = 39.6 \text{ mL}$$

Example 10 *An aqueous solution contains 10% ammonia by mass and has a density 0.99 g cm^{-3}. If K_a for NH_4^+ is 5.0×10^{-10} M, the value of hydroxyl ion concentration will be*

(*a*) 9.27×10^{-13} (*b*) 9.27×10^{-11}
(*c*) 9.27×10^{-10} (*d*) 9.27×10^{-6}

Solution (*a*) Mass of 1 L solution $= 1000 \times 0.99$ g $= 990$ g

NH_3 present in 990 g solution $= 10\%$ of $990 = 99$ g

1 L solution contains $= \frac{99}{17} = 5.8$ mol NH_3

$$\begin{array}{lccccccc} & NH_3 & + H_2O & \rightleftharpoons & NH_4OH & \rightleftharpoons & NH_4^+ & + OH^- \\ \text{At } t = 0 & 5.8 & & & & & 0 & 0 \\ \text{At equilibrium} & (5.8 - x) & & & & & x & x \end{array}$$

$$\therefore \quad K_b = \frac{[NH_4^+][OH^-]}{[NH_3]} = \frac{x \cdot x}{(5.8 - x)} \approx \frac{x^2}{5.8} \quad \text{...(i)}$$

$$\text{Again,} \quad K_b = \frac{K_w}{K_a} = \frac{10^{-14}}{5.0 \times 10^{-10}} = 2 \times 10^{-5} \quad \text{...(ii)}$$

From Eqs. (i) and (ii), we get

$$\frac{x^2}{5.8} = 2 \times 10^{-5}$$

$$x^2 = 5.8 \times 2 \times 10^{-5}$$

i.e., $[OH^-] = x = 1.078 \times 10^{-2}$ M

$\because$ $[H^+][OH^-] = 10^{-14}$

$$\therefore \quad [H^+] = \frac{10^{-14}}{1.078 \times 10^{-2}} = 9.27 \times 10^{-13} \text{ M}$$

Example 11 *How much must be a 0.02 M solution of sodium acetate be diluted at 25°C in order to double the degree of hydrolysis?*

(*a*) 0.25 *times* (*b*) 2 *times*
(*c*) 4 *times* (*d*) 8 *times*

Solution (*c*) Let *h* be the initial degree of hydrolysis.

$$K_h = Ch^2 = 0.2 \times h^2 \quad \text{...(i)}$$

Let the concentration becomes C_1 when degree of hydrolysis is 2*h*.

$$K_h = C_1(2h)^2 = 4C_1h^2 \quad \text{...(ii)}$$

Dividing Eqs. (i) by (ii),

$$\frac{K_h}{K_h} = \frac{0.2\,h^2}{4C_1h^2}, \quad 1 = \frac{0.2}{4C_1}, \quad C_1 = \frac{0.2}{4} = 0.05 \text{ M}$$

Now, from, $M_1V_1 = M_2V_2$, $0.2\,V_1 = 0.05\,V_2$

$$V_2 = \frac{0.2}{0.05} V_1 = 4V_1$$

Therefore, the solution must be diluted four times

Start **Practice** *for* JEE Main

Round I (Topically Divided Problems)

Equilibria in Physical and Chemical Processes

1. In the thermal decomposition of potassium chlorate given as

$2KClO_3 \longrightarrow 2KCl + 3O_2$, law of mass action

(a) can be applied
(b) cannot be applied
(c) can be applied at low temperature
(d) can be applied at high temperature and pressure

2. Which of the following is a characteristic of a reversible reaction?

(a) It can never proceed to completion
(b) It can be influenced by a catalyst
(c) Number of moles of reactants and products are equal
(d) None of the above

3. Which of the following is not a general characteristic of equilibria involving physical processes? **[NCERT Exemplar]**

(a) Equilibrium is possible only in a closed system at a given temperature
(b) All measurable properties of the system remain constant
(c) All the physical processes stop at equilibrium
(d) The opposing processes occur at the same rate and there is dynamic but stable condition

4. In chemical reaction, $A \rightleftharpoons B$, the system will be known in equilibrium when

(a) 50% of A changes to B
(b) A completely changes to B
(c) only 10% of A changes to B
(d) the rate of change of A to B and B to A on both the sides are same

Law of Mass Action, *K* (K_p and K_c) and their Significance

5. The active mass of 45 g of KCl in a 3 L flask would be

(a) 0.20
(b) 2.0
(c) 3
(d) 4

6. According to the law of mass action, rate of a chemical reaction is proportional to

(a) molar concentration of reactants
(b) concentration of reactants
(c) concentration of products
(d) molar concentration of products

7. In the equilibrium, $AB \rightleftharpoons A + B$, if the equilibrium concentration of A is doubled, the equilibrium concentration of B would become

(a) half
(b) twice
(c) $\frac{1}{4}$th
(d) $\frac{1}{8}$th

8. What is the equilibrium expression for the reaction,

$$P_4(s) + 5O_2(g) \rightleftharpoons P_4O_{10}(s) ?$$

(a) $K_c = \frac{1}{[O_2]^5}$
(b) $K_c = [O_2]^5$
(c) $K_c = \frac{[P_4O_{10}]}{5[P_4][O_2]}$
(d) $K_c = \frac{[P_4O_{10}]}{[P_4][O_2]^5}$

9. The equilibrium constant in a reversible reaction at a given temperature

(a) does not depend on the initial concentrations
(b) depends on the initial concentrations of the reactants
(c) depends on the concentration of the products at equilibrium
(d) it is not a characteristic of the reaction

10. $A + B \rightleftharpoons C + D$. If finally the concentration of A and B are equal but at equilibrium, concentration of D will be twice of that of A then what will be the equilibrium constant of reaction?

(a) 2 (b) 4
(c) $\frac{2}{3}$ (d) $\frac{4}{5}$

11. In the reaction, $PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$, the equilibrium concentration of PCl_5 and PCl_3 are 0.4 and 0.2 mol/L respectively. If the value of K_c is 0.5 what is the concentration of Cl_2 in mol/L?

(a) 0.5 (b) 1.0 (c) 1.5 (d) 2.0

12. The rate constant for forward reaction and backward reaction of hydrolysis of ester are 1.1×10^{-2} and 1.5×10^{-3} per minute respectively. Equilibrium constant for the reaction is

$$CH_3COOC_2H_5 + H_2O \rightleftharpoons CH_3COOH + C_2H_5OH$$

(a) 33.7 (b) 7.33
(c) 5.33 (d) 33.3

13. The value of K_c for the reaction,

$$3O_2(g) \rightleftharpoons 2O_3(g)$$

is 2.0×10^{-50} at 25°C. If the equilibrium concentration of O_2 in air at 25°C is 1.6×10^{-2}, what is the concentration of O_3? **[NCERT]**

(a) $2.0 \times 10^{-50} \times (1.6 \times 10^{-2})^3$
(b) 2.86×10^{-28}
(c) $(1.6 \times 10^{-2})^4$
(d) Both (a) and (b)

14. A sample of $HI(g)$ is placed in a flask at a pressure of 0.2 atm. At equilibrium, the partial pressure of $HI(g)$ is 0.04 atm. What is K_p for the given equilibrium? **[NCERT]**

(a) 3 (b) 4 (c) 6 (d) 8

15. A sample of pure PCl_5 was introduced into an evacuated vessel at 473 K. After equilibrium was attained, concentration of PCl_5 was found to be 0.5×10^{-1} mol L^{-1}. If value of K_c is 8.3×10^{-3}, what is the concentration of PCl_3 at equilibrium?

$$PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$$ **[NCERT]**

(a) 4.15×10^{-5} (b) 1.85×10^{-4}
(c) 2×10^{-4} (d) 2×10^{-2}

16. The equilibrium concentration of ICl in the equilibrium when the initial concentration of ICl was 0.78 M is

$$2ICl(g) \rightleftharpoons I_2(g) + Cl_2(g);$$ **[NCERT]**

(a) 0.28 (b) 0.25
(c) 0.38 (d) 0.45

17. For the reaction, $H_2(g) + CO_2(g) \rightleftharpoons CO(g) + H_2O(g)$ if the initial concentration of $[H_2] = [CO_2]$ and x mol/L of hydrogen is consumed at equilibrium, the correct expression of K_p is

(a) $\frac{x^2}{(1-x)^2}$ (b) $\frac{x^2}{(2+x)^2}$
(c) $\frac{x^2}{1-x^3}$ (d) $\frac{(1+x)^2}{(1-x)^2}$

18. The reaction,

$$CO(g) + 3H_2(g) \rightleftharpoons CH_4(g) + H_2O(g)$$

is at equilibrium at 1300 K in a 1 L flask. It also contains 0.30 mole of CO, 0.10 mole of H_2 and 0.02 mole of H_2O and an unknown amount of CH_4 in the flask. Determine the concentration of CH_4 in the mixture. The equilibrium constant, K_c for the reaction at the given temperature is 3.90. **[NCERT]**

(a) 5.85×10^{-2} (b) 4.23×10^{-2}
(c) 5.02×10^{-3} (d) 5.22×10^{-4}

19. In which of the following reactions, the equilibrium remains unaffected on addition of small amount of argon at constant volume? **[NCERT Exemplar]**

(a) $H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$
(b) $PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$
(c) $N_2(g) + 3H_2 \rightleftharpoons 2NH_3$
(d) The equilibrium will remain unaffected in all the three cases

20. Equilibrium constants K_1 and K_2 for the following equilibria

$$NO(g) + \frac{1}{2}O_2 \overset{K_1}{\rightleftharpoons} NO_2(g)$$

and, $2NO_2(g) \overset{K_2}{\rightleftharpoons} 2NO(g) + O_2(g)$ are related as

(a) $K_1 = \frac{1}{K_2}$ (b) $K_2 = \frac{1}{K_1}$
(c) $K_2 = \frac{1}{K_1^2}$ (d) $K_1 = \frac{1}{K_2^2}$

21. At 500 K, equilibrium constant, K_c, for the following reaction is 5.

$$\frac{1}{2}H_2(g) + \frac{1}{2}I_2(g) \rightleftharpoons HI(g)$$

What would be the equilibrium constant K_c for the reaction?

$$2HI(g) \rightleftharpoons H_2(g) + I_2(g)$$ **[NCERT Exemplar]**

(a) 0.04 (b) 0.4
(c) 25 (d) 2.5

22. At 450 K, $K_p = 2.0 \times 10^{10}$/bar for the given reaction at equilibrium,

$$2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g)$$

The value of K_c at this temperature is **[NCERT]**

(a) 7.38×10^{11} (b) 5.24×10^{10}
(c) 5.41×10^{8} (d) 2.67×10^{7}

23. In which of the following reactions, the value of K_p will be equal to K_c?

(a) $PCl_5 \rightleftharpoons PCl_3 + Cl_2$ (b) $2NH_3 \rightleftharpoons N_2 + 3H_2$
(c) $H_2 + I_2 \rightleftharpoons 2HI$ (d) $2SO_2 + O_2 \rightleftharpoons 2SO_3$

24. We know that the relationship between K_c and K_p is $K_p = K_c(RT)^{\Delta n}$.

What would be the value of Δn for the reaction?

$NH_4Cl(s) \rightleftharpoons NH_3(g) + HCl(g)$ **[NCERT Exemplar]**

(a) 1 (b) 0.5
(c) 1.5 (d) 2

25. The unit of equilibrium constant, K for the reaction, $A + B \rightleftharpoons C$, would be

(a) mol L^{-1} (b) mol L
(c) L mol^{-1} (d) dimensionless

Gibbs Free Energy and Relation of α with Vapour Density

26. Ice and water are in equilibrium at 273 K, which of the following statements is correct?

(a) $G_{(ice)} > G_{(H_2O)}$ (b) $G_{(ice)} < G_{(H_2O)}$
(c) $G_{(ice)} = G_{(H_2O)} = 0$ (d) $G_{(ice)} = G_{(H_2O)} \neq 0$

27. Which of the following options will be correct for the stage of half completion of the reaction $A \rightleftharpoons B$? **[NCERT Exemplar]**

(a) $\Delta G^{\ominus} = 0$ (b) $\Delta G^{\ominus} > 0$
(c) $\Delta G^{\ominus} < 0$ (d) $\Delta G^{\ominus} = -RT \log 2$

28. For the reaction $H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$, the standard free energy is $\Delta G^{\ominus} > 0$. The equilibrium constant (K) would be **[NCERT Exemplar]**

(a) $K = 0$ (b) $K > 1$
(c) $K = 1$ (d) $K < 1$

29. The vapour density of PCl_5 is 104.16, but when heated at 230°C, its vapour density is reduced to 62. The percentage of dissociation of PCl_5 at this temperature will be

(a) 6.8% (b) 68%
(c) 46% (d) 64%

30. The vapour density of N_2O_4 at a certain temperature is 30. What is the percentage dissociation of N_2O_4 at this temperature?

(a) 46.5% (b) 36.2%
(c) 53.3% (d) 64.2%

Le-Chatelier's Principle with Applications

31. According to Le-Chatelier's principle, if heat is given to solid-liquid system, then

(a) quantity of solid will reduce
(b) quantity of liquid will reduce
(c) temperature becomes constant
(d) temperature will decrease

32. What is the effect of pressure by doubling the volume on the following system at 500°C?

$$H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$$

(a) Shift to product side (b) Shift to reactant side
(c) Liquifaction of HI (d) No effect

33. In the reaction, $A_2(g) + 4B_2(g) \rightleftharpoons 2AB_4(g), \Delta H < 0$, the formation of AB_4 will be favoured at

(a) low temperature, high pressure
(b) high temperature, low pressure
(c) low temperature, low pressure
(d) high temperature, high pressure

34. The equilibrium which remains unaffected by change in pressure of the reactants is

(a) $N_2(g) + O_2(g) \rightleftharpoons 2NO(g)$
(b) $2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g)$
(c) $2O_3(g) \rightleftharpoons 3O_2(g)$
(d) $2NO_2 \rightleftharpoons N_2O_4(g)$

35. In the manufacture of NH_3 by Haber's process, the condition which would give maximum yield is

$$N_2 + 3H_2 \rightleftharpoons 2NH_3 + Q \text{ kcal}$$

(a) low temperature and high pressure
(b) low temperature, low pressure and low concentration of H_2
(c) high temperature, low pressure and low concentration
(d) high temperature, high pressure and high concentration

36. Under what conditions of temperature and pressure, the formation of atomic hydrogen from molecular hydrogen will be favoured most?

(a) High temperature and high pressure
(b) High temperature and low pressure
(c) Low temperature and low pressure
(d) Low temperature and high pressure

Electrolytes, Concepts of Acids and Bases (Including Ostwald's Dilution law)

37. The extent of ionisation increases
(a) with the increase in concentration
(b) on addition of excess water to the solution
(c) on decreasing the temperature of solution
(d) on stirring the solution vigorously

38. The degree of ionisation of a compound depends
(a) size of solute molecules
(b) nature of solute molecules
(c) nature of vessel used
(d) quantity of electricity passed

39. Which one is the strongest electrolyte in the following?
(a) NaCl (b) CH_3COOH
(c) NH_4OH (d) $C_6H_{12}O_6$

40. Theory of ionisation was given by
(a) Rutherford (b) Graham
(c) Faraday (d) Arrhenius

41. The conjugate base of NH_2^- is
(a) NH_3 (b) NH^{2-} (c) NH_4^+ (d) N_3^-

42. Diacidic base is
(a) $CH_2(OH)_2$ (b) $Ca(OH)_2$
(c) $CH_3CH(OH)_2$ (d) All of these

43. Which of the following behaves as both Lewis and Bronsted base?
(a) BF_3 (b) Cl^-
(c) CO (d) None of these

44. The species which acts as a Lewis but not a Bronsted acid is
(a) NH_2^- (b) O^{2-}
(c) BF_3 (d) OH^-

45. Which of the following is the strongest conjugate base?
(a) Cl^- (b) CH_3COO^-
(c) SO_4^{2-} (d) NO_2^-

46. Which of the following is a conjugated acid-base pair?
(a) HCl, NaOH (b) NH_4Cl, NH_4OH
(c) H_2SO_4, HSO_4^- (d) KCN, HCN

47. The ionisation constant of an acid, K_a, is the measure of strength of an acid. The K_a values of acetic acid, hypochlorous acid and formic acid are 1.74×10^{-5}, 3.0×10^{-8} and 1.8×10^{-4} respectively. Which of the following orders of pH of 0.1 mol dm^{-3} solutions of these acids is correct? **[NCERT** Exemplar]
(a) Acetic acid > hypochlorous acid > formic acid
(b) Hypochlorous acid > acetic acid > formic acid
(c) Formic acid > hypochlorous acid > acetic acid
(d) Formic acid > acetic acid > hypochlorous acid

48. Acidity of BF_3 can be explained on the basis of which of the following concepts? **[NCERT** Exemplar]
(a) Arrhenius concept
(b) Bronsted Lowry concept
(c) Lewis concept
(d) Bronsted Lowry as well as Lewis concept

49. The degree of dissociation of 0.1 M HCN solution is 0.01%. Its ionisation constant would be
(a) 10^{-3} (b) 10^{-5}
(c) 10^{-7} (d) 10^{-9}

50. The ionisation constant of acetic acid is 1.74×10^{-5}. The degree of dissociation of acetic acid in its 0.05 M solution and its pH are respectively **[NCERT]**
(a) 1.86×10^{-2}, 4 (b) 1.24×10^{-3}, 3
(c) 1.24×10^{-3}, 4 (d) 1.86×10^{-2}, 3

51. Ionisation constant of CH_3COOH is 1.7×10^{-5} and $[H^+]$ is 3.4×10^{-4}. Then, initial concentration of CH_3COOH molecules is
(a) 6.8×10^{-3} (b) 2.5×10^{-4}
(c) 3.5×10^{-3} (d) 4.5×10^{-3}

pH, Salt Hydrolysis, Buffer Solution

52. The pH of a sample of vinegar is 3.76. Calculate the concentration of hydrogen ion in it. **[NCERT]**
(a) 1.84×10^{-4} (b) 1.97×10^{-4}
(c) 1.738×10^{-4} (d) 1.283×10^{-4}

53. The pH of a 10^{-10} M NaOH solution is nearest to
(a) 10 (b) 7 (c) 4 (d) −10

54. 0.01 mole of lime (CaO) was dissolved in 100 cm^3 of water. Assuming the base is completely ionised in the solution, the pH of the solution will be
(a) 13.3 (b) 8.5 (c) 6 (d) 8

55. NaOH(*aq*), HCl(*aq*) and NaCl(*aq*) concentration of each is 10^{-3} M. Their pH will be respectively
(a) 10, 6, 2 (b) 11, 3, 7
(c) 10, 2, 6 (d) 3, 4, 7

56. pH of a solution of a strong acid is 5.0. What will be the pH of the solution obtained after diluting the given solution 100 times? **[NCERT** Exemplar]
(a) 5.8 (b) 6.7
(c) 9.3 (d) 13

57. To a 10 mL of 10^{-3} N H_2SO_4 solution water has been added to make the total volume 1 L. Its pOH would be

(a) 9
(b) 3
(c) 12
(d) 4

58. The pH of a solution formed by mixing equal volumes of two solutions, A and B of a strong acid having $pH = 6$ and $pH = 4$ respectively is **[NCERT Exemplar]**

(a) 5
(b) 4.3
(c) 6
(d) 5.5

59. pH of 0.08 mol dm^{-3} HOCl solution is 2.85. Calculate its ionisation constant. **[NCERT Exemplar]**

(a) 24.9×10^{-6}
(b) 28.6×10^{-5}
(c) 2.5×10^{-6}
(d) 24.9×10^{-5}

60. What will be the value of pH of 0.01 mol dm^{-3} $CH_3COOH\,(K_a = 1.74 \times 10^{-5})$? **[NCERT Exemplar]**

(a) 3.4
(b) 3.9
(c) 3.6
(d) 3.0

61. The pH of neutral water at 25°C is 7.0. As the temperature increases, ionisation of water increases, however, the concentration of H^+ ions and OH^- ions are equal. What will be the pH of pure water at 60°C? **[NCERT Exemplar]**

(a) Equal to 7.0
(b) Greater than 7.0
(c) Less than 7.0
(d) Equal to zero

62. What will be the pH and % α respectively for the salt BA of 0.1 M concentration? Given, K_a for $HA = 10^{-6}$ and K_b for $BOH = 10^{-6}$.

(a) 7, 10%
(b) 5, 10%
(c) 5, 0.1%
(d) 7, 1%

63. K_a for CH_3COOH is 1.8×10^{-5} and K_b for NH_4OH is 1.8×10^{-5}. The pH of ammonium acetate will be **[NCERT Exemplar]**

(a) 7.005
(b) 4.75
(c) 7.0
(d) between 6 and 7

64. An aqueous solution of sodium carbonate is alkaline because sodium carbonate is a salt of

(a) weak acid and weak base
(b) strong acid and weak base
(c) weak acid and strong base
(d) strong acid and strong base

65. The aqueous solution of $AlCl_3$ is acidic due to the hydrolysis of

(a) aluminium ion
(b) chloride ion
(c) Both aluminium and chloride ion
(d) None of the above

66. 0.5 M ammonium benzoate is hydrolysed to 0.25 per cent. Hence, its hydrolysis constant is

(a) 2.5×10^{-5}
(b) 1.25×10^{-5}
(c) 3.125×10^{-6}
(d) 6.25×10^{-6}

67. A weak acid HX has the dissociation constant 1×10^{-5} M. It forms a salt NaX on reaction with alkali. The degree of hydrolysis of 0.1 M solution of NaX is

(a) 0.0001%
(b) 0.01%
(c) 0.1%
(d) 0.15%

68. A buffer solution can be prepared from a mixture of

(i) sodium acetate and acetic acid in water
(ii) sodium acetate and hydrochloric acid in water
(iii) ammonia and ammonium chloride in water
(iv) ammonia and sodium hydroxide in water

(a) (i), (ii)
(b) (ii), (iii)
(c) (iii), (iv)
(d) (i), (iii)

69. How much sodium acetate should be added to 0.1 M solution of CH_3COOH to give a solution of $pH = 5.5$ (pK_a of $CH_3COOH = 4.5$)?

(a) 0.1 M
(b) 0.01 M
(c) 1.0 M
(d) 10.0 M

70. The pK_a of HCN is 9.30. The pH of a solution prepared by mixing 2.5 moles of KCN and 2.5 moles of HCN in water and making up the total volume of 500 mL, is

(a) 9.30
(b) 7.30
(c) 10.30
(d) 8.30

71. Which of the following will produce a buffer solution when mixed in equal volumes? **[NCERT Exemplar]**

(a) 0.1 mol dm^{-3} NH_4OH and 0.1 mol dm^{-3} HCl
(b) 0.05 mol dm^{-3} NH_4OH and 0.1 mol dm^{-3} HCl
(c) 0.1 mol dm^{-3} NH_4OH and 0.05 mol dm^{-3} HCl
(d) 0.1 mol dm^{-3} CH_3COONa and 0.1 mol dm^{-3} NaOH

Common Ion Effect and Solubility Product

72. Which pair will show common ion effect?

(a) $BaCl_2 + Ba(NO_3)_2$
(b) $NaCl + HCl$
(c) $NH_4OH + NH_4Cl$
(d) $AgCN + KCN$

73. If acetic acid is mixed with sodium acetate then H^+ ion concentration will

(a) increase
(b) decrease
(c) remain unchanged
(d) pH decreases

74. When ammonium chloride is added to a solution of ammonium hydroxide,
(a) dissociation of NH_4OH increases
(b) concentration of OH^- decreases
(c) concentration of NH_4^+ and OH^- increases
(d) concentration of NH_4^+ decreases

75. If the solubility product of $BaSO_4$ is 15×10^{-10} in water, its solubility, in moles per litre, is
(a) 1.5×10^{-9} (b) 3.9×10^{-5}
(c) 7.5×10^{-5} (d) 1.5×10^{-5}

76. Solubility of BaF_2 in a solution of $Ba(NO_3)_2$ will be represented by the concentration term
(a) $[Ba^{2+}]$ (b) $[F^-]$
(c) $\frac{1}{2}[F^-]$ (d) $2[NO_3^-]$

77. For a concentrated solution of a weak electrolyte A_xB_y of concentration 'C', the degree of dissociation 'α' is given as
(a) $\alpha = \sqrt{K_{eq}/C(x+y)}$
(b) $\alpha = \sqrt{K_{eq}C/(xy)}$
(c) $\alpha = (K_{eq}/C^{x+y-1}x^x y^y)^{1/(x+y)}$
(d) $\alpha = (K_{eq}/Cxy)$

78. In which of the following solvents is silver chloride most soluble? **[NCERT Exemplar]**
(a) 0.1 mol dm^{-3} $AgNO_3$ solution
(b) 0.1 mol dm^{-3} HCl solution
(c) H_2O
(d) Aqueous ammonia

79. The solubility product of Ag_2CrO_4 is 32×10^{-12}. What is the concentration of CrO_4^- ions in that solution?
(a) 2×10^{-4} M (b) 16×10^{-4} M
(c) 8×10^{-4} M (d) 8×10^{-8} M

80. A sparingly soluble salt gets precipitated only when the product of concentration of its ions in the solution (K_{sp}) becomes greater than its solubility product. If the solubility of $BaSO_4$ in water is 8×10^{-4} mol dm^{-3}, calculate its solubility in 0.01 mol dm^{-3} of H_2SO_4. **[NCERT]**
(a) 6.4×10^{-5} (b) 6.4×10^{-12}
(c) 6.3×10^{-6} (d) 6.4×10^{-10}

81. The solubility product of $Al(OH)_3$ is 2.7×10^{-11}. Its solubility in gL^{-1} and pH of this solution are respectively (Atomic mass of Al = 27 u) **[NCERT Exemplar]**
(a) 7.8×10^{-2}, 11.5 (b) 7.8×10^{-3}, 9.5
(c) 7.8×10^{-2}, 9.5 (d) 7.8×10^{-3}, 11.5

82. Calculate the volume of water required to dissolve 0.1 g lead (II) chloride to get a saturated solution. (K_{sp} of $PbCl_2 = 3.2 \times 10^{-8}$, atomic mass of Pb = 207 u) **[NCERT]**
(a) 100 mL (b) 180 mL
(c) 120 mL (d) 150 mL

Round II (Mixed Bag)

Only One Correct Option

1. In Haber's process, 30 L of dihydrogen and 30 L of dinitrogen were taken for reaction which yielded only 50% of the expected product. What will be the composition of gaseous mixture under the aforesaid condition at the end?
(a) 10 L NH_3, 25 L N_2, 15 L H_2
(b) 20 L NH_3, 20 L N_2, 20 L H_2
(c) 20 L NH_3, 25 L N_2, 15 L H_2
(d) 20 L NH_3, 10 L N_2, 30 L H_2

2. When $NaNO_3$ is heated in a closed vessel, O_2 is liberated and $NaNO_2$ is left behind. At equilibrium,
(i) addition of $NaNO_3$ favours forward reaction
(ii) addition of $NaNO_2$ favours backward reaction
(iii) increasing pressure favours reverse reaction
(iv) increasing temperature favours forward reaction

Correct options are
(a) (i), (ii), (iii) (b) (ii), (iii), (iv)
(c) (i), (iii), (iv) (d) (i), (ii), (iii), (iv)

3. The pK_a of acetylsalicylic acid (aspirin) is 3.5. The pH of gastric juice in human stomach is about 2–3 and the pH in the small intestine is about 8. Aspirin will be
(a) unionised in the small intestine and in the stomach
(b) completely ionised in the small intestine and in the stomach
(c) ionised in the stomach and almost unionised in the small intestine
(d) ionised in the small intestine and almost unionised in the stomach

4. A precipitate of AgCl is formed when equal volumes of the following are mixed [K_{sp} for $AgCl = 10^{-10}$]

(a) 10^{-4} M $AgNO_3$ and 10^{-7} M HCl

(b) 10^{-5} M $AgNO_3$ and 10^{-6} M HCl

(c) 10^{-5} M $AgNO_3$ and 10^{-4} M HCl

(d) 10^{-6} M $AgNO_3$ and 10^{-6} M HCl

5. A decimolar solution of ammonium hydroxide is ionised to the extent of 1.3%. If $\log 1.3 = 0.11$, what is the pH of the solution?

(a) 11.11
(b) 9.11
(c) 8.11
(d) Unpredictable

6. $K_p = 0.04$ atm at 899 K for the equilibrium shown below. The equilibrium concentration of C_2H_6 when it is placed in a flask at 4.0 atm pressure and allowed to come to equilibrium is **[NCERT]**

$$C_2H_6(g) \rightleftharpoons C_2H_4(g) + H_2(g)$$

(a) 0.30
(b) 3.6
(c) 4.0
(d) 2.8

7. If first dissociation of $X(OH)_3$ is 100%, second dissociation is 50% and third dissociation is negligible then the pH of 4×10^{-3} M $X(OH)_3$ is

(a) 7.5
(b) 9.54
(c) 11.78
(d) 13.25

8. Conjugate acid of a weak base is always stronger. The decreasing order of basic strength of the following conjugate bases is

$OH^-, RO^-, CH_3COO^-, Cl^-$ **[NCERT Exemplar]**

(a) $RO^- > OH^- > CH_3COO^- > Cl^-$

(b) $OH^- > RO^- > CH_3COO^- > Cl^-$

(c) $Cl^- > RO^- > OH^- > CH_3COO^-$

(d) $CH_3COO^- > RO^- > OH^- > Cl^-$

9. Arrange the following in increasing order of pH. $KNO_3(aq)$, $CH_3COONa(aq)$, $NH_4Cl(aq)$, $C_6H_5COONH_4(aq)$ **[NCERT Exemplar]**

(a) $CH_3COONa < C_6H_5COONH_4 < NH_4Cl < KNO_3$

(b) $KNO_3 < NH_4Cl < CH_3COONa < C_6H_5COONa$

(c) $NH_4Cl < KNO_3 < CH_3COONa < C_6H_5COONH_4$

(d) $NH_4Cl < KNO_3 < C_6H_5COONH_4 < CH_3COONa$

10. The ionisation constant of benzoic acid is 6.46×10^{-5} and K_{sp} for silver benzoate is 2.5×10^{-13}. How many times is silver benzoate more soluble in a buffer of pH 3.19 as compared to its solubility in pure water? **[NCERT]**

(a) 1.5
(b) 2.8
(c) 3.2
(d) 2.3

11. The ionisation constant of chloroacetic acid is 1.35×10^{-3}. The pH of 0.1 M acid and its 0.1 M sodium salt solution are respectively **[NCERT]**

(a) 1.94, 1.85
(b) 1.94, 7.94
(c) 7.94, 1.85
(d) 1.94, 8.25

12. The solubility product constant of Ag_2CrO_4 and AgBr are 1.1×10^{-12} and 5.0×10^{-13} respectively. Calculate the ratio of the molarities of their saturated solutions. **[NCERT]**

(a) 85
(b) 23
(c) 15
(d) 92

13. pH of which of the following solutions is highest? **[NCERT]**

(a) 2g of TlOH dissolved in water to give 2 L of solution

(b) 0.3 g of $Ca(OH)_2$ dissolved in water to give 500 mL of solution

(c) 0.3 g of NaOH dissolved in water to give 200 mL of solution

(d) 1 mL of 13.6 M HCl is diluted with water to give 1 L of solution

14. At 1127 K and 1 atm pressure, a gaseous mixture of CO and CO_2 in equilibrium with solid carbon has 90.55% CO by mass.

$$C(s) + CO_2(g) \rightleftharpoons 2CO(g)$$

K_c for this reaction at the above temperature is **[NCERT]**

(a) 0.153
(b) 0.513
(c) 0.283
(d) 0.365

15. Bromine monochloride, BrCl decomposes into bromine and chlorine and reaches the equilibrium,

$$2BrCl(g) \rightleftharpoons Br_2(g) + Cl_2(g)$$

for which $K_c = 32$ at 500 K. If initially pure BrCl is present at a concentration of 3.3×10^{-3} mol L^{-1}, what is its molar concentration in the mixture at equilibrium? **[NCERT]**

(a) 2.68×10^{-5}
(b) 0.268×10^{-4}
(c) 26.8×10^{-5}
(d) 0.223×10^{-6}

16. What mole of $Ca(OH)_2$ is dissolved in 250 mL aqueous solution to give a solution of pH 10.65, assuming full dissociation?

(a) 0.47×10^{-4}
(b) 0.48×10^{-4}
(c) 0.56×10^{-4}
(d) 0.68×10^{-4}

17. K_a for HCN is 5×10^{-10} at 25°C. For maintaining a constant pH = 9, the volume of 5 M KCN solution required to be added to 10 mL of 2 M HCN solution is

(a) 2 mL
(b) 4 mL
(c) 8.2 mL
(d) 6.4 mL

18. 2.5 mL of $\frac{2}{5}$ M weak monoacidic base ($K_b = 1 \times 10^{-12}$ at 25°C) is titrated with $\frac{2}{15}$ M HCl in water at 25°C. The concentration of H^+ at equivalence point is ($K_w = 1 \times 10^{-14}$ at 25°C)

(a) 3.7×10^{-13} M
(b) 3.2×10^{-7} M
(c) 3.2×10^{-2} M
(d) 2.7×10^{-2} M

19. Solubility product constant (K_{sp}) of salts of types MX, MX_2 and M_3X at temperature T are 4.0×10^{-8}, 3.2×10^{-14} and 2.7×10^{-15}, respectively. Solubilities (mol dm^{-3}) of the salts at temperature T are in the order

(a) $MX > MX_2 > M_3X$
(b) $M_3X > MX_2 > MX$
(c) $MX_2 > M_3X > MX$
(d) $MX > M_3X > MX_2$

20. Ammonia under a pressure of 15 atm at 27°C is heated to 347°C in a closed vessel in the presence of catalyst. Under the conditions, NH_3 is partially decomposed according to the equation, $2NH_3 \rightleftharpoons N_2 + 3H_2$. The vessel is such that the volume remains effectively constant whereas pressure increases to 50 atm. Calculate the percentage of NH_3 actually decomposed.

(a) 61.3%
(b) 63.5%
(c) 65.3%
(d) 66.6%

21. One of the reaction that takes place in producing steel from iron ore is the reduction of iron(II) oxide by carbon monoxide to give iron metal and CO_2.

$$FeO(s) + CO(g) \rightleftharpoons Fe(s) + CO_2(g);$$
$$K_p = 0.265 \text{ atm at } 1050 \text{ K}$$

The equilibrium partial pressures of CO and CO_2 at 1050 K, if the initial partial pressures are; $p_{CO} = 1.4$ atm and $p_{CO_2} = 0.80$ atm, are respectively **[NCERT]**

(a) 1.739, 0.461
(b) 0.461, 0.461
(c) 0.461, 1.739
(d) None of these

22. The concentration of sulphide ion in 0.1 M HCl solution saturated with hydrogen sulphide is 1.0×10^{-19} M. If 10 mL of this is added to 5 mL of 0.04 M solution of the following : $FeSO_4$, $MnCl_2$, $ZnCl_2$ and $CdCl_2$, in which of these solutions precipitation will take place?

(Given, K_{sp} of FeS $= 6.3 \times 10^{-18}$, K_{sp} of MnS $= 2.5 \times 10^{-13}$ K_{sp} of ZnS $= 1.6 \times 10^{-24}$, K_{sp} of CdS $= 8.0 \times 10^{-27}$) **[NCERT]**

(a) $FeSO_4$ only
(b) $CdCl_2$ and $ZnCl_2$
(c) Both $MnCl_2$ and $ZnCl_2$
(d) Both $CdCl_2$ and $FeSO_4$

More than One Correct Option

23. For the reaction $N_2O_4(g) \rightleftharpoons 2NO_2(g)$, the value of K is 50 at 400 K and 1700 at 500 K. Which of the following options is correct? **[NCERT Exemplar]**

(a) The reaction is endothermic
(b) The reaction is exothermic
(c) If $NO_2(g)$ and $N_2O_4(g)$ are mixed at 400 K at partial pressures 20 bar and 2 bar respectively, more $N_2O_4(g)$ will be formed.
(d) The entropy of the system increases

24. 138 g of $N_2O_4(g)$ is placed in 8.2 L container at 300 K. The equilibrium vapour density of mixture was found to be 30.67. Then ($R = 0.082$ L atm mol^{-1} K^{-1})

(a) total pressure at equilibrium = 6.75 atm
(b) degree of dissociation of N_2O_5 = 0.25
(c) the density of equilibrium mixture = 16.83 g/L
(d) K_p of $N_2O_4 \rightleftharpoons 2NO_2(g)$ will be 9 atm

25. A reaction mixture containing 0.050 atm N_2, 3.0 atm H_2 and 0.050 atm NH_3 is heated to 450°C. The value of K_p is 4.28×10^{-5} atm^{-2}.

$$N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$$

The correct statement(s) is/are

(a) reaction goes towards the left
(b) reaction goes towards the right
(c) N_2 and H_2 combine to form ammonia
(d) ammonia gas decomposes into H_2 and N_2

26. pH of following solution is not affected by dilution

(a) 0.01 M CH_3COONH_4
(b) 0.01 M NaH_2PO_4
(c) 0.01 M NaCl
(d) 0.01 M $NaHCO_3$

27. The solubility of a sparingly soluble salt A_xB_y in water at 25°C is 1.4×10^{-4} M. The solubility product is 1.1×10^{-11}. The possibilities are

(a) $x = 1, y = 2$
(b) $x = 2, y = 1$
(c) $x = 3, y = 1$
(d) $x = 1, y = 3$

Assertion and Reason

Directions (Q. Nos. 28 to 32) *Each of these questions contains two statements : Statement* I *(Assertion) and Statement* II *(Reason). Each of these questions also has four alternative choices, only one of which is the correct answer. You have to select one of the codes (a), (b), (c), (d) given below*

(a) Statement I is true; Statement II is true; Statement II is a correct explanation for Statement I.
(b) Statement I is true; Statement II is true; Statement II is not a correct explanation for Statement I.
(c) Statement I is true; Statement II is false.
(d) Statement I is false; Statement II is true.

28. **Statement I** The reaction,

$2NO(g) + O_2(g) \rightleftharpoons 2NO_2(g)$ is favoured in the forward direction with increase of pressure.

Statement II The reaction is exothermic.

29. **Statement I** Buffer system of carbonic acid and sodium bicarbonate is used for the precipitation of hydroxides of third group elements.

Statement II It maintains the pH to a constant value, about 7.4.

30. **Statement I** The ionisation of hydrogen sulphide in water is low in the presence of hydrochloric acid.

Statement II Hydrogen sulphide is a weak acid.

[NCERT Exemplar]

31. **Statement I** Aqueous solution of ammonium carbonate is basic.

Statement II Acidic/ basic nature of a salt solution of a salt of weak acid and weak base depends on K_a and K_b value of the acid and the base forming it.

[NCERT Exemplar]

32. **Statement I** In the dissociation of PCl_5 at constant pressure and temperature addition of helium at equilibrium increases the dissociation PCl_5.

Statement II Helium removes Cl_2 from the field of action. [NCERT Exemplar]

Comprehension Based Questions

Directions (Q. Nos. 33 to 35) The rate of the reaction is directly proportional to the product of the active masses of the reactants raised to the suitable powers, at a given temperature.

$$aA + bB + cC \longrightarrow \text{Product}$$
$$\text{Rate} = k[a]^a\,[B]^b[C]^c$$

If the reaction is written in reversed direction

$$k_b = \frac{1}{k_f}$$

For gaseous reaction, equilibrium constant, can also be expressed in terms of partial pressure.

Equilibrium constant, K_c for

$$aA + bB \rightleftharpoons cC + dD \text{ is}$$
$$K_c = \frac{[C]^c[D]^d}{[A]^a[B]^b} \text{ and } K_p = \frac{p_C{}^c\, p_D{}^d}{p_A{}^a\, p_B{}^b}$$

K_p and K_c are related with each other as $K_p = K_c\,(RT)^{\Delta n_g}$.

33. Calculate the partial pressure of carbon monoxide from the following data

$$CaCO_3(s) \overset{\Delta}{\rightleftharpoons} CaO(s) + CO_2\uparrow; \qquad K_p = 8\times 10^{-2}$$
$$CO_2(g) + C(s) \rightleftharpoons 2CO(g); \qquad K_p = 2$$

(a) 0.2 atm (b) 0.6 atm
(c) 0.8 atm (d) 0.4 atm

34. A vessel at 1000 K contains CO_2 with a pressure of 0.5 atm. Some of CO_2 is converted into CO on addition of graphite. The value of K at equilibrium when total pressure is 0.8 atm will be [AIEEE 2011]

(a) 2.5 atm (b) 3.6 atm
(c) 1.8 atm (d) 0.9 atm

35. For the following equilibrium

$$N_2O_4(g) \rightleftharpoons 2NO_2(g)$$

K_p is found to be equal to K_c. This is attained when

(a) $T = 1$ K
(b) $T = 273$ K
(c) $T = 12.18$ K
(d) $T = 17.15$ K

Directions (Q. Nos. 36 to 38) Radiochemical methods can be used to determine solubility product estimation. The measurement of radioactivity can be used to find the concentration in a solubility equilibrium giving a fair idea about various equilibrium concentrations. In an experiment, 50.00 mL of a 0.010 M $AgNO_3$ solution containing a silver isotope with a radioactivity of 75000 counts per min per mL were mixed with 100 mL of a 0.03 M $NaIO_3$ solution. The mixed solution was diluted to 500 mL and filtered to remove all the $AgIO_3$ precipitate leaving behind a radioactive solution. Molar mass of $AgIO_3$ = 285 g/mol.

36. The percentage of unprecipitated silver ions is

(a) 0.25% (b) 0.66%
(c) 0.43% (d) 0.57%

37. The K_{sp} of $AgIO_3$ are

(a) 5.3×10^{-8}
(b) 6.9×10^{-12}
(c) 4.2×10^{-10}
(d) 2.8×10^{-8}

38. The remaining solution was found to have a radioactivity of 50 counts per min per mL. Then, find the mass of the ppt of $AgIO_3$ obtained separated.

(a) 242 (b) 283
(c) 332 (d) 285

Previous Years' Questions

39. The equilibrium constant (K_c) for the reaction, $N_2(g) + O_2(g) \longrightarrow 2NO(g)$ at temperature T is 4×10^{-4}. The value of K_c for the reaction $NO(g) \longrightarrow \frac{1}{2}N_2(g) + \frac{1}{2}O_2(g)$ at the same temperature is **[AIEEE 2012]**

(a) 0.02
(b) 2.5×10^2
(c) 4×10^{-4}
(d) 50.0

40. The pH of a 0.1 molar solution of the acid HQ is 3. the value of the ionisation constant, K_a of the acid is **[AIEEE 2012]**

(a) 3×10^{-1}
(b) 1×10^{-3}
(c) 1×10^{-5}
(d) 1×10^{-7}

41. The K_{sp} for $Cr(OH)_3$ is 1.6×10^{-30}. The molar solubility of this compound in water is **[AIEEE 2011]**

(a) $\sqrt[2]{1.6 \times 10^{-30}}$
(b) $\sqrt[4]{1.6 \times 10^{-30}}$
(c) $\sqrt[4]{1.6 \times 10^{-30} / 27}$
(d) $1.6 \times 10^{-30} / 27$

42. Three reactions involving $H_2PO_4^-$ are given below

I. $H_3PO_4 + H_2O \longrightarrow H_3O^+ + H_2PO_4^-$
II. $H_2PO_4^- + H_2O \longrightarrow HPO_4^{2-} + H_3O^+$
III. $H_2PO_4^- + OH^- \longrightarrow H_3PO_4 + O^{2-}$

In which of the above does $H_2PO_4^-$ act as an acid? **[AIEEE 2010]**

(a) II only
(b) I and II
(c) III only
(d) I only

43. In aqueous solution, the ionisation constants for carbonic acid are **[AIEEE 2010]**

$$K_1 = 4.2 \times 10^{-7} \text{ and } K_2 = 4.8 \times 10^{-11}$$

Select the correct statement for a saturated 0.034 M solution of the carbonic acid.

(a) The concentration of CO_3^{2-} is 0.034 M
(b) The concentration of CO_3^{2-} is greater than that of HCO_3^{2-}
(c) The concentration of H^+ and HCO_3^{2-} are approximately equal
(d) The concentration of H^+ is double that of CO_3^{2-}

44. Solubility product of silver bromide is 5.0×10^{-13}. The quantity of potassium bromide (molar mass taken as 120 g mol^{-1}) to be added to 1 L of 0.05 M solution of silver nitrate to start the precipitation of AgBr is **[AIEEE 2010]**

(a) 1.2×10^{-10} g
(b) 1.2×10^{-9} g
(c) 6.2×10^{-5} g
(d) 5.0×10^{-8} g

45. At 25°C, the solubility product of $Mg(OH)_2$ is 1.0×10^{-11}. At which pH, will Mg^{2+} ions start precipitating in the form of $Mg(OH)_2$ from a solution of 0.001 M Mg^{2+} ions? **[AIEEE 2010]**

(a) 9
(b) 10
(c) 11
(d) 8

46. Solid $Ba(NO_3)_2$ is gradually dissolved in a 1.0×10^{-4} M Na_2CO_3 solution. At what concentration of Ba^{2+} will a precipitate begin to form? (K_{sp} for $BaCO_3 = 5.1 \times 10^{-9}$) **[AIEEE 2009]**

(a) 4.1×10^{-5} M
(b) 5.1×10^{-5} M
(c) 8.1×10^{-8} M
(d) 8.1×10^{-7} M

47. For the following three reactions I, II and III, equilibrium constants are given

I. $CO(g) + H_2O(g) \rightleftharpoons CO_2(g) + H_2(g); K_1$
II. $CH_4(g) + H_2O(g) \rightleftharpoons CO(g) + 3H_2(g); K_2$
III. $CH_4(g) + 2H_2O(g) \rightleftharpoons CO_2(g) + 4H_2(g); K_3$

Which of the following relations is correct? **[AIEEE 2003]**

(a) $K_1\sqrt{K_2} = K_3$
(b) $K_2K_3 = K_1$
(c) $K_3 = K_1K_2$
(d) $K_3K_2^3 = K_1^2$

48. Four species are listed below

I. HCO_3^-
II. H_3O^+
III. HSO_4^-
IV. HSO_3F

Which one of the following is the correct sequence of their acid strength? **[AIEEE 2008]**

(a) IV < II < III < I
(b) II < III < I < IV
(c) I < III < II < IV
(d) III < I < IV < II

49. The equilibrium constants K_{p_1} and K_{p_2} for the reactions $X \rightleftharpoons 2Y$ and $Z \rightleftharpoons P + Q$, respectively are in the ratio of 1 : 9. If the degree of dissociation of X and Z be equal, then the ratio of total pressure at these equilibria is **[AIEEE 2008]**

(a) 1 : 36
(b) 1 : 1
(c) 1 : 3
(d) 1 : 9

50. The pK_a of a weak acid, HA, is 4.80. The pK_b of a weak base, BOH, is 4.78. The pH of an aqueous solution of the corresponding salt, BA, will be **[AIEEE 2008]**

(a) 9.58
(b) 4.79
(c) 7.01
(d) 9.22

51. In a saturated solution of the sparingly soluble strong electrolyte $AgIO_3$ (molecular mass = 283) the equilibrium which sets in, is

$$AgIO_3(s) \rightleftharpoons Ag^+(aq) + IO_3^-(aq)$$

If the solubility product constant, K_{sp} of $AgIO_3$ at a given temperature is 1.0×10^{-8}, what is the mass of $AgIO_3$ contained in 100 mL of its saturated solution? **[AIEEE 2007]**

(a) 28.3×10^{-2} g (b) 2.83×10^{-3} g

(c) 1.0×10^{-7} g (d) 1.0×10^{-4} g

52. The equilibrium constant K_c for the reaction

$$SO_3(g) \rightleftharpoons SO_2(g) + \frac{1}{2} O_2(g)$$

is 4.9×10^{-2}. The value of K_c for the reaction

$$2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g)$$

will be **[AIEEE 2006]**

(a) 416 (b) 2.40×10^{-3}

(c) 9.8×10^{-2} (d) 4.9×10^{-2}

53. Phosphorus pentachloride dissociates as follows, in a closed reaction vessel,

$$PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$$

If total pressure, at equilibrium, of the reaction mixture is p and degree of dissociation of PCl_5 is x, the partial pressure of PCl_3 will be **[AIEEE 2006]**

(a) $\left(\frac{x}{x+1}\right)p$ (b) $\left(\frac{2x}{1-x}\right)p$

(c) $\left(\frac{x}{x-1}\right)p$ (d) $\left(\frac{x}{1-x}\right)p$

54. An amount of solid NH_4HS is placed in a flask already containing ammonia gas at a certain temperature and 0.50 atm pressure. Ammonium hydrogen sulphide decomposes to yield NH_3 and H_2S gases in the flask. When the decomposition reaction reaches at equilibrium, the total pressure in the flask rises to 0.84 atm. The equilibrium constant for the decomposition of NH_4HS at this temperature is **[AIEEE 2005]**

(a) 0.11 (b) 0.17 (c) 0.18 (d) 0.30

55. For the reaction,

$$2NO_2(g) \rightleftharpoons 2NO(g) + O_2(g)$$

[$K_c = 1.8 \times 10^{-6}$ at 184°C, $R = 0.00831$ kJ/(mol K)]

When K_p and K_c are compared at 184°C it is found that **[AIEEE 2005]**

(a) whether K_p is greater than, less than or equal to K_c depends upon the total gas pressure

(b) $K_p = K_c$

(c) K_p is less than K_c

(d) K_p is greater than K_c

56. What is the conjugate base of OH^-? **[AIEEE 2005]**

(a) O^{2-} (b) O^-

(c) H_2O (d) O_2

57. The solubility product of a salt having general formula MX_2, in water is 4×10^{-12}. The concentration of M^{2+} ions in the aqueous solution of the salt is **[AIEEE 2005]**

(a) 4.0×10^{-10} M

(b) 1.6×10^{-4} M

(c) 1.0×10^{-4} M

(d) 2.0×10^{-6} M

58. For the reaction,

$CO(g) + Cl_2(g) \rightleftharpoons COCl_2(g)$, the K_p / K_c is equal to **[AIEEE 2004]**

(a) $1/RT$ (b) RT

(c) $\sqrt{RT}$ (d) 1.0

59. Consider the reaction equilibrium

$$2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g); \quad \Delta H° = -198 \text{ kJ}$$

On the basis of Le-Chatelier's principle, the condition favourable for the forward reaction is **[AIEEE 2003]**

(a) lowering of temperature as well as pressure

(b) increasing temperature as well as pressure

(c) lowering the temperature and increasing the pressure

(d) any value of temperature and pressure

60. Which one of the following species acts as both Bronsted acid and base ? **[AIEEE 2002]**

(a) $H_2PO_2^-$

(b) HPO_3^{2-}

(c) HPO_4^{2-}

(d) All of the above

Answers

Round I

the Guidance

Round I

1. Thermal decomposition of potassium chlorate is irreversible. So, law of mass action cannot be applied on this reaction.

2. In a reversible reaction some amount of the reactants remains unconverted into products and it never go for completion.

3. At the stage of equilibrium, process does not stop but the opposite processes *i.e.*, forward and reverse process occur with the same rate.

5. Active mass $= \dfrac{\text{moles of KCl}}{\text{volume of solution in L}} = \dfrac{45}{74.5 \times 3} = 0.20$

7. $AB \rightleftharpoons A + B$

$$K = \frac{[A][B]}{[AB]}$$

If concentration of A is doubled, the equilibrium concentration of B becomes half to maintain K constant.

8. $P_4(s) + 5O_2(g) \rightleftharpoons P_4O_{10}(s)$

$$K_c = \frac{[P_4O_{10}(s)]}{[P_4(s)][O_2(g)]^5}$$

We know that concentration of a solid component is always taken as unity.

$$K_c = \frac{1}{[O_2]^5}$$

10. $A + B \rightleftharpoons C + D$

$x \quad x \qquad 0 \quad 0$

$2x \quad 2x$ At equilibrium

$$K_c = \frac{[C][D]}{[A][B]} = \frac{2x \cdot 2x}{x \cdot x} = 4$$

11. $K_c = \dfrac{[PCl_3][Cl_2]}{[PCl_5]} = \dfrac{0.2 \times x}{0.4} = 0.5$

$\therefore \qquad x = 1$

12. $k_f = 1.1 \times 10^{-2}, k_b = 1.5 \times 10^{-3}$

$$K_c = \frac{k_f}{k_b} = \frac{1.1 \times 10^{-2}}{1.5 \times 10^{-3}} = 7.33$$

13. $3O_2(g) \rightleftharpoons 2O_3(g)$

Equili. conc. $\quad 1.6 \times 10^{-2} \qquad ?$

$$K = \frac{[O_3]^2}{[O_2]^3}$$

$$2.0 \times 10^{-50} = \frac{[O_3]^2}{[1.6 \times 10^{-2}]^3}$$

$$[O_3]^2 = 2.0 \times 10^{-50} \times [1.6 \times 10^{-2}]^3$$

$$[O_3]^2 = 8.192 \times 10^{-56}$$

$$[O_3] = 2.86 \times 10^{-28} \text{ mol L}^{-1}$$

14.

$$\begin{array}{llll} & 2HI(g) & \rightleftharpoons H_2(g) & + \; I_2(g) \\ \text{Initial pressure} & 0.2 \text{ atm} & 0 & 0 \\ \text{Equili. pressure} & 0.04 \text{ atm} & 0.08 \text{ atm} & 0.08 \text{ atm} \end{array}$$

(Decrease in pressure of HI = 0.2 − 0.04 = 0.16 atm; so equilibrium pressure of H_2 is $\frac{0.16}{2} = 0.08$ atm and for I_2 is $\frac{0.16}{2} = 0.08$ atm as two moles of HI on dissociation gives 1 mol H_2 and 1 mol I_2)

$$K_p = \frac{p_{H_2} \cdot p_{I_2}}{p_{HI}^2} = \frac{0.08 \text{ atm} \times 0.08 \text{ atm}}{(0.04 \text{ atm})^2} = 4.0$$

15.

$$\begin{array}{llll} & PCl_5(g) & \rightleftharpoons PCl_3(g) & + \; Cl_2(g) \\ \text{At equili.} & 0.05 \text{ M} & x & x \end{array}$$

Given, $[PCl_5]_{\text{equili.}} = 0.5 \times 10^{-1}$ mol L^{-1} (= 0.05 mol L^{-1})

$$K_c = 8.3 \times 10^{-3}$$

$$K_c = 8.3 \times 10^{-3} = \frac{[PCl_3]\,[Cl_2]}{[PCl_5]}$$

$$8.3 \times 10^{-3} = \frac{x^2}{0.05} \qquad (\text{because } [PCl_3] = [Cl_2])$$

$$x^2 = 0.415 \times 10^{-3} = 4.15 \times 10^{-4}$$

$$x = 2.037 \times 10^{-2} \approx 2.04 \times 10^{-2} \text{ mol L}^{-1}$$

Hence, $[PCl_3] = [Cl_2] = 2.04 \times 10^{-2}$ mol L^{-1}

16.

$$\begin{array}{llll} & 2ICl(g) & \rightleftharpoons I_2(g) & + \; Cl_2(g) \\ \text{Initial conc.} & 0.78 \text{ M} & 0 & 0 \\ \text{Equili conc.} & 0.78 - 2x & x & x \end{array}$$

$$K_c = \frac{[I_2]\,[Cl_2]}{[ICl]^2} = \frac{x \,.\, x}{(0.78 - 2x)^2} = 0.14$$

or $$\frac{x}{(0.78 - 2x)} = \sqrt{0.14} = 0.374$$

or $$x = 0.29172 - 0.748x$$

or $$1.748x = 0.29172$$

or $$x = \frac{0.29172}{1.748} = 0.1668$$

$$[\,ICl]_{\text{equili}} = 0.78 - (2 \times 0.1668) = 0.45$$

17.

$$\begin{array}{lllll} & H_2(g) & + \; CO_2(g) & \rightleftharpoons CO(g) & + \; H_2O(l) \\ \text{Initial conc.} & 1 & 1 & 0 & 0 \\ \text{At equilibrium} & (1-x) & (1-x) & x & x \end{array}$$

$$K_p = \frac{p_{CO} \cdot p_{H_2O}}{p_{H_2} \cdot p_{CO_2}} = \frac{x \cdot x}{(1-x)(1-x)} = \frac{x^2}{(1-x)^2}$$

18. $CO(g) + 3\,H_2(g) \rightleftharpoons CH_4(g) + H_2O(g)$;

$K_c = 3.90$ at 1300 K.

$$K_c = \frac{[CH_4] \cdot [H_2O]}{[CO]\;[H_2]^3}$$

$$3.90 = \frac{[CH_4]\;[0.02]}{[0.30]\;[0.10]^3}$$

(Molar concentration means number of moles present in 1 L and volume of the flask is 1 L.)

$$[CH_4] = \frac{3.90 \times 0.30 \times (0.10)^3}{0.02} = 0.0585 \text{ M}$$

$$[CH_4]_{eq} = 5.85 \times 10^{-2} \text{M}$$

19. At constant volume, the equilibrium remain unaffected on addition of small amount of inert gas like argon.

20.

$$K_1 = \frac{[NO_2]}{[NO][O_2]^{1/2}} \qquad \text{...(i)}$$

$$K_2 = \frac{[NO]^2[O_2]}{[NO_2]^2} \qquad \text{...(ii)}$$

$$\therefore \quad \frac{1}{K_2} = \frac{[NO_2]^2}{[NO]^2[O_2]}$$

or, $$\frac{1}{\sqrt{K_2}} = \frac{[NO_2]}{[NO][O_2]^{1/2}} \qquad \text{...(iii)}$$

From Eqs. (i) and (iii),

$$K_1 = \frac{1}{\sqrt{K_2}}$$

$$\therefore \quad K_2 = \frac{1}{K_1^2}$$

21. For the reaction, $\frac{1}{2}H_2(g) + \frac{1}{2}I_2(g) \rightleftharpoons HI(g)$

$$K_c = \frac{[HI]}{[H_2]^{1/2}[I_2]^{1/2}} = 5$$

Thus, for the reaction,

$$2HI(g) \rightleftharpoons H_2(g) + I_2(g)$$

$$K_{c_1} = \frac{[H_2][I_2]}{[HI]^2} = \left(\frac{1}{K_c}\right)^2 = \left(\frac{1}{5}\right)^2 = \frac{1}{25} = 0.04$$

22. $2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g)$

$$K_p = K_c(RT)^{\Delta n_g}$$

$$\Delta n_g = 2 - 3 = -1$$

$$2.0 \times 10^{10} = K_c\,(0.0821 \times 450)^{-1}$$

$$K_c = 2.0 \times 10^{10} \times 0.082 \times 450$$

$$= 7.38 \times 10^{11}$$

23. If $n_P = n_R$, then $K_p = K_c$

[where, n_P = number of moles of products

n_R = number of moles of reactants]

24. Δ_{n_g} = Moles of gaseous products − moles of gaseous reactants

$$= 2 - 0 = 2$$

25. $A + B \rightleftharpoons C$

$$K = \frac{[C]}{[A][B]}$$

$$= \frac{\text{mol L}^{-1}}{\text{mol L}^{-1} \times \text{mol L}^{-1}}$$

$$= (\text{mol L}^{-1})^{-1} = \text{mol}^{-1}\text{ L}$$

27. $\Delta G^{\ominus} = -RT \ln K$

At the stage of half completion of reaction $[A] = [B]$. Therefore, $K = 1$. Thus, $\Delta G^{\ominus} = 0$

28. $\Delta G°$ and K are related as $\Delta G° = -2.303\, RT \log k_c$

When $\Delta G° > 0$, *i.e.*, + ve then $K_c < 1$

29. $\alpha = \dfrac{D - d}{d} = \dfrac{104.16 - 62}{62} = 0.68 = 68\%$

31. On increasing temperature, equilibrium will shift in forward direction due to decrease in intermolecular forces of solid.

32. We know that

$$pV = nRT$$

p become $\frac{1}{2}p$ and V becomes $2V$, so

$$\frac{1}{2}p \times 2V = pV = nRT$$

Hence, there is no effect in equation.

33. Since the reaction is exothermic (as $\Delta H < 0$), low temperature favours forward reaction. Moreover $n_p < n_R$, high pressure favours forward reaction.

34. In the reaction, $N_2(g) + O_2(g) \rightleftharpoons 2NO(g)$, the number of moles of reactants and products are equal, thus it remains unaffected by change in pressure.

41. $NH_2^- \rightleftharpoons NH^{2-} + H^+$

42. $Ca(OH)_2$, being an ionic compound readily gives two hydroxyl ions when dissolved in water, hence it is a diacidic base.

$$\underset{\text{diacidic base}}{Ca(OH)_2} \longrightarrow Ca^{2+} + 2OH^-$$

44. BF_3 can accept a pair of electrons, but it cannot give H^+ ions in the aqueous solution, hence BF_3 acts as Lewis acid but not as a Bronsted acid.

45. CH_3COO^-, because it is the conjugate base of weak acid.

$$CH_3COOH \rightleftharpoons CH_3COO^- + H^+$$

46. $H_2SO_4 \rightleftharpoons H^+ + HSO_4^-$

47. As the acidity or K_a value increases, pH decreases, thus, the order of pH value of the acids is

$$\underset{(3.0 \times 10^{-8})}{\text{Hypochlorous acid}} > \underset{(1.74 \times 10^{-5})}{\text{acetic acid}} > \underset{(1.8 \times 10^{-4})}{\text{formic acid}}$$

$$\left[\textbf{Note}\ K_a \propto \frac{1}{\text{pH}}\right]$$

50. $$\underset{\substack{C \\ C - C\alpha}}{CH_3COOH} + H_2O \rightleftharpoons \underset{\substack{0 \\ C\alpha}}{CH_3COO^-} + \underset{\substack{0 \\ C\alpha}}{H_3O^+} \quad \begin{matrix}\text{Initially} \\ \text{At time } t\end{matrix}$$

$$K_a = \frac{[CH_3COO^-]\ [H_3O^+]}{[CH_3COOH]}$$

Given, $K_a = 1.74 \times 10^{-5}$, $[CH_3COOH] = 0.05$ M

$[CH_3COO^-] = [H_3O^+] = \sqrt{K_a \cdot [CH_3COOH]}$

$[CH_3COO^-] = [H_3O^+] = \sqrt{1.74 \times 10^{-5} \times 0.05}$

$[CH_3COO^-] = [H_3O^+] = \sqrt{17.4 \times 10^{-6} \times 5.0 \times 10^{-2}}$

$= 9.33 \times 10^{-4}$ M

$[CH_3COO^-] = [H_3O^+] = C \cdot \alpha$

Degree of dissociation, $\alpha = \dfrac{[H_3O^+]}{C}$

$= \dfrac{9.33 \times 10^{-4}}{0.05} = 1.86 \times 10^{-2}$

pH = $-\log [H_3O^+]$

pH = $-\log [9.33 \times 10^{-4}]$

pH = $4 - 0.9699 = 3.0301$

51. $[H^+] = \sqrt{K_a \cdot C}$

where, C = initial concentration of the weak acid

$$C = \frac{[H^+]^2}{K_a} = \frac{(3.4 \times 10^{-4})^2}{1.7 \times 10^{-5}}$$

$$C = 6.8 \times 10^{-3}\ \text{M}$$

Alternatively

$$K_a = \frac{[CH_3COO^-][H^+]}{[CH_3COOH]}$$

$$1.7 \times 10^{-5} = \frac{[3.4 \times 10^{-4}]^2}{[CH_3COOH]}$$

$[\because\ [CH_3COO^-] = [H^+]]$

$[CH_3COOH] = 6.8 \times 10^{-3}$ M

52. pH = 3.76 = $-\log [H^+]$

$\log [H^+] = -3.76$

[Before taking antilog add -1 in characteristic (-3) and $+1$ in mantissa (0.76), *i.e.*, $-3.76 - 1 + 1 = \overline{4}.24$]

$\log [H^+] = \overline{4}.24$ or $[H^+] = \text{antilog } \overline{4}.24$

$[H^+] = 1.738 \times 10^{-4}$ M

54. $[Ca(OH)_2] = 0.01 \text{mol}/100 \text{ cc} = 0.1 \text{ mol L}^{-1}$

Assuming complete ionisation,

$[OH^-] = 0.2$ M, $[H^+] = \dfrac{10^{-14}}{0.2} = 5 \times 10^{-14}$

pH $= -\log [H^+]$

$= -\log (5 \times 10^{-14})$

$= 14 - 0.698 = 13.3$

55. NaOH $= [OH^-] = 10^{-3}$

$[H^+][OH^-] = 10^{-14}$

$[H^+] = 10^{-11}$

pH $= -\log [H^+]$

$= -\log [10^{-11}] = 11$

$$HCl(aq) = [H^+] = 10^{-3}$$

$$pH = -\log [10^{-3}] = 3$$

$NaCl(aq)$ = Neutral; $[H^+] = [OH^-] = 10^{-7}$

i.e., $pH = 7$

56. $pH = 5$

$$[H^+] = 10^{-5} \text{ mol L}^{-1}$$

On diluting the solution 100 times,

$$[H^+] = \frac{10^{-5}}{100} = 10^{-7} \text{ mol L}^{-1}$$

Total H^+ ion concentration = H^+ ions from acid + H^+ ions from water

$$[H^+] = 10^{-7} + 10^{-7} = 2 \times 10^{-7} \text{ M}$$

$$pH = -\log [2 \times 10^{-7}]$$

$$pH = 7 - 0.3010 = 6.699$$

57.

$$N_1V_1 = N_2V_2$$

$$10^{-3} \times 10 = N_2 \times 1000$$

$$N_2 = 10^{-5}$$

$$pH = 5$$

So, $pOH = 14 - 5 = 9$

58. pH of solution $A = 6$. Hence, $[H^+] = 10^{-6}$ mol L^{-1}

pH of solution $B = 4$. Hence, $[H^+] = 10^{-4}$ mol L^{-1}

On mixing 1 L of each solution, molar concentration of total H^+ is halved.

Total $$[H^+] = \frac{10^{-6} + 10^{-4}}{2} \text{ mol L}^{-1}$$

$$[H^+] = \frac{1.01 \times 10^{-4}}{2} = 5.05 \times 10^{-5} \text{ mol L}^{-1}$$

$$[H^+] = 5.0 \times 10^{-5} \text{ mol L}^{-1}$$

$$pH = -\log [H^+]$$

$$pH = -\log (5.0 \times 10^{-5})$$

$$pH = 5 - \log 5 = 5 - 0.6990$$

$$pH = 4.3010 \approx 4.3$$

59. pH of $HOCl = 2.85$

But, $-pH = \log [H^+]$

$\therefore$ $-2.85 = \log [H^+]$

$\Rightarrow$ $\bar{3}.15 = \log [H^+]$

$\Rightarrow$ $[H^+] = 1.413 \times 10^{-3}$

For weak monobasic acid, $[H^+] = \sqrt{K_a \times C}$

$\Rightarrow$ $$K_a = \frac{[H^+]^2}{C} = \frac{(1.413 \times 10^{-3})^2}{0.08}$$

$$= 24.957 \times 10^{-6} = 2.4957 \times 10^{-5}.$$

60. $[H^+] = \sqrt{K_a \cdot C} = \sqrt{1.74 \times 10^{-5} \times 0.01}$

$$= 4.17 \times 10^{-4}$$

$$pH = -\log[H^+] = -\log (4.17 \times 10^{-4}) = 3.4$$

61. With rise in temperature pH decreases, thus, for water becomes less than 7 at 60° C.

62. $\because$ $pH = \frac{1}{2} pK_w + \frac{1}{2} pK_a - \frac{1}{2} pK_b$

$$= \frac{1}{2} \times 14 + \frac{1}{2} \times 6 - \frac{1}{2} \times 6$$

$pH = 7$

$$\alpha = \sqrt{\frac{K_w}{K_a \times K_b}} = \sqrt{\frac{10^{-14}}{10^{-6} \times 10^{-6}}} = \sqrt{10^{-2}}$$

$$= 10^{-1} = 0.1 \quad \text{or} \quad 10\%$$

63. Ammonium acetate is a salt of weak acid and weak base. For such salts,

$$pH = 7 + \frac{pK_a - pK_b}{2}$$

$$= 7 + \frac{[-\log 1.8 \times 10^{-5}] - [-\log 1.8 \times 10^{-5}]}{2}$$

$$= 7 + \frac{4.74 - 4.74}{2} = 7.00$$

64. $Na_2CO_3 + 2H_2O \rightleftharpoons 2NaOH + H_2CO_3$. It is a salt of strong base and weak acid, so it is basic.

65. Aqueous solution of $AlCl_3$ is acidic due to the hydrolysis of aluminium ion.

$$AlCl_3 \xrightarrow{\text{Hydrolysis}} Al(OH)_3 + H^+$$

66. $K_h = Ch^2 = 0.5 \times \left(\frac{0.25}{100}\right)^2 = 3.125 \times 10^{-6}$

67. $X^- + H_2O \rightleftharpoons HX + OH^-$

$$K_h = \frac{10^{-14}}{10^{-5}} \text{ so, } h = \sqrt{\frac{K_h}{C}} = \sqrt{\frac{10^{-9}}{10^{-1}}} = 10^{-4}$$

$$= 100 \times 10^{-4} = 10^{-2}$$

So, degree of hydrolysis is 0.01%.

69. We know that,

$$pH = pK_a + \log \frac{[\text{salt}]}{[\text{acid}]}$$

$$5.5 = 4.5 + \log \frac{[\text{salt}]}{[0.1]}$$

$$[\text{salt}] = 1.0 \text{ M}$$

70. $pH = pK_a + \log \frac{[KCN]}{[HCN]} = 9.3 + \log \frac{2.5}{2.5} = 9.30$

71. When the concentration of NH_4OH (weak base) is higher than the strong acid (HCl), a mixture of weak base and its conjugate acid is obtained, which acts as basic buffer.

	NH_4OH +	HCl $\longrightarrow$	NH_4Cl +	H_2O
Initially	0.1 M	0.05 M	0	0
After reaction	0.05 M	0	0.05 M	0

72. $NH_4OH \rightleftharpoons \boxed{NH_4^+} + OH^-$

$NH_4Cl \rightleftharpoons \boxed{NH_4^+} + Cl^-$

common ion

73. $CH_3COOH \rightleftharpoons CH_3COO^- + H^+$

On adding CH_3COONa, $[H^+]$ decreases.

75. $BaSO_4 \rightleftharpoons Ba^{2+} + SO_4^{2-}$

Solubility product $= s \times s$

$15 \times 10^{-10} = s^2 : s = \sqrt{15 \times 10^{-10}} : s = 3.9 \times 10^{-5}$

76. $Ba(NO_3)_2$ gives NO_3^- and Ba^{2+} ions, hence Ba^{2+} ion increases. To keep K_{sp} constant, $[F^-]$ decreases. Thus, it is represented as $\frac{1}{2}[F^-]$.

77. The weak electrolyte A_xB_y dissociates as follows

$$\begin{array}{llll} A_xB_y & \rightleftharpoons \; xA^{y+} & + \; yB^{x-} & \\ C & 0 & 0 & \text{Initially} \\ C(1-\alpha) & xC\alpha & yC\alpha & \text{At equilibrium} \end{array}$$

where, α = degree of dissociation, C = concentration

$$K_{eq} = \frac{[A^{y+}]^x [B^{x-}]^y}{[A_xB_y]} = \frac{[xC\alpha]^x [yC\alpha]^y}{C(1-\alpha)}$$

$$= \frac{x^x \cdot C^x \cdot \alpha^x \cdot y^y \cdot C^y \cdot \alpha^y}{C} \qquad [\because 1 - a \approx 1]$$

$$= x^x \cdot y^y \cdot \alpha^{x+y} \cdot C^{x+y-1}$$

$$\alpha^{x+y} = \frac{K_{eq}}{x^x \cdot y^y \cdot C^{x+y-1}}$$

$$\alpha = \left(\frac{K_{eq}}{x^x \cdot y^y \cdot C^{x+y-1}}\right)^{\left(\frac{1}{x+y}\right)}$$

78. Among the given, AgCl is most soluble in aqueous ammonia solution because it forms a soluble complex with it.

79. $\underset{s}{Ag_2CrO_4} \longrightarrow \underset{2s}{2Ag^+} + \underset{s}{CrO_4^{2-}}$

$$K_{sp} = (2s)^2 s = 4s^3$$

$$s = \left(\frac{K_{sp}}{4}\right)^{1/3} = \left(\frac{32 \times 10^{-12}}{4}\right)^{1/3} = 2 \times 10^{-4}\ \text{M}$$

80. $\underset{(1-s)}{BaSO_4(s)} \rightleftharpoons \underset{s}{Ba^{2+}(aq)} + \underset{s}{SO_4^{2-}(aq)}$

At equili.

K_{sp} for $\quad BaSO_4 = [Ba^{2+}][SO_4^{2-}] = s \times s = s^2$

But $\quad s = 8 \times 10^{-4}$ mol dm^{-3}

$\therefore \quad K_{sp} = (8 \times 10^{-4})^2 = 64 \times 10^{-8}$

In the presence of 0.01 M H_2SO_4, the expression for K_{sp} will be

$$K_{sp} = [Ba^{2+}][SO_4^{2-}]$$

$$K_{sp} = (s) \cdot (s + 0.01)$$

(0.01 M SO_4^{2-} ions from 0.01 M H_2SO_4)

$$64 \times 10^{-8} = s \cdot (s + 0.01)$$

$$s^2 + 0.01s - 64 \times 10^{-8} = 0$$

$$s = \frac{-0.01 \pm \sqrt{(0.01)^2 + (4 \times 64 \times 10^{-8})}}{2}$$

$$= 5 \times 10^{-3}(-1 + 1.012719)$$

$$= 6.4 \times 10^{-5}\ \text{mol dm}^{-3}$$

Note $s <<< 0.01$, so, $s + 0.01 \approx 0.01$ and $64 \times 10^{-8} = s \times 0.01$

$$s = \frac{64 \times 10^{-8}}{0.01} = 6.4 \times 10^{-5}$$

81. Let s be the solubility of $Al(OH)_3$.

	$Al(OH)_3$ $\rightleftharpoons$	$Al^{3+}(aq)$ +	$3OH^-(aq)$
Concentration at $t = 0$	1	0	0
Concentration at equilibrium	$1 - s$	s	$3s$

$$K_{sp} = [Al^{3+}][OH]^{-3} = (s)(3s)^3 = 27s^4$$

$$s^4 = \frac{K_{sp}}{27} = \frac{27 \times 10^{-11}}{27 \times 10} = 1 \times 10^{-12}$$

$$s^4 = 1 \times 10^{-3}\ \text{mol L}^{-1}$$

Molar mass of $Al(OH)_3$ is 78 g. Therefore, solubility of $Al(OH)_3$ in g L^{-1} $= 1 \times 10^{-3} \times 78$ g L^{-1}

$$= 78 \times 10^{-3}\ \text{g L}^{-1}$$

$$= 7.8 \times 10^{-2}\ \text{g L}^{-1}$$

pH of the solution

$$s = 1 \times 10^{-3}\ \text{mol L}^{-1}$$

$$[OH^-] = 3s = 3 \times 1 \times 10^{-3} = 3 \times 10^{-3}$$

$$\text{pOH} = 3 - \log 3$$

$$\text{pH} = 14 - \text{pOH} = 11 + \log 3 = 11.4771$$

82. Suppose solubility of $PbCl_2$ in water is s mol L^{-1}.

$$\underset{(1-s)}{PbCl_2(s)} \rightleftharpoons \underset{s}{Pb^{2+}(aq)} + \underset{2s}{2Cl^-(aq)}$$

$$K_{sp} = [Pb^{2+}] \cdot [Cl^-]^2$$

$$K_{sp} = [s][2s]^2 = 4s^3$$

$$3.2 \times 10^{-8} = 4s^3$$

$$s^3 = \frac{3.2 \times 10^{-8}}{4} = 0.8 \times 10^{-8}$$

$$s^3 = 8.0 \times 10^{-9}$$

Solubility of $PbCl_2$, $s = 2 \times 10^{-3}$ mol L^{-1}

Solubility of $PbCl_2$ in g L^{-1} $= 278 \times 2 \times 10^{-3} = 0.556$ g L^{-1}

($\because$ Molar mass of $PbCl_2 = 207 + (2 \times 35.5) = 278$)

0.556 g of $PbCl_2$ dissolve in 1 L of water.

$\therefore$ 0.1 g of $PbCl_2$ will dissolve in $\frac{1 \times 0.1}{0.556}$ L of water

$$= 0.1798\ \text{L} = 179.8\ \text{mL} \approx 180\ \text{mL}$$

Round II

1.

$$\begin{array}{llll} N_2 & + \; 3H_2 & \rightleftharpoons \; 2NH_3 & \\ 30 & 30 & 0 & \text{Initially} \\ (30-x) & (30-x) & 2x & \text{At equilibrium} \end{array}$$

$$2x = 10, \quad \therefore \; x = \frac{10}{2} = 5 \quad [\because \text{ yield is } 50\%]$$

$$N_2 = 30 - 5 = 25 \text{ L}$$

$$H_2 = 30 - 3 \times 5 = 15 \text{ L}$$

$$NH_3 = 2 \times 5 = 10 \text{ L}$$

2. $2NaNO_3 \rightleftharpoons 2NaNO_2 + O_2$

According to Le-Chatelier principle, low pressure, high temperature and addition of $NaNO_3$ favour forward reaction.

3. Aspirin is a weak acid. Due to common ion effect, it is unionised in acid medium but completely ionised in alkaline medium.

4. For the precipitation of an electrolyte, it is necessary that the ionic product must exceed its solubility product.

5.

$$\begin{array}{llll} & NH_4OH & \rightleftharpoons \; NH_4^+ & + \; OH^- \\ \text{At } t = 0 & 0.1 \text{ M} & 0 & 0 \\ \text{At equilibrium} & \left(0.1 - \frac{1.3 \times 0.1}{100} \text{ M}\right) & 0.0013 \text{ M} & (0.0013 \text{ M}) \\ & = 0.1 \text{ M} & & \end{array}$$

$$[OH^-] = 0.0013 \text{ M} = 13 \times 10^{-4} \text{ M}$$

$$pOH = -\log [OH^-] = -\log (13 \times 10^{-4}) = 2.89$$

$$pH = 14 - 2.89 = 11.11$$

6.

$$\begin{array}{llll} & C_2H_6(g) & \rightleftharpoons \; C_2H_4(g) & + \; H_2(g) \\ \text{Initial pressure} & 4.0 \text{ atm} & 0 & 0 \\ \text{Equili. pressure} & (4.0 - p) \text{ atm} & p & p \end{array}$$

$$K_p = \frac{p_{C_2H_4} \cdot p_{H_2}}{p_{C_2H_6}} = \frac{p.p}{4.0 - p}$$

$$0.04 = \frac{p^2}{4.0 - p} \quad \text{or} \quad 0.16 - 0.04p = p^2$$

$$p = \frac{-0.04 \pm \sqrt{0.0016 - 4(-0.16)}}{2}$$

$$p = \frac{-0.04 \pm 0.80}{2}$$

$$p = 0.38 \qquad \text{(by taking positive value)}$$

Hence, $p_{C_2H_6} = 4.0 - 0.38 = 3.62$ atm

7. First dissociation

$$X(OH)_3 \longrightarrow X(OH)_2^+ + OH^-$$

Second dissociation

$$X(OH)_2^+ \longrightarrow X(OH)^{2+} + OH^-$$

$$\text{Total } [OH^-] = 4 \times 10^{-3} + 2 \times 10^{-3} = 6 \times 10^{-3}$$

$$pOH = 3 - \log 6 = 3 - 0.78 = 2.22$$

$$pH = 14 - 2.22 = 11.78$$

8. Conjugate acids of the given bases are, H_2O, ROH, CH_3COOH and HCl. Order of acidic strength is

$$HCl > CH_3COOH > H_2O > ROH$$

Hence, order of basic strength of their conjugate bases is

$$R\bar{O} > \bar{O}H > CH_3CO\bar{O} > Cl^-$$

9.
(i) KNO_3 is a salt of strong acid and strong base, hence its aqueous solution is neutral; pH = 7

(ii) CH_3COONa is a salt of weak acid and strong base, hence, its aqueous solution is basic; pH > 7.

(iii) NH_4Cl is a salt of strong acid and weak base, hence its aqueous solution is acidic; pH < 7.

(iv) $C_6H_5COONH_4$ is a salt of weak acid, C_6H_5COOH and weak base, NH_4OH. But NH_4OH is slightly stronger than C_6H_5COOH. Hence, pH is slightly > 7.

Therefore, increasing order of pH of the given salts is

$$NH_4Cl < KNO_3 < C_6H_5COONH_4 < CH_3COONa$$

10.

$$C_6H_5COOAg(s) \rightleftharpoons C_6H_5COO^- + Ag^+; \quad K_1 = K_{sp}$$

$$C_6H_5COO^- + H^+ \rightleftharpoons C_6H_5COOH; \quad K_2 = \frac{1}{K_a}$$

$$C_6H_5COOAg(s) + H^+ \rightleftharpoons C_6H_5COOH + Ag^+; \quad K_3 = \frac{K_{sp}}{K_a}$$

$$K_3 = \frac{[C_6H_5COOH][Ag^+]}{[H^+]} = \frac{s \cdot s}{[H^+]} = \frac{s^2}{[H^+]} = \frac{K_{sp}}{K_a}$$

where, s is the solubility of C_6H_5COOAg.

In a buffer of pH = 3.19

$$\log [H^+] = -3.19 = \bar{4}.81$$

$$[H^+] = \text{antilog } \bar{4}.81 = 6.46 \times 10^{-4}$$

$$\frac{s^2}{[H^+]} = \frac{K_{sp}}{K_a} \text{ or } s^2 = \frac{K_{sp} \times [H^+]}{K_a}$$

$$s = \sqrt{\frac{2.5 \times 10^{-13} \times 6.46 \times 10^{-4}}{6.46 \times 10^{-5}}}$$

$$s = \sqrt{2.5 \times 10^{-13} \times 10}$$

$$s = 1.6 \times 10^{-6} \text{ M (in buffer)}$$

In aqueous solution, solubility of C_6H_5COOAg :

$$K_{sp} = [C_6H_5COO^-][Ag^+] = s \cdot s = s^2$$

$$s = \sqrt{K_{sp}} = \sqrt{2.5 \times 10^{-13}} = 5 \times 10^{-7} \text{ M}$$

$$\frac{s_{(C_6H_5COOAg)} \text{ in buffer}}{s_{(C_6H_5COOAg)} \text{ in aqueous solution}} = \frac{1.6 \times 10^{-6}}{5.0 \times 10^{-7}} = 3.2$$

C_6H_5COOAg is 3.2 times more soluble in buffer than in pure water.

11. $CH_2ClCOOH + H_2O \rightleftharpoons CH_2ClCOO^- + H_3O^+$

$$K_a = 1.35 \times 10^{-3} \qquad \text{(given)}$$

$$pK_a = -\log K_a = -\log [1.35 \times 10^{-3}]$$

$$= 3 - 0.13 = 2.87$$

By Ostwald's dilution law,

$$[H_3O^+] = \sqrt{K_a \cdot C} = \sqrt{1.35 \times 10^{-3} \times 0.1}$$

$$[H_3O^+] = 1.16 \times 10^{-2} M$$

$$\text{pH of acid} = -\log [H_3O^+] = -\log (1.16 \times 10^{-2})\ M$$

$$pH = 2 - 0.06 = 1.94$$

0.1 M $CH_2ClCOONa$ (sod. chloroacetate) is basic due to hydrolysis.

$$CH_2ClCOO^- + H_2O \rightleftharpoons CH_2ClCOOH + OH^-$$

For a salt of strong base + weak acid,

$$pH = 7 + \frac{pK_a + \log C}{2} = 7 + \frac{2.87 + \log 0.1}{2}$$

$$pH = 7 + \frac{2.87 + (-1)}{2} = 7 + \frac{1.87}{2}$$

$$= 7 + 0.935 \approx 7.94$$

$$pH = 7.94$$

12. $Ag_2CrO_4 \rightleftharpoons 2Ag^+ + CrO_4^{2-}; \qquad K_{sp} = 1.1 \times 10^{-12}$

$s \qquad 2s \qquad s$ (Solubility of Ag_2CrO_4 is s mol L^{-1})

$$K_{sp} = [Ag^+]^2[CrO_4^{2-}]$$

$$K_{sp} = (2s)^2 \cdot s = 4s^3$$

or $$s^3 = \frac{K_{sp}}{4} = \frac{1.1 \times 10^{-12}}{4} = 0.275 \times 10^{-12}$$

$$s^3 = 2.75 \times 10^{-13}$$

$$3 \log s = \log 2.75 \times 10^{-13}$$

$$3 \log s = -13 + 0.4393 = -12.5607$$

$$\log s = \frac{-12.5607}{3} = -4.1869 = \bar{5}.8131$$

$$s = \text{antilog } \bar{5}.8131 = 6.503 \times 10^{-5}\ M$$

Solubility of $[Ag_2CrO_4] = 6.503 \times 10^{-5}$ M

$$AgBr \rightleftharpoons Ag^+ + Br^-; \quad K_{sp} = 5.0 \times 10^{-13}$$

$s \qquad s \qquad s$

(Solubility of AgBr is s mol L^{-1})

$$K_{sp} = [Ag^+][Br^-] = s \cdot s = s^2$$

or $$s = \sqrt{K_{sp}} = \sqrt{5.0 \times 10^{-13}}$$

$$= \sqrt{50 \times 10^{-14}}$$

$$s = 7.07 \times 10^{-7}\ M$$

Ratio of their solubilities

$$\frac{s\,(Ag_2CrO_4)}{s\,(AgBr)} = \frac{6.50 \times 10^{-5}\ M}{7.07 \times 10^{-7}\ M} = 91.93 \approx 92$$

Ag_2CrO_4 is 92 times more soluble than AgBr.

13. (a) Molecular mass of TlOH = 204 + 16 + 1 = 221 g mol^{-1}

Conc. in mol L^{-1} (molarity)

$$= \frac{\text{Mass of TlOH (g)}}{\text{Molar mass of TlOH} \times \text{Volume of solution (L)}}$$

$$= \frac{2}{221 \times 2} = 0.00452 = 4.52 \times 10^{-3}\ M$$

$$pH = -\log [OH^-] = -\log [4.52 \times 10^{-3}]$$

$$pOH = 3 + (-0.6551) = 2.344$$

$$pH + pOH = 14$$

or $$pH = 14 - 2.334 = 11.656 \approx 11.66$$

(b) Molecular mass of $Ca(OH)_2 = 40 + [(16+1) \times 2]$

$$= 74 \text{ g mol}^{-1}$$

Molarity, M

$$= \frac{\text{Mass of } Ca(OH)_2(g) \times 1000}{\text{Molar mass of } Ca(OH)_2 \times \text{Volume of solution (mL)}}$$

$$M = \frac{0.3 \times 1000}{74 \times 500} = 0.0081$$

One mole of $Ca(OH)_2$ gives 2 moles of OH^-. So

$$[OH^-] = 2 \times 0.0081 = 0.0162\ M$$

$$pOH = -\log [OH^-] = -\log [0.0162]$$

$$pOH = -\log [1.62 \times 10^{-2}]$$

$$= 2 + (-0.2095) = 1.7905 \approx 1.79$$

$$pH + pOH = 14 \quad \text{or } pH = 14 - 1.79 = 12.21$$

(c) Molecular mass of NaOH = 23 + 16 + 1 = 40

$$M = \frac{\text{Mass of NaOH}(g) \times 1000}{\text{Molar mass of NaOH} \times \text{Volume of solution (mL)}}$$

$$= \frac{0.3 \times 1000}{40 \times 200} = 0.0375$$

$$pOH = -\log [0.0375] = -\log [3.75 \times 10^{-2}]$$

$$pOH = 2 + (-0.5740) = 1.426 \approx 1.43$$

$$pH + pOH = 14 \quad \text{or} \quad pH = 14 - 1.43 = 12.57$$

(d) In case of dilution $M_1V_1 = M_2V_2$

$$13.6 \times 1 \text{ (mL)} = M_2 \times 1000 \text{ (mL)}$$

$$M_2 = \frac{13.6 \times 1}{1000} = 0.0136 = 1.36 \times 10^{-2}\ M$$

$$pH = -\log [1.36 \times 10^{-2}]$$

$$= 2 + (-0.1335) = 1.8665$$

$$pH = 1.87$$

14. 90.55% CO by mass means 90.55 g CO and 9.45 g CO_2 are present in 100 g mixture.

No. of moles of CO, $n_{CO} = \frac{90.55}{28} = 3.234$ mol

(Molar mass of CO = 28 g mol^{-1})

No. of moles of CO_2, $n_{CO_2} = \frac{9.45}{44} = 0.215$ mol

(Molar mass of CO_2 = 44 g mol^{-1})

Partial pressure of CO, $p_{CO} = x_{CO} \cdot p_{total}$

$$\left(x_{CO} = \frac{3.234}{3.234\ +\ 0.215} = 0.938\right)$$

$$p_{CO} = 0.938 \times 1\,\text{atm} = 0.938\ \text{atm}$$

Similarly, $p_{CO_2} = x_{CO_2} \cdot p_{total}$

$$\left(x_{CO_2} = \frac{0.215}{3.234\ +\ 0.215} = 0.062\right)$$

$$p_{CO_2} = 0.062 \times 1\,\text{atm} = 0.062\ \text{atm}$$

$$C(s)\ +\ CO_2\,(g) \rightleftharpoons 2\ CO(g)$$

$$K_p = \frac{p^2_{CO}}{p_{CO_2}} = \frac{(0.938)^2}{0.062} = 14.19$$

$$\Delta n_g = 2 - 1 = 1$$

$$K_p = K_c\ (RT)^{\Delta n_g}$$

$$K_c = \frac{K_p}{RT} \qquad (\because\ \Delta n_g = 1)$$

$$K_c = \frac{14.19}{0.0821 \times 1127} = 0.15336 \approx 0.153$$

15. $2BrCl(g) \rightleftharpoons Br_2(g)\ +\ Cl_2(g);\ K_c = 32$ at 500 K

Initial conc. 3.30×10^{-3} mol L^{-1} 0   0

Equili. conc. $(3.30 \times 10^{-3} - x)$ mol L^{-1} $\frac{x}{2}$ mol L^{-1} $\frac{x}{2}$ mol L^{-1}

$$K_c = \frac{[Br_2]\ [Cl_2]}{[BrCl]^2}$$

$$= \frac{x/2 \cdot x/2}{(3.30 \times 10^{-3} - x)^2} = 32$$

$$\frac{x^2}{4 \times (3.30 \times 10^{-3} - x)^2} = 32$$

$$\frac{x}{2 \times (3.30 \times 10^{-3} - x)} = \sqrt{32} = 5.656$$

$$\frac{x}{3.30 \times 10^{-3} - x} = 2 \times 5.656 = 11.312$$

$$x = 11.312(3.30 \times 10^{-3} - x)$$

$$x = 0.03732 - 11.312x$$

$$x + 11.312\ x = 0.03732$$

$$x = \frac{0.03732}{12.312} = 3.032 \times 10^{-3}\ \text{mol L}^{-1}$$

$$[BrCl]_{equili.} = (3.30 \times 10^{-3} - 3.032 \times 10^{-3})\ \text{mol L}^{-1}$$

$$= 2.68 \times 10^{-4}\ \text{mol L}^{-1}$$

16. $\text{pOH} = 14 - \text{pH} = 14 - 10.65 = 3.35$

$$\text{pOH} = -\log\,[OH^-]$$

$$-3.35 = \log\,[OH^-]$$

$$\therefore \quad [OH^-] = 4.466 \times 10^{-4}\ M$$

$$Ca(OH)_2 = Ca^{2+} + \underset{4.466 \times 10^{-4}\ M}{2OH^-}$$

$$\frac{[OH^-]}{2} = [Ca(OH)_2] = 2.2335 \times 10^{-4}\ M$$

Hence, in 250 mL, moles of

$$Ca(OH)_2 = \frac{2.2335 \times 10^{-4} \times 250}{1000} = 0.56 \times 10^{-4}$$

17. $\text{pH} = -\log\,(5 \times 10^{-10}) + \log\left[\frac{5 \times V}{V+10} \bigg/ \frac{10 \times 2}{V+10}\right]$

$$9 = -\log\,(5 \times 10^{-10}) + \log\frac{V}{4}$$

On solving, $V = 2$ mL

18. Weak monoacidic base, *e.g.*, BOH is neutralised as follows

$$BOH + HCl \longrightarrow BCl + H_2O$$

At equivalence point, all BOH get converted into salt. Remember! the concentration of H$^+$ (or pH of solution) is due to hydrolysis of the resultant salt (BCl, cationic hydrolysis here.)

$$\underset{C\,(1-h)}{B^+} + H_2O \rightleftharpoons \underset{Ch}{BOH} + \underset{Ch}{H^+}$$

Volume of HCl used up,

$$V_a = \frac{N_b V_b}{N_a} = \frac{2.5 \times 2 \times 15}{2 \times 5} = 7.5\ \text{mL}$$

Concentration of salt,

$$[BCl] = \frac{\text{conc. of base}}{\text{total volume}}$$

$$= \frac{2 \times 2.5}{5\ (7.5 + 2.5)}$$

$$= \frac{1}{10} = 0.1$$

$$K_h = \frac{Ch^2}{1-h} = \frac{K_w}{k_b}$$

(h should be estimated whether that can be neglected or not)

On calculating, $h = 0.27$ (significant, not negligible)

$$[H^+] = Ch = 0.1 \times 0.27 = 2.7 \times 10^{-2}\ M$$

19.

Salt	Solubility product	Solubility
MX	$S_1^2 = 4.0 \times 10^{-8}$	$S_1 = 2 \times 10^{-4}$
MX_2	$4S_2^3 = 3.2 \times 10^{-14}$	$S_2 = 2 \times 10^{-5}$
M_3X	$27S_3^4 = 2.7 \times 10^{-15}$	$S_3 = 1 \times 10^{-4}$

Thus, solubility order is $MX > M_3X > MX_2$.

20. $2NH_3 \rightleftharpoons N_2\ +\ 3H_2$

Initial moles a 0   0

At equilibrium $(a - 2x)$ x $3x$

Initial pressure of NH$_3$ if 'a' mole = 15 atm at 27°C. The pressure of 'a' mole of NH$_3$ = p atm at 347°C

$$\therefore \qquad \frac{15}{300} = \frac{p}{620}$$

$$\therefore \qquad p = 31\ \text{atm}$$

At constant volume and at 347°C,

$$\text{mole} \propto \text{pressure}$$

$$a \propto 31 \qquad \text{(before equilibrium)}$$

$$\therefore \quad (a-2x) \propto 50 \qquad \text{(after equilibrium)}$$

$$\therefore \quad \frac{(a-2x)}{a} = \frac{50}{31}$$

$$\therefore \quad x = \frac{19}{62}a$$

$$\therefore \text{ \% of } NH_3 \text{ decomposed} = \frac{2x}{a} \times 100 = \frac{2 \times 19a}{62 \times a} \times 100 = 61.29\%$$

21. $FeO(s) + CO(g) \rightleftharpoons Fe(s) + CO_2(g)$;

Initial pressure 1.4 atm 0.80 atm

$$K_p = 0.265 \text{ at } 1050 \text{ K}$$

$$Q_p = \frac{p_{CO_2}}{p_{CO}} = \frac{0.80}{1.4} = 0.571 \quad [\because \text{Fe and FeO are solids.}]$$

$Q_p > K_p$, the reaction will go in reverse direction. Due to this pressure of CO_2 will decrease and that of CO will increase to attain equilibrium. Hence, $p_{CO_2} = (0.80 - p)$ and $p_{CO} = (1.4 + p)$

(Suppose p is the decrease in pressure of CO_2 and p is the increase in pressure of CO).

$$K_p = \frac{p_{CO_2}}{p_{CO}} = 0.265 = \frac{(0.80 - p)}{(1.4 + p)}$$

$$1.265\,p = 0.80 - 0.371$$

$$1.265\,p = 0.429$$

$$p = \frac{0.429}{1.265} = 0.339 \text{ atm}$$

Hence, at equilibium,

$$p_{CO_2} = 0.80 - 0.339 = 0.461 \text{ atm}$$

and $$p_{CO} = 1.4 + 0.339 = 1.739 \text{ atm}$$

22. $[S^{2-}] = 1 \times 10^{-19}$ M

10 mL of S^{2-} is mixed with 5 mL of 0.04 M solution of different solutes so that final volume of solution is 15 mL.

$$\therefore \quad [S^{2-}]_{mix} = \frac{10 \times 10^{-19}}{15} = 6.67 \times 10^{-20} \text{ M}$$

$$[M^{2+}] = \frac{5 \times 0.04}{15} = 1.33 \times 10^{-2} \text{ M}$$

where, $[M^{2+}] = Fe^{2+}, Mn^{2+}, Zn^{2+}$ or Cd^{2+}

$$[M^{2+}][S^{2-}]\ 1 = .33 \times 10^{-2} \times 6.67 \times 10^{-20}$$

Ionic product of $[M^{2+}][S^{2-}] = 8.87 \times 10^{-22}$

IP of $[M^{2+}][S^{2-}] > K_{sp}$ of ZnS and CdS

So, these ($CdCl_2$ and $ZnCl_2$) are precipitated as CdS and ZnS.

23. Since, value of K increases with rise in temperature, the reaction is endothermic.

Since, number of moles of gaseous products are greater than the number of moles of gaseous reactants. Thus, higher pressure favours the backward reaction, *i.e.,* more $N_2O_4(g)$ will be obtained, if $p_{product} > p_{reactant}$.

$$\Delta n_g = n_p - n_r > 0 \qquad \therefore \quad \Delta S > 0$$

24. $N_2O_4 \rightleftharpoons 2NO_2$

a 0 Initial

$a(1-\alpha)$ $2a\alpha$ At equilibrium

$$\text{Vapour density} = \frac{46}{1+\alpha} : 30.67$$

$$\text{So,} \quad (1+\alpha) = \frac{46}{30.67} = 1.5 \quad \text{or} \quad \alpha = 50\%$$

$$\text{Total pressure} = \frac{1.5 \times 1.5 \times 0.082 \times 300}{8.2} = 6.75 \text{ atm}$$

$$\text{So,} \quad K_p = \frac{4\alpha^2}{1-\alpha^2} = 9 \text{ atm}$$

$$\text{Density of mixture} = \frac{138}{8.2} \text{ g/L} = 16.83 \text{ g/L}$$

25. $$\text{Reaction quotient} = \frac{p^2_{NH_3}}{p_{N_2} \cdot p^3_{H_2}} = \frac{(0.05 \text{ atm})^2}{(0.05 \text{ atm})(3.0 \text{ atm})^3}$$

$$= 1.85 \times 10^{-3} \text{ atm}^{-2}$$

The value of K_p is 4.28×10^{-5} atm^{-2}. The numerical value of Q_p is more than that of K_p. The reaction goes towards the left and thus, ammonia decomposes into H_2 and N_2.

26. In aqueous solution, a salt of weak acid and a weak base acts as a buffer solution. The pH of a buffer solution do not change on dilution. Thus, pH of 0.01 M CH_3COONH_4 will not change on dilution. HCO_3^- from $NaHCO_3$ and $H_2PO_4^-$ from NaH_2PO_4 are amphiprotic anions. The pH of solution containing amphiprotic anions do not change on dilution.

27. $K_{sp} = 1.1 \times 10^{-11} = (1.4 \times 10^{-4})^{x+y} \cdot x^x \cdot y^y$

So, we have $x + y = 3$

$$\text{So,} \quad x^x \cdot y^y = \frac{1.1 \times 10^{-11}}{1.4 \times 1.4 \times 1.4 \times 10^{-12}} = 4$$

Hence, $x = 1,\ y = 2$

or $y = 1,\ x = 2.$

28. According to Le-Chatelier's principle with increase of pressure, equilibrium shifts in that direction in which lesser number of gaseous moles are produced.

29. In biological systems buffer system of carbonic acid and sodium bicarbonate is found in our blood. It maintains the pH of blood to a constant value of about 7.4.

30. H_2S is a weak acid and also a weak electrolyte, thus its ionisation is suppressed when small amount of strong electrolyte like HCl is added due to common ion effect.

$$H_2S \rightleftharpoons 2H^+ + S^{2-}$$

$$HCl \longrightarrow \underbrace{H^+}_{\text{common ion}} + Cl^-$$

31. $$\begin{array}{l} (NH_4)_2CO_3 \longrightarrow 2NH_4^+ + CO_3^{2-} \\ \qquad 2H_2O \longrightarrow 2OH^- + 2H^+ \\ \qquad\qquad\qquad\quad \downarrow \qquad \downarrow \\ \qquad\qquad\quad NH_4OH + H_2CO_3 \\ \qquad\qquad\quad \text{weak base} \quad \text{weak acid} \end{array}$$

If K_b of $NH_4OH > K_a$ of H_2CO_3

The solution is basic.

Or if K_a of $H_2CO_3 > K_b$ of NH_4OH the solution is acidic.

32. $PCl_5 \longrightarrow PCl_3 + Cl_2$

At constant pressure, when He is added to the equilibrium, volume increases. Thus, in order to maintain the K constant, degree of dissociation of PCl_5 increases.

He is unreactive towards chlorine gas.

33. $CaCO_3(s) \overset{\Delta}{\rightleftharpoons} CaO(s) + CO_2(g) \qquad K_{p_1} = 8 \times 10^{-2}$

$$CO_2(g) + C(s) \longrightarrow 2CO(g) \qquad K_{p_2} = 2$$

$$K_p{}' = K_{p_1} \times K_{p_2}$$

$$= 8 \times 10^{-2} \times 2 = 16 \times 10^{-2}$$

$$K_p{}' = (p_{CO}(g))^2$$

$$p_{CO} = \sqrt{K_p{}'} = \sqrt{16 \times 10^{-2}} = 4 \times 10^{-1}$$

$$= 0.4 \text{ atm}$$

34. $CO_2(g) + C(s) \rightleftharpoons 2CO(g)$

$$\begin{array}{llll} 0.5 & & & \text{Initial} \\ (0.5 - x) & & 2x & \text{At equilibrium} \end{array}$$

Total pressure $= 0.5 - x + 2x = 0.5 + x$

$$0.5 + x = 0.8$$

$$x = 0.8 - 0.5 = 0.3$$

$$p_{CO} = 2x = 2 \times 0.3 = 0.6 \text{ atm}$$

$$K = \frac{(p_{CO})^2}{p_{CO_2}} = \frac{(0.6)^2}{0.2} = 1.8 \text{ atm}$$

35. $K_p = K_c(RT)^{\Delta n}$

Here, $\qquad K_p = K_c, \quad \Delta n = 2 - 1 = 1$

$$(RT)^{\Delta n} = 1$$

$$(0.0821 \times T) = 1$$

$$T = \frac{1}{0.0821} = 12.18 \text{ K},$$

36. % of unprecipitated $Ag^+ = \dfrac{\text{unprecipitated } Ag^+}{\text{total } Ag^+ \text{ taken}} \times 100$

$$= \frac{1 - \left(\dfrac{149}{150}\right)}{1} \times 100 = 0.666\%$$

37. $K_{sp} = [Ag^+][IO_3^-]$

$$= \frac{(10 - x)}{500} \cdot \frac{(3 - x)}{500} = \frac{6.66 \times 10^3 \times 2}{25 \times 10000} = 5.3 \times 10^{-8}$$

38. Moles of $AgIO_3$ precipitated $= \dfrac{149}{150}$ millimol

Mass of $AgIO_3$ precipitated $= 285 \times \dfrac{149}{150}$ g $= 283.1$ g

39. $N_2(g) + O_2(g) \longrightarrow 2NO(g)$

$$K_c = \frac{[NO]^2}{[N_2][O_2]} = 4 \times 10^{-4}$$

$$2NO(g) \longrightarrow N_2(g) + O_2(g)$$

$$K_c{}' = \frac{1}{K_c} = \frac{[N_2][O_2]}{[NO]^2}$$

$$= \frac{1}{4 \times 10^{-4}} = \frac{10^4}{4}$$

$$NO(g) \longrightarrow \frac{1}{2} N_2(g) + \frac{1}{2} O_2(g)$$

$$K_c{}'' = \frac{[N_2]^{1/2}[O_2]^{1/2}}{[NO]}$$

$$= \sqrt{K_c{}'} = \sqrt{\frac{10^4}{4}} = \frac{100}{2} = 50$$

40. $HQ \longrightarrow H^+ + Q^-$

$$[H^+] = \sqrt{K_a C} \qquad \text{(by Ostwald's dilution law)}$$

$$[H^+] = 10^{-pH} = 10^{-3} \text{ M}$$

$$C = 0.1 \text{ M}$$

Thus, $\qquad 10^{-3} = \sqrt{K_a \times 0.1}$

$$10^{-6} = K_a \times 0.1$$

$\therefore \qquad K_a = 10^{-5}$

41. Let molar solubility of $Cr(OH)_3 = s$ mol L^{-1}

$$Cr(OH)_3(s) \rightleftharpoons \underset{s}{Cr^{3+}}(aq) + \underset{3s}{3OH^-}(aq)$$

$$K_{sp} = 1.6 \times 10^{-30}$$

$$= [Cr^{3+}][OH^-]^3$$

$$= (s)(3s)^3 = 27s^4$$

$\therefore \qquad s^4 = \dfrac{1.6 \times 10^{-30}}{27}$

$\therefore \qquad s = \sqrt[4]{\dfrac{1.6 \times 10^{-30}}{27}}$

42. Only in reaction (II) $H_2PO_4^-$, gives H^+ to H_2O, thus behaves as an acid.

43. $H_2CO_3 \rightleftharpoons H^+ + HCO_3^-; \quad K_1 = 4.2 \times 10^{-7}$

$HCO_3^- \rightleftharpoons H^+ + CO_3^{2-}; \qquad K_2 = 4.8 \times 10^{-11}$

$$K_1 >> K_2$$

$\therefore \qquad [H^+] = [HCO_3^-]$

$$K_2 = \frac{[H^+][CO_3^{2-}]}{[HCO_3^-]}$$

So, $\qquad [CO_3^{2-}] = K_2 = 4.8 \times 10^{-11}$

44. $K_{sp} = [Ag^+][Br^-] = 5.0 \times 10^{-13}$

$$[Ag^+] = 0.05\text{ M}$$

$$[Br^-] = \frac{5.0 \times 10^{-13}}{0.05} = 1 \times 10^{-11}\text{ M}$$

Moles of KBr $= 1 \times 10^{-11} \times 1 = 1 \times 10^{-11}$

Weight of KBr $= 1 \times 10^{-11} \times 120 = 1.2 \times 10^{-9}$ g

45. $Mg(OH)_2 \rightleftharpoons Mg^{2+} + 2OH^-$

$$K_{sp} = [Mg^{2+}][OH^-]^2$$

$$[OH^-] = \sqrt{\frac{K_{sp}}{[Mg^{2+}]}} = 10^{-4}$$

$$\text{pOH} = 4$$

and $\quad \text{pH} = 10$

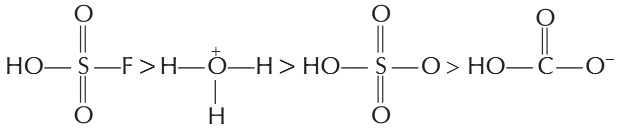
46. $K_{sp}[BaCO_3] = [Ba^{2+}][CO_3^{2-}]$

$$[Ba^{2+}] = \frac{K_{sp}}{[CO_3^{2-}]} = \frac{5.1 \times 10^{-9}}{1 \times 10^{-4}}$$

$$[Ba^{2+}] = 5.1 \times 10^{-5}\text{ M.}$$

47. As equation 'III' is obtained on adding equation 'I' and equation 'II', so $K_3 = K_1 \cdot K_2$.

48. Acidity order



$$HO-\overset{O}{\underset{O}{\overset{\|}{\underset{\|}{S}}}}-F > H-\overset{+}{\underset{H}{O}}-H > HO-\overset{O}{\underset{O}{\overset{\|}{\underset{\|}{S}}}}-O > HO-\overset{O}{\overset{\|}{C}}-O^-$$

(conjugate anion decreases acidity)

49.

Initially $\quad X \rightleftharpoons 2Y \quad$ 1 $\quad$ 0

At equilibrium $\quad 1 - x \quad 2x$

Total number of moles $= 1 + x$

$$K_{p_1} = \frac{\left[\frac{2x}{1+x} \cdot p_1\right]^2}{\left(\frac{1-x}{1+x}\right) \cdot p_1} = \frac{4x^2}{(1-x)} \cdot \frac{p_1}{(1+x)}$$

Initially $\quad Z \rightleftharpoons P + Q \quad$ 1 $\quad$ 0 $\quad$ 0

At equilibrium $\quad 1 - x \quad x \quad x$

Similarly, $\quad K_{p_2} = \frac{x^2}{(1-x)} \cdot \frac{p_2}{(1+x)}$

$$\frac{K_{p_1}}{K_{p_2}} = \frac{1}{9}$$

So, $\quad \frac{4 \times p_1}{p_2} = \frac{1}{9}$

$\Rightarrow \quad \frac{p_1}{p_2} = \frac{1}{36}$

50. For salt of weak acid and weak base

$$\text{pH} = -\frac{1}{2}[\log K_a + \log K_w - \log K_b]$$

$$= \frac{1}{2}\text{p}K_a + \frac{1}{2}\text{p}K_w - \frac{1}{2}\text{p}K_b$$

$$= \frac{1}{2} \times 4.80 + 7 - \frac{1}{2} \times 4.78 = 7.01$$

51. $AgIO_3(s) \rightleftharpoons Ag^+(aq) + IO_3^-(aq)$

Let solubility of $AgIO_3$ be S

$$K_{sp} = [Ag^+][IO_3^-]$$

$$1.0 \times 10^{-8} = S^2 \quad \text{or} \quad S = 1 \times 10^{-4}\text{ mol/L}$$

In 1000 mL moles of $AgIO_3$ dissolved $= 1 \times 10^{-4}$ mol

In 100 mL moles of $AgIO_3$ dissolved $= 1 \times 10^{-5}$ mol

Mass of $AgIO_3$ in 100 mL $= 1 \times 10^{-5} \times 283 = 2.83 \times 10^{-3}$

52. Equilibrium constant for the reaction,

$$SO_2(g) + \frac{1}{2}O_2(g) \rightleftharpoons SO_3(g)$$

$$K_c = \frac{1}{4.9 \times 10^{-2}}$$

and for, $2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g)$

$$K_c = \left(\frac{1}{4.9 \times 10^{-2}}\right)^2$$

$$= \frac{10^4}{(4.9)^2} = 416.490$$

53. $\quad PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$

Initially $\quad$ 1 $\quad$ 0 $\quad$ 0

At equilibrium $\quad (1 - x) \quad x \quad x$

Total number of moles at equilibrium $= (1 - x) + x + x = 1 + x$

$$p_{PCl_3} = \left[\frac{x}{1+x}\right] \times p$$

54. $\quad NH_4HS(s) \rightleftharpoons NH_3(g) + H_2S(g)$

Initially $\quad$ 1 $\quad$ 0.5 $\quad$ 0

At equilibrium $\quad (1 - x) \quad (0.5 + x) \quad x$

Total pressure at equilibrium $= p_{NH_3} + p_{H_2S}$

$$= 0.5 + x + x = 0.84$$

$\therefore \quad x = 0.17$ atm

$\therefore \quad p_{NH_3} = 0.50 + 0.17 = 0.67$ atm

$\quad p_{H_2S} = 0.17$ atm

$\therefore \quad K_p = p_{NH_3} \cdot p_{H_2S} = 0.67 \times 0.17 = 0.114$ atm

55. $2NO_2(g) \rightleftharpoons 2NO(g) + O_2(g)$

$$K_c = 1.8 \times 10^{-6} \text{ at } 184^\circ\text{ C } (= 457\text{ K})$$

$$R = 0.00831\text{ kJ mol}^{-1}\text{ K}^{-1}$$

$$K_p = K_c\,(RT)^{\Delta n_g}$$

where,

$$\Delta n_g = (\text{gaseous products} - \text{gaseous reactants})$$
$$= 3 - 2 = 1$$
$$\therefore \quad K_p = 1.8 \times 10^{-6} \times 0.00831 \times 457$$
$$= 6.836 \times 10^{-6} > 1.8 \times 10^{-6}$$

Thus, $K_p > K_c$

56. Conjugate base is formed by loss of H^+.

$$OH^- \longrightarrow \underset{\text{conjugate base}}{O^{2-}} + H^+$$

O^{2-} is the conjugate base of OH^-.

57. $MX_2 \rightleftharpoons \underset{S}{M^{2+}} + \underset{2S}{2X^-}$

$$K_{sp} = [M^{2+}][X^-]^2$$

If solubility be S, then

$$K_{sp} = (S)(2S)^2 = 4S^3$$
$$4S^3 = 4 \times 10^{-12}$$
$$\therefore \quad S = 1 \times 10^{-4}\ \text{M}$$
$$\therefore \quad M^{2+} = S = 1 \times 10^{-4}\ \text{M}$$

58. $K_p = K_c\,(RT)^{\Delta n_g}$

Δn_g = Sum of coefficients of gaseous products – sum of coefficients of gaseous reactants.

$$CO(g) + Cl_2(g) \longrightarrow COCl_2(g)$$
$$\therefore \quad \Delta n_g = 1 - 2 = -1$$
$$\therefore \quad K_p = K_c\,(RT)^{-1}$$
$$\therefore \quad \frac{K_p}{K_c} = (RT)^{-1} = \frac{1}{(RT)}$$

59.

Δn_g = – ve	$\Delta H°$ = – ve
Takes place with decrease in number of moles or pressure, hence increase in pressure shifts equilibrium in forward side.	Takes place with evolution of heat or increase in temperature, hence decrease in temperature shifts this equilibrium in forward side.

60. $HPO_4^{2-} + H_2O \rightleftharpoons H_2PO_4^- + OH^-$

$$HPO_4^{2-} + H_2O \rightleftharpoons PO_4^{3-} + H_3O^+$$

$H_2PO_2^-$ is a conjugate base of H_3PO_2 (a monobasic acid) and does not give H^+, HPO_3^{2-} is a conjugate base of H_2PO_3 and does not ionise further, since H_3PO_3 is a dibasic acid.

7 Redox Reactions

JEE Main MILESTONE

- Oxidation Number
- Oxidation and Reduction
- Oxidising and Reducing Agent
- Redox Reactions
- Molecular and Ionic Equations
- Balancing of Redox Reactions

7.1 Oxidation Number

The real or imaginary charge which an atom appears to have in its combined state, is called **oxidation state** or **oxidation number** of that atom.

The oxidation number (or oxidation state) of an element in a compound is determined as the number of electrons that have passed from one atom of a given element to other atom (positive oxidation) or to one atom of a given element from other atom (negative oxidation). We can also say that, oxidation state is the oxidation number per atom.

The reaction which involves oxidation and reduction as its two half-reactions is called ***redox reaction.*** *Normally it is found that oxidation and reduction reactions are complementary to each other and occur simultaneously. Their simultaneous occurrence is seen in the form of redox reaction.*

Rules for Assigning Oxidation Number

The oxidation number of an element or atom can be calculated with the help of following rules

1. The oxidation number of an atom in its free or elemental state is zero, *e.g.*, oxidation number of H in H_2, S in S_8, P in P_4, O in O_2 or O_3 is zero.
2. Oxidation number of fluorine is always −1 in all of its compounds.
3. Oxidation number of oxygen is always −2 in all of its compounds except peroxides, superoxides and oxygen fluorides. In peroxides, its oxidation number is −1, in superoxides, its oxidation number is $-\frac{1}{2}$ while in OF_2 its oxidation number is +2.
4. The oxidation number of hydrogen in metallic hydrides is −1 while in rest of the compounds it has +1 oxidation number.
5. The oxidation number of an ion is equal to the electrical charge present on it.
6. For complex ions, the algebraic sum of oxidation numbers of all the atoms is equal to the net charge on the ion.
7. In case of neutral molecules, the algebraic sum of the oxidation numbers of all the atoms present in the molecule is zero.

(Wherever there is doubt, the more electronegative atom takes the lower oxidation number.)

The most common oxidation states of representative elements are tabulated below

Table 7.1 **Common Oxidation States of Representative Elements**

Group	Common oxidation states except zero in free state
1st (IA)	+1
2nd (IIA)	+2
13th (IIIA)	+3, +1
14th (IVA)	+4, +3, +2, +1, −1, −2, −3, −4
15th (VA)	+5, +3, +1, −1, −3 N → shows all possible oxidation states from +5 to −3 including $-\frac{1}{3}$ in N_3H.
16th (VIA)	+6, +4, +2, −2
17th (VIIA)	+7, +5, +3, +1, −1
18th (zero group)	Zero

Caution Point *Transition elements exhibit a large number of oxidation states due to involvement of $(n-1)d$ electrons also besides ns electrons.*

Hot Spot 1

FINDING Oxidation State

Finding oxidation state is an important topic of this chapter and easiest also as by just remembering a few rules, you can find the oxidation state of the desired element.

The various steps used to find out the oxidation state are

Step I Assign oxidation state of all other elements except the one, oxidation state which has to be found. (Use the rules for assigning oxidation states of elements.) *e.g.*, In $KMn0_4$, we have to find the oxidation state of Mn.

$$\overset{+1}{K}\overset{x}{Mn}\overset{-2}{0_4}$$

Step II The algebric sum of oxidation states of all the elements of a netural molecule is zero. (In case of ion, it is equal to charge on the ion.)

$KMn0_4$

$$+1 + x + (-2)4 = 0$$
$$+1 + x - 8 = 0$$
$$x - 7 = 0$$

or $$x = 7$$

Thus, the oxidation state of Mn is +7.

Sample **Problem 1** *Assign oxidation number to the underlined elements in each of the following species.* **[NCERT]**

(*i*) $NaH_2\underline{P}O_4$ (*ii*) $NaH\underline{S}O_4$

(*iii*) $H_4\underline{P}_2O_7$ (*iv*) $\underline{Mn}O_4^{2-}$

(*v*) $Ca\underline{O}_2$ (*vi*) $Na\underline{B}H_4$

(*vii*) $H_2\underline{S}_2O_7$ (*viii*) $KAl(\underline{S}O_4)_2\cdot 12H_2O$

Interpret (i) $NaH_2\underline{P}O_4$

Let the oxidation number of P be *x*. Writing the oxidation number of each atom above its symbol, we get $\overset{+1}{Na}\overset{+1}{H_2}\overset{x}{P}\overset{-2}{O_4}$

In neutral compounds, the sum of the oxidation numbers of all the atoms is zero.

$$\therefore \quad 1(+1) + 2(+1) + x + 4(-2) = 0$$
$$3 + x + (-8) = 0$$
$$x = 8 - 3 = 5$$

Hence, the oxidation number of P in NaH_2PO_4 is + 5.

(ii) $NaH\underline{S}O_4$

Let the oxidation number of S be *x*.

$$\overset{+1}{Na}\overset{+1}{H}\overset{x}{S}\overset{-2}{O_4}$$

$$1(+1) + 1(+1) + x + 4(-2) = 0$$
$$2 + x + (-8) = 0$$
$$x = +6$$

Hence, the oxidation number of S in $NaHSO_4$ is + 6.

(iii) $H_4\underline{P}_2O_7$

Let the oxidation number of P in $H_4P_2O_7$ be x.

$$\overset{+1}{H_4}\ \overset{x}{P_2}\ \overset{-2}{O_7}$$

$$4\,(+1) + 2(x) + 7\,(-2) = 0$$
$$4 + 2x + (-14) = 0$$
$$2x = +10 \quad \text{or} \quad x = +\frac{10}{2} = +5$$

Hence, the oxidation number of P in $H_4P_2O_7$ is + 5.

(iv) $\underline{Mn}O_4^{-2}$

Let the oxidation number of Mn in MnO_4^{2-} be x.

$$\overset{x}{Mn}\ \overset{-2}{O_4}{}^{-2}$$

$$x + 4\,(-2) = -2 \qquad [\because \text{Charge on the ion is } -2]$$
$$x - 8 = -2 \text{ or } x = +6$$

(v) $\underline{Ca}O_2$

Let the oxidation number of O be x.

$$\overset{+2}{Ca}\ \overset{x}{O_2}$$

(Ca is an alkaline earth metal, so its oxidation number is + 2.)

$$1(+2) + 2x = 0$$
$$2x = -2 \text{ or } x = -1$$

Hence, the oxidation number of O in CaO_2 is – 1.

(vi) $Na\underline{B}H_4$

Let the oxidation number of B be x.

$\overset{+1}{Na}\,\overset{x}{B}\,\overset{-1}{H}_4$ (In $NaBH_4$, H exists as hydride ion, H^-, so its oxidation number is – 1)

$$1(+1) + x + 4\,(-1) = 0$$
$$1 + x - 4 = 0 \text{ or } x = +3$$

Hence, the oxidation number of B in $NaBH_4$ is + 3.

(vii) $H_2\underline{S}_2O_7$

Let the oxidation number of S be x.

$$\overset{+1}{H_2}\ \overset{x}{S_2}\ \overset{-2}{O_7}$$

$$2\,(+1) + 2x + 7\,(-2) = 0$$
$$2 + 2x - 14 = 0$$
$$2x = +12 \quad \text{or} \quad x = +6$$

Hence, the oxidation number of S in $H_2S_2O_7$ is + 6.

(viii) $KAl(\underline{S}O_4)_2 \cdot 12H_2O$

Let the oxidation number of S in $KAl(SO_4)_2 \cdot 12H_2O$ be x.

$$\overset{+1}{K}\ \overset{+3}{Al}\ (\overset{x}{\underline{S}}\ \overset{-2}{O_4})_2 \cdot 12\,\overset{+1}{H_2}\overset{-2}{O}$$

$$1(+1) + 1(+3) + 2x + 8\,(-2) + 12\,(2 \times 1 + (-2)) = 0$$
$$4 + 2x - 16 = 0$$
$$2x = +12 \quad \text{or} \quad x = +6$$

Note H_2O is a neutral molecule, therefore sum of oxidation numbers of all atoms in H_2O is zero.
Hence, the oxidation number of S in $KAl(SO_4)_2 \cdot 12H_2O$ is + 6.

Fractional Oxidation States

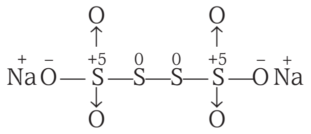
Fractional oxidation states are often used to represent the average oxidation states of several atoms in a structure. For example, in KO_2, the superoxide ion has a charge of −1 divided among two equivalent atoms, so each oxygen is assigned an oxidation state of −1/2. This ion is described as a resonance hybrid of two Lewis structures and each oxygen has oxidation state 0 in one structure and −1 in the other.

For the cyclopentadienyl ion $C_5H_5^-$, the oxidation state of C is $(-1) + (-1/5) = -6/5$. The −1 occurs because each C is bonded to one less electronegative H, and the −1/5 because the total ionic charge is divided among five equivalent C.

Exceptional Cases of Oxidation States

1. **Oxidation State of Sulphur in $Na_2S_4O_6$**

Let us see the structure of $Na_2S_4O_6$.



From the structure , it is clear that the sulphur atoms acting as donor atoms have + 5 oxidation number (each). On the other hand, the sulphur atom involved in pure covalent bond formation has zero oxidation number.

2. **Oxidation State of Fe in Fe_3O_4**

In FeO $\longrightarrow$ $x - 2 = 0, x = +2$
In Fe_2O_3 $\longrightarrow$ $2x - 6 = 0, x = +3$
In Fe_3O_4 $\longrightarrow$ $3x - 8 = 0, x = +8/3$(fractional)

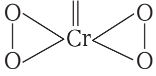
Here, in Fe_3O_4, oxidation number is the average of those in FeO and Fe_2O_3.

$$FeO + Fe_2O_3 = Fe_3O_4$$

Average oxidation number of Fe in

$$Fe_3O_4 = \frac{+2 + 2(+3)}{3} = +\frac{8}{3}$$

3. **Oxidation State of Chromium in CrO_5** CrO_5 has butterfly structure having two peroxo bonds as



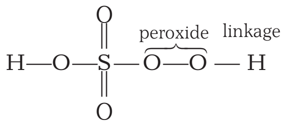
Per oxygen has (–1) oxidation state.

Let the oxidation state of chromium be '*x*'

$$x + 4(-1) + (-2) = 0$$
$$\therefore \qquad x = +6$$

4. **Oxidation State of S in H_2SO_5 and $H_2S_2O_8$**

   In H_2SO_5 (Caro's acid) one peroxide linkage is present.



$$H-O-\overset{\overset{O}{\|}}{\underset{\underset{O}{\|}}{S}}-\overbrace{O-O}^{\text{peroxide linkage}}-H$$

   Thus, the oxidation number of S is obtained as

$$\underset{(\text{for H})}{2\times(+1)}+\underset{(\text{for S})}{x}+\underset{(\text{for O})}{3\times(-2)}+\underset{(\text{for O—O})}{2\times(-1)}=0$$

$$2+x-6-2=0 \text{ or } x=+6$$

   Similarly, in $H_2S_2O_8$, the oxidation number of S is + 6.

5. **Oxidation State of Cl in $CaOCl_2$** In $CaOCl_2$ (bleaching powder) or Ca(OCl) Cl, the two Cl atoms are in different oxidation states. The oxidation state of Cl^- is -1 and that present in OCl^- is + 1.

6. **Oxidation Number of Sulphur in $(CH_3)_2SO$** (dimethyl sulphoxide) Here, oxidation number of $O=-2$ oxidation number of each CH_3 group is + 1.

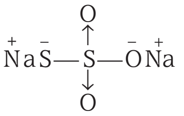
$$\therefore \quad +2+x-2=0 \text{ or } x=0$$

   Thus, sulphur lies in zero oxidation state.

7. **Oxidation Number of Sulphur in hypo, $Na_2S_2O_3$** Let the average oxidation number of sulphur be '*x*'.

$$\therefore \quad +2+2x-6=0 \quad \therefore\ x=+2$$

   Structure of hypo may be drawn as



$$\overset{+}{Na}\overset{-}{S}-\overset{\overset{O}{\uparrow}}{\underset{\underset{O}{\downarrow}}{S}}-\overset{-}{O}\overset{+}{Na}$$

   Here, the two sulphur atoms have different oxidation states

   (i) Oxidation number of donor sulpur atom is + 5. It gives up four electrons in coordination and one electron in covalent bond formation with oxygen.

   (ii) Sulphur, bonded with Na, lies in -1 state since one electron of Na lies towards the sulphur. Electrons of S–S bond are equally shared between two sulphur atoms.

   Thus, + 5 and -1 are two oxidation states of the two sulphur atoms.

Sample **Problem 2** *Oxidation state of nitrogen in hydrazoic acid is*

(*a*) -3 (*b*) -2
(c) $-1/2$ (*d*) $-1/3$

Interpret (*d*) Hydrazoic acid is N_3H.

$$N_3H$$

$$3x+1=0$$

$$3x=-1$$

$$x=-1/3$$

Oxidation number of nitrogen is $-1/3$.

Oxidation State in Covalent Compounds

We should take into consideration the following fundamental aspects of bonding while counting the oxidation state of covalently bonded molecules.

1. Single covalent bond contributes one unit for oxidation number.
2. Negative oxidation number is assigned to more electronegative atom and positive oxidation number to less electronegative atom.
3. Coordinate bond is represented by an arrow from donor atom to acceptor atom.

$$\underset{\text{donor}}{A} \longrightarrow \underset{\text{acceptor}}{B}$$

If donor atom is less electronegative and acceptor is more , then + 2 state is given to donor and -2 state is given to acceptor.

But it should be noted that if the donor is more electronegative than the acceptor, then contribution of coordinate bond for both atoms regarding oxidation state is negleted. *e.g.*,

(i) **Oxidation state of N and C in HCN**

$$H-C\equiv N$$

$$+1+a-3=0$$

$$a=+2$$

Carbon is in + 2 state and nitrogen is in -3 state. Each bond contributes -1 state to more electronegatve atom.

(ii) **Oxidation state of N and C in HNC** $H-N\equiv C$

Oxidation state of H = + 1
Oxidation state of nitrogen = $(-1)+(-2)+(0)=-3$

Covalent bond with hydrogen contributes (-1) and covalent bond with carbon contributes (-2) and there is zero contribution of coordinate bond. Let the oxidation state of carbon be '*x*'.

$$+1-3+x=0;\ x=+2$$

(iii) $Fe_{0.94}O$ (Oxidation state of iron is to be determined)

$$0.94x-2=0$$

$$x=2/0.94=200/94$$

(iv) NH_2-NH_2 (Oxidation state of nitrogen is to be determined)

$$2x+4=0$$

$$x=-2$$

Stock Notations

While naming the ion or compound, it is desirable to **put oxidation number per atom** (*i.e.,* oxidation state) in Roman figures within brackets (anion end with ate) (Table 7.2). Such representation is called *Stock notation* given by German chemist *Alfred Stock*.

For example, nitrogen forms five oxides, *i.e.*, N_2O, NO, NO_2, N_2O_4 and N_2O_5 having the oxidation number $+1, +2, +4, +4$ and $+5$ respectively. Therefore, according to Stock notation, they are represented as $N_2(I)O$, $N_2(II)O$, $N(IV)O_2$, $N_2(IV)O_4$, and $N_2(V)O_5$, respectively.

Note Hg_2Cl_2 is also called calomel and is an ionic compound while $HgCl_2$ is also called corrosive sublimate and is a covalent compound and poisonous. Antidote of this is white of an egg.

Table 7.2 **Naming the Acid and its Ions**

Oxoanions	Formula	Acids	Formula
Bromate (I)	BrO^-	Bromic (I)	$HBrO$
Bromate (III)	BrO_2^-	Bromic (III)	$HBrO_2$
Bromate (V)	BrO_3^-	Bromic (V)	$HBrO_3$
Bromate (VII)	BrO_4^-	Bromic (VII)	$HBrO_4$
Chromate (VI)	CrO_4^{2-}	Chromic (VI)	H_2CrO_4
Nitrate (V)	NO_3^-	Nitric	HNO_3
Nitrate (III)	NO_2^-	Nitrous	HNO_2
Phosphate (V)	PO_4^{3-}	Phosphoric	H_3PO_4
Sulphate (IV)	SO_3^{2-}	Sulphurous	H_2SO_3
Sulphate (VI)	SO_4^{2-}	Sulphuric	H_2SO_4
Peroxodisulphate (VI)	$S_2O_8^{2-}$	Peroxy -disulphuric	$H_2S_2O_8$

Sample **Problem 3** *Write the formulae for the following compounds.*

(i) Mercury (II) chloride	*(ii) Nickel (II) sulphate*
(iii) Tin (IV) oxide	*(iv) Thallium (I) sulphate*
(v) Iron (III) sulphate	*(vi) Chromium (III) oxide* **[NCERT]**

Interpret While writing the formula of a compound oxidation state (or valency) of cation is written as the subscript of anion and valency of anion is written as the subscript of cation.

Valency of chloride (Cl^-), sulphate (SO_4^{2-}) and oxide (O^{2-}) are $-1, -2$ and -2 respectively, valencies of metals are given in brackets.

Hence, the formulae of the given compounds is as

(i) $Hg\,(II)\,Cl_2$ (ii) $Ni\,(II)\,SO_4$ (iii) $Sn\,(IV)\,O_2$

(iv) $Th_2(I)\,SO_4$ (v) $Fe_2\,(III)\,(SO_4)_3$ (vi) $Cr_2\,(III)\,O_3$

Difference Between Valency and Oxidation Number

These two terms have different meanings as explained above in the Table 7.3

Table 7.3 **Difference Between Oxidation Number and Valency**

S.No.	Oxidation number	Valency
1.	Oxidation number is the residual charge left on the atom when other atoms are removed as ions.	It is the combining capacity of an element. It is also defined as the number of H atom or twice the number of O atoms with which an atom of the element reacts.
2.	It can be zero, *e.g.*, oxidation number of C in CH_2Br_2 is zero.	It can never be zero. It is always positive.
3.	It refers to the charge, which can be positive or negative, *e.g.*, in $CuCl_2$, the oxidation number of Cu is $+2$ and that of Cl is -1.	It is only a number and it is not assigned as positive or negative. For example, in $CuCl_2$, the valency of Cu is 2 and that of Cl is 1.
4.	It can have fractional value, *e.g.*, oxidation number of S in $K_2S_2O_8$ is $+5/2$.	It is always a whole number, since atoms always combine in simple whole numbers.
5.	Oxidation number of an element can be different in different compounds, *e.g.*, oxidation number of C in CH_4, C_2H_6, CH_3Br, CCl_4, and $CHBr_3$ are $-4, -3, -2, +4$ and $+2$, respectively.	It is fixed in all its compounds, *e.g.*, the valency of C is 4 in all its compounds, such as CH_4, C_2H_6, CH_3Br, CCl_4 and $CHBr_3$.

Applications of Oxidation Number

Oxidation number helps in comparing acidity and basicity of different substances. Moreover, these also help in naming compounds.

Some such applications are described below

(i) Acidic Character

Greater the oxidation number of the element forming oxyacids, greater the acid strength except for oxyacids of phosphorus Thus, acid strength increases as,

$$\left.\begin{array}{l} H_2\overset{+2}{S}_2O_3 < H_2\overset{+4}{S}O_3 < H_2\overset{+6}{S}O_4 \\ H\overset{-1}{Cl} < H\overset{+1}{Cl}O < H\overset{+3}{Cl}O_2 < H\overset{+5}{Cl}O_3 < H\overset{+7}{Cl}O_4 \end{array}\right\}$$

order of acid strength

(ii) Basic Strength

Greater the oxidation number of the element in conjugate bases, smaller the basic strength. Basic strength of conjugate bases of oxyacids of Cl will be in the order

$$ClO_4^- < ClO_3^- < ClO_2^- < ClO^-$$

(iii) Naming of Ternary Acids

Ternary acids (oxoacids) are compounds of hydrogen, oxygen and usually a non-metal. Non-metals that exhibit more than one oxidation state form more than one ternary acid. These ternary acids differ in the number of oxygen atoms they contain. The suffixes "-ous" and "-ic" indicate lower and higher oxidation states, respectively. The common ternary "-ic" acids are shown below.

Acids containing one fewer oxygen atom per central atom are named in the same way except that the "-ic" suffix is changed to "ous". **The oxidation number of the central element is lower by 2 in the "-ous"** acid than in the "-ic" acid.

Thus, oxoacids of chlorine can be named as

Formula	Oxidation number	Name
HClO	+1	Hypochlorous acid
$HClO_2$	+3	Chlorous acid
$HClO_3$	+5	Chloric acid
$HClO_4$	+7	Perchloric acid

Naming ternary acids and their anions.

Decreasing oxidation number of central atom ↓

Ternary acid	Anion
PerXXXic acid	PerXXXate
XXXic acid	XXXate
XXXous acid	XXXite
HypoXXXous acid	HypoXXXite

Decreasing number of oxygen atom of central atom ↓

The stem (XXX) represents the stem of the name *e.g.*, "nitr", "sulphur" or "chlor"

Ternary acids that have one fewer O atoms than the "-ous" acids (two fewer O atoms than the "-ic" acids) are named using the prefix "hypo-" and the suffix "-ous".

Formula	Oxidation number	Name
HClO	+1	Hypochlorous acid
H_3PO_2	+1	Hypophosphorus acid
HIO	+1	Hypoiodous acid
$H_2N_2O_2$	+1	Hyponitrous acid

Acids containing one more oxygen atom per central non-metal atom than the normal "-ic acid" are named "-per" acids.

Formula	Oxidation number	Name
$HClO_4$	+7	Perchloric acid
$HBrO_4$	+7	Perbromic acid
HIO_4	+7	Periodic acid

Check Point 1

1. In $H_2S_2O_3$, the oxidation number of S is + 6, not + 7, Explain.
2. In OF_2, the oxidation number of O is + 2, but not − 2, Explain.
3. Why the oxidation number of O in peroxide is − 1?
4. Why the oxidation state of H in metal hydrides is − 1?

7.2 Oxidation and Reduction

The term **oxidation** was first used for those chemical reactions in which oxygen is added to an element or a compound. The reverse of such a process can be defined as **reduction.** Both the above written terms can be defined in many ways as

Oxidation is a process which involves

(i) **Addition of oxygen *e.g.,***

$$2Mg + O_2 \longrightarrow 2MgO$$ (Oxidation of magnesium)

$$S + O_2 \longrightarrow SO_2$$ (Oxidation of sulphur)

$$2CO + O_2 \longrightarrow 2CO_2$$ (Oxidation of carbon monoxide)

(ii) **Removal of hydrogen *e.g.,***

$$H_2S + Cl_2 \longrightarrow 2HCl + S$$ (Oxidation of hydrogen sulphide)

$$4HI + O_2 \longrightarrow 2H_2O + 2I_2$$ (Oxidation of hydrogen iodide)

(iii) **Addition of an electronegative element *e.g.,***

$$Fe + S \longrightarrow FeS$$ (Oxidation of iron)

$$SnCl_2 + Cl_2 \longrightarrow SnCl_4$$ (Oxidation of stannous chloride)

$$2Fe + 3F_2 \longrightarrow 2FeF_3$$ (Oxidation of iron)

(iv) **Removal of an electropositive element *e.g.,***

$$2KI + H_2O_2 \longrightarrow 2KOH + I_2$$ (Oxidation of potassium iodide)

$$2K_2MnO_4 + Cl_2 \longrightarrow 2KCl + 2KMnO_4$$ (Oxidation of potassium manganate)

$$2KI + Cl_2 \longrightarrow 2KCl + I_2$$ (Oxidation of potassium iodide)

Reduction is just the reverse of oxidation. It is a process which involves

(i) **Removal of oxygen** *e.g.,*

$$CuO + C \longrightarrow Cu + CO$$ (Reduction of cupric oxide)

$$\underset{\text{steam}}{H_2O} + \underset{\text{coke}}{C} \longrightarrow \underbrace{CO + H_2}_{\text{water gas}}$$ (Reduction of water)

$$Fe_3O_4 + 4H_2 \longrightarrow 3Fe + 4H_2O$$

(Reduction of magnetic oxide *i.e.*, iron oxide)

(ii) **Addition of hydrogen** *e.g.*,

$$Cl_2 + H_2 \longrightarrow 2HCl \quad \text{(Reduction of chlorine)}$$

$$S + H_2 \longrightarrow H_2S \quad \text{(Reduction of sulphur)}$$

$$C_2H_4 + H_2 \longrightarrow C_2H_6 \quad \text{(Reduction of ethene)}$$

(iii) **Removal of an electronegative element** *e.g.*,

$$2HgCl_2 + SnCl_2 \longrightarrow Hg_2Cl_2 + SnCl_4$$

(Reduction of mercuric chloride)

$$2FeCl_3 + H_2 \longrightarrow 2FeCl_2 + 2HCl$$

(Reduction of ferric chloride)

$$2FeCl_3 + H_2S \longrightarrow 2FeCl_2 + 2HCl + S$$

(Reduction of ferric chloride)

(iv) **Addition of an electropositive element**

$$HgCl_2 + Hg \longrightarrow Hg_2Cl_2$$

(Reduction of mercuric chloride)

$$CuCl_2 + Cu \longrightarrow Cu_2Cl_2$$

(Reduction of cupric chloride)

Modern Concept

According to the modern concept, **loss of electrons** (*i.e.*, increase in the oxidation number) is called **oxidation** while **gain of electrons** (*i.e.*, decrease in the oxidation number) is called **reduction.**

Oil	**Ring**
oxidation is loss	reduction is gain

e.g., The equation shows a simple redox reaction which can obviously be described in terms of oxygen transfer.

$$CuO + Mg \longrightarrow Cu + MgO$$

Copper (II) oxide and magnesium oxide are both ionic. The metals obviously are not. If you rewrite this as an ionic equation, it becomes

Reduction by gain of electrons

$$Cu^{2+} + Mg \longrightarrow Cu + Mg^{2+}$$

Oxidation by loss of electrons

7.3 Oxidising and Reducing Agent

A substance which undergoes oxidation acts as **reducing agent** and the other one which undergoes reduction acts as **oxidising agent.**

In other words

In case of reducing agent

(i) loses one or more electrons
(ii) undergoes oxidation
(iii) oxidation number of atom increases

Table 7.4 **Some Important Reducing Agent**

Reducing agent	Effective change	Increase in oxidation number per atom
Iron (II) salts (acid)	$Fe^{2+} \longrightarrow Fe^{3+}$	1
Tin (II) salts (acid)	$Sn^{2+} \longrightarrow Sn^{4+}$	2
Ethanedioates (acid)	$C_2O_4^{2-} \longrightarrow CO_2$	1
Sulphites (acid)	$SO_3^{2-} \longrightarrow SO_4^{2-}$	2
Hydrogen sulphide	$S^{2-} \longrightarrow S$	2
Iodides (dilute acid)	$I^- \longrightarrow I$	1
Iodides (conc acid)	$I^- \longrightarrow I^+$	2
Metals, *e.g.*, Zn	$Zn \longrightarrow Zn^{2+}$	2
Hydrogen	$H \longrightarrow H^+$	1

An oxidising agent

(i) gains one or more electrons
(ii) undergoes reduction
(iii) oxidation number of atom decreases

$Mg, S, Cu, H_2S, HI, H_2, C, KI$ are reducing agents, while $O_2, Cl_2, F_2, H_2O_2, FeCl_3, CuCl_2, Fe_3O_4, CuO$, etc., are oxidising agents in the above examples. Some other examples are tabulated below.

Table 7.5 **Some Important Oxidising Agent**

Oxidising agent	Effective change	Decrease in oxidation number per atom
$KMnO_4$ in acid solution	$MnO_4^- \longrightarrow Mn^{2+}$	5
$KMnO_4$ in alkaline solution	$MnO_4 \longrightarrow MnO_2$	3
$K_2Cr_2O_7$ in acid solution	$Cr_2O_7^{2-} \longrightarrow Cr^{3+}$	3
Dilute HNO_3	$NO_3^- \longrightarrow NO$	3
Concentrated HNO_3	$NO_3^- \longrightarrow NO_2$	1
Concentrated H_2SO_4	$SO_4^{2-} \longrightarrow SO_2$	2
Manganese (IV) oxide	$MnO_2 \longrightarrow Mn^{2+}$	2
Chlorine	$Cl_2 \longrightarrow Cl^-$	1
Chloric (I) acid	$ClO^- \longrightarrow Cl^-$	2
KIO_3 in dilute acid	$IO_3^- \longrightarrow I_2$	5
KIO_3 in concentrated acid	$IO_3^- \longrightarrow I^-$	6

Equivalent Mass of Oxidant/Reductant

Equivalent mass of oxidant/reductant is calculated by dividing their molecular mass by number of electrons taking part in the reaction, *i.e.*,

Equivalent mass of oxidising/reducing agent

$$= \frac{\text{mol. mass of oxidising / reducing agent}}{\text{no. of electrons taking part in the reaction}}$$

Hot Spot 2

FINDING Oxidising and Reducing Agent

Generally question based on oxidant, reductant, oxidised and reduced species has been seen in previous year JEE Main (AIEEE) examination papers so it is an important topic for this examination. The level of questions is generally easy.

Steps involved to find out these reagents are

Step I Find the oxidation state of each species. *e.g.*, in the equation

$$\overset{+1\ -2}{H_2S} + \overset{0}{O_2} \longrightarrow \overset{+1\ -2}{H_2O} + \overset{0}{2S}$$

Step II Find the atom/species oxidation state of which is increasing. This species is oxidised and is called the reducing agent. *e.g.,* In the above equation, oxidation state of S is increasing from −2 to 0, thus , it is oxidised and is called the reducing agent.

Step III Find the atom/species, oxidation state of which is decreasing. This species is reduced and is called the oxidising agent. *e.g.,* In the above equation, oxidation state of O is decreasing from 0 to −2 thus, it is reduced and is called the oxidising agent.

Sample **Problem 4** *In the following reaction which species is oxidised?*

$$K[Ag(CN)_2] + Zn \longrightarrow 2Ag + K_2[Zn(CN)_4]$$

(*a*) $[Ag(CN)_2]^-$ (*b*) $[Zn(CN)_4]^{2-}$

(*c*) Ag (*d*) Zn

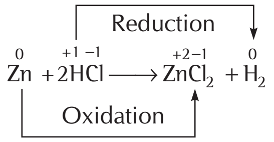
Interpret (*a*) In this reaction oxidation state of Zn is increasing from 0 to + 2. Thus, it is oxidised in this reaction.

Sample **Problem 5** *Identify the correct statement (s) in relation to the following reaction.* **[NCERT Exemplar]**

$$Zn + 2HCl \longrightarrow ZnCl_2 + H_2$$

(*a*) *Zinc is acting as an oxidant*
(*b*) *Chlorine is acting as a reductant*
(*c*) *Hydrogen ion is acting as an oxidant*
(*d*) *Zinc is acting as a reductant*

Interpret (*c, d*)



$$\overset{0}{Zn} + \overset{+1\ -1}{2HCl} \longrightarrow \overset{+2-1}{ZnCl_2} + \overset{0}{H_2}$$

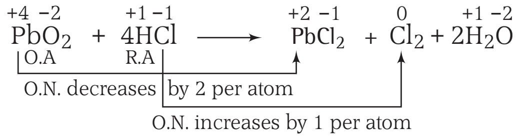
In the above reaction Zn is oxidised and H^+ is reduced so Zn acts as reducing agent and hydrogen ion (or HCl) as oxidising agent or oxidant.

7.4 Redox Reactions

These reactions involve oxidation as well as reduction as its two half reactions. In other words, those reactions in which oxidation and reduction processes occur simultaneously are called redox reactions. *e.g.,*

$$\overset{+4\ -2}{PbO_2} + \overset{+1\ -1}{4HCl} \longrightarrow \overset{+2\ -1}{PbCl_2} + \overset{0}{Cl_2} + \overset{+1\ -2}{2H_2O}$$

In PbO_2, Pb is in +4 oxidation state. Due to inert pair effect, Pb in + 2 oxidation state is more stable. So, Pb in +4 oxidation state (PbO_2) acts as an oxidising agent . It oxidises Cl^- to Cl_2 and itself gets reduced to Pb^{2+}.



$$\overset{+4\ -2}{PbO_2} + \overset{+1\ -1}{4HCl} \longrightarrow \overset{+2\ -1}{PbCl_2} + \overset{0}{Cl_2} + \overset{+1\ -2}{2H_2O}$$

Sample **Problem 6** *Which of the following reactions are redox reactions?* **[NCERT]**

(*I*) $CuO(s) + H_2(g) \longrightarrow Cu(s) + H_2O(g)$
(*II*) $Fe_2O_3(s) + 3CO(g) \longrightarrow 2Fe(s) + 3CO_2(g)$
(*III*) $4BCl_3(g) + 3LiAlH_4(s) \longrightarrow 2B_2H_6(g) + 3LiCl(s) + 3AlCl_3(s)$
(*IV*) $2K(s) + F_2(g) \longrightarrow 2K^+F^-(s)$
(*V*) $4NH_3(g) + 5O_2(g) \longrightarrow 4NO(g) + 6H_2O(g)$

(*a*) *I, III* and *IV* (*b*) *II, III* and *IV*

(*c*) *I, II* and *III* (*d*) *All of these*

Interpret (*d*) *Redox reactions are those reactions in which one reactant is oxidised while the other is reduced. So, first find the oxidation state of each element to find the substance undergoing oxidation or reduction, and then tell is it redox reaction or not?*

(i) $CuO(s) + H_2(g) \longrightarrow Cu(s) + H_2O(g)$

Assign oxidation numbers of each atom above its symbol.

$$\overset{+2\ -2}{CuO}(s) + \overset{0}{H_2}(g) \longrightarrow \overset{0}{Cu}(s) + \overset{+1\ -2}{H_2O}(g)$$

Oxidation number of Cu in CuO is + 2. It decreases from + 2 to zero in Cu. While oxidation number of hydrogen increases from 0 (in H_2) to +1 (in H_2O). This shows that CuO is reduced to Cu but H_2 is oxidised to H_2O. Hence, it is an example of redox reaction.

(ii) $\overset{+3\ -2}{Fe_2O_3}(s) + 3\overset{+2-2}{CO}(g) \longrightarrow 2\overset{0}{Fe}(s) + 3\overset{+4-2}{CO_2}(g)$

Oxidation number of Fe decreases from +3 (in Fe_2O_3) to zero (in Fe) and oxidation number of C increases from + 2 (in CO) to + 4 (in CO_2). This shows that Fe_2O_3 is reduced to Fe and CO is oxidised to CO_2. Hence, it is a redox reaction.

(iii) $4\overset{+3}{B}\overset{-1}{Cl_3}(g) + 3\overset{+1}{Li}\overset{+3}{Al}\overset{-1}{H_4}(s) \longrightarrow 2\overset{-3}{B_2}\overset{+1}{H_6}(g) + 3\overset{+1}{Li}\overset{-1}{Cl}(s) + 3\overset{+3}{Al}\overset{-1}{Cl_3}(s)$

Oxidation number of B decreases from + 3 (in BCl_3) to − 3 (in B_2H_6) and oxidation number of H increases from −1 (in $LiAlH_4$) to +1 (in B_2H_6). This shows that BCl_3 is reduced to B_2H_6 and $LiAlH_4$ is oxidised. Hence, it is a redox reaction.

(iv) $2\overset{0}{K}(s) + \overset{0}{F_2}(g) \longrightarrow 2\overset{+1}{K}\overset{-1}{F}(s)$

Oxidation number of K increases from zero (in K) to +1 (in KF) and oxidation number of F reduces from zero (in F_2) to −1 (in KF). This shows that K is oxidised and F_2 is reduced. Hence, it is a redox reaction.

(v) $4\overset{-3}{N}\overset{+1}{H_3}(g) + 5\overset{0}{O_2}(g) \longrightarrow 4\overset{+2}{N}\overset{-2}{O}(g) + 6\overset{+1}{H_2}\overset{-2}{O}(g)$

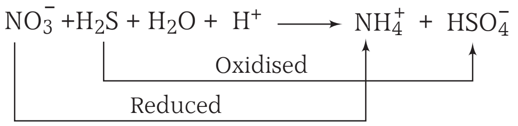
Oxidation number of N increases from − 3 (in NH_3) to +2 (in NO) and oxidation number of O decreases from zero (in O_2) to − 2 (in NO and H_2O). This shows that NH_3 is oxidised and O_2 is reduced. Hence, it is a redox reaction.

Types of Redox Reactions

Redox reactions are divided into two main types

(a) **Intermolecular Redox Reactions**

In such redox reactions, molecule of one reactant is oxidised whereas molecule of other reactant is reduced. *e.g.*,



$NO_3^- + H_2S + H_2O + H^+ \longrightarrow NH_4^+ + HSO_4^-$

(b) **Intramolecular Redox Reactions**

If one atom of a molecule is oxidised and other atom of same molecule is reduced then the reaction is called intramolecular redox reaction.

e.g., $NH_4NO_3 \xrightarrow{\Delta} N_2O + 2H_2O$

There are two types of nitrogen, one in NH_4^+ ion (oxidation number = −3) and the other in NO_3^- (oxidation number = +5). On decomposition, N_2O (oxidation number = + 1) is formed. Thus, NH_4^+ is oxidised to N_2O and NO_3^- is reduced to N_2O.

Since, both the elements are in the same initial substance, reactions of this kind are known as **intramolecular oxidation-reduction or redox reactions.**

In another example, $\underset{\text{(O.N.)}\ +5\ -1}{\underset{\uparrow\ \uparrow}{PCl_5}} \xrightarrow{\Delta} \underset{+3\ -1}{\underset{\uparrow\ \uparrow}{PCl_3}} + \underset{0}{\underset{\uparrow}{Cl_2}}$

Phosphorus (V) of PCl_5 is thus reduced to P(III) of PCl_3. Cl (−1) is oxidised to Cl_2(0).

Thus, it is an **intramolecular redox reaction.**

(c) **Disproportionation Reactions**

In such reactions, compounds are simultaneously formed that contain a given element in a more oxidised and more reduced state than the initial one. The initial substance displays functions of both an oxidising and a reducing agent. *Such reactions are possible if the relevant element is in an intermediate oxidation state in the initial compound.* In the following disproportionation reaction

$$4H_3PO_3 \longrightarrow 3H_3PO_4 + PH_3$$

Oxidation number of P (in H_3PO_3) is +3 which is the intermediate of +5 (in H_3PO_4) and −3 (in PH_3). Such substances have **oxidation-reduction duality.**

The reaction between chlorine and cold dilute sodium hydroxide solution is

$$Cl_2 + 2OH^- \longrightarrow Cl^- + ClO^- + H_2O$$

Obviously the chlorine has changed oxidation state because it has ended up in compounds starting from the original element. Checking all the oxidation states shows

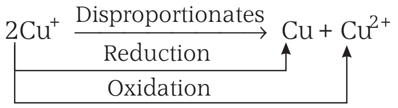
$$\underset{0}{\underset{\uparrow}{Cl_2}} + \underset{-2\ +1}{\underset{\uparrow\ \uparrow}{2OH^-}} \longrightarrow \underset{-1}{\underset{\uparrow}{Cl^-}} + \underset{+1\ -2}{\underset{\uparrow\ \uparrow}{ClO^-}} + \underset{+1\ -2}{\underset{\uparrow\ \uparrow}{H_2O}}$$

The chlorine is the only thing to have changed oxidation state. One atom has been reduced because its oxidation state has fallen. The other has been oxidised. This is a good example of disproportionation reaction.

Thus, a disproportionation reaction is one in which a single substance (element) is both oxidised and reduced.

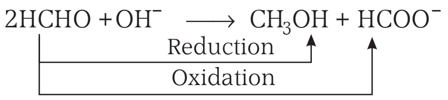
Other examples of disproportionation reaction (autoxidation-autoreduction) are

(i)



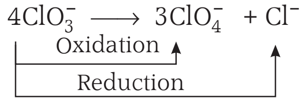
$2Cu^+ \xrightarrow{\text{Disproportionates}} Cu + Cu^{2+}$

(ii)



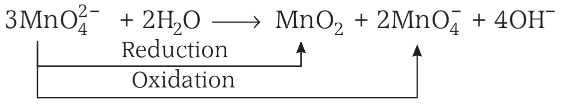
$2HCHO + OH^- \longrightarrow CH_3OH + HCOO^-$

(iii)



$4ClO_3^- \longrightarrow 3ClO_4^- + Cl^-$

(iv)



$3MnO_4^{2-} + 2H_2O \longrightarrow MnO_2 + 2MnO_4^- + 4OH^-$

(v) $$\begin{array}{l}\text{CHO}\\ |\\ \text{CHO}\end{array} + \text{OH}^- \longrightarrow \begin{array}{l}\text{CH}_2\text{OH}]\ \text{Reduction}\\ |\\ \text{COO}^-\ ]\text{Oxidation}\end{array}$$

$$2H_2O_2 \longrightarrow 2H_2O + O_2$$

Sample Problem 7 *Find the disproportionation reaction among the following.*

(a) $Te(s) + NO_3^-(aq) \longrightarrow TeO_2(s) + NO(g)$

(b) $H_2O_2(aq) + Fe^{2+}(aq) \longrightarrow Fe^{3+}(aq) + H_2O(l)$

(c) $Mn(s) + NO_3^-(aq) \longrightarrow Mn^{2+}(aq) + NO_2(g)$

(d) $Mn^{3+}(aq) \longrightarrow MnO_2(s) + Mn^{2+}(aq)$

Interpret (d) (a) $\underset{0}{Te}(s) + \underset{+5}{N}O_3^-(aq) \longrightarrow \underset{+4}{Te}O_2(s) + \underset{+2}{N}O(g)$

Oxidation $Te(s) \longrightarrow TeO_2(s)$

Reduction $NO_3^-(aq) \longrightarrow NO(g)$

(b) $H_2\underset{-1}{O_2}(aq) + \underset{+2}{Fe^{2+}}(aq) \longrightarrow \underset{+3}{Fe^{3+}}(aq) + H_2\underset{-2}{O}(l)$

Oxidation $Fe^{2+}(aq) \longrightarrow Fe^{3+}(aq)$

Reduction $H_2O_2(aq) \longrightarrow H_2O(l)$

(c) Oxidation $Mn(s) \longrightarrow Mn^{2+}(aq)$

Reduction $NO_3^-(aq) \longrightarrow NO_2(g)$

(d) Oxidation $Mn^{3+}(aq) \longrightarrow MnO_2(s)$

Reduction $Mn^{3+}(aq) \longrightarrow Mn^{2+}(aq)$

In this reaction, Mn^{3+} has been oxidised to $MnO_2(s)$ as well as reduced to $Mn^{2+}(aq)$. Thus, it is a **disproportionation reaction.**

Equivalent weight of the element of compound in disproportionation reaction Equivalent weight is the sum of the equivalent weights in oxidation and reduction reaction, *i.e.*, $(M/n_1 + M/n_2)$, where M is the molecular mass of the compound and n_1 and n_2 are the number of electrons in oxidation and reduction reactions, respectively. *e.g.*, the equivalent weight of P_4 in the disproportionation reaction shown below is

$$P_4 + 3\overset{\ominus}{O}H + 3H_2O \longrightarrow PH_3 + 3H_2PO_2^{\ominus}$$

$$12e^- + P_4 \longrightarrow 4PH_3 \qquad \text{(reduction)}$$

$$4x = 0 \quad 4x + 12 = 0$$

$$4x = -12 \qquad \text{(oxidation)}$$

$$P_4 \longrightarrow 4H_2PO_2^{\ominus} + 4e^-$$

$$4x = 0 \quad 8 + 4x - 16 = -4$$

$$4x = +4$$

$$\text{Eq. wt} = \left(\frac{M}{4} + \frac{M}{12}\right) = \left(\frac{31\times 4}{4} + \frac{31\times 4}{12}\right)$$

$$= \left(31 + \frac{31}{3}\right) = 41.33$$

Sample Problem 8 *For the reaction,*

$$3Br_2 + 6OH^{\ominus} \longrightarrow Br^{\ominus} + BrO_3^{\ominus} + 3H_2O$$

equivalent weight of Br_2 *(molecular weight M) is*

(a) $\frac{M}{2}$

(b) $\frac{M}{10}$

(c) $\left(\frac{M}{2} + \frac{M}{10}\right)$

(d) $\left(\frac{M}{6}\right)$

Interpret (c) Here, Br_2 disproportionates (simultaneous oxidation and reduction), so, its equivalent weight is the sum of equivalent weights of the half reactions.

$$2e^- + Br_2 \longrightarrow 2Br^{\ominus}\ (x = 2) \qquad \text{(reduction)}$$

$$Br_2 \longrightarrow 2BrO_3^{\ominus} + 10e^-\ (x = 10) \qquad \text{(oxidation)}$$

$$2x = 0 \quad 2x - 12 = -2 \Rightarrow 2x = 10$$

$$\therefore \qquad \text{Eq. wt} = \frac{M}{2} + \frac{M}{10}$$

Conproportionation Reaction

This reaction is the reverse of disproportionation reaction. For example, $Br^{\ominus}$ and $BrO_3^{\ominus}$ in acidic medium undergoes oxidation and reduction respectively to give Br_2.

$$2Br^{\ominus} \longrightarrow Br_2 + 2e^-] \times 5$$

$$12H^{\oplus} + 10e^- + 2BrO_3^{\ominus} \longrightarrow Br_2 + 6H_2O$$

$$2x - 12 = -2 \qquad 2x = 0$$

$$2x = 10$$

$$\overline{10Br^{\ominus} + 2BrO_3^{\ominus} + 12H^{\oplus} \longrightarrow 6Br_2 + 6H_2O}$$

Or $$5Br^{\ominus} + BrO_3^{\ominus} + 6H^{\oplus} \longrightarrow 3Br_2 + 3H_2O$$

Check Point 2

1. It is not possible to oxidise HNO_3. Explain it.
2. H_2S acts only as a reducing agent while SO_2 can act both as a reducing agent and an oxidising agent. Explain, why?
3. Why conproportionation reactions are called the reverse of disproportionation reactions?
4. $NaCl + KNO_3 \longrightarrow NaNO_3 + KCl$

   The above reaction is not a redox reaction. Explain, why?

7.5 Molecular and Ionic Equations

When the reactants and products have been written in molecular forms, the equation is termed as molecular equation *e.g.*, Consider the reaction between solutions of ferric chloride and stannous chloride. When they are mixed, ferrous chloride and stannic chloride are formed. The chemical change can be represented by the following equation

$$2FeCl_3 + SnCl_2 \longrightarrow 2FeCl_2 + SnCl_4$$

Since, the reactants and products involved in the chemical change are ionic compounds, these will be present in the form of ions in the solution. So, the above chemical change can also be written in the following manner.

$$2Fe^{3+} + 6Cl^- + Sn^{2+} + 2Cl^- \longrightarrow 2Fe^{2+} + 4Cl^- + Sn^{4+} + 4Cl^-$$

or $$2Fe^{3+} + Sn^{2+} \longrightarrow 2Fe^{2+} + Sn^{4+}$$

The ferric ions combine with stannous ions to form ferrous ions and stannic ions. This is an **ionic equation** for the above chemical change.

The ions which do not undergo any electronic change during a chemical change are termed as **spectator ions.** The spectator ions are not included in the final balanced equations.

The rules to be followed for writing ionic equations are

(i) All soluble ionic compounds involved in a chemical change are expressed in ionic symbols while covalent substances are written in molecular form *i.e.*, H_2O, NH_3, NO_2, NO, SO_2, CO, CO_2, etc., are expressed in molecular form.

(ii) Highly insoluble ionic compound is expressed in molecular form.

(iii) The ions which are common and equal in number on both sides, *i.e.*, spectator ions, are cancelled.

(iv) Besides the atoms, the ionic charges must also be balanced on both the sides.

Sample **Problem 9** *Choose the correct ionic form of the following equation.*

$$K_2Cr_2O_7 + 7H_2SO_4 + 6FeSO_4 \longrightarrow 3Fe_2(SO_4)_3 + Cr_2(SO_4)_3 + 7H_2O + K_2SO_4$$

(*a*) $Cr_2O_7^- + 7H^+ + 6Fe^{2+} \longrightarrow 6Fe^{3+} + 2\,Cr^{3+} + 7H_2O$

(*b*) $Cr_2O_7^{2-} + 14H^+ + 6Fe^{2+} \longrightarrow 6Fe^{3+} + 2Cr^{3+} + 7H_2O$

(c) $Cr_2O_7^{2-} + 7H + 6Fe^{3+} + 13SO_4^{2-} \longrightarrow 6Fe^{3+} + 13SO_4^{2-} + 2Cr^{3+} + 7H_2O$

(*d*) $Cr_2O_7^{2-} + 2K^+ + 14H^+ + 6Fe^{2+} \longrightarrow 6Fe^{3+} + 13SO_4^{2-} + 2Cr^{3+} + 2K^+$

Interpret (*b*) In this equation except H_2O, all are ionic in nature. Representing these compounds in ionic forms.

$$2K^+ + Cr_2O_7^{2-} + 14H^+ + 7SO_4^{2-} + 6Fe^{2+} + 6SO_4^{2-} \longrightarrow$$
$$6Fe^{3+} + 9SO_4^{2-} + 2Cr^{3+} + 3SO_4^{2-} + 2K^+ + SO_4^{2-} + 7H_2O$$

$2K^+$ ions and $13\,SO_4^{2-}$ ions are common on both sides, so these are cancelled. The desired ionic equation reduces to,

$$Cr_2O_7^{2} + 14H^+ + 6Fe^{2+} \longrightarrow 6Fe^{3+} + 2\,Cr^{3+} + 7H_2O$$

Total charges are equal on both sides; thus, the balanced ionic equation is the same as above.

Sample **Problem 10** *Write the following ionic equation in the molecular form if the reactants are chlorides.*

$$2Fe^{3+} + Sn^{2+} \longrightarrow 2Fe^{2+} + Sn^{4+}$$

(*a*) $FeCl_2 + SnCl_2 \longrightarrow FeCl_3 + SnCl_4$

(*b*) $Fe^{3+} + Sn^{2+} + Cl^- \longrightarrow Fe^{2+} + Sn^{4+} + Cl^-$

(*c*) $FeCl_3 + 2SnCl_2 \longrightarrow 2\,FeCl_2 + SnCl_4$

(*d*) $2FeCl_3 + SnCl_2 \longrightarrow 2FeCl_2 + SnCl_4$

Interpret (*d*) For writing the reactants in molecular forms, the requisite number of chloride ions are added.

$$\underbrace{2Fe^{3+} + 6Cl^-} + \underbrace{Sn^{2+} + 2Cl^-}$$

or $$2FeCl_3 + SnCl_2$$

Similarly $8Cl^-$ ions are added on RHS to neutralise the charges.

$$\underbrace{2Fe^{2+} + 4Cl^-} + \underbrace{Sn^{4+} + 4Cl^-}$$

or $$2FeCl_2 + SnCl_4$$

Thus, the balanced molecular equation is

$$2FeCl_3 + SnCl_2 \longrightarrow 2FeCl_2 + SnCl_4$$

7.6 Balancing of Redox Reactions

The redox reactions can be balanced through

1. Ion-electron method
2. Oxidation number method

1. Ion-Electron Method

The ion-electron method for balancing redox reactions was given by **Jette** and **Lamev** in 1927.

The method involves the following steps

Step I Write the redox reaction in ionic form.

Step II Split the redox reaction into its two half-reactions, *i.e.*, the oxidation-half and the reduction-half.

Step III Balance atoms of each half-reaction by using simple multiples (not applicable for hydrogen and oxygen)

Step IV For balancing H and O.

(i) Use simple multiples if possible.

(ii) **For acidic and neutral solutions** add water molecules to the side deficient in oxygen and H^+ to the side deficient in hydrogen.

(iii) **In case of alkaline solution** for each excess of oxygen add one water molecule to the same side and two OH^- ions on the other side. If hydrogen is still unbalanced add one OH^- ion for each excess of hydrogen on the same side and one water molecule to the other side.

Step V Add electrons to the side deficient in electrons, so as to equalise the charge on both the sides.

Step VI Multiply one or both the half-reactions by a suitable number so that the numbers of electrons become equal in both the equations.

Step VII Add the two balance half-reactions and cancel any term common to both the sides.
e.g., in the reaction,

$$Cu + HNO_3 \longrightarrow Cu(NO_3)_2 + NO + H_2O$$

Stepwise approach is,

Step I Ionic equation.

$$Cu + H^+ + NO_3^- \longrightarrow Cu^{2+} + NO + H_2O$$

Step II and III Splitting of ionic reaction into two half-reactions.

$$Cu \xrightarrow{\text{Oxidation-half}} Cu^{2+}$$

$$NO_3^- \xrightarrow{\text{Reduction-half}} NO$$

Step IV Adding H_2O and H^+ to the side deficient in oxygen and hydrogen respectively (according to simple multiple approach)

$$Cu \xrightarrow{\text{Oxidation-half}} Cu^{2+};$$

$$NO_3^- + 4H^+ \longrightarrow NO + 2H_2O$$

Step V and VI Adding electrons to the side deficient in electrons

$$[Cu \xrightarrow{\text{Oxidation-half}} Cu^{2+} + 2e^-] \times 3$$

$$[NO_3^- + 4H^+ + 3e^- \xrightarrow{\text{Reduction-half}} NO + 2H_2O] \times 2$$

For balancing electrons, oxidation-half reaction is to be multiplied by 3 and the reduction-half reaction is to be multiplied by 2. Hence, we get,

$$3Cu \longrightarrow 3Cu^{2+} + 6e^- ;$$

$$2NO_3^- + 8H^+ + 6e^- \longrightarrow 2NO + 4H_2O$$

Step VII Adding both the half-reactions

$$3Cu + 2NO_3^- + 8H^+ \longrightarrow 3Cu^{2+} + 2NO + 4H_2O$$

Converting the complete reaction into molecular form (while doing so we add $6NO_3^-$ to both the sides), we get

$$3Cu + 2NO_3^- + 8H^+ + 6NO_3^- \longrightarrow 3Cu^{2+} + 2NO + 6NO_3^- + 4H_2O$$

or $3Cu + 8HNO_3 \longrightarrow 3Cu(NO_3)_2 + 2NO + 4H_2O$

2. Oxidation Number Method

This method is based upon the fact that total increase in oxidation number must be equal to total decrease in oxidation number.

The stepwise approach is

Step I Write the skeleton equation (if not given) representing the chemical change.

Step II Assign oxidation number to the atoms in the equation and find out which atoms are undergoing oxidation and reduction. Write separate equations for the atoms undergoing oxidation and reduction.

Step III Find the change in oxidation number in each equation. Make the change equal in both the equations by multiplying with suitable integers. Add both the equations.

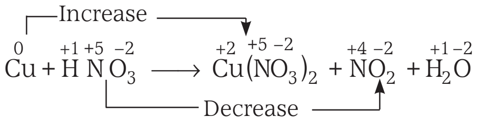
Step IV Complete the balancing. First balance those substance which undergone change in oxidation number and then other atoms except H and O. Lastly balance H and O by putting H_2O molecules whenever needed.

e.g., balance the equation,

$$Cu + HNO_3 \longrightarrow Cu(NO_3)_2 + NO_2 + H_2O$$

Stepwise approach

Step I and II Writing oxidation numbers of all the atoms



$$\overset{0}{Cu} + \overset{+1}{H}\,\overset{+5}{N}\,\overset{-2}{O_3} \longrightarrow \overset{+2}{Cu}(\overset{+5}{N}\overset{-2}{O_3})_2 + \overset{+4}{N}\overset{-2}{O_2} + \overset{+1}{H_2}\overset{-2}{O}$$

Change in oxidation number is shown by arrows as,

$$\overset{0}{Cu} \xrightarrow{\text{Increase}} \overset{+2}{Cu}(NO_3)_2$$

$$H\overset{+5}{N}O_3 \xrightarrow{\text{Decrease}} \overset{+4}{N}O_2$$

Thus, in case of Cu, oxidation number is increased by 2 units while in the case of nitrogen, oxidation number is decreased by 1 unit.

Step III To make increase and decrease equal, the lower equation is to be multiplied by 2. Thus, the equation will be,

$$Cu + 2HNO_3 \longrightarrow Cu(NO_3)_2 + 2NO_2 + H_2O$$

Step IV Balancing nitrate ions, H and O gave the result as,

$$Cu + 4HNO_3 \longrightarrow Cu(NO_3)_2 + 2NO_2 + 2H_2O$$

Sample **Problem 11** *Balance the following equation in basic medium by ion-electron method and oxidation number methods and identify the oxidising agent and the reducing agent.* [**NCERT**]

$$P_4(s) + OH^-(aq) \longrightarrow PH_3(g) + H_2PO_2^-(aq)$$

Interpret $P_4(s) + OH^-(aq) \longrightarrow PH_3(g) + H_2PO_2^-(aq)$

By ion electron method

Reduction half reaction

$$\overset{0}{P_4}(s) \longrightarrow \overset{-3}{P}H_3(g) \qquad \text{...(i)}$$

$$\text{Balance P atoms } \underset{0}{\overset{0}{P_4}}(s) \longrightarrow 4\,\underset{-12}{\overset{-3}{P}}H_3(g) \qquad \text{...(ii)}$$

Balance oxidation number by adding electrons,

$$P_4(s) + 12e^- \longrightarrow 4PH_3(g) \qquad \text{...(iii)}$$

Balance charge by adding OH^- ions,

$$P_4(s) + 12e^- \longrightarrow 4PH_3(g) + 12OH^-(aq) \text{...(iv)}$$

Balance 'O' atoms by adding H_2O

$$12H_2O + P_4(s) + 12e^- \longrightarrow 4PH_3(g) + 12OH^-(aq) \text{ ...(v)}$$

Oxidation half reaction

$$P_4(s) \longrightarrow H_2PO_2^-(aq) \qquad \text{...(vi)}$$

Balance P atoms,

$$\overset{0}{P_4}(s) \longrightarrow 4H_2\overset{+1}{P}O_2^-(aq) \qquad \text{...(vii)}$$

Balance oxidation number by adding electrons,

$$P_4(s) \longrightarrow 4H_2PO_2^-(aq) + 4e^- \qquad \text{...(viii)}$$

Balance charge by adding OH^- ions

$$P_4(s) + 8OH^-(aq) \longrightarrow 4H_2PO_2^-(aq) + 4e^- \quad \text{...(ix)}$$

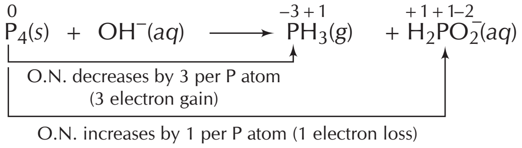
Oxygen and hydrogen are balanced automatically.

First multiply Eq. (ix) by 3 to equalise number of electrons gain and lose and add it to Eq. (v), Thus, we get,

$$4P_4(s) + 12OH^-(aq) + 12H_2O(l) \longrightarrow 4PH_3(g) + 12H_2PO_2^-(aq)$$

$$\text{or} \quad P_4(s) + 3OH^-(aq) + 3H_2O(l) \longrightarrow PH_3(g) + 3H_2PO_2^-(aq)$$

By oxidation number method



In a balanced chemical reaction loss of electrons = gain of electrons

So, multiply $H_2PO_2^-$ by 3 and we get

$$P_4(s) + OH^-(aq) \longrightarrow PH_3(g) + 3H_2PO_2^-$$

Multiply OH^- by 3 to balance the charge

$$P_4(s) + 3OH^-(aq) \longrightarrow PH_3(g) + 3H_2PO_2^-(aq)$$

Balance H by adding $3H_2O$ to LHS

$$P_4(s) + 3H_2O(l) + 3OH^-(aq) \longrightarrow PH_3(g) + 3H_2PO_2^-(aq)$$

In this equation P_4 acts both as an oxidising agent as well as a reducing agent.

WORKED OUT
Examples

Example 1 *In the reaction,*

$$H_2O_2 + Na_2CO_3 \longrightarrow Na_2O_2 + CO_2 + H_2O$$

the substance undergoing oxidation is

(*a*) H_2O_2 (*b*) Na_2CO_3
(*c*) Na_2O_2 (*d*) None of these

Solution (*d*) $\overset{+1}{H_2}\overset{-1}{O_2} + \overset{+1}{Na_2}\overset{+4}{C}\overset{-2}{O_3} \longrightarrow \overset{+1}{Na_2}\overset{-1}{O_2} + \overset{+4}{C}\overset{-2}{O_2} + \overset{+1}{H_2}\overset{-2}{O}$

Here, the oxidation state of all the elements remain the same as before. Thus, it does not involve oxidation or reduction processes. None of the elements changes its oxidation number.

Example 2 *In the following reaction,*

$$4P + 3KOH + 3H_2O \longrightarrow 3KH_2PO_2 + PH_3$$

(*a*) P *is only oxidised*
(*b*) P *is only reduced*
(*c*) P is *both oxidised as well as reduced*
(*d*) *None of the above*

+1 unit increases

Solution (*c*) $4\overset{0}{P} + 3KOH + 3H_2O \longrightarrow 3KH_2\overset{+1}{P}O_2 + \overset{-3}{P}H_3$

−3 unit decreases

Hence, P is both oxidised as well as reduced.

Example 3 *Which of the following is not a redox reaction?*

(*a*) $CaCO_3 \longrightarrow CaO + CO_2$
(*b*) $Na + H_2O \longrightarrow NaOH + \frac{1}{2}H_2$
(*c*) $MnCl_3 \longrightarrow MnCl_2 + \frac{1}{2}Cl_2$
(*d*) $O_2 + 2H_2 \longrightarrow 2H_2O$

Solution (*a*) In redox reactions, oxidation and reduction takes place simultaneously.

$$\overset{+2}{Ca}\,\overset{+4}{C}\overset{-2}{O_3} \longrightarrow \overset{+2}{Ca}\overset{-2}{O} + \overset{+4}{C}O_2$$

Since, in this reaction, there is no change in the oxidation state of elements, *i.e.*, there is no oxidation or reduction in this reaction. Thus, it is not a redox reaction. (All other given reactions involve the change in oxidation state, *i.e.*, oxidation and reduction.)

Example 4 *The equivalent weight of* H_2SO_4 *in the following reaction is*

$$Na_2Cr_2O_7 + 3SO_2 + H_2SO_4 \longrightarrow 3Na_2SO_4 + Cr_2(SO_4)_3 + H_2O$$

(*a*) 98 (*b*) $\frac{98}{6}$ (*c*) $\frac{98}{2}$ (*d*) $\frac{98}{8}$

Solution (*b*) In this reaction, 6 moles of electron are involved with 1 mole of H_2SO_4.So, H_2SO_4 acts here as acidic medium.

$$6e^- + Cr_2O_7^{2-} \longrightarrow 2Cr^{3+} (x = 6) \text{ (reduction)}$$

$$2x - 14 = -2 \qquad 2x = 6$$
$$2x = 12$$

$$SO_2 \longrightarrow SO_4^{2-} + 2e^-] \times 3 \; (x = 6)$$

$$x - 4 = 0 \qquad x - 8 = -2$$
$$x = 4 \qquad x = 6$$

$$\text{So, equivalent weight of } H_2SO_4 = \frac{M}{6} = \frac{98}{6}$$

Example 5 *For the redox reaction,*

$$MnO_4^- + C_2O_4^{2-} + H^+ \longrightarrow Mn^{2+} + CO_2 + H_2O$$

Correct stoichiometric coefficients of MnO_4^-, $C_2O_4^{2-}$ *and* H^+ *are respectively*

(*a*) 2, 16, 5 (*b*) 2, 5, 16
(*c*) 16, 5, 2 (*d*) 5, 16, 2

Solution (*b*) The following steps are involved to balance this equation.

(i) Split the equation into oxidation and reduction half- reactions.

$$MnO_4^- \longrightarrow Mn^{2+};$$
$$C_2O_4^{2-} \longrightarrow CO_2$$

(ii) Balance the atoms other than O and H.

$$MnO_4^- \longrightarrow Mn^{2+};$$
$$C_2O_4^{2-} \longrightarrow 2CO_2$$

(iii) Add H_2O to the side deficient in O and H^+ to the side deficient in H.

$$MnO_4^- + 8H^+ \longrightarrow Mn^{2+} + 4H_2O;$$
$$C_2O_4^{2-} \longrightarrow 2CO_2$$

(iv) Balance the charge by adding electrons.

$$MnO_4^- + 8H^+ + 5e^- \longrightarrow Mn^{2+} + 4H_2O$$
$$C_2O_4^{2-} \longrightarrow 2CO_2 + 2e^-$$

(v) Equalise the number of electrons and then add both the equations.

$$[MnO_4^- + 8H^+ + 5e^- \longrightarrow Mn^{2+} + 4H_2O] \times 2$$
$$[C_2O_4^{2-} \longrightarrow 2CO_2 + 2e^-] \times 5$$
$$\overline{2MnO_4^- + 16H^+ + 5C_2O_4^{2-} \longrightarrow 2Mn^{2+} + 10CO_2 + 8H_2O}$$

Thus, the coefficients of MnO_4^-, $C_2O_4^{2-}$ and H^+ are respectively 2, 5 and 16.

Start **Practice** *for* JEE Main

Round I (Topically Divided Problems)

Oxidation State

1. Oxidation number of S in SO_4^{2-}
(a) +6 (b) +3
(c) +2 (d) −2

2. Oxidation number of nitrogen is highest in
(a) N_3H (b) N_2O_4
(c) NH_2OH (d) NH_3

3. In which of the following compounds, an element exhibits two different oxidation states? **[NCERT Exemplar]**
(a) NH_2OH (b) NH_4NO_3
(c) N_2H_4 (d) N_3H

4. The oxidation number of oxygen in OF_2 is
(a) + 2 (b) − 2
(c) + 1 (d) − 1

5. The oxidation number of Cr in CrO_5 is
(a) + 3 (b) + 5 (c) + 6 (d) 0

6. The oxidation states of iodine in HIO_4, H_3IO_5 and H_5IO_6 are respectively
(a) +1, + 3, + 7 (b) +7, + 7, + 3
(c) +7, + 7, + 7 (d) +7, + 5, + 3

7. In which of the following compounds, the oxidation number of iodine is fractional?
(a) IF_3 (b) IF_5 (c) I_3^- (d) IF_7

8. The oxidation number of an element in a compound is evaluated on the basis of certain rules. Which of the following rules is not correct in this respect? **[NCERT Exemplar]**
(a) The oxidation number of hydrogen is always +1.
(b) The algebraic sum of all the oxidation numbers in a compound is zero.
(c) An element in the free or the uncombined state bears oxidation number zero.
(d) In all its compounds, the oxidation number of fluorine is −1

9. The oxidation number of chromium in potassium dichromate is
(a) +2 (b) +4
(c) +6 (d) +8

10. In the conversion of Br_2 to BrO_3^-, the oxidation number of Br changes from
(a) zero to +5 (b) +1 to +5
(c) zero to −3 (d) +2 to +5

11. In permonosulphuric acid (H_2SO_5), the oxidation number of sulphur is
(a) +8 (b) +4
(c) +5 (d) +6

12. The oxidation number of N and Cl in $NOClO_4$ respectively are
(a) +2 and + 7 (b) +3 and + 7
(c) −3 and + 5 (d) +2 and − 7

13. The largest oxidation number exhibited by an element depends on its outer electronic configuration. With which of the following outer electronic configurations the element will exhibit largest oxidation number? **[NCERT Exemplar]**
(a) $3d^1 4s^2$ (b) $3d^3 4s^2$
(c) $3d^5 4s^1$ (d) $3d^5 4s^2$

14. Find the oxidation state of C_1 and C_2 in the following compound. $\overset{2}{\underline{C}}H_3\overset{1}{\underline{C}}H_2OH$ **[NCERT]**
(a) 0, 2 (b) −2, 0
(c) −2, −2 (d) −2, +2

15. Oxidation state of C in $\underline{C}H_3\underline{C}OOH$ is **[NCERT]**
(a) 0 (b) 1
(c) 2 (d) 3

16. The oxidation state of two sulphur atoms in $H_2S_2O_8$ is
(a) −6 (b) −2
(c) +6 (d) −4

17. When $K_2Cr_2O_7$ is converted into K_2CrO_4, the change in oxidation number of chromium is
(a) 0 (b) 5 (c) 7 (d) 9

Redox Reactions

18. Which of the following is the best description of the behaviour of bromine in the reaction given below?

$$H_2O + Br_2 \longrightarrow HOBr + HBr$$

(a) Proton acceptor only
(b) Both oxidised and reduced
(c) Oxidised only
(d) Reduced only

19. Which of the following is not an intermolecular redox reaction?
(a) $MgCO_3 \longrightarrow MgO + CO_2$
(b) $O_2 + 2H_3 \longrightarrow 2H_3O$
(c) $K + H_2O \longrightarrow KOH + (1/2)H_2$
(d) $MnBr_3 \longrightarrow MnBr_2 + (1/2)Br_2$

20. Which conversion is an oxidation?
(a) $SO_4^{2-} \longrightarrow SO_3^{2-}$ (b) $Cu^{2+} \longrightarrow Cu$
(c) $H^+ \longrightarrow H$ (d) $H^- \longrightarrow H$

21. In the reaction,

$$3Cl_2 + 6NaOH \longrightarrow NaClO_3 + 5NaCl + 3H_2O$$

the element which loses as well as gains electrons is
(a) Na (b) O
(c) Cl (d) None of these

22. Of the following reactions, only one is a redox reaction. Identify this reaction.
(a) $Ca(OH)_2 + 2HCl \longrightarrow CaCl_2 + 2H_2O$
(b) $2S_2O_7^{2-} + 2H_2O \longrightarrow 2SO_4^{2-} + 4H^+$
(c) $BaCl_2 + MgSO_4 \longrightarrow BaSO_4 + MgCl_2$
(d) $Cu_2S + 2FeO \longrightarrow 2Cu + 2Fe + SO_2$

23. White phosphorus reacts with caustic soda, the products are PH_3 and NaH_2PO_2. This reaction is an example of
(a) oxidation (b) reduction
(c) disproportionation (d) neutralisation

24. Which of the following is the strongest reducing agent in aqueous medium?
(a) Mg (b) Na (c) Li (d) Ca

25. In the reaction,

$$2FeCl_3 + H_2S \longrightarrow 2FeCl_2 + 2HCl + S$$

(a) $FeCl_3$ acts as an oxidising agent
(b) Both H_2S and $FeCl_3$ are oxidised
(c) $FeCl_3$ is oxidised while H_2S is reduced
(d) H_2S acts as an oxidising agent

26. Which of the following is the strongest oxidising agent?
(a) I_2 (b) F_2
(c) Cl_2 (d) Br_2

27. In the reaction, $SO_2 + 2H_2S \longrightarrow 3S + 2H_2O$ the substance that oxidises is
(a) H_2S (b) SO_2
(c) S (d) H_2O

28. Which of the following acts as an oxidising agent?
(a) HNO_3
(b) Cl_2
(c) $FeCl_3$
(d) All of the above

29. Identify disproportionation reaction **[NCERT Exemplar]**
(a) $CH_4 + 2O_2 \longrightarrow CO_2 + 2H_2O$
(b) $CH_4 + 4Cl_2 \longrightarrow CCl_4 + 4HCl$
(c) $2F_2 + 2OH^- \longrightarrow 2F^- + OF_2 + H_2O$
(d) $2NO_2 + 2OH^- \longrightarrow NO_2^- + NO_3^- + H_2O$

30. MnO_4^{2-} undergoes disproportionation reaction in acidic medium but MnO_4^- does not because **[NCERT Exemplar]**
(a) In MnO_4^{2-}, Mn is in intermediate oxidation state
(b) In MnO_4^-, Mn is in lowest oxidation state
(c) In MnO_4^-, Mn is in intermediate oxidation state
(d) None of the above

31. Which of the following is a redox reaction?
(a) H_2SO_4 with NaOH
(b) In atmosphere, O_3 from O_2 by lightening
(c) Nitrogen oxides from nitrogen and oxygen by lightening
(d) Evaporation of H_2O

32. The reaction,

$$Cl_2(g) + 2OH^-(aq) \longrightarrow ClO^-(aq) + Cl^-(aq) + H_2O(l)$$

represents the process of bleaching. Identify and name the species that bleaches the substances due to its oxidising action. **[NCERT Exemplar]**
(a) Cl^- (b) Cl_2
(c) OH^- (d) ClO^-

33. Whenever a reaction between an oxidising agent and a reducing agent is carried out **[NCERT]**
(a) a compound of lower oxidation state is formed if the reducing agent is in excess
(b) a compound of higher oxidation state is formed if the oxidising agent is in excess
(c) Both (a) and (b)
(d) None of the above

Balancing of Redox Reactions

34. The coefficients of I^-, IO_3^- and H^+ in the redox reaction, $I^- + IO_3^- + H^+ \longrightarrow I_2 + H_2O$ in the balanced form respectively are

(a) 5,1,6 (b) 1,5,6 (c) 6,1,5 (d) 5,6,1

35. In the equation $NO_2^{\ominus} + H_2O \longrightarrow NO_3^{\ominus} + 2H^{\oplus} + ne^-$ n stands for

(a) 1 (b) 2 (c) 3 (d) 4

36. The value of n in

$$MnO_4^- + 8H^+ + ne^- \longrightarrow Mn^{2+} + 4H_2O \text{ is}$$

(a) 5 (b) 4 (c) 2 (d) 3

37. $aK_2Cr_2O_7 + bKCl + cH_2SO_4 \longrightarrow xCrO_2Cl_2 + yKHSO_4 + zH_2O$

The above equation balances when

(a) $a = 2, b = 4, c = 6$ and $x = 2, y = 6, z = 3$
(b) $a = 4, b = 2, c = 6$ and $x = 6, y = 2, z = 3$
(c) $a = 6, b = 4, c = 2$ and $x = 6, y = 3, z = 2$
(d) $a = 1, b = 4, c = 6$ and $x = 2, y = 6, z = 3$

38. In the reaction, $8Al + 3Fe_3O_4 \longrightarrow 4Al_2O_3 + 9Fe$ the number of electrons transferred from the reductant to the oxidant is

(a) 8 (b) 4
(c) 16 (d) 24

39. The value of 'n' in the reaction $Cr_2O_7^{2-} + 14H^+ + nFe^{2+} \longrightarrow 2Cr^{3+} + nFe^{3+} + 7H_2O$ will be

(a) 2 (b) 3
(c) 6 (d) 7

40. The Mn^{3+} ion is unstable in solution and undergoes disproportionation to give Mn^{2+}, MnO_2 and H^+ ion. The balanced ionic equation for the reaction is **[NCERT]**

(a) $Mn^{3+} + 2H_2O \longrightarrow Mn^{2+} + 4H^+ + MnO_2$
(b) $2Mn^{3+} + H_2O \longrightarrow Mn^{2+} + 2H^+ + MnO_2$
(c) $2Mn^{3+} + 2H_2O \longrightarrow Mn^{2+} + MnO_2 + 4H^+$
(d) None of the above

Round II (Mixed Bag)

Only One Correct Option

1. What are the oxidation numbers of the three I atoms, in KI_3? **[NCERT]**

(a) 0, 0, −1 (b) −1, 0, −1
(c) $0, -\frac{1}{3}, 0$ (d) $-\frac{1}{3}, -\frac{1}{3}, 0$

2. Which of the following acts as an oxidising as well as reducing agent?

(a) Na_2O (b) Na_2O_2
(c) $NaNO_3$ (d) $NaNO_2$

3. During a redox titration involving a solution containing Fe^{2+} ions against MnO_4^- in the presence of excess of H^+ ions, the number of electrons that gets transferred is

(a) 6 (b) 5 (c) 4 (d) 2

4. When sulphur dioxide is passed in an acidified $K_2Cr_2O_7$ solution, the oxidation state of sulphur is changed from

(a) 4 to 0 (b) 4 to 2 (c) 4 to 6 (d) 6 to 4

5. In the following reaction,

$$M^{x+} + MnO_4^- \longrightarrow MO_3^- + Mn^{2+} + \frac{1}{2}O_2$$

If one mole of MnO_4^- oxidises 2.5 moles of M^{x+} then the value of x is

(a) 5 (b) 3 (c) 4 (d) 2

6. $3KClO_3 + 3H_2SO_4 \longrightarrow 3KHSO_4 + HClO_4 + 2ClO_2 + H_2O$

Equivalent weight of $KClO_3$ is

(a) $\frac{M}{4}$ (b) $\frac{M}{2}$ (c) $\left(M + \frac{M}{2}\right)$ (d) $\left(\frac{M}{4} + \frac{M}{2}\right)$

7. The equivalent weight of HNO_3 (molecular weight = 63) in the following reaction is

$$3Cu + 8HNO_3 \longrightarrow 3Cu(NO_3)_2 + 2NO + 4H_2O$$

(a) $\frac{4 \times 63}{3}$ (b) $\frac{63}{5}$ (c) $\frac{63}{3}$ (d) $\frac{63}{8}$

8. A mole of N_2H_4 loses 10 moles of electrons to form a new compound Y. Assuming that all the nitrogen appears in the new compound, what is the oxidation state of nitrogen in Y? (There is no change in the oxidation number of hydrogen.)

(a) −1 (b) −3 (c) +3 (d) +5

9. Which of the following reactions do not involve oxidation reduction?

I. $2Rb + 2H_2O \longrightarrow 2RbOH + H_2$
II. $2CuI_2 \longrightarrow 2CuI + I_2$
III. $NH_4Br + KOH \longrightarrow KBr + NH_3 + H_2O$
IV. $4KCN + Fe(CN)_2 \longrightarrow K_4[Fe(CN)_6]$

(a) I, II (b) I, III
(c) I, III, IV (d) III, IV

10. In which of the following pairs is there the greatest difference in the oxidation numbers of the underlined elements?

(a) $\underline{N}O_2$ and $\underline{N}_2O_4$
(b) $\underline{P}_2O_5$ and $\underline{P}_4O_{10}$
(c) $\underline{N}_2O$ and $\underline{N}O$
(d) $\underline{S}O_2$ and $\underline{S}O_3$

11. Cerric ammonium sulphate and potassium permanganate are used as oxidising agents in acidic medium for the oxidation of ferrous ammonium sulphate to ferric sulphate. The ratio of number of moles of cerric ammonium sulphate required per mole of ferrous ammonium sulphate to the number of moles of $KMnO_4$ required per mole of ferrous ammonium sulphate, is

(a) 5.0
(b) 0.2
(c) 0.6
(d) 2.0

12. Oxidation states of X, Y, Z are $+2, +5$ and -2 respectively. Formula of the compound formed by these will be

(a) X_2YZ_6
(b) XY_2Z_6
(c) XY_5
(d) X_3YZ_4

13. In which of the following reactions hydrogen is acting as an oxidising agent?

(a) With Li to form LiH
(b) With I_2 to give HI
(c) With S to give H_2S
(d) None of these

14. The number of peroxide bonds in perxenate ion $[XeO_6]^{4-}$ is

(a) 0
(b) 2
(c) 3
(d) 1

15. Oxidation states of the metal in the minerals haematite and magnetite, respectively, are

(a) II, III in haematite and III in magnetite
(b) II, III in haematite and II in magnetite
(c) II in haematite and II, III in magnetite
(d) III in haematite and II, III in magnetite

16. Mn^{2+} can be converted into Mn^{7+} by reacting with

(a) SO_2
(b) Cl_2
(c) PbO_2
(d) $SnCl_2$

17. While sulphur dioxide and hydrogen peroxide can act as oxidising as well as reducing agents in their reactions, ozone and nitric acid act only as oxidants. This is because **[NCERT]**

(a) in SO_2 and H_2O_2, S and O are in their lowest oxidation state
(b) in O_3 and HNO_3, N and O are in their highest oxidation state
(c) in O_3 and HNO_3, N and O are in their lowest oxidation state
(d) Both (a) and (b)

18. Thiosulphate reacts differently with iodine and bromine in the reactions given below **[NCERT Exemplar, NCERT]**

$$2S_2O_3^{2-} + I_2 \longrightarrow S_4O_6^{2-} + 2I^-$$
$$S_2O_3^{2-} + 2Br_2 + 5H_2O \longrightarrow 2SO_4^{2-} + 4Br^- + 10H^+$$

Which of the following statements justifies the above dual behaviour of thiosulphate?

(a) Bromine is a stronger oxidant than iodine
(b) Bromine is a weaker oxidant than iodine
(c) Thiosulphate undergoes oxidation by bromine and reduction by iodine in these reactions
(d) Bromine undergoes oxidation and iodine undergoes reduction in these reactions

19. Which of the following statements is not correct?

(a) The oxidation number of S in $(NH_4)_2S_2O_8$ is $+6$
(b) The oxidation number of Os in OsO_4 is $+8$
(c) The oxidation number of S in H_2SO_5 is $+8$
(d) The oxidation number of O in KO_2, is $-1/2$

More than One Correct Option

20. Which of the following reactions should be balanced in basic medium?

(a) $NH_3 + MnO_4^{\ominus} \longrightarrow MnO_2 + NO_2$
(b) $Cr(OH)_2 + I_2 \longrightarrow Cr(OH)_2 + 2I^{\ominus}$
(c) $HNO_3 + Fe^{2+} \longrightarrow Fe^{3+} + NO_2$
(d) $H_2O_2 + Fe^{3+} \longrightarrow O_2 + Fe^{2+}$

21. Which of the following statements is/are correct?

In the reaction

$$xCu_3P + yCr_2O_7^{2-} \longrightarrow Cu^{2+} + H_3PO_4 + Cr^{3+}$$

(a) Cu in Cu_3P is oxidised to Cu^{2+} whereas P in Cu_3P is also oxidised to PO_4^{3-}
(b) Cu in Cu_3P is oxidised to Cu^{2+} whereas P in Cu_3P is reduced to H_3PO_4
(c) In the conversion of Cu_3P to Cu^{2+} and H_3PO_4 11 electrons are involved
(d) The value of x is 6

22. Which of the following statements about the following reaction is / are wrong?

$$2Cu_2O(s) + Cu_2S(s) \longrightarrow 6Cu(s) + SO_2(g)$$

(a) Both Cu_2O and Cu_2S are reduced
(b) Only Cu_2S is reduced
(c) Cu_2S is the oxidant
(d) Only Cu_2O is reduced

23. Which of the following has/have been arranged in order of decreasing oxidation state of sulphur?

(a) $H_2S_2O_7 > Na_2S_4O_6 > Na_2S_2O_3 > S_8$
(b) $SO^{2+} > SO_4^{2-} > SO_3^{2-} > HSO_4^-$
(c) $H_2SO_5 > H_2SO_3 > SCl_2 > H_2S$
(d) $H_2SO_5 > SO_2 > H_2S > H_2S_2O_8$

24. Which of the following statements(s) is/are not true about the following decomposition reaction?

$$2KClO \longrightarrow 2KCl + 3O_2$$ **[NCERT** Exemplar**]**

(a) Potassium is undergoing oxidation
(b) Chlorine is undergoing oxidation
(c) Oxygen is reduced
(d) None of the species are undergoing oxidation or reduction

Assertion and Reason

Directions (Q. Nos. 25 to 27) *Each of these questions contains two statements : Statement* I (*Assertion*) *and Statement* II (*Reason*). *Each of these questions also has four alternative choices, only one of which is the correct answer. You have to select one of the codes* (*a*), (*b*), (*c*), (*d*) *given below*

(a) Statement I is true, Statement II is true; Statement II is a correct explanation for Statement I.
(b) Statement I is true, Statement II is true; Statement II is not a correct explanation for Statement I.
(c) Statement I is true; Statement II is false.
(d) Statement I is false; Statement II is true.

25. Statement I Among halogens fluorine is the best oxidant .

Statement II Fluorine is the most electronegative atom. **[NCERT** Exemplar**]**

26. Statement I In the reaction between potassium permanganate and potassium iodide, permanganate ions act as oxidising agent.

Statement II Oxidation state of manganese changes from +2 to +7 during the reaction. **[NCERT** Exemplar**]**

27. Statement I The decomposition of hydrogen peroxide to form water and oxygen is an example of disproportionation reaction.

Statement II The oxygen of peroxide is in –1 oxidation state and it is converted to zero oxidation state in O_2 and –2 oxidation state in H_2O. **[NCERT** Exemplar**]**

Comprehension Based Questions

Directions (Q. Nos. 28 to 30) Consider the following unbalanced redox reaction

$$H_2O + AX + BY \longrightarrow HA + OY + X_2B$$

The oxidation number of X is – 2, and neither X nor water is involved in the redox process.

28. The element(s) undergoing oxidation is / are

(a) A	(b) B
(c) Y	(d) B or Y or both

29. The possible oxidation states of B and Y in BY are respectively

(a) +1, – 1	(b) +2, – 2
(c) +3, – 3	(d) All of these

30. If the above reaction is balanced with smallest whole number coefficients, the sum of the stoichiometric coefficients of all the compounds is

(a) 9	(b) 8
(c) 7	(d) 6

Directions (Q. Nos. 31 to 34) Redox equations are balanced either by ion electron method or by oxidation number method. Both methods lead to the correct form of the balanced equation. The ion electron method has two advantages, so some chemists prefer to use the ion electron method for redox reactions carried out in dilute aqueous solution, where free ions have more or less independent existence.

The oxidation state method for redox reactions is mostly used for solid chemicals or for reactions in concentrated acid media.

31. For the reaction

$$K_4[Fe(CN)_6] \longrightarrow Fe^{3+} + CO_2 + NO_3^{\ominus}$$

the n-factor is

(a) 1	(b) 11
(c) $\frac{5}{3}$	(d) 61

32. For the reaction,

$$FeS_2 \longrightarrow Fe^{3+} + SO_2$$

the n-factor is

(a) 1	(b) 11
(c) 28	(d) 61

33. For the reaction,

$$2Br_2 + 2NaOH \longrightarrow NaBrO_3 + NaBr + H_2O$$

the n-factor is

(a) 11	(b) 28
(c) 61	(d) $\frac{5}{3}$

34. For the reaction,

$$As_2S_3 \longrightarrow As^{5+} + SO_4^{2-}$$

the n-factor is

(a) 11	(b) 28
(c) 61	(d) $\frac{5}{3}$

Previous Years' Questions

35. What products are expected from the disproportionation reaction of hypochlorous acid? [AIEEE 2006]

(a) $HClO_3$ and Cl_2O
(b) $HClO_2$ and $HClO_4$
(c) HCl and Cl_2O
(d) HCl and $HClO_3$

36. Which of the following chemical reactions depicts the oxidising behaviour of H_2SO_4? [AIEEE 2006]

(a) $2HI + H_2SO_4 \longrightarrow I_2 + SO_2 + 2H_2O$
(b) $Ca(OH)_2 + H_2SO_4 \longrightarrow CaSO_4 + 2H_2O$
(c) $NaCl + H_2SO_4 \longrightarrow NaHSO_4 + HCl$
(d) $2PCl_5 + H_2SO_4 \longrightarrow 2POCl_3 + 2HCl + SO_2Cl_2$

37. The oxidation state of chromium in the final product formed by the reaction between KI and acidified potassium dichromate solution is [AIEEE 2005]

(a) + 3 (b) + 2
(c) + 6 (d) + 4

38. Oxidation number of Cl in $CaOCl_2$ (bleaching powder) is [AIEEE 2004]

(a) zero, since it contains Cl_2
(b) −1, since it contains Cl^-
(c) +1, since it contains ClO^-
(d) +1 and −1, since it contains ClO^- and Cl^-

39. MnO_4^- is a good oxidising agent in different medium changing to

$$MnO_4^- \longrightarrow Mn^{2+} \longrightarrow MnO_4^{2-} \longrightarrow MnO_2 \longrightarrow Mn_2O_3$$

Changes in oxidation number respectively are [AIEEE 2002]

(a) 1, 3, 4, 5 (b) 5, 4, 3, 2
(c) 5, 1, 3, 4 (d) 2, 6, 4, 3

40. Which of the following is a redox reaction? [AIEEE 2002]

(a) $NaCl + KNO_3 \longrightarrow NaNO_2 + KCl$
(b) $CaC_2O_4 + 2HCl \longrightarrow CaCl_2 + H_2C_2O_4$
(c) $Ca(OH)_2 + 2NH_4Cl \longrightarrow CaCl_2 + 2NH_3 + 2H_2O$
(d) $2K[Ag(CN)_2] + Zn \longrightarrow 2Ag + K_2[Zn(CN)_4]$

the Guidance

Round I

1. The sum of oxidation states of all elements in an ion is equal to charge on it.

Let the oxidation state of S in $SO_4^{2-} = x$

$\therefore \quad x + (-2 \times 4) = -2$ or $x = +6$

2. In N_3H

Oxidation number of $N = -\frac{1}{3}$

In N_2O_4 oxidation number of $N = +4$

In NH_2OH oxidation number of $N = -1$

In NH_3 oxidation number of $N = -3$

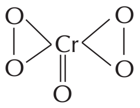
Hence, in N_2O_4 the oxidation number of nitrogen is highest.

3. NH_4NO_3 is actually NH_4^+ and NO_3^-. In NH_4^+, oxidation state of N is −3 and in NO_3^- oxidation state of N is + 5.

4. $\overset{+2}{O}\overset{-1\times2}{F_2}$: $x - 2 = 0 \Rightarrow x = 2$

$\therefore$ Oxidation number of O = + 2

5.



i.e., it has four peroxide bonded oxygen each having an oxidation number of −1 and one double bond in which oxidation number of O is −2.

Therefore, $x + 4 \times (-1) + 1 \times (-2) = 0$

$\therefore \quad x = +6$

6. The oxidation state of iodine in HIO_4 is + 7 as

$$1 + x + 4(-2) = 0$$
$$x = +7$$

The oxidation state of iodine in H_3IO_5 is + 7 as

$$3 + x + 5(-2) = 0$$
$$x = +7$$

The oxidation state of iodine in H_5IO_6 is + 7 as

$$5 + x + 6(-2) = 0$$
$$x = +7$$

7. Oxidation number of iodine in the given species is as follows

Oxidation number of iodine in $IF_3 = +3$

Oxidation number of iodine in $I_3^- = -\frac{1}{3}$

Oxidation number of iodine in $IF_5 = +5$

Oxidation number of iodine in $IF_7 = +7$

9. Let the oxidation number of Cr be x

$\therefore$ For $K_2Cr_2O_7$

$$+1 \times 2 + 2x + 7(-2) = 0$$
$$2 + 2x - 14 = 0$$
$$2x = 12$$
$$x = 6$$

10. Bromine has zero oxidation state because it is in free state.

$$\overset{0}{Br_2} \longrightarrow BrO_3^-$$

Let the oxidation number of Br in BrO_3^- is x.

$$x + (-2 \times 3) = -1$$
$$x + (-6) = -1$$
$$x = +6 - 1$$
$$= +5$$

So, oxidation number changes from 0 to + 5.

11. Permonosulphuric acid (H_2SO_5) has two oxygen atoms in peroxide linkage, hence,

$$2(+1) + x + 2(-1) + 3(-2) = 0$$
$$2 + x - 2 - 6 = 0$$

$\therefore \quad x = +6$

12. Oxidation number of N in NO^+ is

$$(1 \times x) + 1 \times (-2) = +1$$
$$x = +3$$

Oxidation number of Cl in ClO_4^- is

$$(1 \times x) + 4 \times (-2) = -1$$

$\therefore \quad x = +7$

13. Maximum oxidation state for d-block elements $= (n-1)$ unpaired $de^- + nse^-$

For $3d^5, 4s^2$ configuration,

Maximum oxidation number = 5 + 2 = 7

14. $\underline{C}H_3\underline{C}H_2OH$

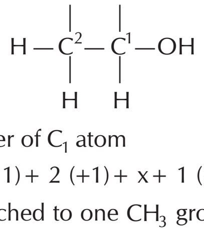
$$\overset{x}{C_2}\overset{+1}{H_6}\overset{-2}{O}$$

$$2x + 6(+1) + 1(-2) = 0$$
$$2x = -4$$

or $\quad x = -2$

Therefore, the average oxidation number of C is −2.

Let us consider the structure of CH_3CH_2OH



$$H-\overset{H}{\underset{H}{C^2}}-\overset{H}{\underset{H}{C^1}}-OH$$

Oxidation number of C_1 atom

$$= 1(+1) + 2(+1) + x + 1(-1) = 0$$

[$\therefore C_1$ atom is attached to one CH_3 group (oxidation number = + 1), two H atoms and one —H group (Ox. no. = −1)]

$\therefore \qquad x = -2$

Oxidation number of C_2 atom $= 3(+1) + x + 1(-1) = 0$

[C_2 atom is attached to three H-atoms and one $—CH_2OH$ group (Ox. no. $= -1$)]

$\therefore y = -2$

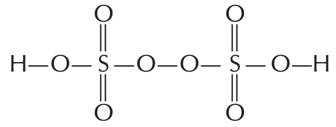
15. $\underline{C}H_3\underline{C}OOH$

$$\overset{x}{C_2}\overset{+1}{H_4}\overset{-2}{O_2}$$

$$2x + 4(+1) + 2(-2) = 0$$

$$2x + 4 + (-4) = 0 \text{ or } x = 0$$

16. The chemical structure of $H_2S_2O_8$ is as follows



$$\underset{\text{For H}}{2x(+1)} + \underset{\text{For S}}{2 \times x} + \underset{\text{For O}}{6 \times (-2)} + \underset{\text{For O–O}}{2 \times (-1)} = 0$$

$$+2 + 2x - 12 - 2 = 0$$

$$2x = +12$$

$$x = +6$$

17. Let the oxidation state of Cr in $K_2Cr_2O_7 = x$

$$(+1 \times 2) + 2x + (-2 \times 7) = 0$$

or $\qquad +2 + 2x - 14 = 0$

$\therefore \qquad x = +6$

Let the oxidation state of Cr in $K_2CrO_4 = x$

$$+1 \times 2 + x + (-2 \times 4) = 0$$

$$2 + x - 8 = 0$$

$$x = 6$$

$\therefore$ Change in oxidation state of Cr is zero when it changes from $K_2Cr_2O_7$ to K_2CrO_4.

18. It is a disproportionation reaction.

19. Intermolecular redox reaction and redox reactions are same.

20. Loss of an electron or increase in oxidation number is oxidation process. *i.e.,*

$$H^- \longrightarrow H + e^-$$

21. It is a disproportionation reaction, so Cl_2 undergoes both oxidation and reduction.

Oxidation

22. $\overset{+1}{Cu_2}\overset{-2}{S} + 2\overset{+2}{Fe}\overset{-2}{O} \longrightarrow 2\overset{0}{Cu} + 2\overset{0}{Fe} + \overset{+4}{S}\overset{-2}{O_2}$

Reduction

Reduction

In this reaction Cu and Fe undergo reduction while sulphur undergoes oxidation. Hence, this is a redox reaction.

23. In this reaction phosphorus is simultaneously oxidised and reduced. It is a disproportionation reaction.

$$\overset{0}{P_4} + 3NaOH + 3H_2O \longrightarrow 3Na\overset{+1}{H_2}PO_2 + \overset{-3}{P}H_3$$

24. In an aqueous medium, Li is the strongest reducing agent, since the high negative enthalpy of hydration compensates high IE_1.

25. $e^- + Fe^{3+} \longrightarrow Fe^{2+}$ (Reduction)

Therefore, $FeCl_3$ acts as an oxidising agent.

26. Reduction potential order is $F_2 > Cl_2 > Br_2 > I_2$.

So, F_2 is the strongest oxidising agent.

(Moreover, F_2 has great tendency to get reduced into F^- due to its highly electronegative nature.)

28. All these substances can accept electrons and can decrease their oxidation number and hence, all these act as oxidising agent.

$$H\overset{+5}{N}O_3 \longrightarrow \overset{+4}{N}O_2 \text{ or } \overset{+2}{N}O$$

$$Cl_2 \longrightarrow 2Cl^-$$

$$\overset{+3}{Fe}Cl_3 \longrightarrow \overset{+2}{Fe}Cl_2$$

Oxidation

29. $2\overset{+4}{N}O_2 + 2OH^- \longrightarrow \overset{+3}{N}O_2^- + \overset{+5}{N}O_3^- + H_2O$

Reduction

Since in this reaction, the same element , *i.e.,* N is reduced as well as oxidised, so it is a disproportionation reaction.

Note In OF_2, oxidation state of F is -1.

30. In MnO_4^{2-}, the oxidation number of Mn is $+6$. It can increase its oxidation number (to $+7$) or decrease its oxidation number to $+4, +3, +2, 0$). Hence, it undergoes disproportionation reaction is acidic medium.

$$3\overset{+6}{Mn}O_4^{2-} + 4H^+ \longrightarrow 2\overset{+7}{Mn}O_4^- + \overset{+4}{Mn}O_2 + 2H_2O$$

Ox. no. increases by 1 per atom

Ox. no. decreases by 2 per atom

In MnO_4^-, Mn is in its highest oxidation state, *i.e.,* $+7$. It can only decrease its oxidation number. Hence, it cannot undergo disproportionation reaction.

31. a. Neutralisation

b. It is the change of an element in one form (oxidation state $= 0$) to another form.

c. Redox reaction [$\overset{0}{N_2} + \overset{0}{O_2} \longrightarrow \overset{\neq 0 \neq 0}{NO}$]

d. Physical change

32. $\overset{0}{Cl_2}(g) + 2\overset{-2\,+1}{OH^-}(aq) \longrightarrow \overset{+1\,-2}{ClO^-}(aq) + \overset{-1}{Cl^-}(aq) + \overset{+1\,-2}{H_2O}(l)$

In this reaction, oxidation number of Cl increases from 0 (in Cl_2) to 1 (in ClO^-) as well as decreases from 0 (in Cl_2) to -1 (in Cl^-). So, it acts as both reducing agent as well as oxidising agent. This is an example of disproportionation reaction. In this reaction, ClO^- species bleaches the substances due to its oxidising action. [In hypochlorite ion (ClO^-), Cl can decrease its oxidation number from $+1$ to 0 or -1.]

33. Both the statements are correct. This can be proved by following example.

P_4 is a reducing agent and Cl_2 is an oxidising agent.

(i) $\underset{\text{Excess}}{\overset{0}{P_4}}\ (s) + 6Cl_2(g) \longrightarrow \underset{\text{Lower oxidation state of P}}{4\overset{+3}{P}Cl_3}$

(ii) $\underset{\text{Excess}}{\overset{0}{P_4}(s) + 10Cl_2(g)} \longrightarrow \underset{\text{Higher oxidation state of P}}{4\overset{+5}{P}Cl_5}$

Therefore, when P_4 (reducing agent) is in excess, PCl_3 is formed in which oxidation state of P is +3 and if Cl_2 (oxidising agent) is in excess, PCl_5 is formed in which oxidation state of P is + 5.

34. $I^- + \overset{+5}{I}O_3^- + H^+ \longrightarrow \overset{0}{I_2} + H_2O$

$$2I^- \longrightarrow I_2 + 2e^-]\times 5 \qquad \ldots(i)$$

$$10e^- + 2\overset{+5}{I}O_3^- \longrightarrow \overset{0}{I_2} \qquad \ldots(ii)$$

On adding Eq. (i) and (ii), we get

$$10I^- + 2IO_3^- \longrightarrow 6I_2$$

To balance O atom, add $6H_2O$ molecules on RHS and $12H^+$ on LHS, then

$$10I^- + 2IO_3^- + 12H^+ \longrightarrow 6I_2 + 6H_2O$$

or $\quad 5I^- + IO_3^- + 6H^+ \longrightarrow 3I_2 + 3H_2O$

35. $NO_2^{\ominus} + H_2O \longrightarrow NO_3^{\ominus} + 2H^{\oplus} + 2e^-$

Balance charge on both sides.

36. $MnO_4^- + 8H^+ + 5e^- \longrightarrow Mn^{2+} + 4H_2O$

37. $\underset{1}{a}K_2Cr_2O_7 + \underset{4}{b}KCl + \underset{6}{c}H_2SO_4 \longrightarrow \underset{2}{x}CrO_2Cl_2 + \underset{6}{y}KHSO_4 + \underset{3}{z}H_2O$

38. $8Al \longrightarrow 8Al^{3+} + 24e^-$

$9Fe^{8/3+} + 24e^- \longrightarrow 9Fe$

39. $Cr_2O_7^{2-} + 14H^+ + nFe^{2+} \longrightarrow 2Cr^{3+} + nFe^{3+} + 7H_2O$

$Cr_2O_7^{2-} + 14H^+ + 6e^- \longrightarrow 2Cr^{3+} + 7H_2O$ (reduction)...(i)

$Fe^{2+} \longrightarrow Fe^{3+} + e^-$ (oxidation) ...(ii)

Eq. (ii) is multiplied by 6

$$6Fe^{2+} \longrightarrow 6Fe^{3+} + 6e^-$$

Thus, balanced equation is

$$Cr_2O_7^{2-} + 14H^+ + 6Fe^{2+} \longrightarrow 2Cr^{3+} + 6Fe^{3+} + 7H_2O$$

Hence, the value of *n* is 6

40. The skeletal equation is,

$$Mn^{3+}(aq) \longrightarrow Mn^{2+}(aq) + MnO_2(s) + H^+(aq)$$

Reduction half reaction

$$Mn^{3+}(aq) + e^- \longrightarrow Mn^{2+} \qquad \ldots(i)$$

Oxidation half reaction

$$Mn^{3+}(aq) \longrightarrow \overset{+4}{Mn}O_2 + e^- \qquad \ldots(ii)$$

Balance charge by adding $4H^+$ to RHS and then balance O atoms by adding $2H_2O$ to LHS

$$Mn^{3+}(aq) + 2H_2O(l) \longrightarrow MnO_2(s) + e^- + 4H^+(aq) \qquad \ldots(iii)$$

By adding (i) and (iii) we get

$$2Mn^{3+}(aq) + 2H_2O(l) \longrightarrow Mn^{2+} + MnO_2(s) + 4H^+(aq)$$

This represents the final balanced redox reaction (disproportionation reaction).

Round II

1. $\overset{+1}{K}\overset{x}{I_3}$

$1(+1) + 3x = 0$ or $x = -\frac{1}{3}$

Therefore, the average oxidation number of I is $-\frac{1}{3}$. It is wrong because oxidation number cannot be fractional. Let us consider the structure of KI_3.

$\overset{+}{K}(I-I\leftarrow I)^{-1}$, In this structure, a coordinate bond is formed between I_2 molecule and I^- ion. Hence, the oxidation number of three I atoms in KI_3 are 0, 0 (in I_2) and −1 respectively.

2. $NaNO_2$ (sodium nitrite) acts both as oxidising as well as reducing agent because in it N-atom is in + 3 oxidation state (intermediate oxidation state).

Oxidising property

$$2NaNO_2 + 2KI + 2H_2SO_4 \longrightarrow Na_2SO_4 + K_2SO_4 + 2NO + 2H_2O + I_2$$

Reducing property

$$H_2O_2 + NaNO_2 \longrightarrow NaNO_3 + H_2O$$

3. $MnO_4^- + 8H^+ + 5e^- \longrightarrow Mn^{2+} + 4H_2O$

$[Fe^{2+} \longrightarrow Fe^{3+} + e^-]\times 5$

$MnO_4^- + 8H^+ + 5Fe^{2+} \longrightarrow Mn^{2+} + 5Fe^{3+} + 4H_2O$

∴ Five electrons gets transferred.

4. Acidified $K_2Cr_2O_7$ solution oxidises SO_2 into $Cr_2(SO_4)_3$.

$$3\overset{+4}{S}O_2 + K_2Cr_2O_7 + H_2SO_4 \longrightarrow K_2SO_4 + Cr_2(\overset{+6}{S}O_4)_3 + H_2O$$

Hence, oxidation state of sulphur changes from + 4 to + 6.

5.

Oxidation

Change in oxidation state = 2

$$5M^{x+} + 2\overset{+7}{Mn}O_4^- \longrightarrow \overset{+5}{M}O_3^- + Mn^{2+} + \frac{1}{2}O_2$$

Change in oxidation state = 5

Reduction

$$x + 2 = 5$$

$$\therefore \quad x = 5 - 2 = +3$$

6. Disproportionation reaction.

$$\mathrm{ClO_3^{\ominus}} \longrightarrow \mathrm{ClO_4^{\ominus}} + 2\,e^-(x=2)\ \text{(oxidation)}$$

$x-6=-1$ $\quad$ $x-8=-1$

$x=5$ $\quad$ $x=7$

$$e^- + \mathrm{ClO_3^{\ominus}} \longrightarrow \mathrm{ClO_2}\,(x=1)\ \text{(reduction)}$$

$x=5$ $\quad$ $x-4=0$

$x=4$

$$\text{Equivalent weight} = M + \frac{M}{2}$$

7. In this case only 2 moles of $\mathrm{NO_3^{\ominus}}$ undergo reduction.

$$3e^- + \mathrm{NO_3^-} \longrightarrow \mathrm{NO}\,(x=3)\ \text{(reduction)}$$

$x-6=-1$ $\quad$ $x-2=0$

$x=5$ $\quad$ $x=2$

6 moles of $\mathrm{HNO_3}$ are not changing so $6\mathrm{NO_3^{\ominus}}$ are added in the reaction to get 3 moles of $\mathrm{Cu(NO_3)_2}$.

$$\text{Equivalent weight} = M + \frac{M}{3} = \frac{4M}{3} = \frac{4\times 63}{3}$$

8. $\mathrm{N_2H_4} \longrightarrow 2Y + 10e^-$

$2x+4=0 \quad 2y=2x$

$2x=-4$

$$\underbrace{\uparrow\;2x-(-4)=10\;\uparrow}_{x=3}$$

9. I. $\mathrm{Rb} \longrightarrow \mathrm{Rb^+} + e^-$ (Oxidation)

$$\mathrm{H_2O} + e^- \longrightarrow \overset{\ominus}{\mathrm{O}}\mathrm{H} + \frac{1}{2}\mathrm{H_2}\ \text{(Reduction)}$$

Hence, redox reaction.

II. $e^- + \mathrm{Cu^{2+}} \longrightarrow \mathrm{Cu^+}$ (Reduction)

$$2\mathrm{I}^{\ominus} \longrightarrow \mathrm{I_2} + 2e^-\ \text{(Oxidation)}$$

Hence, redox reaction.

III. $\overset{\oplus}{\mathrm{N}}\mathrm{H_4} \longrightarrow \mathrm{NH_3}$ (No change in oxidation number)

$x=-3$ $\quad$ $x=-3$

Hence, reaction is not redox.

IV. No change in the oxidation number of either $\mathrm{Fe^{2+}}$ or $\mathrm{CN^{\ominus}}$ in both reactant and product, hence, not redox reaction.

10. (a) $\mathrm{NO_2}(x=4), \mathrm{N_2O_4}(x=4)$

Difference in oxidation state of $\mathrm{N}=0$

(b) $\mathrm{P_2O_5}$ and $\mathrm{P_4O_{10}}$ (Difference in oxidation state of P is zero)

(c) $\mathrm{N_2O}\,(x=1)$ and $\mathrm{NO}\,(x=2)$,

Difference in oxidation state of $\mathrm{N}=1$.

(d) $\mathrm{SO_2}\,(x=4)$ and $\mathrm{SO_3}\,(x=6)$

Difference in oxidation state of $\mathrm{S}=2$

11. $\mathrm{Fe^{2+}} + \mathrm{Ce^{4+}} \longrightarrow \mathrm{Fe^{3+}} + \mathrm{Ce^{3+}}$

$$5\mathrm{Fe^{2+}} + \mathrm{MnO_4^-} + 8\mathrm{H^+} \longrightarrow 5\mathrm{Fe^{3+}} + \mathrm{Mn^{2+}} + 4\mathrm{H_2O}$$

$$\therefore \frac{\text{Moles of cerric ammonium sulphate}}{\text{Moles of potassium permanganate}} = \frac{1}{1/5} = 5.0$$

12. The oxidation state of X, Y and Z are $+2, +5$ and -2 respectively.

I. In $X_2YZ_6 = 2\times 2 + 5 + 6(-2) \neq 0$

II. In $XY_2Z_6 = 2 + 5\times 2 + 6(-2) = 0$

III. In $XY_5 = 2 + 5\times 2 \neq 0$

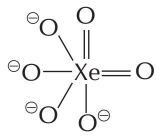
IV. In $X_3YZ_4 = 3\times 2 + 5 + 4(-2) \neq 0$

Hence, the formula of the compound is XY_2Z_6.

13. $\mathrm{Li} + \overset{0}{\mathrm{H_2}} \longrightarrow 2\,\overset{+1\,-1}{\mathrm{Li\,H}}$

Oxidation number of hydrogen is decreasing from 0 to −1. So, $\mathrm{H_2}$ is acting as oxidising agent in this reaction.

14. No peroxide bond in $[\mathrm{XeO_6}]^{4-}$. Structure is



15. Haematite is $\mathrm{Fe_2O_3}$, in which oxidation number of iron is III. Magnetite is $\mathrm{Fe_3O_4}$ which is infact a mixed oxide $(\mathrm{FeO\cdot Fe_2O_3})$, hence iron is present in both II and III oxidation state.

16. $2\mathrm{MnCl_2} + 5\mathrm{PbO_2} + 6\mathrm{HNO_3} \longrightarrow$

$$2\mathrm{HMnO_4} + 2\mathrm{PbCl_2} + 3\mathrm{Pb(NO_3)_2} + 2\mathrm{H_2O}$$

17. An element, in its lowest oxidation state, can behave only as reductant while in its highest oxidation state can behave only as oxidants. In intermediate oxidation states, elements can behave as oxidant as well as reductant.

(i) In $\mathrm{SO_2}$, S is in + 4 oxidation state. It can have minimum oxidation number − 2 and maximum oxidation number + 6. Therefore, S in $\mathrm{SO_2}$ can either decrease or increase its oxidation number. So, $\mathrm{SO_2}$ can act both as oxidising as well as reducing agent.

(ii) In $\mathrm{H_2O_2}$, O is in − 1 oxidation state. It can have minimum oxidation number − 2 and maximum oxidation number zero (+1 and +2 also possible in $\mathrm{O_2F_2}$ and $\mathrm{OF_2}$ respectively). Therefore, 'O' in $\mathrm{H_2O_2}$ can either decrease or increase its oxidation number. So, $\mathrm{H_2O_2}$ can act both as oxidising as well as reducing agent.

(iii) In $\mathrm{O_3}$, O is in zero oxidation state. It cannot increase its oxidation number, it can only decrease its oxidation number from zero to − 1 or − 2. So, ozone can act only as an oxidising agent.

(iv) In $\mathrm{HNO_3}$, the oxidation number of N is +5. It is maximum. So, N in $\mathrm{HNO_3}$ can only decrease its oxidation number. So, it can act as an oxidising agent only.

18. $2\,\overset{+2}{\mathrm{S}}_2\overset{-2}{\mathrm{O}}{}_3^{2-}(aq) + \overset{0}{\mathrm{I}}_2(s) \longrightarrow \overset{2.5}{\mathrm{S}}_4\overset{2-}{\mathrm{O}}{}_6^{2-}(aq) + 2\mathrm{I^-}(aq)$

$$\overset{+2}{\mathrm{S}}_2\overset{-2}{\mathrm{O}}{}_3^{2-}(aq) + 2\,\overset{0}{\mathrm{B}}\mathrm{r_2}(l) + 5\mathrm{H_2O}(l) \longrightarrow$$

$$2\overset{+6}{\mathrm{S}}\overset{2-}{\mathrm{O}}{}_4^{2-}(aq) + 4\mathrm{Br^-}(aq) + 10\mathrm{H^+}(aq)$$

Bromine being stronger oxidising agent than I_2, oxidises S of $S_2O_3^{2-}$ to SO_4^{2-} whereas I_2 oxidises it only into $S_4O_6^{2-}$ ion.

19. (a) $(N\overset{+1}{H}_4)_2S_2O_8^{2-}$

$\therefore$ Oxidation state of S $= +6$

(Since $S_2O_8^{2-}$ has one peroxide bond)

(b) Oxidation state of Os $= +8$

(c) Oxidation state of S in $H_2SO_5 = +6$

(Since it has one peroxide bond)

(d) $K^{1+}O_2^{1-}$ oxidation state of O $= -1/2$

20. In (a) $MnO_4^{\ominus} \longrightarrow MnO_2$ occurs only in basic medium

In (b) $Cr(OH)_2 \longrightarrow Cr(OH)_3$ occurs only in basic medium. (c) and (d) occurs only in acidic medium.

21.

$$4H_2O + \overset{+1\times 3}{Cu_3}\overset{-3}{P} \longrightarrow 3Cu^{2+} + H_3PO_4 + 11e^- + 5H^{\oplus}] \times 6$$

$$6e^- + 14H^{\oplus} + Cr_2O_7^{2-} \longrightarrow 2Cr^{3+} + 7H_2O] \times 11$$

$$6Cu_3P + 124H^{\oplus} + 11Cr_2O_7^{2-} \longrightarrow 18Cu^{2+} + 6H_3PO_4 + 22Cr^{3+} \times 53H_2O$$

22. In Cu_2O and Cu_2S, the oxidation state of Cu is $+1$. So they are reduced to $Cu^0 (Cu^{1+} + e^- \longrightarrow Cu^0)$

23. (a)

$$\left.\begin{array}{r} H_2S_2O_7 : 2 + 2x - 14 = 0 \Rightarrow x = 6 \\ Na_2S_4O_6 : 2 + 4x - 12 = 0 \Rightarrow x = 2.5 \\ Na_2S_2O_3 : 2 + 2x - 6 = 0 \Rightarrow x = 2 \\ S_8 : 8x - 0 \Rightarrow x = 0 \end{array}\right] \text{Oxidation state of S}$$

(c) H_2SO_5 (Peroxo linkage) Oxidation state of S $= +6$

$H_2SO_3 : 2 + x - 6 = 0$

Oxidation state of S $= +4$

$SCl_2 : x - 2 = 0$ Oxidation state of S $= +2$

$H_2S : 2 + x = 0$ Oxidation state of S $= -2$

24.

Reduction

$$2\,\overset{+1}{K}\,\overset{+5}{Cl}\,\overset{-2}{O_3} \longrightarrow 2\,\overset{+1}{K}\overset{-1}{Cl} + 3\,\overset{0}{O_2}$$

Oxidation

25. Fluorine being most electronegative element is the best oxidant.

26.

$$10KI + 2K\overset{+7}{Mn}O_4 + 8H_2SO_4 \longrightarrow 2\overset{+2}{Mn}SO_4 + 6K_2SO_4 + 8H_2O + 5I_2$$

27.

Oxidation

$$2H_2\overset{-1}{O_2} \longrightarrow 2H_2\overset{-2}{O} + \overset{0}{O_2}$$

Reduction

Thus, the above reaction is an example of disproportionation reaction.

28. Oxidation state of $X = -2 \Rightarrow \overset{+2}{A}\overset{-2}{X}$

Oxidation state of $O = -2 \Rightarrow \overset{-2}{O}\overset{+2}{Y}$

Oxidation state of $X = -2, \Rightarrow \overset{-2\times 2}{X_2}\overset{+4}{B}$

$$\therefore \quad \overset{+2}{A}\overset{-2}{X} + BY + H_2O \longrightarrow \overset{+1}{H}\overset{-1}{A} + \overset{-2}{O}\overset{+2}{Y} + \overset{-2\times 2}{X_2}\overset{+4}{B}$$

$$e^- + A^{2+} \longrightarrow A^{1-} \text{ (reduction)}$$

$$\overset{+a}{B}\overset{-a}{Y} \longrightarrow B^{4+} + Y^{2+} \text{ (oxidation)}$$

Therefore, B or Y or both might have been oxidised.

29. In BY, the oxidation state of $B \le +2$

Oxidation state of $Y \le +2$.

If the oxidation state of B is +1 and that of Y is −1, then both will be oxidised.

If the oxidation state of B is +2 and that of Y is −2, then both will be oxidised.

If the oxidation state of B is +3 and that of Y is −3, then both will be oxidised.

30.

$$A^{2+} + H^{\oplus} + 3e^- \longrightarrow HA] \times 2$$

$$BY + H_2O \longrightarrow B^{4+} + OY + 2H^{\oplus} + 6e^-$$

$$2A^{2+} + BY + H_2O \longrightarrow 2HA + B^{4+} + OY$$

Or

$$\underset{2}{\underline{2AX}} + \underset{1}{\underline{BY}} + \underset{1}{\underline{H_2O}} \longrightarrow \underset{2}{\underline{2HA}} + \underset{1}{\underline{BX_2}} + \underset{1}{\underline{OY}} = 8$$

$$2 + 1 + 1 + 2 + 1 + 1$$

The sum of all the coefficients is 8.

31. $\overset{+1\times 4}{K_4}\left[Fe^{2+}(\overset{-1\times 6}{CN})_6\right]^{-4}$ Oxidation state of Fe is +2

$$Fe^{2+} \longrightarrow Fe^{3+} + e^-$$

$$6(CN)^{\ominus} \longrightarrow 6CO_2 + 12e^-$$

$6(x - 3 = -1)$ $\quad$ $6(x - 4 = 0)$

$6(x = 2)$ $\quad$ $6(x = 4)$

$$6(CN)^{\ominus} \longrightarrow 6NO_3^{\ominus} + 48e^-$$

$\left(\begin{array}{c}\text{Oxidation number} \\ \text{of } N = -3\end{array}\right)$ $\quad$ $6(x - 6 = -1)$

$6(x = 5)$

$$Fe^{2+}(CN)_6]^{4-} \longrightarrow Fe^{3+} + 6CO_2 + 6NO_3^{\ominus} + 61e^-$$

32.

$$Fe^{2+} \longrightarrow Fe^{3+} + e^- \text{ Total } e^- = 11$$

$$S_2^{2-} \longrightarrow 2SO_2 + 10e^-$$

$2x = -2$ $\quad$ $2x - 8 = 0$

$2x = 8$

33.

$$Br_2 \longrightarrow 2BrO_3^{\ominus} + 10e^-$$

$2x = 0$ $\quad$ $2x - 12 = -2$

$2x = 10$

$$2e^- + Br_2 \longrightarrow 2Br^{\ominus}] \times 5$$

$$\underline{6Br_2 \longrightarrow 2BrO_3^{\ominus} + 10Br^{\ominus}}$$

$$\text{Equivalent weight of } Br_2 = \frac{6\,[Br_2]}{10} = \frac{3}{5}$$

$$n\text{-factor} = \frac{5}{3}$$

34. $As_2^{3+} \longrightarrow 2As^{5+} + 4e^-$

$2x=6 \qquad 2x=10$

$S_3^{2-} \longrightarrow 3SO_4^{2-} + 24e^- \quad n\text{-factor} = 28$

$3x=-6 \qquad 3x-24=-6$

$3x=18$

35. $3HOCl \longrightarrow 2HCl + HClO_3$

36. $2\overset{-1}{H I} + H_2\overset{+6}{S}O_4 \longrightarrow \overset{0}{I_2} + \overset{+4}{S}O_2 + 2H_2O$

$$\underset{\text{oxidising agent}}{H_2SO_4} \text{ Reduced to} \longrightarrow SO_2$$

37. $Cr_2O_7^{2-} + 14H^+ + 6I^- \longrightarrow 2Cr^{3+} + 7H_2O + 3I_2$

$Cr_2O_7^{2-}$ is reduced to Cr^{3+}.

Thus, final state of Cr is +3.

38. $CaOCl_2$ is written basically as Ca(OCl)Cl

$OCl^- \longrightarrow$ Cl has + 1 oxidation state

$Cl^- \longrightarrow$ Cl has − 1 oxidation state

39. $\overset{+7}{Mn}O_4^- \longrightarrow Mn^{2+}$ change 5

$\longrightarrow \overset{+6}{Mn}O_4^{2-}$ change 1

$\longrightarrow \overset{+4}{Mn}O_2$ change 3

$\longrightarrow \overset{+3}{Mn_2}O_3$ change 4

40. (a) $\overset{+1}{Na}\overset{-1}{Cl} + \overset{+1}{K}\overset{-1}{NO_3} \longrightarrow \overset{+1}{Na}\overset{-1}{NO_3} + \overset{+1}{K}\overset{-1}{Cl}$

(b) $\overset{+2}{Ca}\,C_2\overset{-2}{O_4} + 2\,\overset{+1}{H}\overset{-1}{Cl} \longrightarrow \overset{+2}{Ca}\overset{-1}{Cl_2} + \overset{+1}{H_2}\,C_2\,\overset{-2}{O_4}$

(c) $\overset{+2}{Ca}(O\overset{-1}{H})_2 + 2\,\overset{+3}{N}\,\overset{+1}{H}_4\overset{-1}{Cl} \longrightarrow \overset{+2}{Ca}\overset{-1}{Cl_2} + 2\,\overset{-3}{N}\overset{+1}{H_3} + 2\,\overset{+1}{H_2}\overset{-2}{O}$

In all these cases during reaction, there is no change in oxidation state of ion or molecule or constituent atom, these are simply ionic reactions.

(d) $2K[Ag(CN)_2] + Zn \longrightarrow 2Ag + K_2[Zn(CN)_4]$

$Ag^+ \longrightarrow Ag$ gain of e^-, reduction

$Zn \longrightarrow Zn^{2+}$ loss of e^-, oxidation.

8

Classification of Elements and Periodicity in Properties

JEE Main MILESTONE

- Earlier Attempts to Classify Elements
- Long Form of Periodic Table
- Classification of Elements
- Prediction of Group, Period and Block of an Element
- Nomenclature of the Elements having Atomic Number > 100
- Periodic Properties
- Elements Showing Highest and Lowest Properties

8.1 Earlier Attempts to Classify Elements

Several attempts have been made for the classification of elements into groups and it leads to the development of periodic law and Periodic Table *e.g.*,

Prout's Hypothesis

This hypothesis, given in 1815, is also called **unitary theory** as according to it hydrogen atom was considered as the fundamental unit from which all other atoms were made.

In Periodic Table the elements are arranged in rows and columns. Using the position of an element in the Periodic Table, it is possible to predict its chemical behaviour. The regular gradation in the properties is called periodicity and such properties are called periodic properties.

Dobereiner's Triads

Dobereiner, between 1815-1829, gave his law of triads. A triad is a certain group of three elements with similar properties. According to him, in the triads the atomic weight of the middle element was approximately the arithmetic mean of the other two, *e.g.,*

Element	Li	Na	K
Atomic weight	7	23	39

Mean of atomic masses $= \frac{7+39}{2} = 23$

Similarly,

Element	Cl	Br	I
Atomic weight	35.5	80	127

Mean of atomic masses $= \frac{35.5+127}{2} = 81.25$

and

Element	**Ca**	**Sr**	**Ba**
Atomic weight	40	88	137

$$\text{Mean of atomic masses} = \frac{40 + 137}{2} = 88.5$$

But in some triads, all the three elements possessed nearly equal atomic masses, *e.g.,* Fe, Co, Ni, Os, Ir, Pt, etc., hence, the law was rejected.

Newland's Law of Octaves

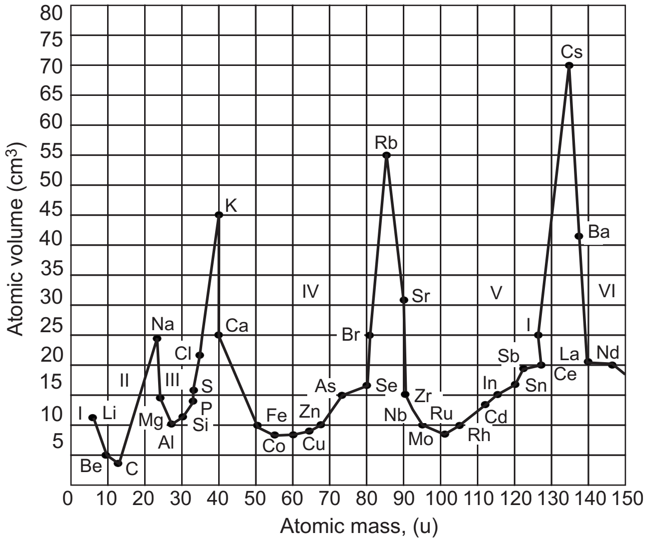
Newland in 1864 presented the **law of octaves** which is considered as first serious attempt to classify the elements. According to this law, if the known elements were arranged in increasing order of atomic weight, the 8th element starting from a given one, was a kind of repetition of the first, like the 8th note in the octave of music, *i.e.,*

Sa	Re	Ga	Ma	Pa	Dha	Ne
H	Li	Be	B	C	N	O
F	Na	Mg	Al	Si	P	S

The above law worked quite well for lighter elements but failed in the case of heavier elements. Moreover, after the discovery of noble gases, it is the ninth element that resembles with the first, which is not in accordance to the law.

Lothar Meyer's Atomic Volume Curve

Lothar Meyer presented the classification in the form of a curve between atomic volume and atomic masses and said, "the properties of the elements were the periodic functions of their atomic volumes".



Lothar Meyer's curve

He calculated atomic volumes with the help of the formula

$$\text{Atomic volume} = \frac{\text{molecular mass}}{\text{density}}$$

The findings of Meyer were

1. Alkali metals having the largest atomic volumes occupy the maxima of the curve.
2. The alkaline earth metals (Mg, Ca, Sr, Ba) occupy the mid point positions on the descending portions of the curve.
3. Halogens occupy positions on ascending portions before inert gases.
4. The transition elements occupy minima of the curve.

Remember that **Lothar Meyer** (Germany) and **Mendeleef** (Russia) quite independently evolved identical classification of elements in 1869. Both of them showed the connection between the periodicity of properties and atomic masses of elements, with the difference that Mendeleef considered the chemical properties while Lothar Meyer considered the physical properties of elements in their explanations.

Mendeleef's Periodic Law

It states the properties of elements are the periodic function of their atomic masses. In other words, if the elements are arranged in the order of their increasing atomic weights, after a regular interval similar properties of elements are repeated.

His law infact was an impressive version of the law of octaves and formed the basis for the modern classification of elements in the form of a table, called *Periodic Table*.

In his original table, Mendeleef arranged the elements in horizontal rows but subsequently he modified the original table and rearranged the elements in vertical rows.

Mendeleef's original table consisted of 8 vertical columns, called *groups* and 12 horizontal rows, called *series* or *periods*.

When Mendeleef presented the Periodic Table only 63 elements were known and a number of gaps were left for unknown elements. The properties of those unknown elements were also predicted on the basis of periodic law, which helped future scientists in the discovery of such elements.

Zero group was not known at Mendeleef's time. It was added later on in the modified Mendeleef's Periodic Table.

Uses of Mendeleef's Periodic Table

1. Atomic weights of elements were determined with the help of Periodic Table.
   Atomic weight = Valency × Equivalent weight.
2. Atomic weight of elements were corrected. Atomic weight of Be was calculated to be $3 \times 4.5 = 13.5$ by considering its valency 3 but, Mendeleef calculated it $2 \times 4.5 = 9$
3. In Mendeleef's Periodic Table two consecutive members differ by two or three units in the atomic weight. Where this gap was more, the gaps were left in the Periodic Table. This helped in discovering of new elements.

Defects of Mendeleef's Periodic Table

1. Position of hydrogen is uncertain. It has been placed in IA and VIIA groups because of its resemblance with elements of both the groups.
2. No separate positions were given for isotopes.
3. No separate group for lanthanides and actinides.
4. Although there is no resemblance except valency of subgroups A and B, they have been put in the same group.
5. Order of increasing atomic weights is not strictly followed in the arrangement of elements in the Periodic Table. *e.g.,* Co (At. wt. 58.9) is placed before I (127) and Ar (39.9) before K (39).

Modern Periodic Table

Moseley, while working in Rutherford's team in 1913, studied the wavelength of the characteristic X-rays by using different metals as anti-cathode and showed that the square root of the frequency of a line (of X-ray spectrum) is related to the atomic number, Z of the target material as

$$\sqrt{\nu} = a(Z - b)$$

where, a = proportionality constant
b = another constant (It has same value for all the lines of X-rays spectrum)
Z = atomic number.

He thereby showed that atomic number is more fundamental property of an element than its atomic mass and on this basis gave a law, which states *"The physical and chemical properties of the elements are periodic functions of their atomic numbers"*.

The Moseley's law is called *"modern periodic law"* and considered as the basis of *modern Periodic Table*.

The characteristics of this table are

1. The table consists of 9 vertical columns, called the **groups** and 7 horizontal rows, called the **periods**.
2. The groups are marked 0 to VIII out of which group I to VII are subdivided into subgroups A and B.
3. The group IA elements (Li, Na, K, Rb, Cs and Fr) are called **alkali metals** and the group II A elements (Be, Mg, Ca, Sr,Ba and Ra) are called **alkaline earth metals**. Elements in group VII A (F, Cl, Br, I and At) are known as **halogens** and elements in group VIII A (He, Ne, Ar, Kr, Xe and Rn) are called *noble gases* or *rare gases*.
4. The group VIII has three similar elements placed together in one place. These are called **transition triads,** *e.g.,* Fe, Co and Ni; Ru, Rh and Pd; Os, Ir and Pt etc.
5. Starting from hydrogen to heaviest elements uranium, there are 92 elements which are arranged in different periods as follows :

1st period	2 elements	Shortest period
2nd period	8 elements	Ist short period
3rd period	8 elements	IInd short period
4th period	18 elements	Ist long period
5th period	18 elements	IInd long period
6th period	32 elements	Longest period
7th period	6 elements	Incomplete period

6. In the 6th period, 14 elements from lanthanum ($Z = 57$) to lutetium ($Z = 71$) are given one position in 3rd B group, termed as *rare earths* or *lanthanides*.
7. Afterwords, 14 elements from actinium ($Z = 89$) to lawrencium ($Z = 103$) are also added to same place and called them *actinides*.
8. Every period starts from a member of alkali group and ends with a member of zero group. The first period however starts with hydrogen.
9. There is a gradual change in properties seen from one end to the other.

8.2 Long Form of Periodic Table

The Modern Periodic Table was further modified to *extended form* or *long form of Periodic Table*. This modification was not done by a single person, but it incorporates the modifications by many scientists especially *Rang, Werner, Bohr, Bury* etc.

This table is just graphical representation of *Aufbau principle*. The electronic configuration based classification of elements was given by Bohr that's why the table is also called **Bohr's Periodic Table.**

In this table, elements are arranged in increasing order of atomic number (Z) (same as that seen in modern Periodic Table). The isotopes are all grouped together as they have the same atomic number.

The table contains 7 periods (representing 7 orbits) and 18 groups (1–18). The concept of subgroup A and B is removed and groups are given no. 1 to 18. The transitional triad elements of modern Periodic Table (group 8) are included in group 8, 9 and 10. The name of zero group is changed to group 18.

A new period begins with the occupancy of new energy shell (principal quantum number) by the first electron. Thus, a period begins with the element having ns^1configuration ($n = 1, 2, 3, \ldots$ for 1st, 2nd and 3rd period respectively).

A period usually terminates at electronic configuration $ns^2\, np^6$ except 1st period which terminates on $1s^2$ as K orbit lacks p -orbital.

The 3rd group is the largest group of Periodic Table containing 32 elements.

On the basis of electronic configuration, elements are classified into following **four groups**

1. Inert gases
2. Representative elements
3. Transitional elements
4. Inner-transitional elements

(Although such a classification is convenient for the understanding of chemical properties, it overlooks the specific characteristics of individual atoms.)

Representative elements (*s*-block elements)

Transition elements (*d*-block elements)

Representative elements (*p*-block elements)

Noble gases

1 H $1s^1$

Period Number	GROUP NUMBER 1 IA	2 IIA	3 IIIB	4 IVB	5 VB	6 VIB	7 VIIB	8 ←	9 VIII	10 →	11 IB	12 IIB	13 IIIA	14 IVA	15 VA	16 VIA	17 VIIA	18 0
1																		2 He $1s^2$

Two super heavy elements, element 113 and element 115 have been discovered by scientist. Element 113 is produced *via* the alpha decay of element 115. Experiment of this discovery was made between July 14 and August 10, 2003. The results have been published in Physical Review C.

8.3 Classification of Elements

Depending upon the orbital in which last electron enters, the elements are classified as

s-Block Elements

The ***s*-block** elements are present on the extreme left in the Periodic Table. All of these are highly reactive metals except hydrogen.

Their general electronic configuration is:

$$[\text{inert gas}]\ ns^x\ \ (x = 1, 2)$$

If $x = 1$, elements constitute a group of *alkali metals* placed in group 1 (IA) and if $x = 2$, elements constitute a group of *alkaline earth metals* placed in group 2 (IIA).

Alkali metals form monovalent cations while alkaline earth metals form divalent cations.

The important characteristics of elements of this block are

1. They are soft metals with low melting and boiling points.
2. They posses metallic character and reactivity of metal increases down the group .
3. They are highly electropositive and having low ionisation enthalpies.
4. Most of the metals of this block impart characteristic colour to the flame.
5. They are strong reducing agents and good conductor of heat and electricity.
6. Na, Mg and Al all have extensive three-dimensional atomic networks, which are held together by forces characteristic of the metallic state.

p-Block Elements

These elements are present in the right portion of Periodic Table. A clear demarcation line separates the metals and non-metals here. Semi-metals are present along the sides of line. This line begins from B, runs in a *zig-zag* manner and terminates at Po. *Thus, this is the only block that contains metals, semi-metals and non-metals.*

General electronic configuration of *p*-block elements is $\boldsymbol{ns^2np^x}$ (where, $x = 1$ to 6). Group number of an element of this block is $(2 + x)$ A based on old system like IIIA, IVA, ... etc., and $(12 + x)$ based on new IUPAC system like, 13, 14, 15, ..., etc.

Metals are solids generally but Hg is liquid at room temperature. Non-metals may be solid, liquid or gas.

Si is a metalloid; it has a giant three-dimensional structure in which the Si atoms are held together very strongly. Starting with phosphorus, the elements exist in simple, discrete molecular units (P_4, S_8, Cl_2 and Ar) which have low melting points and boiling points.

These elements mostly form covalent compounds.

d-Block Elements

The elements having incompletely filled *d*- orbitals in the ground state or in excited or chemically combined state are called *transitional elements* (*d*-families) or *d-block elements*. All the elements of *d-block* are present in the middle portion of Periodic Table, in between the *s* and *p*-block elements and are all metals.

By the strict definition, *lutetium* (Z=71) and *lawrencium* (Z=103) should be included in the *d*-families, but their properties justifies their inclusion in the inner-transitional elements. Further, as in these elements $4f$ and $5f$ levels are just filled up, these can be termed as the *bridging elements* between transition (*d*-block) and inner-transition (*f*-block) elements.

There are three complete series of 10 transition elements, called $3d$($_{21}$Sc to $_{30}$Zn), $4d$($_{39}$Y to $_{48}$Cd) and $5d$($_{57}$La; $_{72}$Hf to $_{80}$Hg) whereas, $6d$ series is incomplete. $_{21}$Sc is the lightest transition metal.

Although by definition zinc (group 12) does not belong to the *d*-family but for chemical reasons it is classified as *d*-block elements with d^{10} configuration.

The transitional elements show striking resemblances to one another in their characteristics such as melting and boiling points, metallic nature, etc., as they have almost same outermost shell configuration.

The general electronic configuration of the shells of transitional elements is therefore

$$(n-1)\,s^2p^6d^xns^{1\text{ or }2}$$

here, $x = 1$ to 10 for d-1 to d-10 families.

or $\quad (n-1)d^xns^y$

where, x = number of electrons in $(n-1)d$-orbital

= 1 to 10 (except 4 and 9)

y = number of electrons in ns-orbital.

= 2 in all cases [except in group 6(VIB) and 2(IB), $y = 1$]

According to IUPAC (new pattern) group = $(x + y)$, but old group number is decided by

1. group number is [$(x + y)$B], if $x < 6$
2. group number is [VIII], if $x = 6, 7, 8$
3. group number is [yB], if $x = 10$

Important characteristics of elements of this block are

1. These are hard, ductile and malleable metals with high melting and boiling points.
2. Ionisation energy is between s and *p*- block elements.
3. They show variable oxidation states and are good conductors of heat and electricity.
4. They form both ionic and covalent compounds. These compounds are generally coloured and paramagnetic in nature. Most of the transition metals form alloys.

f-Block Elements

The *inner-transition* elements or *f*-block elements have their $(n-2)f$ orbitals incompletely filled. There are 2 series of inner-transition elements, namely, $4f$ and $5f$ series. The $4f$ series begins with *cerium* ($Z = 58$) and ends on *lutetium* (Z=71) and the $5f$ series contains elements from *thorium* (Z=90) to *lawrencium* (Z=103).

The members of $4f$ series are called *lanthanons* or *rare earth* or *lanthanides* as these follow *lanthanum* ($Z = 57$) in their properties.

The member of $5f$ series are called *actinons* or *actinides* as these follow *actinium* (Z=89) in their properties.

The generalised electronic configuration of $4f$ and $5f$ series is

$$(n-2)f^{1-14}\,(n-1)s^2p^6d^{0-1}ns^2 \text{ i.e.,}$$

for $4f$ series, $4f^{1-14}, 5s^2p^6d^{0-1}, 6s^2$

for $5f$ series, $5f^{1-14}, 6s^2p^6d^{0-1}, 7s^2$

The elements of both the series show striking resemblance in their properties due to almost similar configurations of their outer two shells and same size.

The *f*-**block** elements are positioned in the bottom portion of Periodic Table and are included in the 3rd group (III B of modern Periodic Table). This group is considered as the largest group of Periodic Table. Elements with atomic number greater than 92 (U_{92}) are called the *transuranium elements*. All these elements are man-made through artificial nuclear reactions. At present, transuranium elements with atomic numbers up to 118 have been reported.

The tendency to lose f-electrons is more seen in the case of actinons as their electrons are less firmly held by the nuclear charge in comparison with those of $4f$ family.

Lanthanides show reduction in their sizes from left to right, called the *Lanthanide contraction***.** This can be explained on the basis of constant *poor screening* or *shielding effect* of *f*- electrons by other *f*-electrons.

Important characteristics of elements of this block are

1. They are heavy metals with high melting and boiling points.
2. They show variable oxidation states and compounds are generally coloured.
3. Most of the elements of the actinide series are radioactive.

Sample **Problem 1** *An element belongs to 3rd period and group-13 of the Periodic Table. Which of the following properties will be shown by the element?* **[NCERT Exemplar]**

(a) *Good conductor of electricity*

(b) *Liquid, metallic*

(c) *Solid, metallic*

(d) *Solid, non-metallic*

Interpret (*a, c*) Except B, all elements of group 13 are metallic. These exists as solid. Being metallic in nature, it (Al) is good conductor of electricity.

8.4 Prediction of Group, Period and Block of an Element

We can easily predict the group, period and block of an element from its electronic configuration by the following ways

1. Principal quantum number of the valence shell corresponds to the period of an element.
2. The orbital containing the last electron indicates the block of an element.
3. The group of an element is predicted from the number of electrons in the valence shell or a penultimate shell ($n-1$) as follows
   - (i) **For *s*-block elements**, group number is equal to the number of valence electrons.
   - (ii) **For *p*-block elements** group number is equal to 10 + number of electrons in the valence shell.
   - (iii) **For *d*-block elements,** group number is equal to the number of electrons in $(n-1)$ *d*-subshell + number of electrons in valence shell (n^{th} shell).

     Alternately you can calculate group number = Number of electrons in (penultimate shell + valence shell) −8.
   - (iv) **For *f*-block elements,** group number is always $III^{rd}/3B$.

Sample **Problem 2** *In terms of period and group where would you locate the element with $Z = 114$?* [**NCERT**]

(a) *7 period 14 group* (b) *6 period 14 group*
(c) *6 period 4 group* (d) *7 period 4 group*

Interpret (*a*) In order to solve out such problems, first write electronic configuration of the given element. Highest value of *n* shows the period of element and group number = 10 + number of electrons in *ns* and *np* shells.

$$_{114}Z = {}_{86}[\text{Rn}]\, 7s^2, 5f^{14}, 6d^{10}, 7p^2$$

In the Periodic Table, the element with $Z = 114$ is located in Block – *p*-block (as last electron enters in *p*-subshell).

Period – 7th (as $n = 7$ for valence shell)

Group – 14th (for *p*-block elements, group number = 10 + number of electrons in the valence shell which is 7th here).

Sample **Problem 3** *Which of the following is not an actinoid?* [**NCERT** Exemplar]

(a) *Curium* ($Z = 96$)
(b) *Californium* ($Z = 98$)
(c) *Uranium* ($Z = 92$)
(d) *Terbium* ($Z = 65$)

Interpret (*d*) Element from atomic number 89 to 103 are called actinides. Thus, terbium ($Z = 65$) is not an actinoid.

8.5 Nomenclature of the Elements having Atomic Number >100

CNIC (Commission on Nomenclature of Inorganic Chemistry) appointed by IUPAC in 1994, approved official names for elements with atomic number 104 to 109. For the elements having $Z > 109$, IUPAC recommended a nomenclature to be followed for naming these elements until their names are officially recognised. This nomenclature is based on the Latin words for the atomic numbers of the elements.

The names are derived by using roots for the three digits in the atomic number of the elements and adding the ending -ium. The roots for the numbers are as

Digit	0	1	2	3	4	5	6	7	8	9
Name	nil	un	bi	tri	quad	pent	hex	sept	oct	enn
Abbreviation	n	u	b	t	q	p	h	s	o	e

e.g., the element with atomic number 109 will be named as *un-nil-ennium* and symbolised as *une* (u for 1, *n* for 0 and e for 9).

Table 8.1 **IUPAC Nomenclature of Elements with Atomic Number Above 100**

Atomic number	Name	Symbol	IUPAC official name	IUPAC Symbol
101	Un-nil-unnium	Unn	Mendelevium	Md
102	Un-nil-bium	Unb	Nobelium	No
103	Un-nil-trium	Unt	Lawrencium	Lr
104	Un-nil-quadium	Unq	Rutherfordium	Rf
105	Un-nil-pentium	Unp	Dubnium	Db
106	Un-nil-hexium	Unh	Seaborgium	Sg
107	Un-nil-septium	Uns	Bohrium	Bh
108	Un-nil-octium	Uno	Hassnium	Hs
109	Un-nil-ennium	Une	Meitnerium	Mt
110	Un-un-nillium	Uun	Darmstadtium*	Ds
111	Un-un unnium	Uuu	Roentgenium*	Rg
112	Un-un-bium	Uub	**	
113	Un-un-trium	Uut	**	
114	Un-un-quadium	Uuq	**	
115	Un-un-pentium	Uup	**	
116	Un-un-hexium	Unh	**	
117	Un-un-septium	Uus	***	
118	Un-un-octium	Uno	***	

*IUPAC approved the name on August 16, 2003.

• IUPAC name announced on 1 Nov, 2004.

**Reported but not fully authenticated.

***Elements yet to be reported.8.7 Periodic Properties

Check Point 1

1. Why do elements in the same group have similar physical and chemical properties?
2. Predict the position of the element in the Periodic Table satisfying the electronic configuration $(n-1)\,d^3\,ns^2$ for $n = 4$.
3. The elements having atomic number 118 and 120 are yet to be discovered. In which family/group would you place them when discovered? Also give the IUPAC names of these elements.

8.6 Periodic Properties

In a period and as well as in a group there is a regular gradation (gradual increase or decrease in a particular property) in physical and chemical properties of elements with the change in atomic number. *This regular gradation in properties is called periodicity*. The main cause of periodicity in properties is the repetition of similar electronic configuration at regular intervals.

Before discussing the periodic properties, it is essential to know screening or shielding effect, as it greatly affects the periodic properties.

Screening or Shielding Effect

Electrons present in the inner orbits of an atom are themselves attracted more towards the nucleus and decreases the nuclear attractive forces on the electrons of outermost orbit. This is due to the reason, that the actual force of attraction on these valence electrons is decreased by the repulsive forces between electrons acting in opposite direction. Such an effect *in which the electrons of inner orbits work as a curtain between the nucleus and the electrons of outermost orbit is called screening or shielding effect.*

The magnitude of screening effect depends upon the number of inner electrons *i.e.,* higher the number of inner electrons, greater shall be the value of screening effect.

The screening effect and effective nuclear charge (the charge felt by the electrons of a particular orbit) are very closely related. *Slater* gave the relation between them which is written as :

$$Z' = Z - \sigma$$

where, Z' = effective nuclear charge

Z = atomic number

σ = screening constant or *Slater's constant*

There are some simple rules for estimating the degree to which electrons in the various types of orbitals shield other electrons from the nucleus and hence, for estimating the Z_{eff} experienced by other electrons.

1. For finding σ, write the full electronic configuration, rearrange it in the following groupings. Group *ns* and *np* orbitals together while all other types of orbitals are grouped separately, *e.g.*,

   $(1s)\,(2s, 2p)\,(3s, 3p)\,(3d)\,(4s, 4p)\,(4d)\,(4f)\,(5s, 5p)\ldots$
2. Electrons to the right of the group of electrons in question, contribute nothing to the shielding of that group of electrons.
3. All other electrons in the same group as the electron in question, shield that electron to an extent of 0.35 unit of nuclear charge each.
4. If the electron in question is a *s* or *p*-electron.
   - (i) All electrons with principal quantum number one less than the electron in question, shield it to an extent of 0.85 unit of nuclear charge each.
   - (ii) All electrons with principal quantum number two or more less than the electron in question, shield it completely *i.e.,* to an extent of 1 unit.
5. If the electron in question is a *d* or *f* electron.

   All electrons to the left of the group of the electron in question, shield the *d* or *f* electron completely (to an extent of 1 unit). This is due to poor penetration effect of *d* or *f* electron.
6. Sum the shielding constants from steps 2-5 and subtract them from the actual nuclear charge (Z) of the atom in question to obtain the Z_{eff} felt by the electron in question.

Thus, in short the value of Slater's constant can be given as

$$\sigma = (0.35 \times \text{no. of } e^- \text{ in } n\text{th orbit} + 0.85 \times \text{no. of } e^- \text{ in } (n-1)\text{th orbit} + 1 \times \text{rest of the } e^-)$$

[Take 0.30 instead of 0.35 for 1st orbit *i.e.,* ($n = 1$)]

Trends of Screening Constant and Z_{eff}

The magnitude of σ increases across a period or down the group for the elements of groups 1, 2, 13, 14, 15, 16, 17.

The magnitude of effective nuclear charge, Z' increases in a period but it remains almost same in the case of elements of groups 1, 2, 13, 14, 15, 16, 17.

Screening effect of all the inner electrons is not equal. It also depends upon the subshell in which electrons are present. For a given orbit, the screening effect of electron belonging to different subshells decreases in the order

$$s > p > d > f$$

The screening effect of *d* and *f*-orbitals is taken as almost constant.

Caution Points

(*i*) *For second period with n valence electrons,*

$$Z' = 0.65\,(1 + n)$$

(*ii*) *For third period with n valence electrons*

$$Z' = 1.55 + 0.65\,n$$

(*iii*) *For higher periods with d and f-orbitals variation may differ.*

Factors Affecting Atomic Radius

Atomic radius is affected by serval factors which are as follows

1. As the number of shells in an atom increases, atomic radii increases.
2. Atomic radii varies inversely with nuclear charge, *i.e.,*

   $$\text{Atomic radii} \propto \frac{1}{\text{nuclear charge}}$$
3. Atomic radii varies directly with shielding effect, *i.e.,* greater the shielding effect, larger will be the atomic radii.
4. Atomic radii is shorter in case of electrovalent compounds.
5. As the bond order increases, atomic radii decreases.

Hot Spot 1

Trends in Atomic Radii

Variation of atomic and ionic radii of different elements along a period and a group is the very important topic for JEE Main and AIEEE examination. The questions are generally based on order of radii and easy in nature.

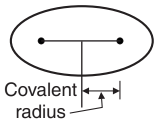
Atomic and Ionic Radius

It is defined as the distance from the centre of the nucleus to the outermost shell of electrons. The definition is imaginary because according to quantum mechanics there is no certainty about the exact position of an electron in an atom. Thus, for practical purposes, atomic radius can be defined in four ways

(a) Covalent Radius

It is defined as **the half of the internuclear distance between two identical or almost identical atoms bonded by a single covalent bond.**

For a diatomic molecule,



Distance $(A - A)$ = radius of A + radius of A

or $d = 2r_A$ or $r_A = \dfrac{d}{2}$

Similarly, for a heteronuclear diatomic molecule,

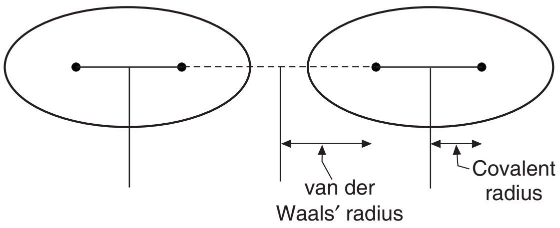
Distance $(A - B)$ = radius of A + radius of B

The above relations hold good only when the bond is purely covalent.

(b) van der Waals' Radius

It is defined as **half of the internuclear distance between the nuclei of two non-bonded adjacent atoms belonging to different molecules having identical atoms in solid state.** This radius is taken into consideration for those cases where intermolecular attractive forces are less strong, *e.g.,* weak dispersion forces. The examples of such molecules are molecules of noble gases, saturated molecules etc.

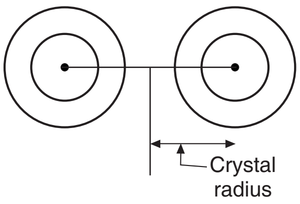
The covalent radius is always smaller than van der Waals' radius for a given element.



Representation of different radii

(c) Crystal Radius

The atomic radius of metals and inert gases in solid state is called their **crystal radius** and is defined as **half of the inter-nuclear distance between two non-bonded adjacent atoms in closed packed crystal lattice.**



Representation of crystal radius

A crystal radius is 10-15% greater than the covalent radius of a particular atom but is smaller than its van der Waals' radius.

The variations in atomic radii of various elements show the following trend

1. Atomic radii of elements increases on moving down the group due to increase in the number of shells by a factor of 1 and increase in screening effect, which reduces effective nuclear charge.
2. Atomic radius of elements decreases while moving from left to right in a period. This is due to the fact that effective nuclear charge increases as number of inner electrons remain the same throughout the period and the change occur only in the number of valence electrons.

However, in case of transition elements, atomic radii remains almost same because the electrons add to penultimate, *i.e.,* $(n-1)\,d$ subshell. Consequently, the increased nuclear charge is almost compensated by the screening effect.

Sample **Problem 4** *Choose the correct order of atomic radii of fluorine and neon (in pm) out of the options given below.*

[NCERT Exemplar]

(*a*) 72, 160 (*b*) 160, 160 (*c*) 72, 72 (*d*) 160, 72

Interpret (*a*) Atomic radius of F is expressed in terms of covalent radius while atomic radius of neon is usually expressed in terms of van der Waals' radius. van der Waals' radius of an element is always larger than its covalent radius. Therefore, atomic radius of F is smaller than atomic radius of Ne (F = 72 pm, Ne = 160 pm).

(d) Ionic Radius

For ions, it is difficult to consider all the above written radii as cations and anions have differences in their sizes. The above written methods are used for identical or almost identical atoms. For ions, thus we have to consider the imaginary definition written in the beginning *i.e.*, the distance between the centre of nucleus and its outermost shell or the distance between the nucleus and the point at which nucleus exerts its influence, in an ion **is called ionic radius.** For the determination of cationic and anionic radii, X-ray diffraction techniques are used.

Radii of Cation

The radius of cation is always smaller than its neutral atom, because of increase in the effective nuclear charge on electrons left and decrease in the number of orbits for most of the cases.

If various cations have same number of electrons (isoelectronic), the cation having greater number of proton is smallest in size.

	Na^+ >	Mg^{2+} >	Al^{3+}
Number of e^- :	10	10	10
Number of p :	11	12	13

Greater is the positive charge on the cation of a given atom, smaller is its ionic radius. *e.g.,*

$$Fe^+ > Fe^{2+} > Fe^{3+}$$

Similarly, $Sn > Sn^{2+} > Sn^{4+}$

Radius of Anion

Radius of anion is always greater than its neutral atom. It is due to decrease in effective nuclear charge.

In case of isoelectronic anions, the anion having greater number of protons is smallest in size. *e.g.,*

	N_3^- >	O^{2-} >	F^-
Number of e^-	10	10	10
Number of p	7	8	9

Greater is the negative charge on an atom, greater is its radius. *e.g.*, out of O^{2-}, O^- and O the order of size is $O^{2-} > O^- > O$.

Trend in Ionic Radius

In case of isoelectronic species, the ionic radii decreases with increase in atomic number.

In a group, the ionic radius of cation as well as anion increases on moving downwards.

The above written generalised facts for cations and anions can be evaluated with the help of formula $\frac{Z}{e} \propto \frac{1}{r}$

where, Z = atomic number of element, e = number of electrons

r = radius of ion

The formula must be used separately for cation and anions.

Sample **Problem 5** *Consider the isoelectronic species,* Na^+, Mg^{2+}, F^- *and* O^{2-}. *The correct order of increasing length of their radii is* **[NCERT Exemplar]**

(*a*) $F^- < O^{2-} < Mg^{2+} < Na^+$ (*b*) $Mg^{2+} < Na^+ < F^- < O^{2-}$

(*c*) $O^{2-} < F^- < Na^+ < Mg^{2+}$ (*d*) $O^{2-} < F^- < Mg^{2+} < Na^+$

Interpret (*b*) In case of isoelectronic species

$$\text{ionic radii} \propto \frac{1}{\text{atomic number}}$$

Ion	Mg^{2+} <	Na^+ <	F^- <	O^{2-}
Atomic number.	(12)	(11)	(9)	(8)

Thus, ionic radii have the following order

$$Mg^{2+} < Na^+ < F^- < O^{2-}$$

Ionisation Energy

The *ionisation energy* of an element is defined as *"the amount of energy required to remove an electron from the outermost orbit of an isolated gaseous atom."* (When such a definition is written in the terms of work done, *i.e.,* the amount of work done in removing an electron, the property is called *ionisation potential*)

The unit of ionisation energy is **kJ/mol** (when the property is written as ionisation potential, the units are taken as **eV/atom.**) This is denoted by word I.

An atom can have as many ionisation energies as number of electrons it has. These are denoted as I_1, I_2, I_3, … etc., for 1st electron, 2nd electron, 3rd electron and so on respectively.

The value of second ionisation energy (I_2) *is always greater than first ionisation energy* (I_1). Similarly that of I_3 is greater than I_2 and so on. The reason for such an increase is increased effective nuclear charge after removal of one electron from the neutral atom resulting in more difficulty in removing the second electron from the outermost orbit of cation formed.

Factors Affecting Ionisation Enthalpy

Important factors that affect the Ionisation Enthalpy are as follows.

1. The ionisation energy of an element depends upon its size as

   $$\text{IE} \propto \frac{1}{\text{size of atom / ion}}$$

   i.e., smaller the atom/ion, larger will be the ionisation energy.

2. Atoms and ions having inert gas configuration *i.e.,* stable (half-filled) configuration have high ionisation energy *i.e.,* it is relatively easy to remove an electron from a partially filled valence shell, where Z_{eff} is lower but it is relatively difficult to remove an electron from an atom or ion that has a filled valence shell, when Z_{eff} is higher.

3. The order of energy required to remove an electron from different subshells (if rest of the conditions are same) is

   $$s > p > d > f$$

   It is due to the closeness of above written subshells with the nucleus. Out of the four given subshells, the *s*-subshell is nearest to the nucleus while *f*-subshell is farthest from the nucleus.

Hot Spot 2

Trends in Ionisation Energy

Questions based on order of ionisation enthalpy have been seen frequently in AIEEE and JEE Main examination, which reveals the importance of the topic for this examination. The level of the question is generally easy and sometimes moderate.

In general, the first ionisation energy decreases in a regular way on descending the main groups.

On moving across a period, the atomic size decreases and nuclear charge increases and therefore the force of attraction exerted by the nucleus on the electron in outermost shell increases. Hence, (IE) increases along a period from left to right.

Exceptions of above written trend are

1. **First ionisation energy of group 2 (IIA) elements is greater than the corresponding elements of group 13(IIIA).** It is due to the presence of fully filled *s*-orbitals in case of group 2 elements (their outermost electronic configuration is ns^2). It is always difficult to pull out electron from stable configuration.
2. **First ionisation energies of group 15(VA) elements is greater than the corresponding elements of group 16(VIA).** It is due to the presence of stable half-filled electronic configuration in group 15 elements. (Their outermost electronic configuration is ns^2np^3).
3. In case of transition elements opposite trends are observed. Thus, $(\text{IE})_1$ of the corresponding elements of 3*d* and 4*d*-series are almost similar but these are smaller than the $(\text{IE})_1$ of the 5*d*-series elements. Certainly the higher values of ionisation energies of the 5*d*-transition elements are consistent with the relatively small size of the atoms.

Sample **Problem 6** *The first ionisation enthaplies of* Na, Mg, Al *and* Si *are in the order* **[NCERT Exemplar]**

(*a*) $\text{Na} < \text{Mg} > \text{Al} < \text{Si}$ (*b*) $\text{Na} > \text{Mg} > \text{Al} > \text{Si}$
(*c*) $\text{Na} < \text{Mg} < \text{Al} < \text{Si}$ (*d*) $\text{Na} > \text{Mg} > \text{Al} < \text{Si}$

Interpret (a) Follow the following steps to solve out such problems.

	Steps	Apply
Step I	Write the electronic configuration to find position in the Periodic Table.	$\text{Na}_{11} = [\text{Ne}]3s^1$, $\text{Mg}_{12} = [\text{Ne}]3s^2$, $\text{Al}_{13} = [\text{Ne}]3s^2 3p^1$, $\text{Si}_{14} = [\text{Ne}]3s^2,3p^2$
Step II	Arrange them in the order as they are in the Periodic Table.	1 2 13 14 Na Mg Al Si
Step III	Follow the general trend and also keep in mind the exception.	The IP increases along a period from left to right but IP of Mg is higher than that of Al due to completey filled 3*s* orbital in Mg.
Step IV	On the above basis find the order.	The order of IP is $\text{Na} < \text{Mg} > \text{Al} < \text{Si}$. Thus, (a) is the correct option.

Important Facts Related to Ionisation Enthalpy

1. Transition elements have almost same ionisation enthalpy. However, the first ionisation enthalpy of elements of group 12 (IIB) is higher than their immediate neighbours. This is because of the stable configuration, *i.e.*, $(n-1)\,d^{10}ns^2$ of these elements.
2. Alkali metals have the lowest and inert gases have the highest IE in a period.
3. Among all the known elements, He has the highest and Cs has the lowest ionisation energy.
4. As the ionisation energy increases, basic character of hydroxides increases. Thus, IE gives a rough idea about basic character of hydroxides.
5. The IE, of the metalloids generally fall between those of metals and non-metals. The difference in IE suggests why metals always form cations and non-metals form anions.
6. Metallic or electropositive character of elements increases as the value of ionisation potential decreases. So, in a group moving from top to bottom, metallic or electropositive character increases because IP value decreases. In a period, moving from left to right the values of IP increases so metallic or electropositive character decreases. Non-metallic character increases.
7. The relative reactivity of the metals increases with the decrease in IP values. The IP values of inert gases are

very high. So they are almost inactive. In a group moving from top to bottom the reactivity of metal atoms increases because their IP value decreases.

8. The reducing power of elements increases as the values of IP decreases because tendency to lose the electron increases. The reducing power increases on going down a group because the IP value decreases.

$$\text{Li} > \text{Cs} > \text{Rb} > \text{K} > \text{Na}$$

Electron Gain Enthalpy

The energy liberated when an extra electron is added to an isolated gaseous atom is called the *electron affinity* (A_e) of that atom while the energy change occurring during this process is called the *electron gain enthalpy* ($\Delta e_g H$). The units of electron affinity or electron gain enthalpy are eV/atom or kJ/g-atom.

Electron affinity and electron gain enthalpy have same magnitude but opposite sign. Indeed electron affinities are defined at absolute zero while electron gain enthalpy at 298 K. These two quantities at a given temperature are related as

$$\Delta e_g H = -A_e - \frac{5}{2}RT$$

For the process, $\text{Cl}(g) + e^- \longrightarrow \text{Cl}^-(g) + E_A$

Electron affinity is positive but $\Delta_{eg}H$ is negative.

Electron affinity describes the tightness with which an atom binds the extra electron added to it *i.e., greater the value of* $\boldsymbol{A_e}$ (energy liberated) *or* $\Delta e_g H$, *greater is the binding force.*

The value of $\Delta e_g H$ second onwards is always positive, *i.e.*, here for addition of electron, energy is to be absorbed from the system. *e.g.*, the electron affinity of oxygen has positive value (141kJ/mol), which means that the process

$$\text{O}(g) + e^- \longrightarrow \text{O}^-(g); \Delta H = -141\text{kJ/mol}$$

is exothermic. On the other hand, the electron affinity of the O^- ion is highly negative (−780kJ/mol), which means the process

$$\text{O}^-(g) + e^- \longrightarrow \text{O}^{2-}(g); \Delta H = 780\text{kJ/mol}$$

is endothermic even though O^{2-} ion has a stable noble gas configuration. This process is unfavourable in the gas phase because the resulting increase in electron-electron repulsion outweighs the stability gained by achieving a noble gas configuration. In solid phase, the process becomes favoured because O^{2-} ions stabilized by the adjacent cations to form ionic lattice releasing lattice energy.

Factors Affecting Electron Gain Enthalpy

Various factors which affect the $\Delta e_g H$ *are*

1. Magnitude of $\Delta e_g H \propto Z_{\text{eff}}$
2. Magnitude of $\Delta e_g H \propto \dfrac{1}{\text{atomic size}}$
3. Magnitude of $\Delta e_g H \propto$ penetrating power

   Therefore, the order of $\Delta e_g H$ is $s > p > d > f$.
4. Stability of half-filled and completely filled orbitals.

Hot Spot 3

Trends in Electron Gain Enthalpy

It is again an important topic of the chapter JEE Main examination. Here generally the questions are based on exceptions and their cause, although here also their level is not typical.

In a period, the electron gain enthalpy (negative) increases on moving from left to right. Thus, the tendency to accept electrons in a period and the electron gain enthalpy values become more and more negative. **The halogens have the highest electron affinity values in a given period.**

The value of electron gain enthalpy (negative) in a group decreases. This variation is related with the size of atom and electron density in the outermost shell of the atom concerned.

There are few exceptions also to the above written trend.

1. **$\Delta e_g H$ of the elements of group 2 (IIA) and group 15 (VA) is positive.** It is due to the presence of outer fully filled *s*-orbital in 2 group and half-filled *p*-orbital in 15 group because of which these atoms do not have the tendency to accept electron.
2. The noble gases have no or very little tendency to accept electrons, thus all the noble gases have electron gain enthalpy more than zero. This means that the anions of noble gases (if formed) would be inherently unstable.
3. In general, the $\Delta e_g H$ values (negative) of the elements of third **period are higher than the $\Delta e_g H$ values of the elements of second period.** It is due to small radius and high electron density in the outermost orbit of second period elements. The small size signifies limited capacity to release energy, while high electron density signifies greater repulsive forces which extra electron experiences while it is to be added *e.g.*, the $\Delta e_g H$ value of Cl is higher than that of F as Cl belongs to 3rd period while F belongs to 2nd period.
4. The electron gain enthalpy of metals are generally lower (less negative) than those of non-metals.
5. It has been found that elements having higher negative values of $\Delta e_g H$ *e.g.*, F_2, Cl_2, O_2, Br_2 etc., are good oxidants.

***Sample* Problem 7** *Among halogens, the correct order of amount of energy released in electron gain (electron gain enthalpy) is* **[NCERT Exemplar]**

(*a*) $F > Cl > Br > I$
(*b*) $F < Cl < Br < I$
(*c*) $F < Cl > Br > I$
(*d*) $F > Cl < Br < I$

Interpret (*c*) To solve out such problem, follow the same steps as shown in sample problem 6.
From this you get the order $F < Cl > Br > I$

***Sample* Problem 8** *Electronic configuration of some elements is given in column I and their electron gain enthalpies are given in column II. Match the electronic configuration with electron gain enthalpy and select the correct option.*

	Column I (Electronic configuration)		Column II (Electron gain enthalpy /kJ mol^{-1})
A.	$1s^2, 2s^2, 2p^6$	(i)	-53
B.	$1s^2, 2s^2, 2p^6, 3s^1$	(ii)	-328
C.	$1s^2, 2s^2, 2p^5$	(iii)	-141
D.	$1s^2, 2s^2, 2p^4$	(iv)	$+48$

[NCERT Exemplar]

Codes

	A	B	C	D		A	B	C	D
(*a*)	(i)	(ii)	(iii)	(iv)	(*b*)	(iv)	(iii)	(ii)	(i)
(*c*)	(iv)	(i)	(ii)	(iii)	(*d*)	(i)	(iv)	(iii)	(ii)

Interpret (*c*) Except (B), all configurations of elements belong to the second period and along a period as the number of electrons increases, $\Delta e_g H$ increases except in case of half or completely filled orbitals where $\Delta e_g H$ is positive.

For B, $\Delta e_g H$ is very less as it is an alkali metal but negative. Thus, the correct match is

A–(iv); B–(i); C–(ii); D–(iii)

Electronegativity and Electronegative Character

The tendency of an atom to attract the shared pair of electrons towards itself in a covalent bond is called *electronegativity* of that atom. Remember it is different from *electronegative character of an atom* which is infact the tendency of an element to form the anion by gaining the electron. *The first term is comparative while the second term is used for a single atom.*

Factors Affecting the Magnitude of Electronegativity

Various factors affecting the magnitude of electronegativity are as follows

1. As the atomic radius of the elements increases, the electronegativity value decreases.
   $$\text{Electronegativity} \propto \frac{1}{\text{Atomic radius}}$$
2. The electronegativiy value increases as the effective nuclear charge on the atomic nucleus increases.
   $$\text{Electronegativity} \propto \text{Effective nuclear charge } (Z_{\text{eff}})$$
3. The electronegativity increases as the oxidation state (*i.e.,* the number of positive charge) of the atom increases.
4. If the *s*-character in the hybridisation state of the atom increases, electronegativity also increases because *s*-electrons are comparatively near to the nucleus *e.g.,* the electronegativity values of C-atom in various hybridisation states are as under

Hybridisation states	sp^3	sp^2	sp
s-character	25%	33.33%	50%
Electronegativity	2.48	2.75	3.25

$$\longrightarrow$$

s-character is increasing,

So, the electronegativity value is increasing.

Trends in Electronegativity

Different tends shown by electronegativity along periods and groups are given below

1. In a period, on moving from left to right, the electronegativity increases due to the increase in effective nuclear charge/increase in ionisation energy.
2. In a period the electronegativity value of IA group elements (alkali metal) is minimum and that of VIIA (halogens) is maximum/with decrease in ionisation energy.
3. In a group on moving from top to bottom, the electronegativity decreases because atomic radius increases.
4. The electronegativity value of F is maximum and that of Cs is minimum in the Periodic Table.

Diagonal Relationship and Electronegativity

As we move from left to right across a period, the increased nuclear charge holds the electrons more tightly to the atom. On moving downwards one place in a group, the extra shell of electrons decreases the attraction of the nucleus for the outer electrons. A *diagonal* move means that these effects tend to compensate for one another.

The electronegativity increases as we go from Li to Be but it decreases as we move from Be to Mg. As we move diagonally, these two effects partly cancel each other and there is no marked change in electronegativity and thus, Li and Mg have close values of electronegativities. Because of this, Li and Mg show similarity in properties–*a diagonal relationship* (between elements lying diagonally in Periodic Table). *e.g.,* Li—Mg, Be—Al and B—Si

Measurement of Electronegativity

Since electronegativity is a tendency and tendencies cannot be measured accurately, electronegativity of different elements is calculated on different scales.

Some important of these scales are as

(i) **Pauling scale** at which F is the most electronegative element of the Periodic Table. The electronegativity of fluorine is arbitrarily assigned 4.0 by Pauling. The electronegativity of other elements is calculated against this standard. The calculations are done with the help of bond energies used in the formula

$$X_A - X_B = 0.208\sqrt{\Delta}$$

where, $\Delta = E_{A-B} - \sqrt{E_{A-A} \times E_{B-B}}$

$X_A - X_B$ = electronegativity difference between two atoms A and B.

E_{A-B}, E_{A-A}, and E_{B-B} are the bond energies of the molecules AB, A_2 and B_2 respectively.

Some other elements have following values of electronegativity based on Pauling's scale.

						H
						2.1
Li	Be	B	C	N	O	F
1.0	1.5	2.0	2.5	3.0	3.5	4.0
Na	Mg	Al	Si	P	S	Cl
0.9	1.2	1.5	2.8	2.1	2.5	3.0
K	Ca	Ga	Ge	As	Se	Br
0.8	1.0	1.6	1.8	2.0	2.4	2.8
Rb						I
0.8						2.5
Cs						
0.7						

***Sample* Problem 9** *The electronegativity of carbon if* $E_{\text{H—H}} = 104.2\ kcal\ mol^{-1}$, $E_{\text{C—C}} = 83.1\,kcal\ mol^{-1}$, $E_{\text{C—H}} = 98.8\ kcal\ mol^{-1}$, $X_{\text{H}} = 2.1$, *is*

(a) 2.1 (b) 3.7 (c) 2.6 (d) 2.9

Interpret (c) We know that,

$$X_{\text{C}} - X_{\text{H}} = 0.208\sqrt{\Delta}$$
$$\Delta = E_{\text{C—H}} - \sqrt{E_{\text{C—C}} \times E_{\text{H—H}}}$$
$$= 98.8 - \sqrt{83.1 \times 104.2}$$
$$= 98.8 - 93.05 = 5.74$$

$$\therefore \quad X_C - X_H = 0.208\sqrt{5.74}$$

$$X_C - X_H = 0.498$$

$$X_C = 0.498 + X_H$$

$$= 0.498 + 2.1$$

$$= 2.59 \approx 2.6$$

(ii) **Mulliken scale** at which electronegativity is determined from the values of A_e and IE of atom. This method is not much in use. On this scale electronegativity is denoted by word chi (χ) which can be calculated as

$$\chi = \frac{\text{IE} + A_e}{2}$$

1. If IE and A_e are determined in eV then

$$\chi = (\text{IE} + A_e) / 5.6 \text{ eV}$$

2. If IE and A_e are determined in kJ/g-atom then

$$\chi = (\text{IE} + A_e) / 125 \text{ kcal/g-atom}$$

3. If IE and A_e are in kJ/mol then

$$\chi = (\text{IE} + A_e) / 544 \text{ kJ/mol}$$

***Sample* Problem 10** *The ionisation energy and electron affinity of an element are 12.0 eV and 3.8 eV respectively. Its electronegativity on the Pauling scale is*

(a) 3.0 (b) 4.0

(c) 3.5 (d) 2.7

Interpret (d) Electronegativity on the Mulliken's scale $= \frac{1}{2}(12.0 + 3.8) = 7.9$. But since Mulliken's values are nearly 2.8 times as large as Pauling values, therefore, electronegativity of the element on the more commonly used Pauling scale is $\frac{7.9}{2.8} = 2.7$.

(iii) **Allred-Rochow's scale** is considered as the real scale as it is based upon covalent radius of an atom. According to Allred-Rochow, electronegativity is a force which is exerted by the nucleus on the electrons of outermost orbit *i.e.*,

$$E_n = \frac{0.359 \times Z_{\text{eff}}}{r^2} + 0.744$$

where, r = covalent radius

$Z_{\text{effective}}$ = effective nuclear charge

Applications of Electronegativity

1. The electronegativity values are used to predict the nature of $A - B$ bond as
   (i) Greater is the difference in the electronegativity of elements A and B, greater will be the ionic character of bond between A and B or weaker will be the covalent character.
   (ii) If electronegativities of A and B are equal or difference is very small, the bond between A and B is supposed to be purely covalent.
2. The electronegativity value also gives an idea about the bond lengths. As the electronegativity difference increases, bond length decreases.
3. If the electronegativity difference of covalently bonded atoms (Δx) increases, the bond energy of the covalent bond also increases *e.g.,* the order of the H—X bond strength is H — F > H — Cl > H — Br > H — I.

   As the bond strength is decreasing, the acid strength is increasing. So order of increasing acid strength is HF < HCl < HBr < HI. The acidic nature of the oxides of normal elements increase as we move from left to right in a period.
4. In a period from left to right the electronegativity of the elements increases.

   The order of acidic or basic nature of the oxides of third period elements may be given under

$$\underrightarrow{\text{Na}_2\text{O} \quad \text{MgO} \quad \text{SiO}_2 \quad \text{P}_2\text{O}_5 \quad \text{SO}_3 \quad \text{Cl}_2\text{O}_7}$$

   Basic nature is decreasing or acidic nature is increasing.
5. The metallic character decreases as the electronegativity of the elements increases. On moving from left to right in a period, the electronegativity of the elements increases. So the metallic character decreases. On moving down a group, the electronegativity of the elements decreases. So the metallic character increases.

Electropositive or Metallic Character

The tendency of an element to form the cation by the loss of electron is called its *electropositive character* or *metallic character*. Thus, metals are the elements which have the tendency to lose electrons.

Trend in Periodic Table The variation of electropositive or metallic character in the Periodic Table will be seen as

→Decrease (across the period)
↓ Electropositive or metallic character
Increase (down the group)

This tendency varies inversely with ionisation energy of an element.

Check Point 2

1. Why does the van der Waals' radius of an element is always larger than the covalent radius?
2. Explain, why cations are smaller and anions are larger than their parent atoms?
3. The first IP of Na is lower as compared to Mg but reverse is true for second IP. Explain, why?
4. The formation of F^- from F is exothermic whereas that of O^{2-} from O is endothermic. Explain.

Periodic Trends in Chemical Properties

(a) Valency

It is the combining capacity of an element and can never be equal to zero. It is only a number and is not assigned as positive or negative. *e.g.,* the valency of C in CH_4, CCl_4, CH_2Br_2 all is 4.

Along a period from left to right it increases from 1 to 7 with respect to hydrogen and from 1 to 4 and then decreases to 1 with respect to oxygen.

For the elements of a group it remains the same because the number of valence electrons (electrons of valence or outer shells) remains the same.

(b) Oxidation States

It is the residual charge left on an atom of a molecule when other atoms of the molecule are removed as ions. Its value can be zero, positive, negative or fractional. An element can have different oxidation states in different compounds *e.g.,* oxidation state of N in NO_2, NO, N_2O_3 and N_2O_5 are + 4, + 2, + 3 and + 5 respectively.

In case of alkali and alkaline earth metals it is fixed *i.e.,* + 1 and + 2 respectively.

It is generally variable for other elements. Higher *p*-block elements exhibit more stability for lower oxidation state due to inert pair effect. *e.g.,* Pb^{4+} is less stable than Pb^{2+}.

In case of *d*-block elements,

max. oxidation state = $(n-1)\, d\, e^-$ (unpaired) + $ns\, e^-$.

In general, the stability of the higher oxidation states is in the order

$$3d << 4d < 5d$$

(c) Chemical Reactivity

It is highest at the two extremes of a period and is lowest at the centre. This is because the elements present at left extreme of a period have the lowest ionisation enthalpy and that present at the right extreme have the highest electron affinity.

Highly reactive elements are always found in combined state.

In the groups, the reactivity of former elements (that present at left extreme) increases while that of latter decreases.

***Sample* Problem 11** *Which element among strontium, magnesium, potassium and lithium is most reactive?*

(a) *Magnesium* (b) *Potassium*
(c) *Lithium* (d) *Strontium*

Interpret (*b*) Potassium is the most reactive among the given metals as reactivity of metals decreases along a period and increases on moving down the group.

(d) Reducing and Oxidising Properties

Reducing agents provide electrons, thus metals act as good reducing agents. The *reducing power* of elements in the Periodic Table shows the following trend

→ Decrease (across the period)
↓ Reducing power of elements
Increase (down the group)

Oxidising agents accept electrons, thus non-metals are good oxidising agents. The *oxidising power* of elements shows following trend in the Periodic Table :

→ Increase (across the period)
↓ Oxidising power of elements
Decrease (down the group)

Thus, alkali metals are powerful reducing agents while halogens are powerful oxidising agents in the Periodic Table.

(e) Nature of Oxides

Metal oxides are basic *i.e,* form alkaline solutions when dissolved in water. Similarly, non-metal oxides are acidic while semi-metal oxides are amphoteric in nature. Thus, the basic character of oxides shows following trend in the Periodic Table.

→ Decreases (across the period)
↓ Basic nature of oxide
Increases (down the group)

Similarly, acidic nature of oxides shows the following trend

→ Increases (across the period)
↓ Acidic nature of oxides
Decreases (down the group)

The oxides CO, N_2O, NO and H_2O are neutral in nature. The oxides of Al, Zn, Sn, As and Sb along with metalloids are amphoteric in nature.

The acidic character of the oxides of a non-metal increases with increase in oxygen content in it, *e.g.,* $N_2O_3 < N_2O_5$; $SO_2 < SO_3$; $Cl_2O < Cl_2O_3 < Cl_2O_7$.

Non-metal oxides when dissolved in water form oxy-acids, thus, they are called *anhydrides* of the acid formed.

Sample Problem 12 *Which one of the following is the most acidic?*

(a) *Aluminium oxide*
(b) *Sodium oxide*
(c) *Magnesium oxide*
(d) *Calcium oxide*

Interpret (a) On moving from left to right in a period, acidic character of oxides increases. Thus, Al_2O_3 is the most acidic oxide among the given.

Table 8.2 **Summary of Variation of Periodic Properties**

S.No.	Periodic property	Variation	
		Along a period	Along a group
1.	Atomic radius	Decreases	Increases
2.	Ionic radius	Decreases	Increases
3.	Metallic nature	Decreases	Increases
4.	Reducing power	Decreases	Increases
5.	Basic nature of oxides	Decreases	Increases
6.	Electron gain enthalpy	Increases	Decreases
7.	Ionisation energy	Increases	Decreases
8.	Electronegativity	Increases	Decreases
9.	Acidic nature of oxide	Increases	Decreases

Some Other Properties of Elements

(a) Density

There is no regular trend in the variation of density in a group or period. *Density of osmium* (Os) *is the highest* (**d = 22.6** g/cc) *among all the known elements.* Lightest metal is lithium (d = 0.54 g/cc). *Density of* H_2 *is lowest among all the known elements.*

(b) Melting and Boiling Points

There is no regular trend in the variation of melting point and boiling point in a group or period. *Tungsten* (W) *has the highest melting poing among all the metals. Mercury has the lowest melting poing* (−38°C) *among all the metals.* Carbon in the form of diamond has highest melting point (3277°C) among all the known elements. Helium has lowest melting point (−270°C) among all the elements. In a period, inert gases have lowest melting point and boiling point

In a group, the melting and boiling points of metals usually decreases while that of non-metals increases.

(c) Atomic Volume

Volume occupied by one gram atom of an element in solid state is called its atomic volume.

Atomic volume = mass of one gram atom/density

Atomic volume of elements increases on moving down a group due to the presence of extra shell of electrons. On moving from left to right in a period atomic volume first decreases and becomes minimum in the middle and then again begins to increase.

On plotting a graph between atomic number of elements and their atomic volume, a curve is obtained in which alkali metals are present at peaks while elements of 'boron family' Ni, Ru and H etc., are present at troughs.

8.7 Elements Showing Highest and Lowest Properties

Many a times questions based on highest and lowest of some properites are seen in the examination. Here with we are given some elements showing highest and lowest properties.

Table 8.3 **Highest and Lowest of Some Properties**

Highest melting point	Carbon (diamond)
Highest EA	Chlorine
Highest electronegativity	F
Highest ionisation potential	He
Lowest ionisation potential	Cs
Highest density	Os
Lowest melting point	He
Lowest density	H_2
Lowest density among metals	Li
Highest melting point among metals	Tungsten
Smallest anion	H^-
Largest anion	I^-
Smallest cation	H^+
Largest cation	Cs^+

Check Point 3

1. In a group, all the elements have same valency. Is it true? Explain, why?
2. Alkali metals as well as halogens are highly reactive, however, the former occupy the left corner while the latter occupy the right corner. Explain, why?
3. The melting and boiling points of metals increase while that of non-metals decrease on moving down the group. Explain.
4. $\Delta_{eg}H$ of Cl is more negative than F why?

WORKED OUT Examples

Example 1 *An atom with atomic number 21 belongs to the category of*

(a) *d-block elements* (b) *s-block elements*
(c) *f-block elements* (d) *p-block elements*

Solution (*a*) The electronic configuration of the given element is

$$= 1s^2, 2s^2, 2p^6, 3s^2, 3p^6, 4s^2, 3d^1$$

Since the last electron enters in *d*-block, its a *d*-block element.

Example 2 *The ionisation energy of* Li *is* 520 *kJ mol*$^{-1}$. *The amount of energy required to convert* 140 *mg of* Li *atoms into gaseous* Li$^+$ *ion, is*

(a) 10.4 *kJ* (b) 520 *kJ*
(c) 72.8 *kJ* (d) 3.71 *kJ*

Solution (*a*) Number of moles of $\text{Li} = \dfrac{\text{mass}}{\text{atomic mass}}$

$$= \frac{140 \times 10^{-3}}{7}$$

$$= 2 \times 10^{-2} \text{ mol}$$

$\because$ For the conversion of 1 mole atoms of Li into Li$^+$, the energy required $= 520$ kJ mol^{-1}

$\therefore$ For the conversion of 2×10^{-2} mole atoms of Li into Li$^+$ ions, the energy required will be $520 \times 2 \times 10^{-2}$

$$= 10.4 \text{ kJ}$$

Example 3 *Sodium can't exhibit* +2 *oxidation state because its second ionisation potential value is*

(a) *zero*
(b) *equal to first*
(c) *less than first*
(d) *much higher than the first*

Solution (*d*) IE$_2$ of Na is extremely high because after the removal of one electron, inert gas configuration is obtained. As a result sodium cannot show an oxidation state of +2.

Example 4 *The covalent radius of silicon is* 1.175 Å. *Calculate the electronegativity of silicon using Allred-Rochow method.*

(a) 1.73 (b) 3.80
(c) 2.94 (d) 4.28

Solution (*a*) Allred-Rochow equation is

$$x = 0.359 \times \frac{Z_{\text{eff}}}{r^2} + 0.744$$

Z_{eff} is calculated on the basis of Slater's rules taking all the electrons.

Electronic configuration of Si is $1s^2, 2s^2, 2p^6, 3s^2, 3p^2$

$$Z_{\text{eff}} = 14 - (0.35 \times 4 + 0.85 \times 8 + 2 \times 1) = 3.80$$

On putting values $x = 1.73$

Example 5 *The amount of energy when million atoms of iodine are completely converted into* I$^-$ *ions in the vapour state according to the equation*

$\text{I}(g) + e^- \longrightarrow \text{I}^-(g)$ *is* 4.9×10^{-13} J. *The electron gain enthalpy of iodine (in eV per atom) is*

(a) −295 (b) −3.06
(c) −6.45 (d) −622

Solution (*b*) Electron gain enthalpy per mol

$$= -\frac{4.9 \times 10^{-13} \times 6.023 \times 10^{23}}{10^6}$$

$$= -29.5 \times 10^4 \text{ J}$$

$$= -295 \text{ kJ}$$

$$= -\frac{295}{96.49} = -3.06$$

Example 6 *The* I^{st} *IE of* Li *is* 5.4 *eV and the electron gain enthalpy of* Cl *is* 3.6 *eV. If the following reaction,*

$$\text{Li}(g) + \text{Cl}(g) \longrightarrow \text{Li}^+ + \text{Cl}^-,$$

is carried out at such a low pressure that resulting ions do not combine with each other, the ΔH *of the reaction (in kcal mol*$^{-1}$*) is*

(a) 118.8 (b) 124.52
(c) 83.0 (d) 41.508

Solution (*d*) Given, $\text{Li}(g) \longrightarrow \text{Li}^+(g) + e^-$; $\Delta E_1 = 5.4$ eV

$$\text{Cl}(g) + e^- \longrightarrow \text{Cl}^-(g); \quad \Delta E_2 = -3.6 \text{ eV}$$

$$\Delta H = 5.4 - 3.6 = 1.8 \text{ eV}$$

$$= 1.8 \times 23.06 \text{ kcal mol}^{-1}$$

$$= 41.508 \text{ kcal mol}^{-1}$$

Example 7 *The number of chlorine atoms that can be ionised in the process* $Cl \longrightarrow Cl^{+} + e^{-}$*, by the energy liberated for the process* $Cl + e^{-} \longrightarrow Cl^{-}$ *for one Avogadro number of atoms is* [$IE = 13.0\,eV$, $\Delta e_g H = 3.60\,eV$]

(a) 2.17×10^{24} (b) 1.67×10^{23}

(c) 1.286×10^{22} (d) 6.023×10^{22}

Solution (*b*) Let *n* Cl atoms are ionised.

Thus, $6.02 \times 10^{23} \times \Delta e_g H = n \times \text{IE}$

$$n = \frac{6.02 \times 10^{23} \times 3.6}{13.0}$$

$$= 1.667 \times 10^{23}$$

Example 8 *For the following reaction,*

$$K(g) + F(g) \longrightarrow K^{+}(g) + F^{-}(g),$$

ΔH was calculated to be 19 kcal under conditions where the cations and anions were prevented by electrostatic separation from combining with each other. The IE of potassium is 4.3 *eV, the magnitude of* $\Delta e_g H$ *of* F *is*

(a) -4.3 (b) -0.82

(c) $+4.3$ (d) $+3.48$

Solution (*d*) $K(g) \longrightarrow K^{+}(g) + e^{-}$; IE = 4.3 eV

$$F(g) + e^{-} \longrightarrow F^{-}(g) \quad \Delta e_g H = -E \text{ eV}$$

$$\Delta H = \text{IE} + \Delta e_g H$$

$$\frac{19.0}{23.06}\text{ eV} = 4.3 - E$$

$$\therefore \qquad E = 4.3 - 0.82 = 3.48$$

Example 9 *The electronic configuration of four elements are*

(*i*) $[Xe]\,5s^1$ (*ii*) $[Xe]\,4f^{14}, 5d^1, 6s^2$

(*iii*) $[Ar]\,4s^2 4p^5$ (*iv*) $[Ar]\,3d^7, 4s^2$

Select the incorrect statement about these elements.

(a) (*i*) *is a strong reducing agent*

(b) (*ii*) *is a d-block element*

(c) (*iii*) *has high magnitude of* $\Delta e_g H$

(d) (*iv*) *exhibits variable oxidation states.*

Solution (*b*) (i) Since, in it the last electron enters in *s*-orbital, it is a *s*-block element and *s*-block elements are good reducing agents.

(ii) Since, the last electron enters in *f*-block, it is a *f*-block element (element of 4*f* series).

(iii) Electronic configuration reveals that it contains 7 electrons in its outer shell, so it is a halogen and halogens have high magnitude of $\Delta e_g H$.

(iv) The last electron enters in *d*-orbital, so it is a *d*-block element and variable oxidation states is an important feature of *d*-block elements.

Example 10 $\frac{N_0}{2}$ *atoms of* $X(g)$ *are converted into* $X^{+}(g)$ *by energy* ΔH_1 *and* $\frac{N_0}{2}$ *atoms of* $X(g)$ *are converted into* $X^{-}(g)$ *by energy* ΔH_2*. The* (*IE*) *and* (*EA*) *of* $X(g)$ *are respectively*

(a) $\frac{2\Delta H_1}{N_0}, \frac{2(\Delta H_2 - \Delta H_1)}{N_0}$ (b) $\frac{\Delta H_1}{N_0}, \frac{\Delta H_2}{N_0}$

(c) $\frac{2\Delta H_1}{N_0}, \frac{\Delta H_2}{N_0}$ (d) $\frac{2(\Delta H_2 - \Delta H_1)}{N_0}, \frac{\Delta H_2}{N_0}$

Solution (*a*) Let (IE) of $X(g) = I$ per atom and EA of $X(g) = -E$ per atom

(i) $X(g) \longrightarrow X^{+}(g) + e^{-}$

Energy required to ionise $\frac{N_0}{2}$ atoms of $X(g) = \frac{N_0 I}{2}$

$$\frac{N_0 I}{2} = \Delta H_1$$

$$I = \frac{2\Delta H_1}{N_0}$$

(ii) $X(g) \longrightarrow X^{+}(g) + e^{-}$ Energy $= \frac{N_0 I}{2}$ for $\frac{N_0 I}{2}$ atoms

$X(g)\ e^{-} \longrightarrow X^{-}(g)$ Energy $= -\frac{N_0 E}{2}$ of $\frac{N_0}{2}$ atoms

$$\frac{N_0 I}{2} - \frac{N_0 E}{2} = \Delta H_2$$

$$-\frac{N_0 E}{2} = \Delta H_2 - \Delta H_1$$

$$-E = \frac{2(\Delta H_2 - \Delta H_1)}{N_0}$$

Ionization energy (IE) $= \frac{2\Delta H_1}{N_0}$ atoms^{-1}

Electron affinity (EA) $= \frac{2(\Delta H_2 - \Delta H_1)}{N_0}$ atoms^{-1}

Start Practice for JEE Main

Round I (Topically Divided Problems)

Classification of Elements

1. Who developed the long form of the Periodic Table?

(a) Niels Bohr (b) Moseley

(c) Mendeleef (d) Lothar Meyer

2. The basis of keeping the elements in the groups of the Periodic Table is

(a) ionisation potential

(b) electronegativity

(c) electron affinity

(d) number of valence electrons

3. Which of the following pairs has both members of the same period of the Periodic Table?

(a) Na—Cl (b) Na—Ca

(c) Ca—Cl (d) Cl—Br

4. Write the atomic number of the element present in the third period and seventeenth group of the Periodic Table. **[NCERT]**

(a) 15 (b) 17

(c) 21 (d) 9

5. Which element do you think would have been named by Lawrence Berkeley laboratory? **[NCERT]**

(a) Berkelium (b) Lawrencium

(c) Both (a) and (b) (d) Seaborgium

6. Why do elements in the same group have similar physical and chemical properties? **[NCERT]**

(a) Because of same electronic configuration

(b) Because of same number of electrons

(c) Because of same number of protons

(d) Because of same valence electrons

7. The electronic configuration of gadolinium (Atomic number = 64) is **[NCERT Exemplar]**

(a) [Xe] $4f^3, 5d^5, 6s^2$ (b) [Xe] $4f^7, 5d^2, 6s^1$

(c) [Xe] $4f^7, 5d^1, 6s^2$ (d) [Xe] $4f^8, 5d^6, 6s^2$

8. The statement that is not correct for periodic classification of elements is **[NCERT Exemplar]**

(a) the properties of elements are periodic functions of their atomic numbers

(b) non-metallic elements are less in number than metallic elements

(c) for transition elements, the $3d$-orbitals are filled with electrons after $3p$-orbitals and before $4s$-orbitals

(d) the first ionisation enthalpies of elements generally increase with increase in atomic number as we go along a period

9. Which of the following is a metalloid?

(a) Sb (b) Mg

(c) Zn (d) Bi

10. Be resembles much with

(a) Li (b) Al

(c) Zn (d) Ra

11. An element with atomic number 20 will be placed in which period of the Periodic Table?

(a) 1 (b) 2

(c) 3 (d) 4

12. The position of the element having outer electronic configuration, ns^2np^4 for $n = 3$ is **[NCERT]**

(a) II period, fourth group

(b) III period, fourth group

(c) II period, 16 group

(d) III period, 16 group

13. Find the element having outer electronic configuration $(n-1)\,d^2ns^2$ for $n = 4$. **[NCERT]**

(a) Scandium

(b) Vanadium

(c) Titanium

(d) Tungsten

14. The element with outer shell configuration $(n-2)f^7(n-1)d^1ns^2$ for $n=6$ is [NCERT]
(a) uranium (b) gadolinium
(c) lead (d) niobium

15. The period number in the long form of the Periodic Table is equal to [NCERT Exemplar]
(a) magnetic quantum number of any element of the period
(b) atomic number of any element of the period
(c) maximum principal quantum number of any element of the period
(d) maximum azimuthal quantum number of any element of the period

16. The elements with atomic numbers 9, 17, 35, 53, 85 are all
(a) halogens (b) noble gases
(c) heavy metals (d) light metals

17. In which block does 106th element belong?
(a) s-block (b) p-block
(c) d-block (d) f-block

18. Which of the following electronic configurations in the outermost shell is characteristic of alkali metals?
(a) $ns^2p^6d^1$ (b) $(n-1)s^2p^6, ns^1$
(c) $(n-1)s^2p^6, ns^2p^1$ (d) $(n-1)s^2p^6d^{10}, ns^1$

19. Which one of the following belongs to representative group of elements in the Periodic Table?
(a) Aluminium (b) Chromium
(c) Argon (d) Lanthanum

20. In the modern Periodic Table, the period indicates the value of [NCERT]
(a) atomic number
(b) atomic mass
(c) principal quantum number
(d) azimuthal quantum number

21. Which of the following statements related to the modern Periodic Table is incorrect? [NCERT]
(a) The p-block has 6 columns, because a maximum of 6 electrons can occupy all the orbitals in a p-shell
(b) The d-block has 8 columns because a maximum of 8 electrons can occupy all the orbitals in a d-subshell
(c) Each block contains a number of columns equal to the number of electrons that can occupy that subshell
(d) The block indicates value of azimuthal quantum number (l) for the last subshell that received electrons in building up the electronic configuration

22. Which group of the Periodic Table does not contain only metals?
(a) IB (b) IA (c) IIA (d) IIIA

23. Which pair of atomic numbers represents s-block elements?
(a) 3, 12 (b) 6, 12
(c) 7, 15 (d) 9, 17

24. The tenth elements in the Periodic Table resembles with the
(a) first period (b) second period
(c) fourth period (d) ninth period

25. According to IUPAC nomenclature, a newly discovered element has been named as Uun. The atomic number of the element is
(a) 111 (b) 112
(c) 109 (d) 110

26. Mendeleef 's Periodic Table is upset by the fact that
(a) many elements have several isotopes
(b) noble gases do not form compounds
(c) some groups stand divided into two sub groups A and B
(d) atomic weights of elements are not always whole numbers

27. Variable valency in general, is exhibited by
(a) transition elements (b) gaseous elements
(c) non-metals (d) s-block elements

Atomic and Ionic Radii

28. In third row of the Periodic Table, the atomic radii from Na to Cl
(a) continuously decreases
(b) continuously increases
(c) remains constant
(d) increases but not continuously

29. The screening effect of d-electrons is
(a) equal to that of p-electrons
(b) more than that of p-electrons
(c) same as f-electrons
(d) less than p-electrons

30. Which of the following has largest ionic radius?
(a) Li^+ (b) K^+ (c) Na^+ (d) Cs^+

31. Which of the following ion is the smallest ion?
(a) O_2 (b) O_2^+ (c) O_2^- (d) O_2^{2-}

32. The order of screening effect of electrons of s, p, d and f orbitals of a given shell of an atom on its outer shell electrons is [NCERT]
(a) $s > p > d > f$ (b) $f > d > p > s$
(c) $p < d < s > f$ (d) $f > p > s > d$

33. Anything that influences the valence electrons will affect the chemistry of the element. Which one of the following factors does not affect the valence shell? **[NCERT]**

(a) Valence principal quantum number (n)
(b) Nuclear charge (Z)
(c) Nuclear mass
(d) Number of core electrons

34. Consider the following species

N^{3-}, O^{2-}, F^-, Na^+, Mg^{2+} and Al^{3+}

What is common in them? **[NCERT]**

(a) Number of electrons
(b) Number of valence electrons
(c) Number of protons
(d) All of the above

35. The correct order of increasing ionic radii is

(a) $Na^+ < Mg^{2+} < Al^{3+} < N^{3-} < O^{2-} < F^-$
(b) $Al^{3+} < Mg^{2+} < Na^+ < N^3 < O^{2-} < F^-$
(c) $Al^{3+} < Mg^{2+} < Na^+ < F^- < O^{2-} < N^{3-}$
(d) $F^- < O^{2-} < N^{3-} < Al^{3+} < Mg^{2+} < Na^+$

36. Which has the smallest size?

(a) Na^+ (b) Mg^{2+} (c) Al^{3+} (d) P^{5+}

37. Which of the following statements is correct?

(a) X^- ion is larger in size than X-atom
(b) X^+ ion is larger in size than X-atom
(c) X^+ ion is larger in size than X^- ion
(d) X^+ and X^- ions are equal in size

Ionisation Energy

38. Arrange the elements N, P, O and S in the order of increasing first ionisation enthalpy. **[NCERT]**

(a) P < S < O < N (b) S < P < O < N
(c) S < O < P < N (d) P < S < N < O

39. The correct increasing order of non-metallic character is **[NCERT]**

(a) P < S < O < N (b) S < P < O < N
(c) S < O < P < N (d) P < S < N < O

40. Among the elements B, Al, C and Si, element with the highest first ionisation enthalpy is **[NCERT]**

(a) B (b) Al (c) C (d) Si

41. As one moves along a given row in the Periodic Table, ionisation energy

(a) increases from left to right
(b) decreases from left to right
(c) first increases, then decreases
(d) remains the same

42. Ionisation potential is lowest for

(a) alkali metals (b) inert gas
(c) halogens (d) alkaline earth metals

43. The first ionisation energy of lithium will be

(a) greater than Be (b) less than Be
(c) equal to that of Na (d) equal to that of F

44. When the first ionisation energies are plotted against atomic number, the peaks are occupied by

(a) alkali metals (b) halogens
(c) transition metals (d) rare gases

45. The ionisation energy of nitrogen is larger than that of oxygen because of

(a) greater attraction of electrons by the nucleus
(b) the size of nitrogen atom being smaller
(c) the half-filled p-orbitals possess extra stability
(d) greater penetration effect

46. Highest energy will be absorbed to eject out the electron in the configuration

(a) $1s^2 2s^2 2p^1$ (b) $1s^2 2s^2 2p^3$
(c) $1s^2 2s^2 2p^2$ (d) $1s^2 2s^2 2p^4$

47. The correct order of ionisation energy for comparing carbon, nitrogen and oxygen is

(a) C < N > O (b) C > N < O
(c) C > N > O (d) C < N < O

48. Which of the following isoelectronic ions has lowest ionisation energy?

(a) Cl^- (b) Ca^{2+} (c) K^+ (d) S^{2-}

49. Which of the following relation is correct?

(a) I^{st} IE of C > I^{st} IE of B
(b) I^{st} IE of C < I^{st} IE of B
(c) II^{nd} IE of C > II^{nd} IE of B
(d) Both (b) and (c)

50. If the IP of Na is 5.48 eV, the ionisation potential of K will be

(a) same as that of Na (b) 4.34 eV
(c) 5.68 eV (d) 10.88 eV

51. The first ionisation energy of oxygen is less than that of nitrogen. Which of the following is the correct reason for this observation?

(a) Lesser effective nuclear charge of oxygen than nitrogen
(b) Lesser atomic size of oxygen than nitrogen
(c) Greater inter-electron repulsion between two electrons in the same p-orbital counter balances the increase in effective nuclear charge on moving from nitrogen to oxygen
(d) Greater effective nuclear charge of oxygen than nitrogen

52. Among the second period elements the actual ionisation enthalpies are in the order

$$\text{Li} < \text{B} < \text{Be} < \text{C} < \text{O} < \text{N} < \text{F} < \text{Ne}$$

Be has higher $\Delta_i H$ than B. This is because
(a) of the stable configuration of B from which electron has to be removed
(b) of the fact p orbital being larger attracted more towards nucleus
(c) $2s$ orbital is closer to nucleus as compared to $2p$ orbital
(d) $2p$ orbital is of higher stability than $2s$ orbital

53. O has lower $\Delta_i H$ than N and F because
(a) its size is smaller than F but larger than N
(b) F is smaller but N have stable configuration
(c) N is smaller and F have stable configuration
(d) its size is smaller than N but larger than F

Electron Affinity and Other Periodic Properties

54. Electron affinity is the
(a) energy released when an electron is added to an isolated atom in the gaseous state
(b) energy absorbed when an electron is added to an isolated atom in the gaseous state
(c) energy required to take out an electron from an isolated gaseous atom
(d) power of an atom to attract an electron to itself

55. Which of the following pairs show reverse properties on moving along a period from left to right and from top to down in a group?
(a) Nuclear charge and electron affinity
(b) Ionisation energy and electron affinity
(c) Atomic radius and electron affinity
(d) None of the above

56. Which of the following has highest electron affinity?
(a) N (b) O
(c) F (d) Cl

57. With respect to chlorine, hydrogen will be
(a) electropositive (b) electronegative
(c) neutral (d) None of these

58. Of the following elements, which one has the highest electronegativity?
(a) F (b) Cl
(c) Br (d) I

59. The values of electronegativity of atom A and B are 1.20 and 4.0 respectively. The percentage of ionic character of A–B bond is
(a) 58.3% (b) 48%
(c) 79.6% (d) 73.6%

60. Elements of which group form anions most readily?
(a) Halogens
(b) Alkali metals
(c) Oxygen family
(d) Nitrogen group

61. The halogen that most easily reduced is
(a) F_2 (b) Cl_2
(c) Br_2 (d) I_2

62. Which element has the lowest electronegativity?
(a) Li (b) F
(c) Cl (d) Fe

63. The elements X, Y, Z and T have the indicated electronic configurations. Starting with the innermost shell, which is the most metallic element?
(a) X = 2,8,4 (b) Y = 2,8,8
(c) Z = 2, 8, 8, 1 (d) T = 2, 8, 8, 7

64. The outermost electronic configuration of the most electronegative element is
(a) ns^2np^3 (b) ns^2np^4
(c) ns^2np^5 (d) ns^2np^6

65. Fluorine has low electron affinity than chlorine because of
(a) bigger radius of fluorine, less density
(b) smaller radius of fluorine, high density
(c) smaller radius of chlorine, high density
(d) smaller radius of chlorine, less density

66. The outermost configuration of the least reactive element is
(a) ns^2p^3 (b) ns^2p^4
(c) ns^2p^5 (d) ns^2p^6

67. Which one of the following process requiring absorption of energy?
(a) $Cl \longrightarrow Cl^-$ (b) $H \longrightarrow H^-$
(c) $O \longrightarrow O^{2-}$ (d) $F \longrightarrow F^-$

68. Among alkali metals which element do you expect to be least electronegative? **[NCERT]**
(a) K (b) Na
(c) Cs (d) Fr

69. The electron gain enthalpy of fluorine is less negative than that of chlorine because **[NCERT]**
(a) the added electron experience greater force of attraction from the other electron in case of F
(b) the added electron experience greater force of repulsion from the other electrons in case of F
(c) the size of F is smaller than Cl
(d) Both (b) and (c)

70. As we go from left to right in period two of the periodic table, gram atomic volume of the elements

(a) will change indefinitely
(b) decreases
(c) increase at a constant rate
(d) first increase then decrease

71. Metallic nature and basic nature of the oxides...... as we move along a period.

(a) increases
(b) decreases
(c) remains constant
(d) first increase then decreases

72. The metal having highest melting point is

(a) Cr
(b) Ag
(c) diamond
(d) W

73. Which of the following metals exhibits more than one oxidation state?

(a) Na
(b) Mg
(c) Al
(d) Fe

74. The maximum valency of an element with atomic number 7 is

(a) 2
(b) 3
(c) 4
(d) 5

75. The correct order of reactivity of halogens is

(a) F > Br > Cl > I
(b) F > Cl > Br > I
(c) I > Br > Cl > F
(d) Cl > I > Br > F

76. The correct order of increasing oxidising power is

(a) $F_2 < Cl_2 < Br_2 < I_2$
(b) $I_2 < F_2 < Cl_2 < Br_2$
(c) $Br_2 < I_2 < F_2 < Cl_2$
(d) $I_2 < Br_2 < Cl_2 < F_2$

77. Which of the following oxides is most basic?

(a) Na_2O
(b) SiO_2
(c) SO_2
(d) All are equally basic

Round II (Mixed Bag)

Only One Correct Option

1. The statement that is true for the long form of the Periodic Table is

(a) it reflects the sequence of filling the electrons in the order of sub-energy levels *s*, *p*, *d* and *f*
(b) it helps to predict the stable valency states of the elements
(c) it reflects trends in physical and chemical properties of the elements
(d) All of the above

2. The radii of F, F^-, O and O^{2-} are in the order of

(a) $F^- > O^{2-} > F > O$
(b) $F > F^- > O > O^{2-}$
(c) $O^{2-} > F^- > O > F$
(d) $F > O > F^- > O^{2-}$

3. Which of the following does not represent the correct order of the property indicated?

(a) $Sc^{3+} > Cr^{3+} > Fe^{3+} > Mn^{3+}$ — ionic radii
(b) Sc < Ti < Cr < Mn — density
(c) $Mn^{2+} > Ni^{2+} > Co^{2+} < Fe^{2+}$ — ionic radii
(d) FeO < CaO < MnO < CuO — basic nature

4. The first ionisation enthalpies for two isotopes of the same elements are **[NCERT]**

(a) same
(b) different
(c) some what different
(d) $IE_I = 2IE_{(\text{II isotope})}$

5. The size of isoelectronic species; F^-, Ne and Na^+ is affected by **[NCERT]**

(a) nuclear charge (Z)
(b) valence principal quantum number (n)
(c) electron-electron interaction in the outer orbitals
(d) none of the factors because their size is the same

6. Energy of an electron in the ground state of the hydrogen atom is -2.18×10^{-18} J. Calculate the ionisation enthalpy of atomic hydrogen in terms of J mol^{-1}. **[NCERT]**

(a) 2.18×10^{-18}
(b) 13.12×10^{5}
(c) 3.16×10^{-13}
(d) 2.21×10^{6}

7. The correct order of radii is

(a) N < Be < B
(b) $F^- < O^{2-} < N^{3-}$
(c) $Fe^{3+} < Fe^{2+} < Fe^{4+}$
(d) Na < Li < K

8. The correct order of ionic radius is

(a) $Ti^{4+} < Mn^{7+}$
(b) $^{35}Cl^- > {}^{37}Cl^-$
(c) $K^+ > Cl^-$
(d) $P^{3+} > P^{5+}$

9. The bond length of LiF will be

(a) equal to that of KF
(b) more than that of KF
(c) equal to that of NaF
(d) less than that of NaF

10. The ionic radius of 'Cr' is minimum in which of the following compounds?

(a) CrO_2
(b) K_2CrO_4
(c) CrF_3
(d) $CrCl_3$

11. The incorrect statement among the following is
- (a) the first ionisation potential of Al is less than the first ionisation potential of Mg
- (b) the second ionisation potential of Mg is greater than the second ionisation potential of Na
- (c) the first ionisation potential of Na is less than the first ionisation potential of Mg
- (d) the third ionisation potential of Mg is greater than that of Al

12. $A \rightarrow A^+ + e,\ E_1$ and $A^+ \rightarrow A^{2+} + e,\ E_2$. The energy required to pull out the two electrons are E_1 and E_2 respectively. The correct relationship between two energy would be

(a) $E_1 < E_2$ (b) $E_1 > E_2$
(c) $E_1 = E_2$ (d) $E_1 \neq E_2$

13. Which ionisation potential (IP) in the following equations involves the greatest amount of energy?

(a) $K^+ \longrightarrow K^{2+} + e^-$ (b) $Na \longrightarrow Na^+ + e^-$
(c) $C^{2+} \longrightarrow C^{3+} + e^-$ (d) $Ca^+ \longrightarrow Ca^{2+} + e^-$

14. The first four ionisation energy values of an element are 191, 578, 872 and 5962 kcal. The number of valence electrons in the element is

(a) 1 (b) 2 (c) 3 (d) 4

15. The I^{st} IEs of four consecutive elements present in the second the period of Periodic Table are 8.3, 11.3, 14.5 and 13.6 eV respectively. Which of these is the IE of nitrogen?

(a) 13.6 (b) 8.3
(c) 14.5 (d) 11.3

16. Which of the following transitions involves maximum amount of energy?

(a) $M^-(g) \longrightarrow M(g)$ (b) $M(g) \longrightarrow M^+(g)$
(c) $M^+(g) \longrightarrow M^{2+}(g)$ (d) $M^{2+}(g) \longrightarrow M^{3+}(g)$

17. The formation of the oxide ion, $O^{2-}(g)$, from oxygen atom requires first an exothermic and then an endothemic step as shown below.

$$O(g) + e^- \longrightarrow O^-(g)\,;\quad \Delta H^\ominus = -141\ \text{kJ mol}^{-1}$$
$$O^-(g) + e^- \longrightarrow O^{2-}(g)\,; \Delta H^\ominus = +780\ \text{kJ mol}^{-1}$$

Thus, process of formation of O^{2-} in gas phase is unfavourable even though O^{2-} is isoelectronic with neon. It is due to the fact that **[NCERT Exemplar]**
- (a) oxygen is more electronegative
- (b) addition of electron in oxygen results in larger size of the ion
- (c) electron repulsion outweighs the stability gained by achieving noble gas configuration
- (d) O^- ion has comparatively smaller size than oxygen atom

18. The electronic configuration of four elements are given below. Which element does not belong to the same family?

(a) $[Xe]\,4f^{14}5d^{10}6s^2$ (b) $[Kr]\,4d^{10}5s^2$
(c) $[Ne]\,3s^2 3p^5$ (d) $[Ar]\,3d^{10}4s^2$

19. Which of the following sequence correctly represents the decreasing acidic nature of oxides?
- (a) $Li_2O > BeO > CO_2 > N_2O_3 > B_2O_3$
- (b) $CO_2 > N_2O_3 > B_2O_3 > Li_2O > BeO$
- (c) $N_2O_3 > CO_2 > B_2O_3 > BeO > Li_2O$
- (d) $CO_2 > BeO > Li_2O > B_2O_3 > N_2O_3$

20. Which is not the correct order for the stated property?
- (a) Ba > Sr > Mg, atomic radius
- (b) F > O > N, first ionisation enthalpy
- (c) Cl > F > I, electron affinity
- (d) O > Se > Te, electronegativity

21. The electron affinity values (in kg mol^{-1}) of three halogens X, Y and Z are respectively –349, –333 and –325. Then X, Y and Z respectively, are

(a) F_2, Cl_2 and Br_2 (b) Cl_2, F_2 and Br_2
(c) Cl_2, Br_2 and F_2 (d) Br_2, Cl_2 and F_2

22. Which of the following has the highest second ionisation energy?

(a) Calcium (b) Chromium
(c) Iron (d) Cobalt

23. Electronic configuration of four elements A, B, C and D are given below

(A) $1s^2, 2s^2, 2p^6$ (B) $1s^2, 2s^2, 2p^4$
(C) $1s^2, 2s^2, 2p^6, 3s^1$ (D) $1s^2, 2s^2, 2p^5$

Which of the following is the correct order of increasing tendency to gain electron? **[NCERT Exemplar]**

(a) $A < C < B < D$ (b) $A < B < C < D$
(c) $D < B < C < A$ (d) $D < A < B < C$

24. Which one of the following arrangements represents the correct order of electron gain enthalpy (with negative sign) of the given atomic species?

(a) Cl < F < S < O (b) O < S < F < Cl
(c) S < O < Cl < F (d) F < Cl < O < S

25. In which one of the following pairs, the radius of the second species is greater than that of the first?

(a) Na, Mg (b) O^{2-}, N^{3-}
(c) Li^+, Be^{2+} (d) Ba^{2+}, Sr^{2+}

26. For d-block elements the first ionisation potential is of the order
- (a) Zn > Fe > Cu > Cr
- (b) Sc ≈ Ti < V ≈ Cr
- (c) Zn < Cu < Ni < Co
- (d) V > Cr > Mn > Fe

27. Match the correct atomic radius with the element.

	Element		Atomic radius (pm)
(A)	Be	(i)	74
(B)	C	(ii)	88
(C)	O	(iii)	111
(D)	B	(iv)	77
(E)	N	(v)	66

[NCERT Exemplar]

Codes

	A	B	C	D	E
(a)	(iii)	(iv)	(v)	(i)	(ii)
(b)	(iii)	(iv)	(v)	(ii)	(i)
(c)	(iv)	(iii)	(v)	(ii)	(i)
(d)	(v)	(iii)	(iv)	(i)	(ii)

28. Match the correct ionisation enthalpies and electron gain enthalpies of the following elements.

	Elements		ΔH_1	ΔH_2	$\Delta_{eg} H$
(A)	Most reactive non-metal	(i)	419	3051	– 45
(B)	Most reactive metal	(ii)	1681	3374	– 328
(C)	Least reactive element	(iii)	738	1451	– 40
(D)	Metal forming binary halide	(iv)	2372	5251	+ 48

[NCERT Exemplar]

Codes

	A	B	C	D		A	B	C	D
(a)	(ii)	(i)	(iv)	(iii)	(b)	(i)	(ii)	(iv)	(iii)
(c)	(i)	(iv)	(iii)	(iv)	(d)	(ii)	(i)	(iii)	(iv)

29. If Aufbau rule is not followed, K-19 will be placed in

(a) *s*-block
(b) *p*-block
(c) *d*-block
(d) *f*-block

30. Which of the following is correct order of increasing size?

(a) $Br^- > S^{2-} > Cl^- > Na^+ > Mg^{2+} > Be^{2+}$
(b) $Be^{2+} > Mg^{2+} > Na^+ > S^{2-} > Cl^- > Br^-$
(c) $S^{2-} > Cl^- > Br^- > Na^+ > Mg^{2+} > Be^{2+}$
(d) $Na^+ > Mg^{2+} > Be^{2+} > Br^- > Cl^- > S^{2-}$

31. Which is the correct order of ionic sizes?

(At. no. : Ce = 58, Sn = 50, Yb = 70 and Lu = 71)

(a) Ce > Sn > Yb > Lu
(b) Sn > Yb > Ce > Lu
(c) Sn > Ce > Yb > Lu
(d) Lu > Yb > Sn > Ce

32. In the isoelectronic species the ionic radii (Å) of N^{3-}, O^{2-} and F^- are respectively given by

(a) 1.71, 1.40, 1.36
(b) 1.71, 1.36, 1.40
(c) 1.36, 1.40, 1.71
(d) 1.36, 1.71, 1.40

33. The trivalent ion having largest size in lanthanide series is

(a) Ti
(b) Zr
(c) Hf
(d) La

34. A sudden large jump between the values of second and third ionisation energies of an element would be associated with the electronic configuration

(a) $1s^2, 2s^2, 2p^6, 3s^2$
(b) $1s^2, 2s^2, 2p^6, 3s^1$
(c) $1s^2, 2s^2, 2p^6, 3s^2, 3p^1$
(d) $1s^2, 2s^2, 2p^6, 3s^2, 3p^2$

35. The first ionisation potential (eV) of Be and B respectively are

(a) 8.29 eV, 8.29 eV
(b) 8.29 eV, 9.32 eV
(c) 9.32 eV, 9.32 eV
(d) 9.32 eV, 8.29 eV

36. The second electron affinity is zero for

(a) alkali metals
(b) halogens
(c) noble gases
(d) transition metal

37. A trend common to both group I and VII elements in the Periodic Table as atomic number increases is

(a) atomic radius increases
(b) oxidising power increases
(c) reactivity with water increases
(d) maximum valency increases

38. An element X which occurs in the first short period has an outer electronic structure $s^2 p^1$. What are the formula and acid-base character of its oxides?

(a) XO_3, basic
(b) X_2O_3, basic
(c) X_2O_3, amphoteric
(d) XO_2, acidic

More than One Correct Option

39. Which of the following pairs of species have nearly same size?

(a) Rb^+, O^{2-}
(b) Cl^-, Na^+
(c) Mg^{2+}, Na^+
(d) Li^+, Mg^{2+}

40. Which of the following statements is/are true?

(a) Metallic and covalent radii of potassium are 2.3 Å and 2.03 Å respectively
(b) Atomic and ionic radii of niobium and tantalum are almost same
(c) Ionisation energy is inversely proportional to the screening effect
(d) The first ionisation energies of Be and Mg are more than ionisation energies of B and Al respectively

41. Which of the following elements will gain one electron more readily in comparison to other elements of their group? [NCERT Exemplar]

(a) S (*g*)
(b) Na (*g*)
(c) O (*g*)
(d) Cl (*g*)

42. Which of the following statements are correct? **[NCERT Exemplar]**

(a) Helium has the highest first ionisation enthalpy in the Periodic Table
(b) Chlorine has less negative electron gain enthalpy than fluorine
(c) Mercury and bromine are liquids at room temperature
(d) In any period, atomic radius of alkali metal is the highest

43. Which of the following sets contain only isoelectronic ions? **[NCERT Exemplar]**

(a) $Zn^{2+}, Ca^{2+}, Ga^{3+}, Al^{3+}$ (b) $K^{+}, Ca^{2+}, Sc^{3+}, Cl^{-}$
(c) $P^{3-}, S^{2-}, Cl^{-}, K^{+}$ (d) Ti^{4+}, Ar, Cr^{3+}, V^{5+}

Assertion and Reason

Directions (Q. Nos. 44 to 48) *Each of these questions contains two statements : Statement* I *(Assertion) and Statement* II *(Reason). Each of these questions also has four alternative choices, only one of which is the correct answer. You have to select one of the codes* (*a*), (*b*), (*c*), (*d*) *given below :*

(a) Statement I is true; Statement II is true; Statement II is a correct explanation for Statement I.
(b) Statement I is true; Statement II is true; Statement II is not a correct explanation for Statement I.
(c) Statement I is true; Statement II is false.
(d) Statement I is false; Statement II is true.

44. **Statement I** Ionisation energy of nitrogen (7) is more than that of oxygen (8).

Statement II Half-filled *p*-orbitals in nitrogen ($2p^3$) are more stable.

45. **Statement I** Manganese has a less favourable electron affinity than its neighbours in either side.

Statement II The magnitude of an element's electron affinity depends on the element's valence shell electronic configuration.

46. **Statement I** Shielding effect increases as we go down the group.

Statement II More is the electrons in the penultimate shell, more is shielding.

47. **Statement I** Generally, ionisation enthalpy increases from left to right in a period.

Statement II When successive electrons are added to the orbitals in the same principal quantum level, the shielding effect of inner core of electrons does not increase very much to compensate for the increased attraction of the electron to the nucleus. **[NCERT Exemplar]**

48. **Statement I** Electron gain enthalpy becomes less negative as we go down a group.

Statement II Size of the atom increases on going down the group and the added electron would be farther from the nucleus. **[NCERT Exemplar]**

Comprehension Based Questions

Directions (Q.Nos. 49 to 51) In the modern Periodic Table, elements are arranged in order of increasing atomic numbers which is related to the electronic configuration. Depending upon the type of orbitals receiving the last electron, the elements in the Periodic Table have been divided into four block, *viz*, *s*, *p*, *d* and *f*. The modern Periodic Table consists of 7 periods and 18 groups. Each period begins with the filling of a new energy shell. In accordance with the Aufbau principle, the seven periods (1 to 7) have 2, 8, 8, 18, 18, 32 and 32 elements respectively. The seventh period is still incomplete. To avoid the Periodic Table being too long, the two series of *f*-block elements, called lanthanoids and actinoids are placed at the bottom of the main body of the Periodic Table.

49. Which of the elements whose atomic numbers are given below, cannot be accommodated in the present set up of the long form of the Periodic Table?

(a) 107 (b) 118 (c) 126 (d) 102

50. The electronic configuration of the element which is just above the element with atomic number 43 in the same group is **[NCERT Exemplar]**

(a) $1s^2, 2s^2, 2p^6, 3s^2, 3p^6, 3d^5, 4s^2$
(b) $1s^2, 2s^2, 2p^6, 3s^2, 3p^6, 3d^5, 4s^2, 4p^6$
(c) $1s^2, 2s^2, 2p^6, 3s^2, 3p^6, 3d^6, 4s^2$
(d) $1s^2, 2s^2, 2p^6, 3s^2, 3p^6, 3d^7, 4s^2$

51. The elements with atomic numbers 35, 53 and 85 are all **[NCERT Exemplar]**

(a) noble gases (b) halogens
(c) heavy metals (d) light metals

Directions (Q.Nos. 52 and 53) Screening effect is the effect produced by intervening electrons between nucleus and valence electrons. They shield the nucleus from valence electron and hence, effective nuclear charge decreases. If there is less shielding effect, the effective nuclear charge decreases. Valence electrons are attracted by nucleus and repelled by other electrons.

Net attractive force on electron under consideration = $Z - S$ = (nuclear charge – screening effect)

It is the Slater's formula for screening constant.

If one electron is present in outermost orbit, there will be no screening in that orbital.

Each electron contributes 0.35 (total electrons minus 1) present in outermost shell.

In penultimate energy level, electrons contribute 0.85.

A contribution of 1.0 is from remaining electrons (present in last but one energy level)

52. The effective nuclear charge for 4*s* electrons of Zn will be
(a) 26.85 (b) 4.35 (c) 15.30 (d) 10

53. The atomic size of Ga and Al are almost same because
(a) of poor shielding effect of electrons in *d*-orbitals, due to which effective nuclear charge increases in gallium
(b) more shielding effect of *d*-electrons
(c) poor shielding effect of *f*-orbital in gallium
(d) high shielding effect of 3*s*, 3*p* and 3*d* electrons

Directions (Q.Nos. 54 to 56) Ionic radius is the effective distance from the nucleus of an ion up to which it has its influence on its electron cloud. A cation is always much smaller than the corresponding atom. Further, more the number of electrons removed, smaller will be the size of the resulting positive ion. For example $r_{Fe} > r_{Fe^{2+}} > r_{Fe^{3+}}$.

A cation formed by the loss of electrons may result in the complete disappearance of the outer shell and since, the remaining inner shells do not extend so far in space, the cation is much smaller than the metal atom. For example

$$\underset{(2,\,8,\,1)}{\text{Na}} \longrightarrow \underset{(2,\,8)}{\text{Na}^+}$$

In case of isoelectronic ions, the greater the nuclear charge, the greater is the attraction for electrons and smaller is ionic radius.

54. The size of the species Pb, Pb^{2+} and Pb^{4+} decreases as
(a) $Pb^{4+} > Pb^{2+} > Pb$ (b) $Pb > Pb^{2+} > Pb^{4+}$
(c) $Pb^{4+} > Pb > Pb^{2+}$ (d) $Pb^{2+} > Pb^{4+} > Pb$

55. The species which has the same number of electrons in the outermost as well as penultimate shell is
(a) F^- (b) Ca^{2+}
(c) O^{2-} (d) Mg^{2+}

56. Which out of the following has the largest size?
(a) Mg^{2+} (b) Na^+
(c) Rb^+ (d) Li^+

Directions (Q.Nos. 57 to 59)

The first ($\Delta_i H_1$) and the second ($\Delta_i H_2$) ionisation enthalpies (in kJ mol^{-1}) and the ($\Delta e_g H$) electron gain enthalpy (in kJ mol^{-1}) of a few elements are given below

Elements	ΔH_1	ΔH_2	$\Delta e_g H$
I	520	7300	– 60
II	419	3051	– 48
III	1681	3374	– 328
IV	1008	1846	– 295
V	2372	5251	+48
VI	738	1451	– 40

57. Which of the above elements is likely to be the least reactive element?
(a) I (b) V (c) VI (d) III

58. The metal which can form a stable binary halide of the formula MX_2(X = halogen) is
(a) V (b) VI (c) IV (d) I

59. The metal which can form a predominantly stable covalent halide of the formula MX (X = halogen) is
(a) I (b) II (c) III (d) IV

Previous Years' Questions

60. The increasing order of the ionic radii of the given isoelectronic species is [AIEEE 2012]
(a) $Cl^-, Ca^{2+}, K^+, S^{2-}$ (b) $S^{2-}, Cl^-, Ca^{2+}, K^+$
(c) $Ca^{2+}, K^+, Cl^-, S^{2-}$ (d) $K^+, S^{2-}, Ca^{2+}, Cl^+$

61. Which one of the following order presents the correct sequence of the increasing basic nature of the given oxides? [AIEEE 2011]
(a) $Al_2O_3 < MgO < Na_2O < K_2O$
(b) $MgO < K_2O < Al_2O_3 < Na_2O$
(c) $Na_2O < K_2O < MgO < Al_2O_3$
(d) $K_2O < Na_2O < Al_2O_3 < MgO$

62. The correct order of electron gain enthalpy with negative sign of F, Cl, Br and I, having atomic number 9, 17, 35 and 53 respectively, is [AIEEE 2011]
(a) I > Br > Cl > F (b) F > Cl > Br > I
(c) Cl > F > Br > I (d) Br > Cl > I > F

63. The correct sequence which shows decreasing order of the ionic radii of the elements is [AIEEE 2010]
(a) $Al^{3+} > Mg^{2+} > Na^+ > F^- > O^{2-}$
(b) $Na^+ > Mg^{2+} > Al^{3+} > O^{2-} > F^-$
(c) $Na^+ > F^- > Mg^{2+} > O^{2-} > Al^{3+}$
(d) $O^{2-} > F^- > Na^+ > Mg^{2+} > Al^{3+}$

64. The set representing the correct order of ionic radius is [AIEEE 2009]
(a) $Li^+ > Be^{2+} > Na^+ > Mg^{2+}$
(b) $Na^+ > Li^+ > Mg^{2+} > Be^{2+}$
(c) $Li^+ > Na^+ > Mg^{2+} > Be^{2+}$
(d) $Mg^{2+} > Be^{2+} > Li^+ > Na^+$

65. The charge/size ratio of a cation determines its polarising power. Which one of the following sequences represents the increasing order of the polarising power of the cationic species, K^+, Ca^{2+}, Mg^{2+}, Be^{2+}? **[AIEEE 2007]**

(a) $Mg^{2+} < Be^{2+} < K^+ < Ca^{2+}$
(b) $Be^{2+} < K^+ < Ca^{2+} < Mg^{2+}$
(c) $K^+ < Ca^{2+} < Mg^{2+} < Be^{2+}$
(d) $Ca^{2+} < Mg^{2+} < Be^{2+} < K^+$

66. Which one of the following sets of ions represents a collection of isoelectronic species? **[AIEEE 2006]**

(a) $K^+, Cl^-, Ca^{2+}, Sc^{3+}$ (b) $Ba^{2+}, Sr^{2+}, K^+, S^{2-}$
(c) $N^{3-}, O^{2-}, F^-, S^{2-}$ (d) $Li^+, Na^+, Mg^{2+}, Ca^{2+}$

67. The ionic mobility of alkali metal ions in aqueous solution is maximum for **[AIEEE 2006]**

(a) K^+ (b) Rb^+
(c) Li^+ (d) Na^+

68. The increasing order of the first ionisation enthalpies of the elements B, P, S and F (lowest first) is **[AIEEE 2006]**

(a) F < S < P < B
(b) P < S < B < F
(c) B < P < S < F
(d) B < S < P < F

69. Following statements regarding the periodic trends of chemical reactivity of the alkali metals and the halogens are given. Which of these statements give the correct picture? **[AIEEE 2006]**

(a) The reactivity decreases in the alkali metals but increases in the halogens with increase in atomic number down the group
(b) In both the alkali metals and the halogens, the chemical reactivity decreases with increase in atomic number down the group
(c) Chemical reactivity increases with increase in atomic number down the group in both the alkali metals and halogens
(d) In alkali metals the reactivity increases but in the halogens it decreases with increase in atomic number down the group

70. In which of the following arrangements the order is not according to the property indicated against it? **[AIEEE 2005]**

(a) Li < Na < K < Rb: Increasing metallic radius
(b) I < Br < F < Cl: Increasing electron gain enthalpy (with negative sign)
(c) B < C < N < O: Increasing first ionisation enthalpy
(d) $Al^{3+} < Mg^{2+} < Na^+ < F^-$: Increasing ionic size

71. Which one of the following ions has the highest value of ionic radius? **[AIEEE 2004]**

(a) Li^+ (b) B^{3+}
(c) O^{2-} (d) F^-

72. The formation of the oxide ion $O^{2-}(g)$ requires first an exothermic and then an endothermic step as shown below

$$O(g) + e^- = O^-(g)\,; \quad \Delta H^\circ = -142 \text{ kJ mol}^{-1}$$
$$O^-(g) + e^- = O^{2-}(g)\,; \Delta H^\circ = 844 \text{ kJ mol}^{-1}$$

This is because **[AIEEE 2004]**

(a) oxygen is more electronegative
(b) oxygen has high electron affinity
(c) O^- ion will tend to resist the addition of another electron
(d) O^- ion has comparatively larger size than oxygen atom

73. Among Al_2O_3, SiO_2, P_2O_3 and SO_2 the correct order of acid strength is **[AIEEE 2004[**

(a) $SO_2 < P_2O_3 < SiO_2 < Al_2O_3$
(b) $SiO_2 < SO_2 < Al_2O_3 < P_2O_3$
(c) $Al_2O_3 < SiO_2 < SO_2 < P_2O_3$
(d) $Al_2O_3 < SiO_2 < P_2O_3 < SO_2$

74. According to the periodic law of elements, the variation in properties of elements is related to their **[AIEEE 2003]**

(a) atomic masses
(b) nuclear masses
(c) atomic numbers
(d) nuclear neutron-proton number ratios

75. The radius of La^{3+} (atomic number : La = 57) is 1.06 Å. Which one of the following given values will be closest to the radius of Lu^{3+} (atomic number : Lu = 71)? **[AIEEE 2003]**

(a) 1.60 Å (b) 1.40 Å
(c) 1.06 Å (d) 0.85 Å

76. The atomic numbers of vanadium (V), chromium (Cr), manganese (Mn) and iron (Fe) are, respectively 23, 24, 25 and 26. Which one of these may be expected to have the highest second ionisation enthalpy? **[AIEEE 2003]**

(a) V (b) Cr (c) Mn (d) Fe

77. Ce^{3+}, La^{3+}, Pm^{3+} and Yb^{3+} have ionic radii in the increasing order as **[AIEEE 2002]**

(a) $La^{3+} < Ce^{3+} < Pm^{3+} < Yb^{3+}$
(b) $Yb^{3+} < Pm^{3+} < Ce^{3+} < La^{3+}$
(c) $La^{3+} = Ce^{3+} < Pm^{3+} < Yb^{3+}$
(d) $Yb^{3+} < Pm^{3+} < La^{3+} < Ce^{3+}$

the Guidance

Round I

3. Na—Cl Both belongs to III period.

4. General configuration for 17th group elements is ns^2np^5. In the third period, the principal quantum number for valence shell is three, so the electronic configuration of valence shell for the given element is $3s^2, 3p^5$. Third period starts from atomic number, $Z = 11$ and end at $Z = 18$. Hence, the atomic number of the given element is $10 + 7 = 17$.

5. Lawrencium $(Z = 103)$ and Berkelium $(Z = 97)$ were named by Lawrence Berkeley laboratory.

6. Same group elements have same number. of valence electrons therefore, have similar physical and chemical properties

8. In case of transition elements (or any elements), the order of filling of electrons in variou orbitals is $3p < 4s < 3d$

Thus, $3d$ orbital is filled when $4s$ orbital gets completely filled.

11. $1s^2, 2s^2, 2p^6, 3s^2, 3p^6, 4s^2$

Principal quantum number is 4, so it belongs to 4th period.

12. ns^2np^4 for $n = 3$

$n = 3$ means element belongs to third period. Since, last electron enters in the p-orbital, it belongs to p-block. For p-block elements, the group number $= 10 +$ valence shell electrons $= 10 + (2 + 4) = 16$

Hence, the element belongs to 16th group.

The complete electronic configuration of the element is as follows,

$$1s^2, 2s^2, 2p^6, 3s^2, 3p^4$$

Thus, the element is sulphur.

13. $(n-1)\,d^2\,ns^2$ for $n = 4$

$n = 4$ means the element belongs to fourth period. Since, last electron enters in d-orbital, the given element belongs to d-block. For d-block elements, group number = number of d-electrons + number of ns electrons $= 2 + 2 = 4$

Hence, the element belongs to 4th group.

The complete electronic configuration of the element is as follows,

$$1s^2, 2s^2, 2p^6, 3s^2, 3p^6, 3d^2, 4s^2$$

Thus, the element is titanium.

14. $(n-2)\,f^7\,(n-1)\,d^1\,ns^2$ for $n = 6$

$n = 6$ means, the element belongs to sixth period.

Since, last electron enters in f-orbital, the given element belongs to f-block and all f-block elements are the members of third group. Hence, the element belongs to third group.

The complete configuration of the element is as follows,
$1s^2, 2s^2, 2p^6, 3s^2, 3p^6, 3d^{10}, 4s^2, 4p^6, 4d^{10},$
$5s^2, 5p^6, 4f^7, 5d^1, 6s^2$

Thus, the element is gadolinium (Gd).

15. Period number = Maximum n of any element (where , $n =$ principal quantum number)

16. These atomic numbers give the configuration ns^2np^5 which is of halogen group or VIIth group.

17. The electronic configuration of the element having atomic number 106 is $[Rn]_{86}, \ 7s^1, 5f^{14}, 6d^5$.

Since, the last electron enters in *d*-orbit, it is a *d*-block element. Its IUPAC name is unnilhexium (Unh).

20. In the modern Periodic Table, the period indicates the value of principal quantum number.

21. Statement (b) is incorrect. The correct statement (b) is; the *d*-block has 10 columns, because a maximum of 10 electrons can occupy all the orbitals in a *d*-subshell.
All other given statements are correct.

22. IIIA group contains both metals and non-metals.

23. $3 = 1s^2, 2s^1$
$12 = 1s^2, 2s^2, 2p^6, 3s^2$

Since, last electron enters in *s*-orbital, these are *s*-block elements.

24. Each period consists of a series of elements whose atoms have the same principal quantum number (n) of the outermost shell, *i.e.,* in second period, $n = 2$, this shell has four orbitals (one $2s$ and three $2p$) which can have eight electrons, hence second period contains 8 elements from atomic number 3 to 10.

26. Mendeleef failed to assign positions to isotopes on the basis of atomic mass according to his periodic law.

27. Variable valency is the characteristic feature of transition elements.

28. Since effective nuclear charge increases from left to right in a period thus, atomic radii decreases.

30. Ionic radii increases in a group.

31. Cation has small size than parent atom and anion has larger size than parent atom.

33. Nuclear mass (protons + neutrons) does not affect the valence shell, only protons, *i.e.,* nuclear charge affects the valence shell.

34. All the given species have same number of electrons ($10e^-$)

Therefore, all are isoelectronic.

35. The ionic radii of isoelectronic species decreases with increase in atomic number (as magnitude of the nuclear charge increases with increase in atomic number). Therefore, their ionic radii increase in the order
Isoelectronic ions $= Al^{3+} < Mg^{2+} < Na^+ < F^- < O^{2-} < N^{3-}$
Atomic number, $Z = 13 \quad 12 \quad 11 \quad 9 \quad 8 \quad 7$

36. As the nuclear charge per electron is maximum in P^{5+}. therefore, its size is smallest.

38.

Period	Group 15	Group 16
2nd period	N	O
3rd period	P	S

Ionisation enthalpy of nitrogen ($_7N = 1s^2, 2s^2, 2p^3$) is greater than oxygen ($_8O = 1s^2, 2s^2, 2p^4$) due to extra stable exactly half-filled $2p$-orbitals. Similarly, ionisation enthalpy of phosphorus ($_{15}P = 1s^2, 2s^2, 2p^6, 3s^2, 3p^3$) is greater than sulphur ($_{16}S = 1s^2, 2s^2, 2p^6, 3s^2, 3p^4$).

On moving down the group, ionisation enthalpy decreases with increasing atomic size. So, the order is
$S < P < O < N \rightarrow$ First ionisation enthalpy increases.

39. Non-metallic character across a period (left to right) increases but on moving down the group it decreases. So, the order is
$P < S < N < O \rightarrow$ Non-metallic character increases.

40.

Period	Group 13	Group 14
2nd period	Boron	Carbon
3rd period	Aluminium	Silicon

Ionisation enthalpy increases along a period (as we move from left to right in a period) with decrease in atomic size and decreases down the group with increase in atomic size. Hence, carbon has the highest first ionisation enthalpy.

47. Nitrogen has more ionisation potential than carbon and oxygen because its outermost orbit is half-filled. So the order is $C < N > O$.

48. S^{2-} has the largest size and hence, has the lowest ionisation energy.

49. $_6C \longrightarrow 1s^2, 2s^2, 2p^2$
$_5B \longrightarrow 1s^2, 2s^2, 2p^1$

In first case IE_1 of $C > IE_1$ of B. Since, carbon is smaller than B in size. But $IE_2(B) > IE_2(C)$ because electron are paired as well as present in inner *s*-orbital whereas for carbon it will be still in $2p$-orbital and in unpaired state.

50. Ionisation potential decreases down the group.

51. The electronic configuration of nitrogen is

$$_7N = 1s^2, 2s^2, 2p^3$$

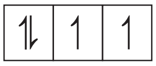
$$2p^3 \quad \underbrace{\boxed{\uparrow \mid \uparrow \mid \uparrow}}_{\text{half-filled } p\text{-orbital}}$$

Due to the presence of half-filled *p*-orbitals a large amount of energy is required to remove an electron from nitrogen. Hence, first ionisation energy of nitrogen is greater than that of oxygen.

The electronic configuration of oxygen is

$$_8O = 1s^2,\ 2p^2,\ 2p^4$$

$2p^4$



The other reason for the greater IP of nitrogen is that in oxygen, there is a greater inter-electronic repulsions between the electrons present in the same *p*-orbital which counter balance the increase in effective nuclear charge from nitrogen to oxygen.

52. Be has higher $\Delta_i H$ (ionisation enthalpy) than boron. In both the cases, the electron to be removed belongs to the same principal shell. In $_4Be = (1s^2,\ 2s^2)$, it is 2*s*-electron while in boron $_5B = (1s^2, 2s^2, 2p^1)$ it is 2*p*-electron. The penetration of a 2*s*-electron to the nucleus is more than that of a 2*p*-electron. It means 2*s*-electrons are more strongly attracted by the nucleus than 2*p*-electrons. Therefore, higher amount of energy is required to remove a 2*s*-electron than a 2*p*-electron. Hence, Be has higher $\Delta_i H$ than B.

53. O has lower $\Delta_i H$ than N and F

$$_7N = 1s^2, 2s^2, 2p_x^1, 2p_y^1, 2p_z^1;$$
$$_8O = 1s^2, 2s^2, 2p_x^2, 2p_y^1, 2p_z^1;$$
$$_9F = 1s^2, 2s^2, 2p_x^2, 2p_y^2, 2p_z^1$$

Across a period, ionisation enthalpy increases as we move from left to right due to decrease in atomic size. But $\Delta_i H$ of nitrogen is greater than oxygen. It is becasue of the more stable electronic configuration (exactly half filled orbitals are more stable) of nitrogen, so it is difficult to remove an electron from nitrogen than from oxygen. That's why oxygen has lower ionisation enthalpy than nitrogen and fluorine.

56. The electron affinities of some of the elements of second period (*i.e.*, N, O, F, etc.) are however, lower than the corresponding elements (*i.e.*, P, S, Cl, etc.) of the third period. This is due to the reason that the elements of second period have the smallest atomic size amongst the elements in their respective groups. As a result, there are considerable electron-electron repulsion within the atom itself and hence, the additional electron is not accepted with the same ease as is the case with the remaining elements in the same group.

58. F has the highest electronegativity because of its smallest size.

59. If the EN difference is 1.9, then bond is 50% ionic. The difference in electronegativity is 2.8, therefore, percentage ionic character due to EN difference of 2.8 is

$$\frac{2.8}{1.9} \times 50 = 73.6\%$$

61. Fluorine being most electronegative atom, has a high tendency to gain electron. Thus, it readily forms anions.

62. $_3Li - 1s^2,\ 2s^1$ donates one electron easily.

63. $Z = 2, 8, 8, 1$. Because it would donate electron more easily.

64. Halogens are most electronegative. Their general configuration is ns^2np^5.

65. Fluorine has low EA than chlorine because of smaller size of fluorine and compact 2*p*-orbital where interelectronic repulsion is more.

67. Second electron affinity of oxygen is endothermic and greater than first electron affinity, which is exothermic.

68. On moving down the group, electronegativity decreases because atomic size increases. Fr has the largest size, therefore it is least electronegative.

69. Electron gain enthalpy of F is less negative than that of Cl because when an electron is added to F, the added electron goes to the smaller $n = 2$ quantum level and suffers repulsion from other electrons present in this level. In case of Cl, the added electron goes to the larger $n = 3$ quantum level and suffers much less repulsion from other electrons.

74. Valency is according to valence shell configuration which here is $1s^2, 2s^2, 2p^3$, *i.e.*, 5.

75. Fluorine is more reactive than chlorine, bromine and iodine.

76. Oxidising power decreases in a group.

77. In a period, from left to right basic character of oxides decreases, thus Na_2O is most basic.

Round II

1. Periodic Table reflects trends in physical and chemical properties of the elements.

2. Atomic radius decreases on going from left to right in a period. Thus, size of O > F. As O^{2-} and F^- are isoelectronic, therefore, size of $O^{2-} > F^-$.

3. $Sc^{3+} > Cr^{3+} > Fe^{3+} > Mn^{3+}$, the correct order is $Cr^{3+} > Mn^{3+} > Fe^{3+} > Sc^{3+}$.

4. First ionisation enthalpies of two isotopes of the same element are expected to be same because ionisation enthalpy depends upon the electronic configuration and effective nuclear charge. Isotopes of an element have same electronic configuration and thus, the same nuclear charge.

5. The size of isoelectronic species; F^-, Ne and Na^+ is affected by nuclear charge (Z). With increase in nuclear charge (atomic number), the size of the isoelectronic species decreases.

6. Ionisation energy is the amount of energy required to remove the electron from the ground state (E_1) to infinity (E_∞).

$$E_1 = -2.18 \times 10^{-18}\ \text{J}$$
$$E_\infty = 0$$

$$\Delta E = E_{\infty} - E_1 = 0 - (-\,2.18 \times 10^{-18}\ \text{J})$$
$$= 2.18 \times 10^{-18}\ \text{J}$$

Ionisation enthalpy per hydrogen atom $= 2.18 \times 10^{-18}$ J

$\therefore$ Ionisation enthalpy per mole of hydrogen atoms

$$= 2.18 \times 10^{-18} \times 6.022 \times 10^{23}\ \text{Jmol}^{-1}$$
$$= 13.12 \times 10^{5}\ \text{J mol}^{-1}$$

Note Energy of an electron at infinity = 0.

7. Ionic radii decreases significantly from left to right in a period among representative elements.

8. Ionic radius $\propto \dfrac{1}{Z_{\text{eff}}}$

Since, P^{5+} has higher Z_{eff} as compared to P^{3+}, it has smaller ionic radii.

9. Down the group, size of atom increases. Therefore, bond length of LiF is less than that of NaF.

10. In K_2CrO_4, the oxidation state of Cr is $+6$. Therefore, Cr has the minimum radius in K_2CrO_4.

11. IE (II) of Na is higher than that of Mg because in case of Na, the second e^- has to be removed from the noble gas core while in case of Mg removal of second e^- gives a noble gas core.

Mg has high first ionisation potential than Na because of its stable ns^2 configuration.

12. $E_1 < E_2$, because second IE is greater than first IE.

13. $K^+ \longrightarrow K^{2+} + e^-$. Since, electron is to be removed from stable configuration.

14. Since, the IVth IE is very high, *i.e.*, electron is to be removed from stable configuration, thus it has 3 valence electrons.

15. Generally in a period, IE increases but nitrogen due to the presence of half-filled *p*-subshell (stable configuration) has higher IE as compared to its consecutive elements. Thus, the IE of nitrogen is 14.5.

16. $M^{2+} \longrightarrow M^{3+}$, after the removal of $2e^-$, the nuclear charge per electron increases due to which high energy is required to remove $3e^-$.

17. Although O^{2-} has noble gas configuration but its formation is unfavourable because here, the electronic repulsion outweigh the stability gained by achieving inert gas configuration.

18. In order to belong with the same family, the outer configuration must be the same. Thus, element with $[\text{Ne}]\,3s^2 3p^5$ configuration belongs to a different family.

19. On passing from left to right in a period, acidic character of the normal oxides of the element goes on increasing with increase in electronegativity. Thus, the correct order is

$$N_2O_3 > CO_2 > B_2O_3 > BeO > Li_2O$$

20. On moving along a period, ionisation enthalpy increases. Thus, the order of ionisation enthalpy should be as follows :

$$F > O > N$$

But N has half-filled configuration, therefore it is more stable than O and has higher ionisation enthalpy.

21. Generally electron affinity decreases on moving down a group but Cl_2 has higher electron affinity than F_2 due to its larger size as compared to F. Thus, chlorine has the highest electron affinity value.

So, the correct order of electron affinity will be

$$Cl_2 > F_2 > Br_2$$

22. $\text{Cr}(24) = [\text{Ar}]_{18}\ 3d^5, 4s^1$

Chromium after losing one electron gain stable configuration due to the presence of half-filled *d*-orbitals, therefore its second ionisation enthalpy is highest.

23. Element with *A*, *B* and *D* configuration belong to second period. *D* being a halogen (*i.e.,* because of its smaller size in the period) has the highest ΔH_e among the given followed by *B*. *A* is an inert gas, so ΔH_e is zero or negative. Thus, the correct order of ΔH_e is $A < C < B < D$.

24. The correct order of electron gain enthalpy is

$$O < S < F < Cl$$

Element	O	S	F	Cl
Electron gain enthalpy (in eV)	1.48	2.07	3.45	3.61

25. O^{2-} and N^{3-} both are isoelectronic but differ in the charge possessed by them. As the negative charge increases, the electrons are held less and less tightly by the nucleus, therefore, radius increases from O^{2-} to N^{3-}.

26. The ionisation energy increases with increase in atomic number in a period. The trend is irregular among *d*-block elements.

Element	Sc	Ti	V	Cr	Mn	Fe	Co	Ni	Cu	Zn
IE° (kJ/mol)	631	656	650	652	717	762	758	736	745	905

Hence, correct order is Zn > Fe > Cu > Cr.

27. All the given elements are of same period and along a period atomic radii decreases because effective nuclear charge increases. Thus, the order of atomic radii is

$$O < N < C < B < Be$$

or Be = 111, O = 66, C = 77, B = 88, N = 74.

28. (ii) is the most reactive non-metal because of its higher IE and $\Delta_{eg}H$.

(i) is the most reactive metal because of its lowest Ist IE. [There is a larger difference in IE_1 and IE_2 in case of (i)]

(iv) is a least reactive element because of its high IEs and positive $\Delta_{eg}H$.

(iii) is a bivalent metal because of less difference in ΔH_1 and ΔH_2.

29. If Aufbau rule is not followed then 19th electron in K enters in $3d$ sub-shell, not in $4s$.

30. Size $\propto \dfrac{1}{Z_{\text{eff}} \text{ or nuclear charge}}$

Thus, the correct order of size is

$$\text{Br}^- > \text{S}^{2-} > \text{Cl}^- > \text{Na}^+ > \text{Mg}^{2+} > \text{Be}^{2+}$$

31. $\text{Ce}_{58} = [\text{Xe}]\, 4f^2\, 5d^0\, 6s^2$

$\text{Sn}_{50} = [\text{Kr}]\, 4d^{10}\, 5s^2\, 5p^2,$

$\text{Yb}_{70} = [\text{Xe}]\, 4f^{14}\, 6s^2$

$\text{Lu}_{71} = [\text{Xe}]\, 4f^{14}\, 5d^1\, 6s^2$

Among lanthanoids size reduces from La to Lu thus, the order of size is Ce > Yb > Lu. Size of Sn is greater than Ce.

32. As the negative charge increases, effective nuclear charge decreases, thus size increases. Thus, the order of ionic radii is

$$\text{F}^- < \text{O}^{2-} < \text{N}^{3-}, 1.36 < 1.40 < 1.71$$

33. In lanthanide series, size decreases from La to Lu due to lanthanide contraction. Thus, La is largest among lanthanides.

34. $1s^2, 2s^2, 2p^6, 3s^2$ configuration after losing two electrons acquire noble gas configuration, thus a large amount of energy is required to remove a third electron *i.e.,* there is a large jump between the values of second and third IEs.

35. First IP of Be > B because of stable ns^2 configuration.

36. Halogens (ns^2np^5) after getting one electron occupy ns^2np^6 configuration, thus have EA_2 zero.

37. For both group I and VII elements, atomic radii increases on moving down the group.

38. The outer electronic configuration = s^2p^1

Thus, valency $= 2 + 1 = 3$

Therefore, the formula of the oxide is X_2O_3.

Since, it is an oxide of III group element, its nature is amphoteric.

39. Li and Mg show diagonal relationship, thus have same size. Rb^+ and O^{2-} also have similar size.

40. (a) $r_{\text{metallic}} > r_{\text{covalent}}$ because covalent bond formation involves the overlapping of orbitals.

(b) Due to lanthanide contraction.

(c) If screening effect increases, the valence shell electron get loosely bound. Hence, ionisation energy decreases.

(d) Be and Mg have ns^2 configuration, *i.e.,* stable configuration, thus have higher IE.

41. Cl and S due to less electronic repulsion, gain one electron more readily in comparison to other elements of their group.

42. Cl has more negative electron gain enthalpy than fluorine. All other given statements are correct.

43. $\text{K}^+ = 19 - 1 = 18, \quad \text{P}^{3-} = 15 + 3 = 18$

$\text{Ca}^{2+} = 20 - 2 = 18, \quad \text{S}^{2-} = 16 + 2 = 18$

$\text{Sc}^{3+} = 21 - 3 = 18, \quad \text{Cl}^- = 17 + 1 = 18$

$\text{Cl}^- = 17 + 1 = 18, \quad \text{K}^+ = 19 - 1 = 18$

So the only sets $\text{K}^+, \text{Ca}^{2+}, \text{Sc}^{3+}, \text{Cl}^-$ and $\text{P}^{3-}, \text{S}^{2-}, \text{Cl}^-, \text{K}^+$ contain isoelectronic ions.

44. Symmetrical configuration (half-filled) is stable. Oxygen also gains half-filled configuration by losing an electron.

45. ${}_{25}\text{Mn} = 3d^5, 4s^2; \quad {}_{24}\text{Cr} = 3d^5, 4s^1; \quad {}_{26}\text{Fe} = 3d^6, 4s^2$

Electron affinity of an element depends upon electronic configuration.

46. The phenomenon in which the penultimate shell, *i.e.,* $(n-1)$ electrons act as shield in between nucleus and valence shell electrons thereby reducing the effective nuclear charge is known as shielding effect.

47. Both the statements are correct but statement II is not a correct explanation for I as IE increases along a period because effective nuclear charge increases and atomic size decreases.

48. Electron gain enthalpy becomes less as we go down a group size of the atom increases. This is because in group screening effect increase on going downward and the added electron would be a farther from the nucleus.

49. The long form of the Periodic Table contain element with atomic numbers 1 to 118.

50. The element which is just above the element with atomic number 43 in the same group is Mn(at. no. = 25).

Electronic configuration $= 1s^2, 2s^2, 2p^6, 3s^2\, 3p^6, 3d^5, 4s^2$

51. All the halogens have seven electrons ($ns^2\, np^5$) in their outermost shell.

The elements with atomic numbers 35, 53 and 85 are all halogen because the element with atomic number 35, 53 and 85 have seven electrons ($ns^2\, np^5$) in their outermost shell.

52. $\text{Zn} = (1s^2)\, (2s^2, 2p^6)\, (3s^2, 3p^6)\, (3d^{10})\, (4s^2)$

$S = 18 \times 1 + 10 \times 0.85 + 1 \times 0.35 = 26.85$

53. $\text{Al}_{13} = 1s^2, 2s^2, 2p^6, 3s^2, 3p^1$

$\text{Ga}_{31} = 1s^2, 2s^2, 2p^6, 3s^2, 3p^6, 3d^{10}, 4s^2, 4p^1$

Electronic configuration reveals that extra 3*d* electron are present in case of Ga which have lower shielding tendency and hence, Z_{eff} is more. Because of this atomic size decreases and becomes almost equal to Al.

54. Higher is the positive charge, smaller is the size of the atom.

55. Ca^{2+} has the electronic configuration 2, 8, 8 but $\text{Mg}^{2+}, \text{O}^{2-}$ and F^- are all isoelectronic with the configuration 2, 8.

56. Down the group size increases with increase in nuclear charge. Then, Rb^+ is largest among the given.

57. The least reactive element is element (V) because it has highest $\Delta_i H_1$ (first ionisation enthalpy) and positive electron gain enthalpy ($\Delta_{eg} H$). The element (V) is an inert gas because inert gases have positive electron gain enthalpy. The given values for element (V) match with He.

58. The metal which can form a stable binary halide of the formula MX_2 is element (VI). Element VI is alkaline earth metal because it has low $\Delta_i H_1$ but higher than that of alkali metals. Moreover, the difference between $\Delta_i H_1$ and $\Delta_i H_2$ is very less. The given values for element VI match with Mg.

59. Element I has low $\Delta_i H_1$ but a very high $\Delta_i H_2$. It has less negative electron gain enthalpy. So, element (I) is alkali metal. The given values for element I match with Li. Lithium forms predominantly stable covalent halide of the formula MX.

60. For isoelectronic species, $r_n \propto \frac{1}{Z}$

Species	Z	Electrons
Cl^-	17	18
Ca^{2+}	20	18
K^+	19	18
S^{2-}	16	18

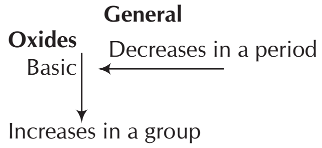
Thus, ionic size is in order

$$Ca^{2+} < K^+ < Cl^- < S^{2-}$$

61. Oxides when dissolved in water form hydroxides.

$$Na_2O + H_2O \longrightarrow 2NaOH$$
$$MgO + H_2O \longrightarrow Mg(OH)_2$$
$$Al_2O_3 + 3H_2O \longrightarrow 2Al(OH)_3$$

Smaller the size of cation, larger the charge, greater the polarising power of cation, hence greater the covalent character, hence smaller the basic nature.



Charge $Al^{3+} > Mg^{2+} > Na^+ = K^+$

Size $Al^{3+} < Mg^{2+} < Na^+ < K^+$

Polarising power $Al^{3+} > Mg^{2+} > Na^+ > K^+$

Basic nature of oxides

$$Al_2O_3 < MgO < Na_2O < K_2O$$

62. As we go down the group in Periodic Table, atomic size increases, force of attraction for the added electron decreases, hence electron gain enthalpy decreases.

$$X(g) + e^- \longrightarrow X^-(g)$$

Actual order is $Cl > F > Br > I$

The fact that fluorine has a less electron gain enthalpy than chlorine seems to be due to the relatively greater effectiveness of $2p$-electron in the small F-atom to repel the additional electron entering the atom than do $3p$-electrons in the larger Cl-atom.

63. $O^{2-}, F^-, Na^+, Mg^{2+}$ and Al^{3+} are isoelectronic species and higher the nuclear charge, smaller the size of isoelectronic species.

64. The ionic radius in general increases on moving top to bottom and further decreases on moving from left to right. So, the correct order is

$$\underset{0.98\,Å}{Na^+} > \underset{0.68\,Å}{Li^+} > \underset{0.65\,Å}{Mg^{2+}} > Be^{2+}$$

65. Higher the charge/size ratio, more is the polarising power.

$\therefore$ $K^+ < Ca^{2+} < Mg^{2+} < Be^{2+}$

66. Isoelectronic means having same number of electrons, $K^+, Cl^-, Ca^{2+}, Sc^{3+}$ (all are having 18 electrons).

67. Li^+ is having largest hydrated ionic size while Rb^+ is having smallest.

Smaller the size, greater the mobility.

68. Examine the positions in Periodic Table

B C N O F
P S

Phosphorus is having stable half-filled configuration.

Hence, order is B < S < P < F.

69. In alkali metal reactivity increases down the group as electropositivity increases, but for halogens F_2 is more reactive as on moving down molecular stability increases.

70. (a) Metallic radii increases in a group from top to bottom.

Thus, Li < Na < K < Rb is true.

(b) Electron gain enthalpy of Cl > F and decreases along a group.

Thus, I < Br < F < Cl is true.

(c) Ionisation enthalpy increases along a period from left to right but due to the presence of half-filled orbitals in N, ionisation enthalpy of N > O.

Thus, B < C < N < O is incorrect.

71. All the ions belong to same period, thus for them cations will be smaller than anions. Now, O^{2-} and F^- are isoelectronic and $r_n \propto \frac{1}{Z}$. Thus, ionic radius of $O^{2-}\ (Z = 8) > F^-\ (Z = 9)$

72. $O^-(g) + e^- \longrightarrow O^{2-}(g);\ \Delta H^\circ = 844\ \text{kJ mol}^{-1}$.

This process is unfavourable in the gas phase because the resulting increase in electron-electron repulsion overweighs the stability gained by achieving the noble gas configuration.

73. While moving along a group from top to bottom, acidic nature of oxides decreases and along a period from left to right, acidic nature increases.

$$\begin{array}{ccccc} & Al & Si & P & S \\ Z & 13 & 14 & 15 & 16 \\ & Al_2O_3 & SiO_2 & P_2O_3 & SO_2 \\ \multicolumn{5}{c}{\xrightarrow{\hspace{6cm}}} \\ & \text{amphoteric} & \text{acidic} & \text{max.} & \text{acidic} \end{array}$$

Thus, $Al_2O_3 < SiO_2 < P_2O_3 < SO_2$

74. According to periodic law, all physical and chemical properties of elements are periodic function of their atomic number.

75. Due to lanthanide contraction there occurs net decrease in size. Only 0.85Å is smaller one.

76. $Fe^+\ (26) = [Ar]\,3d^6, 4s^1$

$Mn^+\ (25) = [Ar]\,3d^5\ 4s^1$

$V^+ (23) = [Ar]\,3d^2\ 4s^2$

$Cr^+\ (24) = [Ar]\,3d^5\ 4s^0$

(By first IP)

The electronic configuration of Cr^+ is most stable, hence formation of Cr^{2+} by second IP requires maximum enthalpy.

77. r_n (radius) $\propto \frac{1}{Z}$

9 Hydrogen

JEE Main MILESTONE

- Occurrence of Hydrogen
- Position of Hydrogen in the Periodic Table
- Isotopes, Allotropes and Molecular forms of Hydrogen
- Dihydrogen or Hydrogen Gas
- Different Atomic forms of Hydrogen
- Water
- Heavy Water or Deuterium Oxide (D_2O)
- Hydrogen Peroxide (H_2O_2)
- Hydrides

9.1 Occurrence of Hydrogen

Hydrogen is the most abundant element in the universes (70% of universe's total mass). However, it does not occur in the earth's atmosphere in its free form because of the absence of enough gravitational pull to hold the lighter hydrogen molecules but forms 90% of Sun's atmosphere. The giant planets Jupiter and Saturn consist mostly of hydrogen.

9.2 Position of Hydrogen in the Periodic Table

Hydrogen consists of 1 proton in its nucleus with 1 planetary electron present in the s-orbital of K-shell or first orbital. *Neutron is absent in its nucleus.* Thus, its electronic configuration is $1s^1$. This configuration is responsible for dual nature of hydrogen, *i.e.,* behaviour like an electropositive element (or alkali metals) and as an electronegative element (or halogens).

Due to its resemblance with alkali metals as well as halogens, its position is uncertain in the Periodic Table.

Hydrogen, the lightest element, is the first member of the Periodic Table. It was first isolated by an english chemist and physicist ***Henry Cavendish*** *but the name hydrogen was given by* ***Lavoisier*** *due to its water producing nature.*

(a) Resemblance with Alkali Metals

Hydrogen shows following resemblance with alkali metals

1. All (including hydrogen) have similar outermost electronic configuration, *i.e.,* ns^1.

H—$1s^1$

Li—$1s^2, 2s^1$

Na—$1s^2, 2s^2 2p^6, 3s^1$

K—$1s^2, 2s^2 2p^6, 3s^2, 3p^6, 4s^1$

Rb—$1s^2, 2s^2 2p^6, 3s^2 3p^6 3d^{10}, 4s^2 4p^6, 5s^1$

Cs—$1s^2, 2s^2 2p^6, 3s^2 3p^6 3d^{10}, 4s^2 4p^6 4d^{10}, 5s^2 5p^6, 6s^1$

2. All of them are strongly electropositive, *i.e.,* have tendency to lose solitary electron of their outermost shell and to change into unipositive ions.
3. Normal valency of all is 1.
4. All form stable oxides (like H_2O, Na_2O, K_2O etc.) and peroxides (like H_2O_2, Na_2O_2 etc).
5. All are good reducing agents due to their high electropositive character.

(b) Resemblance with Halogens

Hydrogen shows following similarities with halogens.

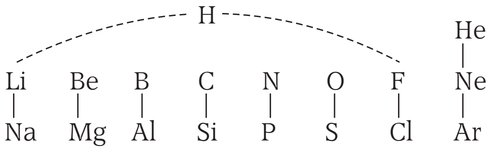
1. Hydrogen, like halogens, have the tendency to gain an electron, thus change to H^- ion (hydride ion) and acquire the stable configuration ($1s^2$).
2. Ionisation energy of hydrogen is 313 kcal. Halogens also show the ionisation energy of same order, *i.e.,* fluorine = 402 kcal; chlorine = 300 kcal; bromine = 273 kcal; iodine = 241 kcal.
3. In its molecular state, hydrogen (H_2) is a gas. Similarly among halogens F_2 and Cl_2 are gases; Br_2 is volatile liquid and I_2 is a volatile solid.
4. All of them have **diatomic configuration** in their molecular state.
5. Hydrogen in organic compounds can be replaced by halogens.

(c) Dissimilarities with Halogens

Hydrogen and halogens also have some points of differences

1. Hydrogen has much smaller tendency to form H^- ions as compared to halogens.
2. Electron affinity of hydrogen (17.3 kcal/mol) is much smaller than that of halogens (more than 70 kcal/mol).

It is, therefore, suggested that hydrogen be alloted a separate position and not grouped with either alkali metals or halogens. Thomson assigned a separate independent position to hydrogen on the top of the Periodic Table as shown below.



This does not disturb the symmetry of the table and there is no violation of periodic law.

In some respects, hydrogen also resembles carbon of the group IV, since both have a half-filled shell of electrons.

H 1 (half of first shell maximum capacity of 2 electrons)

C 2, 4 (half of second shell maximum capacity of 8 electrons).

There are a number of similarities between hydrogen and organometallic compounds since the group CH_3— and H— both have one remaining valency. Thus, the position of hydrogen is not fixed and hydrogen is best treated as a group on its own. Hydrogen is sometimes referred as a **'roque element'.**

However, on the basis of its electronic configuration ($1s^1$) hydrogen is placed above lithium in the first group of Bohr's Periodic Table *but still, it is not considered as the member of that group.*

9.3 Isotopes, Allotropes and Molecular forms of Hydrogen

Hydrogen exists in several forms that are described below one by one.

Isotopes

There are three known isotopes of hydrogen, each possessing an atomic number 1 and atomic mases 1, 2 and 3 respectively. These are named as protium, (^1H) deuterium (^2H or D) and tritium (^3H or T).

The most common is the ordinary hydrogen, usually called **protium** with atomic mass 1.008123. It consists of one proton in the nucleus and an electron revolving around it. This isotope constitutes 99.984 per cent of the total hydrogen available in nature.

The second isotope of hydrogen is called **heavy hydrogen** or **deuterium**. It consists of one proton and one neutron in the nucleus and an electron revolving around it. Its atomic mass is 2.0142. It constitutes only 0.016 per cent of the total hydrogen occurring in nature. It is represented by the symbol D or $_1^2H$.

The third isotope of hydrogen is called **tritium.** It consists of one proton and two neutrons in the nucleus and an electron revolving around it. Its atomic mass is 3.0170. It constitutes only 1×10^{-15} per cent of the total natural hydrogen. This isotope is unstable and exhibits radioactivity.

Allotropes

Ortho hydrogen (o-H_2) and *para* hydrogen (p-H_2); similarly *ortho* and *para* deuterium (o and p-D_2) and *ortho* and *para* tritium (o and p-T_2).

The *ortho* isomer shows *parallel spins* while *para* isomer shows *opposite spins or antiparallel spins of protons.*

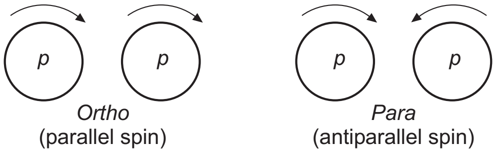


Fig. 9.1 *Ortho* and *para* hydrogen

The two forms differ in their physical properties like specific heat, thermal conductivity, boiling point, etc., but show similar chemical properties. Both the forms are interconvertible.

Para form has lower energy and at absolute zero, the gas contains 100% *para* form. Due to their interconvertible nature as the temperature rises, *para* form starts converting into *ortho* form. At room temperature, these are in dynamic equilibrium with equilibrium mixture containing 75% *ortho* form and 25% *para* form. On decreasing the temperature, quantity of *para* form increases in the solution. Thus, it is clear that *para hydrogen is favoured at lower temperature.*

Its three times more presence at room temperature suggests that *ortho* hydrogen is more stable than *para* hydrogen at room temperature. *Ortho* and *para* interconversion is a slower process in the absence of catalyst. The suitable catalyst include activated charcoal, atomic hydrogen, metals, *e.g.,* like Fe, Ni, Pt, W, etc., along with paramagnetic substances like O_2, NO, NO_2, Co^{2+}, Cr_2O_3 etc.

Molecular Forms

Due to its high reactivity protium or hydrogen combines with its own atoms or with the atoms of isotopes and exists in molecular forms as $^1H_2$ (dihydrogen), $^2H_2$ or D_2 (dideuterium), $^3H_2$ or T_2 (ditritium), along with HD, HT, DT etc.

Sample **Problem 1** *What is the mass ratio of isotopes of hydrogen?* **[NCERT]**

(*a*) 1:1:1
(*b*) 1 : 2 :1
(*c*) 1 : 2 : 3
(*d*) 1 : 3 : 2

Interpret (*c*) Protium (H^1), deuterium (H^2) and tritium (H^3) are three isotopes of hydrogen. Thus, their mass ratio is 1 : 2 : 3.

9.4 Dihydrogen or Hydrogen Gas

Being highly reactive, hydrogen always exists in its diatomic form, called the dihydrogen or simply the hydrogen.

Hot Spot 1

GENERAL METHODS of Preparation of Dihydrogen

Analysis of previous years' examination papers reveals that the preparation of hydrogen is an important topic of this chapter and generally question from this topic can be seen in JEE Main AIEEE examination. The level of the question is moderate.

(a) Laboratory Method

In laboratory, dihydrogen is produced by the reaction of Zn with dilute H_2SO_4 as,

$$Zn + H_2SO_4 \longrightarrow ZnSO_4 + H_2\uparrow$$

Actual changes takes place here are,

$$Zn \longrightarrow Zn^{2+} + 2e^-$$
$$H_2SO_4 \longrightarrow H^+ + HSO_4^-$$
$$2H^+ + 2e^- \longrightarrow 2H \longrightarrow H_2\uparrow$$

(b) By the Electrolysis of Water

In the electrolysis method, water is electrolysed as

$$\underset{\text{(containing small amount of acid or alkali)}}{\text{Water}} \xrightleftharpoons[\text{using suitable electrodes}]{\text{Electrolysed}} \underset{\text{cathode}}{H_2\uparrow} + \underset{\text{anode}}{O_2\uparrow}$$

At cathode Hydrogen gas is liberated due to discharge of H^+ ions as,

$$2H^+ + 2e^- \longrightarrow 2H \longrightarrow H_2\uparrow$$

At anode Hydroxyl ions are discharged to give O_2 gas as,

$$2(OH)^- \longrightarrow H_2O + 2e^- + O$$
$$O + O \longrightarrow O_2\uparrow$$

Case I Suppose the hydrolysis is carried out in acidic medium (*e.g.*, in the presence of H_2SO_4) then at anode, SO_4^{2-} ions are not discharged (although present in much larger quantity) due to very high discharge potential of these ions as compared to that of OH^- ions.

Case II Similarly, if hydrolysis is carried out in the alkaline medium (*e.g.*, in the presence of KOH) then at cathode, K^+ ions are not discharged (although present in much large quantity) due to very high discharge potential of K^+ ions as compared to that of H^+ ion.

(c) By the Electrolysis of Barium Hydroxide Solution

Pure dihydrogen is prepared by the electrolysis of a warm concentrated solution of $Ba(OH)_2$ in hard glass U-tube with Ni electrodes. Here, H_2 is liberated at cathode and O_2 is liberated at anode. The H_2 liberated is passed over heated Pt gauze to remove O_2 as an impurity which is converted into H_2O. This H_2O is removed by passing the gas over solid KOH and P_2O_5. The H_2 gas formed is finally readsorbed over Pd foil. From here, it can be recovered whenever required by heating it to dull red heat.

For the above process $Ba(OH)_2$ *is preferred over* NaOH, *because, if any* CO_2 *is absorbed in the process,* $BaCO_3$ *is produced which being insoluble, settles down at the bottom and does not interfere with the process, while* Na_2CO_3 *(formed if we use* NaOH*) is soluble in water and may interfere in the process.*

(d) From Active and Moderately Active Metals

Active metals when reacts with water or any other protic solution, evolve hydrogen. Alkali metals are most active for this reaction. The reaction is violent in almost each case when we use any of the alkali metal for the purpose (least reactive is the Li and reactivity increases as we move down the group). Large amount of heat is given in the reaction and very often H_2 evolved catches fire.

However, not all the metals give this reaction. Among *s*-block elements, **Be does not react with water** (hot or cold) to evolve H_2, Mg reacts only with hot water (steam) while rest of the other members react with cold water in non-violent manner. Zn and Fe are even less reactive, they decompose water only when superheated steam is led over them at high temperature.

$$3Fe + 4H_2O \longrightarrow Fe_3O_4 + 4H_2\uparrow$$

Most other elements are far less reactive to displace H_2 from water. The process involves release of electrons by these metals which is taken up by H^+ present in the solution. The H^+ is then converted in atomic hydrogen. This atomic hydrogen combines with other similar atom to form molecular hydrogen.

Besides above written metals, elements like Sn and Al also give similar type of reactions but not with water. They give such type of reactions with dilute acid solutions.

Certain metals like Zn, Sn, Al react with alkali to evolve H_2 as,

$$2Al + 2NaOH + 2H_2O \longrightarrow 2NaAlO_2 + 3H_2\uparrow$$
$$Zn + 2NaOH \longrightarrow Na_2ZnO_2 + H_2\uparrow$$
$$Sn + 2NaOH + H_2O \longrightarrow Na_2SnO_3 + 2H_2\uparrow$$

(e) From Ionic Hydrides

The ionic hydrides of **alkali and alkaline earth metals** also evolve H_2 on reaction with water as,

$$CaH_2 + 2H_2O \longrightarrow Ca(OH)_2 + 2H_2\uparrow$$

Industrial Methods of Preparation of Dihydrogen

Besides the above written processes, the industrial preparation of dihydrogen involve following processes

(a) Electrolysis

In the **electrolysis process**, dihydrogen is produced by the electrolysis of water containing 15-20% H_2SO_4. Here also, H_2 is liberated at cathode while O_2 is liberated at anode.

(b) Bosch Process

In the **Bosch process,** dihydrogen is prepared through the reaction of water vapours (steam) by carbon as

$$\underset{\substack{\text{coke}\\ \text{at 400–660°C}}}{C} + \underset{\substack{\text{superheated}\\ \text{steam}}}{H_2O} \longrightarrow \underset{\boxed{\substack{\text{water gas}\\ \text{or } syn \text{ gas}}}}{CO + H_2}$$

$$\Big\downarrow \text{ Reacts with steam again in the presence of catalyst, usually a mixture of Fe, Cr and Co.}$$

$$CO_2 + H_2$$

The CO_2 is removed either by washing under pressure of 25–30 atmosphere or by reacting with KOH (alkali).

(c) Lane Process

In the *Lane process*, dihydrogen is produced as

$$\underset{\substack{\text{heated to}\\ \text{900°C}}}{3Fe} + \underset{\substack{\text{superheated}\\ \text{steam}}}{4H_2O} \longrightarrow Fe_3O_4 + 4H_2\uparrow$$

$$\Big\downarrow \text{ CO is passed over it}$$

$$\text{reduces to Fe}$$

(d) From Nelson or Castner Kellner Process

H_2 is also produced in **Nelson** or **Castner Kellner cell** by the electrolysis of brine solution (*aq* NaCl) in them.

(e) From Petrochemicals

Presently near about 77% of the industrial hydrogen is produced from petrochemicals *e.g.,* 18% from coal, 4% from electrolysis of brine solution and 1% from other sources.

Caution Point *H_2 and CO_2 can be easily separated from each other by bubbling the gaseous mixture through water in which CO_2 is fairly soluble and H_2 is virtually insoluble.*

$$H_2O + CO_2 \longrightarrow H_2CO_3$$

Sample Problem 2 *In the method of bulk preparation of hydrogen by electrolytic method, the role of electrolyte is* **[NCERT]**

(*a*) *decrease the boiling point of water*
(*b*) *increase the boiling point of water*
(*c*) *increase the ionisation of water*
(*d*) *increase the charge carrying particles in water*

Interpret (*d*) Electrolysis of acidified **water** using platinum electrodes gives hydrogen.

$$2H_2O(l) \xrightarrow[\text{Traces of acid/base}]{\text{Electrolysis}} 2H_2(g) + O_2(g)$$

The role of an electrolyte is to make water conducting by increasing the number of charge carrying particles, *i.e.,* ions.

Sample Problem 3 *Which of the following reactions increases the production of dihydrogen from synthesis gas?* **[NCERT Exemplar]**

(*a*) $CH_4(g) + H_2O(g) \xrightarrow[\text{Ni}]{1270\text{ K}} CO(g) + 3H_2(g)$

(*b*) $C(s) + H_2O(g) \xrightarrow{1270\text{ K}} CO(g) + H_2(g)$

(*c*) $CO(g) + H_2O(g) \xrightarrow[\text{Catalyst}]{673\text{ K}} CO_2(g) + H_2(g)$

(*d*) $C_2H_6 + 2H_2O \xrightarrow[\text{Ni}]{1270\text{ K}} 2CO + 5H_2$

Interpret (*c*) The process of producing *syn* gas or synthesis gas from coal is called 'coal gasification'.

$$\underset{\text{coal}}{C(s)} + \underset{\text{steam}}{H_2O(g)} \xrightarrow[\text{Ni}]{1270\text{ K}} \underbrace{CO(g) + H_2(g)}_{syn\text{ gas}}$$

The production of hydrogen can be increased by reacting carbon monoxide of the *syn* gas with steam in the presence of iron chromate as catalyst at 673 K.

$$CO(g) + H_2O(g) \xrightarrow{FeCrO_4,\ 673\text{ K}} CO_2(g) + H_2(g)$$

CO_2 is removed by scrubbing with a solution of sodium arsenite.

Physical and Chemical Properties of Dihydrogen

Various characteristics exhibited by dihydrogen or hydrogen gas are as follows

(a) Physical Properties

Hydrogen is a colourless, odourless, tasteless diatomic ($C_p/C_V = 1.40$) gas. It is the **lightest element known** (density = 0.0695 g/cc). Being non-polar H_2 molecules, have very weak intermolecular forces. Due to which its melting point and boiling point are very low. Its critical temperature is –236.9°. It can be liquefied at −252.8° and solidifies at −259.8°. Metals like Ni, Pt, Pd, Fe, Au, etc., can adsorb or occlude large volumes of H_2 gas at different temperatures (Pd can occlude 1000 times of its own volume).

The bonding forces within the H_2 molecule are exceptionally strong and hence, it is thermally stable.

(b) Reaction with Non-metals

On combination with non-metals (like O_2, N_2, F_2, Cl_2, Br_2, etc.), it forms covalent compounds (like H_2O, NH_3, HX etc.) at higher temperatures. However, it remains unreactive with above written elements at ordinary (room) temperatures because at ordinary temperatures, H_2 exists in molecular state in which atoms have stable He structure. To be converted into atomic hydrogen either high temperature (700–800°C) or a catalyst (like Ni, Pt, Pd, etc., which bring down the temperature to about 250°) is required after which H_2 molecules dissociate into atoms. These atoms then combine with non-metals to form requisite product.

(c) Reaction with Metals

On combination with metals (like Li, Na, K, Cs, Ca etc.), electrovalent hydrides are formed. These are good reducing agents and are infact good sources of H_2. The hydrides so formed can conduct electricity in fused or molten state and possess high melting points.

(d) Reducing Property

H_2 has the property to reduce the oxides of less electropositive elements, *e.g.,*

$$CuO + H_2 \longrightarrow Cu + H_2O$$

Similarly, $$Fe_3O_4 + 4H_2 \longrightarrow 3Fe + 4H_2O$$

Certain chlorides also get reduced as

$$2AgCl + H_2 \longrightarrow 2Ag + 2HCl$$

However, hydrogen does not have the ability to reduce the oxides of alkali metals and alkaline earth metals.

Uses of Dihydrogen

The important uses of dihydrogen are as follows :

1. Manufacture of NH_3 by Haber's process.
2. Manufacture of hydrocarbons and their derivatives.
3. Manufacture of HCl, metal hydrides etc.
4. Reduction of heavy metal oxides to metals in metallurgical processes.
5. In oxy-hydrogen and oxy-atomic hydrogen torches for cutting and welding.
6. Besides, dihydrogen is also used as rocket fuel, in bubble chambers as liquid hydrogen for the study of high energy particles and in fuel cells. Remember that *dihydrogen is considered as very good fuel as it does not cause any pollution and produces greater energy per unit mass of fuel as compared to gasoline or other fuels.*

9.5 Different Atomic forms of Hydrogen

The hydrogen can also be

Nascent Hydrogen (H)

It is the hydrogen produced in contact with the substance to be reduced. *Its sources are*

1. **Metal + protic solution,** *e.g.,* Zn/acid, Sn/acid, Na + alcohol, Zn/Cu couple + water or alcohol, Zn—Hg/HCl etc.
2. **Complex metal hydrides,** *e.g.,* $LiAlH_4$, $NaAlH_4$, $NaBH_4$ dibal-H (di *iso*butyl aluminium hydride) etc.
3. **Acidulated water** (by its electrolysis)

However, pratical existence of nascent hydrogen is not proven.

Active H is much more reactive because hydrogen at the moment of its formation is more reactive than the ordinary H_2 gas. For example, when ordinary hydrogen is passed through acidified potassium permanganate solution or ferric chloride solution, neither of them is reduced. However, when zinc pieces are added, both get reduced.

$$\begin{tikzcd} \text{Ordinary Hydrogen} \arrow[r] & \underset{\text{Purple coloured solution}}{KMnO_4/H_2SO_4} \arrow[r] \arrow[d, "\begin{array}{l}+\text{ Zn pieces}\\(Zn + \text{dil. } H_2SO_4 \rightarrow \text{Hydrogen liberated})\end{array}"] & \text{No change in colour as reduction does not occur} \\ & \begin{array}{c}\text{Decolourisation occurs,}\\ \textit{i.e.,}\text{ liberated hydrogen}\\ \text{reduces acidified } KMnO_4\end{array} & \end{tikzcd}$$

It is believed that a part of energy liberated in the reaction producing hydrogen become associated with hydrogen molecules and thus, make them hyper active.

Atomic Hydrogen

When hydrogen is passed through an electric arc established between two tungsten filaments, hydrogen is dissociated into atoms. This form of hydrogen is known as atomic hydrogen.

$$H_2 \underset{}{\overset{\text{Electric arc}}{\rightleftharpoons}} 2H - 104.5\,\text{kcal}$$

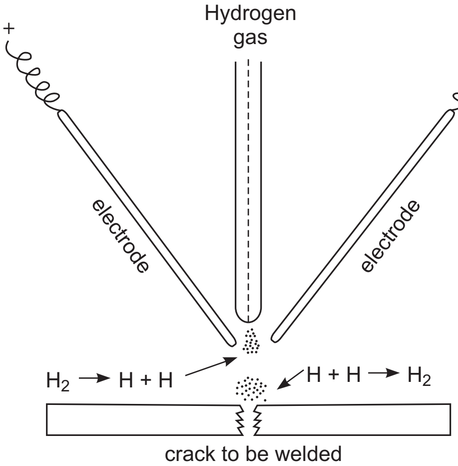

Fig. 9.2 Atomic hydrogen welding torch

The life period of atomic hydrogen is 0.3 s. It readily returns to ordinary form. This conversion is highly exothermic and used for welding purposes.

The important reactions of active hydrogen are

1. Reaction with non-metals like S, P, As, Sb and Bi etc., at ordinary (room) temperature to form hydrides, with O_2 (at very low temperature) to form H_2O_2. However, it does not combine with N_2.
2. Reaction with metals like Li, Na, Ca etc., at room temperature to form hydrides. It combines with metals like Ag and Hg at even very low temperature (– 180°C) to form their hydrides as

$$Ag + H \xrightarrow{-180^\circ C} AgH$$

$$Hg + H \xrightarrow{-180^\circ C} HgH$$

3. It is more powerful reducing agent as
   (i) It reduces oxides, chlorides and sulphides of certain metals like Cu, Hg, Ag, Bi etc., at ordinary (room) temperatures as

$$CuS + 2H \longrightarrow H_2S + Cu$$
$$CuO + 2H \longrightarrow Cu + H_2O$$
$$AgCl + H \longrightarrow Ag + HCl$$

   (ii) It reduces CO_2 and CO as

$$CO_2 + 2H \longrightarrow HCOOH$$

and $$CO + 2H \longrightarrow HCHO$$

   (iii) It reduces P_2O_5 as

$$P_2O_5 + 16H \longrightarrow 2PH_3 + 5H_2O$$

   (iv) It reduces alkali metal salts, *e.g.,* nitrates, amides and cyanides to free metals as

$$NaNO_3 + H \longrightarrow Na + HNO_3$$
$$NaNH_2 + H \longrightarrow Na + NH_3$$
$$NaCN + H \longrightarrow Na + HCN$$

   However, it does not affect the sulphates and halides of alkali metals.

4. Atomic hydrogen makes hydrogenation process more easier and at lower temperature than molecular hydrogen in organic compounds.

Active Hydrogen (H_3)

When steam of H_2 is subjected to silent electric discharge (at ordinary temperature), active hydrogen is produced. It is denoted by H_3 and have a half-life of 1/3rd of a second. It shows great chemical activity, *e.g.,* combines directly with Pb and S at ordinary temperature to form hydrides. Similarly, it reduces CuO to Cu at ordinary temperature.

Check Point 1

1. Why does hydrogen occur in diatomic form rather than in a monoatomic form under normal conditions?
2. Pure dihydrogen is not prepared by the electrolysis of NaOH. Explain, why?
3. Why is dihydrogen not preferred in balloons these days?
4. Dihydrogen combines with non-metals only at high temperature. Explain, why?
5. Hydrogen is evolved when an active or moderately active metal reacts with acid but not in case of less active metal. Explain.
6. How does the atomic hydrogen or oxy-hydrogen torch function for cutting and welding purposes? Explain.

[NCERT]

9.6 Water

Water is very essential for the existence of life. It constitutes about three fourth of earth's surface and two third of human body. *Its high importance is because of its ability to dissolve large number of substances.*

Although it is most often perceived as a liquid at normal atmospheric pressure, water exists as a solid below 0°C and as a gas above 100°C. The terms ice and steam are used to described the solid and gaseous states of water. Water occurs in the following natural forms

(i) **Rain water** It is the purest of natural waters. Usually, the first few showers of rain are not very pure as it absorbs atmospheric gases, but afterwards the rain water can be quite pure.

(ii) **Sea water** It is an impure water. It contains about 3.5 per cent of dissolved substances out of which 2.5 per cent is sodium chloride. This water is not fit for drinking purposes.

(iii) **Surface water** It includes streams, rivers and lakes is most important source of water for all purposes. It contains many soluble impurities and near cities gets contaminated with refuse and sewage.

The estimated world's water supply by oceans and in land seas is 97.34%, by polar ice and glaciers is 2.04 and by rivers is only 0.0001% of the total.

Purification of Drinking Water

The purification of water, needed for drinking purposes in towns and cities, requires two major operations (i) removal of the suspended impurities and (ii) destroying the bacteria. The removal of suspended materials is achieved by filteration through large filter beds made of layers of sand and gravel. The addition of aluminium sulphate helps in the coagulation of colloidal particles. Various methods are used for destroying bacteria such as aeration, chlorination, ozonisation, etc.

Structure of Water

H_2O is a bent molecule in gas phase with bond angle of 104.5° C and OH bond length of 95.7 pm. It is highly polar due to the presence of highly electronegative atom like oxygen in it.

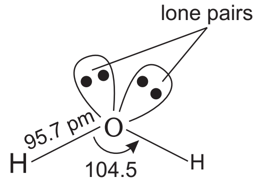

Fig. 9.3 Structure of H_2O in the gas phase

H_2O *in its solid form (ice) is less dense than its liquid form due to which an ice cube can float on water.* It is because in ice, each H_2O molecule is surrounded by three H_2O molecules in hexagonal honey comb manner as shown in the Fig. 9.4.

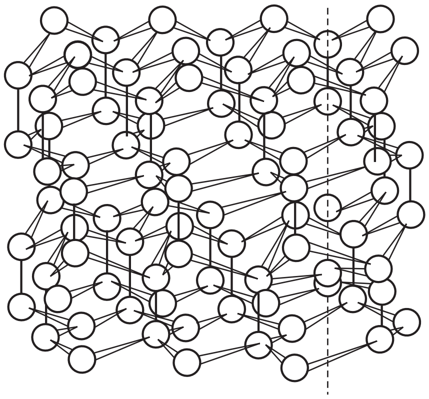

Fig. 9.4 Structure of H_2O in solid form (ice); (only O atoms are shown)

This arrangement gives rise to an open-cage like structure. There are evidently a number of 'holes' or open spaces. In such a structure lesser number of molecules are packed per mL. When ice melts a large number of hydrogen bonds are broken. The molecules, therefore, move into the holes or open spaces and come closer to each other than they were in solid state. This results sharp increase in the density. Thus, *ice has lower density than water and there is contraction in volume. The contraction continues from* 0°*C to* 4°*C* as the hydrogen bonds are broken progressively. Thus, *the density of water is maximum at* 4°*C*.

Physical Properties of Water

Water is a colourless, volatile liquid with many unusual properties. Some of the physical properties of water and heavy water (D_2O) are tabulated below.

Table 9.1 **Properties of Water and Heavy Water**

S. No.	Property	H_2O	D_2O
1.	Melting point	273 K	276.8 K
2.	Boiling point	373 K	374.4 K
3.	Temperature of maximum density	276.98 K	284.2 K
4.	Dielectric constant	78.39 K	78.06 K

Due to its high dielectric constant and polar nature, water is an excellent solvent for polar and ionic substances.

The peculiar properties of water in its condense phases (liquid and solid) are due to the presence of extensive hydrogen bonding between water molecules. Some of these properties include abnormally high freezing point, boiling point, heat of vaporisation, heat of fusion as compared to hydrides of other elements of same group.

Besides, *high specific heat, thermal conductivity and high heat capacity are the properties which are responsible for making water a vital content of our life.*

Chemical Properties of Water

The chemical characteristics exhibited by water are as follows

(a) Nature

Water is neutral in nature with pH 7. In pure water $[H^+] = [OH^-] = 10^{-7}$ at 25°C. Water undergoes self-ionisation (autoprotolysis) and hence, amphoteric in nature.

(b) Decomposition

Water containing either alkali or acid when electrolysed gets decomposed into H_2 and O_2.

$$2H_2O \longrightarrow 2H_2 + O_2$$

When heated at 2500°C, it breaks up into hydrogen and oxygen to a small extent (4%).

(c) Reaction with Metals

It reacts with active metals and evolves hydrogen. The reaction is highly exothermic in the case of alkali and alkaline earth metals and the hydrogen evolved catch fire.

$$2Na + 2H_2O \longrightarrow 2NaOH + H_2$$

$$Ca + 2H_2O \longrightarrow Ca(OH)_2 + H_2$$

It is decomposed by metals like Zn, Mg, Fe, etc., when steam is passed over hot metals.

$$Zn + H_2O \longrightarrow ZnO + H_2$$

$$3Fe + 4H_2O \longrightarrow Fe_3O_4 + 4H_2$$

$$Mg + 2H_2O \longrightarrow Mg(OH)_2 + H_2$$

Pb and Cu decompose water only at a white heat. Ag, Au, Hg and Pt metals do not decompose water.

(d) Reaction with Non-metals

Fluorine decomposed cold water.

$$\left.\begin{array}{l} 2F_2 + 2H_2O \longrightarrow 2H_2F_2 + O_2 \\ 3F_2 + 3H_2O \longrightarrow 3H_2F_2 + O_3 \end{array}\right\} \text{Ozonised oxygen}$$

Chlorine decomposes cold water forming HCl and HClO.

$$Cl_2 + H_2O \longrightarrow HCl + \underset{\text{hypochlorous acid}}{HClO}$$

However, in the presence of sunlight only HCl is formed with liberation of oxygen.

$$2Cl_2 + 2H_2O \xrightarrow{\text{Sunlight}} 4HCl + O_2$$

(e) Hydrolysis

Many salts specially the salts of strong bases with weak acids, weak bases with strong acids and weak bases with weak acids undergo hydrolysis with water.

$$CH_3COONa + H_2O \rightleftharpoons CH_3COOH + NaOH$$

$$CH_3COONH_4 + H_2O \rightleftharpoons CH_3COOH + NH_4OH$$

$$FeSO_4 + 2H_2O \rightleftharpoons Fe(OH)_2 + H_2SO_4$$

However, salts of strong acid and strong base are not hydrolysed with water.

Some salts on hydrolysis form oxy compounds.

$$BiCl_3 + H_2O \longrightarrow \underset{\text{bismuth oxychloride}}{BiOCl} + 2HCl$$

$$SbCl_3 + H_2O \longrightarrow \underset{\text{antimony oxychloride}}{SbOCl} + 2HCl$$

Halides of non-metals are decomposed by water.

$$PCl_5 + 4H_2O \longrightarrow H_3PO_4 + 5HCl$$

$$PCl_3 + 3H_2O \longrightarrow H_3PO_3 + 3HCl$$

$$SO_2Cl_2 + 2H_2O \longrightarrow H_2SO_4 + 2HCl$$

$$SiCl_4 + 3H_2O \longrightarrow H_2SiO_3 + 4HCl$$

(f) Reaction with Hydrides, Carbides, Nitrides and Phosphides

Water decomposes these compounds with the evolution of hydrogen, acetylene (or methane), ammonia, phosphine gas respectively.

$$CaH_2 + 2H_2O \longrightarrow Ca(OH)_2 + 2H_2$$

$$CaC_2 + 2H_2O \longrightarrow Ca(OH)_2 + C_2H_2$$

$$Al_4C_3 + 12H_2O \longrightarrow 4Al(OH)_3 + 3CH_4$$

$$Mg_3N_2 + 6H_2O \longrightarrow 3Mg(OH)_2 + 2NH_3$$

$$Ca_3P_2 + 6H_2O \longrightarrow 3Ca(OH)_2 + 2PH_3$$

(g) Water in Associated Forms

The association of water is essentially of 5 types namely **coordinated water** (or water of crystallisation as found in $CuSO_4 \cdot 5H_2O$), *hydrogen bonded water, lattice water, zeolitic water and clathrate water.*

Zeolites have SiO_4 and AlO_4 tetrahedrons, linked together in a three dimensional open structure in which 4 or 6 membered rings predominates. The open structure permits the formation of channels and cavities in which water and other smaller molecules like NH_3, CO_2, C_2H_5OH etc., can be trapped.

Clathrate (Latin clathratus = enclosed or protected by crossbars or graftings) is a substance in which one component, **the host molecule,** crystallises with an open structure that contains holes or channels in which atoms or molecules of appropriate size like H_2O, NH_3, CO_2, inert gases, etc., can be trapped easily.

Tests of Water

1. A drop of water when added to anhydrous copper sulphate, changes its colour from white to blue.
2. Water reacts with CaC_2 to evolve acetylene which burns with bright flame.

Sample Problem 4 *Which of the following reaction involves hydration?* **[NCERT]**

(a) $PbS(s) + H_2O_2(aq) \longrightarrow$

(b) $CaO(s) + H_2O(g) \longrightarrow$

(c) $AlCl_3(g) + H_2O(l) \longrightarrow$

(d) $Ca_3N_2(s) + H_2O(l) \longrightarrow$

Interpret (*d*) Addition of water is called hydration.

(a) $PbS(s) + 4H_2O_2(aq) \longrightarrow PbSO_4(s) + 4H_2O(l)$ (Redox reaction)

(b) $CaO(s) + H_2O(g) \longrightarrow Ca(OH)_2(aq)$ (Hydrolysis reaction)

(c) $AlCl_3(g) + 6H_2O(l) \longrightarrow [Al(OH_2)_6]^{3+}(aq) + 3Cl^-(aq)$ (Hydrogen reaction)

(d) $Ca_3N_2(s) + 6H_2O(l) \longrightarrow 3Ca(OH)_2(aq) + 2NH_3(aq)$ (Hydrolysis reaction)

Among the given reactions, water is added only with $AlCl_3$ so it is an example for hydration reaction.

Sample Problem 5 *Give reasons lakes freeze from top towards bottom.* **[NCERT]**

Interpret Density of ice is less than that of liquid water. During severe winter, the temperature of lake water keeps on decreasing. Since, cold water is heavier, therefore, it moves towards bottom of the lake and warm water from the bottom moves towards surface. This process continues. The density of water is maximum at 277 K. Therefore, any further decrease in temperature of the surface water will decrease the density. The temperature of surface water keeps on decreasing and ultimately it freezes. Thus, the ice layer at lower temperature floats over the water below it. Due to this freezing of water into ice takes place continuously from top towards bottom.

Hard and Soft Water

Water can be soft or hard depending upon the nature of substances dissolved in it. **Hard water** on one hand contains bicarbonates, chlorides and sulphates of Ca and Mg while **soft water** is free from all such impurities. In hard water, soap does not leather as sodium sterate changes to corresponding Ca or Mg salt which precipitates out as,

$$2C_{17}H_{35}COONa + Ca^{2+}/Mg^{2+} \longrightarrow (C_{17}H_{35}COO)_2Ca/Mg + 2Na^+$$

Soft water, on the other hand, readily lathers with the soap.

The hardness of water may be temporary or permanent. The **temporary hardness** is due to the presence of bicarbonates of Ca and Mg while **permanent hardness** is due to the soluble sulphates and chlorides of Ca and Mg. The former one can be removed by

(a) Boiling

Through boiling soluble bicarbonates change to insoluble carbonates and get precipitated as

$$M(HCO_3)_2 \overset{\Delta}{\rightleftharpoons} MCO_3\downarrow + H_2O + CO_2\uparrow$$

here, M = Mg or Ca

(b) Clark's Process

In this process, addition of calculated quantity of lime causes precipitation of $CaCO_3$ as

$$Ca(HCO_3)_2 + Ca(OH)_2 \longrightarrow 2CaCO_3\downarrow + 2H_2O$$

or $$Mg(HCO_3)_2 + 2Ca(OH)_2 \longrightarrow 2CaCO_3\downarrow + Mg(OH)_2 + 2H_2O$$

Permanent hardness on the other hand can be removed by following methods.

(a) By Treatment with Na_2CO_3

$$CaSO_4 + Na_2CO_3 \rightleftharpoons CaCO_3\downarrow + Na_2SO_4$$

$$MgCl_2 + Na_2CO_3 \rightleftharpoons MgCO_3\downarrow + 2NaCl$$

(b) Using Calgon

Calgon is chemically sodium polymetaphosphate (or sodium hexa metaphosphate). The Ca^{2+} and Mg^{2+} ions present in hard water react with calgon to form soluble complexes as

$$\underset{\text{(from hard water)}}{2M^{2+}} + Na_2[Na_4(PO_3)_6] \longrightarrow \underset{\text{soluble}}{Na_2[M_2(PO_3)_6]} + 4Na^+$$

(here, $M^{2+} = Mg^{2+}$ or Ca^{2+})

The complexes, so obtained, do not cause hinderance in the lather formation.

(c) Using Permutit (Ion exchange method)

When hard water is treated with permutit (also called zeolite or hydrated sodium aluminium silicate, $Na_2Al_2Si_2O_8\cdot xH_2O$), the cations present in hard water are exchanged with Na^+ ions.

$$\underset{\text{sodium zeolite}}{Na_2Z} + \underset{\text{(from hard water)}}{MCl_2} \longrightarrow MZ + 2\,NaCl$$

(here, M = Ca or Mg)

In this process, zeolite gets exhausted because of its conversion into Ca and Mg salt. When 10% NaCl solution is percolated through it, the exhausted resin gets regenerated.

(d) Ion Exchange Resins

Ion exchange resins are the most popular water softners these days. The cation exchanger are granular insoluble organic acid resin having giant molecules with $—SO_3H$ or —COOH group while the anion exchanger contains giant organic molecules with basic groups derived from amines. Ion exchange resins remove all soluble minerals from water. The hard water is first passed through a bed of cation exchanger, which removes the cations like Na^+, Mg^{2+}, Ca^{2+} and others by exchanging with H^+ ions.

$$\underset{\text{resin}}{2RH} + Ca^{2+} \longrightarrow (R)_2Ca + 2H^+$$

The water coming from cation exchanger is acidic on account of free H^+ ions. This water is then passed through another bed containing anion exchanger. This exchanger removes anions like Cl^-, SO_4^{2-}, NO_3^- by exchanging with OH^- ions.

$$\underset{\text{resin}}{R—NH_3OH} + Cl^- \longrightarrow R—NH_3Cl + OH^-$$

The OH^- ions neutralise the H^+ ions.

$$H^+ + OH^- \rightleftharpoons H_2O$$

This process gives distilled water and can be used in laboratories.

The cation exchanger is regenerated by the action of an acid and the anion exchanger is regenerated by using an alkali solution.

Disadvantages of Hard Water

Hard water cannot be used

(i) for domestic purposes as it spoils the utensils lustre, result in scale formation and require a large amount of soap.

(ii) for boiler as it results in the formation of scales and bubbles, corroids the boiler surface.

(iii) in industries like dyeing, printing, textiles, sugar etc., as plenty of water is required.

Degree of Hardness

It is the measure of quantity of Ca and/or Mg salts in a certain volume of water and is defined as the number of parts by mass of $CaCO_3$ (equivalent to various Ca and Mg salts) present in a million parts by mass of water. It is measured in ppm.

Sample **Problem 6** *One litre of a water sample contains 1 mg of* $CaCl_2$ *and 1 mg of* $MgCl_2$*. The total hardness in terms of parts of* $CaCO_3$ *per* 10^6 *parts of water by mass is*

(a) 0.9 *ppm* (b) 1.05 *ppm*
(c) 1.95 *ppm* (d) 0.15 *ppm*

Interpret (c) 111 g of $CaCl_2 \equiv 100$ g of $CaCO_3$

$$1 \text{ mg of } CaCl_2 = \frac{100}{111} \times 1 \text{ mg of } CaCO_3 = 0.9 \text{ mg } CaCO_3$$

$$95 \text{ g of } MgCl_2 \equiv 100 \text{ g of } CaCO_3$$

$$1 \text{ mg of } MgCl_2 = \frac{100}{95} \times 1 \text{ mg } CaCO_3 = 1.05 \text{ mg of } CaCO_3$$

Thus, 1 L sample contains

$$= 0.9 + 1.05$$
$$= 1.95 \text{ mg of } CaCO_3$$
$$= 1.95 \text{ ppm}$$

9.7 Heavy Water or Deuterium Oxide (D_2O)

The credit for the discovery of heavy water goes of **Urey** who first proved that ordinary water contains one part of heavy water in 6000 parts of it. **Lewis** and **Donald,** in 1933, were able to isolate Few millilitres of pure D_2O by continuous electrolysis of water containing alkali.

Preparation

Heavy water (D_2O) is obtained mainly by the multistage electrolysis of ordinary water as shown by Washburn and Urey. It is also obtained by fractional distillation of ordinary water or by fractional freezing.

Physical Properties

Heavy water is a colourless, odourless and tasteless mobile liquid. Nearly all the physical constants are higher for heavy water than the corresponding values for ordinary water.

Chemical Properties

It gives all the reactions that are given by ordinary water but with a slower rate. This is called **isotopic effect.** *e.g.*,

$$2Na + 2D_2O \longrightarrow 2NaOD + D_2$$
$$SO_2 + D_2O \longrightarrow D_2SO_3$$
$$CaC_2 + 2D_2O \longrightarrow Ca(OD)_2 + C_2D_2$$

It also reacts with a number of compounds containing labile hydrogen atoms, where H-atom is partially or completely replaced by D-atom as,

$$NaOH + D_2O \rightleftharpoons NaOD + HOD$$
$$HCl(aq) + D_2O \rightleftharpoons DCl + HOD$$
$$NH_4Cl + 4D_2O \rightleftharpoons ND_4Cl + 4HOD$$

(If the compound contains ionic (polar) hydrogen atoms, the exchange reactions take place more readily in comparison to compounds containing non-ionic hydrogen).

Heavy water like ordinary water may be associated with salts as water of crystallisation, giving deutero-hydrate, *e.g.,* $Na_2SO_4 \cdot 10D_2O$, $CuSO_4 \cdot 5D_2O$, $MgSO_4 \cdot 7H_2O$, etc.

Biological and Physiological Effects

It has been established that heavy water of high concentration retards the growth of plants and animals. Pure heavy water kills small fishes, tadpoles and mice, when fed on with it.

Taylor has shown that heavy water has germicide and bactericide properties. Water containing small quantity of D_2O acts as a tonic and stimulates vegetable growth. Certain moulds have been found to develop better in heavy water in comparison to ordinary water.

Uses

Heavy water is used as a moderator in nuclear reactors, in the study of mechanisms of chemical reactions involving hydrogen and its compounds etc. It is also used for the preparation of deuterium.

9.8 Hydrogen Peroxide (H_2O_2)

It was discovered by the French chemist, **L.J. Thenard,** in 1818, by the action of sulphuric acid on barium peroxide. Initially it was named **oxygenated water.**

It occurs in traces in air, rain, snow, some natural waters and juices of certain plants.

General Methods of Preparation

Following methods are used to prepare H_2O_2 *in laboratory.*

(a) By the Action of Dilute HCl on Anhydrous BaO_2

Thenard, a French scientist, prepared H_2O_2 accidentally in 1818 by the action of dil HCl on BaO_2 (barium peroxide) while he was trying to evolve some new methods for the preparation of water. He called it as **oxygenated water,** *i.e.,* the water with more oxygen.

$$BaO_2 + 2HCl \longrightarrow BaCl_2 + H_2O_2$$

(b) By the Action of Dilute H_2SO_4 on Anhydrous Na_2O_2

While preparing H_2O_2 through dil H_2SO_4 and Na_2O_2, the later is added slowly to ice cold 20% H_2SO_4. On cooling crystals of $Na_2SO_4 \cdot 10H_2O$ separate out from H_2O_2. These are filtered off while some impurity, as Na_2SO_4, remains present in H_2O_2. The reaction proceed as,

$$Na_2O_2 + \text{dil } H_2SO_4 (20\%) \longrightarrow Na_2SO_4 + H_2O_2$$

(c) By the Action of Dilute H_3PO_4 on Hydrated BaO_2

A bit modified form of the above written process mixed with the application of Thenard's reaction is used more commonly for the preparation of H_2O_2 in laboratory. Here, *hydrated* BaO_2 *is used instead of anhydrous* BaO_2 (because $BaSO_4$ formed as the by-product of reaction, forms a layer on BaO_2, thus preventing further reaction but with hydrated BaO_2 such a problem does not arise).

Secondly, the H_2SO_4 *used, catalyses the decomposition of* H_2O_2 *also, hence comparatively weaker acids like* H_3PO_4 *and* H_2CO_3 *etc., are used in the place of* H_2SO_4.

$$3BaO_2 + 2H_3PO_4 \longrightarrow \underset{\text{ppt.}}{Ba_3(PO_4)_2} + 3H_2O_2$$

Insoluble barium phosphate is filtered off. The filtrate consists of hydrogen peroxide.

The barium phosphate is decomposed by dilute sulphuric acid.

$$Ba_3(PO_4)_2 + 3H_2SO_4 \longrightarrow 3BaSO_4 + 2H_3PO_4$$

$BaSO_4$ is removed by filtration and orthophosphoric acid is used again.

(d) Merck's Process

H_2O_2 can be obtained by passing a current of CO_2 through a cold pasty solution of barium peroxide in water.

$$BaO_2 + CO_2 + H_2O \longrightarrow BaCO_3 + H_2O_2$$

Barium carbonate being insoluble is filtered off.

Industrial Preparation of H_2O_2

Following methods are used for the industrial preparation of H_2O_2.

(a) By the Electrolysis of H_2SO_4 or NH_4HSO_4 at a High Current Density

The **electrolysis of 50% H_2SO_4** is done at 0°C using Pt electrodes. Here, perdisulphuric acid ($H_2S_2O_8$) is formed at anode as,

$$H_2SO_4 \rightleftharpoons H^+ + HSO_4^-$$

At **cathode** (reduction) $2H^+ + 2e^- \longrightarrow 2H \longrightarrow H_2$

At **anode** (oxidation) $2HSO_4^- \longrightarrow H_2S_2O_8 + 2e^-$

This $H_2S_2O_8$ on hydrolysis gives H_2O_2 which is separated by distillation under reduced pressure.

When $(NH_4)_2SO_4$ and H_2SO_4 are mixed in 1 : 1 ratio, NH_4HSO_4 is formed, which is electrolysed to give ammonium persulphate by using Pt electrodes at 0°C.

$$2NH_4HSO_4 \rightleftharpoons 2H^+ + 2NH_4SO_4^-$$

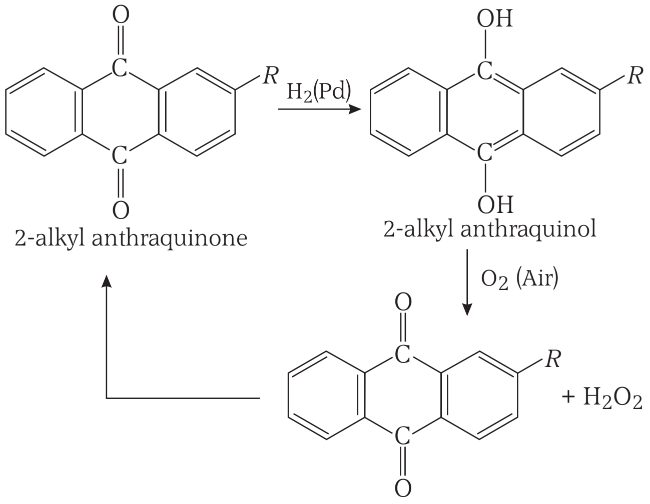
At **cathode** (reduction) $2H^+ + 2e^- \longrightarrow 2H \longrightarrow H_2$

At **anode** (oxidation) $2NH_4SO_4^- \longrightarrow (NH_4)_2S_2O_8 + 2e^-$

The ammonium persulphate so formed is hydrolysed by heating with water at low pressure (43 mm of Hg) resulting in H_2O_2.

(b) By the Auto-oxidation of 2-alkyl Anthraquinol

2-alkyl anthraquinol is oxidised as



The reaction is carried out in a mixture of organic solvents, *e.g.*, ester/hydrocarbon or octanol/methyl naphthalene. The solvent must

1. dissolve quinol and quinone,
2. resist oxidation,
3. be immiscible with water.

Concentration of H_2O_2 Solution

Hydrogen peroxide obtained by the above methods is always in the form of dilute aqueous solution. The concentration of this solution is difficult due to explosive nature of hydrogen peroxide. It is done by using the following steps.

Step I The dilute solution is concentrated on a water bath at 60–70°C. By this the 30% solution is obtained.

Step II The obtained 30% solution is distilled at 35–40°C under reduced pressure of about 15 mm. Repeated distillation gives 90% H_2O_2.

Step III Further concentration is achieved by cooling 90% solution with the help of solid CO_2 and ether both till crystallisation occurs. The crystals are washed, separated, melted and refrozen to obtain 99% pure H_2O_2.

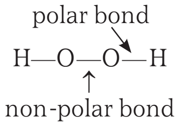
Storage of H_2O_2

H_2O_2 gets easily decomposed in the presence of metals, rough surfaces, sunlight, dust particles, glass and alkali. Thus, it is stored in vessels of pure aluminium or in stone jars in dark. Concentrated solutions of hydrogen peroxide are stored these days in polythene bottles kept in refrigerators. Small amounts of stabilizers such as orthophosphoric acid, acetanilide or sodium stannate are also added to the solutions to be stored to prevent its decomposition.

Physical Properties of H_2O_2

The important physical properties of H_2O_2 *are as follows*

1. It is light blue in pure anhydrous form, odourless, syrupy liquid, produces blisters on skin and soluble in water, alcohol and ether.
2. Its boiling point is 152°C and freezing point is −0.89°C. The further increase in the boiling point of H_2O_2 in comparison with water is due to the reason that here intermolecular hydrogen bonding is even more stronger than water.
3. Density of H_2O_2 at 0°C is 1.45 g/cc and dielectric constant is 93.7.
4. H_2O_2 molecule is diamagnetic, polar and its dipole moment is 2.1 D.
5. It has both **polar** and **non-polar bonds** as



Chemical Properties of H_2O_2

H_2O_2 *exhibits following chemical properties*

(a) Decomposition

H_2O_2 decomposes on heating. It is an unstable liquid. Finely divided Fe, Cu, Au, Pt, MnO_2, metal ions like Cu^{2+}, Ni^{2+} and traces of base act as **positive catalyst** (destabilisers) for its decomposition while H_3PO_4, $C_6H_5NHCOCH_3$ (acetanilide), C_2H_5OH, glycerol, etc., act as **negative catalyst** (stabilisers) for its decomposition.

(b) Nature

H_2O_2 is acidic in nature but its aqueous solution is neutral towards litmus. It dissociates in water to give hydronium ion as,

$$H_2O_2 + H_2O \longrightarrow H_3O^+ + HO_2^- \quad (K_a = 1.4 \times 10^{-12} \text{ at } 298\text{ K})$$

Value of its dissociation constant suggests that its aqueous solution is more acidic than water (for water $K_w = 10^{-14}$ at 298 K).

The acidic nature of H_2O_2 is confirmed by its reactions with **alkalies and carbonates.** In these reactions, corresponding peroxides are formed.

$$H_2O_2 + 2NaOH \longrightarrow Na_2O_2 + 2H_2O$$
$$H_2O_2 + Ba(OH)_2 \longrightarrow BaO_2 + 2H_2O$$
$$H_2O_2 + Na_2CO_3 \longrightarrow Na_2O_2 + CO_2 + H_2O$$

Formation of H_2O *and* CO_2 *in the last reaction instead of* H_2CO_3 *suggests that* H_2O_2 *is even stronger acid than* H_2CO_3.

(c) Oxidising Property

H_2O_2 is a strong oxidising agent. It accepts the electron easily and itself gets reduced in alkaline as well as acidic medium as,

$$H_2O_2 + 2H^+ + 2e^- \longrightarrow 2H_2O \qquad (E° = +1.77\ V)$$
$$HO_2^- + H_2O + 2e^- \longrightarrow 3OH^- \qquad (E° = +0.87\ V)$$

Thus, in acidic medium, H_2O_2 is reduced into H_2O and in alkaline medium into OH^-. In both the cases oxidation number of oxygen decreases. Here, the important point to be remember is that **in alkaline solution these reactions are generally faster.**

Some examples of oxidising reactions are

(i) Lead sulphide (PbS) is oxidised into $PbSO_4$,

$$PbS + 4H_2O_2 \longrightarrow PbSO_4 + 4H_2O$$

(ii) KNO_2 is oxidised into KNO_3,

$$KNO_2 + H_2O_2 \longrightarrow KNO_3 + H_2O$$

(iii) Na_2SO_3 is oxidised into Na_2SO_4,

$$Na_2SO_3 + H_2O_2 \longrightarrow Na_2SO_4 + H_2O$$

(iv) Sodium arsenite (Na_3AsO_3) is oxidised into sodium arsenate,

$$Na_3AsO_3 + H_2O_2 \longrightarrow Na_3AsO_4 + H_2O$$

(v) Hydrogen sulphide is oxidised into sulphur,

$$H_2S + H_2O_2 \longrightarrow 2H_2O + S$$

(vi) Ferrous sulphate is oxidised into ferric sulphate,

$$2FeSO_4 + H_2SO_4 + H_2O_2 \longrightarrow Fe_2(SO_4)_3 + 2H_2O$$

(vii) KI is oxidised into I_2,

$$2KI + H_2SO_4 + H_2O_2 \longrightarrow K_2SO_4 + 2H_2O + I_2$$

(viii) Formaldehyde (HCHO) is oxidised into formic acid,

$$HCHO + H_2O_2 \longrightarrow HCOOH + H_2O$$

(ix) Potassium ferrocyanide is oxidised into potassium ferricyanide,

$$2K_4[Fe(CN)_6] + H_2SO_4 + H_2O_2 \longrightarrow 2K_3[Fe(CN)_6] + K_2SO_4 + 2H_2O$$

(x) In the presence of $FeSO_4$ benzene is oxidised into phenol,

$$C_6H_6 + H_2O_2 \xrightarrow{FeSO_4} C_6H_5OH + H_2O$$

(xi) Hg is oxidised into HgO,

$$Hg + H_2O_2 \longrightarrow HgO + H_2O$$

(xii) In alkaline medium, it oxidises manganese sulphate (a manganeous salt) to manganese dioxide.

$$MnSO_4 + H_2O_2 + 2NaOH \longrightarrow MnO_2 + Na_2SO_4 + 2H_2O$$
$$\text{or} \qquad Mn^{2+} + H_2O_2 \longrightarrow Mn^{4+} + 2OH^-$$

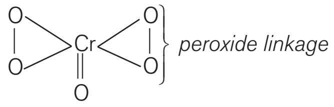
(xiii) It dissolves the chromic hydroxide precipitate present in NaOH solution forming a yellow solution of sodium chromate.

$$\begin{array}{rcl} [H_2O_2 & \longrightarrow & H_2O + O] \times 3 \\ 2Cr(OH)_3 + 4NaOH + 3O & \longrightarrow & 2Na_2CrO_4 + 5H_2O \\ \hline 2Cr(OH)_3 + 4NaOH + 3H_2O_2 & \longrightarrow & 2Na_2CrO_4 + 8H_2O \end{array}$$

Caution Point *When cold* H_2O_2 *is added in cold mixture of* $K_2Cr_2O_7$ *and conc.* H_2SO_4 (*i.e.,* $K_2Cr_2O_7$ *in acidic medium*), *a blue solution of blue perchromate is obtained as,*

$$K_2Cr_2O_7 + H_2SO_4 \longrightarrow K_2SO_4 + H_2Cr_2O_7$$
$$H_2Cr_2O_7 + 4H_2O_2 \longrightarrow \underset{\text{blue perchromate}}{2CrO_5} + 5H_2O$$

The structure for blue perchromate is



Because of the presence of two peroxide linkages, the oxidation state of Cr *in* CrO_5 *is* +6, *not* +10.

(d) Reducing Property

Due to electron donating property of H_2O_2, it also acts as a reducing agent in acidic as well as in alkaline medium and proceeds as

$$H_2O_2 \longrightarrow O_2 + 2H^+ + 2e^-$$
$$H_2O_2 + 2OH^- \longrightarrow 2H_2O + O_2 + 2e^-$$

Some important examples in which H_2O_2 acts as a reducing agent are

(i) Silver oxide (Ag_2O) is reduced to Ag,

$$Ag_2O + H_2O_2 \longrightarrow 2Ag + H_2O + O_2$$

(ii) Lead dioxide (PbO_2) is reduced to PbO,

$$PbO_2 + H_2O_2 \longrightarrow PbO + H_2O + O_2$$

(iii) Cl_2 is reduced to HCl,

$$Cl_2 + H_2O_2 \longrightarrow 2HCl + O_2$$

(iv) Gold oxide is reduced to gold,

$$Au_2O + H_2O_2 \longrightarrow 2Au + H_2O + O_2$$

(v) In acid medium, MnO_2 is reduced to $MnSO_4$,

$$MnO_2 + H_2SO_4 + H_2O_2 \longrightarrow MnSO_4 + 2H_2O + O_2$$

(vi) Acidified $KMnO_4$ is reduced by H_2O_2. Pink colour of $KMnO_4$ disappears.

$$2KMnO_4 + 3H_2SO_4 + 5H_2O_2 \longrightarrow K_2SO_4 + 2MnSO_4 + 8H_2O + 5O_2$$

(vii) In alkaline medium, potassium ferricyanide is reduced to potassium ferrocyanide,

$$2K_3[Fe(CN)_6] + 2KOH + H_2O_2 \longrightarrow 2K_4[Fe(CN)_6] + 2H_2O + O_2$$

(e) Reaction with Ozone

H_2O_2 on reaction with O_3 shows the following reaction,

$$H_2O_2 + O_3 \longrightarrow H_2O + 2O_2$$

i.e., both reduce each other.

(f) Bleaching Property

H_2O_2 also exhibits bleaching property. This property is due to the nascent oxygen which it liberates on decomposition.

$$H_2O_2 \longrightarrow H_2O + [O]$$

The nascent oxygen combines with the colouring matter, which in turn, gets oxidised.

$$\text{Colouring matter} + [O] \longrightarrow \text{colourless matter}$$

It bleaches delicate materials like silk, cotton, wool, hair, feather, ivory etc.

(g) Addition Reactions

H_2O_2 reacts with alkenes to give respective glycols.

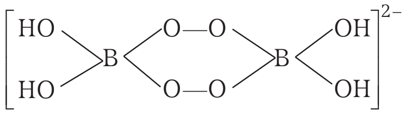
$$\underset{\text{ethene}}{CH_2{=}CH_2} + H_2O_2 \longrightarrow \underset{\text{ethylene glycol}}{CH_2OH—CH_2OH}$$

Uses of H_2O_2

1. H_2O_2 is *germicide* and antiseptic. It is used for washing cuts, wounds, teeth, ears, etc., and in gargles under the name **perhydrol.** (30% solution of H_2O_2)
2. It prevents the purification of milk, liquor etc.
3. Its dilute solution is used in the bleaching of cotton, wool, silk, hair, ivory, paper, pulp etc.
4. Old oil paintings turn black with time due to the formation of black PbS. Hydrogen peroxide oxidises black PbS into white $PbSO_4$ and thus, restore their colour.
5. It is used as an oxidising agent as well as reducing agent.
6. It is used to produce sodium peroxoborate. $Na_2B_2(O_2)_2(OH)_4$. In hexahydrate state, it used as a brightner in washing powders.

   $$2NaBO_2 + 2H_2O_2 + 6H_2O \longrightarrow Na_2[(OH)_2B(O—O)_2B(OH)_2]6H_2O$$

   Structure of preoxoborate ion may be given as



7. It is used as a laboratory reagent in the test of Ti^{4+}, Cr^{3+} and V^{5+} ions.
8. It is used as propellant for rockets, torpedoes, etc., and as a fuel. As a propellant it is used to oxidise alcohol, petrol, hydrazine etc.

   $$N_2H_4 + 2H_2O_2 \longrightarrow N_2 + 4H_2O$$

9. H_2O_2 is used as **antichlor** to remove Cl_2 etc., present in a solution.

Strength of H_2O_2

Strength of H_2O_2 solution may be represented in several ways such as **g/L, mol/L, normality, ppm** (mg/L), volume etc. Some important one among them are

(a) Concentration as Volume

It is equal to the volume of O_2 obtained at STP by decomposing one volume H_2O_2 solution. If the strength of H_2O_2 solution is 20 volume, this means that 1 cc H_2O_2 solution on decomposition gives 20 cc O_2 at STP or 1 L H_2O_2 solution on heating gives 20 L O_2 at STP.

(b) Concentration as Percentage

It is equal to the gram of H_2O_2 present in 100 mL of H_2O_2 solution. Thus, if the strength of a H_2O_2 solution is 8%, this means that 8 g of H_2O_2 is present in its 100 mL solution.

(c) Concentration as Normality

Strength of H_2O_2 as normality is calculated with the help of equivalent weight of H_2O_2 (17) as,

Normality of H_2O_2 solution

$$= \frac{\text{strength of } H_2O_2 \text{ solution in g/L}}{\text{equivalent wt. of } H_2O_2}$$

Conversion of One Concentration Term into Another

Concentration of H_2O_2 is expressed in terms of "volume of O_2." We know that **"10 volume H_2O_2" means that 1 mL of H_2O_2 at NTP gives 10 mL O_2 gas.** These values can be changed into other concentration terms like density, g L^{-1}, normality and molarity as

$$\underset{?}{\underset{68\text{ g}}{2H_2O_2}} \longrightarrow 2H_2O + \underset{x\text{ mL}}{\underset{1\text{ mol}}{O_2}} \quad (22400 \text{ mL at NTP})$$

22400 mL O_2 is obtained from H_2O_2 = 68 g (at NTP)

x mL O_2 gas will be obtained from H_2O_2

$$= \frac{68}{22400} \times x \text{ g (at NTP)}$$

This amount is in 1 mL H_2O_2 (by definition).

Thus, $$1 \text{ mL } H_2O_2 = \frac{68}{22400} \times x \text{ g}$$

$$\text{Density} = \frac{68}{22400} x \text{ g/mL}$$

$$\text{Conc. in g/L} = \frac{68}{22400} x \times 1000$$

$$\text{g/L conc.} = \frac{680x}{224} \text{ g/L}$$

$$\text{Normality } (N) = \frac{\text{conc. in g/L}}{\text{equivalent wt.}} = \frac{680x}{224} \times \frac{1}{17}$$

$$\therefore \quad N = \frac{x}{5.6}$$

$$\text{Molarity } (M) = \frac{\text{conc. in g/L}}{\text{mol. wt.}} = \frac{680x}{224} \times \frac{1}{34}$$

$$\therefore \quad M = \frac{x}{11.2}$$

Sample Problem 7 *The volume strength of* 1.6 *N* H_2O_2 *solution is*

(a) 3.57 (b) 8.96
(c) 9.57 (d) 5.45

Interpret (b) Strength = normality × eq. wt.

$= 1.6 \times 17$ g/L

$\because$ 68 g of H_2O_2 at NTP gives $O_2 = 22400$ mL

$\therefore$ 1.6×17 g H_2O_2 at NTP will give O_2

$$= \frac{22400}{68} \times 1.6 \times 17 \text{ mL}$$

$$= 8960 \text{ mL}$$

But 1.6×17 g H_2O_2 is present in 1000 mL of H_2O_2 solution.

Hence, 1000 mL of H_2O_2 solution will give O_2 (at NTP) = 8960 mL

$\therefore$ 1 mL of H_2O_2 solution will give $O_2 = \frac{8960}{1000}$

$= 8.96$ mL O_2

Hence, the volume strength of 1.6 N H_2O_2 is 8.96 volume.

Sample Problem 8 *5 mL of* H_2O_2 *solution liberates* 0.508 *g of* I_2 *from an acidified* KI *solution. The strength of* H_2O_2 *solution in terms of volume strength at STP will be*

(a) 4.48 (b) 5.6
(c) 9.96 (d) 8.20

Interpret (a) Let the normality of $H_2O_2 = N$

$$\text{Equivalents of } H_2O_2 = \frac{5N}{1000} = \frac{N}{200}$$

$$\text{Equivalents of } I_2 = \frac{0.508}{127}$$

$$\frac{N}{200} = \frac{0.508}{127}$$

$$N = 0.8 \text{ N } H_2O_2$$

If volume strength = x

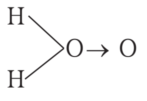
then, $$N = \frac{x}{5.6}$$

$$x = N \times 5.6$$

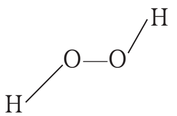
$$= 0.8 \times 5.6 = 4.48 \text{ V}$$

Structure of H_2O_2

Following two structures have been suggested for hydrogen peroxide.



Kingzett's formula



Baeyer's formula

(a) Evidence in Favour of Kingzett's Structure

H_2O_2 is an oxidising agent. Reaction in which H_2O_2 acts as an oxidant, one oxygen atom per H_2O_2 molecule is decreased. Thus, this structure explains the instability of one of the oxygen atom.

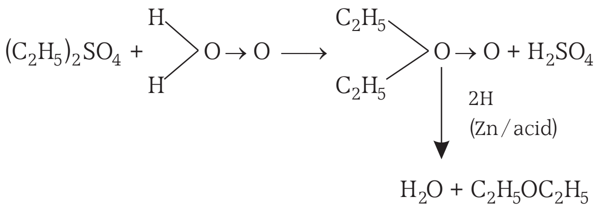
(b) Evidence in Favour of Baeyer's Structure

1. H_2O_2 is a weak dibasic acid. It has two —OH groups. Therefore, it forms two series of salts such as $NaHO_2$ and Na_2O_2.
2. Ethylene glycol is formed by the action of H_2O_2 on ethylene. This confirms the presence of two —OH groups in H_2O_2.
3. H_2O_2 reacts with ethyl sulphate. Diethyl peroxide is formed. This on reduction gives ethyl alcohol. From this reaction, it is concluded that O—O bond is present in H_2O_2 and one H-atom is bonded to each atom.

$$\text{H—O—O—H} + (C_2H_5)_2SO_4 \longrightarrow C_2H_5\text{—O—O—}C_2H_5 + H_2SO_4$$

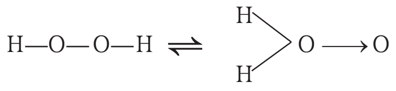
$$C_2H_5\text{—O—O—}C_2H_5 \xrightarrow{2H(Zn/acid)} 2C_2H_5OH$$

If we take Kingzett's structure as the real structure of H_2O_2 then the product for the above reaction should be diethyl ether and not alcohol. As a matter of fact, H_2O_2 gives diethyl ether also as the product for above reaction, *i.e.*,



$$(C_2H_5)_2SO_4 + H_2O \rightarrow O \longrightarrow (C_2H_5)_2O \rightarrow O + H_2SO_4 \xrightarrow{2H\,(Zn/acid)} H_2O + C_2H_5OC_2H_5$$

Formation of ethyl alcohol as well as diethyl ether as the product of the above reaction supports the view that H_2O_2 infact contains both the type of molecules in equilibrium as the tautomeric mixture. In other words, we can say that Kingzett and Baeyer's formulae are infact tautomeric forms of each other.



$$\text{H—O—O—H} \rightleftharpoons H_2O \longrightarrow O$$

4. H_2O_2 (one molecule) reacts with two molecules of chlorosulphonic acid to give perdisulphuric acid. This confirms the O—O bond in H_2O_2.

$$HSO_3\ \boxed{Cl + H}\text{—O—O—}\boxed{H + Cl}\,SO_3H \longrightarrow$$
$$HSO_3\text{—O—O—}SO_3H + 2HCl$$

5. X-ray study confirms the presence of O—O bond in peroxides such as Na_2O_2, BaO_2, etc.

   Dipole moment of H_2O_2 is 2.1 D. This shows that all the four atoms in H_2O_2 are not in one plane.

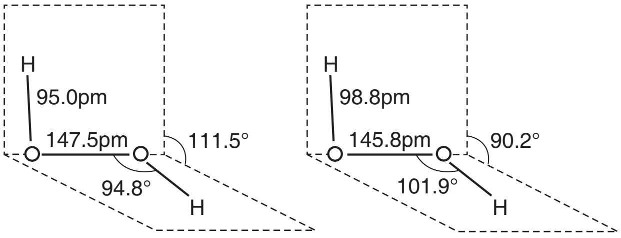
   X-ray studies shows that H_2O_2 is non-polar molecule. H_2O_2 molecule may be pictured as lying on the spine of a book open at an angle of 94.8°. One hydrogen atom is placed on each cover. The two oxygen atoms are present along the axis of the spin of the book. The H—O bonds make an angle of 94.8° with the O—O bond.

   O—O bond length = 1.49 Å

   O—H bond length = 0.97 Å

   O—O—H angle = 94.8°

   For H_2O_2 in solid phase, the dihedral angle between two planes is different and the length of O—H bond is different as shown in the figure.



(a) Gas phase (b) Solid phase

Fig. 9.5 (a) H_2O_2 structure (gas phase), dihedral angle 115.5°, (b) H_2O_2 (solid phase at 110 K). The dihedral angle is reduced to

9.9 Hydrides

The compounds of hydrogen in which hydrogen is suppose to be present as H^- are called **hydrides.** The oxidation state of H in these compounds is –1.

Based upon their physical and chemical properties, hydrides are of the following three types

1. Ionic or Salt Like Hydrides

These are the compounds of hydrogen with most of the *s*-block elements. These are formed by transfer of electrons from metal to hydrogen atom. These are white crystalline solids, have ionic lattices, high boiling and melting points and behave as salts. They can conduct electricity only in fused or molten state. *Their density is higher than that of metals.* Their aqueous solutions are strongly alkaline. These hydrides are famous for complex formation and are used as good reducing agents, *e.g.,*

$$LiH + AlH_3 \longrightarrow Li(AlH_4)$$
$$NaH + BH_3 \longrightarrow Na(BH_4)$$

2. Molecular or Covalent Hydrides

These are the compounds of hydrogen with *p*-block elements. Their bonds are mostly covalent in character (in some cases partly covalent and partly ionic character *e.g.,* HF). These have molecular lattices, soft in texture, with low melting point and boiling point and low electrical conductivity. Acidic character in these hydrides increases while moving left to right in a period, *e.g.,*

$NH_3 \longrightarrow$ base, $H_2O \longrightarrow$ neutral,

$HF \longrightarrow$ acid $PH_3 \longrightarrow$ weak base,

$H_2S \longrightarrow$ weak acid, $HCl \longrightarrow$ strong acid

The molecular hydrides are named with the suffix-ane *e.g.,* phosphane (PH_3); oxidane (H_2O); azane (NH_3) etc., and are of following three types

(i) **Electron deficient hydrides** with elements of 13 group, which normally behave as Lewis acid, *e.g.,* B_2H_6.

(ii) **Electron precise hydrides** with elements of 14 group, *e.g.,* CH_4.

(iii) **Electron rich hydrides** with elements of 15, 16 and 17 group, *e.g.,* H_2O, NH_3, HF etc. Here, the excess electron is being present as lone pair ($NH_3 \rightarrow 1$ lone pair; $H_2O \rightarrow 2$ lone pairs; $HF \rightarrow 3$ lone pairs). The presence of lone pair and highly electronegative elements like O, N and F results in hydrogen bond formation. Presence of hydrogen bonds leads to high boiling points, high permittivities and aggregation in such compounds.

3. Metallic or Interstitial Hydrides

These are formed by the reaction of *d*- and *f*-block metals with hydrogen. These are non-stoichiometric hydrides and show electric conduction.

These hydrides are generally formed by the

(i) transition metals of group 3, 4, 5 of *d*-block;

(ii) Cr metals of group 6 and

(iii) *f*-block elements.

It may be noted that elements of group 7, 8, 9 *of d-block do not form hydrides at all.* This inability of metal of group 7, 8, 9 of the Periodic Table to form hydrides is referred to as *hydride gap* of *d*-block.

In these compounds, H atoms are supposed to occupy interstitial position in the metal lattices. Some scientists consider these compounds as simply solid solutions of hydrogen. The composition of these hydrides may not correspond to simple whole number ratio and therefore, they are also called non-stoichiometric hydrides. Their composition is also found to vary with the conditions of temperature and pressure. Some examples of interestitial hydrides of elements of group 3 to 5 are ScH_2, YH_2, YH_3, LiH_3,

CrH, TiH_2, ZrH_2 HfH_2, VH, NbH, NbH_2, TaH etc.

Check Point 2

1. Can phosphorus with outer configuration $3s^2 3p^3$ form PH_5?
2. Explain, temporary hard water becomes soft on boiling.
3. Saline hydrides when react with water, produce fire violently. Can we use CO_2 to extinguish this fire?
4. Density of ice is lower than water although the density of solid is higher than liquid. Explain, why?
5. Why use of hydrated BaO_2 is preferred during the preparation of H_2O_2?

Hydrogen as a Fuel

Hydrogen has been considered as one of the alternate sources of energy because.

1. It is environmentally clean, giving only water as a combustion product.
2. The heat of combustion of hydrogen per gram is higher than any other fuel as tabulated below :

$$H_2(g) + \left(\frac{1}{2}\right) O_2(g) \longrightarrow H_2O(l); \ \Delta H^\circ = -284 \text{ kJ mol}^{-1}$$

Table 9.2 **Energy Released by the Combustion of Some Substances**

Substance	Energy released (kJ/g)
Hydrogen [combustion product $H_2O(l)$]	142
Gasoline	48
Crude petroleum	43
Typical animal fat	38
Coal	29.3
Charcoal	29
Paper	20
Wood or dung	15

Hydrogen could replace coal and oil as major sources of energy. Our energy needs can be met by gaseous, liquid and solid hydrogen. For heating homes, gaseous hydrogen could be conveyed through underground pipes while liquid hydrogen could be shipped by truck or rail in large vacuum insulated tanks. Automobiles might be powered by solid hydrogen in the form of solid interstitial hydrides. Prototype cars have already been built with their engines modified to run on hydrogen.

Since hydrogen is not a naturally occurring energy source like coal, natural gas etc., cheaper ways of producing hydrogen must be discovered. Direct methods of hydrogen production are very costly. For example, decomposing water with electricity is too expensive but if future methods for generating electricity prove economical, the ocean provide an inexhaustible source of starting material.

If we succeed in developing economically feasible methods for producing hydrogen cheaply and in large quantities, we still face significant problems in **storing** and **transporting** it. In case hydrogen is to be stored and transported in its gaseous state, large, heavy-walled metal cylindrical will be required, *i.e.,* it will be a costly affair. To save space, gases are converted to the liquid state under high pressure as in the case of "bottled gas." But hydrogen must be cooled to −253°C before it liquefies. Thus, keeping hydrogen in liquid state requires low temperatures and high costs.

A number of attempts have been made to tackle the problem of storing H_2. One of these, proposed recently, involves absorbing gaseous H_2 on a solid, such as activated carbon, An another approach involves reacting the H_2 with certain metals to produce compounds called hydrides, which are relatively stable solid that have a reasonably high storage capacity. For example, when 10 litres of H_2 gas at 25°C and 1 atmosphere react with lithium metal, the resulting LiH occupies a mere 4.3 mL.

$$Li(s) + \frac{1}{2} H_2(g) \longrightarrow LiH(s)$$

When such hydrides are reacted with water, they produce H_2, which can be burned.

$$LiH(s) + H_2O(l) \longrightarrow H_2(g) + LiOH(aq)$$

Some of the interstitial hydrides can be made suitable storage compounds for hydrogen. The reactions that form these hydrides are usually reversible; so hydrogen gas can be obtained simply by reducing the pressure above the metal. Fuel cell is an important device where hydrogen and oxygen gases are used as fuels.

WORKED OUT Examples

Example 1 *In which of the properties listed below hydrogen does not show similarity with halogens?*

I. Nature of the oxide
II. Electropositive character
III. Combination with alkali metals
IV. Atomicity

(a) I *and* II (b) III *and* IV
(c) II *only* (d) I *and* III

Solution (a) Hydrogen forms a neutral oxide, *i.e.*, H_2O (water) while the oxide of halogens *i.e.*, HCl, HI, HBr, are acidic. Hydrogen atom is electropositive in nature also while halogens are mostly electronegative in nature.

Example 2 *Mass percentage of deuterium in heavy water is*

(a) *same as that of protium in water*
(b) 11.1
(c) 20.0
(d) *cannot be predicted*

Solution (c) The formula of heavy water is D_2O, *i.e.*, molecular mass = 20

$$\% \text{ of deuterium} = \frac{4}{20} \times 100 = 20$$

Example 3 *In which reaction, hydrogen peroxide neither acts as an oxidising agent nor as a reducing agent?*

(a) $PbS + H_2O_2 \longrightarrow$
(b) $SO_3^- + H_2O_2 \longrightarrow$
(c) $PbO_2 + H_2O_2 \longrightarrow$
(d) $Na_2CO_3 + H_2O_2 \longrightarrow$

Solution (d) H_2O_2 neither acts as an oxidising agent nor as a reducing agent, when reacts with Na_2CO_3 because there is neither gain nor loss of electrons in this reaction.

$$Na_2CO_3 + H_2O_2 \longrightarrow Na_2O_2 + CO_2 + H_2O$$

Example 4 *Given sample of water has degree of hardness equal to 40 ppm. If the entire hardness is due to* $MgSO_4$, *the amount of* $MgSO_4$ *present per kg of water is*

(a) 24 *g* (b) 24 *mg*
(c) 48 *g* (d) 48 *mg*

Solution (d) Degree of hardness of H_2O is 40 ppm,

i.e., 10^6 g of water contains $CaCO_3 = 40$ g

Since, 1 mole of $CaCO_3$ = 1 mole of $MgSO_4$

$\therefore$ 100 g of $CaCO_3$ = 120 g of $MgSO_4$

$$\therefore\ 10^6 \text{ g of water contains } MgSO_4 = \frac{40 \times 120}{100} = 48 \text{ g}$$

Example 5 *Hydrogen peroxide solution (20 mL) reacts quantitatively with a solution of* $KMnO_4$ *(20 mL) acidified with dilute* H_2SO_4. *The same volume of the* $KMnO_4$ *solution is just decolourised by 10 mL of* $MnSO_4$ *in neutral medium simultaneously forming a dark brown precipitate of hydrated* MnO_2. *The brown ppt is dissolved in 10 mL of 0.2 M sodium oxalate under boiling condition in the presence of dilute* H_2SO_4. *The molarity of* H_2O_2 *is*

(a) 0.4 *m* (b) 0.2 *m*
(c) 0.1 *m* (d) 0.02 *m*

Solution (c)

$$\begin{aligned} 2KMnO_4 + 3H_2SO_4 &\longrightarrow K_2SO_4 + 2MnSO_4 \\ &\qquad + 3H_2O + 5[O] \\ [H_2O_2 + [O] &\longrightarrow H_2O + O_2] \times 5 \\ \hline 2KMnO_4 + 3H_2SO_4 + 5H_2O_2 &\longrightarrow K_2SO_4 + 2MnSO_4 \\ &\qquad + 8H_2O + 5O_2 \downarrow \end{aligned}$$

$$\begin{aligned} 3MnSO_4 + 2KMnO_4 + (x+2)H_2O &\longrightarrow \underset{\text{brown ppt.}}{5MnO_2 \cdot xH_2O \downarrow} \\ &\qquad + K_2SO_4 + 2H_2SO_4 \end{aligned}$$

$$\begin{aligned} MnO_2 \cdot xH_2O + Na_2C_2O_4 + 2H_2SO_4 &\longrightarrow MnSO_4 + Na_2SO_4 \\ &\qquad + (x+2)H_2O + 2CO_2 \end{aligned}$$

Millimoles of $Na_2C_2O_4 = 10 \times 0.2 = 2$

Meq. of $Na_2C_2O_4 = 4$ ($\because$ meq. = 2 × millimoles)

Meq. of $MnO_2 \cdot xH_2O$ formed = 4

Meq. of $MnO_2 \cdot xH_2O$ = meq. of $KMnO_4 = 4$

Meq. of $KMnO_4$ = meq. of $H_2O_2 = 4$

Meq. of $H_2O_2 = 4$

Millimoles of $H_2O_2 = 2$ $\left(\frac{\text{Meq.}}{2} = \text{Millimoles for } H_2O_2\right)$

$\therefore$ Moles of H_2O_2 in 20 mL of solution $= 2 \times 10^{-3}$

$$\text{Molarity of solution} = \frac{2 \times 10^{-3}}{20} \times 1000 \text{ M} = 0.1 \text{ M}$$

Round I (Topically Divided Problems)

Hydrogen and its Different Forms

1. Which pair does not show hydrogen isotopes?
(a) *Ortho* hydrogen and *para* hydrogen
(b) Protium and deuterium
(c) Deuterium and tritium
(d) Tritium and protium

2. The sum of protons, electrons and neutrons in the heaviest isotope of hydrogen is
(a) 3 (b) 5 (c) 4 (d) 6

3. The adsorption of hydrogen by metals is called
(a) adsorption (b) occlusion
(c) hydrogenation (d) dehydrogenation

4. Hydrogen resembles halogens in many respects for which several factor are responsible. Of the following factors which one is the most important in this respect? **[NCERT Exemplar]**
(a) Its tendency to lose an electron to form a cation
(b) Its tendency to gain a single electron in its valence shell to attain stable electronic configuration
(c) Its low negative electron gain enthalpy value
(d) Its small size

5. Why does H^+ ion always get associated with other atoms or molecules? **[NCERT Exemplar]**
(a) Ionisation enthlapy of hydrogen resembles that of alkali metals
(b) Its reactivity is similar to halogens
(c) It resembles both alkali metals and halogens
(d) Loss of an electron from hydrogen atom results in a nucleus of very small size as compared to other atoms or ions. Due to small size it cannot exist free

6. Radioactive elements emit α, β and γ rays and are characterised by their half-lives. The radioactive isotope of hydrogen is **[NCERT Exemplar]**
(a) protium (b) deuterium
(c) tritium (d) hydronium

7. Under what conditions of temperature and pressure, the formation of atomic hydrogen from molecular hydrogen will be favoured more?
(a) High temperature and low pressure
(b) Low temperature and low pressure
(c) High temperature and high pressure
(d) Low temperature and high pressure

8. Which of the following reactions is an example of use of water gas in the synthesis of other compounds? **[NCERT Exemplar]**

(a) $CH_4(g) + H_2O(g) \xrightarrow[Ni]{1270\text{ K}} CO(g) + H_2(g)$

(b) $CO(g) + H_2O(g) \xrightarrow[\text{Catalyst}]{673\text{ K}} CO_2(g) + H_2(g)$

(c) $C_nH_{2n+2} + nH_2O(g) \xrightarrow[Ni]{1270\text{ K}} nCO + (2n+1)\,H_2$

(d) $CO(g) + 2H_2(g) \xrightarrow[\text{Catalyst}]{\text{Cobalt}} CH_3OH(l)$

9. Which is the poorest reducing agent?
(a) Atomic hydrogen
(b) Nascent hydrogen
(c) Dihydrogen
(d) All have same reducing strength

Water and Heavy Water

10. Heavy water is
(a) water at 0°C
(b) water containing Fe, Cr, Mn
(c) D_2O
(d) water obtained after a number of distillations

11. Heavy water is used in atomic reactor as
(a) moderator
(b) coolant
(c) both moderator and coolant
(d) neither coolant nor moderator

12. Permutit is the technical name given to
(a) aluminates of calcium and sodium
(b) hydrated silicate of aluminium and sodium
(c) silicates of calcium and magnesium
(d) silicates of calcium and sodium

13. Demineralised water is obtained by **[NCERT]**
(a) boiling (b) treating with calgon
(c) ion-exchange resins (d) All of these

14. If same mass of liquid water and a piece of ice is taken, then why is the density of ice less than that of liquid water? **[NCERT Exemplar]**
(a) Because ice is a solid
(b) Because molecules of ice are closely packed
(c) Because vacant spaces are present in the crystal lattice
(d) The given statement is wrong

15. Which of the following statements do not define the characteristic property of water "water is a universal solvent".?
(a) It has high liquid range
(b) It has very low dielectric constant
(c) It can dissolve maximum number of compounds
(d) None of the above

16. The boiling point of water is high because
(a) water molecule is linear
(b) water molecule is not linear
(c) water molecules possess covalent bond between H and O
(d) water molecules associate due to H-bonding

17. When two ice cubes are pressed over each other they unite to form one cube. Which of the following forces are responsible to hold them together?
(a) Ionic interaction
(b) van der Waals' forces
(c) Covalent interaction
(d) Hydrogen bond formation

18. When zeolite which is hydrated sodium aluminium silicate is treated with hard water, the sodium ions are exchanged with
(a) H^+ ions
(b) Mg^{2+} ion
(c) Ca^{2+} ion
(d) Both Ca^{2+} and Mg^{2+}

19. In the reactions of water with F_2, water acts as **[NCERT]**
(a) oxidant (b) reductant
(c) Both (a) and (b) (d) None of these

20. Deionised water is obtained by passing hard water through
(a) anion exchanger
(b) zeolite
(c) cation exchanger
(d) Both anion and cation exchanger

21. Which of the following ions will cause hardness in water sample? **[NCERT Exemplar]**
(a) Ca^{2+} (b) Na^+ (c) Cl^- (d) K^+

22. Which of the following compounds is used for water softening? **[NCERT Exemplar]**
(a) $Ca_3(PO_4)_2$ (b) Na_3PO_4
(c) $Na_6P_6O_{18}$ (d) Na_2HPO_4

Hydrogen Peroxide

23. Hydrogen peroxide is obtained by the electrolysis of …… . **[NCERT Exemplar]**
(a) water (b) sulphuric acid
(c) hydrochloric acid (d) fused sodium peroxide

24. In laboratory, H_2O_2 is prepared by
(a) cold $H_2SO_4 + BaO_2$ (b) $HCl + BaO_2$
(c) conc. $H_2SO_4 + Na_2O_2$ (d) $H_2 + O_2$

25. The H—O—O bond angle in H_2O_2 is
(a) 107.28° (b) 97° (c) 104.5° (d) 109.28°

26. H_2O_2 is manufactured these days
(a) by burning hydrogen in excess of oxygen
(b) by the action of H_2O_2 on BaO_2
(c) by the action of H_2SO_4 on Na_2O_2
(d) by electrolysis of 50% H_2SO_4

27. Hydrogen peroxide is …… . **[NCERT Exemplar]**
(a) an oxidising agent
(b) a reducing agent
(c) Both an oxidising and a reducing agent
(d) neither oxidising nor reducing agent

28. The oxide that gives H_2O_2 on treatment with dilute H_2SO_4 is **[NCERT Exemplar]**
(a) PbO_2 (b) $BaO_2 \cdot 8H_2O + O_2$
(c) MnO_2 (d) TiO_2

29. When sodium peroxide is treated with dilute sulphuric acid, we get **[NCERT Exemplar]**
(a) sodium sulphate and water
(b) sodium sulphate and oxygen
(c) sodium sulphate, hydrogen and oxygen
(d) sodium sulphate and hydrogen peroxide

30. The volume strength of 1.5 N H_2O_2 solution is
(a) 16.8 L (b) 8.4 L
(c) 4.2 L (d) 5.2 L

31. The strength of 5 volume H_2O_2 is [**NCERT** Exemplar]

(a) 15 (b) 1.5 (c) 150 (d) 0.15

32. Phosphoric acids is preferred over sulphuric acid in preparing hydrogen peroxide from peroxides because [**NCERT** Exemplar]

(a) H_2SO_4 acts as a reducing agent
(b) H_2SO_4 gives $BaSO_4$ which is difficult to separate
(c) H_2SO_4 acts as catalyst
(d) Both (b) and (c)

Hydrides

33. Non-stoichiometric hydrides are

(a) hydrides of all *d*-block elements
(b) deficient in hydrogen
(c) the hydrides having hydrogen atom in interstitial sites
(d) Both (b) and (c)

34. Which of the following hydrides is electron precise hydride? [**NCERT** Exemplar]

(a) B_2H_6 (b) NH_3 (c) H_2O (d) CH_4

35. Elements of which of the following group(s) of Periodic Table do not form hydrides? [**NCERT** Exemplar]

(a) Groups 7, 8, 9 (b) Group 13
(c) Group 15, 16, 17 (d) Group 14

36. Only one element of …… forms hydride [**NCERT** Exemplar]

(a) Group 6 (b) Group 7
(c) Group 8 (d) Group 9

37. When electric current is passed through an ionic hydride in the molten state,

(a) hydrogen is liberated at the cathode
(b) hydrogen is liberated at the anode
(c) hydride ion migrates towards cathode
(d) no reaction takes place

38. The characteristics of an electron deficient hydride with respect to its structure and chemical reactions is [**NCERT**]

(a) these behave as Lewis acids
(b) these reacts with metals as well as non-metals
(c) these have trigonal planar shape
(d) All of the above

39. Saline hydrides are known to react with water violently producing fire. The fire cannot be extinguished by CO_2 because [**NCERT**]

(a) CO_2 is lighter than the gas evolved
(b) CO_2 is heavier than the gas evolved
(c) CO_2 gets reduced by the evolved gas
(d) CO_2 gets oxidised by the evolved gas

40. Metallic hydrides are useful for hydrogen storage because [**NCERT**]

(a) they reacts with hydrogen and form stable compound
(b) they absorb H-atoms
(c) they adsorb H-atoms
(d) they form unstable compounds with hydrogen

Round II (Mixed Bag)

Only One Correct Option

1. Which of the following reactions produces hydrogen?

(a) $H_2S_4O_8 + H_2O$
(b) $BaO + HCl$
(c) $Mg + H_2O$
(d) $Na_2O_2 + 2HCl$

2. Which of the following metals evolves hydrogen on reacting with cold dilute HNO_3?

(a) Fe (b) Cu
(c) Al (d) Mg

3. Which of the following is not true?

(a) D_2O freezes at lower temperature than H_2O
(b) Reaction between H_2 and Cl_2 is much faster than D_2 and Cl_2
(c) Ordinary water electrolysed more rapidly than D_2O
(d) Bond dissociation energy of D_2 is greater than H_2

4. The reagent commonly used to determine hardness of water titrimetrically is

(a) oxalic acid
(b) sodium thiosulphate
(c) sodium citrate
(d) disodium salt of EDTA

5. Polyphosphates are used as water softening agents because they

(a) form soluble complexes with anionic species
(b) precipitate anionic species
(c) precipitate cationic species
(d) form soluble complexes with cationic species

6. An element reacts with hydrogen to form a compound *A*, which on treatment of water liberates hydrogen gas. The element can be

(a) chlorine (b) selenium
(c) calcium (d) nitrogen

7. Which one of the following is used for reviving the exhausted 'permutit'?

(a) HCl solution (b) 10% $CaCl_2$ solution
(c) 10% $MgCl_2$ solution (d) 10% NaCl solution

8. What is formed when calcium carbide reacts with heavy water?

(a) C_2D_2 (b) CaD_2
(c) CaD_2O (d) CD_2

9. Steam is passed over red hot carbon and the gaseous products cooled and passed first through a solution of alkali, then through ammoniacal cuprous chloride and then through water. What is finally collected?

(a) CO_2
(b) A mixture of hydrocarbons
(c) $CO + H_2$
(d) H_2

10. Which of the following statements about H_2O_2 is not true?

(a) H_2O_2 is used to clean oil paintings
(b) H_2O_2 acts as oxidising as well as reducing agent
(c) Two hydroxyl groups in H_2O_2 lie in the same plane
(d) It retains same structure in liquid and solid form

11. The volume strength of perhydrol is

(a) 20 (b) 30
(c) 100 (d) 10

12. Which of the following equations depict the oxidising nature of H_2O_2? **[NCERT Exemplar]**

(a) $2MnO_4^- + 6H^+ + 5H_2O_2 \longrightarrow 2Mn^{2+} + 8H_2O + 5O_2$
(b) $2Fe^{3+} + 2H^+ + H_2O_2 \longrightarrow 2Fe^{2+} + 2H_2O + O_2$
(c) $2I^- + 2H^+ + H_2O_2 \longrightarrow I_2 + 2H_2O$
(d) $KIO_4 + H_2O_2 \longrightarrow KIO_3 + H_2O + O_2$

13. Out of the following metals which will give H_2 on reaction with NaOH

I : Zn II : Mg
III : Al IV : Si

(a) I, II, III, IV
(b) I, III, IV
(c) II, IV
(d) I, III

14. In the absence of hydrogen bonding, boiling point of water would have been

(a) 100°C (b) 0°C
(c) −100°C (d) 373°C

15. H_2 gas is liberated at cathode and anode both by electrolysis of the following aqueous solutions except in

(a) NaH (b) HCOONa
(c) NaCl (d) LiH

16. Which is true statement?

(a) The layer of ice on the surface of river in the winter acts as a thermal insulator between the water below and the air above
(b) The fish and other marine organisms are enabled to survive long periods of freezing weather due to the fact that ice is lighter than water
(c) Both (a) and (b) are correct
(d) None of the above

17. H_2O_2 can be obtained when following reacts with H_2SO_4 except with

(a) PbO_2 (b) BaO_2 (c) Na_2O_2 (d) SrO_2

18. The increasing order of bond dissociation energy in **[NCERT]**

(a) $H—H < D—D < F—F$ (b) $F—F < H—H < D—D$
(c) $F—F < D—D < H—H$ (d) $D—D < F—F < H—H$

19. The increasing order of reducing property of NaH, MgH_2 and H_2O is **[NCERT]**

(a) $NaH < H_2O < MgH_2$ (b) $MgH_2 < H_2O < NaH$
(c) $H_2O < MgH_2 < NaH$ (d) $NaH < MgH_2 < H_2O$

20. Arrange CaH_2, BeH_2 and TiH_2 in the order of increasing electrical conductance. **[NCERT]**

(a) $BeH_2 < CaH_2 < TiH_2$ (b) $TiH_2 < CaH_2 < BeH_2$
(c) $BeH_2 < TiH_2 < CaH_2$ (d) $TiH_2 < BeH_2 < CaH_2$

21. Consider the reactions,

(A) $H_2O_2 + 2HI \longrightarrow I_2 + 2H_2O$
(B) $HOCl + H_2O_2 \longrightarrow H_3O^+ + Cl^- + O_2$

Which of the following statements is correct about H_2O_2 with reference to these reactions? Hydrogen peroxide is …… . **[NCERT Exemplar]**

(a) an oxidising agent in both (A) and (B)
(b) an oxidising agent in (A) and reducing agent in (B)
(c) an reducing agent in (A) and oxidising agent in (B)
(c) a reducing agent in both (A) and (B)

More than One Correct Option

22. H_2O_2 is "5.6 volume", then

(a) it is 1.7% weight by volume
(b) it is 1 N
(c) it is 1 M
(d) it is 5.6 M

23. Which of the following statement(s) is/are correct in the case of heavy water? **[NCERT Exemplar]**

(a) Heavy water is used as a moderator in nuclear reactor
(b) Heavy water is more effective as solvent than ordinary water
(c) Heavy water is more associated than ordinary water
(d) Heavy water has lower boiling point than ordinary water

24. Which of the following statements about hydrogen are correct? [**NCERT** Exemplar]

(a) Hydrogen has three isotopes of which protium is the most common
(b) Hydrogen never acts as cation in ionic salts
(c) Hydrogen ion H^+, exists freely in solution
(d) Dihydrogen does not acts as a reducing agent

25. Some of the properties of water are described below. Which of them is/are not correct? [**NCERT** Exemplar]

(a) Water is known to be a universal solvent
(b) Hydrogen bonding is present to a large extent in liquid water
(c) There is no hydrogen bonding in the frozen state of water
(d) Frozen water is heavier than liquid water

26. Select the correct statement(s) about lime light

(a) Oxy-hydrogen flame
(b) Used in welding
(c) Temperature of lime light is sufficient to melt even platinum
(d) Produced in an endothermic reaction

27. Which of the following substances catalyses the rate of *ortho-para* conversions?

(a) NO (b) NO_2 (c) O_2 (d) Co^{2+}

Assertion and Reason

Directions (Q. Nos. 28 to 32) *Each of these questions contains two statements : Statement* I (*Assertion*) *and Statement* II (*Reason*). *Each of these questions also has four alternative choices, only one of which is the correct answer. You have to select one of the codes* (*a*), (*b*), (*c*), (*d*) *given below :*

(a) Statement I is true; Statement II is true; Statement II is a correct explanation for Statement I.
(b) Statement I is true; Statement II is true; Statement II is not a correct explanation for Statement I.
(c) Statement I is true; Statement II is false.
(d) Statement I is false; Statement II is true.

28. **Statement I** Permanent hardness of water is removed by treatment with washing soda.

Statement II Washing soda reacts with soluble magnesium and calcium sulphate to form insoluble carbonates. [**NCERT** Exemplar]

29. **Statement I** Some metals like platinum and palladium, can be used as storage media for hydrogen.

Statement II Platinum and palladium can adsorb large volumes of hydrogen. [**NCERT** Exemplar]

30. **Statement I** When blood is added to a solution of H_2O_2, the solution bubbles furiously.

Statement II Catalase (an enzyme) present in blood decomposes H_2O_2 and produces bubbles of O_2.

31. **Statement I** In space crafts H_2 gas is used in fuel cells for generating electrical energy and for providing clean drinking water to the astronauts.

Statement II A fuel cell may have an alkaline or acidic electrolyte.

32. **Statement I** Drinking of heavy water (D_2O) mixed water (H_2O) could prove fatal.

Statement II There is slower rate of transfer of D^+ compared with that of H^+ ion in acid-base reactions involved in enzyme catalysis.

Comprehension Based Questions

Directions (Q. Nos. 33 to 35) Depletion of resources of fossil fuels will at some future time make hydrogen, either for use directly by combustion and electrochemically in fuel cells or indirectly *via* hydrogenation of coal, the major alternative to nuclear energy; hence, arises the current interest in the so-called hydrogen economy.
A thermochemical cycle for hydrogen production involves at least one element that can exist in two different oxidation states.

$$2H_2O \longrightarrow 2H_2 + O_2$$

33. Production of H_2 from H_2O requires a net input of energy that would come from

(a) nuclear source
(b) solar source
(c) Both (a) and (b)
(d) None of the above

34. In the above thermochemical cycle, $FeCl_2$ is one of the catalyst involved and thus regenerated at the end of the reaction, after formed into

(a) $FeCl_3$, FeO, Fe_2O_3
(b) $FeCl_3$, Fe_2O_3, Fe_3O_4
(c) $FeCl_3$, FeO
(d) $FeCl_3$, Fe_3O_4

35. H_2 is produced in the following thermochemical reaction

(a) $FeCl_2 + H_2O \longrightarrow$
(b) $Fe_3O_4 + Cl_2 + HCl \longrightarrow$
(c) $FeO + H_2O \longrightarrow$
(d) $FeCl_3 + H_2O \longrightarrow$

Directions (Q. Nos. 36 and 37) Research scholar *A* added zinc pieces into aqueous $FeCl_3$ solution and performed some experiments with resultant solution. Research scholar *B* passed H_2 gas into aqueous $FeCl_3$ solution and performed some experiments with resultant solution."

36. Yellow coloured $FeCl_3$ solution changed to light green (appeared as colourless) in the experiment of

(a) *A* (b) *B*
(c) Both (a) and (b) (d) None of these

37. Select the correct statements.

(a) Zn pieces liberate nascent hydrogen on reaction with acidic solution of $FeCl_3$
(b) $FeCl_3$ solution is reduced to $FeCl_2$ in the experiments of *A* and *B* both
(c) Blue colour complex is formed in both the experiments on reaction with $K_4[Fe(CN)_6]$
(d) All of the above

Previous Years' Questions

38. Very pure hydrogen (99.9) can be made by which of the following processes? **[AIEEE 2010]**

(a) Reaction of methane with steam
(b) Mixing natural hydrocarbons of high molecular weight
(c) Electrolysis of water
(d) Reaction of salts like hydrides with water

39. In context with the industrial preparation of hydrogen from water gas $(CO + H_2)$, which of the following is the correct statement? **[AIEEE 2008]**

(a) CO and H_2 are fractionally separated using differences in their densities
(b) CO is removed by absorption in aqueous Cu_2Cl_2 solution
(c) H_2 is removed through occlusion with Pd
(d) CO is oxidised to CO_2 with steam in the presence of a catalyst followed by absorption of CO_2 in alkali

40. Which one of the following processes will produce hard water? **[AIEEE 2003]**

(a) Saturation of water with $CaCO_3$
(b) Saturation of water with $MgCO_3$
(c) Saturation of water with $CaSO_4$
(d) Addition of Na_2SO_4 to water

the Guidance

Round I

1. *Ortho* and *para* hydrogen show different spin in a hydrogen molecule, hence, these are not the isotopes.

2. $_1H^3$ has 3 nucleons (1 proton + 2 neutrons) and one electron, so sum of these is $3 + 1 = 4$.

4. Hydrogen like halogen accept an electron readily to achieve nearest inert gas configuration.

7. $H_2 \longrightarrow H + H, \ \Delta H = +\text{ve}$

This reaction is favoured by low pressure and high temperature.

9. Because dihydrogen is less reactive.

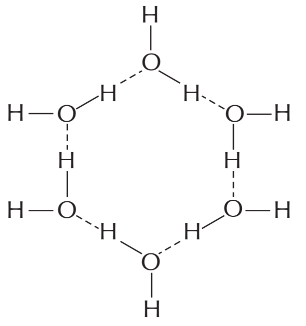
11. Heavy water is used as a moderator to slow down the speed of fast moving neutrons and also as a coolant.

12. It is $Na_2Al_2Si_2O_8 \cdot xH_2O$.

13. Water which is free from all soluble minerals salts is called demineralised water. Demineralised water is obtained by passing water successively through a cation exchange and an anion exchange resins. In cation exchanger, Ca^{2+}, Mg^{2+}, Na^+ and other cations present in water are removed by exchanging them with H^+ ions while in anion exchanger, Cl^-, HCO_3^-, SO_4^{2-}, etc., present in water are removed by exchanging them with OH^- ions.

$$\underset{\text{(released in cation exchanger)}}{H^+} + \underset{\text{(released in anion exchanger)}}{OH^-} \longrightarrow H_2O$$

14. In ice, molecules of H_2O are not packed so closely as in liquid water. There exists vacant spaces in the crystal lattice. This results in larger volume and lower density (density = mass/volume).



Hexagonal honey comb structure of ice

15. Water has high dielectric constant, *i.e.*, 82, high liquid range and can dissolve maximum number of compounds. That's why it is used as universal solvent.

19. Fluorine being more electronegative removes oxygen from water and itself gets reduced to fluoride ion.

$$\underset{\text{oxidant}}{2F_2(g)} + \underset{\text{reductant}}{2H_2O(l)} \longrightarrow O_2(g) + 4H^+(aq) + 4F^-(aq)$$

$$\underset{\text{oxidant}}{3F_2(g)} + \underset{\text{reductant}}{3H_2O(l)} \longrightarrow O_3(g) + 6H^+(aq) + 6F^-(aq)$$

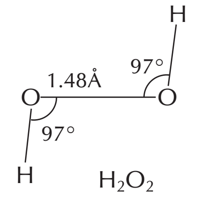
In these reactions, water acts as a reducing agent and hence itself gets oxidised to either oxygen or ozone. Fluorine acts as an oxidising agent and hence is itself gets reduced to F^- ion.

20. Deionised or demineralised water is obtained by passing hard water through both cation and anion exchangers one after the other.

21. Bicarbonates, chlorides and sulphates of Ca and Mg are responsible for the hardness of water.

24. $H_2SO_4 + BaO_2 \longrightarrow BaSO_4 + H_2O_2$

25.



26. Electrolysis of 50% sulphuric acid gives per disulphuric acid ($H_2S_2O_8$) which on distillation yields 30% solution of hydrogen peroxide.

29. $Na_2O_2 + H_2SO_4 \longrightarrow Na_2SO_4 + H_2O_2$

30. Volume strength $= 5.6 \times \text{normality}$

$$= 5.6 \times 1.5 = 8.4 \text{ L}$$

31. 5 volumes H_2O_2 solution means that 1 L of 5 volumes H_2O_2 solution on decomposition produces 5 L of O_2 at NTP.

$$\underset{2 \times 34 \text{ g}}{2H_2O_2} \longrightarrow 2H_2O + \underset{22.7 \text{ L at NTP}}{O_2}$$

22.7 L O_2 at NTP will be obtained from $H_2O_2 = 68$ g

$\therefore$ 5 L of O_2 at NTP will be obtained from $H_2O_2 = \dfrac{68 \times 5}{22.7}$ g

$$= 14.98 = 15 \text{ g}$$

But 5 L of O_2 at NTP is produced from 1 L of 5 volumes H_2O_2

$\therefore$ Strength of H_2O_2 solution = 15 g L^{-1}

or percentage strength of H_2O_2 solution $= \dfrac{15}{1000} \times 100 = 1.5\%$

32. H_2SO_4 acts as a catalyst for decomposition of H_2O_2. Therefore, some weaker acids such as H_3PO_4, H_2CO_3 is preferred over H_2SO_4 for preparing H_2O_2 from peroxides.

$$3BaO_2 + 2H_3PO_4 \longrightarrow \underset{\text{(Insoluble)}}{Ba_3(PO_4)_2} + 3H_2O_2$$

33. Non-stoichiometric hydrides are formed by many *d*-block (except metals of 7, 8 and 9 group) and *f*-block elements. These hydrides are always non-stoichiometric, *i.e.*, deficient in hydrogen. In these hydrides hydrogen atom occupies interstitial sites, *e.g.*, $LaH_{2.87}$, $YbH_{2.55}$, $TiH_{1.5-1.8}$, $PdH_{0.6-0.8}$, etc.

34. Water is an electron precise hydride.

37. $M^+H^- \longrightarrow M^+ + \underset{\text{hydride ion}}{H^-}$

$$H^- \longrightarrow \frac{1}{2}H_2 + e^- \text{ (at anode)}$$

38. Electron deficient hydrides are obtained by elements of group 13 like BF_3, $AlCl_3$ etc. Being electron deficient (or electron accepting) these act as Lewis acids. They have trigonal planar geometry and react with metals as well as non-metals.

39. Saline hydrides (such as NaH, CaH_2, etc.), react with water violently to form the corresponding metal hydroxides with the evolution of dihydrogen.

$$NaH(s) + H_2O(l) \longrightarrow NaOH(aq) + H_2(g)$$
$$CaH_2(s) + 2H_2O(l) \longrightarrow Ca(OH)_2(aq) + 2H_2(g)$$

These reactions are so much exothermic that the evolved H_2 catches fire. This type of fire cannot be extinguished by CO_2 because it gets reduced by the hot metal hydride to form sodium formate.

$$NaH + CO_2 \longrightarrow HCOONa$$

40. In metallic hydrides, hydrogen is adsorbed as H-atoms. This property of adsorption of hydrogen on transition metals is widely used as its storage media. Some of the metals such as Pd, Pt can accommodate a very large volume of hydrogen. This property has high potential for hydrogen storage and as a source of energy. Metallic hydrides on heating decompose to form hydrogen and very finely divided metal.

Round II

1. $Mg + 2H_2O \longrightarrow Mg(OH)_2 + H_2\uparrow$

2. Fe and Al become passive by HNO_3 and Cu being less reactive is unable to react. Mg is an active metal and react with dilute HNO_3 to give H_2 gas.

3. D_2O actually has higher freezing point (3.8°C) than water H_2O (0°C).

4. Disodium salt of EDTA is commonly used to determine the hardness of water.

5. Polyphosphates being negatively charged from soluble complexes with cationic species.

6. $Ca + H_2 \longrightarrow CaH_2 \xrightarrow{2H_2O} Ca(OH)_2 + 2H_2$

Thus, the element is calcium.

7. During the softening process, the reaction takes place as

$$Na_2Z + Ca(HCO_3)_2 \longrightarrow CaZ + 2NaHCO_3$$
$$Na_2Z + Mg(HCO_3)_2 \longrightarrow MgZ + 2NaHCO_3$$

After sometime, the zeolite is completely converted into calcium and magnesium zeolites. Eventually, the bed ceases to soften water, *i.e.*, it gets exhausted. At this stage, the supply of hard water is stopped and the exhausted zeolite is reclaimed by treating the bed with a 10% NaCl solution (brine solution) when the following reaction takes place

$$CaZ \text{ or } MgZ + 2NaCl \longrightarrow \underset{\substack{\text{reclaimed}\\ \text{zeolite}}}{Na_2Z} + CaCl_2 \text{ or } MgCl_2$$

8. $\begin{array}{l} Ca : C_2 \\ OD : D \\ OD : D \end{array} \xrightarrow{D_2O} C_2D_2 + Ca(OD)_2$

9. $$\begin{tikzcd} C + H_2O \arrow[r] & CO + H_2 \arrow[d, "KOH"] \\ & K_2CO_3 + H_2\uparrow \end{tikzcd}$$

10. In H_2O_2, the two —OH groups are not in the same plane.

11. Perhydrol is 30% H_2O_2.

∵ 10 vol $H_2O_2 = 3\%$

∴ 30% H_2O_2 has volume $= \frac{10}{3} \times 30 = 100$ volume

12. The reaction in which H_2O_2 is reduced, *i.e.*, oxidation state of oxygen decreases from –1 to –2 depicts the oxidising nature of H_2O_2. *e.g.*,

Reduction

$$2I^- + 2H^+ + \underset{\text{oxidising agent}}{\overset{-1}{H_2O_2}} \longrightarrow \overset{0}{I_2} + 2H_2\overset{-2}{O}$$

Increase in O.S. (oxidation)

13. $Zn + 2NaOH \longrightarrow Na_2ZnO_2 + H_2$

$$2Al + 2NaOH + 2H_2O \longrightarrow NaAlO_2 + 3H_2$$
$$Si + 2NaOH + H_2O \longrightarrow Na_2SiO_3 + 2H_2$$

14. Force of attraction is minimum thus most volatile.

15. (a) $NaH \rightleftharpoons Na^+ + H^-$

At cathode

$$Na^+ + e^- \longrightarrow Na$$
$$Na + H_2O \longrightarrow NaOH + \frac{1}{2}H_2$$

At anode

$$H^+ + e^- \longrightarrow \frac{1}{2}H_2 + e^-$$

(b) $$HCOONa \rightleftharpoons HCOO^- + Na^+$$

At cathode same as above

At anode

$$HCOO^- \longrightarrow \frac{1}{2}H_2 + CO_2 + e^-$$

(c) $$NaCl \rightleftharpoons Na^+ + Cl^-$$

At cathode same as above

At anode

$$Cl^- \longrightarrow \frac{1}{2}Cl_2 + e^-$$

(d) $$LiH \rightleftharpoons Li^+ + H^-$$

At cathode

$$Li^+ + e^- \longrightarrow Li$$

$$Li + H_2O \longrightarrow LiOH + \frac{1}{2}H_2$$

At anode

$$H^- \longrightarrow \frac{1}{2}H_2 + e^-$$

16. Both the given statements are correct.

17. PbO_2 is a dioxide, not a true peroxide due to the absence of —O—O— (peroxide) linkage. Hence, it does not give H_2O_2 with dilute H_2SO_4.

18. Shorter the bond length, higher the bond dissociation energy. Thus, the correct order is

$$F—F < H—H < D—D$$

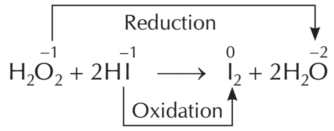
19. Metal hydrides are stronger reducing agents than non-metal hydrides. Thus, H_2O is a weaker reducing agent and NaH due to more electropositive nature of Na is strongest reducing agent among the given. Thus, the correct order is

$$H_2O < MgH_2 < NaH$$

20. More the ionic character, higher is the electrical conductance and larger the electronegativity difference, higher is the ionic character. Thus, the order of electrical conductance is

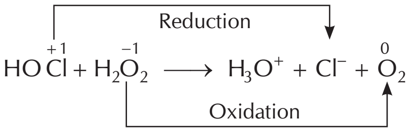
$$BeH_2 < CaH_2 < TiH_2$$

21. (A)



$$\overset{-1}{H_2O_2} + 2H\overset{-1}{I} \longrightarrow \overset{0}{I_2} + 2H_2\overset{-2}{O}$$

Thus, here H_2O_2 oxidises HI into I_2 hence, it behaves as oxidising agent.



$$HO\overset{+1}{Cl} + H_2\overset{-1}{O_2} \longrightarrow H_3O^+ + Cl^- + \overset{0}{O_2}$$

Here, H_2O_2 reduces HOCl to Cl^-, thus, it acts as reducing agent.

22. $$\text{Normality} = \frac{\text{Volume strength}}{5.6} = \frac{5.6}{5.6} = 1\,N$$

It is 1.7% weight by volume.

23. Boiling point of heavy water is higher than ordinary water and it is not as effective in the form of solvent as water due to its low dielectric constant.

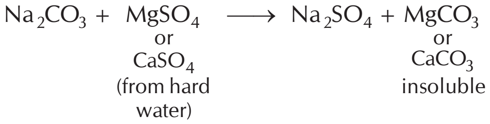
24. Among the three isotopes of hydrogen, protium is the most common. In ionic salts, hydrogen exists as hydride (H^-) ion.

25. Water is a universal solvent and exists to a larger extent in liquid state. It also contains H-bonding in frozen state. The density of ice is lower than that of water (liquid) due to the presence of vacant spaces.

26. Lime light is produced in an exothermic reaction.

27. Paramagnetic substance or ions, which contain unpaired electrons, catalyst *ortho-para* conversion.

28.



$$Na_2CO_3 + \underset{\substack{\text{or}\\ CaSO_4\\ \text{(from hard}\\ \text{water)}}}{MgSO_4} \longrightarrow Na_2SO_4 + \underset{\substack{\text{or}\\ CaCO_3\\ \text{insoluble}}}{MgCO_3}$$

29. Since metals like Pd and Pt adsorb a large volume of hydrogen, these are used as a storage media for it.

30. When blood is added to a solution of H_2O_2, the solution bubble furiously because of the evolution of O_2 which is obtained by the decomposition of H_2O_2 by catalysts present in the blood.

31. Both the statements are correct.

32. Drinking of D_2O mixed water could prove fatal because of the slower transfer rate of D^+ as compared to H^+ in acid-base reaction involved in enzyme catalysis.

33. Nuclear and solar both type of energy source help in the production of H_2 from H_2O.

34. $FeCl_2$ will be regenerated at the end of reaction after formed into $FeCl_3$ and Fe_3O_4.

35. $8FeCl_2 + 8H_2O \xrightarrow{h\nu} 2Fe_3O_4 + 2FeCl_3 + 3H_2 + 10HCl$

36. In the experiment of scholar *A*, the colour get changed because nascent H is obtained on adding zinc which is more reactive. The molecular hydrogen reduces Fe^{3+} into Fe^{2+}.

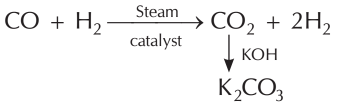
37. Zn generates nascent H.

$$FeCl_3 + [H] \longrightarrow FeCl_2 + HCl$$

38. Hydrides are instant source of hydrogen of higher purity. They react with H_2O forming H_2 gas

$$CaH_2 + 2H_2O \longrightarrow Ca(OH)_2 + 2H_2$$

39. CO is oxidised to CO_2 with steam in the presence of a catalyst followed by absorption of CO_2 in alkali



$$CO + H_2 \xrightarrow[\text{catalyst}]{\text{Steam}} \underset{\substack{\downarrow \text{KOH}\\ K_2CO_3}}{CO_2} + 2H_2$$

40. Alkaline earth metal salts are causing hardness. Temporary hardness caused by soluble Ca and Mg hydrogen carbonates. Calcium and magnesium soluble sulphates and chlorides cause permanent hardness.

Alkali Metals and Their Compounds

10.1 Alkali Metals

Lithium ($Z = 3$), sodium ($Z = 11$), potassium ($Z = 19$), rubidium ($Z = 37$), caesium ($Z = 55$) and francium ($Z = 87$) are the elements of IA (or 1) group of the Periodic Table. These elements because of the highly alkaline nature of their water soluble hydroxides are known as **alkali metals.**

Occurrence

The alkali metals occur in nature only in the form of their compounds, *i.e.,* these never found in free state as these are highly reactive. Sodium and potassium are the sixth and seventh most abundant elements in the earth's crust. Among alkali metals, the less electropositive one, *i.e.,* lithium is found in the form of silicate while the more electropositive elements are found in the form of their chlorides.

Compounds of sodium and potassium are the most abundant, while those of remaining alkali metals occur in nature rarely. Francium is a radioactive element and short lived.

The elements in which the last (valence) electron enters in the ns energy shell are called s-block elements. The maximum capacity of this shell is of two electrons, thus, this block includes two groups : IA or I group having ns^1 configuration and IIA or 2 group with ns^2 configuration. This block lie on the extreme left of the Periodic Table. Because of the presence of 1 or 2 electrons, these elements generally form ionic compounds (with the execption of Li *and* Be).

Electronic Configuration

Atoms of alkali metals have single valence electron and form unipositive cation when they take part in compound formation. All the alkali metals are **paramagnetic** because of the presence of single unpaired valence electron in their valence shell. General outer electronic configuration of alkali metals is ns^1 (where, $n = 2, 3, 4, 5, 6$ and 7). Their penultimate quantum layers have the stable electronic configuration of noble gas s^2p^6, (for lithium s^2).

Element	Configuration
Li(3)	[He] $2s^1$
Na(11)	[Ne] $3s^1$
K(19)	[Ar] $4s^1$
Rb(37)	[Kr] $5s^1$
Cs(55)	[Xe] $6s^1$
Fr(87)	[Rn] $7s^1$

The alkali metal cations, Li^+, Na^+, K^+, Rb^+ and Cs^+ are diamagnetic because of the absence of unpaired electrons. All these cations have stable s^2p^6 noble gas configuration.

Due to the presence of only one electron in the valence shell, they exhibit only +1 oxidation state. *The relatively simple chemistry of alkali metals is probably due to the ease with which their valence electron can be lost in order to achieve stable noble gas electronic configuration.*

General Trends in Physical Properties of Elements

Alkali metals show following trends in their physical properties.

(i) Physical Appearance

They are all silvery white, soft and malleable metals. They are so soft that they can easily be cut with a knife. The reason of softness of alkali metals is the presence of weak metallic bonding because of the presence of only one valence electron in them. This softness increases down the group as increase in number of non-bonding electrons down the group increases repulsion resulting in decrease in cohesive force and energy.

(ii) Atomic and Ionic Radius

Their atomic and ionic radii are largest in the respective period and increases as we move down the group.

(iii) Density

All are light metals with low densities, Li, Na and K are even lighter than water. Density generally increases on moving down the group but K has slightly lower density as compared to Na due to increase in its atomic volume. Li *is the lightest metal known.*

(iv) Melting and Boiling Points

These metals have very low melting and boiling points which decrease on moving down the group. The reason for their low melting and boiling points is the presence of weak intermetallic bonds, which also become more weaker as the size increases.

(v) Ionisation Energy

The first ionisation enthalpy of these elements is the lowest among corresponding period, however their second ionisation enthalpy is very high. On moving down the group, ionisation enthalpies decrease progressively. The ionisation energies of K, Rb and Cs are so less that these show photoelectric effect, *i.e.*, these can emit electrons even with fall of light on them.

(vi) Electropositive or Metallic Character

Alkali metals are the most electropositive in the Periodic Table and their metallic character increases on moving down the group. These all are metals and thus, are good conductors of heat and electricity. They exhibit metallic lusture which is due to the oscillation of free electrons.

(vii) Electronegativity

Because of their electropositive nature, alkali metals have very low tendency to attract the electrons, *i.e.,* their electronegativity is low. The electronegativity decreases from Li to Cs as the electropositive character increases.

(viii) Flame Colouration

The vapours of alkali metals (in the form of their chlorides) impart characteristic colours to the flame. The reason for this is that the loosely bound electron gets excited on heating and jumps to higher energy level. When this excited electron returns to its ground state, energy is emitted in the form of radiations. This extra energy, in visible region give characteristic colour to the flame.

Different alkali metals give different colour to the flame as they have different ionisation energies, *e.g.*, colour obtained by lithium is caramine red, sodium is yellow, K is violet, Rb is violet rose and Cs is blue. In this test, concentrated HCl is added to convert the given salt into volatile chloride.

The various physical properties of alkali metals can be summarised in the form of table as

Table 10.1 **Physical Properties of Alkali Metals**

Property	Lithium	Sodium	Potassium	Rubidium	Caesium
Atomic number	3	11	19	37	55
Molar mass (g mol^{-1})	6.94	22.99	39.10	85.48	132.91
Density at 20°C (g cm^{-3})	0.534	0.972	0.859	1.530	1.903
Molar volume (cm^3 mol^{-1})	12.97	23.68	45.36	55.80	69.95
Melting point (°C)	180.0	97.8	64.0	38.9	28.7
Boiling point (°C)	1326	883	756	688	690
Atomic radius (Å)	1.34	1.54	1.96	2.11	2.25
Ionic radius (Å)	0.60	0.95	1.33	1.48	1.69
Heat of atomisation (kJ mol^{-1})	159.0	108.1	90.2	82.1	78.2
Ionisation energy (kJ mol^{-1})	520.1	495.2	418.7	403.0	375.7
Electronegativity	1.0	0.9	0.8	0.8	0.7
Flame colouration	Crimson red	Golden yellow	Violet	Violet	Violet

(ix) Hydration Enthalpy and Conductivity

The amount of energy released when one mole of gaseous ions combine with water to form hydrated ions is called the **hydration enthalpy**. The extent of hydration varies inversely with size. Thus, the degree of hydration decreases down the group from Li^+ to Cs^+. Consequently the ionic size of these ions in aqueous solution follows the order

$$Li^+ > Na^+ > K^+ > Rb^+ > Cs^+$$

Hence, among alkali metal ions, Cs^+ has the highest and Li^+ has the lowest mobility in aqueous solution.

(x) Reducing Character

Because of their strong tendency to lose the *s*-electron, **the alkali metals are powerful reducing agents.** Lithium in aqueous solution is strong reducing agent as compared to Cs. This is probably due to high hydration energy of small lithium ion, which compensates for high ionisation energy. As a result of high hydration energy, standard reduction potential of Li is lowest among alkali metals.

Thus, most powerful reducing agent in solution is lithium. Reducing power of alkali metals in aqueous solution is

$$Li > Na > K > Rb > Cs$$

Sample **Problem 1** *The alkali metals are low melting. Which of the following alkali metal is expected to melt if the room temperature rises to 30°C?* [**NCERT** Exemplar]

(*a*) Na (*b*) K (*c*) Rb (*d*) Cs

Interpret (*d*) The melting point of caesium, Cs is 28.7°C which is below 30°C. Thus, as the temperature rises above 30°C, it gets melted.

Hot Spot 1

TRENDS in Chemical Properties of Group 1 Elements

The questions based on this topic have seen frequently in JEE Main (AIEEE) examination. The question may be direct or indirect reason based. So deep study of the topic is required.

The chemical properties of alkali metals are as follows

(a) Reactivity

Due to the presence of only one electron in their outermost shell, alkali metals are highly reactive and their reactivity towards all reagents (except nitrogen) increases down the group from lithium to caesium. To prevent their reactivity, these elements are usually stored in kerosene. Lithium is the lightest or least dense of all metals, with a density roughly half that of water, thus it being lighter floats on kerosene. Hence, it is kept wrapped in paraffin wax.

(b) Nature of Compounds

The metals form ionic compounds because they readily give up the *s*-electron of their valence shell. Small highly polarizing ion such as Li^+ tend to form covalent compounds. Most other cations of IA group elements are large and have low charge densities. Hence, they form stable compounds even with polarizing ions such as carbonate, peroxides, tri-iodide etc. **LiCl is soluble in pyridine because of its covalent nature.** Bond present in the molecules like Li_2, Na_2, K_2, etc., is covalent. It should be noted that alkali metals form diatomic molecules such as Li_2, Na_2, K_2, etc. to the extent of 1% in vapour state.

(c) Reaction with Air
(Nature of Oxides and Hydroxides)

Alkali metals when exposed to air, react readily with O_2, H_2O and CO_2 and get tarnished. That's why these metals must be protected from exposure to air. However, when burnt in air, lithium forms monoxide (Li_2O) only, sodium forms monoxide in limited O_2 and peroxide in excess O_2. Other alkali metals form largely the superoxides. In the presence of atmospheric oxygen, we get a mixture of oxides in the case of rest of the metals.

$$2Li + \frac{1}{2} O_2 \longrightarrow Li_2O \qquad 2Na + O_2 \longrightarrow Na_2O_2$$

$$2Na + \frac{1}{2} O_2 \longrightarrow Na_2O \qquad Rb + O_2 \longrightarrow \underset{\substack{\text{(Superoxide,}\\ \text{containing } O_2^- \text{ ion)}}}{RbO_2}$$

The formation and stability of these oxides can be explained on the basis of lattice energy effects. Li^+ ion being a small ion has a strong positive field around it and can stabilise only a small anion, O^{2-} whereas Na^+ being a large cation can stabilise a large ion and so on.

O^{2-}
oxide ion

$[—O—O—]^{2-}$
peroxide ion

superoxide ion

In order to prepare any particular oxide, peroxide or superoxide for K, Rb and Cs with the help of atmospheric oxygen, the metal is dissolved in NH_3 and then, treated with required quantity of oxygen to get requisite product.

The higher oxides, *viz.*, peroxides and superoxides are strong oxidising agents. They react with dilute acids forming hydrogen peroxide and oxygen respectively.

$$Na_2O_2 + H_2SO_4 \longrightarrow Na_2SO_4 + H_2O_2$$

$$4KO_2 + 2H_2SO_4 \longrightarrow 2K_2SO_4 + 2H_2O + 3O_2$$
$$2KO_2 + 2H_2O \longrightarrow 2KOH + H_2O_2 + O_2$$

The peroxides are diamagnetic in nature (all the electrons are paired) and are regarded as the salts of the dibasic acid, H_2O_2. The superoxides are paramagnetic and coloured as odd electron bond is present between two oxygen atoms. Yellow colour of Na_2O_2 is probably due to the presence of small amount of superoxide. Superoxides are even stronger oxidising agents than peroxides.

The normal oxide 'M_2O' react with water to form hydroxides.

$$M_2O + H_2O \longrightarrow 2MOH$$

The basic nature of the oxides (M_2O) increases gradually on moving down in the group. The hydroxides (MOH) are hygroscopic, readily absorb CO_2 from air and destroy glass. These are colourless, strong alkaline and corrosive compounds. These are soluble in water and dissolve with the evolution of heat. The hydroxides are thermally stable except LiOH. The relative strength of the hydroxides increases from LiOH to CsOH.

$$CsOH > RbOH > KOH > NaOH > LiOH$$

They dissociate in solution almost completely.

$$Na + O_2 \longrightarrow Na_2O \xrightarrow{H_2O,\ air} NaOH \xrightarrow{CO_2,\ air} Na_2CO_3$$

(d) Reaction with Water

All alkali metals are more reactive than hydrogen. Thus, these are easily and readily oxidised by water. The reaction with water is so exothermic that the heat generated often ignites the $H_2(g)$ produced, if air is present. These metals displace hydrogen from water.

The vigorous nature of the reaction of water with alkali metals increases from Li to Cs. Lithium is only slowly attacked by water at 298 K, though it liberates more energy in this reaction. Sodium reacts more vigorously, whereas potassium catches fire and rubidium and caesium react violently or explosively.

The fact that lithium reacts with water less vigorously, may probably be due to its higher melting point. Other alkali metals have low melting points (below 373 K) and melt due to the heat liberated in their initial reaction with water, thus exposing more metal surface to attack. The reaction, therefore, proceeds much more rapidly than with lithium which remains in solid state.

(e) Reaction with Oxidising and Non-oxidising Acids

The alkali metals replace hydrogen from non-oxidising acids (*e.g.,* HCl, dil H_2SO_4). While reacting with oxidising acids such as conc. H_2SO_4, conc HNO_3 and dil HNO_3, these metals do not replace hydrogen but H_2S, N_2O and NH_3 are formed respectively as,

$$5H_2SO_4 + 8M \longrightarrow 4M_2SO_4 + H_2S + 4H_2O$$
$$10HNO_3(\text{conc}) + 8M \longrightarrow 8MNO_3 + N_2O + 5H_2O$$
$$9HNO_3(\text{dil}) + 8M \longrightarrow 8MNO_3 + NH_3 + 3H_2O$$

(Here, M = alkali metals)

(f) Reaction with Ammonia

When heated with NH_3 gas at 300–400°C in the presence of Fe, alkali metals form amides of the type MNH_2. The expected order of reactivity of the metals and the corresponding stability of the salt formed is Cs > Rb > K > Na > Li.

The alkali metals are soluble in liquid ammonia giving a solution which is paramagnetic, highly conducting, highly reducing and deep blue in colour. The solution is blue when dilute and acquires a intense blue colour as more metal is added. Blue solutions have a broad absorption band at 1450 nm. Properties of these solutions strongly suggest that alkali metal atoms ionise in liquid ammonia forming **solvated cations** and **solvated electrons.**

Step I Ionisation of alkali metal

$$M(s) \longrightarrow M^+(g) + e^-$$

Step II Cation M^+ and e^- both are solvated by NH_3 forming $[M(NH_3)_x]^+$ and $[e(NH_3)_y]^-$.

$$M^+ + (x + y)NH_3 \longrightarrow [M(NH_3)_x]^+ + [e(NH_3)_y]^-$$

It is the ammoniated electron which is responsible for the blue colour of the solution, and the electrical conductivity is due to the ammoniated cation, $[M(NH_3)_x]^+$, as well as the ammoniated electron, $[e(NH_3)_y]^-$, values of x and y depend on the extent of solvation (by NH_3). Dilute solutions are paramagnetic due to free electrons. In concentrated solutions ammoniated electrons associate to form electron-pairs and their paramagnetic character decreases.

The solutions are strong reducing agents due to the presence of free electrons. It reduces (i) metal halides to metals (ii) N_2O to N_2 (iii) O_2 to O_2^- and then to O_2^{2-}.

(g) Nature of Nitrates

These form nitrates of the type, MNO_3 which are colourless, soluble in water and electrovalent in nature. The nitrates do not hydrolysed. Except $LiNO_3$, the other nitrates decompose to nitrites and oxygen.

$$2MNO_3 \xrightarrow{\Delta} 2MNO_2 + O_2$$

Lithium nitrate decomposes to oxide on heating, it is due to more polarising nature of small Li^+ towards small oxide ion.

$$2LiNO_3 \xrightarrow{\Delta} Li_2O + 2NO_2 + \frac{1}{2}O_2$$

(h) Nature of Sulphates

These form sulphates of the type M_2SO_4 except Li_2SO_4, other sulphates are soluble in water. The sulphates when fused with carbon form sulphides.

$$M_2SO_4 + 4C \longrightarrow M_2S + 4CO$$

The sulphates of alkali metals form double salts with the sulphates of the trivalent metals like Fe, Al, Cr, etc. The double sulphates crystallise with large number of water molecules as potash alum, $K_2SO_4 \cdot Al_2(SO_4)_3 \cdot 24H_2O$ consists of 24 water molecules. Sulphate of lithium are not known to form alum.

(i) Reaction with Nitrogen and Carbon

Despite its high ionisation energy, lithium is the only alkali metal, which reacts directly with nitrogen and carbon to form the nitride and carbide respectively. Other alkali metals do not react directly with either nitrogen or carbon. This is probably due to the fact that small size of the nitride and carbide ions coupled with the small size of Li^+ ions results in high lattice energies for these compounds. Thus, heats of formation of these compounds are also high resulting in more stability.

(j) **Alkali Metal Hydrides**

Hydrides of the type *M*H have been prepared for all alkali metals, except francium. They are colourless, crystalline, ionic solids. The hydrides are largely ionic with the negative hydride ion H^- present in the lattice. *The alkali metal hydrides posses* NaCl *type structure. The ionic character of the bonds in these hydrides increases as the atomic number of metal increases. Their stability decreases in the same order i.e., from* LiH *to* CsH.

Lithium hydride is by far the most stable hydride which dissociates above 1273 K. Sodium and potassium hydrides dissociate below 773 K.

The alkali metal hydrides are strong reducing agents and their reducing property increases with decrease in stability. Lithium also forms some complex, *i.e.,* $LiAlH_4$ and $LiBH_4$, which like simple hydrides, are also good reducing agents.

(k) **Alkali Metal Halides**

Alkali metals readily react with halogens to form *MX* type of halides. These are mainly ionic compounds having NaCl type of structure with a coordination number of 6 : 6 except for CsCl, CsBr and CsI, which have a CsCl type structure with a coordination number of 8 : 8. Due to more favourable lattice energy, lithium also exhibits a coordination number of 6, although the theoretically expected value is 4. Because of small size of Li^+ ion, its all halides form hydrated salts more readily than other alkali metals. In fact, LiCl, LiBr and LiI, all exist as trihydrates, $LiX \cdot 3H_2O$. Other alkali metal halides are anhydrous. All alkali metal halides (except LiF) are soluble in water.

For a substance to dissolve, the hydration energy must be greater than lattice energy. Due to small size of Li^+ ion, the hydration energy of LiF is considerably high, but it has low solubility in water because of its higher lattice energy. The hydration and lattice energies of LiF are −1034 and −1039 kJ/mol respectively.

Caution Points

(*i*) *ΔH_f° for fluorides becomes less negative as we go down the group, while reverse is true for chlorides, bromides and iodides.*

(*ii*) *For a given metal, ΔH_f° always becomes less negative as we go from the fluoride to iodide.*

(l) **Alkali Metal Carbonates** (Oxysalts)

The alkali metals are highly electropositive and hence, their **oxysalts** are quite stable. Carbonates are remarkable stable. Li_2CO_3 is less stable and decomposes readily. *The strong polarising action of the small cation on the large carbonate ion presumably assists the decomposition.*

$$Li_2CO_3 \xrightarrow{\Delta} Li_2O + CO_2$$

The gain in lattice energy resulting from the substitution of a smaller oxide ion from larger CO_3^{2-} ion enables the decomposition. Bicarbonates of all alkali metals, except that of Li, can be obtained in the solid form. All carbonates and bicarbonates are soluble in water. Lithium carbonate is sparingly soluble.

The above written decomposition reaction is not shown by any other alkali metal, i.e., the carbonates of other alkali metals are thermally stable and do not evolve CO_2 *on heating in air.*

(m) **Complex Formation**

Alkali metals have a very little tendency to form complexes. Lithium being small in size forms certain complexes but this tendency decreases as the size increases.

Caution Point *The alkali metals cannot be prepared by the reduction of their oxides, as these metals themselves are strong reducing agents. Electrolysis of the aqueous solutions of their salts produces the metal hydroxide, as the metals are very reactive towards water. For these reasons, the isolation of alkali metals is usually carried out by the electrolysis of their molten salts.*

Sample Problem 2 Li_2CO_3 *decomposed at a lower temperature whereas* Na_2CO_3 *at higher temperature. This is due to* **[NCERT]**

(*a*) *small* Li *ion*

(*b*) *large* CO_3^{2-} *ion*

(*c*) *high hydration enthalpy of* Li

(*d*) *All of the above*

Interpret (*a*) Lithium being very small in size polarises a large CO_3^{2-} ion leading to the formation of more stable Li_2O and CO_2. All the carbonates of alkali metals (except lithium carbonate) are thermally quite stable. That's why Li_2CO_3 is decomposed at a lower temperature whereas Na_2CO_3 at higher temperature.

10.2 **Anomalous Behaviour of Li**

Li, due to its small size and high charge density, differs from rest of the first group elements.

It shows the following anomalous properties :

1. Li is the hardest metal. Its boiling point and melting point are highest among the group.
2. It is the only alkali metal which reacts directly with N_2 to give **nitride** (Li_3N).
3. LiH is much more stable.

$$Li + H_2 \xrightarrow{700-800^\circ C} \text{hydrides}$$

(Remaining hydrides are formed at 350−430°C.)

4. With air or O_2, it only gives Li_2O, *i.e.,* monoxide while remaining gives M_2O_2 (peroxide) and MO_2 (superoxide) also.
5. Lithium hydroxide decomposes at red heat to form Li_2O. Hydroxides of other alkali metals do not decompose.

$$2LiOH \xrightarrow{\text{Red hot}} Li_2O + H_2O$$

$$\text{Other hydroxides} \xrightarrow[\text{hot}]{\text{Red}} \text{No reaction}$$

LiOH shows lowest solubility.

6. $LiHCO_3$ is known in solution but not in solid state while the bicarbonates of other alkali metals are known in solid state.
7. Li_2O is least basic.
8. Fluoride, phosphates, oxalate and carbonates of Li are sparingly soluble while that of other metals are freely soluble.
9. Carbonates and hydroxide of Li are least stable (thermally) while that of other alkalies are highly stable (thermally).
10. $LiNO_3$, on heating gives a mixture of NO_2 and O_2 while nitrates of rest of alkali metals yield only oxygen.

$$LiNO_3 \xrightarrow{\Delta} Li_2O + NO_2\uparrow + O_2\uparrow$$

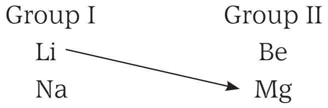
$$NaNO_3 \longrightarrow NaNO_2 + O_2\uparrow \text{ (thermally stable)}$$

(Nitrates of other alkali metals also give same reactions).

11. Li_2SO_4 is the only alkali metal sulphate which does not form double salts, *e.g.,* alum.
12. Lithium reacts with bromine very slowly. Other alkali metals react violently.
13. LiCl is highly deliquescent and soluble in alcohol and pyridine. LiCl separates out from aqueous solution as hydrated crystals $LiCl \cdot 2H_2O$ whereas chlorides of other alkali metals are insoluble in organic solvents and do not form hydrated crystals under ordinary temperature.

10.3 Diagonal Relationship of Li with Magnesium

Lithium shows resemblance with magnesium, (Mg) an element of group IIA placed diagonally opposite. This resemblance is termed as **diagonal relationship.**



Reason for the diagonal relationship are

(i) Comparable electronegativity of Li and Mg (Li = 1.00 and Mg = 1.20)

(ii) Small difference in radii of Li and Mg

Atomic radii (pm)	Li	152	Mg	160
Ionic radii (pm)	Li^+	76	Mg^{2+}	72

(iii) Both have high polarising power (ionic potential)

$$\text{Polarising power } (\Phi) = \frac{\text{Ionic charge}}{(\text{Ionic radius})^2}$$

Lithium resembles magnesium in the following respects

1. Both Li and Mg are harder and have higher melting points than the other metals in their respective groups.
2. Li like Mg decomposes water slowly to liberate hydrogen.

$$2Li + 2H_2O \longrightarrow 2LiOH + H_2$$
$$Mg + 2H_2O \longrightarrow Mg(OH)_2 + H_2$$

3. Lithium forms only monoxide when heated in oxygen. Mg also forms the monoxide.

$$4Li + O_2 \longrightarrow 2Li_2O$$
$$2Mg + O_2 \longrightarrow 2MgO$$

Both the oxides are less soluble in water.

4. Both the elements combine with nitrogen on heating to give nitrides.

$$6Li + N_2 \longrightarrow 2Li_3N$$
$$3Mg + N_2 \longrightarrow Mg_3N_2$$

Both the nitrides get decomposed by water to give ammonia (NH_3).

$$Li_3N + 3H_2O \longrightarrow 3LiOH + NH_3$$
$$Mg_3N_2 + 6H_2O \longrightarrow 3Mg(OH)_2 + 2NH_3$$

5. Carbonates of Li and Mg decompose on heating.

$$Li_2CO_3 \xrightarrow{\Delta} Li_2O + CO_2$$
$$MgCO_3 \xrightarrow{\Delta} MgO + CO_2$$

6. Hydroxides of Li and Mg are weak bases and are slightly soluble in water. Both decompose on heating.

$$2LiOH \xrightarrow{\Delta} Li_2O + H_2O$$
$$Mg(OH)_2 \xrightarrow{\Delta} MgO + H_2O$$

7. Nitrates of Li and Mg decompose on heating giving mixture of nitrogen dioxide and oxygen.

$$4LiNO_3 \xrightarrow{\Delta} 2Li_2O + 4NO_2 + O_2$$
$$2Mg(NO_3)_2 \xrightarrow{\Delta} 2MgO + 4NO_2 + O_2$$

8. Lithium fluoride, phosphate, oxalate and carbonate, like the corresponding salts of Mg, are sparingly soluble in water.
9. Chlorides of both Li and Mg are deliquescent and soluble in alcohol and pyridine. Lithium chloride like magnesium chloride, $(MgCl_2 \cdot 6H_2O)$ separates out from solutions as hydrated crystals, $LiCl \cdot 2H_2O$.
10. Li_2SO_4 like $MgSO_4$ does not form double sulphates, *i.e.,* alums.
11. Lithium salts like magnesium salts undergo hydrolysis.

Compounds of Elements of Group 1

Being highly reactive, all the elements of group 1 form compounds. Although here we will discuss only some important of them.

Sodium Chloride (NaCl)

Sodium chloride (NaCl), also known as **common salt** or **table salt,** is responsible for the salinity of the ocean and of the extracellular fluid of many multicellular organisms. It is commonly used as a flavour enhancer and preservative for food.

Preparation

Now a days, salt is produced by evaporation of seawater or brine from other sources, such as brine wells and salt lakes, and by mining **rock salt,** called halite.

Properties and Uses

A large number of chemicals like NaOH, Na_2CO_3, Cl_2, HCl, bleaching powder etc., are synthesised from sodium chloride. 0.9% NaCl *in water is called a physiological solution as it is iso-osmotic with blood plasma*.

It is used in a plethora of applications from manufacturing pulp and paper to setting dyes in textiles and fabric, to producing soaps and detergents. In the Northern USA, large quantities of NaCl are used to help clear highways of ice during winter.

Sodium Hydroxide or Caustic Soda (NaOH)

Preparation

It is prepared by the electrolysis of NaCl [brine] in **Nelson cell** or **Caster Kellner cell** or in **Kellner Solvay cell.**

(i) Reactions occurring in **Nelson cell** (shown in the figure) are as

$$NaCl \rightleftharpoons Na^+ + Cl^- \quad \text{(in solution)}$$

At cathode $2H_2O + 2e^- \rightleftharpoons H_2 + 2OH^-$

$$Na^+ + OH^- \rightleftharpoons NaOH$$

At anode $2Cl^- \longrightarrow Cl_2 + 2e^-$

The solution containing NaOH and NaCl as impurity is taken out and evaporated to dryness.

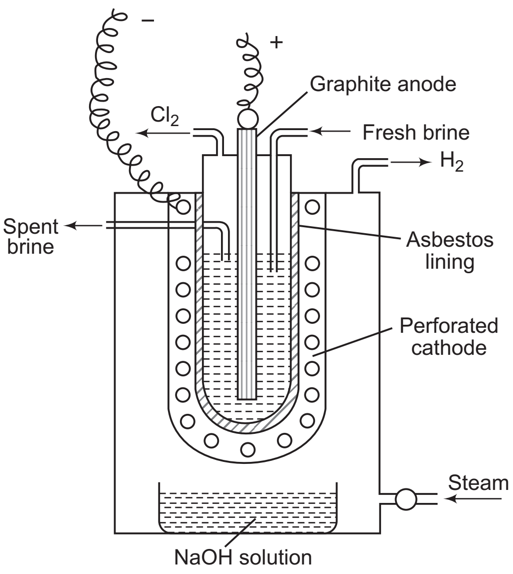


Fig. 10.1 Nelson cell

This process is also called porous diagram process.

(ii) **Castner-Kellner cell** is the common cell in which mercury is used as cathode. The advantage of using Hg as a cathode is that the discharge potential of Na^+ ions is less than that of H^+ ions. Na^+ ions get discharged on mercury and sodium so deposited combines with mercury to form sodium amalgam. The cell is shown in the Fig. 10.2.

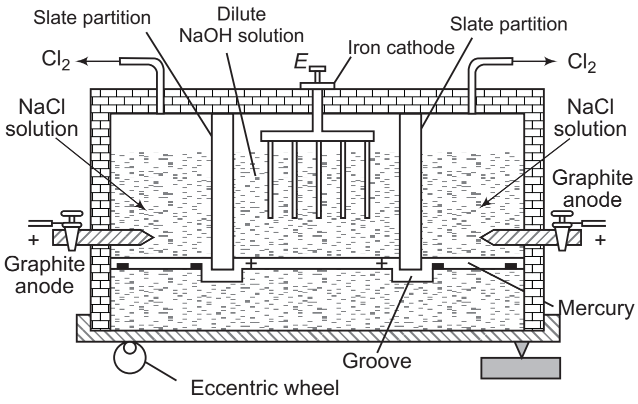

Fig 10.2 Castner-Kellner cell

Reactions occurring in this cell are

$$NaCl \rightleftharpoons Na^+ + Cl^-$$

At anode $2Cl^- \longrightarrow 2Cl + 2e^- \longrightarrow Cl_2$

At anode $Na^+ + e^- \longrightarrow Na$

$Na + Hg \longrightarrow \text{Amalgam}$

The sodium amalgam, thus formed, comes in the inner compartment due to rocking. Here, the sodium amalgam acts as the anode and iron rods act as cathode.

At anode $\text{Na-amalgam} \longrightarrow Na^+ + Hg + e^-$

At cathode $2H_2O + 2e^- \longrightarrow H_2\uparrow + 2OH^-$

The concentrated solution of sodium hydroxide (about 20%) is taken out from inner compartment and evaporated to dryness to get solid NaOH.

(iii) A modified cell is **Kellner-Solvay cell.** It has no compartments. The flowing mercury as shown in figure 10.3 acts as cathode. A number of graphite rods dipping in sodium chloride solution act as anode. A constant level of sodium chloride solution is maintained in the cell. On electrolysis chlorine gas is liberated and Na^+ ions are discharged at cathode (mercury). Discharged sodium dissolves in Hg and forms amalgam. This amalgam flows out in a vessel containing water. Sodium hydroxide is formed with the evolution of hydrogen.

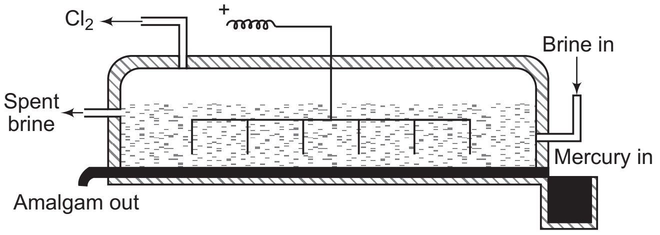

Fig 10.3 Kellner-Solvay cell

Purification of Sodium Hydroxide

Commercial sodium hydroxide is purified with the help of alcohol. Sodium hydroxide dissolves in alcohol while impurities like NaCl, Na_2CO_3, Na_2SO_4, etc., remain insoluble. The alcoholic filtrate is distilled. The alcohol distills off while pure solid sodium hydroxide is left behind.

Properties

1. It is white solid with melting point 318°C. It is hygroscopic, highly soluble in water and gives strongly alkaline solution. However, it is sparingly soluble in alcohol but less soluble than KOH.
2. It decomposes at 1300° as

$$2NaOH \longrightarrow 2Na + H_2 + O_2$$

3. It combines with acidic oxides to form salts, *e.g.,*

$$2NaOH + CO_2 \longrightarrow \underset{\text{sodium carbonate}}{Na_2CO_3} + H_2O$$

$$2NaOH + SO_2 \longrightarrow \underset{\text{sodium sulphite}}{Na_2SO_3} + H_2O$$

$$2NaOH + 2NO_2 \longrightarrow \underset{\text{sodium nitrate}}{NaNO_3} + \underset{\text{sodium nitrite}}{NaNO_2} + H_2O$$

4. It dissolves amphoteric oxides of aluminium, zinc, tin and lead to give corresponding salts.

$$Al_2O_3 + 2NaOH \longrightarrow \underset{\text{sodium meta-aluminate}}{2NaAlO_2} + H_2O$$

$$ZnO + 2NaOH \longrightarrow \underset{\text{sodium zincate}}{Na_2ZnO_2} + H_2O$$

$$PbO + 2NaOH \longrightarrow \underset{\text{sodium plumbite}}{Na_2PbO_2} + H_2O$$

$$PbO_2 + 2NaOH \longrightarrow \underset{\text{sodium plumbate}}{Na_2PbO_3} + H_2O$$

$$SnO + 2NaOH \longrightarrow \underset{\text{sodium stannite}}{Na_2SnO_2} + H_2O$$

$$SnO_2 + 2NaOH \longrightarrow \underset{\text{sodium stannate}}{Na_2SnO_3} + H_2O$$

5. With non-metals (*e.g.,* B, Si, white P, S and halogens) sodium salt of oxyacid of non-metal are obtained, *e.g.,*

   (i) **Halogens** give hypohalites and halides with cold and dilute solution of NaOH.

$$Cl_2 + \underset{\text{cold and dilute}}{2NaOH} \longrightarrow NaCl + \underset{\text{sodium hypochlorite}}{NaClO} + H_2O$$

$$Br_2 + \underset{\text{cold and dilute}}{2NaOH} \longrightarrow NaBr + \underset{\text{sodium hypobromite}}{NaBrO} + H_2O$$

$$I_2 + \underset{\text{cold and dilute}}{2NaOH} \longrightarrow NaI + \underset{\text{sodium hypoiodite}}{NaIO} + H_2O$$

   Halogens form halates and halides with hot and concentrated solution of NaOH.

$$3Cl_2 + \underset{\text{hot and conc.}}{6NaOH} \longrightarrow 5NaCl + \underset{\text{sodium chlorate}}{NaClO_3} + 3H_2O$$

$$3Br_2 + \underset{\text{hot and conc}}{6NaOH} \longrightarrow 5NaBr + \underset{\text{sodium bromate}}{NaBrO_3} + 3H_2O$$

$$3I_2 + \underset{\text{hot and conc}}{6NaOH} \longrightarrow 5NaI + \underset{\text{sodium iodate}}{NaIO_3} + 3H_2O$$

   (ii) Yellow phosphorus (white) when heated with NaOH solution evolves phosphine gas (PH_3) along with the formation of sodium hypophosphite.

$$P_4 + 3NaOH + 3H_2O \longrightarrow \underset{\text{sodium hypophosphite}}{3NaH_2PO_2} + \underset{\text{phosphine}}{PH_3}$$

   (iii) Sulphur on heating with sodium hydroxide solution forms sodium thiosulphate.

$$4S + 6NaOH \longrightarrow \underset{\text{sodium thiosulphate}}{Na_2S_2O_3} + \underset{\text{sodium sulphide}}{2Na_2S} + 3H_2O$$

(iv) Silicon evolves hydrogen when heated with NaOH solution.

$$2NaOH + Si + H_2O \longrightarrow \underset{\text{sodium silicate}}{Na_2SiO_3} + 2H_2$$

(v) Boron also evolves hydrogen when fused with NaOH.

$$2B + 6NaOH \longrightarrow \underset{\text{sodium borate}}{2Na_3BO_3} + 3H_2$$

6. Weakly electropositive metals dissolve in NaOH and evolve H_2, after forming complexes like

$$Zn \longrightarrow \underset{\text{sodium zincate}}{Na_2ZnO_2};$$

$$Al \longrightarrow \underset{\text{sodium meta aluminate}}{NaAlO_2}$$

$$Sn \longrightarrow \underset{\text{sodium stannate}}{Na_2SnO_3}$$

7. It precipitates hydroxide from many salt solutions, *e.g.*, it precipitates $Fe(OH)_2$ from $FeSO_4$ solution. However, hydroxides of amphoteric elements like Al, Zn, etc., are initially precipitated by NaOH followed by re-dissolution due to complex formation like sodium zincate, sodium meta aluminate as,

$$ZnSO_4 + 2NaOH \longrightarrow \underbrace{Na_2SO_4 + Zn(OH)_2\,(ppt.)}$$

$$\Big\downarrow \text{NaOH}$$

$$Na_2ZnO_2 \text{ (soluble)}$$

8. **With CO** under pressure, it gives sodium formate.

$$NaOH + CO \xrightarrow[5\text{–}10\text{ atm.}]{150\text{–}200°C} \underset{\text{sodium formate}}{HCOONa}$$

9. Ammonium salts are decomposed on heating with sodium hydroxide solution with the evolution of ammonia gas.

$$NH_4Cl + NaOH \longrightarrow NH_3\uparrow + NaCl + H_2O$$

$$(NH_4)_2SO_4 + 2NaOH \longrightarrow Na_2SO_4 + 2NH_3\uparrow + 2H_2O$$

10. Sodium hydroxide breaks down the proteins of skin to a pasty mass. On account of this property, it is commonly called as **caustic soda.**

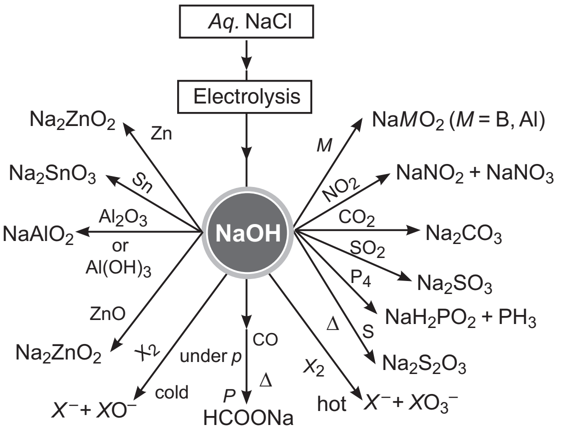

Fig. 10.4 Flow chart showing chemistry of NaOH

Uses

NaOH *is used*

(i) as a reagent in the laboratory.
(ii) in the manufacture of soap.
(iii) in the manufacture of paper and rayon.
(iv) in the manufacture of dyes and drugs.
(v) as an absorber of gases.
(vi) in the manufacture of sodium hypochlorite, sodium chlorate and sodium nitrite.
(vii) for mercerizing cotton.

Sodium Carbonate or Soda Ash (Na_2CO_3)

Since pre-historic times a natural deposit called Trona, $Na_2CO_3 \cdot NaHCO_3 \cdot 2H_2O$ (sesqui-carbonate) has been obtained from dried-up lake beds in Egypt. Trona is sometimes called sodium sesqui-carbonate (sesqui means one and a half) and on heating it, Na_2CO_3 is obtained.

$$2(Na_2CO_3 \cdot NaHCO_3 \cdot 2H_2O) \xrightarrow{\Delta} 3Na_2CO_3 + CO_2 + 5H_2O$$

Preparation

It is manufactured by **Solvay ammonia process.**

The process involves following three steps :

Step I CO_2 is passed through a solution of NH_3, NH_4HCO_3 is produced. The CO_2 used is obtained by heating $CaCO_3$.

$$NH_3 + H_2O + CO_2 \longrightarrow NH_4HCO_3$$

$$CaCO_3 \xrightarrow{\Delta} CaO + CO_2$$

Step II NH_4HCO_3 is then reacted with NaCl. $NaHCO_3$ and NH_4Cl are formed. In this step, ammonia is recovered back from NH_4Cl as

$$NaCl + NH_4HCO_3 \longrightarrow NaHCO_3 + NH_4Cl$$

$$CaO + H_2O \longrightarrow Ca(OH)_2$$

$$2NH_4Cl + Ca(OH)_2 \longrightarrow CaCl_2 + 2NH_3 + 2H_2O$$

Step III The bicarbonate formed, on heating gives Na_2CO_3, H_2O and CO_2.

$$2NaHCO_3 \xrightarrow{\Delta} Na_2CO_3 + H_2O + CO_2$$

Raw materials NaCl, NH_3 and limestone (for CO_2).

Most of NH_3 can be recovered in the process. $CaCl_2$ is the only by-product.

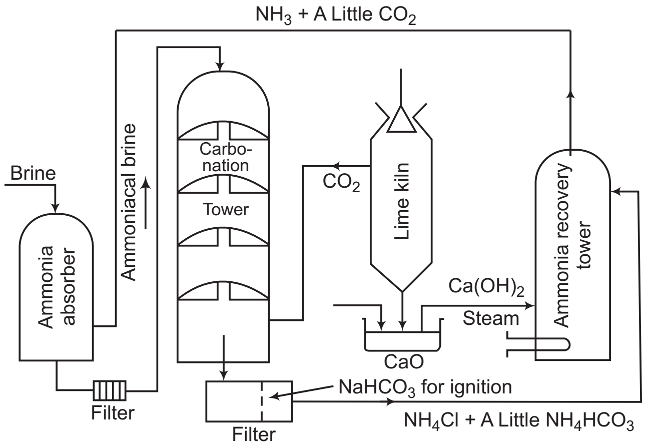

Fig. 10.5 Flow sheet diagram of Solvay's ammonia soda process for the manufacture of sodium carbonate

Caution Point *Le-Blanc process and electrolytic process can also be used to prepare* Na_2CO_3.

Properties

1. It crystallises as decahydrate. (Sodium carbonate decahydrate, $Na_2CO_3 \cdot 10H_2O$, is also known as washing soda). The decahydrate form on standing in air effloresces and crumbles to powder. It is the monohydrate form, $Na_2CO_3 \cdot H_2O$. It also forms a heptahydrate, $Na_2CO_3 \cdot 7H_2O$.

   On heating, the monohydrate changes into the anhydrous form which does not decompose on further heating even to redness. It is the amorphous powder and called **soda ash**. It melts at 852°C.

$$Na_2CO_3 \cdot 10H_2O \xrightarrow[\text{to air}]{\text{On exposure}} \underset{\substack{\text{soluble in water;}\\ \text{solution alkaline}}}{Na_2CO_3 \cdot H_2O} + 9H_2O$$

$$\downarrow \Delta$$

$$\underset{\text{decomposition}}{\text{No}} \longleftarrow \underset{\substack{\text{thermally}\\ \text{stable;}}}{Na_2CO_3}$$

2. It is soluble in water with the evolution of considerable amount of heat. The solution is alkaline in nature due to hydrolysis.

$$Na_2CO_3 + 2H_2O \rightleftharpoons 2NaOH + H_2CO_3$$

   When the hot solution of sodium carbonate is concentrated and cooled, crystals of decahydrate form are obtained.

3. On passing CO_2 through the concentrated solution of sodium carbonate, sodium bicarbonate gets precipitated.

$$Na_2CO_3 + H_2O + CO_2 \longrightarrow 2NaHCO_3$$

4. It is readily decomposed by acids. The reaction occurs in two steps.

$$Na_2CO_3 + HCl \longrightarrow NaHCO_3 + NaCl$$
$$NaHCO_3 + HCl \longrightarrow NaCl + H_2O + CO_2$$

5. When the mixture of sodium carbonate and silica is fused, sodium silicate (soft glass) is formed.

$$Na_2CO_3 + SiO_2 \longrightarrow Na_2SiO_3 + CO_2\uparrow$$

   Sodium silicate is called **soluble glass** or **water glass** as it is soluble in water.

6. When the solution of sodium carbonate and slaked lime is heated, sodium hydroxide is formed.

$$Na_2CO_3 + Ca(OH)_2 \longrightarrow 2NaOH + CaCO_3$$

7. When aqueous solution of sodium carbonate containing sulphur is treated with sulphur dioxide, sodium thiosulphate ($Na_2S_2O_3$) is formed.

$$Na_2CO_3 + SO_2 \xrightarrow{H_2O} Na_2SO_3 + CO_2\uparrow$$
$$Na_2SO_3 + S \longrightarrow Na_2S_2O_3$$

8. Sodium carbonate reacts with metal salts (except alkali metal salts) to form insoluble normal or basic carbonates.

$$CaCl_2 + Na_2CO_3 \longrightarrow CaCO_3 + 2NaCl$$
$$BaCl_2 + Na_2CO_3 \longrightarrow BaCO_3 + 2NaCl$$

9. Carbonates of metals like Fe, Al, Sn, etc., when formed are immediately hydrolysed to hydroxides.

$$Fe_2(SO_4)_3 + 3Na_2CO_3 \longrightarrow Fe_2(CO_3)_3 + 3Na_2SO_4$$
$$Fe_2(CO_3)_3 + 3H_2O \longrightarrow 2Fe(OH)_3 + 3CO_2$$

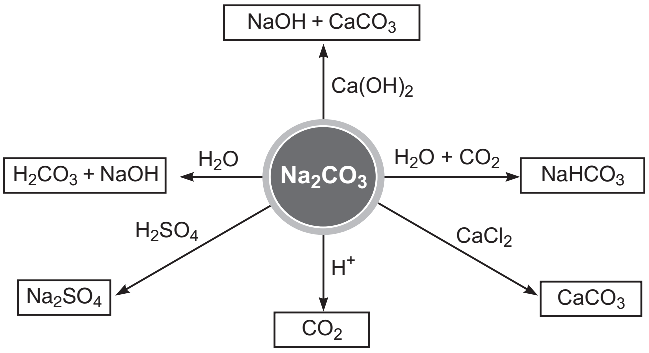

Fig. 10.6 Summary of reactions of Na_2CO_3

Uses

Sodium carbonate is used

(i) in laundries and in softening of water as washing soda.
(ii) in the manufacture of glass, sodium silicate, paper, borax, soap powders, caustic soda, etc.
(iii) in textile and petroleum refining.
(iv) for the preparation of various carbonates of metals.
(v) The mixture of Na_2CO_3 and K_2CO_3, called the **fusion mixture,** is used in quantitative analysis to standarise acid solutions. In qualitative analysis, it is used in the detection of acidic radicals especially of insoluble salts.

Sodium Hydrogen Carbonate ($NaHCO_3$)

It is also called sodium bicarbonate.

Manufacture by Solvay Process in Laboratory

$NaHCO_3$ is prepared by saturating a solution of Na_2CO_3 (cold) with CO_2. In this process, $NaHCO_3$ separates as white crystals (due to its poor solubility in water).

$$Na_2CO_3 + CO_2 + H_2O \longrightarrow \underset{\text{sparingly soluble}}{2NaHCO_3}$$

Properties

1. It is a white crystalline solid, sparingly soluble in water. The solution is alkaline in nature due to hydrolysis. The solution is weakly basic.

   $$NaHCO_3 + H_2O \rightleftharpoons NaOH + H_2CO_3$$

   The solution gives yellow colour with methyl orange but no colour with phenolphthalein.
2. The metal salt which forms basic carbonate with sodium carbonate, gives normal carbonate with sodium bicarbonate.

   $$ZnSO_4 + 2NaHCO_3 \longrightarrow ZnCO_3 + Na_2SO_4 + H_2O + CO_2$$
3. If heated (solid or solution), it decomposes to Na_2CO_3 and CO_2.

   $$2NaHCO_3 \xrightarrow[\text{to}]{\text{Decomposes}} Na_2CO_3 + CO_2$$

   That's why it is used as a constituent of **"baking powder"** and effervescent drinks.

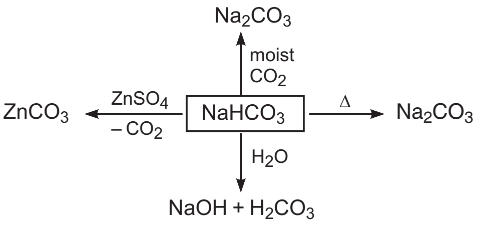

Fig. 10.7 Summary of reactions of $NaHCO_3$

Uses

(i) It is used as a medicine antacid to neutralise the acidity in the stomach.

(ii) It is largely used for making baking powder, a mixture of potassium hydrogen tartrate and sodium bicarbonate.

(iii) It is used in making effervescent drinks.

(iv) It is used in free extinguishers.

(v) It is used for the production of carbon dioxide.

Sodium Thiosulphate or Hypo ($Na_2S_2O_3 \cdot 5H_2O$)

An important salt of thiosulphuric acid is sodium thiosulphate, $Na_2S_2O_3 \cdot 5H_2O$. Unlike thiosulphuric acid, it is quite stable.

Methods of Preparation

1. Sodium thiosulphate is prepared by boiling sodium sulphate solution with flowers of sulphur and stirring till the alkaline reaction has disappeared.

   $$Na_2SO_3 + S \longrightarrow Na_2S_2O_3$$

   - The excess of sulphur is filtered off and the filtrate evaporated to crystallisation when crystals of sodium thiosulphate, $Na_2S_2O_3 \cdot 5H_2O$ separate on slow cooling.
   - Sodium sulphite used above is prepared from sodium carbonate. A concentrated solution of sodium carbonate is prepared. One half of this is saturated with sulphur dioxide and the other half of the solution is then added when we get sodium sulphite.

   $$Na_2CO_3 + 2SO_2 + H_2O \longrightarrow 2NaHSO_3 + CO_2$$
   $$2NaHSO_3 + Na_2CO_3 \longrightarrow 2Na_2SO_3 + H_2O + CO_2$$
2. Sodium thiosulphate is also formed together with sodium sulphide when sulphur is boiled with sodium hydroxide solution.

   $$6NaOH + 4S \xrightarrow{\text{Boil}} Na_2S_2O_3 + 2Na_2S + 3H_2O$$

Properties

Properties of sodium thiosulphate are as follows

1. It is a colourless, crystalline and efflorescent substance of the formula $Na_2S_2O_3 \cdot 5H_2O$. It is soluble in water.
2. On heating, it decomposes to give sulphur dioxide, hydrogen sulphide and sulphur.
3. Dilute acids decompose it with the evolution of sulphur dioxide and precipitation of sulphur.

   $$Na_2S_2O_3 + 2HCl \longrightarrow 2NaCl + SO_2 + S + H_2O$$
4. Silver halides are dissolved by sodium thiosulphate solution (hence, used in photography for fixing).

   $$\underset{\substack{\text{silver}\\\text{bromide}}}{AgBr} + \underset{\substack{\text{sodium}\\\text{thiosulphate}}}{2Na_2S_2O_3} \longrightarrow \underset{\substack{\text{sodium argento}\\\text{thiosulphate}}}{Na_3[Ag(S_2O_3)_2]} + NaBr$$
5. Silver nitrate gives, with a very dilute solution of it, a white precipitate which quickly changes colour to yellow, brown and finally black due to the formation of silver sulphide.

   $$Na_2S_2O_3 + 2AgNO_3 \longrightarrow Ag_2S_2O_3 + 2NaNO_3$$
   $$Ag_2S_2O_3 + H_2O \longrightarrow Ag_2S + H_2SO_4$$

With a concentrated solution of sodium thiosulphate, silver nitrate gives no precipitate. This is because silver thiosulphate formed, is readily soluble in excess of sodium thiosulphate.

$$Ag_2S_2O_3 + 3Na_2S_2O_3 \longrightarrow 2Na_3[Ag(S_2O_3)_2]$$

6. Chlorine oxidises hypo to sodium sulphate while iodine is decolourised due to the formation of tetrathionate.

$$\begin{array}{c} Cl_2 + H_2O \longrightarrow 2HCl + O \\ Na_2S_2O_3 + O \longrightarrow Na_2SO_4 + S \\ \hline Na_2S_2O_3 + Cl_2 + H_2O \longrightarrow Na_2SO_4 + 2HCl + S \\ \hline \end{array}$$

$$2Na_2S_2O_3 + I_2 \longrightarrow \underset{\substack{\text{sodium}\\\text{tetrathionate}}}{Na_2S_4O_6} + 2NaI$$

7. A moderately concentrated solution of sodium thiosulphate gives a white precipitate of barium thiosulphate with barium chloride. *No precipitate is obtained with calcium chloride. Since, calcium thiosulphate is fairly soluble in water.*

$$Na_2S_2O_3 + BaCl_2 \longrightarrow BaS_2O_3 + 2NaCl$$

8. On addition of a few drops of ferric chloride to thiosulphate solution, a violet colouration is obtained due to the formation of ferric thiosulphate.

$$3Na_2S_2O_3 + 2FeCl_3 \rightleftharpoons Fe_2(S_2O_3)_3 + 6NaCl$$

The violet colour disappears quickly due to the reduction of ferric chloride by thiosulphate. This shifts the above equilibrium to the left.

$$\begin{array}{c} [FeCl_3 \longrightarrow FeCl_2 + Cl] \times 2 \\ 2Na_2S_2O_3 + 2Cl \longrightarrow Na_2S_4O_6 + 2NaCl \\ \hline 2FeCl_3 + 2Na_2S_2O_3 \longrightarrow 2FeCl_2 + Na_2S_4O_6 + 2NaCl \\ \hline \end{array}$$

Uses

Sodium thiosulphate is used

(i) in photography for fixing, under the name hypo.
(ii) in textile industry as antichlor.
(iii) in the extraction.
(iv) in the laboratory for the volume estimation of iodine and as a reagent.
(v) in medicine.

Potassium Superoxide (KO_2)

Preparation

It is formed as a chrome-yellow (orange) powder by burning potassium in excess of moisture free oxygen or air.

$$K + O_2 \longrightarrow KO_2$$

Properties and Uses

KO_2 is a better oxidising agent than K_2O_2, since it produces O_2 and H_2O_2 both in aqueous or acidic solution.

$$\begin{array}{rcl} 2KO_2 + 2H_2O & \longrightarrow & 2KOH + H_2O_2 + O_2 \\ 2KO_2 + H_2SO_4 & \longrightarrow & K_2SO_4 + H_2O_2 + O_2 \\ 2KO_2 + CO & \longrightarrow & K_2CO_3 + O_2 \\ 4KO_2 + 2CO_2 & \longrightarrow & 2K_2CO_3 + 3O_2 \\ 4KO_2 + 4CO_2 + 2H_2O & \longrightarrow & 4KHCO_3 + 3O_2 \end{array}$$

KO_2 thus, finds applications in **space capsules, submarines** and **breathing masks,** because it both produces O_2 and removes CO_2 and CO. Both functions are important in life support systems.

Check Point 1

1. Li^+ ions is far smaller than the other alkali metal ions but it moves through a solution less rapidly than others. Explain.
2. Explain, why sodium is less reactive than potassium?
3. Why sodium forms Na^+ ions and not Na^{2+}?
4. Explain, why alkali metals are good reducing agents?
5. Explain, why LiI is more soluble than KI in ethanol?

Alkaline Earth Metals and Their Compounds

10.4 Alkaline Earth Metals

Be, Mg, Ca, Sr, Ba and **Ra** also belong to s-block and are called **alkaline earth metals.** These are called **"alkaline earth metals"** due to the following facts

1. Their hydroxides form alkaline aqueous solutions.
2. Their oxides are **earthen**, *i.e.,* soil like means having very high melting points.

Radium is the radioactive element of this group.

Electronic Configuration

General electronic configuration of alkaline earth metals is ns^2 (where $n \neq 1$), *i.e.,* atoms of IIA group elements have two electrons in their outermost shell. The penultimate layer has, as in case of alkali metals, 8 electrons (s^2p^6), except beryllium, which contains 2 electrons in the penultimate shell, *i.e.,* in the s-subshell. Thus, they possess an inert gas core and two electrons in the s-orbital of the valence shell (ns^2).

Element	Configuration
$_4$Be	[He] $2s^2$
$_{12}$Mg	[Ne] $3s^2$
$_{20}$Ca	[Ar] $4s^2$
$_{38}$Sr	[Kr] $5s^2$
$_{56}$Ba	[Xe] $6s^2$
$_{88}$Ra	[Rn] $7s^2$

Trends in Physical Properties of Elements

Following trends are observed in physical properties of alkaline earth metals.

(a) Physical State

They are all silvery white metals. They have greyish white lustre when freshly cut, but tarnish soon after their exposure in air due to surface oxidation. They are soft in nature but harder than alkali metals because metallic bonding is stronger than IA elements due to possession of 2 valence electrons. However, hardness decreases with increase in atomic number. These elements are malleable and ductile but less than alkali metals.

(b) Atomic Size

These atoms are large in size but smaller than the corresponding alkali metals, since the increased nuclear charge draws the orbitals electrons in. The ionic radii of these metallic ions is also large but smaller as compared to that of alkali metal ions. The metal atom changes into a bipositive ion by the loss of two electrons present in the outermost shell. Then the outer shell is eliminated and the effective nuclear charge further increases. Hence, size of the ion is smaller than the parent atom. *Due to smaller size of their ions, these are more extensively hydrated than alkali metals and form hydrated salts like* $MgCl_2 \cdot 6H_2O$; $CaCl_2 \cdot 6H_2O$ *etc.*

(c) Density

Their density does not show any regular trend but in general these are more dense than alkali metals.

(d) Electropositive Character or Metallic Character

It increases down the group. But these elements are less basic than alkali metals which can be confirmed by the fact that last three alkali metals (K, Rb and Cs) show photoelectric effect which is not shown by any of the alkaline earth metals.

(e) Metallic Bonding and Hardness

These elements are more rigid (harder) than alkali metals due to the stronger metallic bonding in them as compared to alkali metals. More strength of metallic bonding is due to increase in number of electrons available for it (electrons for metallic bonding available in alkali metals is one which is doubled in number as we see alkaline earth metals). But inspite of their hardness these can also be cut by a sharp knife similar to alkali metals.

(f) Melting Point and Boiling Point

The melting and boiling points are not regular in the group, mainly due to different crystal structures of the metals. However, these are higher than those of alkali metals.

(g) Ionisation Energy

Due to larger nuclear charge and smaller atomic radius of IIA group elements (as compared to alkali metals), the valence electrons are more tightly held. Thus, the first ionisation energies of these elements are higher than those of alkali metals. The +1 oxidation state might be easily attained by the alkaline earth metal, but the second ionisation energy is more than four times greater than that required for ionising the alkali metals. This high energy requirement is more than compensated by the energy released during lattice formation and hydration of ions. These elements form colourless, largely ionic compound in +2 oxidation state, *e.g.,* $MgCl_2$.

(h) Electronegativity

Their electronegativities decrease down the group but these are more than the electronegativity values of alkali metals.

(i) Flame Colouration

Like alkali metals, these also impart characteristic colour to the flame. However, Mg and Be, being smaller in size, do not impart colour as electrons are very tightly bound and a large amount of energy is required to excite them.

(j) Reducing Character

The high negative values of standard reduction potentials indicate that metals of IIA group are *good reducing agents but less stronger as compared to alkali metals.* Although the energies required to vaporise and ionise the atoms of IIA group elements to M^{2+} ions are high. The high lattice energies in the solid salts and high hydration energies of $M^{2+}(aq)$ ions compensate for this and hence, E° values are almost near to those of alkali metals.

The above properties of alkaline earth metals can be summarized in the following table :

Table 10.2 **Physical Properties of Alkaline Earth Metals**

Property	Be	Mg	Ca	Sr	Ba	Ra
Atomic number	4	12	20	38	56	88
Molar mass (g mol^{-1})	9.01	24.31	40.08	87.67	137.34	226.05
Molar volume (cm^3 mol^{-1})	4.90	13.97	25.91	34.54	36.72	38.00
Density (g cm^{-3})	1.84	1.74	1.55	2.54	3.75	6.00
Melting point (°C)	1277	650	838	768	714	700
Boiling point (°C)	2770	1107	1440	1380	1640	1140
Atomic radius (Å)	0.90	1.36	1.74	1.92	1.98	—
Ionic radius (Å)	0.30	0.65	0.94	1.10	1.29	1.32
Heat of hydration of ions (kJ mol^{-1})	2494	1921	1577	1443	1305	—
Heat of atomisation (kJ mol^{-1})	78.2	35.2	42.5	39.1	42.2	—
Ionisation energy (kJ mol^{-1}) First	899	737	590	549	503	509
Second	1757	1450	1146	1064	965	979
Electronegativity	1.5	1.0	1.2	1.0	0.9	0.9
Flame colouration	None	None	Brick red	Crimson	Grassy green	Crimson
Oxidation state	+2	+2	+2	+2	+2	+2

Comparison Between the Properties of Alkaline Earth Metals and Alkali Metals

Unlike the members of group IA, the chemistry of IIA group elements is not completely dominated by the chemistry of cations. When compared with alkali metals, it is found that

1. They are less reactive than alkali metals.
2. They are less electropositive, *i.e.,* less metallic than alkali metals.
3. Their reducing power is much less than those of alkali metals.
4. They are less basic than alkali metals.
5. The gradation in properties of these elements is not as regular as in the case of alkali metals, because of different structures of their crystal lattices.

The difference in properties with alkali metals is due to

1. Small size of atoms and ions.
2. Stronger metallic bonds (resulting to more density and hardness).
3. Higher melting and boiling points.

Hot Spot 2

TRENDS in Chemical Properties of Group 2 Elements

It is also an important topic for JEE Main examination. The nature of question is moderate to easy. Learn the trends and reason of the trend to solve out the problems based on this topic.

Alkaline earth metals give all the usual reactions of alkali metals. However, in these reactions, these are less reactive.

(a) Reaction with Air

These are slowly oxidised on exposure to air forming oxides. These oxides are white crystalline solid and basic in nature. However, **the oxide of Be is amphoteric in nature** due to the smaller size of Be^{2+} ion. As a result of smaller size, this ion has more polarising power resulting to appearance of covalent character in the compounds of this ion. **The basic strength of oxides increases down the group.**

BeO is very hard solid (4 : 4 coordination) while rest oxides are with 6 : 6 coordination. These oxides are highly stable due to their large ionic crystal lattice energies. BeO and MgO are almost insoluble in water. **Due to their high melting points, MgO and CaO are used as basic lining of furnaces.**

(b) Reaction with Water

Be shows no reaction with water (cold as well as hot in the forms of steam); Mg does not react with cold water, *i.e.,* it reacts with hot water (steam) only while rest of the members react with cold water as

$$Ca + 2H_2O \longrightarrow Ca(OH)_2 + H_2 \uparrow$$

The basic character and solubility of hydroxides increases down the group. This is because solubility is decided by hydration and the lattice energies which decrease with increase in size of metal ions. Decreasing lattice energy favours increased solubility, whilst decreasing hydration energy favours decreased solubility. Since on moving down the group the lattice energy decreases more rapidly than the hydration energy, the compound becomes more soluble.

The aqueous suspension of $Mg(OH)_2$ is called milk of magnesia and used as anti acid drug (antacid). $Ba(OH)_2$ is almost as strong as the alkali metal hydroxides and most soluble among all hydroxides, while $Be(OH)_2$ is amphoteric.

(c) Reaction with Hydrogen

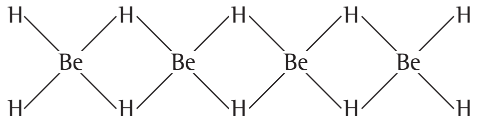
Be does not react directly with hydrogen. Rest of the elements react with hydrogen to form ionic hydrides of MH_2 type. The hydride of Be is prepared by reducing its chloride as

$$2BeCl_2 + LiAlH_4 \longrightarrow 2BeH_2 + LiCl + AlCl_3$$

BeH_2 and MgH_2 are covalent in nature while other hydrides are ionic in nature. Calcium, strontium and barium hydrides liberate hydrogen at anode on electrolysis in the fused state. Ionic hydrides are violently decomposed by water evolving hydrogen. CaH_2 is technically called **hydrolith** and used on large scale for the production of hydrogen.

$$CaH_2 + 2H_2O \longrightarrow Ca(OH)_2 + 2H_2$$

BeH_2 and MgH_2 are known to have polymeric bridge structure with hydrogen present as bridge between two metal atoms.



Three centre bonds are present in which a banana shaped molecular orbital covers three atoms Be---H---Be and contains two electrons. Hydrogen atoms lie in the plane perpendicular to the plane of molecule containing beryllium atoms.

The stability of the hydrides decreases with increasing atomic number because the metallic nature of the elements increases.

(d) Reaction with Halogens

All alkaline earth metals react with halogens at elevated temperatures to form halides of MX_2 type. Among the halides, BeX_2 and MgX_2 have covalent character in them due to the higher polarising powers or more covalent character of their ions. These halides are readily soluble in water and their solubility decreases down the group due to decrease in the hydration energy.

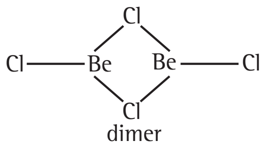
On moving down the group, ionic character increases, thus their melting point and conductivity increases from MgX_2 to BaX_2. These are good conductors in molten state.

The halides are hygroscopic in nature and readily form hydrates, *e.g.,* $MgCl_2 \cdot 6H_2O$, $CaCl_2 \cdot 6H_2O$, $BaCl_2 \cdot 2H_2O$, etc. Calcium chloride has a strong affinity for water and is used as a dehydrating agent.

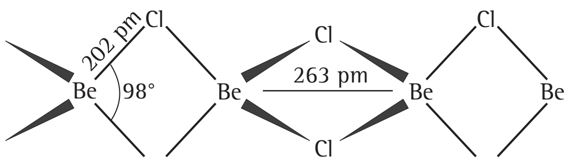
The above statement is not applicable on alkaline earth metals fluorides as these are practically almost insoluble in water.

$BeCl_2$ shows polymeric bridge structure in its solid state which is monomeric in vapour phase with zero dipole moment.

monomer



dimer



polymer

(e) Reaction with Nitrogen

All of them react with nitrogen to form nitrides of M_3N_2 type. These nitrides liberate NH_3 on reaction with water as

$$3Ca + N_2 \longrightarrow Ca_3N_2 \xrightarrow{6H_2O} 3Ca(OH)_2 + 2NH_3\uparrow$$

The ease of formation of nitrides decreases from Be to Ba. This is contrast to alkali metals where only Li_3N is formed. Because the N_2 molecule is very stable, it requires very high energy to form N^{3-} ions. The large amount of energy comes from the very large amont of lattice energy evolved when the crystalline solid is formed. The lattice energy is particularly high because of the high charges on the ions M^{2+} and N^{3-}.

Be_3N_2 is volatile (covalent character) while other nitrides are not volatile as they are ionic crystalline solids.

(f) Carbonates and Bicarbonates of Alkaline Earth Metals

The carbonates of alkaline earth metals are insoluble in water. However, if CO_2 is passed in the saturated solutions of carbonates, their bicarbonates are formed as

$$CaCO_3 + H_2O + CO_2 \longrightarrow Ca(HCO_3)_2$$

Thus, carbonates dissolve in water containing CO_2. Bicarbonates of Ca and Mg impart hardness to water. These bicarbonates can be converted back to carbonates on heating. Thus, hardness imparted by these bicarbonates is removed by boiling the water as these are converted to insoluble carbonates which is normally removed as precipitate. Solubility of carbonates decreases on moving down the group white stability increases.

Increasing stability can be explained on the basis of polarisation and covalent character. Be^{2+} is smallest in size hence show high polarising power. $BeCO_3$ is least ionic and has least stability.

$$\xrightarrow[\text{Increasing ionic character and stability}]{BeCO_3 < MgCO_3 < CaCO_3 < SrCO_3 < BaCO_3}$$

The carbonates are all ionic, but $BeCO_3$ is unusual because it contains hydrated ion $[Be(H_2O)_4]^{2+}$ rather than Be^{2+}.

(g) Sulphates of Alkaline Earth Metals

They form sulphates of the type MSO_4. These are slightly soluble in water and the solubility decreases down the group, *i.e.,* $BaSO_4$ and $RaSO_4$ are almost insoluble. The solubilities of $BeSO_4$ and $MgSO_4$ are due to high energy of solvation of smaller Be^{2+} and Mg^{2+} ions. The values of solubility products which decrease gradually also explain the decrease in solubility on moving down the group.

Metal sulphate	$BeSO_4$	$MgSO_4$	$CaSO_4$	$SrSO_4$	$BaSO_4$
Solubility product	very high	10	2.4×10^{-5}	7.6×10^{-7}	1.5×10^{-9}

The sulphates decompose on heating to give the corresponding oxide (MO).

$$2MSO_4 \xrightarrow{\text{Heat}} 2MO + 2SO_2 + O_2$$

The stability increases as the basic nature of the metal increases.

Sulphates are reduced into sulphides on heating with carbon. There are normally seen as hydrates, *e.g.,* $MgSO_4 \cdot 7H_2O$ (epsom salt), $CaSO_4 \cdot 2H_2O$ (gypsum).

Caution Point $BaSO_4$ *being extremely insoluble, does not pass from digestive system into the circulatory system that's why. it is given to patients prior to taking stomach X-ray, although it is poisonous.*

(h) Nitrates

Alkaline earth metals form nitrates of the type $M(NO_3)_2$. Nitrates of these metals are soluble in water. On heating they decompose into their corresponding oxides with the evolution of a mixture of nitrogen dioxide and oxygen.

$$2M(NO_3)_2 \xrightarrow{\Delta} 2MO + 4NO_2 + O_2$$

Beryllium also forms a basic nitrate in addition to the normal salt. Basic nitrate is a covalent compound.

$$Be(NO_3)_2 \xrightarrow{125°C} \underset{\text{Basic beryllium nitrate}}{[Be_4O(NO_3)_6]}$$

(i) Reaction with Acids

All these metals liberate H_2 with dilute acid solution as

$$Mg + 2HCl \longrightarrow MgCl_2 + H_2\uparrow$$
$$Ca + H_2SO_4 \longrightarrow CaSO_4 + H_2\uparrow$$

(j) Reaction with Mercury and Other Metals

All alkaline earth metals form amalgams with Hg in the same manner as formed by alkali metals but here, in addition, they form **alloy** also with other metals like **magnalium** – Mg + Al;

(k) Solutions of Metals in Liquid Ammonia

Like alkali metals, alkaline earth metals dissolve also in liquid ammonia to form coloured solutions. Dilute solutions are bright blue in colour due to solvated electrons. These solutions decompose very slowly forming amides and evolving hydrogen.

$$M \longrightarrow M^{2+} + 2e^-$$
$$2NH_3 + 2e^- \longrightarrow 2NH_2^- + H_2$$
$$M^{2+} + 2NH_2^- \longrightarrow M(NH_2)_2$$

When the solution is evaporated, hexammoniate, $M(NH_3)_6$, is formed. These slowly decompose to give amides.

$$M(NH_3)_6 \longrightarrow M(NH_2)_2 + 4NH_3\uparrow + H_2\uparrow$$

Concentrated solutions of the metals in ammonia are bronze coloured.

(l) Carbides of Alkaline Earth Metals

Alkaline earth metals form different types of carbides with C, which are useful in preparing different saturated and unsaturated hydrocarbons on reaction with water, *e.g.,* Be forms Be_2C which forms CH_4 on reaction with water, Mg also forms Mg_2C_3 which forms $CH_3-C\equiv CH$ on reaction with water, Mg forms MgC_2 which forms $CH\equiv CH$ with water, Ca to Ba all metals form carbides of MC_2 type which on reaction with water form $CH\equiv CH$.

(m) **Complex Formation**

Generally, the alkaline earth metals do not form complexes. However, the smaller ions have some tendency to form complexes. Beryllium forms stable complexes such as $[BeF_3]^-$, $[BeF_4]^{2-}$ and $[Be(H_2O)_4]^{2+}$. Beryllium is unique in forming a series of stable complexes of formula $[Be_4O(R)_6]$, where R may be NO_3^-, $HCOO^-$, CH_3COO^-, $C_6H_5COO^-$, etc.

The most important complex formed by magnesium is chlorophyll in which magnesium is bonded to the four heterocyclic nitrogen atoms. Calcium, strontium and barium form complexes only with strong complexing agent, like acetylacetone, EDTA, etc.

Sample **Problem 3** *Some of the group 2 metal halides are covalent and soluble in organic solvents. Among the following metal halides, the one which is soluble in ethanol is* **[NCERT Exemplar]**

(*a*) $BeCl_2$ (*b*) $MgCl_2$ (*c*) $CaCl_2$ (*d*) $SrCl_2$

Interpret (*a*) Because of its small size and high charge, Be^{2+} ion has high polarising power, thus, $BeCl_2$ is covalent in nature and hence, dissolves in organic solvents like ethanol (like dissolves like).

Sample **Problem 4** *Metals form basic hydroxides. Which of the following metal hydroxide is the least basic?* **[NCERT Exemplar]**

(*a*) $Mg(OH)_2$ (*b*) $Ca(OH)_2$

(*c*) $Sr(OH)_2$ (*d*) $Ba(OH)_2$

Interpret (*a*) Basicity is the tendency to give hydroxyl ion. As the size of alkaline earth metal ion increases, the *M*—OH bond length increases, *i.e.*, *M*—OH bond weakens and hence, tendency to give OH^- increases. Thus, $Mg(OH)_2$ because of the smaller size of Mg is least basic among alkaline earth metal hydroxides.

Sample **Problem 5** *Which of the carbonates given below is unstable in air and is kept in CO_2 atmosphere to avoid decomposition?* **[NCERT Exemplar]**

(*a*) $BeCO_3$ (*b*) $MgCO_3$

(*c*) $CaCO_3$ (*d*) $BaCO_3$

Interpret (*a*) $BeCO_3$ is least stable among alkaline earth metal carbonates due to the small size of Be^{2+} ion because of which its polarising power and covalent character are high.

10.5 **Anomalous Behaviour of Beryllium**

Beryllium, the first member of alkaline earth metals, shows an anomalous behaviour, *i.e.*, differs in properties due to its small size, high ionisation enthalpy. It differs from rest of the metals in the following properties

1. Beryllium is harder than other members of its group.
2. It has higher melting and boiling points.
3. Beryllium does not react with water even at high temperature while other alkaline earth metals do.
4. Beryllium forms covalent compounds because of high charge density and greater polarising power.
5. Beryllium oxide and hydroxide are amphoteric in nature, whereas, oxides of other alkaline earth metals are basic.

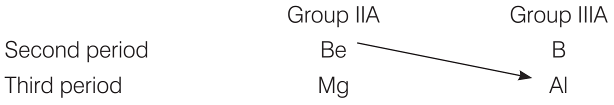
$$BeO + 2HCl \longrightarrow BeCl_2 + H_2O$$
$$BeO + 2NaOH \longrightarrow Na_2BeO_2 + H_2O$$

6. Carbides of beryllium are covalent, whereas carbides of other alkaline earth metals are ionic.
7. Beryllium carbide reacts with water to produce methane while other earth metals give acetylene gas.
8. $BeCO_3$ is unstable to heat and Be_3N_2 is volatile.
9. $BeSO_4$ is soluble in water.
10. $BeCl_2$ is a covalent compound and does not impart any colour to the flame.
11. It has strong tendency to form complex compounds.

10.6 **Diagonal Relationship of Be with Aluminium**

Be exhibits similarities in properties with Al placed diagonally opposite, which is termed as diagonal relationship. The reasons for such a relationship are

1. High polarising power of Be^{2+} and Al^{3+} ion
2. Comparable electronegativity of Be and Al
3. Almost similar E°_{oxi}.



Be shows similarity with Al in the following properties

1. Both are not affected by atmosphere.
2. Both do not decompose water.
3. Both become passive when treated with concentrated HNO_3.
4. Both dissolve in caustic alkalies liberating hydrogen.

$$Be + 2NaOH \longrightarrow Na_2BeO_2 + H_2$$
$$2Al + 2NaOH + 2H_2O \longrightarrow \underset{\text{sod. meta aluminate}}{2NaAlO_2} + 3H_2$$

5. BeO and Al_2O_3 both are amphoteric in nature.

$$BeO + H_2SO_4 \longrightarrow BeSO_4 + H_2O$$
$$BeO + 2NaOH \longrightarrow Na_2BeO_2 + H_2O$$
$$Al_2O_3 + 6HCl \longrightarrow 2AlCl_3 + 3H_2O$$
$$Al_2O_3 + 2NaOH \longrightarrow 2NaAlO_2 + H_2O$$

These oxides are extremely hard, non-volatile and have high melting points.

6. Their hydroxides are also amphoteric in nature.

$$Be(OH)_2 + 2HCl \longrightarrow BeCl_2 + 2H_2O$$
$$Be(OH)_2 + 2NaOH \longrightarrow Na_2BeO_2 + 2H_2O$$
$$Al(OH)_3 + 3HCl \longrightarrow AlCl_3 + 3H_2O$$
$$Al(OH)_3 + NaOH \longrightarrow NaAlO_2 + 2H_2O$$

The hydroxides are insoluble in water and decompose on heating into corresponding oxides.

$$Be(OH)_2 \longrightarrow BeO + H_2O$$
$$2Al(OH)_3 \longrightarrow Al_2O_3 + 3H_2O$$

7. Beryllium and aluminium both form polymeric covalent hydrides.
8. Both combine with nitrogen when strongly heated in its atmosphere.

$$3Be + N_2 \longrightarrow Be_3N_2$$
$$2Al + N_2 \longrightarrow 2AlN$$

Nitrides on action with water evolve ammonia.

$$Be_3N_2 + 6H_2O \longrightarrow 3Be(OH)_2 + 2NH_3$$
$$AlN + 3H_2O \longrightarrow Al(OH)_3 + NH_3$$

9. Both the metals are obtained by the electrolysis of their fused salts in the presence of fluorides.
10. Beryllium carbide (Be_2C) and aluminium carbide (Al_4C_3) both evolve methane on treatment with water.

$$Be_2C + 2H_2O \longrightarrow 2BeO + CH_4$$
$$Al_4C_3 + 6H_2O \longrightarrow 2Al_2O_3 + 3CH_4$$

11. Be^{2+} and Al^{3+} ions have strong tendency to form chelate type complexes. Both form fluoride complexes, like $[BeF_4]^{2-}$, $[AlF_6]^{3-}$ respectively.
12. Both the ions give hydrated ions in solution (aqueous) like $[Be(H_2O)_4]^{2+}$ and $[Al(H_2O)_6]^{3+}$ respectively.
13. The salts of both Be and Al do not impart a colour to the flame when heated in it.

Compounds of Elements of Group 2

All the alkaline earth metals form several compounds. *Some important of which are given below.*

Quick Lime (CaO)

Preparation

It is prepared by heating limestone to 1000°C in lime klines as

$$CaCO_3 \rightleftharpoons CaO + CO_2$$

The reaction is reversible and proceeds efficiently in forward direction when CO_2 is allowed to escape from the system. It is only above 1100 K, the gas escapes freely.

Properties

1. It is an amorphous white solid, with high melting point (2273K), usually obtained in the form of hard lumps.
2. When heated in oxyhydrogen flame, it emits a bright light, called **lime light.**
3. CaO absorbs CO_2 and H_2O easily.

$$CaO + H_2O \longrightarrow Ca(OH)_2$$
$$\text{Exothermic } \Delta H = -64.5 \text{ kJ/mol}$$
$$CaO + CO_2 \longrightarrow CaCO_3$$

The addition of limited quantity of water converts lump of lime to slaked lime (as the process is called slaking). Similarly, if we use soda in the place of water, the product is called **soda lime** (NaOH/CaO).

4. It combines with solid acidic oxides at high temperature to give their salts as

$$CaO + SiO_2 \longrightarrow CaSiO_3$$
$$6CaO + P_4O_{10} \longrightarrow 2Ca_3(PO_4)_2$$

Uses

It is very useful as drying agent, in bleaching powder production (as used for the preparation of slaked lime) and as a constituent of **mortar.** As it has high melting point (2600°C), it is used for furnace linings. It is used as a basic flux in metallurgy as it combines with acidic impurities.

$$CaO + SiO_2 \longrightarrow CaSiO_3$$

It is used as a disinfectant and *germicide,* as a drying agent for ammonia and alcohol. It is employed for the purification of coal gas and softening of water.

Calcium Hydroxide or Slaked Lime

$[Ca(OH)_2]$

Preparation

It is prepared by adding water to quick lime as

$$CaO + 2H_2O \longrightarrow Ca(OH)_2 + H_2\uparrow$$

Properties

1. It is white powder, sparingly soluble in water and the *aqueous solution is called lime water while the aqueous suspension is called milk of lime.* CO_2 has the ability to turn lime water milky as

$$Ca(OH)_2 + CO_2 \longrightarrow \underset{\text{(milky ppt.)}}{CaCO_3} + H_2O$$

This milkiness disappears with excess of CO_2 as soluble calcium hydrogen carbonate is formed.

$$CaCO_3 + H_2O + CO_2 \longrightarrow \underset{\text{soluble}}{Ca(HCO_3)_2}$$

2. Being basic in nature, it reacts with acids and acidic gases forming their salts.
3. On reaction with chlorine, it forms hypochlorite, a constituent of bleaching powder as

$$2Ca(OH)_2 + 2Cl_2 \longrightarrow CaCl_2 + CaOCl_2 + 2H_2O$$

Uses

Slaked lime is used in mortar production, lime water production, disinfectant, bleaching powder production etc.

Calcium Carbonate or Lime Stone

$(CaCO_3)$

It is found as chalk, marble, coral, calcite, aragonite etc. It is a precursor of quick lime and slaked lime.

Preparation

It is prepared as

$$Ca(HCO_3)_2 \xrightarrow{\Delta} CaCO_3 + H_2O + CO_2\uparrow$$

Properties

It gets decomposed easily on heating as

$$CaCO_3 \xrightarrow{\Delta} CaO + CO_2\uparrow$$

Uses

As precipitated chalk it is used in tooth pastes and face powders, in medicine for indigestion, in adhesives, in cosmetics, in paints and distempers. Marble is used, (i) for building purposes, (ii) in the production of CO_2 in laboratory.

Limestone is used, (i) in the manufacture of quick lime, slaked lime, cement, washing soda and glass, (ii) as a flux in the smelting of iron and lead ores.

Plaster of Paris $\left(CaSO_4 \cdot \frac{1}{2}H_2O\right)$

It is chemically calcium sulphate hemihydrate.

Preparation

It is prepared by heating gypsum at 390 K. Gypsum is dihydrate of calcium sulphate.

$$\underset{\text{gypsum}}{2CaSO_4 \cdot 2H_2O} \xrightarrow{390\text{ K}} (CaSO_4)_2H_2O + 3H_2O$$

$$\text{or}\quad \underset{\text{plaster of Paris}}{CaSO_4 \cdot \frac{1}{2}H_2O}$$

In this reaction, temperature plays an important role because if temperature is above 390 K, whole the water of crystallisation is lost and dead burnt plaster or anhydrous $CaSO_4$ is obtained which does not have a property of setting with water.

Properties

1. It is white solid.
2. When mixed with water, it takes up the water of crystallisation and sets into a hard mass.

$$\underset{\text{plaster of Paris}}{CaSO_4 \cdot \frac{1}{2}H_2O} \xrightarrow{H_2O\text{ (setting)}} \underset{\text{orthorhombic}}{CaSO_4 \cdot 2H_2O}$$

$$\xrightarrow{\text{Hardening}} \underset{\text{monoclinic (gypsum)}}{CaSO_4 \cdot 2H_2O}$$

Uses

It is used for producing moulds for industries such as pottery, ceramics etc., for setting fractured bones and for making statues, models and other decorative materials.

Caution Point *The setting of plaster of Paris may be catalysed by sodium chloride, while it is retarded by borax or alum. Addition of alum to plaster of Paris makes the setting very hard. The mixture is known as keen's cement.*

Cement

It is one of the most important building materials at the present time. It is used in the construction of buildings, roads, bridges, dams, etc. It was discovered, in 1824, by an English Mason, **Joseph Aspdin** who observed that when strongly heated mixture of limestone and clay was mixed with water and allowed to stand, it hardened to a stone-like mass which resembled Portland rock–a famous building stone of England. Since then the name Portland cement has been given to a mixture containing high percentage of lime with silica, iron oxide, alumina, etc.

It is a mixture of silicates and aluminates of calcium with small amount of gypsum.

Chemical Composition

Its chemical composition CaO = 50–60%, SiO_2 = 20–25%, Al_2O_3 = 5–10%; MgO = 2–3%, Fe_2O_3 = 1–2%; SO_3 = 1–2%

The essential constituents are lime, silica and alumina. These are generally kept in the following ratio :

$$\frac{\%\text{ Silica}}{\%\text{ }Al_2O_3} = 2.5 - 4.0$$

$$\frac{\%\text{ CaO}}{\%\text{ }SiO_2 + \%\text{ }Al_2O_3 + \%\text{ }Fe_2O_3} = 1.9 - 2.1$$

The cement containing no iron is white.

Essential Raw Materials

Limestone for CaO etc., clay for SiO_2, Al_2O_3, Fe_2O_3 etc.

If lime is in excess ⟶ Cement cracks during settings;

If lime is less ⟶ Cement with weak strength.

Reactions which forms constituents of cement include

$$2CaO + SiO_2 \longrightarrow \underset{\text{dicalcium silicate}}{2CaO \cdot SiO_2}; \underset{\text{tricalcium silicate}}{3CaO \cdot SiO_2}$$

$$3CaO + Al_2O_3 \longrightarrow \underset{\text{tricalcium aluminate}}{3CaO \cdot Al_2O_3}$$

$$4CaO + Al_2O_3 + Fe_2O_3 \longrightarrow \underset{\text{tetracalcium aluminoferrite}}{4CaO \cdot Al_2O_3 \cdot Fe_2O_3}$$

Mechanism of Setting of Cement

The exact mechanism of this setting process is not known. It is believed that various aluminiate and silicates present in the cement form hydrates with water which separate in the form of gel.

$$3CaO \cdot Al_2O_3 + 6H_2O \xrightarrow{\text{Hydration}} \underset{\text{colloidal gel}}{3CaO \cdot Al_2O_3 \cdot 6H_2O}$$

$$2CaO \cdot SiO_2 + xH_2O \xrightarrow{\text{Hydration}} \underset{\text{colloidal gel}}{2CaO \cdot SiO_2 \cdot xH_2O}$$

$$4CaO \cdot Al_2O_3 \cdot Fe_2O_3 + 6H_2O \xrightarrow{\text{Hydration}} \underset{\text{colloidal gel}}{3CaO \cdot Al_2O_3 \cdot 6H_2O} + Fe_2O_3 \cdot CaO$$

At the same time some $Ca(OH)_2$ and $Al(OH)_3$ are formed as precipitates due to hydrolysis.

$$3CaO \cdot SiO_2 + H_2O \xrightarrow{\text{Hydrolysis}} Ca(OH)_2 + 2CaO \cdot SiO_2$$

$$3CaO \cdot Al_2O_3 + 6H_2O \xrightarrow{\text{Hydrolysis}} 3Ca(OH)_2 + 2Al(OH)_3$$

Gypsum combines with tricalcium aluminate to form calcium sulpho-aluminate.

$$3CaO \cdot Al_2O_3 + 3CaSO_4 + 2H_2O \longrightarrow 3CaO \cdot Al_2O_3 \cdot 3CaSO_4 \cdot 2H_2O$$

This reaction slow down the setting.

The gels formed start losing water partly by evaporation and partly by forming hydrates with unhydrated constituents. This results in the formation of a hard mass. $Ca(OH)_2$ binds the particles of calcium silicate together, while $Al(OH)_3$ fills the interstices resulting in hardening the mass.

Caution Point *Setting of cement is an exothermic process. Hence, cement structures have to be cooled during setting by sprinkling water.*

Mortar

Slaked lime is mixed with three to four times its weight of sand and the mixture is made into a thick paste with gradual addition of water which is called mortar and is used in building construction. It sets to a hard mass by loss of water and gradual absorption of CO_2 from the air. Sometimes coal ash is mixed with lime instead of sand. A mortar obtained from hydraulic lime is called hydraulic mortar. It has greater strength and is used for the construction of bridges.

Concrete

A mixture of cement, sand, gravel or small pieces of stone and water is known as concrete. It sets to an exceedingly hard structure. It is mainly used for the construction of floors. If the cement concrete is filled in around a wire netting or skeleton of iron rods and allowed to set, the resulting structure is known as **reinforced concrete**. These structures have great strength and are used for the construction of roofs, bridges, etc.

10.7 Biological Significance of Na, K, Mg and Ca

Biological Significance of Na and K

Sodium and potassium are the vital elements. Na^+ ions are found mainly in extracellular region (outside the cell) and play an important role in the transmission of nerve signals. They also regulate the flow of water across cell membranes and in transport of sugars and amino acids into the cells. Thus, it is essential that human diet must contain a sensible amount of Na. Prolonged sweating results in sodium ion loss in sweat, thus, it is important that Na^+ ions are replaced through proper diet.

Potassium ions are the most abundant cations within cell fluids, where they activate many enzymes, participate in oxidation of glucose to produce ATP (adenosine triphosphate). Potassium ions along with sodium ions are responsible for transmission of nerve signals. The functional features of nerve cells depend upon the sodium-potassium ion gradient that is established in the cell. Their ionic gradients are maintained by sodium-potassium pumps that operate across the cell membranes.

In the body of a 70 kg adult about 90 g Na^+ ions and 170 g K^+ ions are present. The daily requirement of sodium and potassium is about 2 g each.

Biological Significance of Mg and Ca

Mg^{2+} ions are present inside the animal cells while Ca^{2+} ions are in the body fluids, *i.e.,* in the extracellular region, in much the same way as K^+ are inside the cell and Na^+ outside the cell. All enzymes that utilize ATP in phosphate transfer require Mg^{2+} as cofactor. In green plants, magnesium is present in chlorophyll. Ca^{2+} and Mg^{2+} are also essential for the transmission of impulses along nerve fibres.

In bones and teeth, Ca is present as apatite, $Ca_3(PO_4)_2$, and in enamel on teeth as fluorapatite, $3Ca_3(PO_4)_2 \cdot CaF_2$. Ca^{2+} ions play an important role in blood clotting and are required to trigger the contraction of muscles. Ca^{2+} ions also regulate the heart beats. Calcium ions in bones exchange readily with those in the blood plasma. In a normal adult this exchange is in balance, but in elderly people, especially woman, there is sometimes net loss of bone calcium, leading to the disease known as **osteoporosis.**

An adult body contains about 25 g of Mg and 1200 g of Ca. The daily requirement of Mg is about 350 mg while that of Ca is 800 mg. The important source for Ca are milk, cheese and other dairy products while that of Mg are nuts, green vegetables etc.

Check Point 2

1. Explain, why $Be(OH)_2$ is almost insoluble in water, while $Ba(OH)_2$ is soluble?
2. Why $BeCO_3$ is less stable than $MgCO_3$?
3. Be and Mg do not give colour to flame whereas, other alkaline metals do so, explain why?
4. Beryllium chloride fumes in air why? (Hint due to evolution of HCl)
5. Barium ion, Ba^{2+}, is poisonous, yet $BaSO_4$ is given to patients prior to taking stomach X-ray. Why is it safe to use $BaSO_4$ internally?
6. How gypsum slow the rate of setting of cement?

WORKED **OUT**
Examples

Example 1 *A white solid X is a compound of s-block element. A piece of red litmus paper turns white when it is dipped into a freshly made aqueous solution of the white solid. The white solid ' X' is*

(*a*) Na_2O_2 (*b*) Na_2O
(*c*) CaO (*d*) Both Na_2O_2 and Na_2O

Solution (*a*) The substance is Na_2O_2. When N_2O_2 is dissolved in water, it forms NaOH along with H_2O_2. NaOH is a strong base while H_2O_2 is a weak acid.

$$Na_2O_2 + 2H_2O \longrightarrow 2NaOH + H_2O_2$$

H_2O_2 turns colour of red litmus paper white due to its bleaching action (which is due to its oxidising character.)

$$H_2O_2 \longrightarrow H_2O + [O]$$
$$Na_2O + H_2O \longrightarrow 2NaOH$$

NaOH solution turns colour of red litmus paper into blue due to its stronger alkaline character.

Thus, the white solid *X* must be Na_2O_2 and not Na_2O.

Example 2 *Anhydrous potassium nitrate is heated with excess of metallic potassium.*

$$KNO_3(s) + K(s) \longrightarrow X + Y$$

In this reaction, the products X and Y are

(*a*) KNO_2, O_2 (*b*) K_2O, N_2
(*c*) K_2O, N_2O (*d*) K_2O, NO_2

Solution (*b*) $2KNO_3(s) + \underset{\text{(excess)}}{10K(s)} \xrightarrow{\Delta} 6K_2O(s) + N_2$

Example 3 *Identify the product D in the following reaction sequence.*

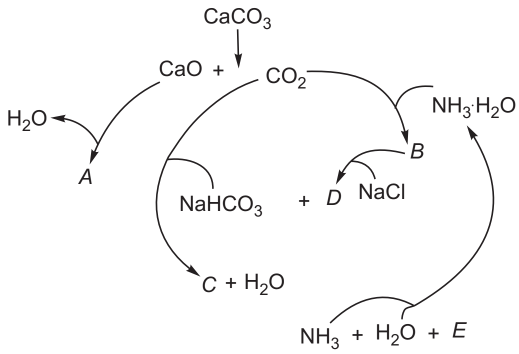
$$Na_2CO_3 \xrightarrow{SO_2} A \xrightarrow{Na_2CO_3} B \xrightarrow[\Delta]{\text{Elemental S}} C \xrightarrow{I_2} D$$

(*a*) Na_2SO_3 (*b*) $Na_2S_2O_3$
(*c*) $Na_2S_4O_6$ (*d*) $NaHSO_3$

Solution (*c*) $Na_2CO_3 + 2SO_2 + H_2O \longrightarrow \underset{A}{2NaHSO_3} + CO_2$

$$2NaHSO_3 + Na_2CO_3 \longrightarrow \underset{B}{2Na_2SO_3} + H_2O + CO_2$$
$$\underset{B}{Na_2SO_3} + S \longrightarrow \underset{C}{Na_2S_2O_3}$$
$$2Na_2S_2O_3 + I_2 \longrightarrow \underset{D}{Na_2S_4O_6} + 2NaI$$

Example 4 *The Haber process can be represented by the following scheme*



Identify D and E in this sequence

(*a*) NH_4HCO_3, Na_2CO_3
(*b*) $NH_4Cl, Ca(OH)_2$
(*c*) $NH_4Cl, CaCl_2$
(*d*) $Ca(OH)_2, CaCl_2$

Solution (*c*) In such scheme

$A = Ca(OH)_2, B = NH_4HCO_3, C = Na_2CO_3, D = NH_4Cl$ and $E = CaCl_2$

Example 5 *Identify X in the following reaction.*

$$Ba\overset{*}{C}O_3 + H_2SO_4 \longrightarrow X(\text{gas}) \quad (C^* \text{ denotes } C^{14})$$

(*a*) $C_2O_4^-$ (*b*) CO_2
(*c*) $\overset{*}{C}O_2$ (*d*) H_2O

Solution (*c*) $Ba\overset{*}{C}O_3 + H_2SO_4 \longrightarrow \underset{(X)}{\overset{*}{C}O_2} + H_2O + \underset{\text{white ppt.}}{BaSO_4\downarrow}$

$$C^* = C^{14}$$

Example 6 *Calcium burns in nitrogen to produce a white powder which dissolves in sufficient water to produce a gas A and an alkaline solution. The solution on exposure to air produces a thin solid layer of B on the surface. The compounds A and B will be*

(*a*) Ca_3N_2, NH_3
(*b*) NH_3, CO_2
(*c*) $Ca(OH)_2, CaCO_3$
(*d*) $NH_3, CaCO_3$

Solution (*d*) $A = NH_3$ and $B = CaCO_3$

The reactions are as follows

$$3Ca + N_2 \longrightarrow \underset{\text{calcium nitride}}{Ca_3N_2}$$

$$Ca_3N_2 + 6H_2O \longrightarrow 3Ca(OH)_2 + \underset{A}{2NH_3}$$

$$Ca(OH)_2 + \underset{\text{from air}}{CO_2} \longrightarrow \underset{B}{CaCO_3} + H_2O$$

(solid layer is due to $CaCO_3$)

Example 7 *Element A burns in nitrogen to give an ionic compound B. Compound B reacts with water to give C and D. A solution of C becomes 'milky' on bubbling carbon dioxide. The element A is*

(*a*) Na
(*b*) Mg
(*c*) Ca
(*d*) Be

Solution (c) $\underset{A}{3M} + N_2 \longrightarrow \underset{B}{M_3N_2}$

$$\underset{B}{M_3N_2} + 6H_2O \longrightarrow \underset{C}{3M(OH)_2} + \underset{D}{2NH_3}$$

$$\underset{C}{M(OH)_2} + CO_2 \longrightarrow \underset{D}{MCO_3} + H_2O$$

M may be either Ca or Ba. It is not magnesium because $Mg(OH)_2$ has very low solubility in water.

Example 8 *An element (A) reacts quitely with water librating a colourless, odourless gas and a solution of (B). Passing* CO_2 *gas through B yield a white precipitate (C) which dissolves in excess of* CO_2*. C gives red colour to Bunsen burner flame. C on heating gives a caustic white compound which on further heating with carbon at 1000°C gives D, a compound of immense commercial importance. Compound D is*

(*a*) $Ca(OH)_2$
(*b*) $CaCO_3$
(*c*) CaO
(*d*) CaC_2

Solution (*d*) CO_2 gives white precipitate (*C*) with *B*, thus, *C* is $CaCO_3$ and *B* is $Ca(OH)_2$. Thus, the compound *A* is CaO. Since, *C* gives red colour to the flame it contains Ca elements.

$$CaCO_3 \xrightarrow{\Delta} CaO + CO_2$$

$$2CaO + 4C \xrightarrow{1000^\circ C} 2CaC_2 + O_2$$

Example 9 *A white salt (A) evolves a colourless gas (B) with dilute* HCl. *Bubbling (B) through lime water gives a precipitate 'C' which dissolves in excess of the gas. 'A' imparts apple green colour to the flame. Compound A is*

(*a*) $CaCO_3$
(*b*) $BaCO_3$
(*c*) $Ca(OH)_2$
(d) $MgCO_3$

Solution (*b*) Since '*A*' imparts apple green colour to the flame, it must contain Ba. Moreover, '*B*' gas turns lime water milky, so *B* is CO_2 and *A* is $BaCO_3$. The reactions are as

$$\underset{'A'}{BaCO_3} \xrightarrow{\Delta} BaO + \underset{'B'}{CO_2}$$

$$CO_2 + Ca(OH)_2 \longrightarrow \underset{\text{white ppt}}{CaCO_3} + H_2O$$

Start Practice for JEE Main

Round I (Topically Divided Problems)

Elements of Group 1

1. Alkali metals react with water vigorously to form hydroxides and dihydrogen. Which of the following alkali metals reacts with water least vigorously? **[NCERT Exemplar]**

(a) Li (b) Na (c) K (d) Cs

2. The reducing power of a metal depends on various factors. Suggest the factor which makes Li, the strongest reducing agent in aqueous solution. **[NCERT Exemplar]**

(a) Sublimation enthalpy
(b) Ionisation enthalpy
(c) Hydration enthalpy
(d) Electron gain enthalpy

3. Shine at freshly cut sodium is because of

(a) oscillation of free electrons
(b) weak metallic bonding
(c) absorption of light in crystal lattice
(d) presence of free valency at the surface

4. Sodium is less reactive than potassium because **[NCERT Exemplar]**

(a) of its higher ionisation enthalpy
(b) of its less negative E°
(c) of its more negative E°
(d) Both (a) and (b)

5. Why are potassium and caesium, rather than lithium used in photoelectric cells? **[NCERT Exemplar]**

(a) Because of their lower IE
(b) Because of their lower EA
(c) Because of their higher IE
(d) Both (a) and (b)

6. The order of decreasing ionisation enthalpy in alkali metals is **[NCERT Exemplar]**

(a) $Na > Li > K > Rb$ (b) $Rb < Na < K < Li$
(c) $Li > Na > K > Rb$ (d) $K < Li < Na < Rb$

7. The characteristic not related to alkali metal is

(a) high ionisation energy
(b) their ions are isoelectronic with noble gases
(c) low melting point
(d) low electronegativity

8. When sodium is dissolved in liquid ammonia, a solution of deep blue colour is obtained. The colour of the solution is due to **[NCERT Exemplar]**

(a) ammoniated electron
(b) sodium ion
(c) sodium amide
(d) ammoniated sodium ion

9. Ions of an element of group 1 participate in the transmission of nerve signals and transport of sugars and amino acids into cells. This element imparts yellow colour to the flame in flame test and forms an oxide and a peroxide with oxygen. Identify the element. **[NCERT Exemplar]**

(a) Sodium (b) Potassium
(c) Francium (d) Caesium

10. Which of the following oxides is formed when potassium metal is burnt in excess of air?

(a) KO_2 (b) K_2O_2 (c) KO (d) K_2O

11. Which sequence of reactions shows correct chemical relation between sodium and its compounds?

(a) $Na + O_2 \longrightarrow Na_2O \xrightarrow{HCl(aq)} NaCl \xrightarrow{CO_2} Na_2CO_3 \xrightarrow{\Delta} Na$

(b) $Na \xrightarrow{O_2} Na_2O \xrightarrow{H_2O} NaOH \xrightarrow{CO_2} Na_2CO_3 \xrightarrow{\Delta} Na$

(c) $Na + H_2O \longrightarrow NaOH \xrightarrow{HCl} NaCl \xrightarrow{CO_2} Na_2CO_3 \xrightarrow{\Delta} Na$

(d) $\text{Na} + \text{H}_2\text{O} \longrightarrow \text{NaOH} \xrightarrow{\text{CO}_2} \text{Na}_2\text{CO}_3 \xrightarrow{\text{HCl}} \underset{\text{(molten)}}{\text{NaCl}} \xrightarrow{\text{Electrolysis}} \text{Na}$

12. Which is the most basic in character?
(a) NaOH (b) KOH
(c) RbOH (d) LiOH

13. Which one of the following is the highest melting halide?
(a) NaCl (b) NaI
(c) NaBr (d) NaF

14. A solid is a compound of group 1 element and it gives a bright red colour in the flame test. The solid is
(a) LiBr (b) CsCl
(c) KCl (d) NaCl

15. Which of the following does not illustrate the anomalous properties of lithium?
(a) Li is much softer than the other group first metals
(b) The m.p. and b.p. of Li are comparatively high
(c) Li forms a nitride Li_3N unlike group first metals
(d) The ion of Li and its compounds are more heavily hydrated than those of the rest of the group elements

Compounds of Elements of Group I

16. Baking powder contains
(a) $NaHCO_3, Ca(H_2PO_2)_2$ and starch
(b) $NaHCO_3, Ca(H_2PO_2)_2$
(c) $NaHCO_3$, starch
(d) $NaHCO_3$

17. In which of the following processes,fused sodium hydroxide is electrolysed at 330°C temperature for the extraction of sodium?
(a) Castner's process (b) Cyanide process
(c) Down's process (d) Both (b) and (c)

18. When sodium chloride solution is electrolysed, the gas that is liberated at the cathode is
(a) oxygen (b) chlorine
(c) hydrogen (d) air

19. In the synthesis of sodium carbonate, the recovery of ammonia is done by treating NH_4Cl with $Ca(OH)_2$. The by product obtained in this process is **[NCERT Exemplar]**
(a) $CaCl_2$ (b) NaCl
(c) NaOH (d) $NaHCO_3$

20. When washing soda is heated
(a) CO_2 is released (b) CO + CO_2 is released
(c) CO is released (d) water vapour is released

21. Sodium thiosulphate is used in photography
(a) as AgBr grain is reduced to non-metallic silver
(b) to convert metallic silver into silver salt
(c) to remove reduced silver
(d) to remove undecomposed AgBr in the form of $Na_3[Ag(S_2O_3)_2]$ (a complex salt)

22. Potassium carbonate cannot be prepared by Solvay process because **[NCERT]**
(a) it is highly unstable
(b) it reacts with the other by products
(c) potassium bicarbonate is highly soluble
(d) it is highly soluble

Elements of Group 2

23. Which of the following elements does not form hydride by direct heating with dihydrogen? **[NCERT Exemplar]**
(a) Be (b) Mg
(c) Sr (d) Ba

24. Which of the following metal carbonates gets decomposed on heating?
(a) Na_2CO_3 (b) $MgCO_3$
(c) K_2CO_3 (d) Rb_2CO_3

25. In the alkaline earth metals, the element forming predominantly covalent compound is
(a) Ca (b) Sr
(c) Mg (d) Be

26. Select the incorrect statement.
(a) Be can form complexes due to its very small size
(b) Mg cannot form complexes
(c) Mg burns in air releasing dazzling light rich in UV rays
(d) $CaCl_2 \cdot 6H_2O$ when mixed with ice gives freezing mixture

27. The right order of the solubility of sulphates of alkaline earth metals in water is
(a) Be > Ca > Mg > Ba > Sr
(b) Mg > Be > Ba > Ca > Sr
(c) Be > Mg > Ca > Sr > Ba
(d) Mg > Ca > Ba > Be > Sr

28. The metal ion, that plays an important role in muscle contraction, is
(a) Be^{2+} (b) Mg^{2+}
(c) Ca^{2+} (d) Ba^{2+}

29. $Be(OH)_2$ is insoluble in water, while $Ba(OH)_2$ is highly soluble due to
(a) lattice energy difference
(b) common ion effect
(c) bond order
(d) hard acid

30. Dehydration of hydrates of halides of calcium, barium and strontium, *i.e.,* $CaCl_2 \cdot 6H_2O$, $BaCl_2 \cdot 2H_2O$, $SrCl_2 \cdot 2H_2O$, can be achieved by heating. These become wet on keeping in air. Which of the following statements is correct about these halides? **[NCERT** Exemplar**]**

(a) Act as dehydrating agent
(b) Can absorb moisture from air
(c) Tendency to form hydrate decreases from calcium to barium
(d) All of the above

31. Beryllium and magnesium do not give colour to the flame whereas other alkaline earth metals do so. This is because of their **[NCERT]**

(a) Small size
(b) High effective nuclear charge
(c) High ionisation energy
(d) All of the above

32. Metal carbonates decompose on heating to give metal oxide and carbon dioxide. Which of the metal carbonates is most stable thermally? **[NCERT]**

(a) $MgCO_3$ (b) $CaCO_3$
(c) $SrCO_3$ (d) $BaCO_3$

33. An element of group 2 forms covalent oxide which is amphoteric in nature and dissolves in water to given an amphoteric hydroxide. Identify the element.

(a) Beryllium (b) Magnesium
(c) Calcium (d) Barium

34. The property of the alkaline earth metals that increases with their atomic number is

(a) solubility of their sulphates
(b) ionisation energy
(c) solubility of their hydroxides
(d) electronegativity

35. A metal M readily forms its sulphate MSO_4 which is water soluble. It forms its oxide MO which becomes inert on heating. It forms its insoluble hydroxide $M(OH)_2$ which is soluble in NaOH solution. Then, M is

(a) Be (b) Ba
(c) Ca (d) Mg

Compounds of Elements of Group 2

36. Plaster of Paris on making paste with little water sets to hard mass due to the formation of

(a) $CaSO_4$ (b) $CaSO_4 \cdot \frac{1}{2} H_2O$
(c) $CaSO_4 \cdot H_2O$ (d) $CaSO_4 \cdot 2H_2O$

37. Setting of plaster of Paris is

(a) dehydration
(b) oxidation with atmospheric oxygen
(c) combination with atmospheric CO_2
(d) hydration to yield another hydrate

38. Gypsum, $CaSO_4 \cdot 2H_2O$ on heating to about 120°C forms a compound which has the chemical composition represented by

(a) $CaSO_4 \cdot H_2O$
(b) $2CaSO_4 \cdot 3H_2O$
(c) $2CaSO_4 \cdot H_2O$
(d) $CaSO_4$

39. The difference of water molecules in gypsum and plaster of Paris is

(a) $\frac{5}{2}$ (b) 2
(c) $\frac{1}{2}$ (d) $1\frac{1}{2}$

40. Which of the following substances is used in the laboratory for fast drying of neutral gases?

(a) Sodium sulphate
(b) Phosphorus pentoxide
(c) Sodium phosphate
(d) Anhydrous calcium chloride

41. By adding gypsum to cement **[NCERT** Exemplar**]**

(a) setting time of cement become less
(b) setting time of cement increases
(c) colour of cement becomes light
(d) shining surface is obtained

42. Suspension of slaked lime in water is known as **[NCERT** Exemplar**]**

(a) lime water
(b) quick lime
(c) milk of lime
(d) aqueous solution of slaked lime

43. Which of the following statements is true about $Ca(OH)_2$? **[NCERT** Exemplar**]**

(a) It is used in the preparation of bleaching powder
(b) It is a light blue solid
(c) It does not possess disinfectant property
(d) It is used in the manufacture of cement

44. A chemical A is used for the preparation of washing soda to recover ammonia. When CO_2 is bubbled through an aqueous solution of A, the solution turns milky. It is used in white washing due to disinfectant nature. What is the chemical formula of A? **[NCERT** Exemplar**]**

(a) $Ca(HCO_3)_2$ (b) CaO
(c) $Ca(OH)_2$ (d) $CaCO_3$

Miscellaneous

45. Which of the following metals has stable carbonate?
(a) Al (b) Si (c) Mg (d) Na

46. Which of the following is weakest base?
(a) $Zn(OH)_2$ (b) NaOH (c) $Ca(OH)_2$ (d) KOH

47. Alkaline earth metals are denser than alkali metals, because metallic bonding in alkaline earth metal is
(a) weaker (b) stronger
(c) volatile (d) not present

48. In India, on the occasion of marriages, the fireworks used give green flame. Which one of the following radicals may be present?
(a) Na (b) K (c) Ba (d) Ca

49. Compared with the alkaline earth metals, the alkali metals exhibit
(a) greater hardness
(b) smaller ionic radii
(c) lower ionisation energies
(d) highest boiling points

50. Which of the following pairs of substances would give same gaseous product on reaction with water?
(a) Na and Na_2O_2
(b) Ca and CaH_2
(c) Ca and CaO
(d) Ba and BaO_2

Round II (Mixed Bag)

Only One Correct Option

1. Which of the following has the highest solubility product?
(a) KOH (b) CsOH
(c) LiOH (d) RbOH

2. Crude common salt is hygroscopic because of the presence of impurities of
(a) $CaSO_4$ and $MgSO_4$
(b) $CaCl_2$ and $MgCl_2$
(c) $CaBr_2$ and $MgBr_2$
(d) $Ca(HCO_3)_2$ and $Mg(HCO_3)_2$

3. Sodium nitrate decomposes above 800°C to give
(a) N_2 (b) O_2
(c) NO_2 (d) Na_2O

4. When sodium is heated with moist air, then the product obtained is
(a) Na_2O_2 (b) Na_2CO_3
(c) NaOH (d) Na_2O

5. On dissolving moderate amount of sodium metal in liquid NH_3 at low temperature, which one of the following does not occur?
(a) Na^+ ions are formed in the solution
(b) Blue coloured solution is obtained
(c) Liquid NH_3 becomes good conductor of electricity
(d) Liquid ammonia remains diamagnetic

6. The solubility of metal halides depends on their nature, lattice enthalpy and hydration enthalpy of the individual ions. Amongst fluorides of alkali metals, the lowest solubility of LiF in water is due to
[NCERT Exemplar]
(a) Ionic nature of lithium fluoride
(b) High lattice enthalpy
(c) High hydration enthalpy for lithium ion
(d) Low ionisation enthalpy of lithium atom

7. Amphoteric hydroxides react with both alkalies and acids. Which of the following group 2 metal hydroxides is soluble in sodium hydroxide?
[NCERT Exemplar]
(a) $Be(OH)_2$ (b) $Mg(OH)_2$
(c) $Ca(OH)_2$ (d) $Ba(OH)_2$

8. A substance which gives brick red flame and breaks down on heating to give oxygen and a brown gas is
[NCERT Exemplar]
(a) magnesium nitrate (b) calcium nitrate
(c) barium nitrate (d) strontium nitrate

9. In curing cement plasters, water is sprinkled from time to time. This helps in
(a) developing interlocking needle like crystals of hydrated silicates
(b) hydrated sand gravel mixed with cement
(c) converting sand into silicic acid
(d) keeping it cool

10. Iron pipes lying under acidic soil are often attached to blocks of magnesium for protection from rusting. Magnesium offers protection to iron against corrosion because it
(a) is more readily converted into positive ions
(b) is more stable than iron
(c) forms a corrosion resistance alloy with iron
(d) prevents air from reaching the surface of iron

11. Chemical '*A*' is used for water softening to remove temporary hardness. *A* reacts with sodium carbonate to generate caustic soda. When CO_2 is bubbled through a solution of '*A*', it turns cloudy. What is the chemical formula of *A*?

(a) CaO (b) $Ca(OH)_2$ (c) $CaCO_3$ (d) $Ca(HCO_3)_2$

12. A metal '*M*' reacts with N_2 to give a compound '*A*' (M_3N). '*A*' on heating at high temperature gives back '*M*' and '*A*' on reacting with H_2O give a gas *B*. '*B*' turns $CuSO_4$ solution blue on passing through it. *M* and *B* can be

(a) Al and NH_3 (b) Li and NH_3
(c) Na and NH_3 (d) Mg and NH_3

13. Which one of the following statements is true for all the alkali metals?

(a) Their nitrates decompose on heating to give NO_2 and O_2
(b) Their carbonates decompose on heating to give CO_2 and the metal oxide
(c) They react with oxygen to give mainly the oxide M_2O
(d) They react with halogens to give the halides *MX*

14. When water is added to compound (*A*) of calcium, solution of compound (*B*) is formed. When carbon dioxide is passed into the solution, it turns milky due to the formation of compound (*C*). If excess of carbon dioxide is passed into the solution milkiness disappears due to the formation of compound (*D*). The milkiness disappears in the last step due to the formation of **[NCERT Exemplar]**

(a) $CaCO_3$ (b) $Ca(HCO_3)_2$
(c) $NaHCO_3$ (d) Na_2CO_3

15. Lithium hydride can be used to prepare other useful hydrides. Beryllium hydride is one of them. The reagents that are required to prepare BeH_2 from lithium hydride are **[NCERT Exemplar]**

(a) $BeCl_2$ only (b) $Al_2Cl_6, BeCl_2$
(c) AlH_3, CH_4 (d) $AlH_3, BeCl_2$

16. LiF is almost insoluble in water whereas LiCl is soluble not only in water but also in acetone. This is because **[NCERT Exemplar]**

(a) of high hydration enthalpy of Li^+
(b) of low hydration enthalpy of Li^+
(c) of more ionic character in LiCl
(d) None of the above

17. Consider the following statements.

I. BeO is insoluble but $BeSO_4$ is soluble in water.
II. BaO is insoluble but $BaSO_4$ is soluble in water.
III. LiI is more soluble than KI in ethanol.

The true statements is/are **[NCERT]**

(a) I and II only (b) I and III only
(c) II and III only (d) I, II and III

18. The product which is not common in the given reaction is **[NCERT Exemplar]**

$$O_2^{2-} + H_2O \longrightarrow$$
$$O_2^{-} + H_2O \longrightarrow$$

(a) OH^- (b) H_2O_2
(c) O_2 (d) None of these

19. In which of the following processes gaseous products are obtained? **[NCERT]**

I. Mg is burnt in air.
II. Quicklime is heated with silica.
III. Chlorine reacts with slaked lime.
IV. Calcium nitrate is heated.

(a) II and IV only (b) I, II and IV only
(c) IV only (d) III and IV only

20. Prepartion of which of the following substance does not involve electrolysis of NaCl as its one step? **[NCERT]**

(a) Na metal (b) NaOH
(c) Na_2O_2 (d) Na_2CO_3

More than One Correct Option

21. Which of the following groups of elements have chemical properties that are most similar?

(a) Be, Al, Ca (b) Mg, Ba, Sr
(c) Be, Ra, Cs (d) Na, K, Ca

22. Several sodium compounds find use in industries. Which of the following compounds are used for textile industry? **[NCERT Exemplar]**

(a) Na_2CO_3 (b) $NaHCO_3$ (c) NaOH (d) NaCl

23. Which of the following compounds are readily soluble in water? **[NCERT Exemplar]**

(a) $BeSO_4$ (b) $MgSO_4$ (c) $BaSO_4$ (d) $SrSO_4$

24. Identify the correct formula of halides of alkaline earth metals from the following. **[NCERT Exemplar]**

(a) $BaCl_2 \cdot 2H_2O$ (b) $BaCl_2 \cdot 4H_2O$
(c) $CaCl_2 \cdot 6H_2O$ (d) $SrCl_2 \cdot 4H_2O$

25. Choose the correct statements from the following. **[NCERT Exemplar]**

(a) Beryllium is not readily attacked by acids because of the presence of an oxide film on the surface of the metal.
(b) Beryllium sulphate is readily soluble in water as the greater hydration enthalpy of Be^{2+} overcomes the lattice enthalpy factor.
(c) Beryllium exhibits coordination number more than four
(d) Beryllium oxide is purely acidic in nature

26. Which of the following are correct reasons for anomalous behaviour of lithium? **[NCERT Exemplar]**

(a) Exceptionally small size of its atom
(b) Its high polarising power
(c) It has high degree of hydration
(d) Exceptionally low ionisation enethalpy

Assertion and Reason

Directions (Q. Nos. 27 to 31) *Each of these questions contains two statements : Statement* I (*Assertion*) *and Statement* II (*Reason*). *Each of these questions also has four alternative choices, only one of which is the correct answer. You have to select one of the codes* (*a*), (*b*), (*c*), (*d*) *given below :*

(a) Statement I is true, Statement II is true; Statement II is a correct explanation for Statement I.
(b) Statement I is true, Statement II is true; Statement II is not a correct explanation for Statement I.
(c) Statement I is true; Statement II is false.
(d) Statement I is false; Statement II is true.

27. Statement I The carbonate of lithium decomposes easily on heating to form lithium oxide and CO_2.

Statement II Lithium being very small in size polarises large carbonate ion leading to the formation of more stable Li_2O and CO_2. **[NCERT Exemplar]**

28. Statement I Potassium and caesium emit electrons on exposure to light.

Statement II Potassium and caesium are used in photo electric cells.

29. Statement I Mg continue to burn in nitric oxide.

Statement II During burning, heat evolved do not decompose NO.

30. Statement I Superoxides of alkali metals are paramagnetic.

Statement II Superoxides contain the ion O^{2-} which has one unpaired electron.

31. Statement I Beryllium carbonate is kept in the atmosphere of carbon dioxide.

Statement II Beryllium carbonate is unstable and decomposes to give beryllium oxide and carbon dioxide. **[NCERT Exemplar]**

Comprehension Based Questions

Directions (Q. Nos. 32 to 34) Lithium only forms monoxide when heated in oxygen. Sodium forms monoxide and peroxide in excess of oxygen. Other alkali metals form superoxide with its oxygen. The abnormal behaviour of lithium is due to its small size. The larger size of higher alkali metals also decides the role of formation of superoxides. All the three anions abstract proton from water. The three anions are related to each other as follows

$$\underset{\text{oxide ion}}{O^{2-}} \xrightarrow{\frac{1}{2}O_2} \underset{\text{peroxide ion}}{O_2^{2-}} \xrightarrow{O_2} \underset{\text{superoxide ion}}{2\,O_2^-}$$

32. In hydrolysis, the alkali metal oxides, peroxides and superoxides act as

(a) Lewis acid (b) Lewis base
(c) Bronsted acid (d) Bronsted base

33. Which anion is unstable towards water?

(a) O_2^- (b) O^{2-}
(c) O_2^{2-} (d) All of these

34. Which compound will liberate oxygen when reacts with water?

(a) KO_2 (b) Na_2O (c) Cs_2O_2 (d) Na_2O_2

Directions (Q. Nos. 35 to 37) A halide of Be(X) sublimes on heating and is a bad conductor of electricity. From its aqueous solution, it is difficult to obtain anhydrous salt. This halide of beryllium (X) is obtained by heating beryllium oxide with carbon tetrachloride at 800°C. This halide of beryllium forms complex of the type $M_2[BeX_4]$.

35. Beryllium chloride forms $Na_2[BeCl_4]$ with NaCl because Be has

(a) smaller size (b) vacant '*d*' orbitals
(c) Both (a) and (b) (d) None of these

36. What compound is formed when $BeCl_2$ is dissolved in water in cold conditions?

(a) BeO_2 (b) BeO
(c) $Be(OH)_2$ (d) $[Be(H_2O)_4]Cl_2$

37. What is compound X?

(a) $BeCl_2$ (b) BeF_2
(c) $BeBr_2$ (d) None of these

Directions (Q. Nos. 38 to 40) Cement is one of the most important building material of the present time. It is a dirty greyish heavy powder containing calcium aluminates and silicates. The important raw materials needed for the manufacture of cement are, limestone, clay and gypsum. The main step in the manufacture of cement is the heating of raw material or slurry in the rotary kiln at a very high temperature 1400-1600°C. Finally 2 or 3% gypsum is added.

When cement is mixed with water and left as such for sometime, it becomes a hard mass. This is known as setting of cement. It is believed that various aluminates and silicates present in the cement form hydrates with water which separate in the form of gel. The gels formed start losing water partly by evaporation and partly by forming hydrates with unhydrated constituents. This results in the formation of a hard mass.

38. Portland cement does not contain
(a) $CaSiO_4$ (b) $CaSiO_3$
(c) $Ca_3 \cdot Al_2O_6$ (d) $Ca_3(PO_4)_2$

39. The percentage of lime in Portland cement is approximately
(a) 20-25% (b) 30-40% (c) 60-65% (d) 40-50%

40. Concrete is a mixture of
(a) cement, sand, gravel and water
(b) cement, limestone and water
(c) cement, slaked lime and water
(d) cement, sand and water

Previous Years' Questions

41. Which of the following on thermal decomposition yields a basic as well as acidic oxide? **[AIEEE 2012]**
(a) $NaNO_3$ (b) $KClO_3$ (c) $CaCO_3$ (d) NH_4NO_3

42. KO_2 is used in space and submarines because it **[AIEEE 2012]**
(a) absorbs CO_2 and increases O_2 concentration
(b) absorbs moisture
(c) absorbs CO_2
(d) produces ozone

43. The products obtained on heating $LiNO_3$ will be **[AIEEE 2011]**
(a) $LiNO_2 + O_2$ (b) $Li_2O + NO_2 + O_2$
(c) $Li_3N + O_2$ (d) $Li_2O + OH + O_2$

44. What is the best description of the change that occurs when $Na_2O(s)$ is dissolved in water? **[AIEEE 2011]**
(a) Oxidation number of sodium decreases
(b) Oxide ion accepts sharing in a pair of electrons
(c) Oxide ion donates a pair of electrons
(d) Oxidation number of oxygen increases

45. Beryllium and aluminium exhibit many properties which are similar. But the two elements differ in **[AIEEE 2004]**
(a) exhibiting maximum covalency in compounds
(b) forming polymeric hydrides
(c) forming covalent halides
(d) exhibiting amphoteric nature in their oxides

46. One mole of magnesium nitride on reaction with an excess of water gives **[AIEEE 2004]**
(a) one mole of ammonia
(b) one mole of nitric acid
(c) two moles of ammonia
(d) two moles of nitric acid

47. The solubilities of carbonates decrease down the magnesium group due to a decrease in **[AIEEE 2003]**
(a) lattice energies of solids
(b) hydration energies of cations
(c) inter ionic attraction
(d) entropy of solution formation

48. The substance not likely to contain $CaCO_3$, is **[AIEEE 2003]**
(a) a marble statue
(b) calcined gypsum
(c) sea shells
(d) dolomite

49. The metallic sodium dissolves in liquid ammonia to form a deep blue coloured solution. The deep blue colour is due to the formation of **[AIEEE 2002]**
(a) solvated electron $e^-(NH_3)_y$
(b) solvated atomic sodium, $Na(NH_3)_y$
(c) $(Na^+ + Na^-)$
(d) $NaNH_2 + H_2$

the Guidance

Round I

1. Among alkali metals , reactivity increases on moving down the group because ionisation energy decreases. Thus, ionisation energy is highest for Li among alkali metals, so it is less reactive and hence, reacts less vigorously with water.

2. Because of its small size hydration energy of Li is high which compensates for its high ionisation energy. Consequently, its reduction potential is lowest amongst alkali metal and hence , it is the strongest reducing agent.

3. Shining at freshly cut sodium is due to oscillation of free electrons.

4. The ionization enthalpy ($\Delta_1 H_1$) of potassium (419 kJ mol^{-1}) is less than that of sodium (496 kJ mol^{-1}) and the standard electrode potential ($E°$) of potassium (-2.925 V) is more negative than that of sodium (-2.714 V) that's why potassium is more reactive than sodium.

5. Metals having very high tendency to lose electrons are used in photoelectric cells. Lower the ionisation energy, higher is the tendency to lose electrons.

Potassium and caesium have much lower ionisation enthalpy than that of lithium. Therefore, these metals on exposure to light emit electrons easily but lithium does not. That's why K and Cs rather than Li are used in photoelectric cells.

6. The distance between the valence electron and nucleus increases as the size of alkali metal increases, *i.e.,* nucleus binds the valence electron less tightly. Thus, the amount of energy required to remove valence electron (*i.e.,* ionisation energy) decreases.

$\therefore$ The order of IE is $\text{Li} > \text{Na} > \text{K} > \text{Rb}$.

8. On dissolving sodium in liquid ammonia, its colour turns deep blue due to the generation of ammoniated electrons.

$$\text{Na} + (x+y)\,\text{NH}_3 \longrightarrow [\text{Na}\,(\text{NH}_3)_x]^+ + \underset{\substack{\text{solvated or}\\ \text{ammoniated}\\ \text{electron}}}{e(\text{NH}_3)_y}$$

9. The element is sodium.

11. $2\text{Na} + 2\text{H}_2\text{O} \longrightarrow 2\text{NaOH} + \text{H}_2\uparrow$

$$2\text{NaOH} + \text{CO}_2 \longrightarrow \text{Na}_2\text{CO}_3 + \text{H}_2\text{O}$$

$$\text{Na}_2\text{CO}_3 + 2\text{HCl} \longrightarrow 2\text{NaCl} + \text{H}_2\text{O} + \text{CO}_2$$

$$\underset{\text{(molten)}}{\text{NaCl}} \xrightarrow{\text{Electrolysis}} \begin{array}{ccc} \text{Na}^+ & + & \text{Cl}^- \\ \big\downarrow {\scriptstyle +e^-} & & \big\downarrow {\scriptstyle -e^-} \\ \text{Na} & & \text{Cl} \end{array}$$

12. $$\xrightarrow[\text{Down the group basic character increases}]{\text{LiOH} < \text{NaOH} < \text{KOH} < \text{RbOH}}$$

13. Because of the smaller size of F-ions, NaF has the highest lattice energy and hence, the highest melting point.

14. Lithium salts impart bright red colour to the flame.

15. Li is much softer than the other group first metals. Actually, Li is harder than other alkali metals.

16. Baking powder contains NaHCO_3, $\text{Ca(H}_2\text{PO}_2)_2$ and starch.

18. $2\text{NaCl} + 2\text{H}_2\text{O} \xrightarrow{\text{Electrolysis}} 2\text{NaOH} + \underset{\text{anode}}{\text{Cl}_2} + \underset{\text{cathode}}{\text{H}_2}$

19. $2\text{NH}_4\text{Cl} + \text{Ca(OH)}_2 \longrightarrow \text{CaCl}_2 + 2\text{NH}_3 + 2\text{H}_2\text{O}$

20. $\text{Na}_2\text{CO}_3\cdot 10\text{H}_2\text{O} \xrightarrow{\Delta} \text{Na}_2\text{CO}_3\cdot\text{H}_2\text{O} \xrightarrow{\Delta}$

$$\text{Na}_2\text{CO}_3 + \text{H}_2\text{O}\uparrow$$

22. Potassium carbonate cannot be prepared by Solvay process because potassium bicarbonate being highly soluble in water, would not be precipitated out.

23. Be because of its small size does not form hydride directly by heating with dihydrogen.

24. $\text{MgCO}_3 \xrightarrow{\text{Heat}} \text{MgO} + \text{CO}_2$

The metal oxide of which is stable, has unstable carbonate.

25. From Be to Ba ionic character increases. Thus, Be forms predominantly covalent compound.

27. On moving down the group, lattice energy remains almost constant as the sulphate is so big that small increase in size of the cations does not make difference. Hydration energy causes decrease in the solubility of the sulphates as the ionic size increases. Thus, the correct order is

$$\text{Be} > \text{Mg} > \text{Ca} > \text{Sr} > \text{Ba}$$

30. CaCl_2, BaCl_2 and SrCl_2 act as dehydrating agent, thus, absorb moisture from air. Their hydrate forming tendency reduces from Ca to Ba because of the large size of Ba.

31. The colour of the flame is due to the excitation of loosely bound electrons of the metal atom.

Be and Mg atoms due to their small size and high effective nuclear charge bind their electrons more strongly. Therefore, they require high excitation energy and are not excited by Bunsen flame. While other alkaline earth metals impart a characteristic colour to the flame, due to easy excitation of electrons to higher energy levels.

32. On moving down the group size of alkaline earth metal ion increases, and hence, its polarising power or covalent character decreases, *i.e.*, $BaCO_3$ is most ionic (have strong interactions) among the given and hence, is most stable thermally.

Note Stability of alkaline earth metal carbonates increases as the size of alkaline earth metal increases due to its low polarising power.

33. The element is beryllium.

36. Plaster of Paris becomes very hard by the process of hydration. It changes into a hard mass, called gypsum, on mixing with water. There is a slight increase in volume during this process.

$$\underset{\text{Plaster of Paris}}{CaSO_4 \cdot \frac{1}{2}H_2O} + 1\frac{1}{2}H_2O \longrightarrow \underset{\text{gypsum}}{CaSO_4 \cdot 2H_2O} + \text{Heat}$$

37. Setting of plaster of Paris is exothermic process.

$$CaSO_4 \cdot \frac{1}{2}H_2O \xrightarrow{H_2O} \underset{\text{orthorhombic}}{CaSO_4 \cdot 2H_2O} \xrightarrow{\text{Heating}} \underset{\substack{\text{mono orthorhombic}\\ \text{gypsum}}}{CaSO_4 \cdot 2H_2O}$$

38. $$\underset{\text{gypsum}}{2(CaSO_4 \cdot 2H_2O)} \xrightarrow[\text{Dehydration}]{120°C} \underset{\text{plaster of Paris}}{2CaSO_4 \cdot H_2O} + 3H_2O$$

39. Formula of gypsum $= CaSO_4 \cdot 2H_2O$

Formula of plaster of Paris $= CaSO_4 \cdot \frac{1}{2}H_2O$

Difference of water molecule $= 2H_2O - \frac{1}{2}H_2O = 1\frac{1}{2}H_2O$

40. Anhydrous calcium chloride is used in the laboratory for fast drying of neutral gases.

41. Gypsum, when added to cement, reduces its setting rate by combining with tricalcium aluminate as

$$3\,CaO \cdot Al_2O_3 + 3\,CaSO_4 + 2\,H_2O \longrightarrow 3CaO \cdot Al_2O_3 \cdot 3\,CaSO_4 \cdot 2H_2O$$

Thus, setting time increases.

42. Milk of lime is a suspension of slaked lime in water.

43. $$\underset{\text{slaked lime}}{Ca(OH)_2} + Cl_2 \longrightarrow \underset{\substack{\text{bleaching}\\ \text{powder}}}{CaOCl_2} + H_2O$$

$Ca(OH)_2$ is colourless and not used in cement manufacturing. It is used in white washing due to its disinfectant nature.

44. Since solution of *A* produces milkiness with CO_2, it must be lime water *i.e.*, solution of $Ca(OH)_2$.

45. When carbonates are heated, they decompose to form the oxide. Sodium carbonate and potassium carbonate do not decompose. The carbonate become more difficult to decompose as we go down the 1st group.

46. The hydroxides of alkali and alkaline earth metals are strong bases. Thus, $Zn(OH)_2$ is the weakest base.

47. Alkaline earth metals (ns^2) are denser than alkali metal (ns^1) because metallic bonding in alkaline earth metal is stronger.

48.

Na	K	Ba	Ca	Sr
yellow	pale violet	apple green	brick red	crimson

49. Because of the larger size and smaller nuclear charge, alkali metals have low ionisation potential relative to alkaline earth metals.

50. The given substances react with water in the following manner

$$\begin{aligned}
Na + H_2O &\longrightarrow NaOH + H_2(g)\\
2Na_2O_2 + 2H_2O &\longrightarrow 4NaOH + O_2(g) + H_2(g)\\
Ca + H_2O &\longrightarrow CaO + H_2\\
CaO + H_2O &\longrightarrow Ca(OH)_2\\
CaH_2 + 2H_2O &\longrightarrow Ca(OH)_2 + 2H_2\\
Ba + 2H_2O &\longrightarrow Ba(OH)_2 + H_2\\
BaO_2 + H_2O &\longrightarrow Ba^{2+} + O_2 + H_2O_2
\end{aligned}$$

Hence, Ca and CaH_2 is the pair that gives same gaseous product on reaction with water.

Round II

1. Higher the solubility, higher is the solubility product. Thus, CsOH being more soluble, has the highest solubility product.

2. $CaCl_2$ and $MgCl_2$ are deliquescent salts so absorb moisture from air to impart hygroscopic nature to crude common salt.

3. $$2\,NaNO_3 \xrightarrow[\text{above } 800°C]{\Delta} 2\,NaNO_2 + O_2$$

4. $$2\,Na + \frac{1}{2}O_2 \xrightarrow{\text{Moist air}} Na_2O$$

$$Na_2O + H_2O \longrightarrow 2\,NaOH$$

5. Due to the presence of free electrons, liquid ammonia becomes paramagnetic.

6. The lattice energy of LiF is much higher due to their comparable size, hence it is less soluble in water.

7. $Be(OH)_2$ being amphoteric reacts with sodium hydroxide to give salt and water.

$$Be(OH)_2 + 2\,NaOH \longrightarrow Na_2BeO_2 + 2\,H_2O$$

All other hydroxides being alkaline in nature do not react with alkali (NaOH).

8. Calcium gives brick red colour to the flame in flame test and calcium nitrate when heated decomposed into oxygen and a brown gas NO_2.

$$2\,Ca(NO_3)_2 \xrightarrow{\Delta} 2\,CaO + O_2 + 4\,NO_2$$

9. Sprinkling water on cement plasters helps in interlocking needle like crystals of hydrated silicates.

10. Due to its electropositive and reactive nature, magnesium is readily converted into positive ions in contact with iron pipes and hence, iron pipes remains as such.

11. $Ca(OH)_2$ is used for the softening of temporary hard water.

12. The formula of 'A' is M_3N suggests that M is a monovalent metal.

$$\underset{(M)}{6\,Li} + N_2 \longrightarrow \underset{\substack{(A)\\ \text{lithium nitride}}}{2\,Li_3N} \xrightarrow{\Delta} 6\,Li + N_2$$

$$Li_3N + 3\,H_2O \longrightarrow 3\,LiOH + \underset{(B)}{NH_3}$$

$$CuSO_4 + 4\,NH_3 \longrightarrow \underset{\text{blue solution}}{[Cu(NH_3)_4]\,SO_4}$$

Hence, M and B are Li and NH_3 respectively.

13. Alkali metals react with halogen to give halides. They are normally represented by M^+X^-.

14. Compound : A : CaO; B : $Ca(OH)_2$; C : $CaCO_3$; D : $Ca(HCO_3)_2$

$Ca(HCO_3)_2$ is soluble in water. Hence, milkiness of solution disappears on passing excess carbon dioxide into the solution of compound B.

15. $8\,LiH + Al_2Cl_6 \longrightarrow 2\,LiAlH_4 + 6\,LiCl$

$LiAlH_4 + 2\,BeCl_2 \longrightarrow 2\,BeH_2 + LiCl + AlCl_3$

16. LiF is almost insoluble in water due to its high lattice energy. But LiCl is soluble in water due to high hydration energy of Li^+ ion. LiCl is also soluble in acetone due to its predominantly covalent nature. (Because covalent character increases with increase in the size of anion).

$$LiF < LiCl < LiBr < LiI$$

17. (i) Lattice energy of BeO is greater than its hydration energy so, it is insoluble in water while in case of $BeSO_4$, hydration energy is greater than lattice energy, so it is readily soluble in water.

(ii) Lattice energy of BaO is much smaller than that of its hydration energy, so it is soluble in water. In $BaSO_4$, lattice energy predominates over hydration energy, so it is insoluble in water.

(iii) LiI is more covalent because Li^+ is smallest and polarised anion (I^-) to maximum extent, so it is more soluble than KI in ethanol.

18. (i) Peroxide ions react with water to form H_2O_2.

$$O_2^{2-} + 2\,H_2O \longrightarrow 2OH^- + H_2O_2$$

(ii) Superoxides react with water to form H_2O_2 and O_2.

$$2O_2^- + 2\,H_2O \longrightarrow 2OH^- + H_2O_2 + O_2$$

19. (i) $2\,Mg(s) + O_2(g) \xrightarrow{\Delta} 2\,MgO\,(s)$

and $3\,Mg(s) + N_2(g) \longrightarrow Mg_3N_2(s)$

(ii) $\underset{\text{quicklime}}{CaO\,(s)} + \underset{\text{silica}}{SiO_2(s)} \longrightarrow \underset{\text{calcium silicate}}{CaSiO_3\,(s)}$

(iii) It reacts with Cl_2 to form calcium hypochlorite, $Ca(OCl)_2$

$$\underset{\text{slaked lime}}{2\,Ca(OH)_2} + 2Cl_2 \longrightarrow \underbrace{CaCl_2 + Ca(OCl)_2}_{\text{bleaching powder}} + 2\,H_2O$$

(iv) $2\,Ca(NO_3)_2(s) \xrightarrow{\Delta} 2\,CaO\,(s) + 4\,NO_2(g) + O_2(g)$

20. (a) **Sodium metal** It is manufactured by electrolysis of fused mixture of NaCl (40%) and $CaCl_2$ (60%) in Down's cell at 873 K. Na, liberated at the cathode is collected, in kerosene oil while Cl_2 is evolved at the anode.

$$NaCl\,(l) \xrightarrow{\text{Electrolysis}} Na^+ + Cl^-$$

At cathode $Na^+ + e^- \longrightarrow Na(l)$

At anode $2Cl^- \longrightarrow Cl_2(g) + 2e^-$

Na metal obtained on oxidation gives Na_2O_2.

(b) **Sodium hydroxide** It is manufactured by electrolysis of an aqueous solution of NaCl (brine) in Castner-Kellner cell using mercury cathode and carbon anode. Sodium metal which is discharged at the cathode combines with mercury to form sodium amalgam. Cl_2 gas is evolved at the anode.

At cathode $Na^+ + e^- \xrightarrow{Hg}$ Na-amalgam

At anode $2\,Cl^- \longrightarrow Cl_2 + 2\,e^-$

21. Mg, Sr and Ba belong to alkaline earth metal while Be and Al are diagonally similar and Ca belongs to alkaline earth metal of Be.

22. Sodium carbonate (Na_2CO_3) and caustic soda (NaOH) are used in textile industry.

23. Since SO_4^{2-} ion is much larger than the alkaline earth metal ions, the lattice enthalpy of sulphates of alkaline earth metals remain almost constant. Thus, the solubility is decided by hydration energy, which decreases from Be to Ba (*i.e.*, with increase in atomic number). Hence, $BeSO_4$ and $MgSO_4$ are soluble in water.

24. The formula of the hydrates of halides of Ca, Ba and Sr are $CaCl_2 \cdot 6\,H_2O, BaCl_2 \cdot 2\,H_2O$ and $SrCl_2 \cdot 2\,H_2O$.

25. Due to the absence of *d*-orbitals, Be cannot extend its coordination number more than four. BeO is an amphoteric oxide *i.e.*, reacts with acids as well as alkalies. Other given statements are true.

26. Lithium because of its exceptionally small size and high polarising power exhibits anomalous behaviour.

27. Lithium carbonate decomposes readily when heated to give Li_2O and CO_2. This is due to the fact that small Li ion polarises large CO_3^{2-} to give more stable Li_2O and CO_2.

28. K and Cs emit electrons on exposure to light due to their low ionisation potential.

29. When Mg is burnt in nitric oxide, it continue to burn because during burning the heat evolved decompose NO to N_2 and O_2. Oxygen thus, produced helps Mg to burn.

30. Presence of one unpaired electron in superoxides of alkali metals make them paramagnetic.

31. $BeCO_3$ is unstable and decomposes readily into BeO and CO_2 so in order to take the reaction in backward direction, *i.e.*, for stabilising $BeCO_3$, concentration of CO_2 must be high (or $BeCO_3$ must be stored in an atmosphere of CO_2).

32. All abstract proton from water so, they are Bronsted bases.

33. All the three ions O^{2-}, O_2^{2-}, O_2^- are unstable in the presence of water and abstract proton from water.

34. All superoxides liberated oxygen with water.

$$2O_2^- + 2H_2O(l) \longrightarrow 2OH^-(aq) + H_2O_2(l) + O_2(g)$$

35. The factors which help in forming complexes are high charge and small size.

$$BeCl_2 + 2NaCl \longrightarrow \underset{\text{complex}}{Na_2[BeCl_4]}$$

36. $BeCl_2 + 4H_2O \xrightarrow{\text{cold}} [Be((H_2O)_4]Cl_2 \xrightarrow{\Delta} Be(OH)_2$
$+ 2HCl + 2H_2O$

37. Since, the halide is obtained by heating BeO with CCl_4. Hence, the halide must be $BeCl_2$.

$$2BeO + CCl_4 \xrightarrow[\Delta]{800^\circ C} 2BeCl_2 + CO_2$$

38. Portland cement does not contain $Ca_3(PO_4)_2$.

39. The percentage of lime in Portland cement is approximately 60-65%.

40. Concrete is a mixture of cement, sand, gravel and water.

41. (a) $2NaNO_3 \xrightarrow{\Delta} 2NaNO_2 + O_2$

(b) $2KClO_3 \xrightarrow{\Delta} 2KCl + 3O_2$

(c) $CaCO_3 \xrightarrow{\Delta} \underset{\text{basic}}{CaO} + \underset{\text{acidic}}{CO_2}$

(d) $NH_4NO_3 \xrightarrow{\Delta} N_2O + 2H_2O$

42. $4KO_2 + 2CO_2 \longrightarrow 2K_2CO_3 + 3O_2$

43. $LiNO_3$ behaves differently from other alkali metal nitrates.

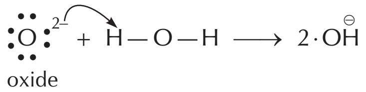
$$2LiNO_3 \xrightarrow{\Delta} Li_2O + 2NO_2 + \frac{1}{2}O_2$$

$$NaNO_3 \xrightarrow{\Delta} NaNO_2 + \frac{1}{2}O_2$$

44.

$$\begin{array}{llll} & Na_2O + & H_2O \longrightarrow & 2NaOH \\ \text{Oxidation number} & \uparrow & & \uparrow \\ \text{of Na} & +1 & & +1 \\ \text{oxygen} & -2 & -2 & -2 \end{array}$$

No change in oxidation number, so (a) and (d) are not true.
(b) is also not true.



Oxide ion donates a pair of electrons, thus changes to OH^-.

45. Be ($Z = 4$) has maximum covalency of 4 while Al ($Z = 13$) has maximum covalency of 6.

46. $\underset{1\text{ mol}}{Mg_3N_2(s)} + 6H_2O(l) \longrightarrow 3Mg(OH)_2 + \underset{2\text{ mol}}{2NH_3(g)}$

47. Solubilites of carbonates decrease down the group because lattice energy decrease is almost constant while decrease in hydration energy happens sharply. Finally difference of hydration energy and lattice energy decreases, thus solubility decreases.

48. Calcined gypsum does not contain $CaCO_3$ (that's sulphate one).

49. All alkali metals dissolve in liquid ammonia.

$$M + (x+y)NH_3 \longrightarrow M^+(NH_3)_x + e^-(NH_3)_x$$

These electrons are excited to higher energy levels and the absorption of photons occurs in the red region of the spectrum. Thus, solution appears blue.

Elements of Group 13(or IIIA) and Their Compounds

11.1 Elements of Group 13 (or IIIA)

The group 13th of long form of the Periodic Table contains 5 elements namely **boron** (B), **aluminium** (Al), **gallium** (Ga), **indium** (In) and **thallium** (Tl). Thallium is also known as Duckbill platypus because of its similarities with many other elements.

Elements belonging to group IIIA, IVA, VA, VIA, VIIA and zero, in which p-orbitals are being progressively filled, are collectively known as ***p-block elements.*** *These elements show regular gradation in properties along a period and along a group.*

Here, we will study only group IIIA and IVA. Remaining groups will be discussed in Ch-7, "p-block elements-II."

Occurrence

Boron occurs in two isotopic forms, *viz*, ${}_5B^{10}$ (18%) and ${}_5B^{11}$ (82%). Its abundance in earth's crust is very low and is found mainly in the form of borax. Aluminium is the third most abundant element and the most abundant metal in the earth's crust. The other members of this family are, however, less common.

Electronic Configuration

General electronic configuration of the elements of boron family is ns^2p^1 (where, $n = 2, 3, 4, \ldots$). These elements have three electrons in their valence shell and exist as M^{3+} (where, $M = 13$ group elements).

Table 11.1 **Electronic Configuration of Elements of Group 13**

Element	Electronic configuration
${}_5$B	[He] $2s^2 2p^1$
${}_{13}$Al	[Ne] $3s^2, 2p^1$
${}_{31}$Ga	[Ar] $3d^{10}\ 4s^2, 4p^1$
${}_{49}$In	[Kr] $4d^{10}, 5s^2, 5p^1$
${}_{81}$Tl	[Xe] $4f^{14}, 5d^{10}, 6s^2 6p^1$

Trends in Physical Properties of Group 13 Elements

The trends of various physical properties of elements of group 13 are discussed below one by one.

(a) Atomic and Ionic Radii

Their atomic and ionic radii are smaller as compared to that of the elements of II group due to increase in effective nuclear charge. On moving down the group, the ionic radii increases while there is an anomaly at gallium in case of atomic radii. **Atomic radii of Ga is lesser as compared to Al.** This is because ten *d*-electrons present in Ga atom do not screen the nucleus effectively. Consequently, electrons of Ga are more attracted by nucleus.

(b) Density

Density increases on moving down the group with Al lying in between having exceptionally low density. The exceptional low density of Al is attributed to its unexpected large molar volume.

(c) Melting and Boiling Points

Melting point decreases considerably on moving down the group up to Ga and then increases again in the case of In and Tl. Ga because of its unusual structure exists as Ga_2 molecules and thus, has low melting point. Due to its property to remain in liquid state even at 2000°C, Ga is used in high temperature thermometry. Boiling points follow a more regular trend. It decreases regularly on moving down the group. This is an indication of the fact that atoms of the elements are held less and less closely as we move down the group.

(d) Ionisation Energy

The first ionisation energy of 13th group elements is rather low as compared to the corresponding ionisation energies of *s*-block elements. The second and third ionisation energies are considerably higher.

It is clear from the table 11.2 that the ionisation energies change in oscillating manner. It decreases from B to Al, increases from Al to Ga, again decreases from Ga to In and again increases from In to Tl.

The ionisation energy of boron is highest in the group since its atomic size is the smallest and the shielding effect is lowest. The sharp decrease from B to Al is due to appreciable increase in atomic size and the shielding effect of *s* and *p* electrons of the penultimate energy shell. In case of Ga, there are 10*d* electrons in the penultimate energy shell which shield the nuclear charge less effectively, so that the outer electron is held firmly by the nucleus. As a result, the ionisation energy remains nearly the same as that of aluminium inspite of the fact that atomic size increases. In case of In, the number of *d* electrons and their shielding effect remains the same as in gallium. The ionisation energy, however, decreases in indium due to increase in atomic size from Ga to In. The increase in ionisation energy from In to Tl is due to poor shielding effect of 14*f* electrons present in the inner energy shell.

Since, the total of three successive ionisation energies is very high, these elements have very little tendency to form trivalent ion, *i.e.,* ions of the type M^{3+}.

Due to its very small size, B does not form M^{3+} ion. The sum of three ionisation energies is so large in the case of B that small atom of B is not able to accommodate that energy even if given artificially from outside. In other words, we can say that if such a quantity of energy is given from outside to B atom, the repulsion between subatomic particles become so large that these cannot be remain together in the form of an atom.

(e) Oxidation States

Boron show consistently +3 oxidation state in its compounds, while rest of the elements show +1 as well as +3 oxidation states. The +1 oxidation state becomes more and more stable as we move down the group, *i.e.,* as compared to the compounds in which Tl is univalent, the compounds which contain trivalent Tl are less stable. Such a presence of two oxidation states in *p*-block elements can be explained on the basis of **inert pair effect.**

The compounds of Tl(I) show close resemblance with alkali metals, *e.g.*, TlOH is highly soluble and a strong base, like NaOH; similarly Tl_2CO_3 show resemblance with Na_2CO_3 and K_2CO_3.

Ga, the third element of the group, appears to be bivalent in some of its compounds, *e.g.,* $GaCl_2$ but infact it is believed to contain univalent and trivalent ions as Ga^+ and $[GaCl_4]^-$ respectively.

Caution Point *The term II inert pair effect" is defined as the tendency of* **s***-electrons to remain together or the reluctance of s-electrons to participate in a reaction. However, this term is some what misleading. In a nut shell, we can say that because of decrease in bond energy with increase in size, the energy required to unpair the* ns^2 *electrons is not compensated by energy released in forming two additional bonds. Thus, two s-electrons develop more and more tendency to remain together as we move down the group.*

(f) Electropositive or Metallic Character

The electropositive (or metallic) character increases from B to Al. B, in fact, is regarded as a **semi-metal** and is more closer to non-metals than to metals in its properties. Aluminium is metal and most electropositive. The increase in electropositive character from boron to aluminium is due to increased size of aluminium. The remaining three elements are weakly metallic in nature and their electropositive nature is less than aluminium and decreases from gallium to thallium. The extra d^{10} electrons in gallium and indium while d^{10} and f^{14} electrons in thallium do not shield the nuclear charge very effectively and therefore, these metals are less electropositive.

(g) Nature of Compounds

Boron have a tendency to form covalent compounds as B^{3+} ion is unstable, while other members form electrovalent compounds as well.

The physical properties of the III A group elements are summarised in the following table

Table 11.2 **Physical Properties of IIIA Group Elements**

Property	Boron	Aluminium	Gallium	Indium	Thallium
Atomic number	5	13	31	49	81
Molar mass (g mol^{-1})	10.81	26.96	69.72	114.82	204.37
Density (g cm^{-3})	2.35	2.70	5.91	7.31	11.90
Melting point (°C)	2030	659	29.8	156.4	303
Boiling point (°C)	2550	2450	2237	2000	1457
Atomic radius (Å)	0.82	1.26	1.24	1.50	1.55
Molar volume (cm^3 mol^{-1})	4.62	10.0	11.8	15.1	17.2
Radius of trivalent ion (Å)	0.20	0.50	0.62	0.80	0.95
Ionisation energy (kJ mol^{-1})					
I	800	577	579	558	589
II	2427	1816	1979	1820	1971
III	3659	2744	2962	2704	2877
Electronegativity	2.0	1.5	1.6	1.7	1.8
Oxidation states	+3	+3	+1, +3	+1, +3	+1, +3
Heat of sublimation (kJ mol^{-1})	564.8	324.3	273.2	241.4	179.1

Caution Point *There is no evidence for the existence of* B^{3+} *and the value of ionic radius is an estimate.*

Hot Spot 1

TRENDS in Chemical Properties of Group 13 Elements

Previous Years' examination papers reveals that the questions are generally asked from this topic. These may be based on gradation of stability, reactivity or any such character or reason based. The level of question is easy to moderate.

(a) Reaction with Air Water and Acid

Pure **boron is unreactive to air** at ordinary temperature. It reacts with air only when heated. It does not react with water. It is attacked only by hot concentrated acids like H_2SO_4, etc. **Al reacts readily with air,** even at ordinary temperature forming a protective layer of oxide. (The oxide film protects it from further reaction). Al decomposes cold water.

$$2B + 3H_2O \longrightarrow B_2O_3 + 3H_2$$

$$2Al + 3H_2O \longrightarrow Al_2O_3 + 3H_2$$

Ga and In are attacked neither by cold water nor by hot water unless oxygen is present. Tl is a little more reactive than Ga and forms an oxide larger on its surface.

$$4Tl + 2H_2O + O_2 \longrightarrow 4TlOH$$

Caution Point *Thallium is preserved under oil or by smearing with vaseline.*

(b) Hydrides

Elements of group 13 do not react directly with hydrogen, however a large number of hydrides (of 13 group elements) are known. Boron forms a number of covalent hydrides with general formulae B_nH_{n+4} and B_nH_{n+6}. These are called **boranes.** The representative compounds of two series include B_2H_6 and B_4H_{10} respectively.

Al forms a polymeric hydride of formula $(AlH_3)_n$, which is commonly known as **alane.** It decomposes on heating above 200°C into its elements. GaH_3 is even less stable, while InH_3 and TlH_3 are extremely unstable.

B, Al and Ga have the tendency to form complex anionic hydrides like $Li[AlH_4]$, $Li[BH_4]$, $Li[GaH_4]$ etc. The formation of these complexes is due to the presence of a vacant *p*-orbital in their outermost shells due to which these readily accepts electron pair from the hydride ion (H^-) as

$$AH_3 + H^- \longrightarrow [AH_4]^- \qquad \text{[Here, } A = \text{Al, Ga and B]}$$

LAH (lithium aluminium hydride) is the most important of these hydrides and is prepared by reacting LiH with $AlCl_3$ as

$$4LiH + \underset{\text{(anhydrous)}}{AlCl_3} \xrightarrow{\text{Ether}} Li^+[AlH_4]^- + 3LiCl$$

These complex hydrides are infact good reducing agents.

(c) Oxides and Hydroxides

All the elements of this group form oxides of M_2O_3 type in which elements are in +3 oxidation state, *e.g.,* $B_2O_3, Al_2O_3, Ga_2O_3, In_2O_3$ and Tl_2O_3 etc. The oxide of B is feebly acidic while that of Al and Ga are amphoteric, In and Tl oxides have strong basic character. Thus, we can say that **basic character of these oxides increases or acidic character decreases down the group.** *e.g.,*

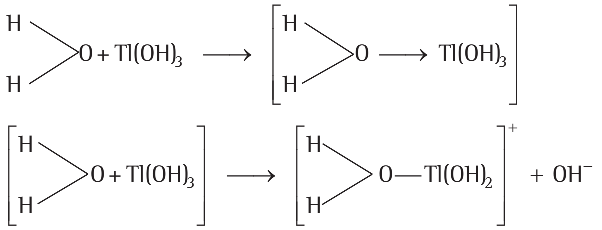
$$\underset{\text{basic oxide}}{CuO} + \underset{\text{acidic oxide}}{B_2O_3} \longrightarrow Cu(BO_2)_2$$

$$\underset{\text{basic oxide}}{Al_2O_3} + \underset{\text{acid}}{6HCl} \longrightarrow 2AlCl_3 + 3H_2O$$

$$\underset{\text{acidic oxide}}{Al_2O_3} + 2NaOH \longrightarrow 2NaAlO_2 + H_2O$$

$$\underset{\text{basic oxide}}{Tl_2O_3} + \underset{\text{acid}}{3H_2SO_4} \longrightarrow Tl_2(SO_4)_3 + 3H_2O$$

The hydroxides of 13th group elements are $M(OH)_3$ type. Tl also give hydroxide of TlOH type which is a very strong base and comparable to hydroxides of alkali metals. $M(OH)_3$ type hydroxides follow the same trend of basicity as shown by oxides. This is because as the size of the ion increases, the tendency to rupture the O—H bond decreases and hence, acidic nature decreases, *i.e.,* basic nature increases. $Al(OH)_3$ and $Ga(OH)_3$ are amphoteric and $In(OH)_3$ and $Tl(OH)_3$ are basic in nature.



(d) Halides

Group 13 elements form trihalides of MX_3 type (where, *M* is the metal and *X* is halogen). All the halides of group 13 elements are known except Tl(III) iodide.

The halides of boron (BX_3) are covalent compounds with sp^2 hybridisation and trigonal planar structure. All the four halides of boron namely boron trifluoride (BF_3), boron trichloride (BCl_3), boron tribromide (BBr_3) and boron triiodide (BI_3) are known. All of them are volatile, monomeric and highly reactive. BF_3 and BCl_3 are gases at room temperature, BBr_3 is a volatile liquid while BI_3 is a solid. They do not conduct electricity in the liquid state. Their boiling points are also very low as compared to the halides of elements of Ist and IInd group.

The fluorides of Al, Ga, In and Tl are ionic and have high melting points while other halides of these elements are covalent when anhydrous, *e.g.,* **anhydrous** $AlCl_3$ **is covalent but in water it gets hydrolysed to give** Al^{3+} *(aq)* **ions.** Change from covalent compound to ionic in aqueous solution (as stated about $AlCl_3$) is mainly due to high hydration energy of Al^{3+} ions which easily compensate its ionisation energy while B does not show this characteristic just because of its small size and inability to accommodate energy given. All other halides of elements of this group also have sp^2 hybridisation and trigonal planar structure.

These halides have an ability of complex formation. The boron trihalides have the tendency to form BX_3L type of complexes, where, *L* is a neutral or anionic donor (*i.e.,* **ligand**) *e.g.,* BF_4^-. **These complexes are tetrahedral in shape.** Tendency to form this type of complexes decreases down the group. The trihalides of other elements of this group have more tendency to form complexes like $[AlF_6]^{3-}$, $[GaCl_6]^{3-}$ and $[InCl_6]^-$, etc., due to the availability of vacant *d*-orbital in central atoms.

The trihalides of Al exist as discrete molecules (monomeric) while the trihalides of other elements **exist as dimers both in vapour state and in non-polar solvent,** *e.g.,*

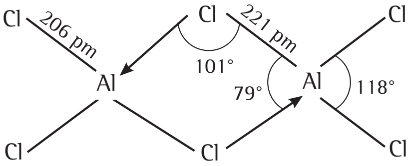


Fig. 11.1 Dimeric structure $AlCl_3$

Dimer structure disappears when the halides are dissolved in water. This is due to high hydration energy when $[M(H_2O)_6]^{3+}$ and $3X^-$ ions are formed making the solution as good conductor of electricity.

The solution becomes acidic owing to hydrolysis.

$$AlCl_3 + 9H_2O \longrightarrow [Al(H_2O)_6](OH)_3 + 3H^+ + 3Cl^-$$

However, B atom owing to its small size, cannot coordinate with four larger halide ions and hence, cannot form the dimeric molecules. That is why boron trihalides always exist in monomeric forms.

The trihalides of all the elements of this group act as Lewis acids, *i.e.,* they are electron deficient and have the tendency to accept the electron pair. The electron accepting tendency of trihalides follow the order

$$B > Al > Ga > In$$

The relative strengths of trihalides of B as Lewis acids have been determined by measuring their heats of formation as well as by studying their infrared spectra. The result of these studies is

$$BF_3 < BCl_3 < BBr_3$$

This order is just the reverse of what should be expected normally from the electronegativities of halogens. This anomalous behaviour can be explained **on the basis of tendency of halogen atom to back donate its electron to the boron atom,** which can be shown as

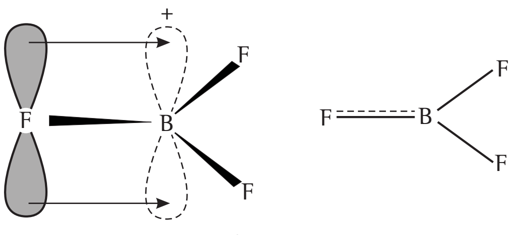

Fig. 11.2 Phenomenon of back bonding in BF_3 molecule

Infact in BF_3 molecule, where the 2*p*-orbitals of each F atom are fully-filled, one of the 2*p*-orbitals of B is vacant. Therefore, an additional *pπ-pπ* bond is established between these 2*p*-orbitals of same energy due to partial transference of electronic character from fully-filled orbital to vacant orbital as shown in the figure above. Thus, the B—F bond acquires some double bond character. This type of bond formation is called **back bonding.** Similar structure for other two B—F bonds are equally probable as

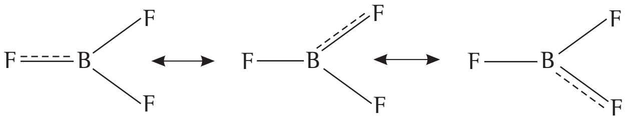

Fig. 11.3 Various resonating structures of BF_3 molecules involving $p\pi$-$p\pi$ back bonding

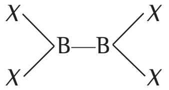
As the result of back donation of electrons from F to B, the electron deficiency of B atom get compensated resulting in decrease in Lewis acid character.

This tendency to form back bonds is maximum in case of BF_3 and falls rapidly as we move to BCl_3 and BBr_3 due to the fact that the energy difference between fully-filled orbital of halogen (Cl–3*p*; Br–4*p*) and vacant orbital of B (2*p*) increases.

In addition to trihalides, these elements form di as well as monohalides. Boron forms dihalides, B_2X_4.



In solid state, B_2X_4 has planar structure but in liquid and vapour state, it has non-eclipsed structure.

(planar molecule) (non-eclipsed structure)

Tetrahalides can be synthesised by heating trihalides with mercury at low pressure.

$$2BCl_3 + 2Hg \xrightarrow[\text{low pressure}]{\text{Electric discharge}} B_2Cl_4 + Hg_2Cl_2$$

Gallium and indium also form dihalides. Gallium dihalide is more properly represented as $Ga^+[GaCl_4]^-$ showing gallium in +1 and +3 oxidation states.

The elements of IIIA group in gaseous state form monohalides, *MX*. These are very unstable halides and they are covalent in nature. The covalent nature decreases and thallium halides are ionic in nature.

(e) Oxyacids

Among 13 group elements, only boron forms several oxyacids, all of which are obtained by adding one or more H_2O molecules to one or more B_2O_3 molecules as

$$B_2O_3 + 3H_2O \longrightarrow \underset{\text{orthoboric acid}}{2H_3BO_3} \quad \text{or } 2B(OH)_3$$

$$B_2O_3 + H_2O \longrightarrow \underset{\text{metaboric acid}}{2HBO_2}$$

$$2B_2O_3 + 3H_2O \longrightarrow \underset{\text{pyroboric acid}}{H_6B_4O_9}$$

$$3B_2O_3 + 2H_2O \longrightarrow \underset{\text{hexaboric acid}}{H_4B_6O_{11}}$$

$$4B_2O_3 + 3H_2O \longrightarrow \underset{\text{octaboric acid}}{H_6B_8O_{15}}$$

Sample **Problem 1** *The higher stability of* BCl_3 *as compared to* $TlCl_3$ *is due to* **[NCERT]**

(*a*) *absence of inert pair effect in* BCl_3
(*b*) *presence of inert pair effect in* BCl_3
(*c*) +3 *oxidation state of* B
(*d*) +3 *oxidation state of* Tl

Interpret (*a*) Boron exhibits only +3 oxidation state. So, it forms BCl_3, a stable compound. On moving down the group, the inert pair effect becomes more and more pronounced therefore, in thallium +1 oxidation state is more stable than +3 oxidation state. That's why BCl_3 is more stable than $TlCl_3$.

Sample **Problem 2** *The exhibition of highest coordination number depends on the availability of vacant orbitals in the central atom. Which of the following elements is not likely to act as central atom in* MF_6^{3-} ? **[NCERT Exemplar]**

(*a*) B (*b*) Al (*c*) Ga (*d*) In

Interpret (*a*) Because of the absence of *d*-orbitals B cannot exceed its covalency or coordination number more than 4. Thus, BF_6^{3-} does not exist.

Sample **Problem 3** *Which of the following oxides is acidic in nature?* **[NCERT Exemplar]**

(*a*) B_2O_3 (*b*) Al_2O_3 (*c*) Ga_2O_3 (*d*) In_2O_3

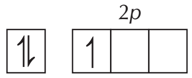
Interpret (*a*) Non-metallic oxides are generally acidic in nature and metallic character increases from B to In. Thus, B is non-metallic and hence, B_2O_3 is an acidic oxide.

Sample **Problem 4** *The geometry of a complex species can be understood from the knowledge of type of hybridisation of orbitals of central atom. The hybridisation of orbitals of central atom in* $[B(OH)_4]^-$ *and the geometry of the complex are respectively* **[NCERT Exemplar]**

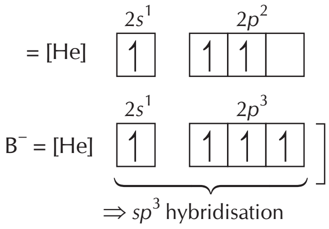
(*a*) sp^3, tetrahedral (*b*) sp^3, square planar
(*c*) sp^3d^2, octahedral (*d*) dsp^2, square planar

Interpret (*a*) In $[B(OH)_4]^-$, the central atom B have 3 valence electrons and one negative charge, thus it can form four σ bonds with $4OH^-$. Hence, its hybridisation is sp^3 and geometry is tetrahedral.

$_5B = [He]\, 2s^2 2p^1$



In first excited state



These four sp^3 hybridised orbitals overlap with four OH^- orbitals to form 4 σ bonds

$\Rightarrow sp^3$ hybridisation

11.2 Unique Behaviour of Boron

Owing to its extremely small size, high electron density, high electronegativity and non-avilability of *d*-electrons, *boron exhibits following anomalous properties*

1. Boron is a typical non-metal, while other members of the group are metals.
2. Its melting and boiling points are higher than the other members of the group.
3. It forms only covalent compounds while other members can form covalent as well as ionic compounds. The maximum covalency of B is four while that of Al is six.
4. Only boron exhibit allotropy and exists in crystalline as well as amorphous forms.
5. Its oxides and hydroxides have acidic nature while that of other members have amphoteric and basic nature.
6. Its hydrides are quite stable while that of other members are not so stable.
7. Like non-metals, it combines with metals to form metal borides (*e.g.*, Mg_3B_2) while other members form alloy with metals.
8. It does not decompose steam while other members do so.

Similarities with Silicon

Boron due to its small size and similar *e/m* ratio, shows resemblance with silicon, present diagonally opposite.

It shows the following similarities

1. Like Si, it also is a typical non-metal with high melting and boiling points and low atomic volumes.
2. It is a bad conductor of electricity and exhibits allotropy like Si.
3. Chlorides of both B and Si fumes in moist air and readily hydrolysed by water.

$$BCl_3 + 3H_2O \longrightarrow B(OH)_3 + 3HCl$$
$$SiCl_4 + 4H_2O \longrightarrow Si(OH)_4 + 4HCl$$

4. Carbides of B and Si both are very hard and used as a abrasive.

11.3 Chemistry of Boron

Boron (B), the first member of 13th group, occurs in two isotopic forms *i.e.*, ^{10}B (19%) and ^{11}B (81%). The abundance of B in the earth crust is less than 0.001% by mass. B occurs mainly as the salts of boric acid.

Extraction of Boron

Ores of Boron

The important ores are

Borax : $Na_2B_4O_7 \cdot 10H_2O$
Colemanite : $Ca_2B_6O_{11} \cdot 5H_2O$
Panderinite : $Ca_2B_6O_{11} \cdot 3H_2O$
Boracite : $2Mg_3B_8O_{15} \cdot MgCl_2$
Kernite (Rasorite) : $Na_2B_4O_5(OH)_4$

Extraction Procedure

Boron is extracted from borax and colemanite minerals using following two steps :

(i) Preparation of B_2O_3 from the mineral
(ii) Reduction of B_2O_3

Step I **From borax** B_2O_3 is obtained by heating it with concentrated acids.

$$\underset{\text{borax}}{Na_2B_4O_7} + 2HCl \longrightarrow 2NaCl + \underset{\text{tetraboric acid}}{H_2B_4O_7}$$
$$Na_2B_4O_7 + H_2SO_4 \longrightarrow Na_2SO_4 + H_2B_4O_7$$
$$H_2B_4O_7 + 5H_2O \longrightarrow \underset{\text{orthoboric acid}}{4H_3BO_3}$$
$$2H_3BO_3 \longrightarrow B_2O_3 + 3H_2O$$

From colemanite mineral, first borax is obtained which on heating with concentrated acids gives B_2O_3 as

$$\underset{\text{colemanite}}{Ca_2B_6O_{11}} + 2Na_2CO_3 \longrightarrow 2CaCO_3 + Na_2B_4O_7 + 2NaBO_2$$

$$\begin{tikzcd} 4NaBO_2 + CO_2 \arrow[r] & Na_2B_4O_7 + Na_2CO_3 \arrow[d, "\Delta"', "\text{acid}"] \\ & B_2O_3 \end{tikzcd}$$

Colemanite also gives B_2O_3 when SO_2 gas is passed in its suspension and the obtained H_3BO_3 is heated.

$$Ca_2B_6O_{11} + 11H_2O + 4SO_2 \longrightarrow 2Ca(HSO_3)_2 + 6H_3BO_3$$
$$2H_3BO_3 \xrightarrow{\Delta} B_2O_3 + 3H_2O$$

Step II B_2O_3 can be reduced by an electropositive metal, *e.g.*,

$$B_2O_3(s) + 6Na(s) \longrightarrow 2B(s) + 3Na_2O(s)$$
$$B_2O_3(s) + 6K(s) \longrightarrow 2B(s) + 3K_2O(s)$$
$$B_2O_3(s) + 3Mg(s) \longrightarrow 2B(s) + 3MgO(s)$$

The fused mass is stirred with iron rod to oxidise the unreacted sodium or potassium. The mass is then boiled with dil. HCl when insoluble boron powder is obtained. It is washed with water and made dry. **This is the amorphous variety of boron.**

Boron can also be obtained by the following methods.

1. Electrolytic reduction of fused borates or tetra-fluoroborates (KBF_4) in molten KCl/KF at 1073 K.
2. By reduction (hydrogenation) of a volatile boron compound with H_2 at high temperature on a heated tantalum filament as,

   $$2BCl_3(g) + 3H_2(g) \xrightarrow{1270\ K} 2B(s) + 6HCl(g)$$

   Boron obtained by this method is of high purity (almost 99.9%).
3. By thermal decomposition of boranes and boron halides at temperatures above than 900°C.

Physical Properties of Boron

Boron is a non-metallic element. It is poor conductor of electricity and is non-fusible under ordinary pressure. Its ionisation energy is highest among the group. It is an extremely hard refractory solid.

The phenomenon of existence of an element in different forms (which generally differ is number of atoms and physical properties) is called **allotropy.** Boron exists in two allotropic forms, called amorphous and crystalline forms. **Amorphous boron** is a brown powder of specific gravity 2.34. It melts at 2030°C and volatiles appreciably even at 1600°C. **Crystalline boron** exists in several different modifications. Atleast four allotrops of B may be obtained under different conditions. However, the transition between different forms is an extremely slow process. All crystalline **allotropes** have structure built up of B_{12} octahedral units as shown in the figure.

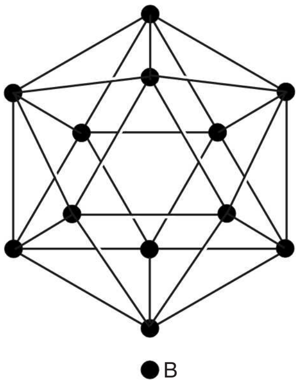


Fig. 11.4 Icosahedron arrangement of 12 B atoms in a crystalline variety

Chemical Properties of Boron

Boron reacts differently with different reagents.

Some of its characteristics reactions are as

(a) Action of Air

When heated in air at 700°C, boron forms boric anhydride with O_2 of air and boron nitride with N_2 of air as

$$4B + 3O_2 \longrightarrow 2B_2O_3$$
$$2B + N_2 \longrightarrow 2BN$$

Since, the compounds formed, form a protective layer over boron surface, these reactions do not proceed to completion.

(b) Action of Acids

B is not attacked by HCl but is oxidised by nitric acid and sulphuric acid as

$$B + 3HNO_3 \longrightarrow H_3BO_3 + 3NO_2$$
$$2B + 3H_2SO_4 \longrightarrow 2H_3BO_3 + 3SO_2$$

(c) Reaction with Alkalies

With fused alkali metal hydroxides, it forms borates and H_2 gas is evolved as

$$2B + 6NaOH \longrightarrow 2Na_3BO_3 + 3H_2$$

(d) Reaction with Metals

B combines with many metals on heating to give the corresponding borides as

$$3Mg + 2B \longrightarrow Mg_3B_2$$

(e) Reaction with Non-metals

B reacts with non-metals as

(i) Boron combines with N_2 at a temperature greater than 900°C to form boron nitride (BN).

(ii) When heated with S, it forms boron sulphide, B_2S_3.

(iii) On heating with C in an electric furnace, an extremely hard substance, called **boron carbide** (B_4C) is formed.

Boron carbide is one of the hardest materials known ranking third behind diamond and cubic boron nitride.

(iv) It also combines with halogens at high temperature to form covalent boron trihalides like BF_3, BCl_3 etc.

(f) Reaction with Water

B does not react with water, but reacts with steam at red heat liberating H_2 as

$$2B + 3H_2O \longrightarrow B_2O_3 + 3H_2\uparrow$$

(g) As a Reducing Agent

B is a powerful reducing agent, since it can replace C from CO_2, silicon from SiO_2 and N_2 from NO as

$$4B + 3CO_2 \longrightarrow 2B_2O_3 + 3C$$
$$4B + 3SiO_2 \longrightarrow 2B_2O_3 + 3Si$$
$$4B + 6NO \longrightarrow 2B_2O_3 + 3N_2$$

Uses of Boron

1. Boron is used for making bullet-proof vests and light composite material for aircrafts.
2. It is used in nuclear industry as protective shields and control rods.
3. It is used in steel industry to increase the hardness of steel.
4. It is used as a semiconductor for making electronic devices.
5. Many important compounds like borax, boric acid etc., are synthesized from it.
6. It is used as a deoxidiser in casting of iron.

11.4 Chemistry of Aluminium

Next to silica and oxygen, **Al is the third widely distributed element.** It is present to the extent of 7.3% of earth crust.

Extraction of Aluminium

Its important ores are bauxite, $Al_2O_3 \cdot H_2O$; cryolite Na_3AlF_6; corundum, Al_2O_3.

(a) Concentration of Ore

Bauxite is the principle ore of aluminium. Usually impurities like ferric oxide, silica and titanium (IV) oxide are associated with it. These are removed by one of the following methods

1. When bauxite contains Fe_2O_3 in excess, Baeyer's process is used

In this process, the ore is powdered and digested with a concentrated solution of sodium hydroxide in an autoclave under pressure at 130°C. By this, alumina present in the ore dissolves as sodium meta aluminate, whereas impurities being insoluble in NaOH, settle down.

Similarly, silica of the ore reacts with NaOH to form sodium silicate which is also present in the solution along with sodium meta aluminate. Solution is filtered leaving insoluble impurities behind. Now, the filtrate containing sodium meta-aluminate and sodium silicate is diluted and seeded with freshly prepared $Al(OH)_3$ solution which induces the precipitation of $Al(OH)_3$ leaving behind sodium silicate in solution.

$$Al_2O_3 + 2NaOH \longrightarrow 2NaAlO_2 + H_2O$$
$$NaAlO_2 + 2H_2O \longrightarrow Al(OH)_3 + NaOH$$

The precipitate is filtered, washed and ignited to obtain pure alumina.

2. If SiO_2 is in excess, Serpeck's process is used

In this method, the ore is mixed with coke and heated at 1800°C in a current of nitrogen. By this, alumina converts into AlN and SiO_2 is reduced into Si. Si being volatile, passes off as vapours. AlN on dilution induces the precipitation of aluminium hydroxide.

$$Al_2O_3 + 3C + N_2 \longrightarrow 2AlN + 3CO$$
$$SiO_2 + 2C \longrightarrow Si + 2CO$$
$$AlN + 3H_2O \longrightarrow Al(OH)_3 + NH_3$$

Alumina is obtained by filtering, washing and igniting the precipitate.

$$2Al(OH)_3 \xrightarrow{\Delta} Al_2O_3 + 3H_2O$$

3. In Hall's process

The bauxite ore is fused with sodium carbonate. The alumina present in the ore dissolves as sodium meta aluminate leaving behind Fe_2O_3 and SiO_2. The fused mass after extraction with water and filtration, is warmed to 58° and CO_2 is passed through it, $Al(OH)_3$ precipitates out.

$$Al_2O_3 \cdot 2H_2O \longrightarrow 2NaAlO_2 + CO_2 + 2H_2O$$
$$2NaAlO_2 + CO_2 + 3H_2O \longrightarrow 2Al(OH)_3 + Na_2CO_3$$

This precipitate, when filtered, washed and ignited gives pure alumina.

(b) Reduction of Alumina to Al Metal

Aluminium is obtained from alumina by electrolysis, called **Hall-Heroult process.** In this process, cathode and anode both are made up of carbon. The electrolyte used contains Na_3AlF_6 (80-85%), CaF_2 (5-7%), AlF_3 (5-7%), Al_2O_3 (2-8%), of which Al_2O_3 is recharged intermittently. When electricity is passed, Al is deposited at cathode while O_2 is liberated at anode which reacts with C electrode to produce CO and then CO_2.

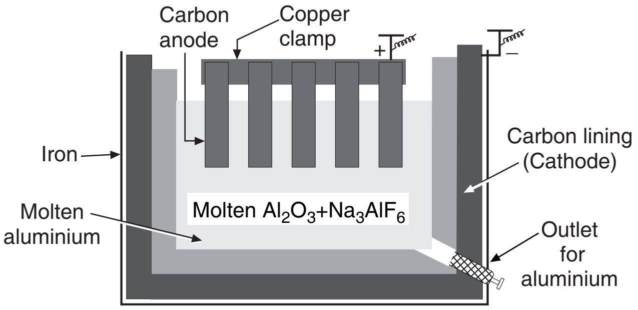

Fig. 11.5 Electrolysis of alumina

Caution Point *The electrolysis of pure alumina faces two difficulties : (i) Pure alumina is a bad conductor of electricity, (ii) The fusion temperature of pure alumina is about 2000°C and at this temperature when the electrolysis is carried of fused mass, the metal formed vaporises as the boiling point of aluminium is 1800°C.*

The above difficulties are overcome by using a mixture of alumina, cryolite (Na_3AlF_6) and fluorspar (CaF_2) in the ratio of 20 : 24 : 20. The fusion temperature of this mixture is 900°C and it is a good conductor of electricity.

The exact mechanism of the electrolysis is not yet known. Two concepts have been proposed.

First concept AlF_3 from cryolite ionises as,

$$AlF_3 \rightleftharpoons Al^{3+} + 3F^-$$

Al^{3+} ions are discharged at cathode and F^- ions at anode.

$$Al^{3+} + 3e^- \longrightarrow Al \qquad \text{(at cathode)}$$

$$2F^- \longrightarrow F_2 + 2e^- \qquad \text{(at anode)}$$

The liberated fluorine reacts with alumina to form AlF_3 and O_2. The oxygen attacks the carbon anodes to form CO and CO_2.

$$Al_2O_3 + 3F_2 \longrightarrow 2AlF_3 + \frac{3}{2}O_2$$

$$2C + O_2 \longrightarrow 2CO$$

$$C + O_2 \longrightarrow CO_2$$

Anodes are replaced frequently.

Second concept Alumina (Al_2O_3) ionises as,

$$Al_2O_3 \rightleftharpoons \underset{\text{cathode}}{Al^{3+}} + \underset{\text{anode}}{AlO_3^{3-}}$$

$$Al^{3+} + 3e^- \longrightarrow Al \text{ (at cathode)}$$

At anode AlO_3^{3-} is oxidised.

$$4AlO_3^{3-} \longrightarrow 2Al_2O_3 + 3O_2 + 12e^- \text{ (at anode)}$$

Thus, the overall chemical reaction taking place during electrolysis is

$$2Al_2O_3 \longrightarrow 4Al + 3O_2$$

Refining of Aluminium

The aluminium obtained by reduction process is about 98% pure. *In order to purify it, Hoope's electrolytic method is used.* The cell used for the refining contains three layers that differ in specific gravities. The upper most layer contains pure aluminium which acts as cathode, the middle layer contains a mixture of fluorides of Al, Na and Ba and acts as electrolyte while the lower layer contains impure aluminium which acts as anode. On electrolysis, pure Al is deposited at cathode from the middle layer and an equivalent quantity of Al is deposited to the lower layer. The aluminium obtained by this process is 99.98% pure.

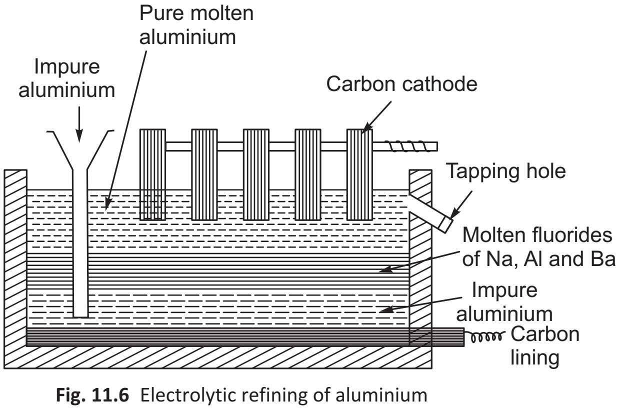

Fig. 11.6 Electrolytic refining of aluminium

Modern Method of Extraction of Al

When vapour of aluminium chloride is passed over fused oxide at 1000°C, aluminium monochloride is formed which on cooling disproportionates to give Al.

$$2Al_2O_3 + 2AlCl_3 \longrightarrow 6AlCl + 3O_2$$

$$3AlCl \longrightarrow AlCl_3 + 2Al$$

The $AlCl_3$ obtained is reused.

Physical Properties of Aluminium

Al is a bluish-white metal with a brilliant lusture which soon get destroyed due to the formation of oxide layer over it.

It is malleable and ductile in nature and can be rolled into sheets, foils and wires. Al is a very light metal (sp. gravity 2.7), good conductor of heat and electricity, melts at 659°C and boils at 2450°C. On a weight to weight basis, the electrical conductivity of Al is twice that of copper.

Chemical Properties of Aluminium

Aluminium is a very reactive metal but formation of oxide layer over its surface reduces its reactivity. Al shows following reactions

(a) With Air

Al is not affected by pure dry air but with moist air, a film of oxide is formed at the surface which protects the metal from further corrosion. It burns readily in oxygen giving out energy. The heat evolved in the oxidation of Al is used in **thermite process** for the reduction of oxides of Cr, Fe, Mn etc.

$$Cr_2O_3 + 2Al \longrightarrow 2Cr + Al_2O_3 + \text{heat}$$

$$Fe_2O_3 + 2Al \longrightarrow 2Fe + Al_2O_3 + \text{heat}$$

$$3Mn_3O_4 + 8Al \longrightarrow 9Mn + 4Al_2O_3 + \text{heat}$$

Al also reduces oxides of non-metals as

$$3CO_2 + 4Al \longrightarrow 2Al_2O_3 + 3C$$

$$3SiO_2 + 4Al \longrightarrow 2Al_2O_3 + 3Si$$

(b) With Water

Pure water does not affect pure Al. However, impure form is readily corroded by water containing salts. It decomposes boiling water evolving hydrogen.

(c) With Alkalies

Al readily dissolves in alkalies evolving H_2 and forming the corresponding aluminates.

$$2Al + 2H_2O + 2NaOH \xrightarrow{\Delta} \underset{\substack{\text{sodium} \\ \text{meta aluminate}}}{2NaAlO_2} + 3H_2$$

The metal also dissolves in hot conc. solution of Na_2CO_3 as

$$2Al + Na_2CO_3 + 3H_2O \xrightarrow{\Delta} 2NaAlO_2 + CO_2 + 3H_2$$

(d) With Acids

The metal dissolves in dil. HCl and dil. H_2SO_4 solutions evolving H_2. With hot conc. H_2SO_4, SO_2 is given out. **Conc. HNO_3 has no reaction, the metal rendered passive due to surface oxidation.**

(e) With Halogen and Nitrogen

The metal gives halides and nitrides respectively on heating with halogens and nitrogen.

(f) Displacement Reactions

Al displaces Cu, Zn and Pb from the solutions of their salts as

$$3ZnSO_4 + 2Al \longrightarrow Al_2(SO_4)_3 + 3Zn$$
$$3CuSO_4 + 2Al \longrightarrow Al_2(SO_4)_3 + 3Cu$$

Uses of Aluminium

Aluminium is used

1. in manufacturing of household utensils, aeroplane parts, precision and surgical instruments etc.
2. in HNO_3 transportation and in construction of tank for chemical plants where HNO_3 is manufactured. (Since, it rendered passive to HNO_3).
3. as aluminium foil, in packing of different objects.
4. for the formation of alums which is used as mordants in dyeing and paints.
5. as a reducing agent.
6. as building material, refractory bricks and ultra-marine.
7. for sizing the paper.
8. in thermite welding processes.
9. in making alloys.

Some of the important alloys of Al *are tabulated below*

Table 11.3 **Important Alloys of Aluminium**

Alloy	Approx. composition	Uses
Magnalium	Al = 94.5%, Mg = 5.5%	Scientific apparatus, machined articles.
Duralumin	Al = 95%, Cu = 4% Mg = 0.5%, Mn = 0.5%	Aircraft parts, railroad cars, bos machinery.
Nickel alloy or Nickeloy	Al = 95%, Cu = 4%, Ni = 1%	Aircraft parts
γ-alloy	Al = 93%, Cu = 4%, Ni = 2%, Mg = 1%	Pistons and machinery parts.
Alnico	Steel = 77%, Ni = 2%, Al = 20%, Co = 1%	For making permanent magnets.
Artificial gold	Al = 10%, Cu = 90%	For making artificial ornaments, pots, paints.

Check Point 1

1. Why does boron not form tripositive ions?
2. Boron forms no compound in unipositive state while the compounds of thallium in unipositive state are quite stable, Explain, why?
3. Explain, why boron halides do not exist as dimers while $AlCl_3$ exists as Al_2Cl_6?
4. Cryolite is added to alumina during electrolysis process, why?
5. Melting point of gallium is lowest among the group. Give reason.
6. Ga and In are less electropositive than Tl, explain why?
7. BF_3 is a weaker Lewis acid as compared to BI_3, why?
8. In aqueous solution $AlCl_3$ does not exist as dimer. Explain.

11.5 Compounds of Elements of Group 13

Some of the important compounds of elements of this group are discussed below

Borax

Chemically borax is sodium tetraborate decahydrate ($Na_2B_4O_7 \cdot 10H_2O$). It is also called **tincal.** Since, borax contains the tetranuclear units $[B_4O_5(OH)_4]^{2-}$, its correct formula is $Na_2[B_4O_5(OH)_4] \cdot 8H_2O$.

Methods of Preparation

1. It is prepared from colemanite, a mineral, by boiling the finely powered mineral with calculated quantity of sodium carbonate solution.

$$2Ca_2B_6O_{11} + 3Na_2CO_3 + H_2O \longrightarrow 3Na_2B_4O_7 + 3CaCO_3\downarrow + Ca(OH)_2$$

   The precipitate of calcium carbonate is removed by filtration and borax is crystallised from the filtrate.

2. It is obtained by neutralising a solution of the boric acid by soda ash.

$$Na_2CO_3 + 4H_3BO_3 \longrightarrow Na_2B_4O_7 + 6H_2O + CO_2$$

Physical Properties

Borax is a crystalline solid which exists in three forms

(i) Prismatic borax ($Na_2B_4O_7 \cdot 10H_2O$) is an ordinary form of borax and is obtained when a solution of the salt is crystallised at ordinary temperature.

(ii) Octahedral borax ($Na_2B_4O_7 \cdot 5H_2O$) is obtained when a solution of the salt is crystallised above 60°C. This is **jeweller's borax.**

(iii) Borax glass ($Na_2B_4O_7$) is anhydrous sodium tetraborate and is obtained by heating ordinary form of borax above its melting point until all the water of crystallisation is removed. It is a colourless glassy substance which absorbs moisture from the atmosphere and converts into prismatic borax.

Chemical Properties

(i) It is sparingly soluble in **cold water** but is readily soluble in hot water. Its aqueous solution is alkaline due to hydrolysis.

$$Na_2B_4O_7 + 7H_2O \rightleftharpoons \underset{\text{strong base}}{2NaOH} + \underset{\text{weak acid}}{4H_3BO_3}$$

(ii) It reacts **with conc. acid** like HCl, H_2SO_4 to form sparingly soluble boric acid as

$$Na_2B_4O_7 + 2HCl + 5H_2O \longrightarrow 2NaCl + 4H_3BO_3$$

(iii) When heated with NH_4Cl, it forms boron nitride.

$$Na_2B_4O_7 + 2NH_4Cl \longrightarrow 2NaCl + \underset{\text{boron nitride}}{2BN} + B_2O_3 + 4H_2O$$

(iv) On heating above its melting point, it loses its water of crystallisation and swells up to form a mass. On further heating, it melts into a liquid which then solidifies to form transparent glassy mass like bead, called the **borax bead.** This bead is employed in qualitative analysis for the detection of certain coloured radicals such as $Ni^{2+}, Co^{2+}, Cr^{3+}, Cu^{2+}$, etc.

When a salt, containing any of these ions, is heated with borax bead on a Pt wire, the salt decomposes to corresponding oxide which combines with B_2O_3 of glassy bead and form coloured meta borate. This test is called **borax bead test.**

$$Na_2B_4O_7 \cdot 10H_2O \xrightarrow{-10H_2O} Na_2B_4O_7 \xrightarrow{\Delta} \underbrace{\underset{\text{sodium meta borate}}{2NaBO_2} + \underset{\text{boric anhydride}}{B_2O_3}}_{\text{glassy mass}}$$

$$CoO + B_2O_3 \xrightarrow{\Delta} \underset{\text{blue}}{Co(BO_2)_2}$$

$$Cr_2O_3 + 3B_2O_3 \xrightarrow{\Delta} \underset{\text{green}}{2Cr(BO_2)_3}$$

Uses

Borax is used

1. in leather and match industries.
2. in making optical glass and heat resistant boro-silicate glassware.
3. as a preservative for food.
4. in borax bead test, for the detection of basic radicals.
5. as a flux in metallurgy.
6. as an antiseptic in the manufacture of medicinal soaps.

Structure

Borax contains the tetrahedral units, *i.e.*, $[B_4O_5(OH)_4]^{2-}$ and its structure can be shown as

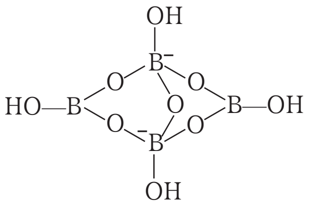

Fig. 11.5 Structure of $[B_4O_5(OH)_4]^{2-}$ ion

2. Orthoboric Acid or Boric Acid

Chemically it is H_3BO_3 or $B(OH)_3$.

Methods of Preparation

(i) It can be prepared from **borax** $(Na_2B_4O_7)$ or **colemenite** ore $(Ca_2B_6O_{11})$ through extraction directly.

(ii) Besides, it can also be prepared by the action of superheated water on boron nitride (BN) and boron sulphide (B_2S_3) as

$$BN + 3H_2O \longrightarrow H_3BO_3 + NH_3$$

$$B_2S_3 + 6H_2O \longrightarrow 2H_3BO_3 + 3H_2S$$

(iii) The acid can also be obtained by the hydrolysis of BCl_3 as

$$BCl_3 + 3H_2O \longrightarrow H_3BO_3 + 3HCl$$

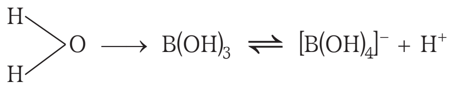
Physical Properties

It is seen as pearly white, needle like crystals with greasy feel. It is moderately soluble in water. The dissolution is accompanied by absorption of heat, *i.e.,* its solubility increases with increase in temperature.

Chemical Properties

Orthoboric acid exhibits the following chemical properties

(i) Boric acid is a weak acid and behaves as a monobasic Lewis acid. This is because in aqueous solution, it coordinates with a molecule of water to form a hydrated species, $\begin{matrix} H \\ H \end{matrix}\!\!>\!O \longrightarrow B(OH)_3$. B^{3+} ion pulls the σ-electron charge of the coordinated O-atom towards itself. The coordinated oxygen, in turn, pulls the σ-electron charge of the O—H bond of the attached water molecule towards itself. This facilitates the removal of H^+ ion from the O—H bond. Thus, the aqueous solution acts as a weak acid.



$$\begin{matrix} H \\ H \end{matrix}\!\!>\!O \longrightarrow B(OH)_3 \rightleftharpoons [B(OH)_4]^- + H^+$$

(ii) H_3BO_3 reacts with the aqueous solution of an alkali (*e.g.,* NaOH, KOH) and gives various types of polymeric metaborates like $NaBO_2 \cdot 2H_2O$, $NaB_3O_5 \cdot 2H_2O$, $Na_2B_4O_7 \cdot 10H_2O$, $KB_5O_8 \cdot 4H_2O$ etc., as

$$B(OH)_3 + NaOH(dil) \longrightarrow \underset{\text{sodium metaborate}}{NaBO_2 \cdot 2H_2O}$$

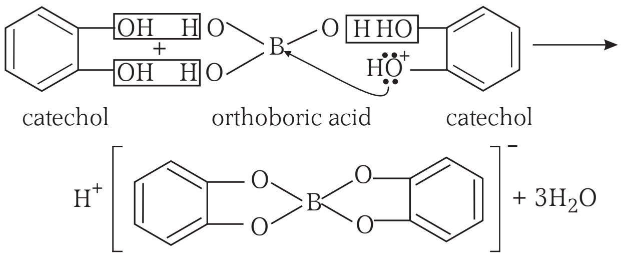
$$\text{or } Na^+[B(OH)_4]^-$$

$$5B(OH)_3 + KOH \longrightarrow KB_5O_8 \cdot 4H_2O + 4H_2O$$

The titration between $B(OH)_3$ and a strong alkali solution (*e.g.,* NaOH) is not possible, because sodium metaborate formed by reaction between $B(OH)_3$ and NaOH gets hydrolysed to regenerate $B(OH)_3$ and NaOH.

$$Na^+[B(OH)_4]^- \longrightarrow B(OH)_3 + NaOH$$

However, some quantity of polyhydroxy compounds like catechol, glycerol, mannitol, sugar etc., if added to the titration solution, a chelated complex compound is formed which makes H_3BO_3 *a strong acid by providing* H^+ *ions.*



chelated complex compound

The titration between $B(OH)_3$ and strong alkali solution, in the presence of polyhydroxy compound (with phenolphthalein indicator) makes the basis for the estimation of the acid and borax phenolphthalein test of glycerol.

(iii) When **heated to 100°C,** H_3BO_3 loses H_2O to give metaboric acid (HBO_2) which on being heated to 160°C, gives tetraboric acid ($H_2B_4O_7$). When $H_2B_4O_7$ is heated to redness, boron trioxide (B_2O_3) is obtained.

$$4H_3BO_3 \xrightarrow[-4H_2O]{100°C} 4HBO_2 \xrightarrow[-H_2O]{160°C} H_2B_4O_7 \xrightarrow[-H_2O]{\text{Red heat}} 2B_2O_3$$

On **heating below 100°C,** it gives pyroboric acid which on dilution further gives H_3BO_3 as

$$4H_3BO_3 \longrightarrow \underset{\text{pyroboric acid}}{H_6B_4O_9} + 3H_2O$$

$$H_6B_4O_9 + 3H_2O \longrightarrow 4H_3BO_3$$

(iv) When H_3BO_3 is treated **with sodium hydroperoxide** NaOOH, dihydrated sodium peroxyborate, $Na_2B_2O_6 \cdot 2H_2O$ is formed.

$$2B(OH)_3 + 2NaOOH \longrightarrow Na_2B_2O_6 \cdot 2H_2O + 2H_2O$$

(v) When H_3BO_3 or any borate is heated **with alcohol** (C_2H_5OH), in the presence of conc. H_2SO_4, volatile triethylborate, $(C_2H_5)_3BO_3$ (ester) is formed.

$$H_3BO_3 + 3C_2H_5OH \xrightarrow{\text{Conc. } H_2SO_4} (C_2H_5)_3BO_3 + 3H_2O$$

This ester burns with a green-edged flame. This property of the ester has been utilised for the identification of BO_3^{3-} radical.

(vi) When H_3BO_3 is heated **with CaF_2 and conc. H_2SO_4,** BF_3 (volatile) is obtained. If BF_3, produced as above, is brought near the Bunsen flame, a green flame is produced due to the burning of volatile BF_3. The formation of green flame, in this way, is used to detect BO_3^{3-} ion in the presence of Cu, given in a salt.

(vii) When H_3BO_3 is neutralised by soda ash, (Na_2CO_3), borax ($Na_2B_4O_7$) is obtained.

$$4H_3BO_3 + Na_2CO_3 \longrightarrow Na_2B_4O_7 + 6H_2O + CO_2$$

(viii) When H_3BO_4 is dissolved **in HF,** fluoroboric acid, $H[BF_4]$ (also called hydrofluoroboric acid) is obtained.

$$H_3BO_3 + 4HF \longrightarrow H^+[BF_4]^- + 3H_2O$$

(ix) When treated with acetic anhydride, $(CH_3CO)_2O$, H_3BO_3 gives boron acetate.

Uses

Boric acid is used

(i) as a preservative for milk and food stuffs.
(ii) as a mild antiseptic in aqueous solution, for washing eyes.
(iii) for preparing heat resistant borosilicate glass.
(iv) for the preparation of glazes in pottery.

Structure of Boric Acid

In solid state, boric acid has layer structure, *i.e.,* boric acid consists of a number of layers, which are linked together by van der Waals' forces and are at a distance of 318 pm from each other. Each layer is composed of various trigonal planar $B(OH)_3$ units. B atom, in each $B(OH)_3$ unit is linked with three OH groups, which are arranged at the corner of an equilateral triangle. The structure of one layer is shown in figure below, from which it may be seen that H-atom acts as a bridge between the two O-atoms, belonging to two different $B(OH)_3$ units.

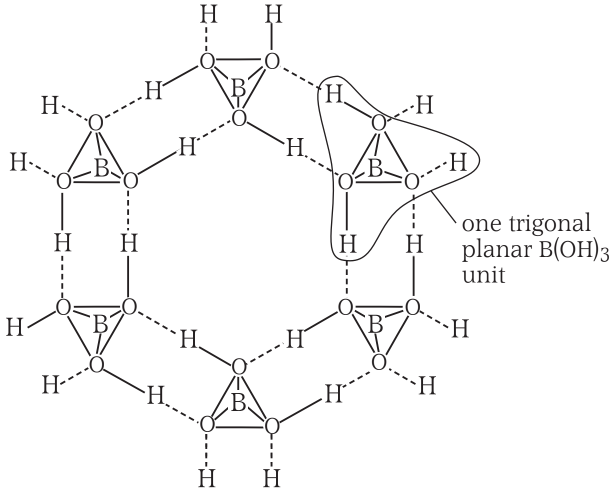


Fig. 11.7 Structure of boric acid

The dotted lines between O*-atom of one* B(OH)$_3$ *unit and H-atom of the other* B(OH)$_3$ *unit indicates hydrogen bonds.* It is due to the layer structure of boric acid which, in the solid state, consists of flakes, that are slippery to touch.

3. Diborane

Its formula is B_2H_6. It is the first member of B_nH_{n+4} series of boron hydrides because BH_3, which should be the first member, is known.

Methods of Preparation

Following methods are used for the preparation of diborane.

(i) By the reduction of boron trifluoride with $LiAlH_4$ in diethyl ether as

$$4BF_3 + 3LiAlH_4 \xrightarrow{\text{Diethyl ether}} 2B_2H_6 + 3LiF + 3AlF_3$$

(ii) By the oxidation of $NaBH_4$ with I_2 in DIGLYME (diethylene glycol methyl ether) as

$$2NaBH_4 + I_2 \xrightarrow{\text{DIGLYME}} B_2H_6 + 2NaI + H_2 \text{ (lab method)}$$

(iii) By the reaction of BF_3 with sodium hydride as

$$2BF_3 + 6NaH \xrightarrow{450\text{ K}} B_2H_6 + 6NaF \text{ (industrial method)}$$

(iv) By passing silent electric discharge through a mixture of hydrogen and BCl_3 vapour at a low pressure as

$$2BCl_3 + 6H_2 \xrightarrow[\text{discharge}]{\text{Silent electric}} B_2H_6 + 6HCl$$

Physical Properties

Diborane is a colourless, highly toxic gas with a boiling point of 180 K. It catches fire spontaneously on exposure to air and burns in oxygen releasing an enormous amount of energy as

$$B_2H_6 + 3O_2 \longrightarrow B_2O_3 + 3H_2O + 1976 \text{ kJ/mol}$$

Most of the higher boranes are also spontaneously flammable in air.

Chemical Properties

Diborane shows the following chemical properties

(i) It gets **hydrolysed** readily as

$$B_2H_6 + 6H_2O \longrightarrow 2H_3BO_3 + 6H_2\uparrow$$

(ii) It dissolves in strong alkali solutions giving metaborates and H_2 as

$$B_2H_6 + 2KOH + 2H_2O \longrightarrow 2KBO_2 + 6H_2\uparrow$$

(iii) It reacts slowly with active metals (Na, K, Ca and their amalgams). However, the reaction is faster in the presence of ether as

$$2B_2H_6 + 2Na \xrightarrow{\text{Ether}} NaBH_4 + \underset{\text{sodium polyborane}}{NaB_3H_8}$$

(iv) It reacts **with CO** at 100°C and 20 atm pressure to form the carbonyl H_3BCO as

$$B_2H_6 + 2CO \xrightarrow[20\text{ atm}]{100°\text{C}} 2H_3BCO$$

(v) It reacts **with halogens** under different conditions to form halo diboranes as

$$B_2H_6 + Cl_2 \xrightarrow[\text{explosive}]{25°\text{C}} \underset{\text{chloro diborane}}{B_2H_5Cl} + HCl$$

$$B_2H_6 + Br_2 \xrightarrow[\text{rapid}]{100°\text{C}} \underset{\text{bromo diborane}}{B_2H_5Br} + HBr$$

(vi) It reacts **with halogen acids** as

$$B_2H_6 + HCl \longrightarrow B_2H_5Cl + H_2\uparrow$$

(vii) It combines **with hydrides of alkali metals** to form complex hydrides as

$$B_2H_6 + 2NaH \longrightarrow 2Na[BH_4]$$

(viii) It adds to **alkanes** and **alkynes** in the presence of a Lewis base like THF (tetrahydro furan) or DIGLYME (diethylene glycol methyl ether) as

$$3RCH{=}CH_2 + BH_3 \xrightarrow[\text{DIGLYME}]{\text{THF or}} \underset{\text{trialkyl borane}}{(RCH_2CH_2)_3B}$$

$$3RC{\equiv}CH + BH_3 \xrightarrow[\text{DIGLYME}]{\text{THF or}} \underset{\text{trialkenyl borane}}{(R{-}CH{=}CH)_3B}$$

This reaction is called **hydroboration reaction** and has been of great synthetic utility in organic chemistry.

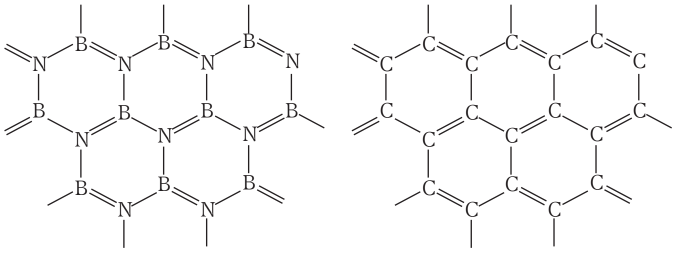
(ix) Diborane reacts **with NH_3** and the products formed depend upon the conditions of reaction as

(a) $B_2H_6 + 2NH_3 \xrightarrow{\text{Low temperature}} \underset{\text{diammoniate of diborane}}{B_2H_6\cdot 2NH_3}$

The compound $B_2H_6\cdot 2NH_3$ is ionic and exists as $[H_3N \longrightarrow BH_2 \longleftarrow NH_3]^+ [BH_4]^-$. It forms borazine on heating.

(b) $nB_2H_6 \xrightarrow[\text{at high temperature}]{\text{Excess } NH_3} \underset{\text{boron nitride}}{(BN)_n}$

Boron nitride is a white crystalline solid and resembles graphite in structure as shown below

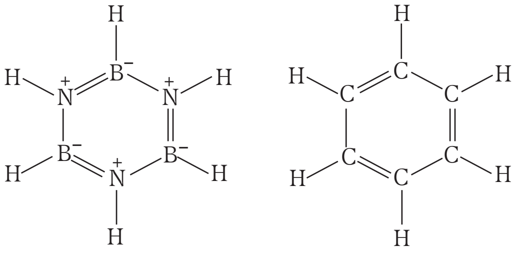


(a) Boron nitride (b) Graphite

Fig. 11.8 Similarity in the structure of boron nitride and graphite

$$\text{(iii) } 3B_2H_6 + 6NH_3 \xrightarrow{200°C} \underset{\substack{\text{borazine}\\ \text{or borazole}}}{2B_3N_3H_6} + 12H_2$$

Borazine or **borazole** can also be prepared by heating BCl_3 and NH_4Cl together or by treating $NaBH_4$ with NH_4Cl. Its structure is similar to that of benzene as shown below

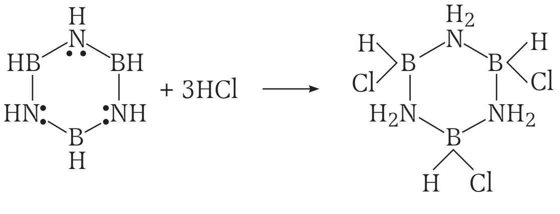


(a) Borazine (b) Benzene

Fig. 11.9 Similarity in the structure of borazine and benzene

Because of its similarity with benzene in structure, and some physical and chemical properties borazine is also called **inorganic benzene.**

However, in benzene the C═C bonds are non-polar and the nucleus is very resistant to addition reactions, whereas borazole nucleus is fairly reactive on account of its polarities. Thus, it readily adds three molecules of H_2O, CH_3OH, CH_3I or HCl, the more negative group generally attaches to boron atoms.



Borazole decomposes slowly on standing and undergoes hydrolysis at high temperatures.

$$B_3N_3H_6 + 9H_2O \longrightarrow 3B(OH)_3 + 3NH_3 + 3H_2$$

Uses

Diborane is used

1. as a reducing agent in organic reaction.
2. for the synthesis of a number of borohydrides like $LiBH_4$, $NaBH_4$ etc.
3. as a fuel for supersonic rockets.

Structure of Diborane

Boranes provide interesting examples of **electron deficient compounds.** The structure of diborane shows that the four terminal hydrogens along with two boron atoms lie in one plane. Two bridging hydrogens are seen to present above and below this plane. The four terminal B—H bonds are regular two centred two electron (2*c*–2*e*) bonds while two bridge bonds (B—H—B) are different and can be described in terms of three centred two electron (3*c*–2*e*) bonds as shown in the figure below.

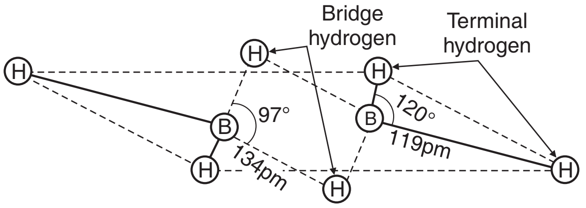


Fig. 11.10 Structure of B_2H_6

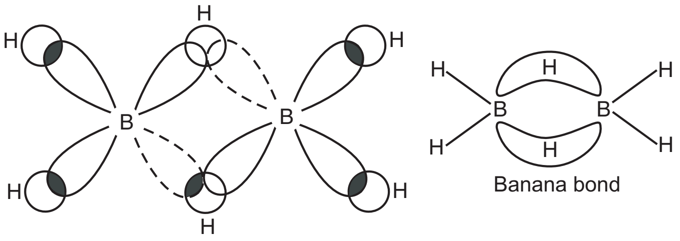

Fig. 11.11 Orbital picture of B_2H_6

According to molecular orbital theory, each B atom uses sp^3-hybrid orbitals for bonding. Out of $4sp^3$-hybrid orbitals one orbital is empty, *i.e.,* without any electron and is shown with broken lines in the figure. So, the involvement of one half-filled orbital of one B atom with one empty orbital of other B atom and half-filled orbital of hydrogen atom results in three centred (B—H—B) two electron (one contributed by one of the B atoms and other by hydrogen atom) electron deficient bridge bond. Such a bond is also called **banana bond** due to its banana like shape as shown in the figure below.

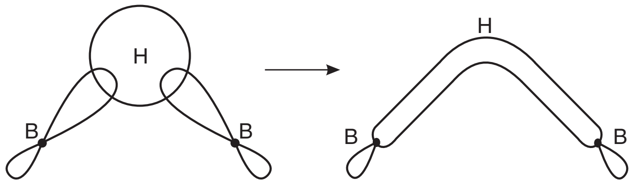

Fig. 11.12 Banana bond in diborane

The structure discussed above is supported by the following additional facts

1. **Heat capacity** measurements shown that the rotation of the two ends of the molecule against each other is very much hindered. This indicates that the bridge hydrogen atoms lie in a plane at right angles to the plane in which the rest of the molecule lies. In a molecule, like ethane (where bridge hydrogen atoms are absent) the hinderance of this type of rotation is very low.
2. Diborane cannot be methylated beyond $(CH_3)_4B_2H_2$. The hydrogens which cannot be methylated, evidently, are in a different environment. These are infact bridged hydrogens.

Boron Trifluoride

It is an electorn deficient compound of formula BF_3. It is generally used as a Lewis acid and catalyses many organic reactions.

Methods of Preparation

(i) BF_3 is obtained as a colourless gas by heating B_2O_3 or borax with calcium fluoride and conc. H_2SO_4 as

$$B_2O_3 + 3CaF_2 + 3H_2SO_4 \longrightarrow 3CaSO_4 + 3H_2O + 2BF_3$$

$$Na_2B_4O_7 + 6CaF_2 + 8H_2SO_4 \longrightarrow 2NaHSO_4 + 6CaSO_4 + 4BF_3 + 7H_2O$$

BF_3 is collected over Hg.

(ii) BF_3 can also be obtained by heating together B_2O_3, ammonium fluoroborate and concentrated sulphuric acid.

$$B_2O_3 + 6NH_4BF_4 + 6H_2SO_4 \longrightarrow 8BF_3 + 6NH_4HSO_4 + 3H_2O$$

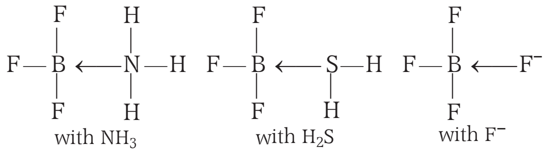
(iii) Pure BF_3 can also obtained by the thermal decomposition of diazonium tetrafluoroborate as

$$C_6H_5N_2BF_4 \xrightarrow{\Delta} C_6H_5F + N_2 + BF_3$$

Physical and Chemical Properties

(i) BF_3 is a colourless pungent gas (mp −127.1°C and bp −99.9°C) which strongly fumes in moist air and possesses a pungent smell. It is exceedingly soluble in water that's why it is collected over Hg.

(ii) BF_3, being an electron deficient compound, can accept a lone pair of electrons, thus behaves as Lewis acid, *e.g.*, with NH_3, H_2S and F^-, it can form complexes like



Due to its electron accepting tendency, it is used as a catalyst in a number of organic reactions.

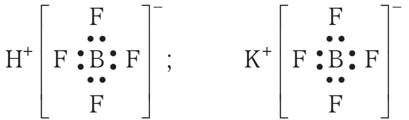
(iii) BF_3 combines with water forming two hydrates, *i.e.*, $BF_3 \cdot H_2O$ (mp 10.18°C) and $BF_3 \cdot 2H_2O$ (mp 6.36°C). It gets hydrolysed in aqueous solutions yielding boric acid and hydrofluoroboric acid as

$$BF_3 + 3H_2O \longrightarrow H_3BO_3 + 3HF$$

If we take BF_3 in excess, it is dissolved in HF to give hydrofluoroboric acid $H[BF_4]$ as

$$BF_3 + HF \longrightarrow H[BF_4]$$

Fluoroboric acid forms definite salts, known as fluoroborates or borofluorides, *e.g.*, KBF_4, in which boron is tetracovalent (as in the acid also).



fluoroboric acid potassium borofluoride

On strong heating, these salts decompose into BF_3 and metal fluoride.

$$KBF_4 \xrightarrow{\Delta} KF + BF_3$$

Sample **Problem 5** *In the following reaction sequence Z is*

$$Z + 3LiAlH_4 \longrightarrow X + 3LiF + 3AlF_3$$

$$X + 6H_2O \longrightarrow Y + 6H_2$$

(*c*) $BF_3, B_3N_3H_6$ (*d*) $B_3N_3H_6, B_2H_6$

Interpret (*a*) $B_3N_3H_6$ or borazene is called inorganic benzene. It is obtained by heating diborane with NH_3.

$$3B_2H_6 + 6NH_3 \longrightarrow \underset{\text{inorganic benzene}}{2B_3N_3H_6} + 12H_2$$

Diborane is also prepared by treating BF_3 with $LiAlH_4$

$$4BF_3 + 3LiAlH_4 \longrightarrow 2B_2H_6 + 3LiF + 3AlF_3$$

Hot Spot 2

ALUMINIUM Chloride

It is also an important topic of this chapter for JEE Main examination. Question based on preparation and properties are generally asked. The nature of question is easy to moderate.

Methods of Preparation

$AlCl_3$ is prepared by dissolving Al in excess of HCl. It is deposited as the crystals of $Al_2Cl_6 \cdot 12H_2O$. This hydrate on heating decomposes to give alumina as

$$Al_2Cl_6 \cdot 12H_2O \xrightarrow{\Delta} Al_2O_3 + 6HCl + 9H_2O$$

So, for preparing anhydrous $AlCl_3$, Al is heated in a steam of dry chlorine or hydrogen chloride gas as

$$2Al + 3Cl_2 \longrightarrow 2AlCl_3$$

This reaction is extremely exothermic.

$$2Al + 6HCl \longrightarrow 2AlCl_3 + 3H_2$$

Anhydrous $AlCl_3$ can also be formed when

1. A mixture of Al_2O_3 and C is strongly heated in dry chlorine gas as

$$Al_2O_3 + 3Cl_2 + 3C \longrightarrow 2AlCl_3 + 3CO$$

2. A mixture of CO and Cl_2 is passed over heated Al_2O_3 as

$$Al_2O_3 + 3CO + 3Cl_2 \longrightarrow 2AlCl_3 + 3CO_2$$

AlI_3, when reacts with CCl_4, also gives $AlCl_3$.

$$4AlI_3 + 3CCl_4 \longrightarrow 4AlCl_3 + 3CI_4$$

Properties

1. $AlCl_3$ is white in its pure form and sublimes at 183°C. It is extremely hygroscopic and fumes strongly in moist air due to the formation of HCl as

$$2AlCl_3 + 6H_2O \longrightarrow 2Al(OH)_3 + 6HCl$$

2. It exists as a monomer above 800°C with sp^2-hybridisation, trigonal planar structure and three pure covalent bond. However, below 400°C, it exists as a dimer with sp^3 hybridisation (three pure covalent and one co ordinate bond). In solid state also, $AlCl_3$ exists as a dimer and is non-conducting.
3. When dissolved in water, it changes into hydrated aluminium chloride which is ionic in nature.

$$Al_2Cl_6 + 12H_2O \longrightarrow 2AlCl_3 \cdot 6H_2O$$

4. Aluminium chloride forms addition compounds with the molecules capable of donating lone pair of electrons, *e.g.*, like NH_3, phosphine, $COCl_2$ etc.

$$Al_2Cl_6 + 12NH_3 \longrightarrow 2(AlCl_3 \cdot 6NH_3)$$

5. When sodium hydroxide is added to the solution of aluminium chloride drop by drop, a white gelatinous precipitate appears which dissolves in excess of sodium hydroxide forming sodium meta-aluminate.

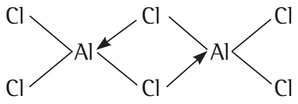
$$AlCl_3 + 3NaOH \longrightarrow Al(OH)_3 + 3NaCl$$
$$Al(OH)_3 + NaOH \longrightarrow NaAlO_2 + 2H_2O$$

Uses

$AlCl_3$ is a strong Lewis acid and readily forms adducts with Lewis base. It is, therefore, use as a catalyst in 'organic chemistry' and also used in the manufacture of dyes, drugs and pharmaceuticals.

Structure

The structure of Al_2Cl_6 can be represented as



The dimeric formula exists in non-polar solvents such as benzene but due to higher heat of hydration, it changes into $[Al(H_2O)_6]^{3+}$ and $3Cl^-$ ions in aqueous solution.

Sample Problem 7 *Which of the following is obtained when aluminium oxide and carbon is strongly heated in dry chlorine gas?*

(a) *Aluminium chloride*
(b) *Hydrated aluminium chloride*
(c) *Anhydrous aluminium chloride*
(d) *None of the above*

Interpret (c) When aluminium oxide and carbon are heated in the presence of dry chlorine gas they result in the formation of anhydrous aluminium chloride.

$$Al_2O_3 + 3Cl_2 + 3C \longrightarrow \underset{\text{anhydrous}}{2AlCl_3} + 3CO$$

Alums

The name *alum*, is given to all double salts with the formula $(M')_2SO_4 \cdot (M'')_2(SO_4)_3 \cdot 24H_2O$.

where, M' = univalent basic radicals like Na^+, K^+, NH_4^+, Ag^+ etc.

M''' = trivalent metal like Al^{3+}, Cr^{3+}, Fe^{3+}, Co^{3+} etc.

Some common examples include $K_2SO_4 \cdot Al_2(SO_4)_3 \cdot 24H_2O$, *potash alum* or *common alum*; $Na_2SO_4 \cdot Al_2(SO_4)_3 \cdot 24H_2O$, *sodium alum*, $(NH_4)_2SO_4 \cdot Al_2(SO_4)_3 \cdot 24H_2O$, *ammonium alum*, $K_2SO_4 \cdot Cr_2(SO_4)_3 \cdot 24H_2O$, *chrome alum*.

Methods of Preparation

Common alum is potash alum, $KAl(SO_4)_2 \cdot 12H_2O$ and is prepared

(i) **From alunite or alum stone** Alunite is boiled with dilute sulphuric acid and filtered. The filtrate is mixed with a requisite amount of potassium sulphate and crystallized.

$$K_2SO_4 \cdot Al_2(SO_4)_3 \cdot 4Al(OH)_3 + 6H_2SO_4 \longrightarrow K_2SO_4 + 3Al_2(SO_4)_3 + 12H_2O$$

$$K_2SO_4 + Al_2(SO_4)_3 + 24H_2O \longrightarrow 2[KAl(SO_4)_2 \cdot 12H_2O]$$

(ii) **From bauxite** Bauxite is dissolved in sulphuric acid, treated with calculated amount of potassium sulphate and crystallized.

(iii) **From pyrites shale $Al_2O_2 \cdot xSiO_2 + FeS_2$.** It is also known as alum shale which is aluminium silicate mixed with iron sulphide. It is roasted in excess of air when ferrous sulphide gives ferrous sulphate and sulphuric acid and the latter then reacts with alumina to form aluminium sulphate.

$$2FeS_2 + 2H_2O + 7O_2 \longrightarrow 2FeSO_4 + 2H_2SO_4$$

$$Al_2O_3 \cdot xSiO_2 + 3H_2SO_4 \longrightarrow Al_2(SO_4)_3 + xSiO_2 + 3H_2O$$

Ferrous sulphate is removed by fractional crystallization and potassium sulphate added to the mother liquor when potash alum crystallizes out. Being an ionic compound it does not contain discrete molecules and is usually represented as $KAl(SO_4)_2 \cdot 12H_2O$.

Properties

All the alums are **isomorphous,** form mixed crystals in all proportions. Each alum has different melting point. These are usually much more soluble in hot water than in cold water. On heating, alum loses its water of crystallisation and swells up leaving behind a porous mass, called the **burnt alum.**

Uses

It is used in purification of water, water proofing of textiles and in dyeing and paper industry. It is also employed as a styptic to arrest bleeding.

Pseudoalums

These are the double sulphate of divalent ions and trivalent ions. These have general formula,

$$MSO_4 \cdot (M'')_2(SO_4)_3 \cdot 24H_2O$$

Here, M = bivalent metal

M'' = trivalent metal.

Pseudoalums are not isomorphous with alums.

Some examples are

$$MnSO_4 \cdot Al_2(SO_4)_3 \cdot 24H_2O$$
$$FeSO_4 \cdot Al_2(SO_4)_3 \cdot 24H_2O$$

Check Point 2

1. Why BF_3 is collected over Hg?
2. Anhydrous aluminium chloride fumes is moist air. Give reason.
3. Why is boric acid slippery to touch?
4. Why borazine gives addition reaction but benzene does not?
5. Anhydrous aluminium chloride is covalent while hydrated aluminium chloride is not. Explain, why?
6. Why does boron trifluoride behave as a Lewis acid?
7. Alum is used in setting muddy water. Give reason.

Elements of Group 14 (or IVA) and their Compounds

11.6 Elements of Group 14 (or IVA)

The group 14 (IVA) contains 5 elements namely **carbon** (C), **silicon** (Si), **germanium** (Ge), **tin** (Sn) and **lead** (Pb). Carbon is an essential constituent of all organic matter while silicon is an important constituent of inorganic matter.

Occurrence

Carbon is the 17th most abundant element and is found both in native and combined state.

Silicon occurs most abundantly, next only to oxygen, up to 26% in earth crust as silica and silicates. Ge occurs rather sparsely. Sn occurs chiefly as SnO_2 while lead occurs mainly as PbS.

Electronic Configuration

General electronic configuration of elements of this group is ns^2p^2 (where, n = 2, 3, 4, ...)

Table 11.4 **Electronic Configuration of Elements of Group 14**

Element	Electronic configuration
$_6C$	[He] $2s^2 2p^2$
$_{14}Si$	[Ne] $3s^2 3p^2$
$_{32}Ge$	[Ar] $3d^{10}, 4s^2 4p^2$
$_{50}Sn$	[Kr] $4d^{10}, 5s^2 5p^2$
$_{82}Pb$	[Xe] $4f^{14}, 5d^{10}, 6s^2 6p^2$

Although they have same number of valence electron, yet these are known to exhibit a variation in properties. This is because, they differ in configuration of penultimate shell.

Trends in Physical Properties of Elements of Group 14

(a) Molar Volumes and Atomic Radius

Molar volumes and atomic radius increase down the group. Their atomic radii are smaller than the corresponding elements of group 13 due to increase in effective nuclear charge.

(b) Melting and Boiling Points

The melting and boiling points of first member *i.e.,* carbon are exceedingly high. The values decrease as we move from carbon to lead. The melting point of Sn and Pb are relatively low because the *M—M* bonds are weaker. They do not use all the four outer electrons for metallic bonding.

(c) Ionisation Energy

Ionisation energy of C is very high and decreases sharply as we move from carbon to silicon. It is because there is an appreciable increase in the size of Si atom. After Si the decrease is regular but not so much and not very sharp from Si to Sn due to appearance of *d*-electrons in them. However, a marginal increase is seen between Sn and Pb. This is because of the further appearance of *f*-electrons in Pb due to which, there is a marginal increase in atomic radius which increases the ionisation energy marginally.

The *d*-electrons and *f*-electrons show very less or almost no screening due to very less electrons density in them. This constant or almost constant screening effect is responsible for such a gradation seen in ionisation energy.

(d) Metallic or Electropositive Character

First two members of the group are non-metals (C and Si); the middle one is semi-metal (Ge) while Sn and Pb are metals. The metallic or electropositive character increases down the group.

$$\underbrace{\text{C}\qquad\text{Si}}_{\text{non-metals}}\qquad\underset{\text{metalloid}}{\text{Ge}}\qquad\underbrace{\text{Sn}\qquad\text{Pb}}_{\text{metals}}$$

The change from non-metallic to metallic character is due to less effective nuclear charge and increased number of available orbitals with increase in the size of the atom.

(e) Electronegativity

C is the most electronegative element of the group. While on moving down the group electronegativity decreases upto Si and then remains constant. Such a different trend in electronegativity is due to the fact that *d*-orbitals are filled up in the case of Ge and Sn while in the case of Pb *f*-orbitals are filled up.

(f) Covalency

Carbon, due to the absence of *d*-orbitals, cannot expand its valence shell and thus, its maximum covalency is four. Other members, however, have vacant *d*-orbital and thus, can expand their covalency beyond four. They form pentacoordinated and hexacoordinated complex. *e.g.,* SiF_4 can combine with $2F^-$ ions.

$$SiF_4 + 2F^- \longrightarrow [SiF_6]^{2-}$$

but $[CF_6]^{2-}$ does not exist.

The physical properties, described above, are summarised in the following table

Table 11.5 **Physical Properties of Elements of Group 14**

Property	Carbon	Silicon	Germanium	Tin	Lead
Atomic number	6	14	32	50	82
Molar mass ($g\ mol^{-1}$)	12.00	28.086	72.59	118.89	207.19
Density ($g\ cm^{-3}$)	3.52	2.49	5.35	7.30	11.34
Atomic radius (Å)	0.77	1.17	1.22	1.41	1.44
Molar volume ($cm^3\ mol^{-1}$)	3.4	11.4	13.6	16.3	18.27
Melting point (°C)	4100	1410	937.5	231.8	327.4
Boiling point (°C)	4833	2680	2830	2270	1725
Electronegativity	2.5	1.8	1.8	1.8	1.8
Ionisation enthalpy ($kJ\ mol^{-1}$)					
$\Delta_i H_1$	1086	786	761	708	715
$\Delta_i H_2$	2352	1577	1537	1411	1450
$\Delta_i H_3$	4620	3228	3300	2942	3081
$\Delta_i H_4$	6220	4354	4409	3929	4082
Oxidation states (stable)	+4	+4	+2, +4	+2, +4	+2, +4

(g) Catenation

The ability of like atoms to link together, through covalent bond is called catenation. Carbon exhibits the remarkable property of catenation. The tendency of catenation depends upon the strength of element-element bond which is described in terms of bond energy. The bond energy values for different elements of this group are given as :

Table 11.6 **Bond Energies of Elements of Carbon Family**

Bond	Bond energy (kJ/mol)
C—C	354
Si—Si	222
Ge—Ge	167
Sn—Sn	155

The table shows that bond energy is maximum in case of carbon and minimum in case of Sn. Thus, we can say the tendency of catenation decreases down the group as

$$C > Si > Ge > Sn > Pb.$$

The reason for greater tendency of carbon for catenation than other elements may further be explained by the fact that C—C bonds energy is approximately of the same value as the energies of bonds between carbon and other elements. On the other hand Si—Si bond is weaker than the bonds between silicon and other elements.

C—C	83 kcal/mol	Si—Si	54 kcal/mol
C—O	86 kcal/mol	Si—O	88 kcal/mol
C—Cl	81 kcal/mol	Si—C	186 kcal/mol

Thus, carbon forms a number of compounds in which large number of carbon atoms are linked together in the form of straight chains, branched chains or closed rings. The property of catenation is responsible for a very large number of compounds of carbon.

Although Sn and Pb have hardly any tendency for catenation.

(h) Allotropy

It is the tendency of an element to exist in different forms. Almost all members of this group show allotropy, *e.g.,* carbon exists in crystalline forms *e.g.,* diamond and graphite and microcrystalline forms *e.g.,* coal, coke, charcoal, carbon black etc. Microcrystalline forms were previously regarded as amorphous. [Amorphous = Without definite structure, Gr. Morpha = form.] All the microcrystalline forms have finely divided graphite structure.

Si also exists in two allotropic forms, *i.e.,* grey crystalline form and brown amorphous powder. These forms differ in particle size and content of impurities. The amorphous variety fuses on strong heating and solidifies on cooling to give the crystalline form.

Germanium exists in two crystalline forms, while tin exists in three solid forms namely grey tin, white tin and rhombic tin. Grey tin is stable below 18°C, white tin above 18°C and rhombic tin above 161°C. Out of these, white tin is the most common form of tin as it shows the stability at room temperature.

$$\text{Grey} \overset{18^\circ\text{C}}{\rightleftharpoons} \text{White} \overset{161^\circ\text{C}}{\rightleftharpoons} \text{Rhombic}$$

The densities of the three forms are 5.74, 7.32 and 6.55 g/cc respectively. White tin is not only the heaviest but also the most stable form. The conversion of white tin into grey tin takes place very slowly at 18°C (transition temperature). However, if the temperature is low as −50°C and a small amount of grey tin is also present, the conversion becomes very rapid. This conversion is known as **tin pest or tin disease.**

Hot Spot 3

OXIDATION STATE

and Nature of Compounds

Stability of oxidation state and finding oxidising and reducing agent on this basis is also a Hot Topic of this chapter for JEE Main examination. The nature of question is direct and level is easy.

All the elements in common, have the oxidation state of +4. C shows only +4 oxidation state but other elements also show +2 oxidation state. **The stability of +2 oxidation state increases down the group due to inert pair effect.** Thus, Pb^{2+} exists as stable ion and is much more stable and common than Pb^{4+} ions. Similarly owing to their small sizes, the M^{4+} ions of Pb have more covalent character than the electrovalent in their compounds. (The covalent nature in the compounds of Pb^{4+} ions can be explained on the basis of high polarisation produced by such ions).

Thus, the stability of ions of this group follow the following order

$$Ge^{2+} < Sn^{2+} < Pb^{2+}$$

$$Ge^{4+} > Sn^{4+} > Pb^{4+}$$

The compounds of Ge^{2+} are unstable while compounds of Ge^{4+} are stable. Thus, the compounds of Ge^{2+} get oxidised into Ge^{4+} easily and act as a reducing agent.

$$\underset{\substack{\text{less stable}\\\text{(reducing agent)}}}{Ge^{2+}} \xrightarrow{-2e} \underset{\text{more stable}}{Ge^{4+}}$$

The compounds of Sn^{2+} are less stable than Sn^{4+}. Thus, Sn^{2+} compounds also act as reducing agents. In the case of lead, Pb^{2+} compounds are more stable than Pb^{4+} compounds. The Pb^{4+} compounds, thus, act as oxidising agents.

$$\underset{\substack{\text{less stable}\\\text{(oxidising agent)}}}{Pb^{4+}} + 2e \longrightarrow \underset{\text{more stable}}{Pb^{2+}}$$

Sample Problem 8 *The most commonly used reducing agent is* [**NCERT** Exemplar]

(*a*) $AlCl_3$ (*b*) $PbCl_2$ (*c*) $SnCl_4$ (*d*) $SnCl_2$

Interpret (*d*) Sn^{4+} is more stable than Sn^{2+} thus, Sn^{2+} have a great tendency to get converted into Sn^{4+} by losing two electrons hence, it is used as reducing agent.

Trends in Chemical Properties of Elements of Group 14

(a) Reactivity

The elements of this group are relatively less reactive but reactivity increase down the group. Lead often appears more unreactive than expected. This is partly due to surface coating of the oxide and partly due to the high overpotential for the reduction of H^+ to H_2 at a lead surface.

(b) Reaction with Water

C, Si and Ge do not react with water while Sn reacts with steam and forms SnO_2 and H_2.

$$Sn(s) + 2H_2O(g) \xrightarrow{\Delta} SnO_2(g) + 2H_2(g)$$

Lead also remains unaffected due to the formation of a protective film of lead oxide over its surface.

(c) Hydrides

All the elements of this group form covalent hydrides. The number of stable hydrides and *the ease of their formation decreases down the group. Owing to which their tendency to act as reducing agent increases down the group.* Hydrides of different elements of the groups are discussed one by one.

Carbon forms a number of hydrides which are known as **hydrocarbons.** We study them completely in 'organic chemistry'.

Hydrides of silicon are similar to those of carbon but are less stable and much less in number. These are called **silanes** and have the general formula Si_nH_{2n+2}. Silanes up to $n = 8$ are known. The first two members are colourless gases while 3rd and subsequent members are liquids. SiH_4 is stable at room temperature and the thermal stability of silanes decreases with increasing chain length.

Some important facts related to silanes are as follows

(i) Silanes are produced by the action of acids on metallic silicides as

$$Mg_2Si + 4HCl \longrightarrow 2MgCl_2 + SiH_4$$

Actually in this reaction a mixture of silanes is obtained with the composition SiH_4(40%), Si_2H_6 (30%), Si_3H_8(12%), Si_4H_{10}(10%) and others 8%.

(ii) Silanes are much less stable than corresponding alkanes and their structure is analogous to that of alkanes. Infact they are spontaneously inflammable and explosive in air. The lower silanes decompose more easily than the higher ones, *e.g.,* SiH_4 decomposes spontaneously when comes in contact with air as

$$SiH_4 + 2O_2 \longrightarrow SiO_2 + 2H_2O$$

(iii) They decompose slowly when brought in contact with water as

$$SiH_4 + 3H_2O \longrightarrow H_2SiO_3 + 4H_2$$

(iv) These are soluble in strong alkali solutions in the presence of air and evolve hydrogen as

$$SiH_4 + 2NaOH + \frac{1}{2}O_2 \longrightarrow Na_2SiO_3 + 3H_2\uparrow$$

(v) Silanes, being oxidised easily, have strong reducing properties. They reduce permangnate to Mn (II), Hg (II) to Hg (I) or even Hg (0); Fe (III) to Fe (II) and copper (II) to copper hydride.

(vi) With Cl_2 and Br_2, they react with violent explosion even at ordinary temperatures. But treatment of SiH_4 with HCl or HBr at 100°C in the presence of $AlCl_3$ as a catalyst results in substitution of hydrogen atoms by chlorine or bromine as

$$SiH_4 + HCl \xrightarrow{AlCl_3} \underset{\text{halo (chloro) silane}}{SiH_3Cl} + H_2\uparrow$$

The hydrides of Ge are called **germanes** and have the general formula $[Ge_nH_{2n+2}]$. Germanes upto $n = 5$ are known. Three hydrides are more commonly known *i.e.,* monogermane (GeH_4), digermane (Ge_2H_6) and trigermane (Ge_3H_8).

Some points related to germanes are as follows

(i) These are prepared in the same way as silanes and the mixture contains mono, di and trigermanes. From the mixture individual germanes can be separated by fractional distillation.

(ii) First two germanes are colourless gases while higher members are liquids. These are less volatile and less reactive than corresponding silanes, *e.g.,* in comparison to SiH_4, the GeH_4 does not ignite when brought in contact with air. Also unlike silanes, they are not attacked by water.

(iii) Monogermane unlike monosilane is not attacked by 30% NaOH or KOH. Digermane, however, evolves hydrogen under these conditions. At higher temperatures these decompose to give germanium and hydrogen.

Two hydrides of tin namely **monostannane** (SnH_4) and **distannane** (Sn_2H_6) are known.

Important points related to stannanes are as follows

(i) SnH_4 is obtained as a gas by reducing tin (IV) chloride with ethereal $Li[AlH_4]$. It is also formed by the action of atomic hydrogen on metallic Sn or by the action of $SnCl_2$ with $NaBH_4$.

(ii) The melting point and boiling point of SnH_4 are −146°C and −52°C respectively. It is not so stable and decomposes slowly even at room temperature into Sn and hydrogen. Decomposition is easier above 145°C. It is resistant to dilute aqueous acids and alkalies.

There is some doubt about the existence of lead hydride although it is claimed that it is formed in minute quantities as a gas when a lead magnesium alloy is dissolved in dilute acids.

(d) **Halides**

The elements of group 14 form MX_4 and MX_2 type halides (where, X = F, Cl, Br, I).

All the tetrahalides (*i.e.,* MX_4) have covalent nature and are sp^3 hybridised. The thermal stability of halides of different elements with a common halogen decreases with increasing atomic number. The thermal stability of tetrahalides of the same element decreases with increase in molecular mass of the tetrahalide.

$$CX_4 > SiX_4 > GeX_4 > SnX_4 > PbX_4$$
$$CF_4 > CCl_4 > CBr_4 > CI_4$$

Other facts related to tetrahalides of element of this group are as follows

(i) The tetrafluorides of C, Si and Ge are gases while the tetrafluorides of Sn and Pb are solids. The last two are more ionic in character than the first three.

(ii) All the tetrachlorides of group 14th elements are liquids with $PbCl_4$ having lesser tendency to become liquid. CCl_4 is used for preparing freons such as $CFCl_3$, CF_2Cl_2 which are used in refrigeration.

(iii) CBr_4 is a solid, while tetrabromides of Si, Ge and Sn are liquids.

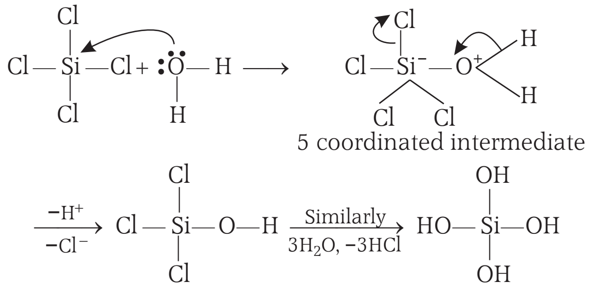
(iv) The tetraiodides of first four elements are solids. However $PbBr_4$ and PbI_4 are unknown.

[Non-existence of $PbBr_4$ and PbI_4 can be explained on the basis of strong oxidising nature of Pb^{4+}. The ions Br^- and I^- are reducing agents, *i.e.,* in the presence of these ions, Pb^{4+} ions are reduced to Pb^{2+} ions.

$$Pb^{4+} + 2Br^- \longrightarrow Pb^{2+} + Br_2$$
$$Pb^{4+} + 2I^- \longrightarrow Pb^{2+} + I_2]$$

(v) *The tetrahalides of* C *are not hydrolysed by water under normal conditions* (due to the absence of *d*-orbitals) while the tetrahalides of other elements are readily hydrolysed due to the availability of empty *d*-orbitals in them.

The mechanism of hydrolysis of $SiCl_4$ is as



Infact hydrolysis of SiF_4 ultimately yields H_2SiF_6 (fluorosilicic acid).

$$3SiF_4 + 2H_2O \longrightarrow SiO_2 + \underset{\text{fluorosilicic acid}}{2H_2SiF_6}$$

Fluorosilicic acid is a strong acid and exists largely in ionised state as

$$H_2SiF_6 + 2H_2O \longrightarrow 2H_3O^+ + [SiF_6]^{2-}$$

(GeF_4 also undergoes hydrolysis in the same manner).

(vi) The tetrahalides of carbon do not form complexes because of the unavailability of empty *d*-orbitals while tetrahalides of other elements form the complexes like $[SiF_6]^{2-}$, $[GeF_6]^{2-}$, $[SnCl_6]^{2-}$. These ions involve sp^3d^2 hybridisation with octahedral structure.

$SnCl_4$ on hydrolysis produces complex acidic compound $H_2[SnCl_3(OH)_3]$ as

$$SnCl_4 + 3H_2O \longrightarrow H_2[SnCl_3(OH)_3] + HCl$$

Carbon does not form dihalides while silicon along with Ge, Sn *and* Pb *form dihalides of* MX_2 *type. These dihalides are more ionic than covalent in character*. These dihalides can be prepared as

$$SiCl_4 + Si \xrightarrow[1100°C]{\text{above}} 2SiCl_2$$

$$GeX_4 + Ge \xrightarrow{\Delta} \underset{\substack{\text{(strong}\\ \text{reducing agent)}}}{2GeX_2}$$

$$SnCl_4 + Sn \xrightarrow{\Delta} \underset{\text{anhydrous}}{2SnCl_2}$$

($SnCl_2$ on reaction with weak alkali followed by dehydration in the absence of air, gives SnO).

$$Pb(NO_3)_2 + 2HF \longrightarrow \underset{\text{ppt.}}{PbF_2\downarrow} + 2HNO_3$$

The stability of dihalides increases on moving down the group. Thus, $PbCl_2 > PbCl_4$ (stability)

Lead dihalides are sparingly soluble in cold water that's why these are obtained differently from other dihalides.

Some trihalides of C, Si and Ge are also known, *e.g.,* $CHCl_3$, $SiHCl_3$, $GeHCl_3$. Lead and tin do not form such compounds.

Sample **Problem 9** *Consider the following statements*

I. *Lead (II) chloride reacts with* Cl_2 *to give* $PbCl_4$
II. *Lead (IV) chloride is highly unstable towards heat*
III. PbI_4 *exists.*

The incorrect statement(s) is/are **[NCERT]**

(a) *II and III only*
(b) *III only*
(c) *I and III only*
(d) *I and II only*

Interpret (c)

(i) Due to inert pair effect, Pb is more stable in +2 state than in +4 oxidation state. Therefore, lead (II) chloride does not react with Cl_2 to give lead (IV) chloride.

(ii) Lead (IV) chloride on heating decomposes to give lead (II) chloride and Cl_2 because lead in +2 oxidation state is more stable than in +4 oxidation state.

$$PbCl_4(l) \longrightarrow PbCl_2(s) + Cl_2(g)$$

(iii) Due to strong oxidising power of Pb^{4+} ion and reducing power of I^- ion, PbI_4 does not exist.

(e) Oxides

14th group elements form two types of oxides, namely, **monoxides** of formula MO, *e.g.,* CO, SiO, GeO, SnO and PbO and **dioxides** of formula MO_2, *e.g.,* CO_2, SiO_2, GeO_2, SnO_2 and PbO_2. The dioxides of Ge and Sn are amphoteric while that of Pb are weakly basic, thus, acidic character of dioxides decreases and basic character increases while moving down the group. *Lead also forms* Pb_3O_4 *which infact is a mixed oxide of* PbO *and* PbO_2 *i.e.,* $2PbO \cdot PbO_2$.

Among monoxide CO is neutral, GeO is acidic, SnO and PbO are amphoteric.

CO_2 is a gas and SiO_2 is a hard solid with a very high melting point. It is due to the fact that smaller atom of C (radius 0.77 Å) does not permit the oxygen to combine with another C-atom while fairly large atom of silica (1.17 Å) permits the sharing of single oxygen atom between two Si atoms as shown below

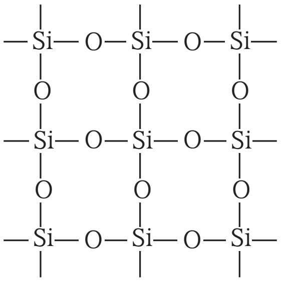


Fig. 11.13 Structure of SiO_2

11.7 Unique Behaviour of Carbon

The size of carbon is smallest among the group but it has high electronegativity and ionisation enthalpy. Moreover, in it, d-orbitals are also not present. Due to these reasons, its properties are quite different from other members of the group.

Some such properties are

(i) The melting and boiling points of carbon are very high as compared to other members of the group.

(ii) It has maximum tendency of catenation.

(iii) It has a high tendency of formation of $p\pi$ - $p\pi$ multiple bonds either with its own atoms (*e.g.,* $C{=}C$, $C{\equiv}C$) or with other atoms such as O, N, S (*e.g.,* $C{=}O, C{\equiv}N, C{=}S$ etc.) while other members do not have this tendency as their atomic orbitals are too large. (Other members have a tendency of $d\pi$ - $p\pi$ bonding.)

(iv) Maximum covalency of carbon is four while other members can expand their covalency upto 6.

(v) Carbon remains unaffected by alkalies while other members reacts with alkali as

$$Si + 2NaOH + \frac{1}{2}O_2 \longrightarrow \underset{\text{sodium silicate}}{Na_2SiO_3} + H_2$$

Similarities with Si

In the following characteristics carbon exhibits resemblence with silicon.

(i) Carbon is the essential constituent of the animal and vegetable kingdom (organic); silicon is the essential constituent of the mineral kingdom (inorganic) entering into the composition of all rocks, mountains, river beds, etc.

(ii) Both of these elements, as seen earlier, possess an electronic configuration ending with ns^2, np^2 grouping and show a tetracovalence.

(iii) They are both typical non-metals and form oxides, hydrides, etc. The higher oxides of both these elements are acidic in nature.

(iv) Carbon and silicon atoms possess a remarkable property of joining with one another in large numbers forming the long chains and rings.

(v) There is a marked similarity between the compounds for carbon and silicon as shown in the table given below

Table 11.7 **Similarity between the Compounds of C and Si**

	Compounds	Carbon	Silicon
(i)	Dioxides	CO_2, acidic formed by burning carbon in air of oxygen.	SiO_2, acidic, formed by burning silicon in air or oxygen
(ii)	Acids	H_2CO_3 (carbonic acid), $(COOH)_2$ (oxalic acid)	H_2SiO_3 (*meta*-silicic acid) $(SiOOH)_2$ (silico-oxalic acid)
(iii)	Hydrides	CH_4 methane C_2H_6 ethane	SiH_4 silico-methane Si_2H_6 Silico-ethane
(iv)	Halides	CCl_4, CI_4	$SiCl_4$, SiI_4
(v)	Other compounds	$CHCl_3$ (chloroform) $CHBr_3, CHI_3$, etc.	$SiHCl_3$ (silico-chloroform) $SiHBr_2, SiHI_3$, etc.

Points of Difference with Si

In spite of the similarity of formulae, the elements and their compounds show important dissimilarities which are as follows.

(i) Carbon dioxide is a gas while silica is a hard solid

(ii) Carbon tetrachloride and chloroform are stable liquids while the corresponding compounds of silicon are not so stable and are easily hydrolysed.

(iii) Similar is the case with the hydrides; those of carbon, *e.g.*, $CH_4C_2H_6$ are very stable while those of silicon, *e.g.*, SiH_4 are easily decomposed by the common reagents, *e.g.*, alkalies, silver nitrate, etc.

(iv) Oxalic acid, $(COOH)_2$ is much more stable than silico-oxalic acid $(SiOOH)_2$.

(v) The maximum covalence of carbon is four while that of silicon is six. Whereas carbon does not melt at all, silicon does melt at high temperature.

(vi) Silicon is a bad conductor of electricity while some varieties of carbon are good conductors.

Allotropes of Carbon

Carbon shows allotropism due to the property of catenation and $p\pi$- $p\pi$ bond formation. It exists in two allotropic forms.

11.8 Crystalline Forms of Carbon

These allotropes have well defined crystal structures. Diamond, graphite and fullerens are crystalline forms of carbon.

(a) Diamond

It is the purest form of carbon and hardest substance known with very high refractive index (2.417) and a very high density (3.15 g/cm^2 at 25°C). It is transparent to X-rays. It is a three dimensional giant molecule of carbon in which C-atoms (sp^3-hybridised) are arranged tetrahedrally by utilising their sp^3 hybrid orbitals. The C—C bond distance is 1.54 Å. Each C-atom seemes to lie at the centre of a regular tetrahedron and is linked to four surrounding C-atoms lying at the corners of the tetrahedron through strong covalent bonds as shown in the figure below.

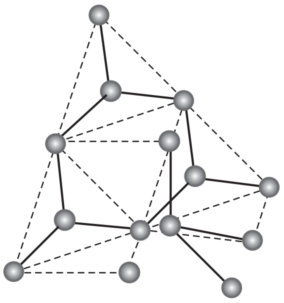

Fig. 11.14 Structure of diamond

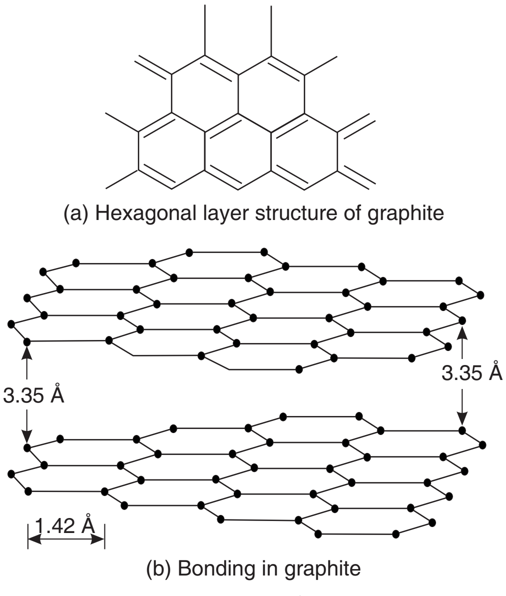
Due to high strength of covalent bonds holding numerous C-atoms together, diamond is very hard and have high density. Since breaking of diamond requires breaking of strong covalent bonds, the melting point of C is unusually high (highest in the Periodic Table) being close to 3500°C. It is a bad conductor of electricity but a very good conductor of heat. Lattice vibrations are responsible for the high thermal conductivity of diamond.

Diamond is used as a gem stone on account of reflection and refraction of light. Impure diamonds (black) are used in knives for cutting glass and rock borers.

(b) Graphite

Unlike diamond, graphite, has a two dimensional structure. In this case, only 3 of the 4 valence electrons of C participate in bonding. Thus, hybridisation is sp^2 having 3 covalent bonds with 3 other C-atoms in the same plane. The 4th electron of C does not participate in the bonding, remains free and is responsible for electrical conductivity of graphite. In fact, the structure of graphite is two dimensional, sheet like consisting a number of hexagonal rings fused together as shown in the figure below



(a) Hexagonal layer structure of graphite

(b) Bonding in graphite

Fig. 11.15 Structure of graphite

The sheet or layers are held together by relatively weak van der Waals' forces. The C—C bond distance is 1.42 Å. The distance between two successive layers is 3.36 Å. This structure is less compact than that of diamond and since the bonding between layers involve only the van der Waals' forces (weak forces) hence, these layers can slide over each other. This gives softness, greasiness and lubricating character to graphite.

Graphite is thermodynamically more stable than diamond and its free energy of formation is 1.9 kJ less than diamond.

$$\text{Graphite} \xrightarrow[\text{50000–60000 atm.}]{1600^\circ\text{C}} \text{Diamond}$$

When graphite is heated with vapours of K, Rb, Cs at 300°C, it forms C_8M. Graphite is diamagnetic but C_8M is paramagnetic.

Uses

Graphite is used

(i) for lining and marking electrodes of electric furnaces.
(ii) in making refractory crucibles.
(iii) in making lead pencils.
(iv) as a moderator in nuclear reactor.
(v) as a lubricant in machinery.

(c) Fullerene

These are the recently discovered allotropes of carbon and called fullerene (or Buckminster fullerenes) due to their resemblance (in structure) with geodesic domes, designed and built by the American architect Robert Buckminster Fuller. *The credit of the discovery of fullerenes goes to HW kroto, RF curl and RE smalley.* Fullerenes are large cage like spheroidal molecules with general formula C_{2n} (where $n \geq 30$). Two important member are C_{60} and C_{70}. C_{60} fullerene looks like a soccer ball (so called bucky ball) and contains 20 six membered and 12 five membered rings of carbon atoms. Six membered rings are fused with both six membered as well as five membered rings while five membered rings are attached only with six membered rings. Each carbon atom in the structure, form three σ bonds with other three carbon atoms and the fourth electron remains free. These free electrons delocalise and provide some aromatic character to the molecule. C_{70}, On the other hand, have rugby ball like structure. It consists of 12 five membered and 25 six membered rings.

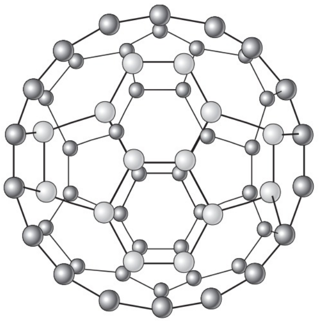


Fig. 11.16 Structure of C_{60}, Buckminster fullerene

Fullerene are prepared from graphite as

$$\text{Graphite} \xrightarrow[\text{He or Ar}]{\text{Electric arc}} \text{vaporised C} \xrightarrow{\text{Condense}} \text{fullerene}$$

soot (C_{60} mainly + C_{70} little)

Fullerenes act as wonderful lubricants and the alkali compounds of C_{60} are used as super conducting substance at the temperature range of 10-40 K.

Microcrystalline Forms

Coke, coal, charcoal, lamp black, gas carbon etc., belong to this category.

(a) Coal

It is formed by the slow carbonisation of vegetable matter buried underneath the earth centuries ago, in limited supply of air under high temperature and pressure. Peat (60% C), lignite (70% C), bituminous (78% C) and anthracite (90% C) are different varities of coal. Out of these, bituminous is the most common and anthracite is purest variety.

(b) Coke

It is a greyish black hard solid and is obtained by destructive distillation of coal.

(c) Charcoal

Depending upon the source from which it is obtained, charcoal can be animal charcoal, wood charcoal, sugar charcoal, and activated charcoal. Wood charcoal adsorbs colouring matter and odoriferous gases, thus used in decolourising sugar solutions and in gas masks.

(d) Lamp Black or Carbon Black

It is the most pure amorphous form, contains about 98-99% carbon. Lamp black is used for making printer ink, black paint, varnishes and carbon papers.

(e) Gas Carbon

It is scraped from the walls of retort used for destructive distillation of coal.

The physical characteristics of the various forms of carbon are summarised below

Table 11.8 **Physical Properties of Allotropes of Carbon**

S. No.		Crystalline forms			Microcrystalline forms			
	Property	Diamond	Graphite	Fullerene	Coal	Charcoal	Animal charcoal	Lamp black
1.	**Colour**	Colourless transparent	Grey	—	Black	Black	Black	Black
2.	**Carbon content**	100%	95–97%	—	60-90%	68-85%	8-10%	98-99%
3.	**Density** (g cm^{-3})	3.51	2.25	—	—	1.4-1.7	—	—
4.	**Hardness**	Hardest substance	Soft marks the paper	Medium	Hard mass	Soft	Soft	Soft
5.	**Electrical Conductivity**	Bad conductor	Good conductor	Good conductor	Bad conductor	Bad conductor	Bad conductor	Bad conductor

Check Point 3

1. Explain, why silicon shows a higher covalency than carbon?
2. Graphite is a conductor of electricity but diamond is not. Explain.
3. The tendency of catenation decreases down the 14 group. Explain, why?
4. Sn(II) is a reducing agent whereas Pb(II) is not. Explain.

11.9 Oxides of Carbon

Carbon forms two oxides. Carbon monoxide and carbon dioxide, which are described ahead.

Carbon Monoxide, CO

It is found in small amounts in volcanic gases, chimney gases, exhaust gases of internal combustion engines and coal gas.

Methods of Preparation

Carbon monoxide is obtained by burning C in limited supply of oxygen. Pure CO can be obtained by heating HCOOH with H_2SO_4 where, H_2SO_4 acts as dehydrating agent.

It is also prepared by

1. By heating carbonates of Ca, Ba or Mg with Zn

$$MgCO_3 + Zn \longrightarrow MgO + ZnO + CO$$

2. By heating potassium ferrocyanide with conc. H_2SO_4.

$$\begin{aligned}
K_4Fe(CN)_6 + 3H_2SO_4 &\longrightarrow 2K_2SO_4 + FeSO_4 + 6HCN \\
6HCN + 12H_2O &\longrightarrow \underset{\text{formic acid}}{6HCOOH} + 6NH_3 \\
6NH_3 + 3H_2SO_4 &\longrightarrow 3(NH_4)_2SO_4 \\
6HCOOH &\xrightarrow{H_2SO_4} 6CO + 6H_2O \\
\hline
K_4Fe(CN)_6 + 6H_2SO_4 + 6H_2O &\longrightarrow 2K_2SO_4 + FeSO_4 + 6CO \\
&\qquad + 3(NH_4)_2SO_4
\end{aligned}$$

Manufacture Carbon monoxide is obtained in the form of water gas and producer gas when air (moist) is passed over a bed of white hot coke. The following reactions may occur.

$$\begin{aligned}
2C + O_2 &\longrightarrow 2CO_2 \\
C + O_2 &\longrightarrow CO_2 \\
C + H_2O &\longrightarrow \underbrace{CO + H_2}_{\text{water gas}}
\end{aligned}$$

Carbon dioxide is reduced by passing the mixture over heated charcoal.

$$CO_2 + C \longrightarrow 2CO$$

The CO produced, always consists of N_2, H_2, CO_2, etc.

Properties

1. It is a colourless and odourless gas.
2. It is slightly soluble in water.
3. Its density is nearly equal to the density of air.
4. It is highly poisonous in nature. One part in 100 parts of air causes death in few minutes. *The poisonous nature of* CO *is due to the fact that it combines with haemoglobin (a red colouring matter of blood which is carrier of oxygen) to form carboxy-haemoglobin which is not capable to absorb oxygen and as a result of this, suffocation takes place.*
5. It is an essential constituent of gaseous fuels like water gas, producer gas etc.
6. CO is highly combustible gas and produces CO_2 on combustion, alongwith a large amount of heat.

$$CO + \frac{1}{2}O_2 \longrightarrow CO_2 + \text{heat}$$

7. It is a good reducing agent and reduces metal oxides to metals as

$$Fe_2O_3 + 3CO \xrightarrow{823\ K} 2Fe + 3CO_2$$

8. It gives phosgene when reacts with Cl_2 in sunlight.
9. It forms metal carbonyls with transition metals like Ni, Fe, Co, etc.

Uses

It is used

1. as industrial fuels, as water gas and producer gas
2. as reducing agent in many metallurgical processes.
3. in the purification of Ni by Mond's process.

Structure

The structure of CO can be represented as

$$C \underset{\leftarrow}{=} O$$

Two pairs of electrons are considered to be shared between carbon and oxygen. Oxygen also donates a lone pair to carbon resulting to a co-ordinate bond. The properties of CO can be explained satisfactorily if we consider CO as the resonance hybrid of following three structures.

$$C{=}\overset{..}{\underset{..}{O}} \longleftrightarrow \overset{-}{C}{\equiv}\overset{+}{O}\!: \longleftrightarrow :\!\overset{+}{C}{-}\overset{..}{\underset{..}{O}}\!:^{-}$$

Carbon Dioxide, CO_2

CO_2 is present in atmosphere to the extent of 0.03–0.05 per cent. It comes to the atmosphere from animal breathing, decay of vegetable matter, burning of carbon and carbonous matter, etc. It is also utilised by plants in photosynthesis. Thus, a carbon dioxide cycle is operating in nature and the proportion of CO_2 in the atmosphere remains about the same. It is found in combined state in the form of carbonates.

Methods of Preparation

CO_2 is obtained by burning C in air (excess). In laboratory, it can be prepared by the action of cold dilute HCl on $CaCO_3$ (marble).

Properties

1. CO_2 is colourless gas with a faint pungent smell and slight acidic taste. It dissolves in water forming H_2CO_3 as

   $$CO_2 + H_2O \rightleftharpoons H_2CO_3$$

   H_2CO_3 is a weak acid and dissolves in alkalies to form salts as

   $$H_2CO_3 + 2NaOH \longrightarrow Na_2CO_3 + 2H_2O$$

2. It turns lime water milky which disappears, if CO_2 is passed for a long time due to the formation of soluble calcium bicarbonate.
3. It reacts with liquid NH_3 at 473 K and 220 atm, and gives ammonium carbonate which subsequently decomposes to give urea.
4. **Solid CO_2 is commonly called "dry ice".** It is a soft white snow like compound with specific gravity 1.53 and m.p. −56.6°C at 5.2 atm pressure. It is produced by evaporating liquid CO_2 at 20°C and 70 atm pressure to a pressure less than 5.2 atm.

Uses

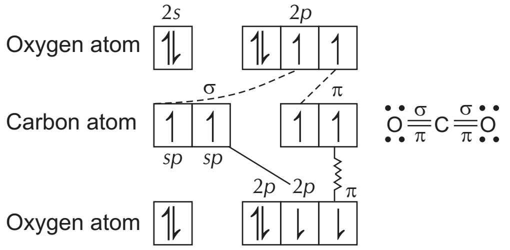
1. It is used as a refrigerant under the commercial name **Drikold.**
2. It is also used as a substitute of ice in cold drinks and in ice cream preparation.
3. In hospitals, it is used for surgical operations of sores.
4. Carbogen (a mixture of 95% O_2 and 5% CO_2) is used for artifical respiration.
5. CO_2 is also used as a fire extinguisher.

Structure

Structure of CO_2 is considered as resonance hybrid of following three structures

$$O{=}C{=}O \longleftrightarrow \overset{-}{O}{-}C{\equiv}\overset{+}{O} \longleftrightarrow \overset{+}{O}{\equiv}C{-}\overset{-}{O}$$

The formation of the molecule can be explained on the basis of hybridisation. Carbon is *sp*-hybridised. The hybrid orbitals form sigma bonds with *p*-orbitals of each oxygen atoms. The unhybridised two *p*-orbitals of carbon atom form two π-bonds with two oxygen atoms.



11.10 Compounds of Silicon

Silicon forms several compounds, some important of these are

1. Silicon Tetrachloride

Its chemical formula is $SiCl_4$.

Methods of Preparation

$SiCl_4$ is prepared by heating Si or SiC with Cl_2.

$$Si(s) + 2Cl_2(g) \xrightarrow{\Delta} SiCl_4(l)$$

$$SiC(s) + 4Cl_2(g) \xrightarrow{\Delta} SiCl_4(l) + CCl_4(l)$$

Properties and Uses

1. It is a volatile liquid with boiling point 330.57 K.
2. On hydrolysis, it gives silicic acid $Si(OH)_4$ which on further heating form silica gel.

$$\underset{}{SiCl_4 + 2H_2O} \xrightarrow{\Delta} \underset{\text{silicic acid}}{Si(OH)_4} \xrightarrow{\Delta} \underset{\text{silica gel}}{SiO_2 \cdot xH_2O}$$

(Silica gel being very porous is used as a catalyst in petroleum industry and as an adsorbent in column chromatography).

3. On reduction, it gets converted into Si. The silicon so obtained is ultrapure and is used for making transistors, computer chips and solar cells.

2. Silica

SiO_2 is commonly called as silica. It occurs in earth's crust as crystalline quartz, tridymite and crystabollite. Amorphous veriety flint is also found.

Methods of Preparation

1. It is obtained by heating silicon in oxygen as

$$Si + O_2 \longrightarrow SiO_2$$

2. Pure SiO_2 is prepared in its amorphous forms as a white powder by reacting $SiCl_4$ or SiF_4 with water as

$$SiCl_4 + 2H_2O \longrightarrow SiO_2 + 4HCl$$
$$SiF_4 + 2H_2O \longrightarrow SiO_2 + 4HF$$

The latter method is normally less used as SiO_2 further reacts with HF to form H_2SiF_6 (fluorosilicic acid).

Properties

1. SiO_2 is insoluble in water and in all acids except HF with which it reacts to form SiF_4 as

$$SiO_2 + 4HF \longrightarrow SiF_4 + 2H_2O$$

If we take HF in excess, SiF_4 further reacts with it to form fluorosilicic acid as

$$SiF_4 + 2HF \longrightarrow H_2SiF_6$$

2. SiO_2 *melts in oxyhydrogen flame above* 1875 *K to colourless glass, called quartz glass.* It has remarkably low coefficient of expansion. Red hot quartz when plunged into water does not shatter to pieces. Owing to this property quartz glass is used for the manufacture of chemical apparatus and optical instruments. It specific gravity is 2.65.
3. Three crystalline modification of SiO_2 are **quartz, cristobalite** and **tridymite** of which quartz and cristobalite are important. quartz is used as a **piezoelectric material** (crystal oscillators and transducers). The specific gravity of cristobalite is 2.25 while that of tridymite is 2.32.
4. SiO_2 is acidic and dissolves in hot conc. alkalies to form sodium silicate as

$$SiO_2 + 2NaOH \longrightarrow Na_2SiO_3 + H_2O$$

5. It acts as a powerful acid anhydride and combines with bases and many metallic oxides to form silicates as,

$$SiO_2 + Na_2O \longrightarrow Na_2SiO_3$$
$$SiO_2 + CaO \longrightarrow CaSiO_3$$

6. It also reacts with carbonates of many metals at high temperatures forming silicates with liberation of CO_2 as

$$SiO_2 + Na_2CO_3 \longrightarrow Na_2SiO_3 + CO_2$$
$$SiO_2 + CaCO_3 \longrightarrow CaSiO_3 + CO_2$$

7. When heated with carbon in an electric furnace, it is reduced to **carborundum** or **silicon carbide** as

$$SiO_2 + 3C \longrightarrow SiC + 2CO$$

Uses

It is used

1. as an adsorbent in column chromatography.
2. as a catalyst in petroleum industry.
3. on mixing with $(NH_4)_2CoCl_4$, as a humidity detector.
4. as Kieselguhr, in filtration plants and as an inert support or filler.

3. Silicates

Silicates are minerals of silicon and occur in earth's crust in the form of numerous silicate minerals and clays. Mica, asbestos, cement, bricks, tiles, porcelains, glass, pottery etc., are made from silicates. All silicates involve Si—O bonds of two types

(i) Terminal Si—O bonds in which oxygen is bonded to a silicon and not other atom.
(ii) Bridging Si—O—Si bonds in which oxygen is bonded to two silicon atoms.

The basic building unit of all silicates is the tetrahedral SiO_4^{4-} ion. The three dimensional tetrahedral structure is represented by a planar structure for convenience

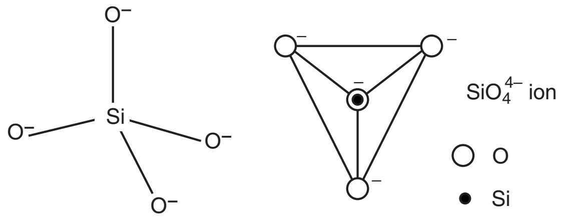


Fig. 11.17 Structure of SiO_4^{4-} ion

Generally the silicates have complex structures but they mainly differ in

1. number of oxygen atoms shared between SiO_4^{4-} tetrahedron.
2. geometric arrangement of tetrahedron.
3. the number, type and arrangement of metallic cations.

On the basis of the way, the SiO_4^{4-} *tetrahedral units are linked together, the silicates minerals are classified into following types*

(a) Orthosilicates

They contain discrete SiO_4^{4-} units in which oxygen atoms are found to associate only with metal ions *e.g.,* **zircon** ($ZrSiO_4$), **wellimite** (Zn_2SiO_4) and **phenacite** (Be_2SiO_4).

(b) Pyrosilicates

Two SiO_4^{4-} tetrahedrons share a corner oxygen atom. They contain $[Si_2O_7]^{6-}$ ions as discrete units. These are also called **island structures.** These silicates are not very common.

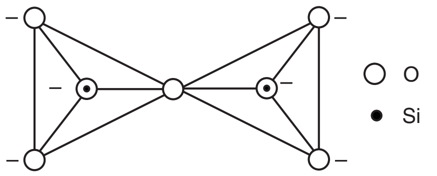

Fig. 11.18 $Si_2O_7^{6-}$ (Anion of pyrosilicate)

e.g., **thorteveitite** ($Sc_2Si_2O_7$) and **hemimorphite** $[Zn_4(OH)_2Si_2O_7]$.

(c) Cyclic Silicates

Two oxygen atoms of each tetrahedron are shared to form a ring with general formula $[SiO_3]_n^{2n-}$. The ring may be

(i) Three membered ring in which discrete units are $[Si_3O_9]^{6-}$ *e.g.,* **wollastonite** $Ca_3Si_3O_9$, **bentonite** $BaTi[Si_3O_9]$.

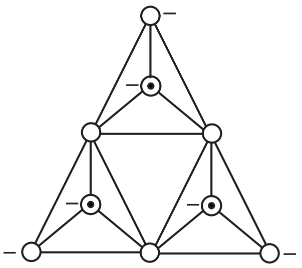

Fig. 11.19 $Si_3O_9^{6-}$ ion (Anion of three membered cyclic silicate)

(ii) Six membered ring in which discrete units are $[Si_6O_{18}]^{12-}$ *e.g.,* **beryl** ($Be_3Al_2Si_6O_8$)

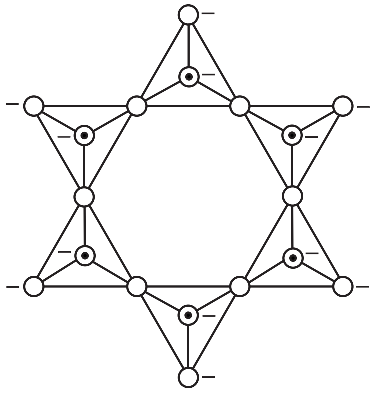

Fig. 11.20 $Si_6O_{18}^{12-}$ ion (Anion of six membered cyclic silicates)

(d) Chain Silicates

Two oxygen atoms per tetrahedron are shared to form an extensively long chain. The primary units is $[SiO_3]^{2-}$ and the simple formula is $[SiO_3]_n^{2n-}$. Two types of chain silicates may be formed.

(i) **Single chain silicates,** in which $[SiO_3]_2^{4-}$ combine to form a chain like polymer, these are also called pyroxenes, *e.g.,* **diopside** $[CaMg(SiO_3)_2]$.

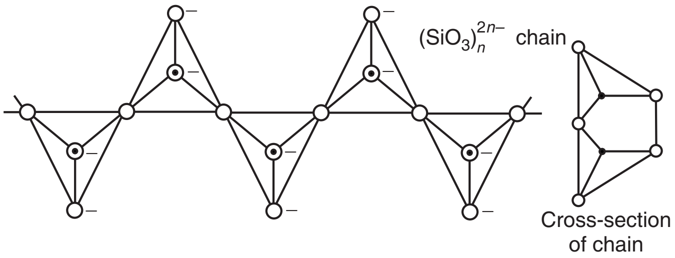

Fig. 11.21 Single chain silicates

(ii) **Double chain silicates,** in which $[Si_4O_{11}]^{6-}$ are primary units. Two simple chains are joined together through the third oxygen atom of SiO_4 tetrahedra. These structures are known as **amphiboles**. Some tetrahedra share three oxygen *e.g.,* **termolite** $Ca_2Mg_5(Si_4O_{11})_2(OH)_2$, **asbestos** $CaMg_3O(Si_4O_{11})$.

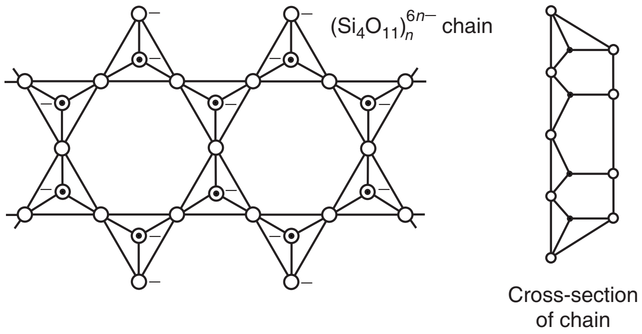

Fig. 11.22 Double chain silicates

(e) Sheet Silicates

Three oxygen atoms per tetrahedron are shared to form an infinite plane sheet, containing $[Si_2O_5]_n^{2n-}$. *e.g.,* **kaolinite** $[Al(OH)_4Si_2O_5]$, talc $[Mg_3(OH)_2(Si_2O_5)_2]$.

Mica minerals too belong to this category and have a variety of compositions.

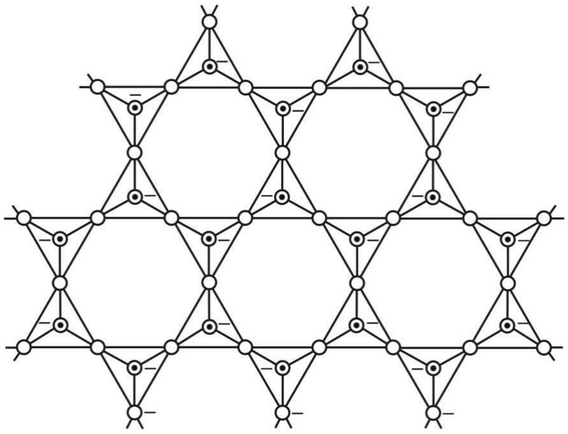

Fig. 11.23 $(Si_2O_5)_n^{2n-}$ sheet

(f) Three Dimensional Silicates

All the four oxygen atoms are shared in each tetrahedron to form an infinite three dimensional structure. Each oxygen atom is bonded to two silicon atoms. Each silicon atom (sp^3 hybridised) is surrounded tetrahedrally by four oxygen atoms and each oxygen atom is linked covalently to two silicon atoms. Various forms of silica occur in three dimensional silicate structure, have general formula $(SiO_3)_n^{2n-}$. These silicates are neutral.

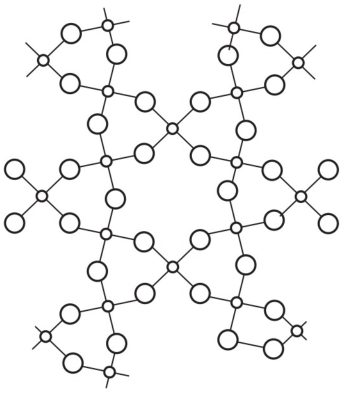

Fig. 11.24 Three dimensional structure of silica

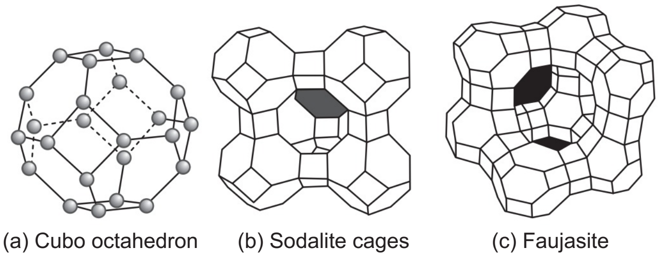
Zeolites

These are microporous aluminosilicate having general formula $M_{x/n}[AlO_2]_x[SiO_2]_y \cdot mH_2O$. Aluminosilicates are obtained by substituting some of the silicon atoms in a three dimensional network silicate by Al^{3+} ions. The negative charge carried by aluminosilicate framework is neutralised by exchangeable cations of valence n, while m water molecules fill the voids. The **cubo** octahedron shown in figure (a) is the building block of zeolites and also called the **sodalite cage.** The sodalite cages are linked to each other through four membered rings to produce two or three dimensional network of inter connected channels and cavities. As a consequence of such packing, the zeolites are highly porous. When sodalite cages are linked through double six-membered rings, Faujasite is obtained.



(a) Cubo octahedron (b) Sodalite cages (c) Faujasite

Fig. 11.25 The three dimensional structure of zeolites

Uses

Zeolites are used as molecular seives and can separate molecules of different sizes. They are also used extensively as catalyst due to their porous structure.

Hot Spot 4

SILICONES

It is again an important topic for JEE Main examination. The questions are generally based on "the preparation of silicones." The level of question is average.

Silicones are organo-silicon polymers containing ...... O–Si–O ...... linkages. These may be linear silicones, cyclic silicones and cross-linked silicones.

Preparation

These are prepared by the hydrolysis of alkyl or aryl derivatives of $SiCl_4$ like $RSiCl_3$, R_2SiCl_2 and R_3SiCl followed by polymerisation of obtained product. Thus, this method consists of the following steps

Step I **To prepare alkyl or aryl derivatives of silicon tetrachloride.** Examples of such derivatives are $RSiCl_3$, R_2SiCl_2 and R_3SiCl where R is an alkyl (*e.g.,* CH_3, C_2H_5 etc.,) or aryl (*e.g.,* C_6H_5) group. These derivatives are prepared by the following methods

1. **Methyl chlorosilanes** [like $(CH_3)SiCl_3$, $(CH_3)_2SiCl_2$ and $(CH_3)_3SiCl$] are prepared by heating methyl chloride, CH_3Cl with Si, catalysed by Cu, at 300°C. This reaction gives a mixture of methyl chlorosilanes.

$$2CH_3Cl + Si \xrightarrow[300°C]{Cu} (CH_3)\underbrace{SiCl_3 + (CH_3)_2SiCl_2 + (CH_3)_3SiCl}_{\substack{\text{Mixture of methyl chlorosilanes}\\ \text{+ other compounds}}}$$

2. Alkyl chlorosilanes can also be obtained by the action of Grignard reagent on $SiCl_4$.

$$RMgCl\text{ (Grignard reagent)} + SiCl_4 \longrightarrow RSiCl_3 + MgCl_2$$
$$2RMgCl + SiCl_4 \longrightarrow R_2SiCl_2 + 2MgCl_2$$
$$3RMgCl + SiCl_4 \longrightarrow R_3SiCl + 3MgCl_2$$

3. Phenyl chlorosilane, $(C_6H_5)SiCl_3$ is obtained by heating C_6H_6 with $HSiCl_3$ at 230-300°C in the presence of a catalyst like BF_3, BCl_3 or $AlCl_3$.

$$C_6H_6 + HSiCl_3 \xrightarrow[\text{Catalyst}]{\Delta} (C_6H_5)SiCl_3 + H_2$$

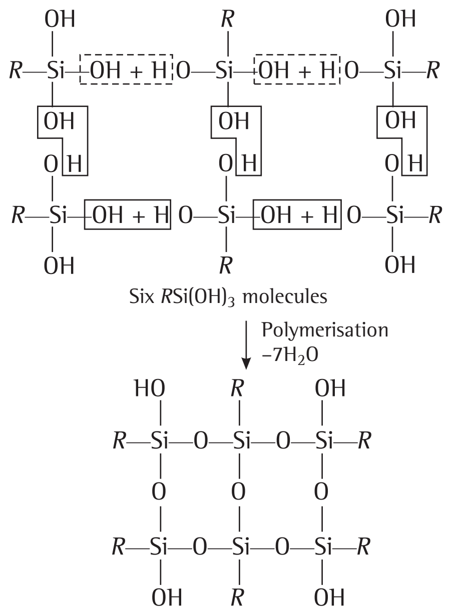
Step II **To prepare alkyl or aryl hydroxy derivatives of silicon tetrachloride** (called silanols or silandiols) These silanols are obtained by the hydrolysis of $RSiCl_3$, R_2SiCl_2 and R_3SiCl respectively, *e.g.*,

$$RSiCl_3 + 3H\cdot OH \xrightarrow{\text{Hydrolysis}} RSi(OH)_3 + 3HCl$$

$$R_2SiCl_2 + 2H\cdot OH \xrightarrow{\text{Hydrolysis}} R_2Si(OH)_2 + 2HCl$$

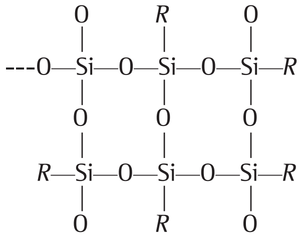
Step III **To allow the alkyl or aryl hydroxy derivatives to undergo polymerisation** The type of silicon obtained depends on the nature of alkyl or aryl hydroxy derivative and the way in which the hydroxy derivative undergoes polymerisation. For example

1. When many molecules of alkyl trihydroxy silane, $RSi(OH)_3$ undergoes polymerisation, a cross-linked two dimensional silicone is obtained as



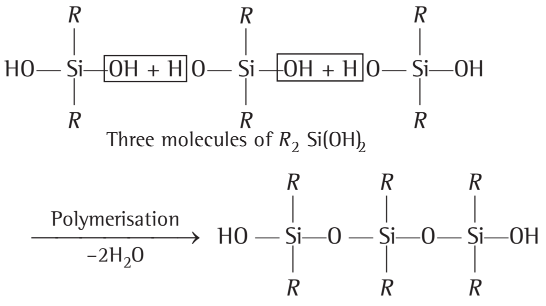
Six $RSi(OH)_3$ molecules

Since, an active OH group is present at each end of the chain, polymerisation continues on both the ends and hence, the length of the chain increases. The increase in the length of the chain produce cross-linked silicone as shown below



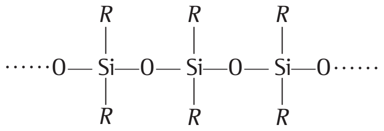
Two dimensional cross-linked silicone

2. When many molecules of dialkyldihydroxysilane, $R_2Si(OH)_2$ undergo polymerisation, a straight chain (linear) or cyclic (ring) silicone is obtained.



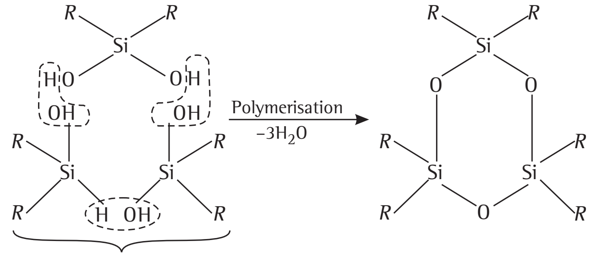
Three molecules of $R_2Si(OH)_2$

Since an active OH group is present at each end of the chain, polymerisation continues and hence, the length of the chain increases and gives rise to the formation of long chain silicon, as shown below



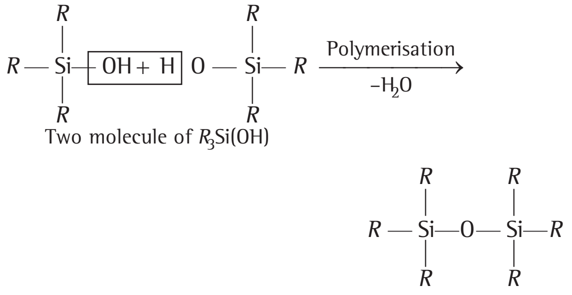
$$\cdots\cdots O-\overset{R}{\underset{R}{Si}}-O-\overset{R}{\underset{R}{Si}}-O-\overset{R}{\underset{R}{Si}}-O\cdots\cdots$$

Linear or straight chain silicone (thermoplastic polymer)



Three molecules of $R_2Si(OH)_2$ **cyclic trimer**

3. When two molecules of trialkyl monohydroxysilane, $R_3Si(OH)$ undergo polymerisation, a straight chain silicon (dimer) is obtained.



Two molecule of $R_3Si(OH)$

straight chain silicon, $R_3Si–O–SiR_3$ (dimer)
(It is a siloxane)

Properties and Uses

Important properties and uses of silicones are as follows

1. They have high **thermal stability** in the absence of air and withstand temperature up to 250–300°C.
2. They remain unaffected by most of the chemical reagents, such as weak acids, alkalies and salt solution. Thus, **silicones are chemically inert.**
3. Many of low molecular weight silicones dissolve in solvents like C_6H_6, ether and CCl_4.
4. They do not become too viscous on cooling and are, therefore, used for low temperature lubrication.
5. They are water repellent, ***i.e.,*** they are not wetted by water and are, therefore, used in making waterproof cloth and paper by exposing cloth or paper to the silicone vapours.
6. **All silicones have good insulating properties and can with stand high temperature without charring.** It is due to these properties that silicones are used as insulating materials for electric motors and other electric appliances.
7. They are non-toxic.

Sample **Problem 10** *Silicon has a strong tendency to form polymers like silicones. The chain length of silicone polymer can be controlled by adding* **[NCERT Exemplar]**

(*a*) $MeSiCl_3$
(*b*) Me_2SiCl_2
(*c*) Me_3SiCl
(*d*) Me_4Si

Interpret (*c*) The product obtained by the hydrolysis of Me_3SiCl contains only one —OH group which when subjected to polymerisation makes the polymer incapable for further polymerisation, thus, controls the chain length.

Check Point 4

1. CO_2 is a gas while SiO_2 is a solid. Explain.
2. Why are zeolites used as catalyst?
3. Why carbon monoxide is a poisonous gas?
4. Solid CO_2 is also called dry ice, why?
5. Silicon are used as insulating materials. Give reason.

WORKED **OUT**

Examples

Example 1 *In the following reaction sequence,*

$$\text{Metal }(A) + N_2 \xrightarrow{\Delta} (B) \xrightarrow{-H_2O} (C) + (D)$$

white ppt (C) is formed and gas (D) is evolved. White ppt (C) dissolves in NaOH *solution, while gas (D) gives white fumes in* HCl. *Metal A is*

(a) B
(b) Al
(c) Ga
(d) C

Solution (b) $\underset{(A)}{2Al} + N_2 \longrightarrow \underset{(B)}{2AlN}$

$$AlN + 3H_2O \longrightarrow \underset{(C)}{Al(OH)_3} + \underset{(D)}{NH_3}$$

Example 2 *A certain salt (X) gives the following tests :*

(i) *Its aqueous solution is alkaline to litmus.*
(ii) *On strong heating, it swells to give a glassy bead.*
(iii) *When concentrated sulphuric acid is added to a hot concentrated solution of (X), white crystal of Z separate out. The salt (Z) is* **[NCERT]**

(a) H_3BO_3
(b) $Na_2B_4O_7$
(c) $NaBO_2$
(d) B_2O_3

Solution (a) (X) is borax, $Na_2B_4O_7 \cdot 10H_2O$ as its aqueous solution is weakly alkaline, it gives a glassy bead on strong heating. The reactions are as follows :

(i) $Na_2B_4O_7 + 7H_2O \rightleftharpoons \underset{\text{strong}}{2NaOH} + \underset{\text{weak}}{4H_3BO_3}$

Due to the presence of a strong base (NaOH), the aqueous solution is alkaline to litmus.

(ii) $Na_2B_4O_7 \cdot 10H_2O \xrightarrow[\text{swells}]{\Delta} Na_2B_4O_7 + 10H_2O$

$$\longrightarrow 2NaBO_2 + \underset{\text{glassy bead}}{B_2O_3}$$

(iii) $Na_2B_4O_7 + H_2SO_4 + 5H_2O \longrightarrow Na_2SO_4 + \underset{Z}{4H_3BO_3}$

Example 3 *Compound X on reduction with* $LiAlH_4$ *gives a hydride (Y) containing 21.72% hydrogen along with other products. The compound (Y) reacts with air explosively resulting in boron trioxide. Compound X and Y are respectively.*

(a) $BCl_3 \cdot B_2H_6$
(b) $B_2H_6 \cdot BCl_3$
(c) $BF_3 \cdot Al_2O_6$
(d) $B_2H_6 \cdot BF_3$

Solution (a) $\underset{(X)}{4BCl_3} + 3LiAlH_4 \longrightarrow \underset{(Y)}{2B_2H_6} + 3AlCl_3 + 3LiCl$

$$\text{Percentage of hydrogen in } B_2H_6 = \frac{6}{27.62} \times 100 = 21.72$$

$$B_2H_6 + 3O_2 \xrightarrow{\text{Explosion}} B_2O_3 + 3H_2O$$

Example 4 *An inorganic compound 'A' shows the following reactions.*

(i) *It is white solid, exists as dimer and fumes in wet air.*
(ii) *It sublimes at 180°C and forms monomer if heated to 400°C.*
(iii) *Its aqueous solution turns blue litmus to red and gives a white precipitate with* $AgNO_3$ *solution, which is soluble in* NH_4OH
(iv) *Addition of* NH_4OH *and* NaOH *separately to the solution of 'A' gives a gelatinous precipitate which in however soluble in excess of* NaOH.

The compound 'A' is

(a) $Al(OH)_3$
(b) Al_2Cl_6
(c) Al_2O_3
(d) $Al_2(SO_4)_3$

Solution (b) Compound 'A' is Al_2Cl_6.

(i) Al_2Cl_6 is a white solid, exists as dimer and fumes in wet air.
(ii) It sublimes at 180°C and converts into $AlCl_3$ at 400°C.
(iii) Its aqueous solution is acidic, so it turns blue litmus to red.

$$Al_2Cl_6 + 6H_2O \longrightarrow \underset{\text{weak base}}{2Al(OH)_3} + \underset{\text{strong acid}}{6HCl}$$

It gives a white ppt with $AgNO_3$ which is soluble in NH_4OH.

(iv) $AlCl_3 + 3NaOH \longrightarrow \underset{\text{white ppt}}{Al(OH)_3} + 3NaCl$

$$Al(OH)_3 + \underset{\text{excess}}{NaOH} \longrightarrow \underset{\text{soluble}}{NaAlO_2} + 2H_2O$$

But in case of NH_4OH, the ppt. of $Al(OH)_3$ does not dissolve in excess of NH_4OH.

Example 5 *An inorganic salt 'A' is a strong reducing agent. Its hydrolysis in water gives a white turbidity (B). Aqueous solution of 'A' gives a white ppt (C) with* NaOH. *'A' reduces auric chloride to produce purple of cassius. 'A' also reduces iodine and gives chromyl chloride test. Inorganic salt 'A' is*

(a) $SnCl_4$
(b) $SnCl_2$
(c) Na_2SnO_2
(d) $Sn(OH)Cl$

Solution (*b*) $\underset{(A)}{SnCl_2} + H_2O \longrightarrow \underset{(B)}{Sn(OH)Cl} + HCl$

$$SnCl_2 + 2NaOH \longrightarrow \underset{(C)}{Sn(OH)_2} + 2NaCl$$

$$Sn(OH)_2 + 2NaOH \longrightarrow Na_2SnO_2 + 2H_2O$$

$$3SnCl_2 + 2AuCl_3 \longrightarrow 3SnCl_4 + 2Au$$

$$SnCl_2 + 2HCl + I_2 \longrightarrow SnCl_4 + 2HI$$

Example 6 *A red coloured oxide* (*X*) *on treatment with conc.* HNO$_3$ *gives a compound* (*Y*). (*Y*) *with* HCl *produces a chloride* (*Z*) *which is insoluble in cold water but soluble in hot water.* (*Z*) *can also be formed by treating* (*X*) *with conc.* HCl. *Compound X, Y and Z are*

(*a*) $Pb_3O_4 \cdot PbO_2 \cdot PbCl_2$
(*b*) $Mn_3O_4, MnO_2, MnCl_2$
(*c*) $Fe_3O_4, Fe_2O_3, FeCl_3$
(*d*) Fe_3O_4, FeO, $FeCl_2$

Solution (*a*) Compound *X*, *Y* and *Z* are Pb_3O_4, PbO_2 and $PbCl_2$.

$$\underset{(X)}{Pb_3O_4} + 4HNO_3 \longrightarrow 2Pb(NO_3)_2 + \underset{(Y)}{PbO_2} + 2H_2O$$

$$PbO_2 + 4HCl \longrightarrow \underset{(Z)}{PbCl_2} + 2H_2O + Cl_2$$

$PbCl_2$ is insoluble in cold water but soluble in hot water.

$$\underset{(X)}{Pb_3O_4} + 8HCl \longrightarrow 3PbCl_2 + 4H_2O + Cl_2$$

Example 7 *A white crystalline compound 'A' swells up on heating and gives violet coloured flame on bunsen flame. Its aqueous solution gives following reactions.*

(*i*) *A white ppt with* BaCl$_2$ *in the presence of* HCl
(*ii*) *It gives white ppt when treated with excess of* NH$_4$OH. *The ppt dissolves in* NaOH *and reappears on boiling with conc solution of* NH$_4$Cl
(*iii*) *It gives yellow ppt with cobalt nitrite solution.*

The compound A is

(*a*) *Potash alum*
(*b*) *Borax*
(*c*) *Diborane*
(*d*) *Aluminium sulphate*

Solution (*a*) Compound '*A*' is **potash alum**.

$$K_2SO_4 \cdot Al_2(SO_4)_3 \cdot 24H_2O$$

It swells on heating due to evolution of water molecule.

It gives violet colour to the flame due to potassium salt.

(i) The solution consists of sulphate ion which combine with Ba^{2+} ion to form white ppt of BaSO$_4$.

(ii) $$Al_2(SO_4)_3 + 6NH_4OH \longrightarrow \underset{\text{ppt}}{2Al(OH)_3} + 3(NH_4)_2SO_4$$

$$Al(OH)_3 + NaOH \longrightarrow \underset{\text{soluble}}{NaAlO_2} + 2H_2O$$

$$NaAlO_2 + NH_4Cl + H_2O \longrightarrow \underset{\text{ppt.}}{Al(OH)_3} + NaCl + NH_3$$

(iii) Potassium salt gives yellow ppt with cobalt nitrite solution.

$$2K_2SO_4 + Na_4[Co(NO_2)_6] \longrightarrow \underset{\text{yellow ppt.}}{K_4[Co(NO_2)_6]} + 2Na_2SO_4$$

Example 8 *The metallic salt XY is soluble in water. When the solution is treated with* NaOH *solution, a white precipitate 'A' is formed. This precipitate is soluble in excess of* NaOH *solution to form a compound 'B'. When this solution is boiled with solid* NH$_4$Cl, *a precipitate of a compound 'C' is formed. An aqueous solution of XY upon treatment with* BaCl$_2$ *solution gave a white precipitate (O).*

The metallic salt XY is

(*a*) Al_2Cl_6
(*b*) $Al_2(SO_4)_3$
(*c*) Alum
(*d*) $BaSO_4$

Solution (*b*) Metallic salt *XY* is $Al_2(SO_4)_3$.

$Al_2(SO_4)_3$ is soluble in water.

When $Al_2(SO_4)_3$ is treated with NaOH, a white ppt of $Al(OH)_3$ is formed which is soluble in excess of NaOH.

$$\underset{XY}{Al_2(SO_4)_3} + 6NaOH \longrightarrow \underset{'A'}{2Al(OH)_3} + 3Na_2SO_4$$

$$Al(OH)_3 + \underset{\text{(excess)}}{NaOH} \longrightarrow \underset{\substack{(B)\\ \text{soluble}}}{NaAlO_2} + 2H_2O$$

The solution when boiled with solid NH$_4$Cl gives white ppt of Al(OH)$_3$.

$$NaAlO_2 + NH_4Cl + H_2O \longrightarrow \underset{\text{white ppt}}{Al(OH)_3} + NaCl + NH_3\uparrow$$

The salt reacts with BaCl$_2$ to give white ppt of BaSO$_4$.

$$Al_2(SO_4)_3 + 3BaCl_2 \longrightarrow Al_2Cl_6 + 3BaSO_4$$

Example 9 *Aluminium trifluoride is treated with anhydrous* HF *and then with* NaF. *When gaseous* BF$_3$ *is passed through the solution obtained, a precipitate is formed, which is of*

[NCERT]

(*a*) $Na_3[AlF_6]$
(*b*) $Na[BF_4]$
(*c*) AlF_3
(*d*) $H_3[AlF_6]$

Solution (*c*) Anhydrous HF is a covalent compound and is strongly H-bonded. Therefore, it does not give F$^-$ ions and hence AlF$_3$ does not dissolve in HF. NaF is an ionic compound. It contains F$^-$ ions which combine with electron deficient AlF$_3$ to form the soluble complex.

$$3NaF + AlF_3 \longrightarrow \underset{\substack{\text{sodium hexafluoroaluminate (III)}\\ \text{(soluble complex)}}}{Na_3[AlF_6]}$$

Boron due to its small size and higher electronegativity has greater tendency to form complexes than aluminium. Hence, precipitation of AlF$_3$ takes place when BF$_3$ is passed through Na$_3$[AlF$_6$] solution.

$$Na_3[AlF_6] + 3BF_3 \longrightarrow \underset{\substack{\text{sodium tetrafluoroborate (III)}\\ \text{(soluble complex)}}}{3Na[BF_4]} + AlF_3(s)$$

Start **Practice** *for* JEE Main

Round I (Topically Divided Problems)

Elements of Group 13

1. The most abundant metal in the earth crust is
(a) Na (b) Al
(c) Ca (d) Fe

2. The element which exists in liquid state for a wide range of temperature and can be used for measuring high temperature is **[NCERT Exemplar]**
(a) B (b) Al
(c) Ga (d) In

3. Which of the following is the electron deficient molecule?
(a) PH_3 (b) C_2H_6
(c) SiH_4 (d) B_2H_6

4. BF_3 exists but BH_3 doesn't because of the absence of **[NCERT Exemplar]**
(a) back bonding in BF_3
(b) back bonding in BH_3
(c) *d* orbital in B
(d) None of the above

5. Ionisation enthalpy ($\Delta_i H_1 \text{kJ mol}^{-1}$) for the elements of Gorup 13 follows the order. **[NCERT Exemplar]**
(a) $B > Al > Ga > In > Tl$ (b) $B < Al < Ga < In < Tl$
(c) $B < Al > Ga < In > Tl$ (d) $B > Al < Ga > In < Tl$

6. Which gas is liberated when Al_4C_3 is hydrolysed?
(a) CH_4 (b) C_2H_2
(c) C_2H_6 (d) CO_2

7. Alumina is
(a) acidic (b) amphoteric
(c) basic (d) None of these

8. AlI_3, when react with CCl_4, gives
(a) $AlCl_3$ (b) Cl_4
(c) Al_4C_3 (d) Al_2O_3

9. BCl_3 exists as monomer whereas $AlCl_3$ dimerises through halogen bridging. This is because of the **[NCERT Exemplar]**
(a) small size of B atom as compare to Al
(b) absence of *d* orbital in B atom
(c) $p\pi$-$p\pi$ back bonding in $AlCl_3$
(d) $p\pi$-$p\pi$ back bonding in BCl_3

10. Which of the following is a Lewis acid? **[NCERT Exemplar]**
(a) $AlCl_3$ (b) $MgCl_2$
(c) $CaCl_2$ (d) $BaCl_2$

11. In electrolysis of aluminium oxide which of the following is added to accelerate the process?
(a) Silica (b) Silicate
(c) Cryolite (d) Nickel

12. In purification of bauxite by Hall's process, bauxite ore is
(a) fused with Na_2CO_3
(b) heated with NaOH solution at 50°C
(c) heated with $NaHCO_3$
(d) fused with coke and heated at 1800°C in a current of nitrogen

13. Purification of aluminium done by electrolytic refining is known as
(a) Hoope's process (b) Serpeck's process
(c) Hall's process (d) Baeyer's process

14. The function of fluorspar in the electrolytic reduction of alumina dissolved in fused cryolite (Na_3AlF_6) is
(a) to decrease the rate of oxidation of carbon at the anode
(b) to lower the temperature of the melt and to make the fused mixture very conducting
(c) as a catalyst
(d) None of the above

15. Aluminium vessels should not be washed with materials containing washing soda since
(a) washing soda reacts with aluminium to form soluble aluminate
(b) washing soda reacts with aluminium to form insoluble aluminium oxide
(c) washing soda is expensive
(d) washing soda is easily decomposed.

16. In extraction of aluminium the electrolyte is
(a) fused cryolite with felspar
(b) pure alumina in molten state
(c) fused cryolite with fluorspar
(d) pure alumina with bauxite and molten cryolite

17. When Al is added to KOH solution,
(a) hydrogen is evolved (b) oxygen is evolved
(c) ozone is evolved (d) no reaction takes place

18. Which one of the following is correct statement?
(a) The hydroxide of aluminium is more acidic than that of boron.
(b) The hydroxide of boron is basic, while that of aluminium is amphoteric
(c) The hydroxide of boron is acidic, while that of aluminium is amphoteric
(d) The hydroxide of boron and aluminium are amphoteric

19. Boron when heated with carbon forms
(a) B_4C (b) BC_4 (c) B_4C_3 (d) B_2C_3

20. In the aluminothermic process, Al acts as a/an
(a) solder (b) oxidising agent
(c) reducing agent (d) flux

21. Which of the following oxides is strongly basic?
(a) Tl_2O (b) B_2O_3
(c) Al_2O_3 (d) Ga_2O_3

22. Aluminium alloys are used for making aircraft bodies because **[NCERT]**
(a) they are tough
(b) they are light
(c) they are resistant towards corrosion
(d) All of the above

23. Concentrated HNO_3 can be transported in aluminium container. This is because **[NCERT]**
(a) Al is a less reactive metal
(b) Al becomes passive by conc HNO_3
(c) Al is a cheap metal
(d) All of the above

24. When hydrated alumina is treated with aqueous NaOH solution, it gives **[NCERT]**
(a) $Al(OH)_3$ (b) pure alumina
(c) $NaAlO_2$ (d) $NaAlO_3$

25. In III A group Tl (thalium) shows +1 oxidation state while other members show +3 oxidation state, why?
(a) Presence of lone pair of electron in Tl
(b) Large ionic radius of Tl ion
(c) Inert pair effect
(d) None of the above

26. In aqueous solution, GaCl disproportionates to
(a) $GaCl_2$ and $GaCl_3$ (b) Ga and $GaCl_3$
(c) $GaCl_2$ and Ga (d) $GaCl_3$ and $GaCl_5$

27. Which is true for an element R present in III group of the Periodic Table?
(a) It has oxidation state of +4
(b) It is gas at room temperature
(c) It forms R_2O_3
(d) It forms RX_2

28. A non-metallic element of group 13, used in making bullet proof vests is extremely hard solid of black colour. It can exist in many allotropic forms and has unusually high melting point. Its trifluoride acts as **[NCERT Exemplar]**
(a) Lewis base (b) Lewis acid
(c) Bronsted acid (d) Bronsted base

29. Which metal is protected by a layer of its own oxide?
(a) Fe (b) Au
(c) Ag (d) Al

Compounds of Elements of Group 13

30. The structure of BF_3 is
(a) planar triangular (b) pyramidal
(c) tetrahedral (d) T-shaped

31. BF_3 acts as Lewis acid as it is **[NCERT]**
(a) electron deficient (b) electron precise
(c) electron rich (d) interstitial compound

32. Which of the following is known as inorganic benzene?
(a) Borazine (b) Phosphonitrilic acid
(c) Boron nitride (d) *p*-dichlorobenzene

33. In the structure of diborane **[NCERT Exemplar]**
(a) all hydrogen atoms lie in one plane and boron atoms lie in a plane perpendicular to this plane.
(b) 2 boron atoms and 4 terminal hydrogen atoms lie in the same plane and 2 bridging hydrogen atoms lie in the perpendicular plane.
(c) 4 bridging hydrogen atoms and boron atoms lie in one plane and two terminal hydrogen atoms lie in a plane perpendicular to this plane.
(d) all the atoms are in the same plane

34. Boron nitride has the structure of the type
(a) graphite type
(b) diamond type
(c) Both diamond and graphite type
(d) NaCl type

35. A compound (A) of boron reacts with NMe_3 to give an adduct (B) which on hydrolysis gives a compound (C) and hydrogen gas. Compound (C) is an acid. The adduct (B) is **[NCERT Exemplar]**
(a) $B_3N_3H_6$ (b) $2BH_3 \cdot NMe_3$
(c) $BH_3 \cdot 2NMe_3$ (d) $2BH_3 \cdot NMe_3$

36. In diborane the two H—B—H angles are nearly
(a) 95°, 120° (b) 60°, 120°
(c) 120°, 180° (d) 95°, 150°

37. Which of the following compounds are formed when BCl_3 is treated with water?
(a) B_2O_3 + HCl (b) B_2H_6 + HCl
(c) H_3BO_3 + HCl (d) None of these

38. $B(OH)_3 + NaOH \rightleftharpoons NaBO_2 \cdot 2H_2O$ or $Na[B(OH)_4]$
How can this reaction is made to proceed in forward direction?
(a) Addition of *cis*-1, 2 diol
(b) Addition of borax
(c) Addition of *trans*-1, 2 diol
(d) Addition of Na_2HPO_4

39. The product obtained when boric acid is red heated is **[NCERT]**
(a) metaboric acid (b) tetraboric acid
(c) boron trioxide (d) boron metal

40. The shapes of BF_3 and $[BH_4^-]$ are respectively **[NCERT]**
(a) planar, tetrahedral (b) tetrahedral, planar
(c) planar, planar (d) tetrahedral, tetrahedral

41. Which of the following statements about H_3BO_3 is not correct?
(a) It is prepared by acidifying an aqueous solution of borax
(b) It has a layer structure in which planar BO_3 units are joined by hydrogen bonds
(c) It does not act as proton donor but acts as Lewis acid by accepting hydroxyl ion
(d) It is a strong tribasic acid

42. Boric acid is an acid because its molecule **[NCERT Exemplar]**
(a) contains replaceable H^+ ion
(b) gives up a proton
(c) accepts OH^- from water releasing proton
(d) combines with proton from water molecule

43. $AlCl_3$ is
(a) anhydrous and ionic
(b) covalent and basic
(c) anhydrous and covalent
(d) coordinate and acidic

44. Alum are used as mordant in dyeing because
(a) dye is adsorbed on $Al(OH)_3$ which is deposited on fibre in the hydrolysis process
(b) dye is adsorbed on KOH formed due to hydrolysis
(c) Both (a) and (b)
(d) None of the above

45. Which of the following is not true about potash alum?
(a) Its aqueous solution is basic
(b) It is used in dyeing industries
(c) On heating it melts to give water of crystallization
(d) Its empirical formula is $KAl(SO_4)_2 \cdot 12H_2O$

46. Aluminium hydroxide is soluble in excess of sodium hydroxide forming the ion
(a) AlO_2^{3+} (b) AlO_2^-
(c) AlO_2^{3-} (d) AlO_3^-

47. In the reaction $B_2O_3 + C + Cl_2 \longrightarrow A + CO$. The A is
(a) CCl_2 (b) BCl_3 (c) BCl_2 (d) B_2Cl_2

Elements of Group 14

48. Which of the following elements is a metalloid?
(a) C (b) Ge
(c) Bi (d) Sn

49. Thermodynamically the most stable form of carbon is
(a) diamond (b) graphite
(c) fullerenes (d) coal

50. Elements of group 14
(a) exhibit oxidation state of + 4 only
(b) exhibit oxidation state of + 2 and + 4
(c) form M^{2-} and M^{4+} ions
(d) form M^{2+} and M^{4+} ions

51. Catenation *i.e.*, linking of similar atoms depends on size and electronic configuration of atoms. The tendency of catenation in Group 14 elements follows the order: **[NCERT Exemplar]**
(a) C > Si > Ge > Sn (b) C >> Si > Ge ≈ Sn
(c) Si > C > Sn > Ge (d) Ge > Sn > Si > C

52. Formation of in-numberable compounds of carbon is due to its
(a) high reactivity
(b) catenation tendency
(c) covalent and ionic tendency
(d) different valency

53. Percentage of lead in lead pencil is

(a) 20
(b) 80
(c) 70
(d) zero

54. In which of the following the inert pair effect is most prominent?

(a) Si
(b) Ge
(c) Pb
(d) C

55. The different layers in graphite are held together by

(a) metallic bonding
(b) covalent bonding
(c) ionic bonding
(d) van der Waals' forces

56. Which of the following statement is correct with respect to the property of elements in the carbon family with an increase in the atomic number? Their

(a) atomic size decreases
(b) stability of +2 oxidation state increases
(c) metallic character decreases
(d) ionization energy increases

57. A tetravalent element forms monoxide and dioxide with oxygen. When air is passed over heated element (1273 K), producer gas is obtained. Monoxide of the element is a powerful reducing agent and reduces ferric oxide to iron. Identify the element. **[NCERT Exemplar]**

(a) Lead
(b) Carbon
(c) Tin
(d) Silicon

58. Because of the lack of which of the following tendency, Si does not form a graphite like structure but carbon does? **[NCERT Exemplar]**

(a) $p\pi$-$d\pi$ bonding
(b) $p\pi$-$p\pi$ bonding
(c) d-orbital
(d) Small size

59. The hybridisation of carbon in CO_3^{2-}, diamond and graphite are respectively **[NCERT]**

(a) sp^2, sp^2, sp^3
(b) sp^2, sp^3, sp^2
(c) sp^2, sp^3, sp^3
(d) sp^3, sp^3, sp^2

60. Diamond is used as abrasive because of its **[NCERT]**

(a) transparent nature
(b) high refractive index
(c) three dimensional network structure
(d) sp^3 hybridisation

61. Monosilane on coming in contact with air burns with a luminous flame producing vortex rings. These rings are of

(a) SiO_2
(b) SiO
(c) Si
(d) H_2SiO_3

62. What is the number of free electrons present on each carbon atom in graphite?

(a) Zero
(b) 3
(c) 2
(d) 1

63. Quartz is extensively used as a piezoelectric material as it contains **[NCERT Exemplar]**

(a) Pb
(b) Si
(c) Ti
(d) Sn

64. The product obtained when silicon dioxide is treated with HF is **[NCERT]**

(a) SiF_4
(b) H_2SiF_4
(c) H_2SiF_6
(d) None of these

65. Carborundum is obtained when silica is heated at high temperature with

(a) carbon
(b) carbon monoxide
(c) carbon dioxide
(d) calcium carbonate

66. PbO is

(a) acidic
(b) amphoteric
(c) basic
(d) neutral

67. Lead pipes are corroded quickly by

(a) dil. H_2SO_4
(b) acetic acid
(c) conc. H_2SO_4
(d) water

Compounds of Elements of Group 14

68. Dry ice is **[NCERT Exemplar]**

(a) solid NH_3
(b) solid SO_2
(c) solid CO_2
(d) solid N_2

69. CO behaves as

(a) Lewis acid
(b) Lewis base
(c) amphoteric oxide
(d) None of these

70. CO_2 in water behaves as

(a) weak dibasic acid H_2CO_3
(b) weak monobasic acid HO—COOH
(c) weak diacid base $CO(OH)_2$
(d) weak monoacid base HO—COOH

71. Sodium oxalate on heating with conc. H_2SO_4 gives

(a) CO only
(b) CO and CO_2
(c) CO_2 only
(d) SO_2 and SO_3

72. Name of the structure of silicates in which three oxygen atoms of $[SiO_4]^{4-}$ are shared is

(a) pyrosilicate
(b) sheet silicate
(c) linear chain silicate
(d) three dimensional silicate

73. Silicones have the general formula

(a) $(SiO_4)^{4-}$
(b) SiO_6^{7-}
(c) $(SiO_3)_n^{-2n}$
(d) $(R_2SiO)_n$

74. When silicon is heated with CH_3Cl at higher temperature in the presence of Cu, **[NCERT]**
(a) $CH_3SiCl_3 + (CH_3)_2 SiCl_2$ obtained
(b) $(CH_3)_3 SiCl$ is obtained
(c) $(CH_3)_4 Si$ is obtained
(d) a mixture of all of the above is obtained

75. If the starting material for the manufacture of silicones is $RSiCl_3$, the product obtained is **[NCERT]**
(a) silicone rubber
(b) silicone oils
(c) cross-linked silicone
(d) linear chain silicone

Miscellaneous

76. Which of the following has highest density?
(a) Pb (b) B (c) Cu (d) Fe

77. Which of the following form dimeric halides?
(a) Al (b) Mg (c) In (d) Ca

78. The hardest substance amongst the following is
(a) Be_2C (b) tritonium
(c) B_4C (d) graphite

79. Which metal burns in air at high temperature with the evolution of much heat?
(a) Cu (b) Pb (c) Hg (d) Al

Round II (Mixed Bag)

Only One Correct Option

1. An aqueous solution of borax is
(a) neutral (b) amphoteric
(c) basic (d) acidic

2. The type of hybridisation of boron in diborane is
(a) sp (b) sp^2
(c) sp^3 (d) dsp^2

3. Identify compound Z in the following reaction sequence.

$$A + 2HCl + 5H_2O \longrightarrow 2NaCl + X$$

$$X \xrightarrow[370\text{ K}]{\Delta} HBO_2 \xrightarrow[>370\text{ K}]{\Delta} Z$$

[NCERT Exemplar]
(a) Borax (b) Orthoboric acid
(c) Metaboric acid (d) Boron trioxide

4. The B—F bond length in BF_3 is shorter than that in BF_4^-. This is because of **[NCERT]**
(a) resonance in BF_3 but not in BF_4^-
(b) $p\pi$-$p\pi$ back bonding in BF_4^- but not in BF_3
(c) $p\pi$-$p\pi$ back bonding in BF_3 but not in BF_4^-
(d) $p\pi$-$d\pi$ back bonding in BF_3 but not in BF_4^-

5. When aqueous solution of borax is acidified with hydrochloric acid, a white crystalline solid is formed which is soapy to touch. The nature of the solid is **[NCERT Exemplar]**
(a) acidic
(b) basic
(c) neutral
(d) depends upon the nature of solvent

6. The order of acidic strength of boron trihalides is
(a) $BF_3 < BCl_3 < BBr_3 < BI_3$
(b) $BI_3 < BBr_3 < BCl_3 < BF_3$
(c) $BCl_3 < BBr_3 < BI_3 < BF_3$
(d) $BBr_3 < BCl_3 < BF_3 < BI_3$

7. Boric acid is used in carom boards for smooth gliding of pawns because
(a) H_3BO_3 molecules are loosely chemically bonded and hence soft
(b) its low density makes it fluffy
(c) it can be powdered to a very small grain size
(d) H-bonding in H_3BO_3 give it a layered structure

8. When BCl_3 is treated with water, it hydrolysis and forms $[B(OH)_4]^-$ only whereas $AlCl_3$ in acidified aqueous solution forms $[Al(H_2O)_6]^{3+}$ ion. The hybridisation of boron and aluminium in these species is respectively. **[NCERT Exemplar]**
(a) sp^3, sp^3d (b) sp^3, sp^3d^2
(c) sp^3d, sp^3d^2 (d) sp^2, sp^3d^2

9. A mixture of dilute NaOH and aluminium pieces is used to open drain because **[NCERT]**
(a) the gas obtained creates higher pressure
(b) they react explosively
(c) they creates fire
(d) the given statement is not true

10. Graphite is used as lubricant because of its **[NCERT]**
(a) layered structure
(b) weak van der Waals' forces between the layers
(c) strong covalent bonding between the layers
(d) tendency to exist in solid form

11. When CO is heated with ZnO, **[NCERT]**
(a) Zn is obtained
(b) CO_2 is obtained
(c) Both (a) and (b)
(d) None of the above

12. Excessive CO_2 content is responsible for global warming. This is because of its **[NCERT]**
(a) higher wavelength IR trapping nature
(b) lower wavelength IR trapping nature
(c) UV wave trapping nature
(d) heating effect

13. In SiF_6^{2-} and $SiCl_6^{2-}$ which one is known and why?
(a) SiF_6^{2-} because of small size of F
(b) SiF_6^{2-} because of large size of F
(c) $SiCl_6^{2-}$ because of small size of Cl
(d) $SiCl_6^{2-}$ because of large size of Cl

14. Aluminium oxide is not reduced by chemical reactions since
(a) aluminium oxide is reactive
(b) reducing agents contaminate
(c) aluminium oxide is highly stable
(d) the process pollutes the environment

15. Anodising can be done by electrolysing dilute H_2SO_4 with Al as anode, this result in
(a) the formation of protective oxide layer
(b) the formation of $Al_2(SO_4)_3$ and SO_2 gas
(c) the formation of AlH_3 and SO_2 gas
(d) the formation of $Al(HSO_3)$ and H_2 gas

16. Solid CO_2 is known as dry ice, because
(a) it evaporates at 40°C
(b) it melts at 0°C
(c) its boiling points is more than 199°C
(d) it evaporates at – 78°C without melting

17. Which one of the following statements about the zeolite is false?
(a) They are used as cation exchangers
(b) Some of the SiO_4^{4-} units are replaced by AlO_4^{5-} and AlO_6^{9-} ions in zeolite
(c) They have open structure which enables them to take up small molecules
(d) Zeolites are aluminosilicates having three dimensional structures

18. Alzeimer's disease is caused due to Al interaction with internal organs of the body if food is contaminated with Al. This disease
(a) induces senility in young persons
(b) causes memory loss
(c) Both (a) and (b)
(d) None of the above

19. Carbon suboxide, C_3O_2 has
(a) bent structure
(b) trigonal planar structure
(c) linear structure
(d) distorted tetrahedral structure

20. Suppose you have to determine the percentage of carbon dioxide in a sample of a gas available in a container. Which is the best absorbing material for the carbon dioxide?
(a) Heated copper oxide
(b) Cold, solid calcium chloride
(c) Cold, solid calcium hydroxide
(d) Heated charcoal

21. When carbon monoxide is passed over solid caustic soda heated to 200°C, it forms
(a) Na_2CO_3 (b) CH_3COONa
(c) $NaHCO_3$ (d) HCOONa

22. For purification of alumina, the modern processes most useful when (i) the impurity present is a lot of iron oxides and (ii) the impurity present is a lot of silica, are
(a) for (i) Hall's process; for (ii) Baeyer's process
(b) for (i) Serpeck's process; for (ii) Baeyer's process
(c) for (i) Hall's process; for (ii) Serpeck's process
(d) for (i) Baeyer's process; for (ii) Serpeck's process

23. The stability of hydrides of carbon family is in the order
(a) $CH_4 > SiH_4 > GeH_4 > SnH_4 > PbH_4$
(b) $CH_4 < SiH_4 < GeH_4 < SnH_4 < PbH_4$
(c) $CH_4 > SnH_4 > GeH_4 > SiH_4 > PbH_4$
(d) None of the above

24. Lead pipes are not suitable for drinking water because
(a) a layer of lead dioxide is deposited over pipes
(b) lead forms basic lead carbonate
(c) lead reacts with water containing air to form $Pb(OH)_2$
(d) lead reacts with air to form litharge

25. When metal *X* is treated with sodium hydroxide, a white precipitate (*A*) is obtained, which is soluble in excess of NaOH to give soluble complex (*B*). Compound (*A*) is soluble in dilute HCl to form compound (*C*). The compound (*A*) when heated strongly gives (*D*), which is used to extract metal. Compound *D* is **[NCERT]**
(a) aluminium hydroxide
(b) sodium aluminate
(c) aluminium chloride
(d) alumina

More than One Correct Option

26. The reason for small radius of Ga compared to Al is **[NCERT Exemplar]**

(a) poor screening effect of *d* and *f* orbitals
(b) increase in nuclear charge
(c) presence of higher orbitals
(d) higher atomic number

27. The linear shape of CO_2 is due to **[NCERT Exemplar]**

(a) sp^3 hybridisation of carbon
(b) sp hybridisation of carbon
(c) $p\pi$-$p\pi$ bonding between carbon and oxygen
(d) sp^2 hybridisation of carbon

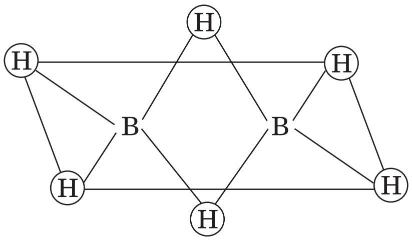
28. Me_3SiCl is used during polymerisation of organo silicones because **[NCERT Exemplar]**

(a) the chain length of organo silicone polymers can be controlled by adding Me_3SiCl
(b) Me_3SiCl blocks the end terminal of silicone polymer
(c) Me_3SiCl improves the quality and yield of the polymer
(d) Me_3SiCl acts as a catalyst during polymerisation

29. Which of the following statements are correct? **[NCERT Exemplar]**

(a) Fullerenes have dangling bonds
(b) Fullerenes are cage-like molecules
(c) Graphite is thermodynamically most stable allotrope of carbon
(d) Graphite is slippery and hard and therefore used as a dry lubrication in machines

30. Which of the following statements are correct? Answer on the basis of figure **[NCERT Exemplar]**



(a) The two birdged hydrogen atoms and the two boron atoms lie in one plane;
(b) Out of six B—H bonds two bonds can be described in terms of 3-centre-2-electron bonds.
(c) Out of six B—H bonds four B—H bonds can be described in terms of 3-centre-2-electron bonds
(d) The four terminal B—H bonds are two centre-two electron regular bonds.

Assertion and Reason

Directions (Q. Nos. 31 to 36) *Each of these questions contains two statements : Statement* I (*Assertion*) *and Statement* II (*Reason*). *Each of these questions also has four alternative choices, only one of which is the correct answer. You have to select one of the codes* (*a*), (*b*), (*c*), (*d*) *given below*

(a) Statement I is true; Statement II is true; Statement II is a correct explanation for Statement I.
(b) Statement I is true; Statement II is true; Statement II is not a correct explanation for Statement I.
(c) Statement I is true; Statement II is false.
(d) Statement I is false; Statement II is true.

31. Statement I BF_3 is a useful organic catalyst for Friedel-Crafts reaction.

Statement II It is covalent, gaseous and hydrolysed by water.

32. Statement I Calcium carbide on hydrolysis gives acetylene.

Statement II Calcium carbide contains C^{4-} anions.

33. Statement I If aluminium atoms replace a few silicon atoms in three dimensional network of silicon dioxide, the overall structure acquires a negative charge.

Statement II Aluminium is trivalent while silicon is tetravalent. **[NCERT Exemplar]**

34. Statement I GeO, SnO and PbO are more basic and ionic than the corresponding GeO_2, SnO_2 and PbO_2.

Statement II GeO is acidic while SnO and PbO are amphoteric.

35. Statement I Si—Si bonds are weaker than Si—O bonds.

Statement II Silicon forms double bonds with itself.

36. Statement I Silicons are water repelling in nature.

Statement II Silicons are organosilicon polymers, which have $\left(R_2SiO \right)$ as repeating unit. **[NCERT Exemplar]**

Comprehension Based Questions

Directions (Q. Nos. 37 to 39) Boric oxide B_2O_3 reacts with water to form boric acid. The net ionisation reaction of boric acid when dissolves in water is

$$B(OH)_3(aq) + 2H_2O(l) \longrightarrow H_3O^+(aq) + [B(OH)_4]^-(aq)$$

Boric acid is quite toxic and slippery. The solution of the salt are generally quite complex because they contain polymers of the borate anions as well as the simple anion $[B(OH)_4]^-$, BO_3^{3-} and BO_4^{5-}. Borates hydrolyse in water to give basic solution and this is why borane is used in some cleaning agents.

37. Which of the following statements is/are correct?
(a) Boric acid is Lewis base
(b) Hybridisation of boron in boric acid is sp^3
(c) Boric acid molecule held together by hydrogen bonding
(d) All of the above

38. The oxidation number of boron in $NaBO_3 \cdot 4H_2O$ is
(a) +1
(b) +2
(c) +3
(d) +4

39. Boric acid is slippery due to
(a) banana bonds
(b) hydrogen bonds
(c) van der Waals' forces
(d) None of these

Directions (Q. Nos. 40 to 42) Like halides of boron, halides of aluminium do not show back bonding because of increase in size of aluminium. Actually aluminium atoms complete their octets by forming dimers. Thus, chloride and bromide of aluminium exist as dimers, both in the vapour state and in polar solvents like benzene while the corresponding boron halides exists as monomer. In boron trihalides the extent of back bonding decreases with increase in size of halogens and thus, Lewis acid character increases.

40. Which of the following reaction is incorrect?
(a) $BCl_3 + 3EtOH \longrightarrow B(OEt)_3 + 3HCl$
(b) $BF_3 + 2H_2O \longrightarrow [BF_3OH]^- + H_3O^+$
(c) $BF_3 + F^- \longrightarrow BF_4^-$
(d) $BCl_3 + 2C_5H_5N \longrightarrow Cl_3B(C_2H_5N)_2$

41. Which statements about anhydrous aluminium chloride is correct?
(a) It is a strong Lewis base
(b) It is not easily hydrolysed
(c) It exists as $AlCl_3$ molecule
(d) It sublimes at 100°C

42. The dimeric structure of aluminium chloride disappears when
(a) it dissolves in water
(b) it dissolves in benzene
(c) it reacts with R_3N
(d) Both (a) and (c)

Directions (Q. Nos. 43 to 45) The heavier elements of group 13 and 14 besides their group oxidation state exhibit another oxidation state which is two units lower than the group oxidation state. The stability of lower oxidation state increases on moving down the group due to inert pair effect.

43. Which of the following statements is incorrect?
(a) Boron exhibits +3 oxidation state only
(b) In Ga +3 oxidation state is more stable than +1 oxidation state
(c) In Sn +2 oxidation state is more stable than +4 oxidation state
(d) In Tl +1 oxidation state is more stable than +3 oxidation state

44. The strongest oxidising agent among the given is
(a) SiO_2
(b) GeO_2
(c) SnO_2
(d) PbO_2

45. Inert pair is not exhibit by
(a) Pb
(b) Bi
(c) Tl
(d) B

Previous Years' Questions

46. Boron can't form which one of the following anions? **[AIEEE 2011]**
(a) BF_6^{3-}
(b) BH_4^-
(c) $B(OH)_4^-$
(d) BO_2^-

47. The bond dissociation energy of B—F in BF_3 is 646 kJ mol^{-1} whereas that of C—F in CF_4 is 515 kJ mol^{-1}. The correct reason for higher B—F bond dissociation energy as compared to that of C—F is **[AIEEE 2009]**
(a) smaller size of B-atom as compared to that of C-atom
(b) stronger σ-bond between B and F in BF_3 as compared to that between C and F in CF_4
(c) significant $p\pi$ - $p\pi$ interaction between B and F in BF_3 whereas there is no possibility of such interaction between C and F in CF_4
(d) lower degree of $p\pi$ - $p\pi$ interaction between B and F in BF_3 than that between C and F in CF_4

48. Among the following substituted silanes the one which will give rise to crosslinked silicone polymer on hydrolysis is **[AIEEE 2008]**
(a) R_4Si
(b) $RSiCl_3$
(c) R_2SiCl_2
(d) R_3SiCl

49. Which one of the following is the correct statement? **[AIEEE 2008]**
(a) Boric acid is a protonic acid
(b) Beryllium exhibits coordination number of six
(c) Chlorides of both beryllium and aluminium have bridged chloride structures in solid phase
(d) $B_2H_6 \cdot 2NH_3$ is known as 'inorganic benzene'

50. The stability of dihalides of Si, Ge, Sn and Pb increases steadily in the sequence **[AIEEE 2007]**
(a) $GeX_2 < SiX_2 < SnX_2 < PbX_2$
(b) $SiX_2 < GeX_2 < PbX_2 < SnX_2$
(c) $SiX_2 < GeX_2 < SnX_2 < PbX_2$
(d) $PbX_2 < SnX_2 < GeX_2 < SiX_2$

51. A metal, M forms chlorides in its +2 and +4 oxidation states. Which of the following statements about these chlorides is correct? **[AIEEE 2006]**

(a) MCl_2 is more volatile than MCl_4
(b) MCl_2 is more soluble in anhydrous ethanol than MCl_4
(c) MCl_2 is more ionic than MCl_4
(d) MCl_2 is more easily hydrolysed than MCl_4

52. Which of the following oxides is amphoteric in character? **[AIEEE 2005]**

(a) SnO_2
(b) SiO_2
(c) CO_2
(d) CaO

53. In silicon dioxide **[AIEEE 2005]**

(a) there are double bonds between silicon and oxygen atoms
(b) silicon atom is bonded to two oxygen atoms
(c) each silicon atom is surrounded by two oxygen atoms and each oxygen atom is bonded to two silicon atoms
(d) each silicon atom is surrounded by four oxygen atoms and each oxygen atom is bonded to two silicon atoms

54. Heating of an aqueous solution of aluminium chloride to dryness will give **[AIEEE 2005]**

(a) $Al(OH)Cl_2$
(b) Al_2O_3
(c) Al_2Cl_6
(d) $AlCl_3$

55. The structure of diborane (B_2H_6) contains **[AIEEE 2005]**

(a) four $2c-2e^-$ bonds and four $3c-2e^-$ bonds
(b) two $2c-2e^-$ bonds and two $3c-3e^-$ bonds
(c) two $2c-2e^-$ bonds and four $3c-2e^-$ bonds
(d) four $2c-2e^-$ bonds and two $3c-2e^-$ bonds

56. Aluminium chloride exists as dimer, Al_2Cl_6 in solid state as well as in solution of non-polar solvents such as benzene. When dissolved in water, it gives **[AIEEE 2004]**

(a) $Al^{3+} + 3Cl^-$ (b) $[Al(H_2O)_6]^{3+} + 3Cl^-$
(c) $[Al(OH)_6]^{3-} + 3HCl$ (d) $Al_2O_3 + 6HCl$

57. The soldiers of Napolean army while at Alps during freezing winter suffered a serious problem as regards to the tin buttons of their uniforms. White metallic tin buttons got converted to grey powder. This transformation is related to **[AIEEE 2004]**

(a) a change in the crystalline structure of tin
(b) an interaction with nitrogen of the air at very low temperatures
(c) a change in the partial pressure of oxygen in the air
(d) an interaction with water vapour contained in the humid air

58. Graphite is a soft solid lubricant extremely difficult to melt. The reason for this anomalous behaviour is that graphite **[AIEEE 2003]**

(a) is a non-crystalline substance
(b) is an allotropic form of diamond
(c) has molecules of variable molecular masses like polymers
(d) has carbon atoms arranged in large plates of rings of strongly bound carbon atoms with weak interplate bonds

59. Alum is widely used to purify water since **[AIEEE 2002]**

(a) it forms complex with clay particles
(b) it coagulates the mud particles
(c) it exchanges Ca^{2+} and Mg^{2+} ions present in hard water
(d) its sulphate ion is water purifier

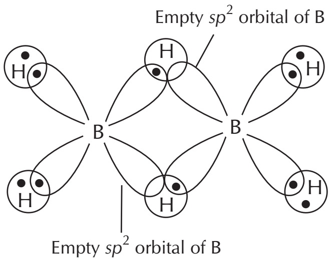
the Guidance

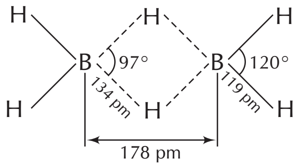
Round I

2. Gallium, Ga because of its unusual structure, exists as Ga_2 molecules and thus has low melting point. It exists as liquid upto 2000°C and hence, used in high temperature thermometry.

3. B_2H_6



4. Boron fluoride exists as BF_3. Due to its small size, B atom cannot coordinate to 4 larger fluoride ions and hence, cannot form the dimeric molecule. On the other hand, boron hydride exists as B_2H_6. This is due to the fact that hydrogen atom in BH_3 has no electron to form $p\pi$-$p\pi$ back bonding. Thus, boron possesses incomplete octet and BH_3 is dimerised to form B_2H_6 molecule with covalent and three centre bonds.



Structure of diborane, B_2H_6

5. Because of its small size and lowest shielding effect, IE is highest for boron and decreases from B to Tl, But not in a regular manner. IE of Ga is greater than that of Al because of poor shielding of 10*d* electrons, while IE of Tl is higher than that of In because of the poor shielding effect of 14*f* electrons present in the inner energy shell. Thus, the correct order is

$$B > Al < Ga > In < Tl$$

6. $Al_4C_3 + 12H_2O \longrightarrow 3CH_4 + 4Al(OH)_3$

7. Alumina is amphoteric oxide, which reacts with acid as well as base.

8. AlI_3, on reaction with CCl_4, gives $AlCl_3$.

$$4AlI_3 + 3CCl_4 \longrightarrow 4AlCl_3 + 3CI_4$$

9. Due to the absence of *d*-orbitals, BCl_3 does not dimerise but in $AlCl_3$, Al contains empty *d*-orbital so it is capable to undergo dimerisation.

10. $AlCl_3$ being electron deficient have a tendency to accept a electron pair, thus acts as Lewis acid.

Note In $MgCl_2$, $CaCl_2$ and $BaCl_2$, octet of all the atoms are complete by the transfer of electrons, thus these cannot act as Lewis acid.

11. Cryolite is added to lower the melting point of alumina and to increase the electrical conductivity.

12. In Hall's process

$$Al_2O_3 \cdot 2H_2O + Na_2CO_3 \longrightarrow 2NaAlO_2 + CO_2 + 2H_2O$$

$$2NaAlO_2 + 3H_2O + CO_2 \xrightarrow{333\text{ K}} 2Al(OH)_3 \downarrow + Na_2CO_3$$

$$2Al(OH)_3 \xrightarrow{1473\text{ K}} Al_2O_3 + 3H_2O$$

15. $2Al + Na_2CO_3 + 3H_2O \xrightarrow{\Delta} 2NaAlO_2 + CO_2 + 2H_2$

17. $2KOH + 2Al + 2H_2O \longrightarrow 2KAlO_2 + 3H_2$

18. $B(OH)_3 \Rightarrow H_3BO_3$ boric acid

$Al(OH)_3 \Rightarrow$ amphoteric

19. It form boron carbide. The molecular formula of boron carbide is $B_{12}C_3$.

$$4B + C \xrightarrow{\Delta} B_4C$$

20. In alumino thermic process, aluminium reduces Fe_2O_3 or Cr_2O_3 to respective metals and acts as a reducing agent.

$$Fe_2O_3 + 2Al \longrightarrow Al_2O_3 + 2Fe$$

21. As we move down the group, the basic nature of the oxides of group 13 elements increases. Tl_2O in aqueous solution gives TlOH which is as strong a base as alkali metal hydroxides.

22. Aluminium alloys such as duralumin is light, tough and resistant to corrosion and hence, it is used in making aircraft body.

23. Al reacts with conc. HNO_3 to form a protective layer of aluminium oxide on its surface which prevents it from further reaction.

$$2Al(s) + 6HNO_3\text{ (conc.)} \longrightarrow \underset{\substack{\text{alumina} \\ \text{(a passive protective layer)}}}{Al_2O_3(s)} + 6NO_2(g) + 3H_2O(l)$$

Therefore, Al becomes passive that's why aluminium containers can be used to transport conc. HNO_3.

24. Alumina dissolves to form sodium meta-aluminate.

$$\underset{\substack{\text{hydrated alumina} \\ \text{or bauxite}}}{Al_2O_3 \cdot 2H_2O\ (s)} + 2NaOH(aq) \xrightarrow{\text{Heat}} \underset{\substack{\text{sodium} \\ \text{meta aluminate}}}{2NaAlO_2} + 3H_2O$$

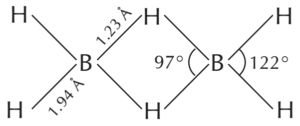
28. The given characteristics are of B and BF_3 because of the presence of electron deficient boron atom, acts as Lewis acid.

29. The thin protective layer of oxide, Al_2O_3 is formed which protects the metal from further attack of air and water and thus, Al is stable in air.

31. BF_3 being electron deficient, is a strong Lewis acid. It reacts with Lewis bases easily to complete the octet around boron.

$$\underset{\text{Lewis acid}}{F_3B} + \underset{\text{Lewis base}}{:NH_3} \longrightarrow F_3B \leftarrow NH_3$$

33. The structure of diborane is as



In this structure, four terminal H atoms along with the two B atoms lie in one plane and two bridging H atoms lie above and below the plane.

35. Since, compound '*A*' of boron reacts with NMe_3 to form an adduct '*B*'. Thus, compound '*A*' is a Lewis acid. Since, adduct '*B*' on hydrolysis gives an acid '*C*' and hydrogen gas, therefore, '*A*' is B_2H_6 and '*C*' is boric acid.

$$\underset{\text{diborane }(A)}{B_2H_6} + 2NMe_3 \longrightarrow \underset{\text{adduct }(B)}{2BH_3 \cdot NMe_3}$$

$$BH_3 \cdot NMe_3 + 3H_2O \longrightarrow \underset{\text{boric acid }(C)}{H_3BO_3} + NMe_3 + 3H_2$$

37. BCl_3 is completely hydrolysed by water yielding boric acid and hydrochloric acid.

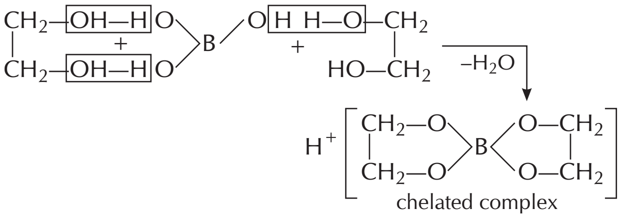
$$BCl_3 + 3H_2O \longrightarrow H_3BO_3 + 3HCl$$

38. $B(OH)_3 + NaOH \rightleftharpoons NaBO_2 \cdot H_2O$ or $Na^+[B(OH)_4]^-$

This reaction is reversible reaction because sodium metaborate, $Na^+[B(OH)_4]^-$ formed by the reaction between $B(OH)_3$ and NaOH gets hydrolysed to regenerate $B(OH)_3$ and NaOH.

$$Na^+[B(OH)_4]^- \xrightarrow[\text{hydrolysis}]{} NaOH + B(OH)_3$$

If, some quantity of polyhydroxy compounds like *cis*-1,2-diol, catechol, glycerol etc., is added to the reaction mixture the $B(OH)_3$ combines with such polyhydroxy compounds to give chelated complex compound. Due to complex compound formation, stability increases and due to higher stability of complex, reaction moves in forward direction.



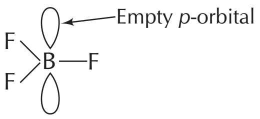
chelated complex compound

39. Boric acid, on heating loses water in three different stages at different temperatures ultimately giving boron trioxide.

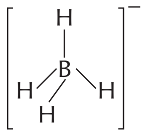
$$\underset{\text{boric acid}}{H_3BO_3} \xrightarrow{370\text{ K}} \underset{\text{metaboric acid}}{HBO_2} + H_2O$$

$$\underset{\text{metaboric acid}}{4HBO_2} \xrightarrow[-H_2O]{410\text{ K}} \underset{\text{tetraboric acid}}{H_2B_4O_7} \xrightarrow{\text{Red heat}} \underset{\text{boron trioxide}}{2B_2O_3} + H_2O$$

40. In BF_3, boron is sp^2-hybridised as it contains three bond pairs and, therefore, BF_3 molecule is trigonal planar in shape. On the other hand, in $[BH_4]^-$ boron is sp^3-hybridised because of the presence of four bond pairs and hence, $[BH_4]^-$ species is tetrahedral in shape.



BF_3 sp^2-hybridised
(trigonal planar shape)



$[BH_4]^-$,sp^3-hybridised
(tetrahedral shape)

41. H_3BO_3 *i.e.,* $B(OH)_3$ is weak mono-basic acid.

42. H_3BO_3, because of the presence of electron deficient B atom, in aqueous medium coordinates with a water molecule to form hydrated species  $H_2O \longrightarrow B(OH)_3.B^{3+}$ ion pulls the σ electron density of coordinated O atom towards itself, which in turn pulls the σ electron density of the O—H bond of attached water molecule towards itself. This facilitates the removal of H^+. Thus, H_3BO_3 behaves as weak Lewis acid.

49. Thermodynamically the most stable form of carbon is graphite.

50. Due to inert pair effect, elements of group 14 exhibit oxidation states of +2 and +4.

51. Since the *E*—*E* (where, $E = C, Si, Ge, Sn$) bond energy decreases with increase in the size, the catenation tendency follows the similar order, as it depends upon the *E*—*E* bond strength.

52. Generally IV group element shows catenation tendency and carbon has more catenation power, so forms a large number of compounds.

54. The inert pair effect is most prominent in Pb because from top to bottom number of shells increases.

55. Graphite has two dimensional sheet like structure in which the various layers are held together by weak van der Waals' forces.

56. In carbon family stability of +2 oxidation state increases on moving down the group in the Periodic Table with an increase in atomic number due to screening effect.

57. Producer gas is a mixture of CO and N_2, therefore, the tetravalent element is carbon and its monoxide and dioxide are CO and CO_2 respectively.

$$2C(s) + \underbrace{O_2(s) + 4N_2(g)}_{\text{air}} \xrightarrow{1273\text{ K}} \underbrace{2CO(g) + 4N_2(g)}_{\text{producer gas}}$$

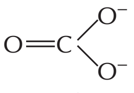
The carbon monoxide is a strong reducing agent and reduces ferric oxide to iron.

$$Fe_2O_3(s) + 3CO(g) \xrightarrow{\Delta} 2\,Fe(s) + 3CO_2(g)$$

58. In graphite, C is sp^2 hybridised. Carbon due to its smallest size and highest electronegativity among group 14 elements has strong tendency to form $p\pi$-$p\pi$ multiple bonds. While silicon due to its larger size and less electronegativity has poor ability to form $p\pi$-$p\pi$ multiple bonds. That's why the silicon does not form a graphite like structure.

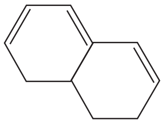
59. Hybridisation depends upon the number of σ bonds, so count the number of σ bonds formed by C. If number of bonds is 4, the hybridisation is sp^3, if σ bonds are 3, hybridisation is sp^2 and if σ bonds are 2, hybridisation is sp.

The state of hybridisation of carbon in CO_3^{2-}, diamond and in graphite is sp^2, sp^3 and sp^2 respectively.



CO_3^{2-}

diamond



graphite

60. In diamond, each sp^3 hybridised carbon atom is linked to four other carbon atoms. It has three dimensional network of carbon atoms. It is very difficult to break extended covalent bonding and therefore diamond is a hardest substance on the earth. That's why it is used as an abrasive.

61. Monosilane (e.g., SiH_4) on coming in contact with air burns with a luminous flame producing vortex ring. These rings are of silica.

$$SiH_4 + 2O_2 \longrightarrow SiO_2 + 2H_2O$$

62. Graphite has a two dimensional structure. In this case only three of the four valence electrons of each carbon atom are involved in bonding. Thus, each carbon atom makes use of sp^2-hybrid orbitals. Hence, the fourth valency of each carbon atom remains unsatisfied *i.e.,* the fourth valency electron remains unpaired or free. This free electron can easily move from one carbon atom to another under the influence of applied potential. So, in structure of graphite only one electron is free on each carbon atom.

63. Quartz is the amorphous form of silicon (Si).

64. When SiO_2 reacts with HF, silicon tetrafluoride is formed which dissolves in excess HF to from hydrofluorosilicic acid.

$$SiO_2 + 4HF \longrightarrow SiF_4 + 2H_2O;$$
$$SiF_4 + 2HF \longrightarrow H_2SiF_6$$

65. Silica on heating with carbon at high temperature gives carborundum (silicon carbide).

$$SiO_2 + 3C \xrightarrow{\Delta} \underset{\text{carborundum}}{SiC} + 2CO$$

Carborundum is very hard substance.

66. It react with alkali as well as acid, so amphoteric.

67. Organic acids dissolve lead in the presence of oxygen.

$$Pb + 2CH_3COOH + \frac{1}{2}O_2 \longrightarrow Pb(CH_3COO)_2 + H_2O$$

68. Because of its snow like appearance and very low melting point (–56.6°C at 5.2 atm pressure), solid CO_2 is commonly known as 'dry ice' or 'drikold'.

70. $CO_2 + H_2O \longrightarrow H_2CO_3$

71. Sodium oxalate react with conc. H_2SO_4 to form CO and CO_2 gas.

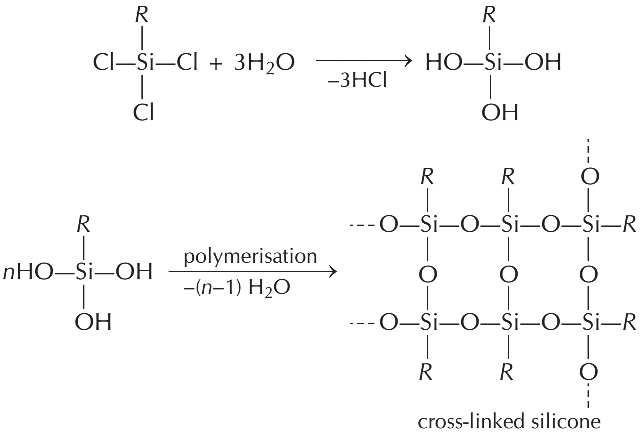
72. Sheet silicates are formed when three oxygen atoms (bridging O-atoms) of each $(SiO_4)^{4-}$ unit are shared. Hence, the general formula of sheet silicates is $(Si_2O_5)^{2n-}$.

73. Silicones are organosilicon compounds having the general formula $(R_2SiO)_n$ which contains repeated R_2SiO units held by Si—O—Si linkages.

74. When Si is heated with CH_3Cl at high temperature in the presence of Cu as a catalyst, a mixture of mono-, di- and trimethylchlorosilanes along with a small amount of tetramethylsilane is formed.

$$\underset{\text{methyl chloride}}{CH_3Cl} + Si \xrightarrow[570\text{ K}]{\text{Cu powder}} CH_3SiCl_3 + (CH_3)_2SiCl_2 + (CH_3)_3SiCl + (CH_3)_4Si$$

75. Hydrolysis of alkyltrichlorosilanes followed by condensation polymerisation gives cross-linked silicones.



$$Cl-\overset{R}{\underset{Cl}{Si}}-Cl + 3H_2O \xrightarrow[-3HCl]{} HO-\overset{R}{\underset{OH}{Si}}-OH$$

$$nHO-\overset{R}{\underset{OH}{Si}}-OH \xrightarrow[-(n-1)\,H_2O]{\text{polymerisation}}$$

cross-linked silicone

77. Al_2Cl_6, In_2Cl_6, Ca_2Cl_6

78. B_4C is the hardest substance along with diamond.

79. Aluminium metal burns in air at high temperature. This reaction is highly exothermic.

$$4Al + 3O_2 \longrightarrow 2Al_2O_3$$

Round II

1. Borax is a salt of strong base (NaOH) and weak acid (H_3BO_3), therefore, its aqueous solution is basic in nature.

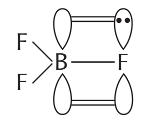
2. In B_2H_6, each boron atom is sp^3-hybridised.

3. (i) $$\underset{\text{borax }(A)}{Na_2B_4O_7} + 2HCl + 5H_2O \longrightarrow 2NaCl + \underset{\substack{\text{orthoboric acid}\\(X)}}{4H_3BO_3}$$

(ii) $$\underset{(X)}{H_3BO_3} \xrightarrow{\Delta,\,370\text{ K}} \underset{\text{metaboric acid}}{HBO_2} + H_2O$$

$$4HBO_2 \xrightarrow[-H_2O]{\Delta,\,>370\text{ K}} \underset{\text{tetraboric acid}}{[H_2B_4O_7]} \xrightarrow{\text{Red heat}} \underset{\substack{\text{boron trioxide}\\(Z)}}{2B_2O_3} + H_2O$$

4. In BF_3, boron is sp^2 hybridised. It has a vacant 2*p*-orbital. Each fluorine in BF_3 has completely filled unutilized 2*p*-orbitals. Since, both of these orbitals belong to same energy level so $p\pi$-$p\pi$ back bonding occurs in which a lone pair of electrons is transferred from unutilized completely filled 2*p*-orbital of F to vacant 2*p*-orbital of B. This type of bond formation is known as back bonding. Therefore, B—F bond has some double bond character. That's why all the three boron-fluorine bonds are shorter than the usual single boron-fluorine bond.



Back bonding in BF_3 molecule

In $[BF_4]^-$ ion, boron is sp^3 hybridised. It does not have empty 2*p*-orbital, so there is no back bonding. In $[BF_4]^-$ ion all the four B—F bonds are purely single bonds. Double bonds are shorter than single bonds. Therefore, B—F bond length in BF_3 is shorter (130 pm) than B—F bond length (143 pm) in $[BF_4]^-$.

5. When an aqueous solution of borax is acidified with HCl, boric acid is formed.

$$\underset{\text{borax}}{Na_2B_4O_7} + 2HCl + 5H_2O \longrightarrow 2NaCl + \underset{\text{boric acid}}{4H_3BO_3}$$

Boric acid is a white crystalline solid. It is soapy to touch because of its planar layered structure. Boric acid is a weak monobasic acid. It is not a protonic acid but acts as a Lewis acid by accepting electrons from a hydroxyl ion.

$$B(OH)_3 + 2HOH \longrightarrow [B(OH)_4]^- + H_3O^+$$

6. Boron trihalides are Lewis acid. The order of their acidic strength is as:

$$BF_3 < BCl_3 < BBr_3 < BI_3$$

7. Boric acid is used in carom boards for smooth gliding of pawns because H-bonding in H_3BO_3 gives it a layered structure.

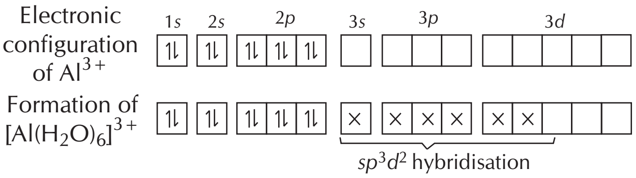
8. BCl_3 on hydrolysis in water forms tetrahedral $[M(OH)_4]^-$ species; in which the hybridisation state of B is sp^3.

$$BCl_3 + 3H_2O \longrightarrow B(OH)_3 + 3HCl$$

$$B(OH)_3 + H_2O \longrightarrow [B(OH)_4]^- + H^+$$

$AlCl_3$ in acidified aqueous solution forms octahedral $[Al(H_2O)_6]^{3+}$ ion. In this complex, the 3d orbitals of Al are involved and the hybridisation state of Al is sp^3d^2.

$$AlCl_3 + \text{water} \xrightarrow{HCl} [Al(H_2O)_6]^{3+} + 3Cl^-(aq)$$



9. NaOH reacts with Al to evolve dihydrogen gas. The pressure of the hydrogen gas can be used to open drains.

$$2Al(s) + 2NaOH(aq) + 2\,H_2O(l) \longrightarrow 2NaAlO_2(aq) + 3H_2(g)$$

10. Graphite has layered structure. Layers are held together by weak van der Waals' forces and hence, can be made to slip over one another. Therefore, graphite acts as a dry lubricant.

11. CO is a strong reducing agent but it cannot reduce ZnO as for $CO \rightarrow CO_2\ \Delta_rG°$ is always higher than that of ZnO. Thus, no reaction takes place.

12. CO_2 is a green house gas. About 75% of the solar energy reaching the earth is absorbed by the earth's surface. The rest of the heat (IR rays) radiates back to the atmosphere. But the heat radiated by the heated surface cannot pass freely into the space because excessive CO_2 in the atmosphere absorb higher wavelength IR rays. This results in increase in the average temperature of the atmosphere. This is known as green house effect.

13. In SiF_6^{2-} and $SiCl_6^{2-}$, SiF_6^{2-} is known due to the small size of F atoms. The small six F atoms can be easily accommodated around Si atom to form SiF_6^{2-} while in $SiCl_6^{2-}$, six large Cl atoms cannot be accommodated around Si atom.

14. Aluminium oxide is highly stable therefore, it is not reduced by chemical reactions.

15. Anodising of Al results in the formation of a protective oxide layer over Al surface.

16. Solid CO_2 is known as dry ice because it evaporates at −78°C without changing in the liquid state.

17. Zeolite have SiO_4 and AlO_4 tetrahedrons linked together in a three dimensional open structure in which four or six membered ring predominate. Due to open chain structure they have cavities and can take up water and other small molecules.

18. Alzeimer disease causes senility and loss of memory.

19. Carbon suboxide has linear structure with C—C bond length equal to 130 Å and C—O bond length equal to 120 Å.

$$O{=}C{=}C{=}C{=}O \longleftrightarrow {}^-O{-}C{\equiv}C{-}C{\equiv}O^+$$

20. CO_2 get is absorbed by $Ca(OH)_2$ to form insoluble $CaCO_3$.

21. $$CO + NaOH \xrightarrow{200°C} \underset{\text{sodium formate}}{HCOONa}$$

22. Iron oxide impurity — Baeyer's process

Silica impurity — Serpeck's process

23. The stability of hydrides of carbon family decreases down the group, hence order is

$$CH_4 > SiH_4 > GeH_4 > SnH_4 > PbH_4$$

24. Lead react with water to form lead hydroxide $Pb(OH)_2$ hence, lead pipes are not suitable for drinking purpose.

25. Since, metal X on treatment with sodium hydroxide gives white precipitate which dissolves in excess of NaOH to give soluble complex (B), therefore, the metal X is Al.

$$\underset{(X)}{Al} + 3NaOH \longrightarrow \underset{\substack{\text{white ppt.}\\(A)}}{Al(OH)_3\downarrow} + 3Na^+$$

$$\underset{(A)}{Al(OH)_3} + \underset{\text{(excess)}}{NaOH} \longrightarrow \underset{\substack{\text{sodium tetrahydroxoaluminate (III)}\\(B)}}{2Na^+[Al(OH)_4]^-}$$

$$\underset{(A)}{Al(OH)_3} + 3HCl(aq) \longrightarrow \underset{(C)}{AlCl_3} + 3H_2O$$

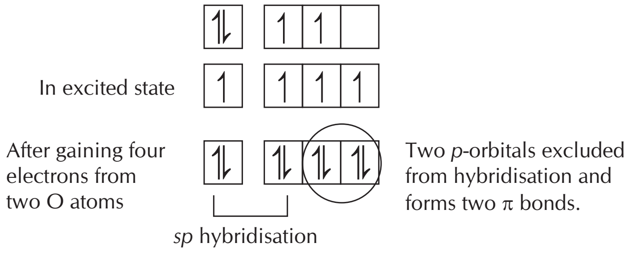
$$\underset{(A)}{2Al(OH)_3} \xrightarrow{\Delta} \underset{(D)}{Al_2O_3} + 3H_2O$$

26. $_{13}Al = 1s^2, 2s^2, 2p^6, 3s^2, 3p^1$

$_{31}Ga = 1s^2, 2s^2, 2p^6, 3s^2, 3p^6, 3d^{10}, 4s^2, 4p^1$

From the electronic configuration it is clear that Ga have extra 10d electrons. Because of the poor screening effect of these electrons, nuclear charge increases and hence, the nucleus holds the outer electrons more tightly and results in reduced radii.

27. $C_6 = 1s^2, 2s^2, 2p^2$



28. Because of the presence of only one —OH group in the hydrolysis product of Me_3SiCl, it blocks the terminal of silicon polymer thus, controls the chain length.

29. Fullerenes are cage-like molecules and graphite is the thermodynamically most stable allotrope of carbon. It is slippery and soft and hence, used as a dry lubricant in machines.

30. The given structure reveals that four terminal H-atoms and two B atoms lie in one plane and two bridged H-atoms lie in a plane perpendicular to the rest of the molecules. Out of the six B—H bonds, two are $3c\text{-}2e^-$ bonds and four are $2c\text{-}2e^-$ bonds.

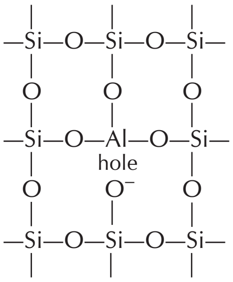
31. $BF_3 + H_2O \longrightarrow H[BF_3OH]$

$BF_3 + 3H_2O \longrightarrow H_3BO_3 + 3HF$

Since B has 6 electrons in the outer shell in BF_3 molecules, it can readily accept a lone pair of electrons from a donor atoms. Thus, acts as a catalyst. Other given is also correct.

32. Calcium carbide on hydrolysis gives acetylene. Calcium carbide contains C_2^{2-} anion.

33. Aluminium is a trivalent metal when it replaces a few Si atoms (tetravalent) from 3D structure of SiO_2, the structure takes the following form.



34. Increased stability of lower valent states on descending a group is illustrated by the facts that Ge^{2+} and Sn^{2+} are strong reducing agent.

35. Si—Si bonds are weaker than Si—O bonds and Si has no tendency to form double bonds with itself.

36. Silicones are organosilicon polymers which have $—R_2SiO—$ as repeating unit. These are water repellant in nature because of the presence of cross-linking in their structure in the presence of moisture.

37. Boric acid is a Lewis acid, in it boron possesses sp^2 hybridisation and their molecules are held together by hydrogen bonding.

38. The more representative formula of $NaBO_3$ is $Na_2[B_2CO_2(OH)_4]\cdot 6H_2O$ with O_2 signifying peroxide linkage and with a +3 oxidation number.

39. Boric acid is slippery due to hydrogen bonding.

40. Only one electron pair of pyridine can be accommodated, not two electron pairs.

41. $AlCl_3$ exists as Al_2Cl_6, It is covalent and gets easily hydrolysed. It is a Lewis acid and due to covalent bonding it has lower melting point.

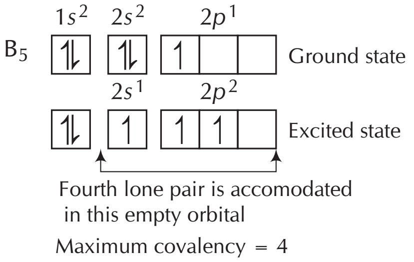
42. Due to high heat of hydration in water, it dedimerises and forms complex of type R_3NAlCl_3 with R_3N.

43. In case of Sn, +4 oxidation state is more stable due to absence of inert pair effect.

44. For Pb the more stable oxidation state is +2 but in PbO_2, it is in +4 oxidation state thus PbO_2 has great tendency to get reduced into PbO (+2 OS). Therefore, it acts as an oxidising agent.

45. Lighter elements of a group like B does not exhibit inert pair effect.

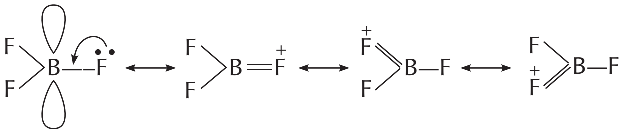
46.



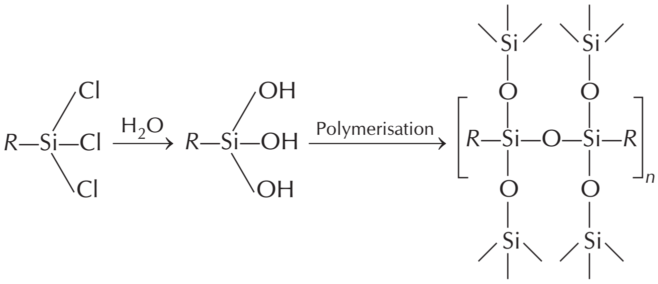
Due to absence of 2*d*-orbital, maximum covalency is four. Thus, BF_6^{3-} is not formed,

Thus (a) is not formed. BH_4^- $(BH_3 + H^-)$, $B(OH)_4^-$ $(B(OH)_3 + OH^-)$ and BO_2^- are formed.

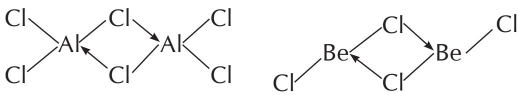
47. In BF_3 there is significant $p\pi$-$p\pi$ interaction between unshared *p*-orbital (having no electron) over boron and the lone pair of electron over fluorine in 2*p*-orbital.



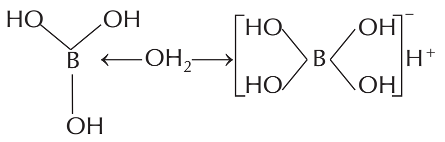
48. $RSiCl_3$ gives cross linked silicone polymer on hydrolysis.



49. Chlorides of both beryllium and aluminium have bridged structures in solid phase



Boric acid is not a protonic acid.



Borazole, inorganic benzene is $B_3N_3H_6$

50. Due to inert pair effect, the stability of +2 oxidation state increases as we move down this group.

$$\therefore \quad SiX_2 < GeX_2 < SnX_2 < PbX_2$$

51. In MCl_2, oxidation state of $M = +2$

In MCl_4, oxidation state of $M = +4$

Higher the oxidation state, smaller the size.

Greater the polarising power, greater the covalent characteristic.

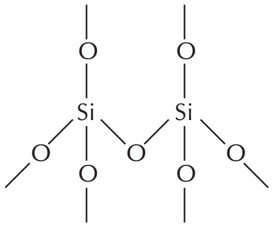
Hence, MCl_4 is more covalent and MCl_2 is more ionic.

52. A species is amphoteric if it is soluble in acid (behaves as a base) as well as in base (behaves as an acid).

$$\underset{\text{basic}}{SnO_2} + \underset{\text{acid}}{4HCl} \longrightarrow SnCl_4 + 2H_2O$$

$$\underset{\text{acid}}{SnO_2} + \underset{\text{base}}{2NaOH} \longrightarrow Na_2SnO_3 + H_2O$$

53.



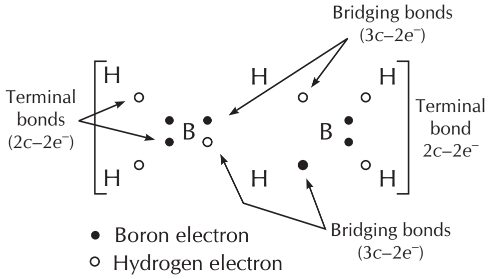
54. Aqueous solution of $AlCl_3$ is acidic due to hydrolysis.

$$AlCl_3 + 3H_2O \rightleftharpoons Al(OH)_3 + 3HCl$$

On strongly heating $Al(OH)_3$ is converted into Al_2O_3.

$$2Al(OH)_3 \xrightarrow{\Delta} Al_2O_3 + 3H_2O$$

55. B_2H_6 has structure



56. $AlCl_3$ is covalent but in water, it becomes ionic due to large hydration energy of Al^{3+}.

$$AlCl_3 + 6H_2O \rightleftharpoons [Al(H_2O)_6]^{3+} + 3Cl^-$$

57. As temperature decreases, white tin (β-form) changes to grey tin (α-form).

$$\alpha\text{-Sn} \xrightleftharpoons{13.2^\circ C} \beta\text{-Sn}$$

α-Sn has a much lower density.

58. C-atoms form covalently bonded plates (layers). Layers are bonded weakly together, that's why one layer can slide over other and cause lubricacy. It cannot be melted easily as large number of atoms being bonded strongly in the layer form big entity.

59. Mud is colloidal charged solution which on treatment with alum (Al^{3+}) gets neutralised or coagulated.

12

Purification and Characterisation of Organic Compounds

JEE Main MILESTONE

- Methods of Purification
- Detection of Carbon, Hydrogen and Oxygen
- Soda Lime Test for Nitrogen
- Lassaigne's Test
- Test for Halogens
- Test for Phosphorus
- Estimation of Carbon and Hydrogen
- Estimation of Nitrogen
- Estimation of Halogens
- Estimation of Sulphur
- Estimation of Phosphorus
- Estimation of Oxygen
- Calculation of Molecular Weight

12.1 Methods of Purification

The methods which are generally employed for the purification of organic compounds are

1. Filtration
2. Crystallisation
3. Fractional crystallisation
4. Sublimation
5. Distillation, [Fractional distillation, Distillation under reduced pressure, Steam distillation, Azeotropic distillation],
6. Differential extraction
7. Chromatography.

Organic compounds either obtained from natural sources or synthesised in the laboratory have some impurities associated with them, i.e., these are not pure. Hence, it is essential to remove these impurities from the organic compound. The process of removal of impurities is called purification.

The pure compound is then tested quantitatively and qualitatively.

1. Filtration

(i) **Principle** It is based on the difference in filterability of different component of a solution.

(ii) **Process** Filtration is used to separate the insoluble solid component of the mixture from the soluble components in a given solvent. Sometime we use the filtrate of hot solution for separation. If the process of filtration is slow then it is carried out under reduced pressure using a Buchner funnel and a filter pump.

(iii) **Applications** Separation of sand from salt by dissolving in water, separation of tea leaves from tea is done by this method.

2. Crystallisation

(i) **Principle** It is based on the difference in the solubilities of the compound and the impurities in a suitable solvent.

(ii) **Process** This method is used to purify organic solids which dissolve in a particular solvent either as such or on heating while the impurities does not dissolve. A hot concentrated solution of the compound is prepared and this upon filtration and cooling gives the crystals of the pure compound.

The solvents commonly used for dissolving organic solids are water, alcohol, ether, chloroform, benzene, petroleum ether, etc.

Table 12.1 **Solvents to be Used for Crystallisation of Different Substances**

S.N.	Substances	Solvents	Polarity of solvents
1.	Hydrocarbons	Pentane, hexane, benzene, petroleum ether	Hydrophobic (non-polar)
2.	Ethers	Diethyl ether; methylene chloride (CH_2Cl_2)	
3.	Halohydrocarbons	Chloroform	
4.	Tertiary amines	Acetone	
5.	Ketones, aldehydes, esters	Ethyl acetate/methyl acetate	
6.	Phenols, alcohols	Ethanol	
7.	Carboxylic acids	Methanol	
8.	Sulphonic acid	Water	
9.	Organic salts	Water	Hydrophilic (polar)

(iii) **Applications** Sugar having common salt as impurity, can be crystallised through hot ethanol as it is soluble in hot ethanol but, common salt does not. Similarly, hot water is used to separate a mixture of benzoic acid and naphthalene.

3. Fractional Crystallisation

(i) **Principle** It is based on the slight difference in solubilities of different components of a mixture in the same solvent.

(ii) **Process** In this method, a hot concentrated solution of mixture is prepared and is allowed to cool. The less soluble component crystallises out earlier as compared to more soluble one. The various fractions are separated from time to time. Now these fractions are subjected to crystallisation.

(iii) **Applications** The mixture of glucose and fructose; sodium sulphate and sodium dichromate, $KClO_3$ + KCl are separated by this method.

4. Sublimation

(i) **Principle** This process is employed for those solids which convert directly into vapours on heating without converting into liquid phase and the vapours upon cooling give back the solid.

$$\text{Solid} \underset{\text{Cool}}{\overset{\text{Heat}}{\rightleftharpoons}} \text{Vapour}$$

(ii) **Process** In this process, the impure solid is taken into China dish and is covered with a perforated filter paper. An inverted funnel is placed over the dish and its stem is plugged with cotton. The dish is heated gently and the substance volatilises as the result. The substance now called **sublimate** is collected over the inner cold surface of the funnel. The non-volatile impurities are left behind in the China dish. The perforated filter paper allows only the vapours to go upwards and check the sublimate from falling back down into the dish.

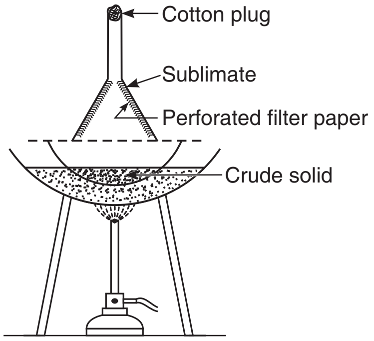


Fig. 12.1 Sublimation

(iii) **Applications** Impure samples of naphthalene, anthracene, camphor, benzoic acid, NH_4Cl, $HgCl_2$, dry ice, salicylic acid, iodine etc., can be purified by this method provided the impurities are non-volatile.

Caution Point *A mixture of two or more sublimates cannot be separated by sublimation. Such mixtures are separated by chemical methods.*

5. Distillation

(i) **Principle** It is based upon the difference in the boiling points of two liquids or two components and is generally used if an organic liquid contains a non-volatile impurity.

(ii) **Process** When a given liquid is heated to its boiling point, it is converted into vapours and the vapours on cooling condense to give back the original liquid in its pure form. The liquid so obtained is called **distillate** and the process is distillation.

Several distillation methods employed to separate mixtures are as follows

(a) **Simple distillation** It is used only for the purification of liquids which boil without decomposition at atmospheric pressure and contain non-volatile impurity. Generally, the impurity and liquid which differ in their boiling points by 30-50K are separated by this process.

A mixture of ether and toluene, hexane and toluene; benzene and aniline etc., is separated by this method.

(b) **Fractional distillation** For the separation of two liquids which have nearly equal boiling points *i.e.,* their boiling points are within the limit of 10 to 15 K (For example, acetone 329 K and methyl alcohol 338 K), the process of simple distillation cannot be used as vapours of both the liquids will be formed simultaneously and thus, the distillate will also contain both of them. In such case, the distillation is done with the help of **specially designed fractionating columns.** Such a distillation is called **fractional distillation.**

A mixture of acetone and methyl alcohol is separated by this process.

(c) **Distillation under reduced pressure** It is used for those liquids which have a tendency to decompose at a temperature below their boiling point. As we know at boiling point,

vapour pressure of liquid = its atmospheric pressure

Hence, under reduced pressure the liquid will boil at low temperature. Thus, temperature for decomposition is not reached. For example, boiling point of glycerol is 563 K but it decomposes much before its boiling temperature. However at 12 mm of Hg pressure, glycerol boils at 453 K without decomposition. Other examples include H_2O_2, concentration of sugar cane juice in sugar industry etc.

(d) **Steam distillation** It is used to purify the substances which

1. are volatile in steam but are immiscible with water.
2. possess sufficiently high vapour pressure at the boiling point of water.
3. contain non-volatile impurities.

The compound to be purified is distilled with steam under reduced pressure at a temperature below its boiling point. The pure compound comes out with steam (as it is volatile with steam) and separates on cooling down (as it is immiscible with water). The impurities being non-volatile remains in mother liquor.

In steam distillation, the liquid boils when the sum of vapour pressure due to the organic liquid (p_1) and that due to water vapour (p_2) becomes equal to the atmospheric pressure.

$$p = p_1 + p_2$$

Since, $p_1 < p_2$, the compound vaporizes at lower temperature than its boiling point.

The process of steam distillation can also be used to separate a mixture of two organic compounds one of which is steam volatile while the other is not. For example, *ortho* and *para* nitrophenols (the latter is non-volatile) compounds like aniline, nitrobenzene, sandal wood oil, terpentine oil, bromobenzene, *o*-hydroxy acetophenone etc., are purified or obtained by this process.

Azeotropic Distillation

The liquid mixtures which have constant boiling point and distill with unchanged composition are called **azeotropes.** These mixtures behave as pure liquids and cannot be separated with simple distillation. The method designed to separate **azeotropes** is called **azeotropic distillation.**

(a) Principle

It is based on the more solubility of a component of azeotrope in another solvent as compared to the other component of the azeotrope.

(b) Process

In this process a suitable solvent is added to form a new azeotrope resulting to the removal of one of the components of older azeotrope with the solvent.

(c) Applications

Dehydration of 96% ethanol (azeotrope with 96% C_2H_5OH + 4% water) to absolute alcohol with the help of benzene, as ethanol is more soluble in benzene as compared to water.

6. Differential Extraction

(i) **Principle** It is based on the more solubility of solute in a suitable organic compound as compared to water.

(ii) **Process** The process of **differential extraction** is used to separate a given organic compound present in an aqueous solution from water present in it. The process involves shaking of solution with a suitable organic solvent in which compound is more soluble as compared to water such as ether, chloroform or benzene, in a separating funnel. While performing such an act one point should be kept in mind that solvent and water must not be miscible with each other. In order to get the more amount of organic solvent, the process is repeated again and again with same sample.

(iii) **Application** Benzoic acid is separated from water by using benzene.

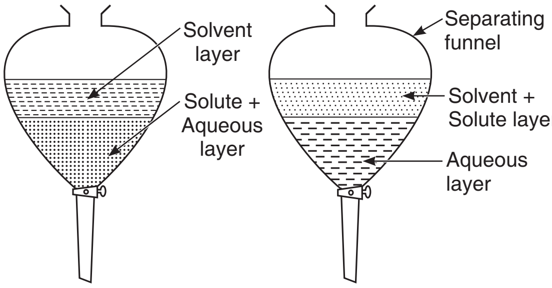

Fig. 12.2 Process of differential extraction

7. Chromatography

It is the modern technique used for separation, isolation, identification and purification of organic compounds (available in small amounts). The method was discovered by **Tswett** (a Russian botanist) in 1906. He used the technique for the separation of coloured pigments from a plant.

(i) **Principle** The process is based upon the principle of distribution of components of a given organic mixture between two phases *i.e.,* the **stationary phase** and the **mobile phase** or in other words, it is based upon the difference in the rates at which the components of a mixture move through a porous medium (stationary phase) under the influence of some solvent or gas (mobile phase).

(ii) **Process and Application** In this technique, the stationary phase can either be solid or liquid supported over a solid and the mobile phase may be a liquid or gas. Over the years the number of techniques has been developed under chromatography which are used in the separation of different compounds according to the need. For example, column or adsorption chromatography, paper chromatography, thin layer chromatography, gas-liquid chromatography etc. A brief outline review of these has been given in the following table.

Table 12.2 **Types of Chromatography**

S.N.	Types of chromatography	Mobile/ Stationary phase	Uses
1.	Adsorption or column chromatography	Liquid/solid	Large scale separations
2.	Thin layer chromatography (TLC)	Liquid/solid	Qualitative analysis
3.	High performance liquid chromatography (HPLC)	Liquid/solid	Qualitative and quantitative analysis
4.	Gas liquid chromatography (GLC)	Gas/liquid	Qualitative and quantitative analysis
5.	Paper or partition chromatography	Liquid/liquid	Qualitative and quantitative analysis

Some Important Facts Related to Chromatography are

1. In chromatography stationary phase is of solid Al_2O_3; SiO_2, starch and charcoal mainly, while mobile phase is of pure solvent.

2. The relative adsorption of each constituent of the mixture is expressed in terms of its **retardation factor,** *i.e.,* R_f value

$$R_f = \frac{\text{Distance moved by the substance from base line } (x)}{\text{Distance moved by the solvent from base line } (y)}$$

$$R_f = \frac{x}{y}$$

3. The R_f value of a substance depends on the
(i) nature of the substance,
(ii) nature of the solvent,
(iii) nature of the filter paper used, and
(iv) temperature. The spots of the coloured compounds are visible on the TLC plate.

4. The spots of colourless compounds are seen under U.V. (ultra violet) light. Another detection method is to place the TLC plate in a covered jar containing crystals of I_2 (iodine). The compound which absorbs I_2 will be seen as brown spots.

5. Sugars are separated by using the solvent BAW (*n*-butanol acetic acid-H_2O in the volume ratio of 4 : 1 : 3) and detected by spraying the plate with aniline hydrogen phthalate solution.

6. If the solvent is placed at the top and the upper end of the filter paper dips in it, the solvent moves downwards. This is called **descending paper chromatography.** If the condition is revers, it is called **ascending paper chromatography.**

Caution Point *In the purification of petroleum and coal tar products for their acidic, basic and neutral components, sulphuric acid is used to separate the basic component and caustic soda solution to separate the acid component.*

Sample **Problem 1** *The fragrance of flowers is due to the presence of some steam volatile organic compounds, called the essential oils. These are generally insoluble in water at room temperature but are miscible with water vapour in vapour phase. A suitable method for the extraction of these oils from the flowers is* **[NCERT Exemplar]**

(*a*) *distillation*
(*b*) *crystallisation*
(*c*) *distillation under reduced pressure*
(*d*) *steam distillation*

Interpret (*d*) Since, essential oils are steam volatile, these are extracted from the flowers by steam distillation.

Sample **Problem 2** *The principle involved in paper chromatography is* **[NCERT Exemplar]**

(*a*) *adsorption* (*b*) *partition*
(*c*) *solubility* (*d*) *volatility*

Interpret (*b*) Paper chromatography is based on the principle of partition.

Sample **Problem 3** *During hearing of court case, the judge suspected that some changes in the documents had been carried out. He asked the forensic department to check the ink used at two different places. According to you which technique can give the best results?* **[NCERT Exemplar]**

(a) *Column chromatography*
(*b*) *Solvent extraction*
(c) *Distillation*
(*d*) *Thin layer chromatography*

Interpret (*d*) Thin layer chromatography is based on different rates of adsorption of different substances, thus found useful for identification and separation of two different dyes.

Check Point 1

1. Under what conditions can the process of steam distillation be used?
2. Why impure glycerol is purified by distillation under reduced pressure?
3. Why sublimation method can't be used for the purification of liquids?
4. In steam distillation, a compound vaporise below its boiling point, why?

Qualitative Analysis

The qualitative analysis of an organic compound implies the detection of all the major elements which can be present in it with the help of suitable chemical tests.

12.2 Detection of Carbon, Hydrogen and Oxygen

The detection of **carbon and hydrogen** is done with the help of copper oxide test. In this test the compound is mixed with double the amount of pure and dry copper oxide. The mixture is heated in a hard glass test tube which is fitted with a bulb containing delivery tube as shown in the figure below

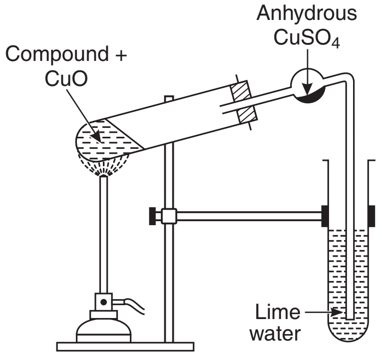

Fig. 12.3 Detection of carbon and hydrogen inorganic compounds

The other end of the delivery tube is dipped in a tube containing lime water. The bulb of delivery tube contains anhydrous $CuSO_4$ in it. The organic compound undergoes combustion as

$$\text{C of organic compound} + 2\,CuO \xrightarrow{\Delta} CO_2 + 2Cu$$

$$\text{H of organic compound} + CuO \xrightarrow{\Delta} H_2O + Cu$$

H_2O vapours turn anhydrous $CuSO_4$ blue and CO_2 evolved turns lime water milky.

$$CuSO_4 + 5H_2O \longrightarrow \underset{\text{hydrated copper sulphate (blue)}}{CuSO_4 \cdot 5H_2O}$$

$$Ca(OH)_2 + CO_2 \longrightarrow \underset{\text{milky}}{CaCO_3} + H_2O$$

Since, oxygen is present almost everywhere, no direct method is available for its detection.

Caution Point *While testing for hydrogen, it is necessary that the apparatus, copper oxide and the substance are absolutely dry. Cupric oxide being hygroscopic in nature, is strongly heated just before use.*

12.3 Sodalime Test for Nitrogen

Sodalime test involves strong heating of compound with sodalime (NaOH / CaO). The evolution of NH_3 gives the indication of nitrogen.

$$CH_3CONH_2 + NaOH / CaO \longrightarrow CH_3COO^-Na^+ + NH_3 \uparrow$$

12.4 Lassaigne's Test

This test is used to detect the presence of elements like N, S, F, Cl, Br, I, etc., and involves two steps

(i) Preparation of Lassaigne's extract
(ii) Detection of elements using Lassaigne extract

To prepare Lassaigne extract the organic substance is fused with small quantity of Na pieces in a fusion tube. The red hot tube is, then, plunged into distilled water contained in a China dish. The contents of dish are boiled for couple of minutes, then cooled and filtered. The filtered liquid is called **sodium extract** or **Lassaigne's extract.** The Lassaigne's extract is usually alkaline. If not, it is made alkaline by adding a few drops of NaOH.

During fusion, the elements like N, S, C, F, Cl, Br, I, etc., present in the organic compound, get fused with Na and convert into their ionic form as

$$Na + C + N \xrightarrow{\text{Fusion}} \underset{\text{sodium cyanide}}{Na^+C^-{\equiv}N}$$

$$2Na + S \xrightarrow{\text{Fusion}} \underset{\text{sodium sulphide}}{Na_2S}$$

$$Na + C + N + S \longrightarrow \underset{\text{sodium sulphocyanide}}{NaSCN}$$

(when N and S both are present)

$$Na + \underset{\text{halogen}}{X} \longrightarrow \underset{\text{sodium halide}}{NaX}$$

Caution Point Li *and* K *both cannot be used in Lassaigne's test in place of* Na *as the former reacts very slowly and forms covalent compounds while later reacts vigorously and thus, cannot be handled properly.*

1. Detection of Nitrogen

To a part of soda extract $FeSO_4$ solution is added and the contents are warmed. A few drops of $FeCl_3$ solution are then added and resulting solution is acidified with conc. HCl. The appearance of **bluish green** or **Prussian blue** colouration confirms the presence of nitrogen. *The reactions that occur during this test are as*

1. On heating the extract with $FeSO_4$, sodium ferrocyanide is formed.

$$2NaCN + FeSO_4 \longrightarrow Na_2SO_4 + Fe(CN)_2$$

$$Fe(CN)_2 + 4NaCN \longrightarrow \underset{\text{sodium ferrocyanide}}{Na_4[Fe(CN)_6]}$$

2. The treatment with $FeCl_3$ yield ferric ferrocyanide which has bluish green or Prussian blue colouration.

$$3Na_4[Fe(CN)_6] + 4FeCl_3 \longrightarrow \underset{\substack{\text{ferric ferro}\\ \text{cyanide}\\ \text{(Prussian blue)}}}{Fe_4[Fe(CN)_6]_3} + 12NaCl$$

3. The function of conc. HCl is destruction of $Fe(OH)_2$ which might have been formed by the action of $FeSO_4$ with NaOH.

$$FeSO_4 + 2NaOH \longrightarrow \underset{\text{green}}{Fe(OH)_2} + Na_2SO_4$$

$$Fe(OH)_2 + 2HCl \longrightarrow FeCl_2 + 2H_2O$$

If this is not done, the green colour of $Fe(OH)_2$ will interfere with the detection of nitrogen.

Caution Point *In the above test, if* Fe^{3+} *ions are in excess, green colour appears instead of blue.*

4. If the compound contains sulphur and nitrogen both sodium sulphocyanide is formed in Lassaigne's extract, which gives blood red colouration of $Fe(SCN)_3$ with $FeCl_3$.

$$Na + C + N + S \longrightarrow \underset{\text{sodium sulphocyanide.}}{NaSCN}$$

$$\xrightarrow{\text{With } FeCl_3} \underset{\substack{\text{ferric sulphocyanide}\\ \text{(blood red)}}}{Fe(SCN)_3} + 3NaCl$$

Sample Problem 4 *Lassaigne's test for the detection of nitrogen fails in*

(*a*) $NH_2CONHNH_2 \cdot HCl$ (*b*) $NH_2NH_2 \cdot HCl$
(*c*) NH_2CONH_2 (*d*) $C_6H_5NHNH_2 \cdot HCl$

Interpret (*b*) Lassaigne's test is positive for nitrogen only when the compound contains carbon alongwith nitrogen. $NH_2NH_2 \cdot HCl$ contains nitrogen but does not contain carbon, thus, NaCN is not formed and hence, test of N is negative.

2. Detection of Sulphur

Following two tests are used to detect the presence of sulphur in organic compounds :

(i) A part of Lassaigne extract is acidified with CH_3COOH and then $(CH_3COO)_2Pb$ solution is added. Formation of black precipitate confirms the presence of sulphur in the compound.

$$Na_2S + (CH_3COO)_2Pb \longrightarrow \underset{\text{black ppt.}}{PbS\downarrow} + 2CH_3COO^-Na^+$$

Caution Point *In this test* H_2SO_4 *cannot be used for dilution because lead acetate itself will react with* H_2SO_4 *to form white ppt. of lead sulphate.*

$$\underset{\text{lead acetate}}{Pb(OCOCH_3)_2} + H_2SO_4 \longrightarrow \underset{\text{white ppt.}}{PbSO_4\downarrow} + 2CH_3COOH$$

Hence, white precipitate of $PbSO_4$ *will interfere with the following test of sulphur.*

$$Pb(CH_3COO)_2 + Na_2S \longrightarrow \underset{\text{black ppt.}}{PbS\downarrow} + 2CH_3COONa$$

However, if acetic acid is used, it does not react with lead acetate, so does not interfere in the test.

(ii) A few drops of sodium nitroprusside solution are added to a part of soda extract. The appearance of purple colouration confirms the presence of sulphur.

$$Na_2S + Na_2[Fe(CN)_5NO] \longrightarrow \underset{\text{purple colour}}{Na_4[Fe(CN)_5NOS]}$$

12.5 Test for Halogens

The soda extract of organic compound is boiled with conc. HNO_3 to expel the gases. Here, the HNO_3 decomposes NaCN and Na_2S (if present) in the soda extract as

$$NaCN + HNO_3 \longrightarrow NaNO_3 + HCN\uparrow$$

$$Na_2S + 2HNO_3 \longrightarrow 2NaNO_3 + H_2S\uparrow$$

$$Na + X \longrightarrow \underset{\text{soda extract}}{NaX} \quad (X = Cl, Br, I)$$

It is then cooled and treated with $AgNO_3$ solution. Formation of

(i) A white ppt. soluble in NH_4OH solution indicates the presence of chlorine in organic compound.

$$NaCl + AgNO_3 \longrightarrow \underset{\text{white ppt.}}{AgCl\downarrow} + NaNO_3$$

(ii) A dull yellow ppt. partially soluble in NH_4OH solution indicates the presence of bromine in the organic compound.

$$NaBr + AgNO_3 \longrightarrow \underset{\text{dull yellow ppt.}}{AgBr\downarrow} + NaNO_3$$

(iii) A yellow ppt insoluble in NH_4OH indicates the presence of iodine in the organic compound.

$$AgNO_3 + NaI \longrightarrow \underset{\text{yellow ppt.}}{AgI} + NaNO_3$$

Caution Points

(*i*) *In the detection of halogens if cyanide and sulphide are not removed before adding silver nitrate solution, these radicals will combine with silver nitrate and produce white and black precipitate of* AgCN *and* Ag_2S *respectively.*

(*ii*) H_2SO_4 *cannot be used instead of* HNO_3 *as it gives white ppt. of* Ag_2SO_4 *with* $AgNO_3$ *which interfere with the test of chlorine.*

Beilstein Test for Halogens

If organic compound gives blue or green colour at the tip of red hot copper wire, this indicates the presence of halogens in the organic compound. Several halogen free compounds such as pyridine, purines, urea, thiourea, etc., also give green colour to the flame, thus this test is not very reliable. However, if no green or blue colour appears, it confirms the absence of halogen. Thus, the test is confirmatory one to show the absence of halogens, rather than to show their presence.

Caution Point *Since* CuF_2 *is non-volatile, fluorine does not give this test.*

Layer Test for Bromine and Iodine

The presence of nitrogen and sulphur does not interfere in this test. In this test acidify a little sodium extract with dil. HNO_3 or dil. H_2SO_4 and add $CHCl_3$ or CCl_4 and excess of chlorine water. If organic layer becomes yellow or brown, bromine is present and if violet, iodine is present.

$$2NaBr + Cl_2 \longrightarrow 2NaCl + Br_2$$

$$CHCl_3 + Br_2 \longrightarrow \text{Yellow brown layer}$$

$$2NaI + Cl_2 \longrightarrow 2NaCl + I_2$$

$$CHCl_3 + I_2 \longrightarrow \text{Violet layer}$$

12.6 Test for Phosphorus

For the detection of phosphorus, organic compound is fused with sodium peroxide, hence phosphorus is converted into sodium phosphate.

$$5Na_2O_2 + \underset{\text{compound}}{2P} \xrightarrow{\text{Fuse}} \underset{\text{sodium phosphate}}{2Na_3PO_4} + 2Na_2O$$

The fused mass is extracted with water and the water extract is boiled with conc HNO_3. Upon cooling a few drops of ammonium molybdate solution are added, a yellow ppt. confirms the presence of phosphorus in the organic compound.

$$Na_3PO_4 + 3HNO_3 \longrightarrow H_3PO_4 + 3NaNO_3$$

$$H_3PO_4 + 12(NH_4)_2MoO_4 + 21HNO_3 \longrightarrow \underset{\text{yellow ppt.}}{(NH_4)_3PO_4\cdot 12MoO_3} + 21NH_4NO_3 + 12H_2O$$

Check Point 2

1. Which halogen gives negative Beilstein test and why?
2. Why does hydrazine give negative Lassaigne's test however, it contains nitrogen?
3. While testing for halogens, the extract is boiled with conc. HNO_3. Explain why?
4. Why is it necessary to use acetic acid and not sulphuric acid for acidification of sodium extract for testing sulphur by lead acetate test? **[NCERT]**
5. For testing halogens in an organic compound with $AgNO_3$ solution, sodium extract (Lassaigne's test) is acidified with dilute HNO_3. What will happen if a student acidifies the extract with dilute H_2SO_4 in place of dilute HNO_3? **[NCERT Exemplar]**

Quantitative Analysis

The next step after the identification of elements is their estimation *i.e.,* to know the percentage of various elements present in an organic compound.

12.7 Estimation of Carbon and Hydrogen

The C and H in an organic compound are estimated by **Liebig method.** In this method, the organic compound is heated with dry cupric oxide in an atmosphere of dry oxygen (or air) free from CO_2. Thus, the C and H present in the organic compound are oxidised to CO_2 and water vapours respectively.

$$C + 2CuO \longrightarrow CO_2 + 2Cu$$

$$2H + 2CuO \longrightarrow H_2O + 2Cu$$

1. CO_2 vapours are passed through weighed potash bulb which absorbs CO_2 completely. The increase in the weight of potash bulb corresponds to the weight of CO_2 produced.

$$2KOH + CO_2 \longrightarrow K_2CO_3 + H_2O$$

2. Water vapours are passed through weighed calcium chloride tube (U-shaped). Increase in the weight of $CaCl_2$ corresponds to the weight of H_2O formed.

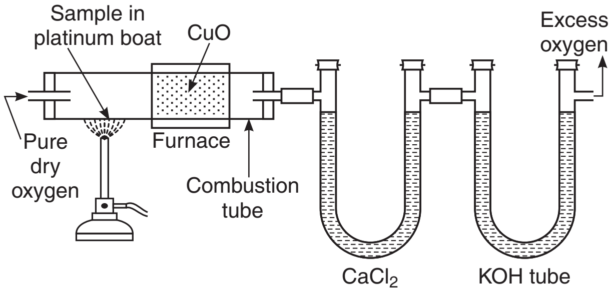

Fig. 12.4 Apparatus for the estimation of carbon and hydrogen

From the respective weights the percentage of C and H can be determined as

(i) $\% \text{ of carbon} = \dfrac{12 \times \text{mass of } CO_2 \times 100}{44 \times \text{mass of organic compound}}$

(ii) $\% \text{ of hydrogen} = \dfrac{2 \times \text{mass of } H_2O \times 100}{18 \times \text{mass of organic compound}}$

Caution Point *In this method, near the exit, a silver foil and a bright copper spiral is placed in order to remove halogen and oxides of nitrogen respectively as* Ag *foil converts halogens into* Ag*X while copper reduces oxides of nitrogen into* N_2.

Sample **Problem 6** *An organic compound contains* 69% *carbon and* 4.8% *hydrogen, the remainder being oxygen. Calculate the masses of carbon dioxide and water produced when* 0.20 *g of this substance is subjected to complete combustion.*

(*a*) 0.69 *g and* 0.048 *g* (*b*) 0.506 *g and* 0.086 *g*
(*c*) 0.345 *g and* 0.024 *g* (*d*) *None of these*

Interpret (*b*) $\%C = \dfrac{12}{44} \times \dfrac{\text{mass of } CO_2 \text{ formed}}{\text{mass of substance taken}} \times 100$

$$69 = \frac{12}{44} \times \frac{\text{Mass of } CO_2 \text{ formed}}{0.2} \times 100$$

$$\therefore \text{ Mass of } CO_2 \text{ formed} = \frac{69 \times 44 \times 0.2}{12 \times 100} = 0.506 \text{ g}$$

$$\%H = \frac{2}{18} \times \frac{\text{mass of } H_2O \text{ formed}}{\text{mass of substance taken}} \times 100$$

$$4.8 = \frac{2}{18} \times \frac{x}{0.2} \times 100$$

$$x = \frac{4.8 \times 18 \times 0.1}{100} = 0.086 \text{ g}$$

12.8 Estimation of Nitrogen

Estimation of nitrogen can be done by two ways

1. Duma's Method

In this method, organic compound is heated with dry cupric oxide in a combustion tube in the atmosphere of CO_2, which is created by heating $NaHCO_3$ and removing its moisture by passing it in conc H_2SO_4. Upon heating C and H present, are oxidised to CO_2 and water vapours respectively, while N_2 is set free. A roll of oxidised copper gauze is placed in combustion tube which prevents the backward diffusion of gases evolved. A small amount of N_2 might be oxidised to its oxides but they are reduced back to N_2 with the help of Cu placed at the end of the combustion tube.

$$2C + 2CuO \xrightarrow{\Delta} 2Cu + 2CO_2 \uparrow$$

$$2H + CuO \xrightarrow{\Delta} Cu + H_2O \uparrow$$

$$N + CuO \longrightarrow N_2 + \text{oxides of N}$$

$\text{Oxides of nitrogen} + Cu \longrightarrow CuO + N_2$

The volume of N_2 evolved is recorded with the help of **Schiff's nitrometer tube** which contains 40% KOH solution and is provided with Hg seal at the bottom to check the backward flow of the liquid. This volume is then reduced to STP by applying the gas equation, $\dfrac{p_1V_1}{T_1} = \dfrac{p_2V_2}{T_2}$

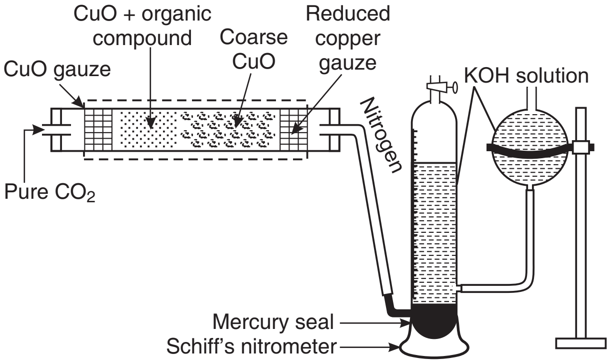

Fig. 12.5 Apparatus for the estimation of nitrogen by Duma's method

From the volume of N_2 at STP, the percentage of nitrogen is calculated as

$$\% \text{ of nitrogen} = \frac{28\,V \times 100}{22400 \times w}$$

Here, V = volume of N_2 evolved at STP

w = weight of organic compound taken

Sample Problem 7 *In Duma's method for the estimation of nitrogen, 0.30 g of an organic compound gave 50 cm^3 of nitrogen collected at 300 K and 715 mm pressure. Calculate the percentage of nitrogen in the compound. (Vapour pressure of water or aqueous tension of water at 300 K is 15 mm.)*

(*a*) 17.46
(*b*) 20.56
(*c*) 28
(*d*) 15.68

Interpret (*a*) Here, mass of the substance taken = 0.30 g

Volume of nitrogen collected = 50 cm^3

Atmospheric pressure = 715 mmHg

Room temperature = 300 K

Vapour pressure of water at 300 K = 15 mm

$\therefore$ Actual pressure of the gas (dry gas) = 715 − 15 = 700 mm Hg

Step I The volume at experimental conditions is converted to volume at STP as

$$p_1 = 700 \text{ mm}, p_2 = 760 \text{ mm}$$
$$V_1 = 50 \text{ cm}^3, V_2 = ?$$
$$T_1 = 300 \text{ K}, T_2 = 273 \text{ K}$$

Experimental STP

$$\frac{p_1V_1}{T_1} = \frac{p_2V_2}{T_2}$$

$$\Rightarrow \quad \frac{700 \text{ mm} \times 50 \text{ cm}^3}{300 \text{ K}} = \frac{760 \text{ mm} \times V_2 \text{ cm}^3}{273 \text{ K}}$$

or $$V_2 = \frac{273 \times 700 \times 50}{300 \times 760} = 41.9 \text{ cm}^3$$

Step II The volume at STP is converted into mass.

According to the definition of gram molar volume,

22400 cm^3 of nitrogen at STP weigh = 28 g

$\therefore$ 41.9 cm^3 of nitrogen at STP will weigh $= \frac{28 \times 41.9}{22400}$ g

Step III The percentage of nitrogen is calculated as

Percentage of nitrogen,

$$= \frac{\text{mass of } N_2 \text{ at STP}}{\text{mass of the substance taken}} \times 100$$

$$= \frac{28 \times 41.9 \times 100}{22400 \times 0.3} = 17.46$$

2. Kjeldahl's Method

This method is based on the principle that when the nitrogenous compound is heated with conc H_2SO_4 in the presence of potassium sulphate, (which raises the boiling point of H_2SO_4) and $CuSO_4$ (catalyst), the nitrogen present in the compound is converted to ammonium sulphate. The ammonium sulphate, so formed, is decomposed with excess of alkali and NH_3 evolved is estimated volumetrically, *i.e.*, by the titration of an acid and NH_3. The percentage of N_2 is then calculated from the amount of NH_3.

The % of nitrogen in a compound $= \frac{1.4 \times N \times V}{w}$

where, N = normality of acid used for the estimation of NH_3 volumetrically

V = volume of acid used

w = weight of organic compound taken

or $$\% \text{ N} = \frac{1.4 \times M \times 2\left(V - \frac{V_1}{2}\right)}{\text{mass of organic compound}}$$

where, V = volume of H_2SO_4 in mL

V_1 = volume of NaOH

M = molarity of H_2SO_4

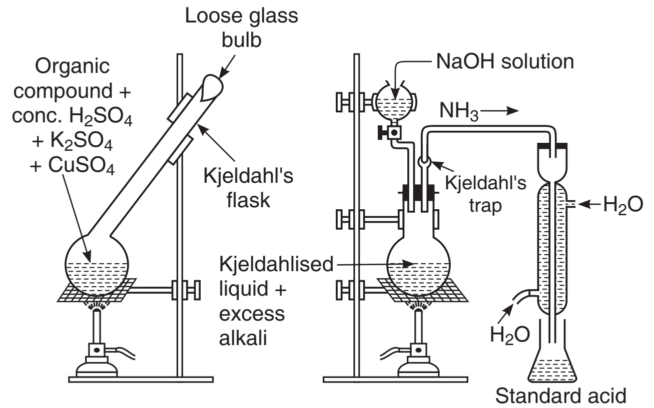

Fig. 12.6 Estimation of nitrogen by Kjeldahl's method

Cauton Point *Kjeldahl's method is not applicable to compounds containing nitrogen in nitro and azo groups and nitrogen present in the ring, as nitrogen of these compounds is not quantitatively converted into ammonium sulphate.*

Sample **Problem 8** *A sample of 0.50 g of an organic compound was treated according to Kjeldahl's method. The ammonia evolved was absorbed in 50 mL of 0.50 M* H_2SO_4. *The residual acid required 60 mL of 0.5 M solution of* NaOH *for neutralisation. Find the percentage composition of nitrogen in the compound.* **[NCERT]**

(*a*) 46%
(*b*) 53%
(*c*) 56%
(*d*) 87%

Interpret (*c*) Volume of the acid taken

$$= 50 \text{ mL of } 0.5 \text{ M } H_2SO_4$$
$$= 25 \text{ mL of } 1.0 \text{ M } H_2SO_4$$

Volume of alkali used for neutralisation of excess acid

$$= 60 \text{ mL of } 0.5 \text{ M NaOH}$$
$$= 30 \text{ mL of } 1.0 \text{ M NaOH}$$

$$H_2SO_4 + 2NaOH \longrightarrow Na_2SO_4 + 2H_2O$$

$$1 \text{ mole of } H_2SO_4 = 2 \text{ moles of NaOH}$$

Hence, 30 mL of 1.0 M NaOH = 15 mL of 1.0 M H_2SO_4

$\therefore$ Volume of acid used by ammonia = 25 − 15 = 10 mL

$$\% \text{ of nitrogen} = \frac{1.4 \times N_1 \times \text{vol. of acid used}}{w}$$

(where, N_1 = normality of acid and w = mass of the organic compound taken)

$$\% \text{ of nitrogen} = \frac{1.4 \times 2 \times 10}{0.5} = 56.0$$

12.9 Estimation of Halogens

In the case of halogens, estimation is done with **Carius method.** Here, the weighed amount of organic compound is heated in a sealed tube with fuming HNO_3 in the presence of $AgNO_3$. As a result, halogen present in the organic compound is converted into AgX which is weighed. The percentage of halogens can be calculated with the help of direct formulae as

$$\% \text{ of chlorine} = \frac{35.5}{143.5} \times \frac{\text{wt. of AgCl} \times 100}{\text{wt. of compound}}$$

$$\% \text{ of bromine} = \frac{80}{188} \times \frac{\text{wt. of AgBr} \times 100}{\text{wt. of compound}}$$

$$\% \text{ of iodine} = \frac{127}{235} = \frac{\text{wt. of AgI} \times 100}{\text{wt. of compound}}$$

Sample **Problem 9** 0.3780 *g of an organic chloro compound gave* 0.5740 *g of silver chloride in Carius estimation. Calculate the percentage of chlorine present in the compound.* **[NCERT]**

(*a*) 40% (*b*) 37% (*c*) 25% (*d*) 85%

Interpret (*b*) The mass of the organic compound taken = 0.3780 g

Mass of AgCl formed = 0.5740 g

$$\text{Percentage of chlorine} = \frac{35.5}{143.5} \times \frac{\text{mass of AgCl formed}}{\text{mass of substance taken}} \times 100$$
$$= \frac{35.5}{143.5} \times \frac{0.5740}{0.3780} \times 100$$
$$= 37.566\%$$

12.10 Estimation of Sulphur

It is also estimated by **Carius method.** In this case, the compound is heated with conc HNO_3, resulting to oxidation of its sulphur to H_2SO_4 which is collected as $BaSO_4$ by using barium chloride solution. The percentage of sulphur is calculated by the formula

$$\% \text{ of sulphur} = \frac{32}{233} \times \frac{\text{wt. of } BaSO_4 \times 100}{\text{wt. of organic compound}}$$

Sample **Problem 10** *In the estimation of sulphur by Carius method,* 0.468 *g of an organic sulphur compound afforeded* 0.668 *g of barium sulphate. Find the percentage of sulphur in the given compound.* **[NCERT]**

(*a*) 15%
(*b*) 20%
(*c*) 45%
(*d*) 50%

Interpret (*b*) The mass of organic compound taken = 0.468 g

Mass of $BaSO_4$ formed = 0.668 g

$$\text{Percentage of sulphur} = \frac{32}{233} \times \frac{\text{mass of } BaSO_4 \text{ formed}}{\text{mass of substance taken}} \times 100$$
$$= \frac{32}{233} \times \frac{0.668}{0.468} \times 100$$
$$= 19.60\%$$

12.11 Estimation of Phosphorus

For the estimation of phosphorus weighed amount of organic compound is heated with conc HNO_3 in a **Carius tube.** Phosphorus present in the compound is converted into phosphoric acid. Contents of the tube are heated with $MgCl_2$ solution in the presence of NH_4Cl and NH_4OH

(magnesia mixture), the $MgNH_4PO_4$ so formed is collected washed, dried and ignited to get magnesium pyrophosphate ($Mg_2P_2O_7$) which is weighed and the percentage of P is calculated with the help of formula

$$\text{Percentage of P} = 62 \times \frac{\text{wt. of } Mg_2P_2O_7 \text{ formed}}{222 \times \text{wt. of the compound}} \times 100$$

12.12 Estimation of Oxygen

The amount of oxygen cannot be calculated by any method. In case, the sum of percentage of all other elements present is less than 100 then,

$$\% \text{ of oxygen} = 100 - \text{sum of } \% \text{ of all other elements}$$

Hot Spot 1

CALCULATION of Empirical Formula

Although this chapter is not very important but the question, if asked, generally based on this topic. It is a very easy topic and with a small practice you can solve out the problems based on this topic easily.

The **empirical formula** of a compound is the simplest formula which expresses the relative number of atoms present in the molecule. It is calculated from the percentage composition of the compound by the following steps.

Step I **Calculation of percentage** Calculate the percentage of elements present from the given data, if percentage is not given. If in the question problem, percentage is given, left this step and start from step II.

Step II **Determination of relative number of atoms** For this divide the percentage composition of each element by its atomic weight. The different numbers so obtained are the relative number of different atoms present in the molecule.

Step III **Determination of simplest ratio** For this divide the relative number of different atoms obtained in the above step by the lowest one among them.

Step IV **Whole number** The numbers expressing the simplest atomic ratio may or may not be whole number. In case any of the number is not whole number *i.e.*, it is fractional, then multiply all the numbers by a common suitable integer to get the smallest possible whole number. Minor fractions are neglected.

Step V **Empirical formula** Write down all the constituent elements of the compound in a line and then put the above whole numbers as subscripts to the lower right corner of each respective element. This gives the empirical or simplest formula.

Sample **Problem 11** *An organic compound is found to contain* C = 40.0%, H = 6.66%. *The empirical formula is*

(*a*) CH_2O (*b*) CHO_2 (*c*) CHO (*d*) C_2H_6O

Interpret (*a*)

Element	Percentage	Atomic weight	Molar ratio	Simplest ratio
C	40	12	3.33	$\frac{3.33}{3.33} = 1$
H	6.66	1	6.66	$\frac{6.66}{3.33} = 2$
O	53.34	16	3.33	$\frac{3.33}{3.33} = 1$

Thus, the empirical formula of the compound is CH_2O.

12.13 Calculation of Molecular Weight

Following methods can be employed to calculate the molecular weight of a compound.

Molecular Weight (*m*) of Volatile Substances

Victor Meyer's Method (applicable only to volatile substances).

$$m = 2 \times \text{V.D.}$$

$$\text{or} \quad m = \frac{\text{wt. of compound} \times 22400}{\text{volume of vapour given by substance at NTP}}$$

Molecular Weight of Non-volatile Substances

(a) **Silver Salt Method** (For organic acids only)

A known mass of an organic acid is converted into its silver salt by using ammoniacal silver nitrate solution. On ignition, the silver salt of the acid leaves a residue of metallic silver.

$$RCOOH \xrightarrow[AgNO_3]{NH_4OH} RCOOAg \xrightarrow{\text{Ignition}} Ag$$

$$m = \text{equivalent wt.} \times \text{basicity}$$

$$\text{Eq. wt.} = \left(\frac{\text{wt. of silver salt} \times 108}{\text{wt. of silver}}\right) - 107$$

Sample Problem 12 *0.759 g of a silver salt of a dibasic organic acid on ignition left 0.463 g metallic silver. The equivalent weight of acid is*

(a) 50 (b) 65 (c) 70 (d) 85

Interpret (c) Eq. weight of silver salt = Eq. weight of Ag

$$\frac{0.759}{E} = \frac{0.463}{108}$$

$\therefore$ Eq. weight of silver salt $= 177$

$\therefore$ Eq. weight of acid $= 177 - 108 + 1 = 70$

(b) **Chloroplatinate Method**

(For organic bases only)

Amines and most organic bases react with chloroplatinic acid (H_2PtCl_6) to form salts, chloroplatinates of general formula $B_2H_2\ PtCl_6$ where, B is a monoacidic base. On heating, the salt decomposes to yield platinum metal.

$$2RNH_3 + H_2PtCl_6 \longrightarrow (RNH_3)_2PtCl_6 \xrightarrow{\text{Ignition}} Pt$$

$$m = \text{Eq. wt.} \times \text{acidity}$$

$$\frac{\text{wt. of chloroplatinate } (W)}{\text{wt. of platinium } (w)} = \frac{2B + 410}{195}$$

or
$$2B = \left(\frac{W}{w} \times 195\right) - 410$$

or
$$B = \left(\frac{W}{w} \times \frac{195}{2}\right) - 205$$

where, B is the equivalent weight of base.

Hot Spot 2

DETERMINATION of Molecular Formula

It is also an important topic for JEE Main alongwith calculation of empirical formula. Generally combined questions based on these two topics are asked.

The formula which expresses the actual number of atoms of various elements present in the molecule of a compound is called its **molecular formula.**

In general, molecular and empirical formula of an organic compound are related as

$$\text{Molecular formula} = (\text{Empirical formula})_n$$

where, n is a whole number. Thus, when the value of $n = 1$, the compound in question has the same empirical and molecular formula.

Further, n is the ratio between the molecular weight and the empirical formula weight of the substance, *i.e.,*

$$n = \frac{\text{molecular weight}}{\text{empirical formula weight}}$$

Thus, for determining the molecular formula of a compound, its empirical formula weight and molecular weight must be known.

Note For problems based on organic qualitative analysis see chapter experimental chemistry.

Check Point 3

1. Some potassium sulphate is added during the estimation of nitrogen by Kjeldahl's method. Why?
2. Why can Kjeldahl's method not used to estimate the percentage of nitrogen in azoxy compounds or in pyridine ?
3. Why is a copper spiral placed near the exit in Leibig method of estimation of carbon and hydrogen ?
4. Why are the results obtained for iodine by Carius method not satisfactory?
5. How a molecular formula is different from the empirical formula?

WORKED **OUT**
Examples

Example 1 *Simple distillation can be used to separate*

- (*a*) *a mixture of ethanol (bp* 78°C*) and water (bp* 100°C*)*
- (*b*) *a mixture of benzene (bp* 80°C*) and toluene (bp* 110°C*)*
- (*c*) *a mixture of ether (bp* 35°C*) and toluene (bp* 110°C*)*
- (*d*) *None of the above*

Solution (*c*) Simple distillation is used when the boiling point of two components differ widely.

Example 2 *An organic compound is heated with* CuO *in a test tube. The evolved gases are allowed to pass into lime water which turns milky. The milkiness of lime is due to*

- (*a*) $CaSO_4$ *and confirms the presence of* S
- (*b*) $CaCO_3$ *and confirms the presence of* C
- (*c*) $CaSO_3$ *and confirms the presence of* C
- (*d*) $CaCO_3$ *and confirms the presence of* S

Solution (*b*)

$$Ca(OH)_2 + SO_2 \longrightarrow \underset{\text{milky}}{CaSO_3} + H_2O$$

$$Ca(OH)_2 + CO_2 \longrightarrow \underset{\text{milky}}{CaCO_3} + H_2O$$

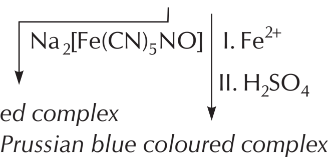
Example 3 *Which of the following compounds will give blood red colour in the Lassaigne's test for* N *?*

- (*a*) $(NH_2)_2C{=}O$
- (*b*) $H_2N(C_6H_4)SO_3H$
- (*c*) $C_6H_5SO_3H$
- (*d*) $CHCl_3$

Solution (*b*) Compounds containing both N and S give blood red colour in Lassaigne's test due to the formation of $Fe(SCN)_3$.

Thus, $H_2N(C_6H_4)SO_3H$ gives blood red colour in Lassaigne's test of nitrogen.

Example 4 *Organic compound '* A*'* $\longrightarrow$ *Lassaigne's extract*



The above Lassaigne's extract on treatment with Fe^{2+} *does not give blood red colour because of the*

- (*a*) *absence of* S *in the organic compound*
- (*b*) *presence of halogen in the organic compound*
- (*c*) *dissociation of* NaSCN *into* Na_2S *and* NaCN
- (*d*) *conversion of* NaSCN *into* HSCN

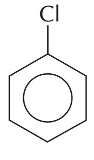
Solution (*c*) Lassaigne's extract gives violet colour complex, it clearly confirms the presence of sulphur. The formation of Prussian blue coloured complex confirms the presence of nitrogen. If that Lassaigne's extract doesn't give red colour complex it means excess of Na metal caused dissociation of NaSCN into Na_2S and NaCN.

$$2Na + NaSCN \xrightarrow{\Delta} Na_2S + NaCN$$

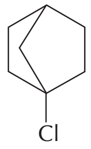
Example 5 *Which of the following compounds produce a white precipitate of* AgCl *on warming with ethanolic silver nitrate solution?*

- (*a*) $CH_2{=}CHCl$
- (*b*) $O_2N{-}CH{=}CH{-}Cl$

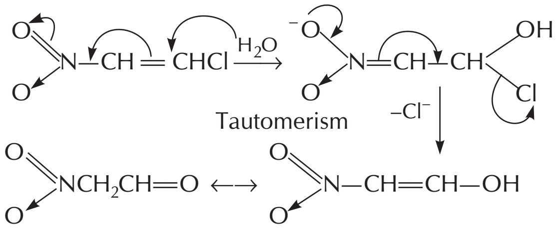
(*c*)



(*d*)



Solution (*b*)



Example 6 *An organic compound of formula* C_3H_7N *was analysed for nitrogen by Duma's method. Calculate the volume of* N_2 *gas evolved at NTP from 2 g of substance.*

- (*a*) 405 *mL*
- (*b*) 342 *mL*
- (*c*) 392 *mL*
- (*d*) 100 *mL*

Solution (*c*) % of N in $C_3H_7N = \frac{14}{57} \times 100$

Further $\quad \% \text{ of N} = \frac{1}{8} \times \frac{\text{volume of } N_2 \text{ at NTP}}{\text{weight of substance}}$

$$\Rightarrow \quad \frac{14}{57} \times 100 = \frac{1}{8} \times \frac{V}{2}$$

$$V = 392 \text{ mL}$$

Example 7 *A gaseous hydrocarbon has 85% carbon and vapour density of 28. The possible formula of the hydrocarbon will be*

(*a*) C_3H_6 (*b*) C_2H_4
(*c*) C_2H_2 (*d*) C_4H_8

Solution (*d*)

Symbol	Percent age	At. mass	Relative no. of atoms	Simplest ratio
C	85	12	$\frac{85}{12}=7.08$	$\frac{7.08}{7.08}=1$
H	15	1	$\frac{15}{1}=15$	$\frac{15}{7.08}=2.11=2$

Empirical formula is CH_2

$$\text{Mol. mass} = 2\times \text{VD} = 2\times 28 = 56$$

$$n = \frac{\text{mol. formula mass}}{\text{emp. formula mass}} = \frac{56}{14} = 4$$

Hence, molecular formula $= (CH_2)_n = (CH_2)_4 = C_4H_8$

Example 8 *60 g of an organic compound on analysis gave following results :* C = 24 g; H = 4 g *and* O = 32 g. *The compound can be*

(*a*) CH_2O_2 (*b*) C_2H_2O
(*c*) $C_2H_2O_4$ (*d*) CH_2O

Solution (*d*) 60 g of the compound contains C = 24 g

$$100 \text{ g of the compound contains C} = \frac{24\times 100}{60} = 40$$

60 g of the compound contains H = 4 g

$$100 \text{ g of the compound contains H} = \frac{4\times 100}{60} = 6.66$$

$\therefore$ Percentage age of oxygen $= 100 - (40 + 6.66) = 53.34$

Element	Percentage	Atomic mass	Relative no. of atoms	Ratio
C	40.0%	12	$\frac{40}{12}=3.33$	$\frac{3.33}{3.33}=1$
H	6.66%	1	$\frac{6.66}{1}=6.66$	$\frac{6.66}{3.33}=2$
O	53.34%	16	$\frac{53.34}{16}=3.33$	$\frac{3.33}{3.33}=1$

So, empirical formula is CH_2O.

Example 9 *In a compound* C, H *and* N *are present in* 9 : 1 : 3.5 *by weight. Molecular weight of the compound is* 108. *Molecular formula of compound is*

(*a*) $C_6H_8N_2$
(*b*) C_3H_4N
(*c*) $C_9H_{12}N_3$
(*d*) $C_2H_6N_2$

Solution (*a*) The mole ratio of C, H and N is

$$\frac{9}{12} : \frac{1}{1} : \frac{3.5}{14}$$

$$0.75 : 1 : 0.25$$

$$3 : 4 : 1$$

Empirical formula $= C_3H_4N$

Empirical formula weight = 54

Molecular weight = 108

$$n = \frac{108}{54} = 2$$

The molecular formula $= C_6H_8N_2$

Example 10 *500 mL of a hydrocarbon gas burnt in excess of oxygen yielded 2500 mL of* CO_2 *and 3.0 L of water vapour. The formula of the hydrocarbon is*

(*a*) C_5H_{12}
(*b*) CH_4
(*c*) C_2H_4
(*d*) C_3H_6

Solution (*a*)

$$\begin{array}{ccccc} C_xH_y & + \left[x+\frac{y}{4}\right]O_2 & \longrightarrow & x\,CO_2 & + \frac{y}{2}H_2O(v) \\ 500 & & & 0 & 0 \\ 0 & & & 500x & \frac{y}{2}\times 500 \end{array}$$

Now, $500x = 2500$

$\therefore$ $x = 5$

$$\frac{500y}{2} = 3000$$

$\therefore$ $y = 12$

$\therefore$ Alkane is C_5H_{12}.

Start Practice for JEE Main

Round I (Topically Divided Problems)

Purification of Organic Compounds

1. In a solution, solvent can be separated from solute by one of the following process

(a) decantation (b) filtration
(c) distillation (d) sedimentation

2. Which of the following is useful for making pure water from a solution of salt in water?

(a) Filtration (b) Distillation
(c) Chromatography (d) Steam distillation

3. A mixture of oil and water is separated by

(a) filtration
(b) fractional distillation
(c) sublimation
(d) separating funnel

4. Fractional crystallisation is carried out to separate a mixture of

(a) organic solids mixed with inorganic solids
(b) organic solids slightly soluble in water
(c) organic solids having small difference in their solubilities in suitable solvent
(d) organic solids having great difference in their solubilities in suitable solvent

5. A mixture of iodine and sodium chloride can be easily separated by

(a) fractional distillation (b) steam distillation
(c) chromatography (d) sublimation

6. Anthracene is purified by

(a) filtration (b) distillation
(c) crystallisation (d) sublimation

7. A mixture of camphor and benzoic acid can be easily separated by

(a) sublimation
(b) extraction with solvent
(c) fractional crystallisation
(d) chemical method

8. A mixture of acetone and methanol can be separated by

(a) steam distillation (b) vacuum distillation
(c) fractional distillation (d) None of these

9. Fractional distillation is useful to obtain

(a) petroleum (b) coal tar
(c) crude alcohol (d) All of these

10. Sublimation is a process in which a solid

(a) changes into vapour form
(b) changes into another allotropic form
(c) changes into liquid form
(d) None of the above

11. Impure glycerine can be purified by

(a) steam distillation (b) simple distillation
(c) vacuum distillation (d) extraction with a solvent

12. The best and latest technique for isolation, purification and separation of organic compounds is **[NCERT]**

(a) crystallisation (b) distillation
(c) sublimation (d) chromatography

13. Absolute alcohol cannot be obtained by simple fractional distillation because

(a) pure C_2H_5OH is unstable
(b) C_2H_5OH forms hydrogen bonds with water
(c) boiling point of C_2H_5OH is very close to that of water
(d) constant boiling azeotropic mixture is formed with water

14. A mixture of iron fillings and sulphur cannot be separated by

(a) heating
(b) magnet
(c) shaking with CS_2
(d) washing in a current of water

15. Chromatography was discovered by

(a) Kekule (b) Pauling
(c) Rutherford (d) Tswett

16. Chromatography technique is used for the separation of
(a) small samples of mixture
(b) plant pigments
(c) dyestuff
(d) All of the above

17. Adsorbent is made of … in TLC.
(a) silica gel (b) alumina
(c) Both (a) and (b) (d) None of these

18. In paper chromatography
(a) mobile phase is liquid and stationary phase is solid
(b) mobile phase is solid and stationary phase is liquid
(c) Both phases are liquids
(d) Both phases are solids

19. Steam distillation is based on the fact that vaporisation of organic liquid takes place at
(a) lower temperature than its boiling point
(b) higher temperature than its boiling point
(c) its boiling point
(d) water and organic liquid both undergo distillation

20. Essential oils can be isolated by
(a) crystallization (b) steam distillation
(c) sublimation (d) distillation

21. Sublimation can't be used for the purification of
(a) benzoic acid (b) camphor
(c) urea (d) naphthalene

22. Which of the substance is purified by sublimation?
(a) Naphthalene (b) Benzoic acid
(c) Camphor (d) All of these

Qualitative Analysis of Organic Compounds

23. The sodium extract of an organic compound on acidification with acetic acid and addition of lead acetate solution gives a black precipitate. The organic compound contains
(a) nitrogen (b) halogen
(c) sulphur (d) phosphorus

24. Which of the following sodium compound/compounds are formed when an organic compound containing both nitrogen and sulphur is fused with sodium?
(a) Cyanide and sulphide
(b) Thiocyanate
(c) Sulphite and cyanide
(d) Nitrate and sulphide

25. The sodium extract of an organic compound on treatment with $FeSO_4$ solution, $FeCl_3$ and HCl gives a red solution. The organic compound contains
(a) both nitrogen and sulphur
(b) nitrogen only
(c) sulphur only
(d) halogen

26. Nitrogen containing organic compound when fused with sodium forms
(a) sodium azide (b) sodium cyanide
(c) sodamide (d) sodium cyanate

27. Lassaigne's test is used for the detection of
(a) carbon only
(b) hydrogen only
(c) oxygen only
(d) nitrogen, sulphur and halogens

28. In Lassaigne's test, the organic compound is fused with a piece of sodium metal in order to
(a) increase the ionisation of the compound
(b) decrease the melting point of the compound
(c) increase the reactivity of the compound
(d) convert the covalent compound into a mixture of ionic compounds

29. Copper wire test of halogens is known as
(a) Liebig's test (b) Lassaigne's test
(c) Fusion test (d) Beilstein's test

30. Which of the following statements is not applicable to Beilstein test?
(a) Green or bluish green flame is due to the formation of volatile cupric halides
(b) It does not tell us to which halogen is present in the organic compound
(c) It is a very sensitive test that can be easily performed
(d) It is a sure test for the presence of halogen

31. Detection of phosphorus in the compound can be done by its conversion into phosphate. Reagent to identify phosphate ion is
(a) sodium nitroprusside
(b) ammonium molybdate
(c) potassium ferrocyanide
(d) potassium ferricyanide

32. The presence of carbon in an organic compound is detected by heating it with
(a) sodium metal to convert it into NaCN
(b) CaO to convert it into CO which burns with a blue flame
(c) CuO to convert it into CO_2 which turns lime water milky
(d) Cu wire to give a bluish green flame

33. The sodium extract of an organic compound on boiling with HNO_3 and then adding of ammonium molybdate solution gives a yellow precipitate. The compound contains
(a) nitrogen (b) phosphorus
(c) sulphur (d) chlorine

34. In Lassaigne's solution, pink/violet colouration is produced when sodium nitroprusside solution is added. It indicates the presence of

(a) sulphur (b) nitrogen
(c) chlorine (d) None of these

35. Select the correct statement about the detection of element in the organic compounds.

(a) Sulphur present in the organic compound on fusion with sodium converts into $Na_2S_2O_3$
(b) $FeCl_3$ gives purple colour when added to the sodium fusion extract
(c) Sodium nitroprusside is used to detect the presence of sulphur
(d) All of the above

36. The function of boiling sodium extract with conc. HNO_3 before testing for halogen is

(a) to make the solution acidic
(b) to make the solution clear
(c) to convert Fe^{2+} to Fe^{3+}
(d) to destroy CN^- and S^{2-} ions

37. In the Lassaigne's test for nitrogen in an organic compound, the Prussian blue colour is obtained due to the formation of **[NCERT]**

(a) $Na_4[Fe(CN)_6]$ (b) $Fe_4[Fe(CN)_6]_3$
(c) $Fe_2[Fe(CN)_6]$ (d) $Fe_3[Fe(CN)_6]_4$

Quantitative Analysis of Organic Compounds

38. Carbon and hydrogen are estimated in organic compounds by

(a) Kjeldahl's method
(b) Duma's method
(c) Liebig's method
(d) Carius method

39. Percentage of hydrogen is maximum in

(a) C_2H_4 (b) CH_4
(c) C_2H_2 (d) C_6H_6

40. Duma's method involves the determination of nitrogen content in the organic compound in the form of

(a) NH_3 (b) N_2
(c) NaCN (d) $(NH_4)_2SO_4$

41. In the estimation of nitrogen by Duma's method, 1.18 g of an organic compound gave 224 mL of N_2 at NTP. The percentage of nitrogen in the compound is

(a) 20.0 (b) 11.8
(c) 47.7 (d) 23.7

42. In Kjeldahl's method for the estimation of nitrogen, the formula used to

(a) $\%\text{ of N} = \frac{1.4\,Vw}{N}$ (b) $\%\text{ of N} = \frac{1.4\,VN}{w}$
(c) $\%\text{ of N} = \frac{VNw}{1.8}$ (d) $\%\text{ of N} = \frac{1.4\,wN}{V}$

43. Mark the incorrect statement for Kjeldahl's method of estimation of nitrogen.

(a) Nitrogen gas is collected over caustic potash solution
(b) Potassium sulphate is used as boiling point elevator of H_2SO_4
(c) Copper sulphate or mercury acts as a catalyst
(d) Nitrogen is quantitatively decomposed to give ammonium sulphate

44. The simplest formula of a compound containing 50% of element X (at. wt. 10) and 50% of element Y (at. wt. 20) is

(a) XY (b) XY_2
(c) X_2Y (d) X_2Y_2

45. A compound containing 80% C and 20% H is likely to be

(a) C_6H_6 (b) C_2H_6
(c) C_2H_4 (d) C_2H_2

46. The empirical formula of an acid is CH_2O_2, the probable molecular formula of the acid may be

(a) $C_2H_4O_2$ (b) $C_3H_6O_4$
(c) $C_2H_2O_4$ (d) CH_2O_2

47. In the estimation of sulphur in an organic compound, fuming nitric acid is used to convert sulphur into

(a) SO_2 (b) H_2S
(c) H_2SO_3 (d) H_2SO_4

48. Phosphorus is estimated as

(a) Na_3PO_4 (b) P_2O_5
(c) P_2O_3 (d) $Mg_2P_2O_7$

49. 0.4 g of a silver salt of a monobasic organic acid gave 0.26 g pure silver on ignition. The molecular weight of the acid is (atomic weight of silver = 108)

(a) 58 (b) 37
(c) 89 (d) 105

50. An organic compound contains 29.27% carbon, 5.69% hydrogen and 65.04% bromine. Its empirical formula is

(a) C_3H_5Br (b) C_3H_3Br
(c) $C_2H_4Br_2$ (d) C_3H_7Br

51. The silver salt of a monobasic acid on ignition gave 60% of Ag. The molecular weight of the acid is

(a) 37 (b) 57
(c) 73 (d) 88

52. How much of sulphur is present in an organic compound, if 0.53 g of the compound gave 1.158 g of $BaSO_4$ on analysis ?

(a) 10% (b) 15%
(c) 20% (d) 30%

Miscellaneous

53. Molecular mass of a volatile substance may be obtained by

(a) Beilstein method
(b) Lassaigne method
(c) Victor Meyer's method
(d) Liebig's method

54. The most satisfactory method to separate sugars is to use

(a) fractional crystallisation
(b) chromatography
(c) Benedict's reagent
(d) Carius method

55. Incorrect statement is

(a) Aniline can be purified by steam distillation
(b) Beilstein test is not given by fluorine
(c) Kjeldahl's method is used for the estimation of sulphur
(d) Lassaigne's test is used in the qualitative detection of elements in organic compounds

Round II (Mixed Bag)

Only One Correct Option

1. During $AgNO_3$ test for detection of halogens, sodium extract is boiled with few drops of conc. HNO_3 to decompose

(a) NaCN (b) Na_2S
(c) Both (a) and (b) (d) None of these

2. In Carius method, 0.099 g organic compound gave 0.287 g AgCl. The percentage of chlorine in the compound will be

(a) 28.6 (b) 71.7
(c) 35.4 (d) 64.2

3. Red colour complex ion formed on adding $FeCl_3$ to sodium extract when N and S both are present in organic compound is

(a) $[Fe(CN)_6]^{4-}$ (b) $[Fe(CNS)]^{2+}$
(c) $[Fe(CNS)_2]^{+}$ (d) $[Fe(CN)_6]^{3-}$

4. Which of the organic compounds will give red colour in Lassaigne's test?

(a) NaCN

(b) $NH_2-\overset{\overset{S}{\|}}{C}-NH_2$

(c) $NH_2-\overset{\overset{O}{\|}}{C}-NH_2$

(d) None of these

5. In kjeldahl's method of estimation of nitrogen, $CuSO_4$ acts as

(a) oxidising agent
(b) reducing agent
(c) catalytic agent
(d) hydrolysis agent

6. 4 g of hydrocarbon on complete combustion gave 12.571 g of CO_2 and 5.143 g of water. What is the empirical formula of the hydrocarbon?

(a) CH (b) C_2H_3
(c) CH_2 (d) CH_3

7. Glycerol can be separated from spent-lye in soap industry by

(a) steam distillation
(b) fractional distillation
(c) distillation under reduced pressure
(d) ordinary distillation

8. The relative adsorption of each component of the mixture is expressed in terms of

(a) adsorption factor (b) retention factor
(c) co-factor (d) sorption factor

9. Which of the following elements can't be detected by direct tests?

(a) N (b) O (c) S (d) Br

10. Mixture of sugar and common salt is separated by crystallisation by dissolving in

(a) H_2O (b) C_2H_5OH
(c) C_6H_6 (d) None of these

11. A hydrocarbon contains 10.5 g carbon and 1 g hydrogen. Its 2.4 g has 1 L volume at 1 atm and 127°C. Hydrocarbon is

(a) C_6H_7 (b) C_6H_8 (c) C_5H_6 (d) C_6H_6

12. 0.5 g of hydrocarbon gave 0.9 g water on combustion. The percentage of carbon in the hydrocarbon is

(a) 60.6 (b) 28.8
(c) 80.0 (d) 68.6

13. An organic compound having carbon, hydrogen and sulphur contains 4% of sulphur. The minimum molecular weight of the compound is

(a) 500 (b) 800 (c) 400 (d) 100

14. When thiourea is heated with metallic sodium, the compound which can't be formed is

(a) NaCNS (b) NaCN

(c) Na_2SO_4 (b) Na_2S

15. If a compound on analysis was found to contain C = 18.5%, H = 1.55%, Cl = 55.04% and O = 24.81%, then its empirical formula is

(a) CH_2OCl (b) CH_2ClO_2 (c) $ClCH_2O$ (d) CHClO

16. An organic compound has carbon and hydrogen percentage in the ratio 6 : 1 and carbon and oxygen percentage in the ratio 3 : 4. The compound has the empirical formula

(a) C_2H_6O (b) CHO_2 (c) CH_4O (d) CH_2O

17. Percentage composition of an organic compound is as follows

$$C = 10.06, H = 0.84, Cl = 89.10$$

Which of the following corresponds to its molecular formula if the vapour density is 60.0?

(a) CH_3Cl (b) $CHCl_3$

(c) CH_2Cl_2 (d) None of these

18. The ammonia evolved from the treatment of 0.30 g of an organic compound for the estimation of nitrogen was passed in 100 mL of 0.1 M sulphuric acid. The excess of acid required 20 mL of 0.5 M sodium hydroxide solution for complete neutralization. The organic compound is

(a) acetamide (b) benzamide

(c) urea (d) thiourea

More than One Correct Option

19. Which of the following statement is correct?

(a) Impure glycerine can be purified by ordinary distillation

(b) Ethanol and water can't be separated from each other completely by simple distillation method as they form azeotropic mixture

(c) Two solid organic substances are said to be different if their mixed melting point is depressed below the melting points of both of these

(d) Naphthalene can be separated from benzoic acid by sublimation

20. Which of the following compounds can be purified by steam distillation?

(a) Nitrobenzene (b) Bromobenzene

(c) Salicylaldehyde (d) *p*-hydroxybenzaldehyde

21. Which of the following statements is/are correct?

(a) Liebig's method is used for the quantitative estimation of both C and H.

(b) Duma's method is used for the quantitative estimation of N in all nitrogen containing organic compounds.

(c) In Liebig's combustion method, ordinary CuO is used.

(d) Silver salt method is a chemical method for the determination of equivalent mass of organic acids.

22. Which of the following statements is/are correct?

(a) When a Lassaigne's solution is heated with HNO_3, cooled, and $AgNO_3$ solution is added, a yellow precipitate, partially soluble in NH_3 or NH_4OH, indicates the presence of iodine in organic compound.

(b) When $(CH_3COO)_2Pb$ solution is added to the acidified Lassaigne's extract of an organic compound having S, a black precipitate of PbS is formed.

(c) An organic compound containing N, on heating with conc. H_2SO_4 gives $(NH_4)_2SO_4$ which liberates NH_3 on treatment with excess of NaOH.

(d) The molecular mass of a non-volatile organic compound is determined either by Duma's method or by Victor Meyer's method.

23. Kjeldahl's method can't be used for the estimation of nitrogen in

(a) pyridine (b) $C_6H_5NO_2$

(c) $C_6H_5NHCOCH_3$ (d) $C_6H_5—N{=}N—C_6H_5$

Assertion and Reason

Directions (Q. No. 24 to 29) *Each of these questions contains two statements : Statement* I (*Assertion*) *and Statement* II (*Reason*). *Each of these questions also has four alternative choices, only one of which is the correct answer. You have to select one of the codes* (*a*), (*b*), (*c*), (*d*) *given below :*

(a) Statement I is true, Statement II is true; Statement II is a correct explanation for Statement I.

(b) Statement I is true, Statement II is true; Statement II is not a correct explanation for Statement I.

(c) Statement I is true; Statement II is false.

(d) Statement I is false; Statement II is true.

24. **Statement I** Benzoic acid is purified by sublimation process.

Statement II Sublimation process is very useful in separating a volatile solid from a non-volatile solid.

25. **Statement I** Essential oils are volatile and are insoluble in H_2O.

Statement II Essential oils are purified by steam distillation.

26. **Statement I** Hydroxylamine (NH_4OH) contains N, and hence gives Prussian blue colour in Lassaigne's test.

Statement II Hydroxylamine does not contain C, so with Na metal, $CN^{\ominus}$ ion is not formed.

27. **Statement I** Duma's method is more applicable to nitrogen containing organic compounds than Kjeldahl's method.

Statement II Kjeldahl's method does not give satisfactory results for compounds in which N is linked to O atom.

28. **Statement I** In Messenger's method, the colourless solution, the liquid is transferred to beaker and barium chloride is added to estimate sulphuric acid as $BaSO_4$ in the usual way.

Statement II If in an experiment 0.36 g of an organic compound gave 0.35 of $BaSO_4$, the percentage of sulphur in the compound is 13.35%.

29. **Statement I** The empirical formula of glucose is CH_2O which represents the relative number of atoms of each element present in the molecule.

Statement II In glucose, the elements C, H, O have combined in the ratio 1 : 2 : 1.

Comprehension Based Questions

Directions (Q. Nos. 30 to 32) In Carius method, a known mass of the organic compound is heated with excess of fuming HNO_3 and a few crystals of $AgNO_3$ in a sealed tube, called the Carius tube. C and H are oxidised to CO_2 and H_2O respectively and the halogens are converted into silver halides. The ppt. of silver halide is filtered, washed, dried and weighed. The percentage of halogen can be calculated from the mass of silver halide formed.

Percentage of

$$\text{Cl} = \frac{35.5}{143.5} \times \frac{\text{mass of AgCl formed}}{\text{mass of substance taken}} \times 100$$

Percentage of

$$\text{Br} = \frac{80}{188} \times \frac{\text{mass of AgBr formed}}{\text{mass of substance taken}} \times 100$$

Percentage of

$$\text{I} = \frac{127}{235} \times \frac{\text{mass of AgI formed}}{\text{mass of substance taken}} \times 100$$

30. When 0.35 g of an organic compound is heated with HNO_3 and $AgNO_3$ in a Carius tube, it gives 0.70 g of silver chloride. The percentage of chlorine in the compound is

(a) 54.8% (b) 49.47%
(c) 34.6% (d) 25.85%

31. Which of the following methods is used to estimate iodine in the laboratory?

(a) Duma's method (b) Liebig's method
(c) Kjeldahl's method (d) Carius method

32. 0.197 g of an organic substance when heated with excess of strong nitric acid and silver nitrate gave 0.3525g of silver iodide. The percentage of iodine in the compound is

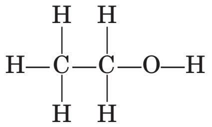
(a) 84.6% (b) 38.6%
(c) 96.68% (d) 53.86%

Directions (Q. Nos. 33 to 35) The molecular formula of a compound gives the actual number of atoms of each element present in a molecule of the compound. It is either the same as the empirical formula or a simple multiple of it.

$$\text{Molecular formula} = (\text{Empirical formula})_n$$

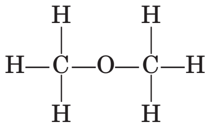
Where, n is a whole number and its value is obtained by dividing the molecular mass of the compound by its empirical formula mass.

Structural formula is that formula which shows in what way different kinds of atoms in a molecule are united or linked together.



$\mathrm{H-\underset{H}{\overset{H}{C}}-\underset{H}{\overset{H}{C}}-O-H}$

ethyl alcohol



$\mathrm{H-\underset{H}{\overset{H}{C}}-O-\underset{H}{\overset{H}{C}}-H}$

dimethyl ether

33. What is the molecular formula of a compound, its empirical formula is CH_2O and its molecular weight is 90?

(a) $C_3H_6O_3$ (b) $C_6H_6O_3$
(c) $C_4H_8O_4$ (d) $C_2H_6O_2$

34. An organic compound contains C = 40%, H = 13.33% and N = 46.67%. Its empirical formula would be

(a) CHN (b) C_2H_2N
(c) C_3H_7N (d) CH_4N

35. The empirical formula of a compound is CH_2. One mole of this compound has a mass of 42 g. Its molecular formula is

(a) C_2H_2
(b) C_3H_6
(c) C_3H_8
(d) CH_4

Previous Years' Questions

36. 29.5 mg of an organic compound containing nitrogen was digested according ot Kjeldahl's method and the evolved ammonia was absorbed in 20 mL of 0.1 M HCl solution. The excess of the acid required 15 mL of 0.1 M NaOH solution for complete neutralisation. The percentage of nitrogen in the compound is [AIEEE 2010]

(a) 59.0 (b) 47.4
(c) 23.7 (d) 29.5

37. An organic compound having molecular mass 60 is found to contain C = 20%, H = 6.67% and N = 46.67% while rest is oxygen. On heating it gives NH_3 along with a solid residue. The solid residue gives violet colour with alkaline copper sulphate solution. The compound is [AIEEE 2005]

(a) $CH_3CH_2CONH_2$ (b) $(NH_2)_2CO$
(c) CH_3CONH_2 (d) CH_3NCO

38. The compound formed in the positive test for nitrogen with the Lassaigne's solution of an organic compound is [AIEEE 2004]

(a) $Fe_4[Fe(CN)_6]_3$ (b) $Na_3[Fe(CN)_6]$
(c) $Fe(CN)_3$ (d) $Na_4[Fe(CN)_5NOS]$

Answers

the Guidance

Round I

1. Distillation is applied to separate a solute from the solvent if organic liquid is stable at its boiling point and contains a non-volatile impurity.

3. Oil and water are immiscible liquids, thus, are separated by using separating funnel.

4. Fractional crystallisation is used to purify organic solids which dissolve in a particular solvent, but their rate of solubility is slightly different.

5. Sublimation is the process employed for those solids which convert directly into vapours on heating without converting into liquid phase like I_2.

7. Camphor and benzoic acid both being sublimate cannot be separated by sublimation. Chemical reagents are used to separate such mixtures.

8. Acetone and methanol have nearly equal boiling point. Thus, they are separated by fractional distillation.

9. Fractional distillation is used for the separation of crude petroleum into various fractions like coal tar, crude alcohol and petroleum.

11. If a liquid decomposes at or below its boiling point like glycerine, it is purified by vacuum distillation.

12. Chromatography is the best and latest technique for the isolation, purification and separation of organic compounds.

13. The components of an azeotropic mixture are separated by special method, *i.e.,* azeotropic distillation. The simple fraction which distils at 337.8 K is a ternary azeotrope consisting of water, some alcohol and benzene.

14. On heating iron reacts with sulphur to give iron sulphide.

19. Organic compounds which are volatile in steam can be purified by steam distillation. It is based on the fact that vaporisation of organic liquid takes place at lower temperature than its boiling point.

21. Only urea does not sublime while naphthalene, camphor and benzoic acid do so.

23. The sulphur containing organic compounds when fused with sodium metal give Na_2S which react with lead acetate and forms black ppt. of PbS.

$$Na_2S + (CH_3COO)_2Pb \longrightarrow \underset{\text{black ppt}}{PbS} + 2CH_3COONa$$

24. When organic compound containing both nitrogen and sulphur is fused with sodium, sodium thiocyanate is formed.

$$Na + S + C + N \longrightarrow NaSCN$$

26. Organic compound containing nitrogen is fused with a small piece of sodium metal to form NaCN.

$$Na + \underbrace{C + N}_{\text{from organic compound}} \longrightarrow NaCN$$

30. If organic compound gives blue or green colour at the tip of red hot copper wire, this indicates the presence of halogens in the compound. However, compounds like urea, thiourea etc also give blue or green colour in this test even in the absence of halogens, thus, it is not a sure test for halogens.

31. Detection of phosphorus in the organic compound can be done by its conversion into phosphate. The ammonium molybdate is used to identify phosphate ion.

$$Na_3PO_4 + 3HNO_3 \longrightarrow H_3PO_4 + 3NaNO_3$$

$$H_3PO_4 + \underset{\text{ammonium molybdate}}{12(NH_4)_2MoO_4} + 21HNO_3 \xrightarrow{\Delta}$$

$$\underset{\text{yellow ppt.}}{(NH_4)_3PO_4 \cdot 12MoO_3} + 21NH_4NO_3 + 12\,H_2O$$

33. Phosphorus gives canary yellow precipitate with HNO_3 and ammonium molybdate.

$$\underset{\text{sod. extract}}{Na_3PO_4} + 3HNO_3 \longrightarrow H_3PO_4 + 3NaNO_3$$

$$H_3PO_4 + 12(NH_4)_2MoO_4 + 21HNO_3 \longrightarrow$$

$$\underset{\text{yellow ppt.}}{(NH_4)_3PO_4 \cdot 12MoO_3} + 21NH_4NO_3 + 12H_2O$$

34. $$\underset{\text{sod. extract}}{Na_2S} + \underset{\text{sodium nitroprusside}}{Na_2[Fe(CN)_5NO]} \longrightarrow \underset{\text{pink/violet colour}}{Na_4[Fe(CN)_5NOS]}$$

Thus, organic compound contains sulphur.

35. Sulphur is present in the sodium extract in the form of sodium sulphide (Na_2S).

$FeCl_3$ gives blood red colour with sodium extract having N and S both.

38. Carbon and hydrogen are estimated in organic compounds by Liebig's method.

$$C + 2CuO \xrightarrow{\Delta} 2Cu + CO_2$$

$$2H + CuO \xrightarrow{\Delta} Cu + H_2O$$

Percentage of carbon and hydrogen is calculated from the weights of CO_2 and H_2O produced.

39. CH_4 has highest ratio of H to C.

40. Duma's method involves the determination of nitrogen content in the organic compound in the form of N_2.

$$N_2O + Cu \longrightarrow N_2 + CuO$$

$$\%\text{ of N} = \frac{28}{22400} \times \frac{\text{volume of } N_2 \text{ at NTP}}{\text{weight of compound}} \times 100$$

41. $$\%\text{ of N} = \frac{28}{22400} \times \frac{\text{volume of } N_2 \text{ at NTP}}{\text{weight of compound}} \times 100$$

$$= \frac{28}{22400} \times \frac{224}{1.18} \times 100$$

$$= \frac{28}{1.18} = 23.72\%$$

43. In case of Kjeldahl's method the percentage of N_2 is then calculated from the amount of NH_3.

44.

Atom	At. mass (*a*)	% (*b*)	$\frac{b}{a}$	Simplest ratio
X	10	50	$\frac{50}{10} = 5$	2
Y	20	50	$\frac{50}{20} = 2.5$	1

Hence, empirical formula = X_2Y

46. Empirical formula of acid $= CH_2O_2$

We know that molecular formula $= n$ (empirical formula)

If $n = 1$, molecular formula $= (CH_2O_2)_1 = CH_2O_2$

If $n = 2$, molecular formula $= (CH_2O_2)_2 = C_2H_4O_4$

If $n = 3$, molecular formula $= (CH_2O_2)_3 = C_3H_6O_6$

Thus, the probable molecular formula $= CH_2O_2$

48. Phosphorus is estimated as $Mg_2P_2O_7$.

$$P \xrightarrow[\Delta]{HNO_3} H_3PO_4$$

$$H_3PO_4 + Mg^{2+} + NH_4OH \longrightarrow MgNH_4PO_4$$

$$2MgNH_4PO_4 \longrightarrow Mg_2P_2O_7 + H_2O + 2NH_3$$

$$\%\text{ of P} = \frac{62 \times \text{wt. of } Mg_2P_2O_7 \times 100}{222 \times w}$$

49. Mass of silver salt $= 0.4$ g

Mass of silver $= 0.26$ g

$$\frac{\text{Eq. mass of silver salt}}{\text{Eq. mass of Ag}} = \frac{\text{wt. of silver salt}}{\text{wt. of silver}}$$

$$\text{Eq. mass of silver salt} = \frac{108 \times 0.4}{0.26} = 166$$

$$\text{Eq. mass of acid} = 166 - 108 = 58$$

50. $C : H : Br = \frac{29.27}{12} : \frac{5.69}{1} : \frac{65.04}{80}$

$= 2.43 : 5.69 : 0.813$

$= 3 : 7 : 1$

or empirical formula $= C_3H_7Br$

51. $\frac{E}{108} = \frac{100}{60}$

Eq. wt. of the silver salt, $E = 108 \times \frac{100}{60} = 180$

$\therefore$ Eq. wt. of the acid $= E - 108 + 1 = 73$

52. $\% \text{ of S} = \frac{32}{233} \times \frac{\text{wt. of } BaSO_4}{\text{wt. of organic compound}} \times 100$

$$= \frac{32}{233} \times \frac{1.158}{0.53} \times 100 = 30\%$$

53. Victor Meyer's method is applicable only for the determination of molecular mass of volatile substances.

55. The correct statement is "Kjeldahl's method is used for estimation of nitrogen".

Round II

1. $NaCN + HNO_3 \xrightarrow{\Delta} HCN\uparrow + NaNO_3$

$Na_2S + 2HNO_3 \xrightarrow{\Delta} H_2S\uparrow + 2NaNO_3$

2. $\% \text{ of chlorine} = \frac{35.5}{143.5} \times \frac{\text{mass of AgCl}}{\text{mass of the compound}} \times 100$

$$= \frac{35.5}{143.5} \times \frac{0.287}{0.099} \times 100 = 71.71\%$$

3. When N and S both are present in the organic compound, a red colour complex ion $[Fe(CNS)]^{2+}$ is formed on adding $FeCl_3$ to sodium extract.

$$NaCNS + FeCl_3 \longrightarrow \underset{\text{blood red colour}}{[Fe(SCN)]Cl_2} + NaCl$$

4. In the Lassaigne's test, if organic compound consists of both N and S then a red colour is obtained on adding aqueous $FeCl_3$ to sodium extract.  $NH_2-\overset{\overset{\displaystyle S}{\|}}{C}-NH_2$ contains both N and S hence, it will give red colour in Lassaigne test.

$$NaCNS + FeCl_3 \longrightarrow \underset{\text{blood red colour}}{[Fe(SCN)]Cl_2} + NaCl$$

5. Kjeldahl's method is used for the estimation of nitrogen. The organic compound is heated with conc. H_2SO_4 in the presence of K_2SO_4 (used to raise boiling point of H_2SO_4) and $CuSO_4$ (used as catalyst) to convert all the nitrogen into $(NH_4)_2SO_4$.

6. $\% \text{ C} = \frac{12}{44} \times \frac{12.571}{4.0} \times 100 = 85.7$

$$\% \text{ H} = \frac{2}{18} \times \frac{5.143}{4.0} \times 100 = 14.3$$

The mole ratio of C to H is $\frac{85.7}{12} : \frac{14.3}{1}$

$$= 7.14 : 14.3 = 1 : 2 = CH_2$$

7. Glycerol can be separated from spent lye in soap industry by the distillation under reduced pressure because it decomposes near its boiling point.

8. In thin layer chromatography, the relative adsorption of each component of the mixture is expressed in terms of retention factor (R_f).

$$R_f = \frac{\text{distance moved by the spot centre from base line}}{\text{distance moved by the solvent from the base line}}$$

9. Oxygen cannot be detected by direct test because oxygen is present in atmosphere and all tests are carried in atmosphere of oxygen.

10. Common salt is not soluble in alcohol but sugar is.

11. $C = 10.5 \text{ g} = \frac{10.5}{12} \text{ mol} = 0.87 \text{ mol}$

$$H = 1 \text{ g} = \frac{1}{1} \text{ mol} = 1 \text{ mol}$$

$$\therefore \quad (C_{0.87}H_1)_7 = C_{6.09}H_7 \approx C_6H_7$$

$$pV = nRT = \frac{w}{m}RT$$

$$1 \times 1 = \frac{2.4}{m} \times 0.082 \times 400$$

$$m = 79$$

Hence, the hydrocarbon is C_6H_7.

12. $\% \text{ of H} = \frac{2}{18} \times \frac{\text{weight of } H_2O}{\text{weight of organic compound}} \times 100$

$$= \frac{2}{18} \times \frac{0.9}{0.5} \times 100 = 20\%$$

$\therefore$ The percentage of carbon $= 100 - 20 = 80\%$

13. As the minimum molecular weight must have at least one S atom, so

$$S\% = \frac{\text{wt. of one S atom}}{\text{min. mol. wt.}} \times 100$$

$$4 = \frac{32}{\text{min mol wt}} \times 100$$

$$\text{min. mol. wt.} = \frac{32 \times 100}{4} = 800$$

14. The chemical formula of thiourea is NH_2CSNH_2 so here Na_2S, NaCN and NaCNS will be formed but not Na_2SO_4.

15. $C : H : Cl : O = \frac{18.5}{12} : \frac{1.55}{1} : \frac{55.04}{35.5} : \frac{24.81}{16} = 1:1:1:1$

16. $C : H : O = 6 : 1 : 8$

$$= \frac{6}{15} \times 100 : \frac{1}{15} \times 100 : \frac{8}{15} \times 100$$

$$= 40 : 6.67 : 53.3$$

$$= \frac{40}{12} : \frac{6.67}{1} : \frac{53.3}{16}$$

$$= 1 : 2 : 1 \quad \textit{i.e.,} \quad CH_2O$$

17.

Atom	Atomic mass (*a*)	Percentage (*b*)	$\frac{b}{a} = x$	Ratio
C	12	10.06	$\frac{10.06}{12} = 0.83$	1
H	1	0.84	$\frac{0.84}{1} = 0.84$	1
Cl	35.5	89.10	$\frac{89.10}{35.5} = 2.50$	3

Empirical formula $= CHCl_3$

Empirical formula mass $= 12 + 1 + 106.5 = 119.5 \approx 120$

Molecular mass $= 2 \times VD = 2 \times 60 = 120$

$$n = \frac{\text{molar mass}}{\text{empirical formula mass}} = \frac{120}{120} = 1$$

Molecular formula $= (CHCl_3)_1 = CHCl_3$

18. Let unreacted 0.1 M (= 0.2 N) $H_2SO_4 = V$ mL

20 mL of 0.5 M NaOH $= V$ mL of 0.2 N H_2SO_4

$$20 \times 0.5 = V \times 0.2$$

$$V = \frac{20 \times 0.5}{0.2} = 50 \text{ mL}$$

Used $\quad H_2SO_4 = 100 - 50 = 50$ mL

$$\% \text{ of N} = \frac{1.4\,NV}{w} = \frac{1.4 \times 0.2 \times 50}{0.30}$$

$$= 46.67\%$$

% of nitrogen in

(a) $CH_3CONH_2 = \frac{14 \times 100}{59} = 23.73\%$

(b) $C_6H_5CONH_2 = \frac{14 \times 100}{121} = 11.57\%$

(c) $NH_2CONH_2 = \frac{28 \times 100}{60} = 46.67\%$

(d) $NH_2CSNH_2 = \frac{28 \times 100}{76} = 36.84\%$

19. Glycerine is purified by vacuum distillation. It boils with decomposition at 563 K but if pressure is lowered to 12 mm, it boils at 453 K without decomposition.

Naphthalene and benzoic acid both sublime thus cannot be separated by sublimation.

Other given statements are true.

20. The process of steam distillation is used for the separation and purification of liquids which are volatile in steam like nitrobenzene, bromobenzene, salicylaldehyde etc.

21. For this method dry CuO is used.

22. Test given in (a) indicates the presence of Br.

(d) Victor Meyer's method is used to determine the molecular mass of volatile organic compound. Duma's method is used to calculate the percentage of nitrogen.

23. Kjeldahl's method can't be used for the estimation of nitrogen in azo compounds and compounds containing nitrogen in the ring since these compounds are not completely converted into $(NH_4)_2SO_4$ during digestion.

24. In sublimation, certain substances like benzoic acid when heated, first directly convert from the solid to the vapour state without melting leaving behind the non-sublimates. The vapour when cooled, give back the pure solid substance.

25. Essential oils being steam volatile, are purified by steam distillation.

26. Hydroxylamine does not give positive test for N since it does not contain carbon. Thus, CN^- ion is not obtain which is essential condition for the test of nitrogen.

27. Both the given statements are correct.

28. Percentage of sulphur

$$= \frac{32}{233} \times \frac{0.35}{0.36} \times 100 = 13.35\%$$

29. The empirical formula of a compound is the simplest formula deduced from its percentage composition showing its composition by mass.

30. $\% \text{ of chlorine} = \frac{35.5}{143.5} \times \frac{\text{wt. of AgCl}}{\text{wt of organic compound}} \times 100$

$$= \frac{35.5}{143.5} \times \frac{0.70}{0.35} \times 100 = 49.47\%$$

31. Carius method is used to estimate iodine.

32. $\underset{(108\,+\,127)}{\text{AgI}} = \underset{127}{\text{I}}$

Thus, percentage of iodine $= \frac{127}{235} \times \frac{0.3525}{0.197} \times 100 = 96.68\%$

33. Empirical formula $= CH_2O$

Molecular weight $= 90$

Empirical formula weight of CH_2O

$$= 12 + (1 \times 2) + 16 = 30$$

$$n = \frac{\text{molecular weight}}{\text{empirical formula weight}} = \frac{90}{30} = 3$$

Molecular formula $= (CH_2O)_3 = C_3H_6O_3$

34. $C : H : N = \frac{40}{12} : \frac{13.33}{1} : \frac{46.67}{14} = 1 : 4 : 1$

So, empirical formula = CH_4N.

35. $CH_2 = 12 + 2 = 14$

$$n = \frac{42}{14} = 3 \text{ mol}$$

Formula $= (CH_2)_3 = C_3H_6$.

36. Weight of organic compound = 29.5 mg

$$NH_3 + HCl \longrightarrow NH_4Cl$$

$$\underset{\text{(remaining)}}{HCl} + \underset{\substack{15 \times 0.1\,M \\ = 1.5\text{ mmol}}}{NaOH} \longrightarrow NaCl + H_2O$$

Total millimole of HCl = 2

Millimole used by $NH_3 = 2 - 1.5 = 0.5$

$$\text{Weight of } NH_3 = 0.5 \times 17 \text{ mg} = 8.5 \text{ mg}$$

$$\text{Weight of nitrogen} = \frac{14}{17} \times 8.5 \text{ mg} = 7 \text{ mg}$$

$$\% \text{ of nitrogen} = \frac{7}{29.5} \times 100 = 23.7\%$$

37.

Element	Percentage	Percentage/at wt	Simple ratio
C	20.0	20.0/12 = 1.66	1.66/1.66 = 1
H	6.67	6.67/1 = 6.67	6.67/1.66 = 4
N	46.67	46.67/14 = 3.33	3.33/1.66 = 2
O	26.66	26.66/16 = 1.66	1.66/1.66 = 1

Empirical formula $= CH_4N_2O$

Empirical formula weight $= 12 + (4 \times 1) + (2 \times 14) + 16 = 60$

$$\therefore \quad n = \frac{\text{mol. formula weight}}{\text{emp. formula weight}} = \frac{60}{60} = 1$$

$\therefore$ Molecular formula $= CH_4N_2O$

Given compound gives biuret test. Thus, given compound is urea, $(NH_2)_2CO$.

38. If organic compound contains nitrogen, NaCN will be present in the sodium extract.

$$Na + C + N \xrightarrow{\text{Fuse}} NaCN$$

$$FeSO_4 + 6NaCN \longrightarrow \underset{\text{'}A\text{'}}{Na_4[Fe(CN)_6]} + Na_2SO_4$$

A changes to Prussian blue $Fe_4[Fe(CN)_6]_3$ on reaction with $FeCl_3$.

$$4FeCl_3 + 3Na_4[Fe(CN)_6] \longrightarrow Fe_4[Fe(CN)_6]_3 + 12NaCl$$

13

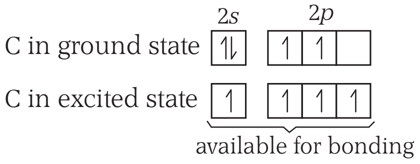
13.1 Tetravalency of Carbon

We are familiar with the fact that carbon is the essential element of all the organic molecules and its electronic configuration is 2,4, or $1s^2, 2s^2, 2p^2$. Two p-orbitals are half-filled, and hence, carbon is expected to exhibit a valency of two. But in all of its compounds, it exhibits tetravalency.

The tetravalency of carbon can be explained by the excited state concept *i.e.*, by moving one of the paired $2s$ electron to empty $2p$ orbital by gaining energy from the system (according to classical concept of bonding) however 4 equivalent C—H bonds in CH_4 is explained on the basis of concept of **hybridisation** (according to modern concept of bonding).



Being tetravalent carbon requires four electrons to complete its octet *i.e.*, to achieve a state of high stability. But it is not possible for carbon to accept or donate four electrons to achieve inert gas configuration (to achieve stability), due to energy conceptions. Thus, carbon always combines with other atoms by mutual sharing of electrons and thus, forms covalent bonds.

Compounds of carbon other than its oxides and carbonates are ***called organic compounds*** *and studied under separate branch of chemistry, called the* ***organic chemistry.***

Organic compounds are vital for sustaining life on the earth and include complex molecules like genetic information bearing DNA (deoxyribonucleic acid) and proteins.

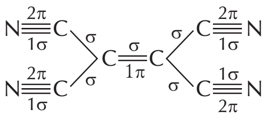
σ and π-Bonding in Organic Compounds

Carbon has a unique property that it can form both the types of covalent bonds, *i.e.,* the σ (called sigma, the bond formed by the linear or axial or end to end overlapping of orbitals) and the π (pi, the bond formed by the parallel or sidewise overlapping of orbitals) bonds. *A single bonds contains only one σ bond. Whereas there are one σ and one π bonds in case of a double bond and one σ and two π bonds in case of a triple bond.*

Sample Problem 1 *The number of σ and π bonds in tetracyanoethylene are respectively*

(a) 5, 1 (b) 9, 1 (c) 9, 9 (d) 9, 3

Interpret (c) The structure of tetracyanoethylene is as



(∵ Single bond contains only σ bond, double bond contains 1σ and 1π bond and triple bond contains 1σ and 2π bonds).

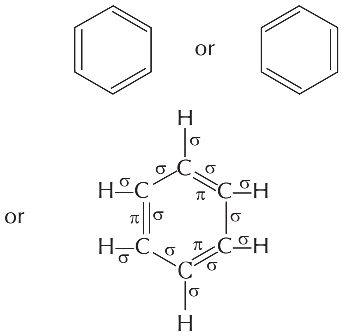
Therefore, there are 9σ and 9π bonds in tetracyanoethylene molecule.

Sample Problem 2 *The ratio of σ and π bonds in benzene is*

(a) 5 : 1 (b) 3 : 12

(c) 1 : 4 (d) 4 : 1

Interpret (d) The structure of benzene is as



In benzene,

number of sigma bonds = 12

number of pi bonds = 3

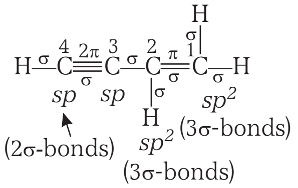
$$\therefore \quad \frac{\text{number of } \sigma \text{ bonds}}{\text{number of } \pi \text{ bonds}} = \frac{12}{3} = 4:1$$

Shapes of Simple Molecules : Hybridisation

The shapes of organic molecules can be decided by the number of σ bonds or concept of hybridisation. We know that organic compounds being covalent are the result of overlapping of orbitals of different elements.

Before overlapping with the orbitals of other element, the orbitals of an element intermix and give the orbitals of almost equal energy. This phenomenon is called hybridisation. Thus, *hybridisation can be defined as "Intermixing of orbitals of almost similar energy to form the same number of orbitals of exactly similar energy".* Because of the absence of *d*-orbitals, the carbon atoms show only three types of hybridisations depending upon the number of σ bonds formed in its compounds. *If there are four σ bonds, the hybridisation is sp^3, if three σ bonds, the hybridisation is sp^2 and if only two σ bonds, the hybridisation is sp.*

Usually saturated hydrocarbons are sp^3 hybridised while unsaturated hydrocarbons may be sp^2 or *sp* hybridised. This can be best understood by the following example. The complete structure of but-1-ene-3-yne is as



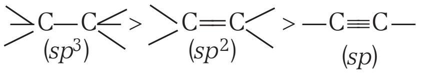
(π bonds give no contribution to hybridisation).

A sp^3 hybridised molecule is generally tetrahedral (if lone pairs are not present), a sp^2 hybridised molecule is generally trigonal planar and a *sp* hybridised molecule is planar.

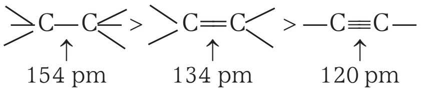
Bond parameters like bond length, bond angle etc, are affected by hybridisation. The effect of hybridisation on different bond parameters is discussed below.

(a) Bond Length

The size of *p*-orbitals is much larger as compared to the size of *s*-orbitals and a larger orbital forms a longer bond, therefore C—C sigma bond length increases as the number of *p*-orbitals (hybridised *p*-orbitals) increases. The carbon bonded through triple bond are *sp* hybridised (50% *p* character), and that bonded through double bond are sp^2 hybridised (66.7% *p*-character) whereas that bonded through single bond are sp^3 hybridised (75% *p*-character). The order of percentage of *p*-character is



Therefore, the order of bond length is also as



Similarly, a C—H bond in alkanes, alkenes and alkynes, may be formed by the overlap of a sp^3, sp^2 or sp-orbital of carbon atoms of alkanes, alkenes and alkynes respectively with an s-orbital of hydrogen, hence, as the size of the hybrid orbital decreases, the C—H bond lengths decrease accordingly.

$$\underset{111\text{ pm}}{C(sp^3)\text{—}H} > \underset{110\text{ pm}}{C(sp^2)\text{—}H} > \underset{108\text{ pm}}{C(sp)\text{—}H}$$

(b) Bond Strengths

Shorter the bond length, greater is the bond strength. Thus, the σ-bond formed by sp-hybridised carbon is the strongest (sp-orbital has highest electron density) while that formed by sp^3 hybridized carbon is the weakest (sp^3-orbital has lowest electron density). The bond energies of different C—H and C—C bonds follow the following order :

(i) $\underset{507\text{ kJ mol}^{-1}}{C(sp)\text{—}H} > \underset{443\text{ kJ mol}^{-1}}{C(sp^2)\text{—}H} > \underset{435\text{ kJ mol}^{-1}}{C(sp^3)\text{—}H}$

(ii) $\underset{433\text{ kJ mol}^{-1}}{C(sp)\text{—}C(sp)} > \underset{383\text{ kJ mol}^{-1}}{C(sp^2)\text{—}C(sp^2)} > \underset{347\text{ kJ mol}^{-1}}{C(sp^3)\text{—}C(sp^3)}$

(The above order is true only for C—C σ bonds.)

A carbon-carbon double bond because of the presence of a strong σ bond and a weak π bond is, however, stronger (598 kJ mol^{-1}) as compared to a carbon-carbon single bond which contains only a σ bond. Similarly, a carbon-carbon triple bond is still stronger (803 kJ mol^{-1}) as compared to a carbon-carbon double bond.

(c) Electronegativity

It varies directly with s-character but inversely with p-character, *i.e.*, greater the s-character of the hybrid orbitals, more is the electronegativity of the atom. Thus, the order of the electronegativity is as

Hybridisation	sp >	sp^2 >	sp^3
Electronegativity	3.3	2.75	2.5

(d) Bond Angles

As the s-character in hybridised orbital decreases, the bond angle also decreases. The bond angle is 180° in sp hybridisation; 120° in case of sp^2 hybridisation and, 109°28′ in case of sp^3 hybridisation.

Sample Problem 3 In *the organic compound* $CH_2{=}CH\text{—}CH_2\text{—}CH_2\text{—}C{\equiv}CH$, *the pair of hybridised orbitals involved in the formation of* $C_2\text{—}C_3$ *bond is* **[NCERT]**

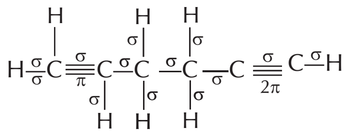
(a) $sp - sp^2$

(b) $sp - sp^3$

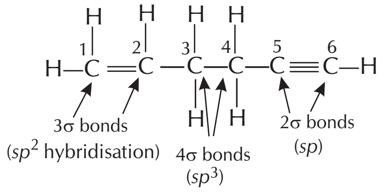
(c) $sp^2 - sp^3$

(d) $sp^3 - sp^3$

Interpret (c) To solve such problems first assign σ and π-bonds as



As we know π-bond does not contribute in hybridisation, count only the number of σ-bond and decide the hybridisation.



Thus, C_2 — C_3 bond involves sp^2-sp^3 hybridised orbitals.

Note : While numbering is done, $=$ bond is preferred over $\equiv$ bond. For details see rules of nomenclature.

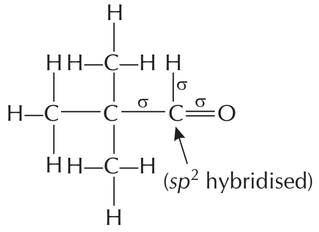
Sample Problem 4 *The compound in which carbon uses only* sp^3*-hybrid orbitals for bond formation is*

(a) $(CH_3)_3C\text{—}CHO$ (b) $(CH_3)_3C\text{—}OH$

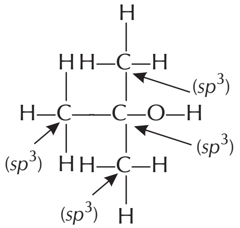
(c) NH_2CONH_2 (d) HCOOH

Interpret (b) The complete structures of the given compounds are as

(a)

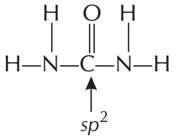


(b)

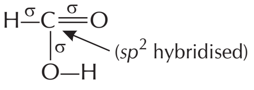


(All carbons are sp^3 hybridised)

(c)



(d)



Thus, $(CH_3)_3C\text{—}OH$ uses only its sp^3-hybrid orbitals for bond formation.

(**Remember** ! if no double or triple bonds are present in a molecule, the carbons of the molecules are usually sp^3 hybridised.)

Sample Problem 5 *A sp^3 hybrid orbital contains*

(a) $\frac{1}{4}$ *s-character* (b) $\frac{1}{3}$ *s-character*

(c) $\frac{1}{2}$ *s-character* (d) $\frac{2}{3}$ *s-character*

Interpret (a) $s\text{-character} = \frac{\text{part of } s\text{- character}}{\text{total character}} \times 100$

In sp^3 hybrid orbital,

$$s\text{-character} = \frac{1}{4} \times 100 = \frac{1}{4} \ s\text{-character}$$

Caution Point (*i*) *For p-character, use the formula,*

$$p\text{ - character} = \frac{\text{part of } p\text{-character}}{\text{total character}} \times 100$$

(*ii*) *Total means total number of orbitals and part means number of p-orbitals.*

Sample Problem 6 *Molecule having the longest bond distance between two adjacent carbon atoms is*

(a) *ethane* (b) *ethene*

(c) *ethyne* (d) *benzene*

Interpret (a) Higher the *p*-character, longer is the bond. In ethane ($CH_3—CH_3$) both the carbons are sp^3 hybridised, thus *p*-character is 75%. In ethene and benzene, the carbon atoms are sp^2 hybridised, thus percentage of *p*-character is 66.7. In ethyne, since carbons are *sp* hybridised, the *p*-character is 50%. Thus, due to the presence of highest *p*-character, C—C bond distance is longest in ethane.

13.2 Organic Compounds

More than a century ago all substances then known were classified on the basis of sources from which they were derived. The compounds which were of mineral origin were called **inorganic** and those of vegetable or animal origin were called **organic** (the word organic signifies life).

It was assumed that the organic compounds could be produced only by living matter inside their body. **Lavoisier** 'Father of Chemistry', in 1785, first of all showed that these organic compounds always contain C and H and frequently N and P. **Berzilius** assumed that some vital force (infact life force) was necessary to produce organic compounds and synthesis of these compounds in laboratory was impossible. (This concept was commonly named as **vital force theory).**

The vital force theory was suffered from death blow in 1828, when German chemist **Friedrich Wholer** heated ammonium cyanate (which was derived from inorganic substances) and obtained the organic compound **urea.** (The urea thus, formed was proved to be identical in all respects with urea isolated from urine).

$$\underset{\text{potassium cyanate}}{KOCN} + NH_4Cl \xrightarrow{\text{Heat}} KCl + \underset{\text{ammonium cyanate}}{NH_4OCN}$$

$$\xrightarrow{\text{Heat}} \underset{\text{urea}}{NH_2CONH_2}$$

This synthesis did not immediately break down the old concept of vital force. A further blow to vital force theory was given by **Kolbe** in 1845, when he synthesised acetic acid (CH_3COOH) (the first organic compound synthesised in laboratory from its elements) and afterwards by **Berthelot** (1865) who synthesised **methane.** Since, then a large number of organic compounds have been synthesised with their formation governed by simple laws of formation.

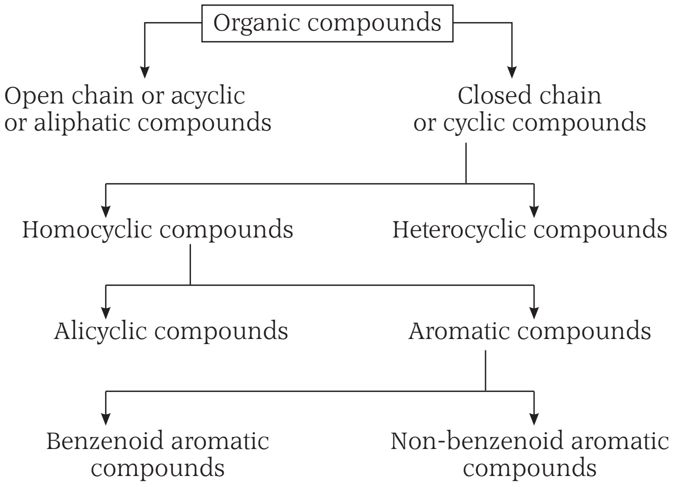
Although the original meaning of the term organic chemistry is no longer applicable, but this word has been retained because so many substances involved in organic chemistry do come directly or indirectly from living matter. In modern terms, **the organic compounds are defined as the hydrides of carbon** (hydrocarbons) **and their derivatives.**

13.3 Classification of Organic Compounds

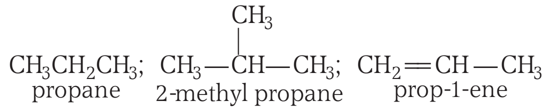
Due to the unique power of catenation in C-atom, organic compounds number in millions. In order to facilitate the study of such a large number of compounds, it is necessary to classify them. The organic compounds have been classified on the basis of **carbon skeleton** (structure) or **functional groups with the concept of homology.**

Classification Based on Structure

Depending on the structure, the organic compounds can be classified as :

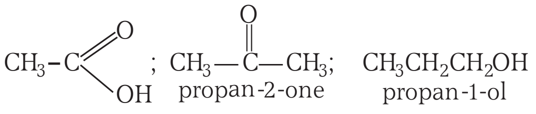


Some examples of aliphatic compounds are



$CH_3CH_2CH_3$; $CH_3-\overset{\overset{CH_3}{|}}{C}H-CH_3$; $CH_2=CH-CH_3$

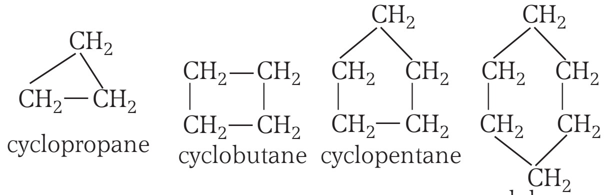
propane; 2-methyl propane; prop-1-ene



$CH_3-\overset{\overset{O}{\|}}{C}-CH_3$; $CH_3CH_2CH_2OH$

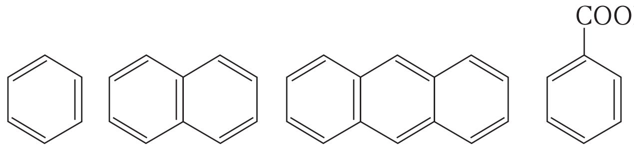
ethanoic acid; propan-2-one; propan-1-ol

Some examples of alicyclic compounds are



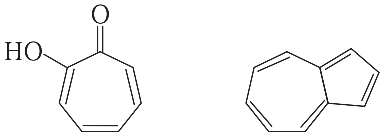
cyclopropane; cyclobutane; cyclopentane; cyclohexane

Some examples of benzenoid aromatic compounds are



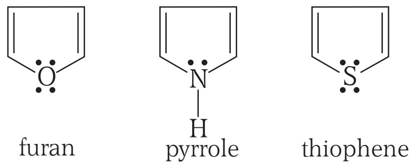
benzene (monocyclic); naphthalene (bicyclic); anthracene (tricyclic); benzoic acid

Some examples of non-benzenoid aromatic compounds are

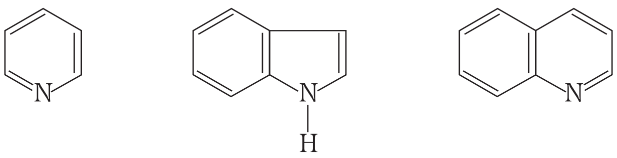


tropolone; azulene

Some examples of heterocyclic compounds are



furan; pyrrole; thiophene

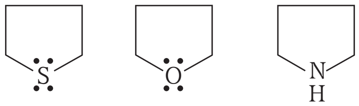


pyridine; indole; quinoline

Sample Problem 7 *Which of the following is alicyclic heterocyclic compound?*

(a) *Tetrahydrothiophene* (b) *Tetrahydrofuran*
(c) *Tetrahydropyrrole* (d) *All of these*

Interpret (d) All those compounds which contain a foreign atom like N, O, S (an atom other than carbon) are called alicyclic heterocyclic compounds. The structures of the given compounds are as



Hence, all these are alicyclic heterocyclic compounds.

Classification Based on Functional Group

The compounds of carbon and hydrogen, *i.e.*, hydrocarbon are considered as the parents of all the organic compounds because all other compounds are obtained from them by the replacement of one or more H-atoms with other atoms or groups.

$$\underset{\text{hydrocarbon}}{R-H}\xrightarrow[-X]{-H}\underset{\text{hydrocarbon derivative}}{R-Y}$$

Thus, all the organic compounds except hydrocarbons, carry two part; one hydrocarbon part (*R*) and other functional group (*Y*). The hydrocarbon part affects the properties whereas, functional group *Y* is responsible for chemical properties. Thus,

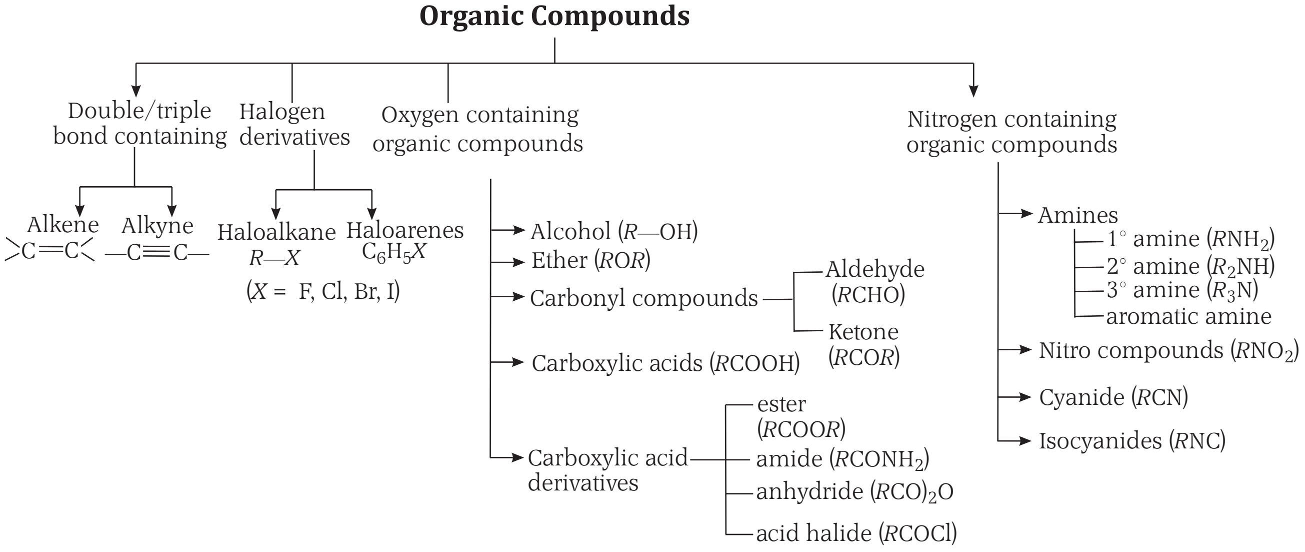
A functional group is an atom or group of atoms, in a molecule, which is responsible for the chemical properties of the molecule. e.g., Double and triple bonds are functional groups. Other examples include –Cl, –Br, –OH, $-NH_2$ etc., groups. In an organic molecule like

$$\boxed{R}-\boxed{F}\longrightarrow \text{functional group}$$

↙ hydrocarbon part

R— can be **alkyl** group (if hydrocarbon portion belongs to alkane *i.e.*, contains only single bond) or **alkenyl** group (if hydrocarbon portion belongs to alkene *i.e.*, contains at least one double bond) or **alkynyl** group (if hydrocarbon portion belongs to alkynes, *i.e.*, contains atleast one triple bond). Each functional group have its own characteristic reactions and by recognising the functional group in a molecule, it is possible to predict the reaction, which that molecule will undergo.

On the basis of functional groups, the organic compounds are classified as



An organic molecule can contain more than one functional group and then said to be **poly-functional.** In poly-functional compounds properties of each functional group may be modified by the presence of the other.

13.4 Homologous Series

Homologous series is a series of compounds in which adjacent members differ by a —CH_2 unit. The individual members are called **homologues,** *e.g.,* the homologous series of alcohols is as follows

CH_3OH	Methyl alcohol
CH_3CH_2OH	Ethyl alcohol
$CH_3CH_2CH_2OH$	Propyl alcohol
$CH_3CH_2CH_2CH_2OH$	Butyl alcohol
$CH_3CH_2CH_2CH_2CH_2OH$	Pentyl alcohol

The general characteristics of a homologous series are

1. All the members of a series contain same elements and the functional group.
2. All the members can be represented by a single general formula. *e.g.,* C_nH_{2n+2} is the general formula for alkanes.

   $C_nH_{2n+1}OH$ is the general formula for alcohols.
3. The molecular formula of each homologue differs from its previous and successive member by —CH_2 unit, *i.e.,* their molecular mass differs by 14 units.
4. All members of a series can be prepared by almost similar methods.
5. There is a gradual variation seen in physical properties of compounds with increasing molecular weight belonging to same homologus series.
6. All the members of a series show almost similar chemical properties.

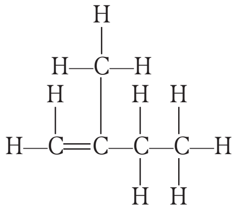
Note For isomerism see the next chapter, chapter 14.

13.5 Structural Representation of Organic Compounds

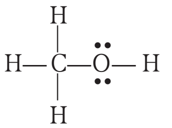
There are following three ways by which an organic compound can be represented. These are complete, condensed and bond line notations.

Complete Notation

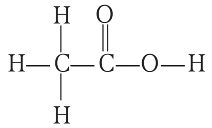
Complete structure means all the bonds (either single or double or triple) present between any two atoms are shown clearly. *e.g.,* the complete structure of 2-methyl butene is as



Similarly, the complete structures of methanol and acetic acid are as



(methanol)



(acetic acid)

Condensed Structure

When all the bonds (except double and triple bonds between two carbon atoms) are omitted, the obtained structure is called condensed structure.

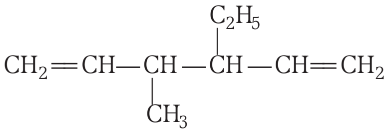
e.g., $CH_2{=}\underset{\underset{CH_3}{|}}{C}{-}CH_2CH_3$; CH_3OH ; CH_3COOH

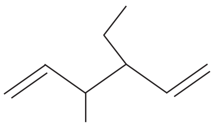
(methanol) (acetic acid)

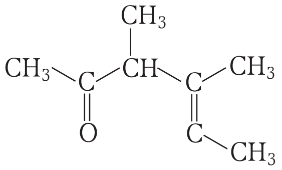
Bond Line Notation

It is a simple and convenient method of representing structures. In this notation bonds are represented by lines and C-atoms by line ends and intersections. It is assumed that required number of H-atoms are present wherever, they are necessary (to satisfy tetravalency of carbon), *e.g.,*

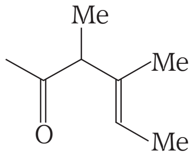


$CH_2{=}CH{-}\underset{\underset{CH_3}{|}}{CH}{-}\overset{\overset{C_2H_5}{|}}{CH}{-}CH{=}CH_2$ can be represented as

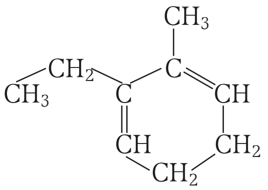




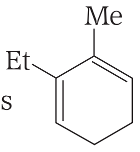
can be written as



Me = Methyl



can be written as



Et = ethyl

13.6 Systems of Nomenclature of Organic Compounds

Trivial System

It is the oldest system of naming organic compounds. These names have no part used in a systematic sense, whenever a new compound was discovered, it was given an individual name. Such a name was assigned at the wish of discoverer and had no system. These names are also called **common names** and are generally based on the source or some property or any other reason. Quite frequently these names had their Latin or Greek roots, *e.g.,*

(i) Acetic acid (*Acetum* = Vinegar). Vinegar is liquid which contain CH_3COOH as its chief constituent.
(ii) Oxalic acid (derived from *Oxalus*)
(iii) Malic acid (derived from *Pyrus malus*)
(iv) Citric acid (derived from *Citrus*)
(v) Formic acid (first obtained from red ants *Formicus*)
(vi) Urea and uric acid (from urine in which both are present)
(vii) Methyl alcohol (from methu hul means wine alcohol)
(viii) Butyric acid (from butyrum *i.e.*, butter)

Semisystematic or Semitrivial System

It is a name in which at least one part is used in a systematic sense, *e.g.,*

Glycer(ol), Acet(one), Styr(ene), 5-α-cholest(ane)

Here, words in brackets are used in systematic sense.

As these names are derived from two sources, hence these are also called **derived names.**

IUPAC System

In 1957, the International Union of Pure and Applied Chemistry evolved a scheme for giving systematic name to organic compounds on the basis of their structure. This is known as the **IUPAC system of nomenclature.** This system has set of rules for naming organic molecules from their structure. One organic compound can have only one IUPAC name and it is always superior to all common and derived names. After knowing the IUPAC names it is possible to draw the structures of organic compounds also. Remember IUPAC amends these rules from time to time and in this book we are following the 1993 (most recent) recommendations of IUPAC nomenclature.

13.7 IUPAC System of Nomenclature

Rules for Writing IUPAC Names

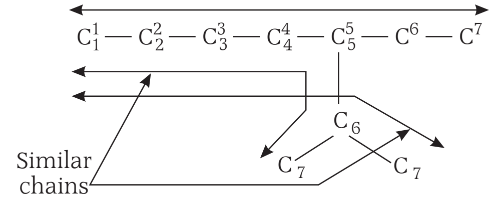
Following rules are followed while giving IUPAC *name to an organic compound.*

Longest Chain Rule

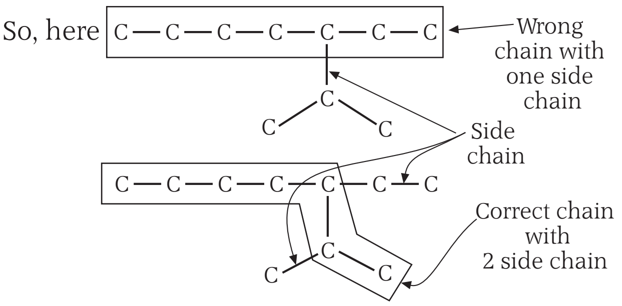
The longest possible chain can be selected in accordance with the following rules

1. Normally the chain with maximum number of C–atoms will be the longest possible chain.

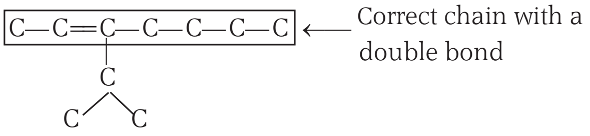
2. In case of two or more chains with same number of C–atoms, select the chain with maximum number of side chains as the longest possible chain. (IUPAC prefers such a situation to avoid complicated names), *e.g.,*



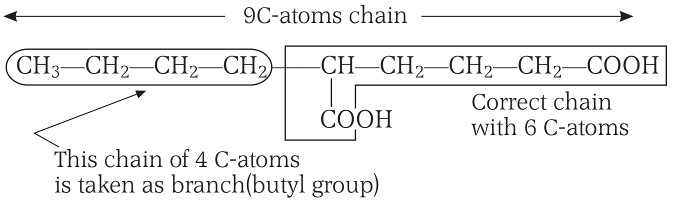
In this example, all the 3 chains possible contain 7 C-atoms in them. Out of these 3, two chains are similar as seen in diagram.



3. If a double bond/triple bond/functional group is present in the molecule, it must be included in the longest possible chain, *e.g.,*



4. Avoid the longest chain rule even if the chain containing multiple bonds or functional group falls smaller than other chains (the rule of exception), *e.g.,*



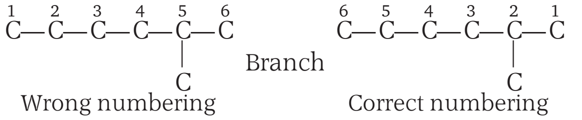
In this particular case although the longest chain is of 9 C-atoms (see figure) but the preference will be given to the chain of 6 C-atoms.

So, the longest possible chain can be defined as *"the chain containing the principal functional group + secondary functional group + multiple bonds as many as possible"*.

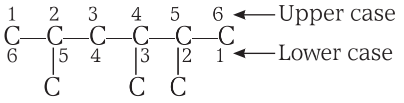
Rules of Numbering the Longest C-Chain

In numbering a chain following rules are considered

1. Numbering can be done from either of its ends for a symmetrical compound.
2. If single branch (side chain) is present in the compound then numbering must be done in such a manner so that the side chain acquires the least possible number, *e.g.,*



3. If more than one side chains are present in the compound and if
   (i) All the chains are of same length, then numbering must be done in accordance with **lowest sum rule** *i.e.,* numbering should be done in such a way that the sum of numbers of side chains will be the least, *e.g.,*



Sum

for upper case 2 + 4 + 5 = 11 (wrong numbering)

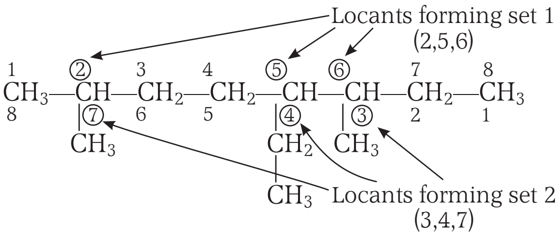
for lower case 2 + 3 + 5 = 10 (correct numbering)

Here, as the sum of lower case is lowest that is why, it is preferred.

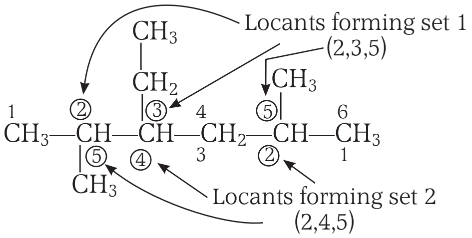
   (ii) In case of branches of different lengths, the numbering must be done in accordance with **"lowest set of locants rule".** (The word "locant" is used by IUPAC for those C-atoms in a chain which bear a branch or a multiple bond or a functional group).

According to this rule "while comparing two or more different sets of locants containing the same number of terms *then that set of locants is lowest which when compared term by term has the lowest term at the first point of difference, e.g.,*

***Case* 1** Suppose in a chain two sets of locants come as (2, 5, 6) and (3, 4, 7) then the first set will be preferred because the first term, *i.e.,* 2 in the first set is lower than the first term in the second set, *i.e.,* 3.

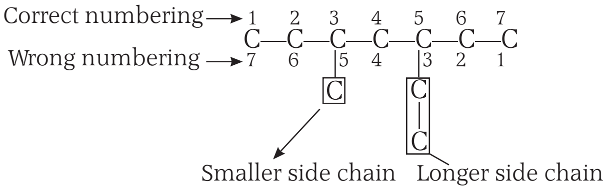


***Case* 2** Similarly, suppose, if 2 sets of locants come as (2, 3, 5) and (2, 4, 5) then here again first set is preferred because the second term (first term is being same in both the sets) in the first set is smaller.

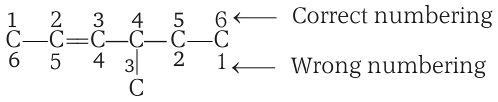


Now, from the above two examples it is clear that we are comparing the set of locants one by one and that set of locants is preferred which has a lower number at the first point of difference. That's why the rule is also called sometimes as **first point of difference rule.**

(iii) If the side chains of different lengths are present at the same distance from the ends, then the chain with lesser number of carbon atoms must get the least possible number, *e.g.,*

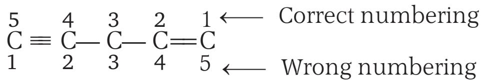


4. If multiple bond* is present alongwith the side chain then numbering must be done in such a manner that multiple bond will get the lowest possible number, *e.g.,*

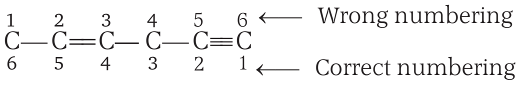


*multiple bond ⇒ double bond or triple bond

5. If double bond and triple bond both are present in the compound then double bond must be preferred.

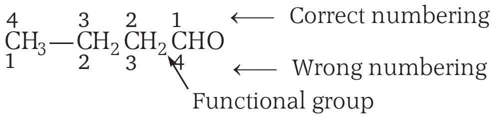


Remember here, the comparison can be made only if the bonds are present on the same footings i.e., situated at equal distance from the ends. e.g.,

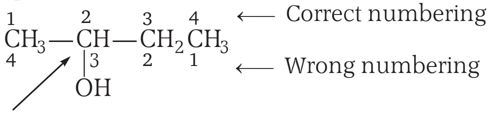


In the above example, triple bond and single bonds are not present at the same footings. Hence, out of these two, triple bond will be preferred *i.e.,* numbering must be done in such a manner that the triple bond will get least possible number.

6. If any other functional group is present in the compound (other than multiple bond) then numbering must be done in such a manner that the functional group will get the lowest possible number, *e.g.,*



The above example is for those functional groups which contain C-atom in them. For those functional groups which does not contain C-atom in them, the example is written below



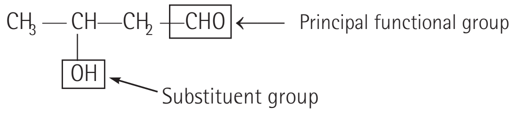
Here, this C-atom is considered as C-atom of functional group and this must get least possible number.

7. If more than one functional groups are present in the compound then the group which comes first in the following preferential order will be considered as **principal functional group** and rest of the functional groups are considered as **substituent groups or branch.**

The order of priority of various functional groups are as

1. Radicals
2. Anions
3. Cations
4. Zwitter ionic compounds
5. Acids (in the order COOH then their S and Se derivatives followed by sulphonic, sulphinic, selenonic, etc., phosphonic, arsonic, etc., acids)
6. Anhydrides
7. Esters
8. Acid halides
9. Amides
10. Hydrazides
11. Imides
12. Nitriles
13. Aldehydes followed by thioaldehydes, selenoaldehydes and telluroaldehydes.
14. Ketones followed by thioketones, selenoketones and telluroketones.
15. Alcohols and phenols followed by thiols, selenols and tellurols.
16. Hydroperoxides followed by thiohydroperoxides, selenohydroperoxides and tellurohydroperoxides.
17. Amines
18. Imines
19. Hydrazines, phosphanes, etc.,
20. Ethers followed by sulphides, selenides and tellurides
21. Peroxides followed by disulphides, diselenides and ditellurides.
22. Alkene
23. Alkyne
24. Halo, nitroso, nitro, alkoxy
25. Oxiranes (cyclic ethers)

The name of principal functional group must be written in suffix and that of substituent groups or branch is written in prefix. *e.g.,*



Hot Spot 1

WRITING the IUPAC Names

Naming an organic compound is an important topic for JEE Main examination point of view. The nature of question may vary from very simple to typical or confusing. A small practice can help you to solve the problem.

Following steps are used to write the IUPAC name of an organic compound :

Step I Locate the longest chain with as many possible secondary functional groups alongwith multiple bonds (*i.e.,* choose the longest possible chain).

Step II Select the word root corresponding to the length of longest possible chain. For one to four carbon atoms, special word roots are used whereas, for five or more carbon atoms, Greek numericals are used. The word roots alongwith the number of carbon atoms are tabulated below

Table 13.1 **Word Root Representing C-Atoms**

Chain length	Word root	Chain length	Word root
C_1	Meth–	C_7	Hept–
C_2	Eth–	C_8	Oct–
C_3	Prop–	C_9	Non–
C_4	But–	C_{10}	Dec–
C_5	Pent–	C_{11}	Undec–
C_6	Hex–	C_{12}	Dodec–

Step III Number the longest possible chain (according to the rules) to give an identification number to each C-atom of longest possible chain.

Step IV Add suitable prefixes and suffixes alongwith numerals to indicate the number and position of each side chain, substituent or functional group present in compound.

Prefix *It is used to indicate the substituents and is of the following two types*

(i) **Primary prefixes** are those prefixes which are usually used to distinguish between cyclic and acyclic compounds just like cyclo, bicyclo etc., or the prefixes used to tell us about the number of substituents present just like bi, di, tri, tetra, tris, tetrakis, ter, quater etc.

(ii) **Secondary prefixes** are infact the names of those groups to which IUPAC consider as substituents or branch either always (*e.g.,* halogens) or under certain conditions *i.e.,* whenever principal functional group is present alongwith the substituents in polyfunctional compounds. These prefixes are always written immediately before the root word. Some of these prefixes are given below

Table 13.2 **Prefixes for Substituents**

Substituent	Prefix	Substituent	Prefix
—F	Fluoro	—N═N—	diazo
—Cl	Chloro	—N ═O	nitroso
—Br	Bromo	$—NO_2$	nitro

Note The prefix used for functional group are given later alongwith their suffix.

Suffix It is used to indicate the functional group. The suffix also may be of two types

(i) **Primary suffixes** are those words which tells us about the saturation or unsaturation of longest possible chain. The three basic primary suffixes are

–ane for saturated chain,

–ene for unsaturated chain with a double bond,

–yne for unsaturated chain with a triple bond.

(ii) **Secondary suffixes** are infact the names of principal functional groups either in monofunctional or in polyfunctional compounds. These are given in the following table.

Table 13.3 **Prefix and Suffix of Various Functional Groups** (in priority order)
(as given under the 1993 recommendations of IUPAC)

S. No.	Class	Formula	Prefix	Suffix
1.	Carboxylic acids	—COOH	carboxy-	–carboxylic acid
		—(C)OOH	—	–oic acid
2.	Sulphonic acids	$—SO_2—OH$	sulpho-	–sulphonic acid
3.	Esters (of carboxylic acids)	—COOR*	(R*)-oxy-carbonyl	(R*)… carboxylate
		—(C)OOR*	(R*)-oxycarbonyl	(R*)…oate

S. No.	Class	Formula	Prefix	Suffix
4.	Acid halides	 $-\overset{O}{\overset{\|}{C}}-X$, $-\overset{O}{\overset{\|}{(C)}}-X$ where, X = halogen	halocarbonyl – —	–carbonyl halide –oyl halide
5.	Amides	$-CO-NH_2$ $-(C)O-NH_2$	carbamoyl– —	–carboxamide –amide
6.	Nitriles	$-C\equiv N$ $-(C)\equiv N$	cyano– —	–carbonitrile –nitrile
7.	Aldehydes	$-CHO$ $-(C)HO$	formyl– —	–carbaldehyde –al
8.	Ketones	$(C)=O$	oxo	–one
9.	Alcohols, Phenols	$-OH$	hydroxy–	–ol
10.	Thiols	$-SH$	sulphanyl-	–thiol
11.	Amines	$-NH_2$	amino–	–amine
12.	Imines	$=NH$ $=NR^*$	imino– (R^*)-imino	–imine
13.	Ethers	$-OR^*$	(R^*)-oxy	–

***In the above table R designates any alkyl group and C-atom in ( ) means when it is included in the main chain while C-atom without ( ) means it is not included in the main chain.**

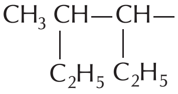
Hence, with the help of steps given above the IUPAC name of a compound can be written as

Prefixes	+	Root word	+	Suffixes
Tells us about the branches or substituents except in the case of multiple bonds		Tells us about the length of longest possible chain		Tells us about the principal functional groups mostly except in the case of halogens

OR

Primary prefix + Secondary prefix + Root word + Primary suffix + Secondary suffix

Sample Problem 8 *Correct IUPAC name for*



$$CH_3\,\underset{\large C_2H_5}{\underset{|}{CH}}-\underset{\large C_2H_5}{\underset{|}{CH}}-CH_3$$

is **[NCERT Exemplar]**

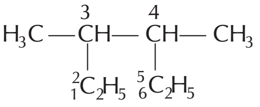
(a) 2-ethyl-3-methylpentane

(b) 3,4 -dimethyl hexane

(c) 2-sec-butyl butane

(d) 2,3- diethyl butane

Interpret (b) In the given compound first of all we choose the longest chain and choose the root word accordingly.



$$H_3C-\overset{3}{\underset{{}^{2}_{1}C_2H_5}{\underset{|}{CH}}}-\overset{4}{\underset{{}^{5}_{6}C_2H_5}{\underset{|}{CH}}}-CH_3$$

Six carbon : Root word = hex

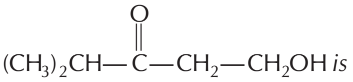
Only single bonds are present and no other functional group is present. So, suffix (ane) is added to the root word.

Moreover, this compound contains two substituents ($-CH_3$) at position 3 and 4, so their prefix with position number are used.

Hence, the name of the given compound is

$$\underbrace{3,4-\text{dimethyl}}_{\text{prefix}}\ \underbrace{\text{hexane}}_{\text{root word suffix}}$$

Sample Problem 9 *The IUPAC name of the compound*



$$(CH_3)_2CH-\overset{O}{\overset{\|}{C}}-CH_2-CH_2OH$$

is

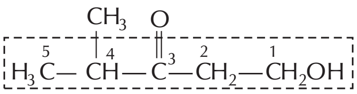
(a) *hexanol*-1-*one*-3

(b) 2-*methyl*-5-*hydroxy*-3-*pentane*

(c) 1-*hydroxy*-4-*methyl*-3-*pentanone*

(d) 4-*methyl*-3-*oxo*-1-*pentanol*

Interpret (d)



$$\overset{5}{H_3C}-\overset{CH_3}{\overset{|}{\underset{4}{CH}}}-\overset{O}{\overset{\|}{\underset{3}{C}}}-\overset{2}{CH_2}-\overset{1}{CH_2OH}$$

Number of C in longest chain = 5 so Root word pent. All bonds between C are single bond so suffix 'ane'. Although $C=O$ have priority but both sides its position is 3 so —OH is taken in main chain. For —OH suffix is –ol.

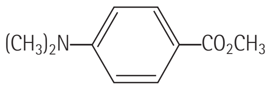
For $>C=O$ prefix is –oxo

Thus, the name of the compound is 4-methyl-3-oxo-1-pentanol.

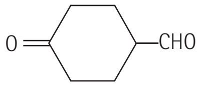
Check Point 1

1. Why carbon cannot exhibit dsp^3, sp^3d etc., hybridisations?
2. $CH\equiv CH$ is more electronegative as compared to $CH_2=CH_2$ Explain.
3. Circle the functional group with highest priority in each structure below.

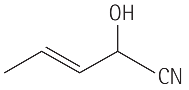
(i)



(ii)



(iii)



4. Provide the systematic name of the following common names (i) propyl bromide, (ii) ethyl methyl ether, (iii) ethyl iodide
5. Between the 2, 5, 6-trimethyl heptane and 3, 4, 7-trimethyl heptane which one is correct? Explain why?

13.8 Functional Groupwise Nomenclature

After the study of rules and steps for writing IUPAC name, you can write the name of any class of compound but here with we are giving a detail of nomenclature of different classes step by step.

Hydrocarbons

Hydrocarbons are the compounds that contain carbon and hydrogen only.

These are of the following types

(a) Alkanes

Alkanes are the hydrocarbons that contain only single bonds (saturated). The first four members of the series are known by their common names *i.e.*, **methane, ethane, propane** and **butane.** The names of larger alkanes are derived from the Greek prefixes that indicate the number of C-atoms in the molecule, *e.g.*, pentane (with 5 C-atoms), hexane (with 6 C-atoms) and so on.

Infact the names of the alkanes are obtained by adding '–ane' to the root word.

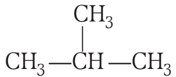
Root word + -ane = alkane

In the common system all isomeric alkanes have the same parent name, *e.g.*, two isomeric C_4H_{10} alkanes are known as butanes. The names of various isomers are distinguished by prefixes. The prefix indicates the type of branching present in the molecule.

1. **Prefix *n*** is used for those alkanes in which all carbons are in one continuous chain. The prefix *n*-stands for normal or straight chain of carbon atoms. *e.g.*,

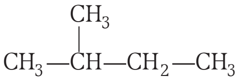
$CH_3CH_2CH_2CH_3$ *n*-butane $CH_3CH_2CH_2CH_2CH_2CH_3$ *n*-hexane

2. **Prefix *iso*** is used for those alkanes which have a methyl group $—CH_3$ attached to the second last carbon atom of the continuous chain. *e.g.*,



$$CH_3-\overset{\overset{CH_3}{|}}{C}H-CH_3$$

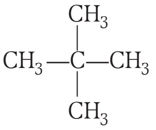
iso-butane



$$CH_3-\overset{\overset{CH_3}{|}}{C}H-CH_2-CH_3$$

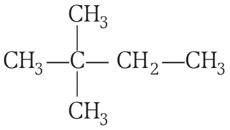
iso-pentane

3. **Prefix *neo*** is used for those alkanes which have two methyl groups attached to the second last carbon atom of the continuous chain. *e.g.*,



$$CH_3-\underset{\underset{CH_3}{|}}{\overset{\overset{CH_3}{|}}{C}}-CH_3$$

neo-pentane



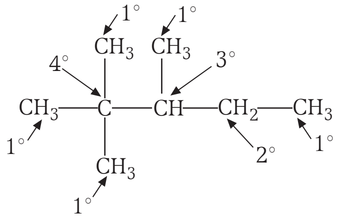
$$CH_3-\underset{\underset{CH_3}{|}}{\overset{\overset{CH_3}{|}}{C}}-CH_2-CH_3$$

neo-hexane

However, IUPAC does not recognise these prefixes.

The structural formula of alkanes contain four types of carbons

1. **Primary carbon** (or 1° carbon atom) is the carbon atom which is attached to one or no other carbon atom.
2. **Secondary carbon** (or 2° carbon atom) is the carbon atom that is attached to two other carbon atoms.
3. **Tertiary carbon** (or 3° carbon) atom is the carbon atom that is attached to three other carbon atoms.
4. **Quaternary carbon** (or 4° carbon) atom is the carbon atom which is attached to four other carbon atoms.



Hydrogen atoms attached to 1°, 2°, 3° carbon atoms are often referred to as primary, secondary and tertiary hydrogen atoms.

However, names of these carbon and hydrogen atoms are not recognised by IUPAC.

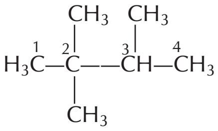
Caution Point *When a hydrogen atom is removed from an alkane, the remaining group is called alkyl group and represented by 'R' e.g.,* $—CH_3$ *(methyl group) is obtained by removing one H-atom from methane* (CH_4).

Sample Problem 10 *In the structure,*

$\overset{1}{H_3C}-\overset{2}{C}(CH_3)_2\overset{3}{C}H(CH_3)\overset{4}{C}H_3$, *which one is a quaternary carbon atom?*

(*a*) C-1 (*b*) C-2 (*c*) C-3 (*d*) C-4

Interpret (*b*) Quaternary carbon is the carbon atom which is attached with four other carbon atoms.



$$H_3\overset{1}{C}-\underset{CH_3}{\overset{CH_3}{\overset{2}{C}}}-\overset{CH_3}{\overset{3}{C}}H-\overset{4}{C}H_3$$

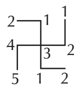
Structure shows that C-2 is attached with four other carbon atoms, so it is a quaternary carbon atom.

Sample Problem 11 *The correct IUPAC name for*

is

(*a*) *neo-nonane* (*b*) *tetraethylmethane*
(*c*) *3-ethylpentane* (*d*) *3,3-diethylpentane*

Interpret (*d*)



Hence, its IUPAC name is 3,3-diethylpentane.

(b) Alkenes

Alkenes are hydrocarbons that contain one or more carbon-carbon double bond. Their common names are obtained by changing the ending **–ane** to **–ene**. *i.e.,*

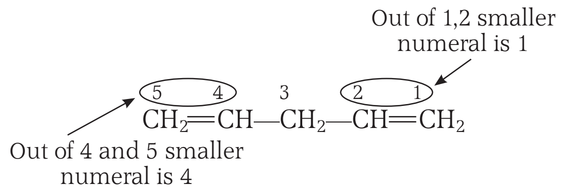
$$\boxed{\textbf{alkane –ane + ene = alkene}}$$

If parent chain contains 2, 3 or 4 double bonds than numerical prefixes like **di** (for two), **tri** (for three) or **tetra** (for four) are added to primary suffix. **Remember in all such cases –a of ane is retained,** *e.g.,* alkadiene, alkatriene etc., *e.g.,*

$$\overset{5}{C}H_2=\overset{4}{C}H-\overset{3}{C}H_2-\overset{2}{C}H=\overset{1}{C}H_2$$

penta-1,4-diene

While writing the position of double bond, always write the smaller numeral of the two atoms between which the bond is present. *e.g.,* in the above example



Hence, 1 and 4 are included in the name *e.g.,* penta-1,4-diene.

(c) Alkynes

Alkynes are the hydrocarbons that contain C—C triple bonds ($C\equiv C$). The IUPAC rules for naming alkynes are analogous to those for alkenes, *i.e.,*

$$\boxed{\textbf{alkane – ane + yne = alkyne}}$$

e.g., $$\underset{1}{C}H_3-\underset{2}{C}\equiv\underset{3}{C}-\underset{4}{C}H_2-\underset{5}{C}H_2-\underset{6}{C}H_3$$

hex-2-yne

If both double and triple bonds are present in the compound, the endings like -en-yne, a (numeral) dien-(numeral)-yne etc., are used. Numbers as low as possible are given to double and triple bonds as a set, e.g.,

$$\underset{5}{C}H_3-\underset{4}{C}H=\underset{3}{C}H-\underset{2}{C}\equiv\underset{1}{C}H \qquad \overset{1}{C}H_2=\overset{2}{C}H-\overset{3}{C}H_2-\overset{4}{C}\equiv\overset{5}{C}H$$

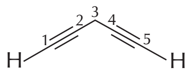
pent-3-en-1-yne pent-1-en-4-yne

***Sample* Problem 12** *The compound*

has the IUPAC name

(*a*) *propane*-1,3-*diyne* (*b*) 1,4-*pentadiyne*
(*c*) 1,3-*pentadiyne* (*d*) *pentanone*-1,3-*diyne*

Interpret (*b*)



The condensed form of this bond line structure is

$$H\overset{1}{C}\equiv\overset{2}{C}-\overset{3}{C}H_2-\overset{4}{C}\equiv\overset{5}{C}H$$

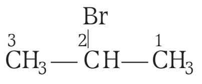
Hence, its IUPAC name is 1,4-pentadiyne,

AlKyl Halides

These are the compounds which contains carbon-halogen bonds. Their name is written by adding prefix 'halo' (chloro, bromo, iodo) with the position number to the name of parent alkane.

$$\boxed{n\text{-halo} + \text{Alkane} \longrightarrow n\text{-haloalkane}}$$

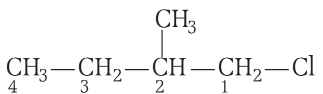
e.g.,



$$\overset{3}{C}H_3-\overset{Br}{\overset{2}{C}H}-\overset{1}{C}H_3$$

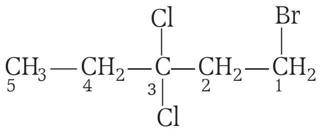
2-bromopropane

If there are two or more identical halogen substituents, the prefix, di, tri, tetra etc., are used *e.g.,*



$$\underset{4}{C}H_3-\underset{3}{C}H_2-\underset{2}{\overset{CH_3}{C}H}-\underset{1}{C}H_2-Cl$$

1-chloro-2-methylbutane



$$\underset{5}{C}H_3-\underset{4}{C}H_2-\underset{\underset{Cl}{3}}{\overset{Cl}{C}}-\underset{2}{C}H_2-\underset{1}{\overset{Br}{C}H_2}$$

1-bromo-3,3-dichloropentane

If the two different halo group occupy the same position from the opposite sides of the parent chain, the perference will be given to the halogen according to alphabetical order *e.g.,*

$$Br\underset{1}{C}H_2-\underset{2}{C}H_2-\underset{3}{C}H_2Cl$$

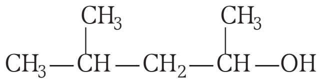
1-bromo-3-chloro propane

Alcohols

Alcohols are compounds in which a hydroxyl group (—OH) is bonded to a saturated carbon. They are classified as primary, secondary, or tertiary, depending upon whether the —OH group is attached to a primary, secondary, or tertiary carbon atom. Abbreviations for these terms are 1°, 2° and 3° respectively. *However, terms primary, secondary and tertiary are not recognised by IUPAC.*

Their name is obtained by dropping the final –e from the name of the alkane that contains the same number of carbon atoms and adding the ending '–ol'. *e.g.,*

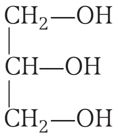
$$\boxed{\textbf{Alkane – e + ol} \longrightarrow \textbf{alkanol}}$$



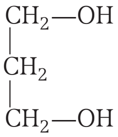
$CH_3—\underset{}{\overset{CH_3}{\overset{|}{C}H}}—CH_2—\overset{CH_3}{\overset{|}{C}H}—OH$

1,3-dimethylbutan-1-ol

Alcohols containing two or three —OH groups are named as alkanediols and alkanetriols respectively. *Note that -'e' of the corresponding alkane name is retained in such cases.*



propane-1,2,3-triol



propane-1,3-diol

Ethers

Ethers are the compounds in which an oxygen atom is bonded to two alkyl groups (*R*–O–*R*). In the common system, the two alkyl groups attached to the oxygen atom are named in alphabetic order and the word ether is added, *e.g.,*

$CH_3OC_2H_5$ methyl ethyl ether

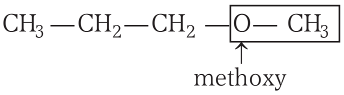
$C_2H_5OC_3H_7$ ethyl propyl ether

If the groups are same then prefix di is used as :

CH_3OCH_3 dimethyl ether

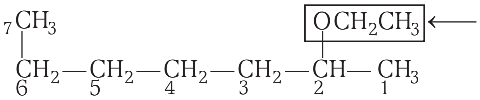
$C_2H_5OC_2H_5$ diethyl ether

In the IUPAC system, ethers are named as **alkoxyalkanes.** The smaller alkyl group plus the oxygen atom is called an **alkoxy substituent.**



$CH_3—CH_2—CH_2—\underset{\text{methoxy}}{\underset{\uparrow}{\boxed{O—CH_3}}}$

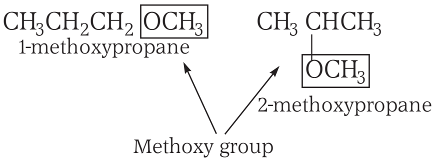
The name of the compound is 1 - methoxypropane



$\underset{6}{\overset{_7CH_3}{\overset{|}{C}H_2}}—\underset{5}{CH_2}—\underset{4}{CH_2}—\underset{3}{CH_2}—\underset{2}{\overset{\boxed{OCH_2CH_3}}{\overset{|}{C}H}}—\underset{1}{CH_3}$ ⟵ Ethoxy

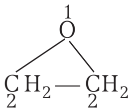
The name of the compound is 2-ethoxyheptane.

Remember always that terminal position cannot be assumed for alkoxy group, it can be placed with any C–atom of the chain, *e.g.,*



Oxiranes

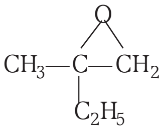
Oxiranes are infact cyclic ethers in which ethereal oxygen is a part of three membered oxirane ring. This ring seems as



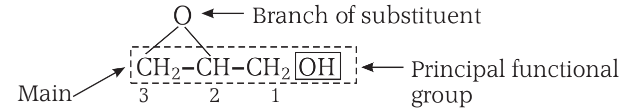
Oxirane ring

Here, oxygen of the ring is given number 1 and both the C–atoms as 2 by IUPAC.

These cyclic ethers are placed at the lowest preference in the preferential order and normally written as prefixes when any functional group present in the compound (except alkyl group). The prefix of this group is **epoxy,** *e.g.,*



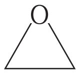
2-ethyl-2-methyl oxirane



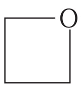
2,3-epoxypropan-1-ol

Oxiranes are also called **epoxides.** As they are readily prepared from alkenes, they are commonly called **alkene oxides.**

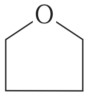
IUPAC name of the some of the oxiranes are as



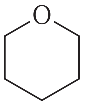
oxirane or 1,2-epoxyethane



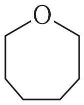
oxetane or 1,3-epoxypropane



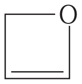
oxolane or 1,4-epoxybutane



oxane or 1,5-epoxypentane



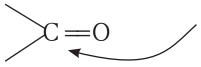
oxepane or 1,6-epoxyhexane



oxetene or 1,3-epoxyprop-1-ene

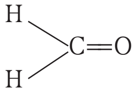
Aldehydes

These are the compounds in which carbonyl group [$>C{=}O$] is bonded to at least one hydrogen (alongwith one alkyl group).

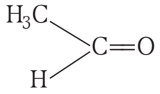


At least one hydrogen atom should be attached to either of these valencies.

Their common names are related to those of carboxylic acids, *e.g.,*



formaldehyde (Related to formic acid)



acetaldehyde (Related to acetic acid)

- Their IUPAC names are obtained by dropping final –e from the name of corresponding alkane and adding the ending -al,

i.e., $\boxed{\text{alkane} - \text{e} + \text{al} = \text{alkanal}}$

e.g., HCHO methanal; CH_3CHO ethanal; CH_3CH_2CHO propanal

Ketones

Ketones are the compounds in which carbonyl group [$>C{=}O$] is bonded to two alkyl groups.

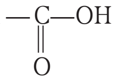
In the IUPAC system, ketones are named as alkanones *i.e.,*

$\boxed{\text{alkane} - \text{e} + \text{one} = \text{alkanone}}$

e.g., $\overset{1}{CH_3}\,\overset{2}{CO}\,\overset{3}{CH_3}$ propan-2-one; $\overset{1}{CH_3}\,\overset{2}{CO}\,\overset{3}{CH_2}\,\overset{4}{CH_3}$ butan-2-one

Carboxylic Acids

These are the compounds which contain



$-\underset{\underset{O}{\|}}{C}-OH$ group.

In IUPAC system these are named as alkanoic acid, *i.e.,*

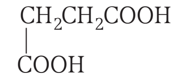
$\boxed{\text{alkane} - \text{e} + \text{oic acid} = \text{alkanoic acid}}$

e.g., HCOOH methanoic acid; CH_3COOH ethanoic acid; CH_3CH_2COOH propanoic acid

For all those functional groups which contain C-atom in them, following two conditions are also applicable

1. Two suffixes are given to these functional groups according to 1993 recommendations. (see table 13.3) *Out of these two, one - oic acid can be used normally while other one (carboxylic acid) is used when it is difficult to count the C-atom of functional group in the main chain, e.g,*

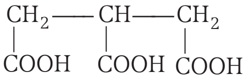
CH_3CH_2COOH propanoic acid



$\underset{|\atop COOH}{CH_2}CH_2COOH$

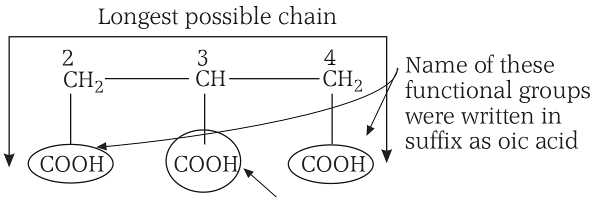
butane-1,4-dioic acid

But when another carboxylic group is attached to the main chain directly as,



$\underset{|\atop COOH}{CH_2}-\underset{|\atop COOH}{CH}-\underset{|\atop COOH}{CH_2}$

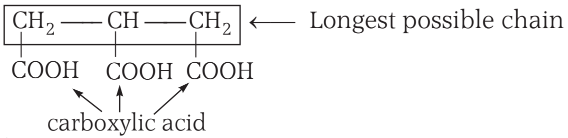
Here, *problem lies in the fact that all the functional groups cannot be taken in the main chain simultaneously.* This situation was not so clear in 1979 recommendations where the —COOH attached to centralised C-atom was written in prefix while rest two —COOH groups attached at terminals were written in suffix as:



The name of the compound according to 1979 recommendations was 3-carboxy pentane-1,5 dioic acid

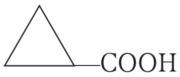
Name of this functional group was written in prefix as- carboxy

But in its recommendations of 1993, IUPAC cleared the situation for such cases and mentioned, *"If an unbranched chain is directly linked to more than two carboxy groups, these carboxy groups are named from the parent hydride by substitutive use of a suffix like carboxylic acid".* So, the name of the above written compound according to 1993 recommendations will be **propane–1, 2, 3 tricarboxylic acid.**

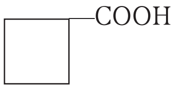


(C-atom of all the three is not included in the longest possible chain.)

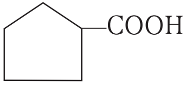
2. Such a situation is also applicable to the cases written below,



cyclopropane carboxylic acid



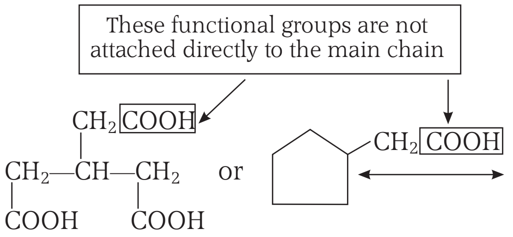
cyclobutane carboxylic acid



cyclopentane carboxylic acid

In all the above cases due to the presence of cyclic hydrocarbon difficulty lies in inclusion of C-atom of functional group within the longest possible chain. Hence, here also the suffix used is carboxylic acid and not the –oic acid which is normally used.

3. However, the suffix carboxylic acid cannot be used in situations like,



3-carboxymethyl, pentane-1,5-dioic acid

2-cyclopentyl ethanoic acid

Carboxylic Acid Derivatives

These are the compounds in which the —OH part of $-\underset{\underset{\text{O}}{\|}}{\text{C}}-\text{OH}$ group is replaced by various other groups. These various derivatives are

(a) Acid Chlorides

Here —OH group is replaced by —Cl group.

The group $-\overset{\overset{\text{O}}{\|}}{\text{C}}-\text{Cl}$ is commonly called as acyl chloride. Their IUPAC name can be written as,

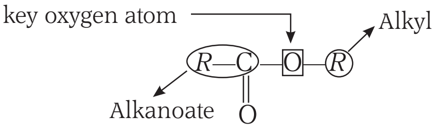
alkanoic acid – ic acid + yl chloride = alkanoyl chloride

e.g., CH_3COCl ethanoyl chloride; CH_3CH_2COCl propanoyl chloride

'Carbonyl chloride' is also assigned in case where this group is a substituent.

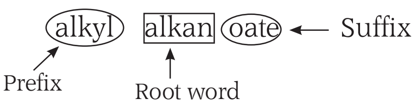
(b) Esters

Here, —OH group of acid is replaced by —O*R* group. Their IUPAC names are written as alkyl alkanoate.



Here, alkyl group present after key oxygen is written as alkyl and rest all the C-atoms before key oxygen are written as alkanoate.

Remember in alkyl alkanoate,



e.g., CH_3COOCH_3 methyl ethanoate; $CH_3COOC_2H_5$ ethyl ethanoate

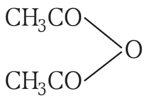
Suffix 'carboxylate' can also be assigned if this group is not present as principal group.

(c) Acid Anhydrides

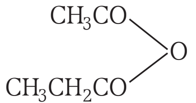
Here, —OH group of acid is replaced by — OC(*R*)═O. They are named as

alkanoic acid – acid + anhydride = alkanoic anhydride

e.g.,



ethanoic anhydride



ethanoic propanoic anhydride

(d) Amides

Here, —OH of carboxylic acid is replaced by $-NH_2$ group. They are named as

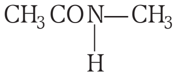
alkanoic acid – oic acid + amide = alkanamide

e.g., CH_3CONH_2 ethanamide; $HCONH_2$ methanamide

Suffix 'carboxamide' is used if $-CONH_2$ group is present as a substituent.

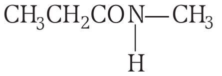
Alkyl group can also be attached to the nitrogen of $-NH_2$ group in place of hydrogen. In such cases the names of amides can be written as N—substituted amides.

e.g.,



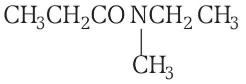
$CH_3CO\underset{\underset{\text{H}}{|}}{\text{N}}-CH_3$

N-methyl ethanamide



$CH_3CH_2CO\underset{\underset{\text{H}}{|}}{\text{N}}-CH_3$

N-methylpropanamide



$CH_3CH_2CO\underset{\underset{CH_3}{|}}{\text{N}}CH_2CH_3$

N-methyl-N-ethylpropanamide

Caution Point *Never treat the* $>C=O$ *and* $-NH_2$ *groups of an amide as separate entities.*

Sulphonic Acid

These compounds contain $-SO_3H$ group. Their IUPAC names are written as

alkane + sulphonic acid = alkane sulphonic acid

e.g., CH_3SO_3H methane sulphonic acid; $CH_3CH_2SO_3H$ ethane sulphonic acid

Nitro Compounds

These are the compounds which contain $-NO_2$ group in them. Their IUPAC names are obtained by adding the prefix 'nitro' to the name of alkane.

Nitro + alkane = Nitroalkane

e.g., CH_3NO_2 nitromethane, $CH_3CH_2NO_2$ nitroethane, $CH_3CH_2CH_2NO_2$ nitropropane

Cyanides or Nitriles

The compounds which contain —CN group are named as alkane nitriles in IUPAC system.

Alkane + nitrile ⟶ Alkane nitrile

e.g., $\overset{4}{CH_3}\,\overset{3}{CH_2}\,\overset{2}{CH_2}\,\overset{1}{CN}$ butane nitrile; CH_3CN ethane nitrile

CH_3CH_2CN propane nitrile; HCN methane nitrile

Like acids and others, for cyanides also two suffix, *i.e.,* carbonitrile and nitrile are assigned.

Amines

Amines are the derivatives of ammonia in which one or more hydrogen atoms have been replaced by alkyl/aryl groups. In the common system they are classified as primary (1°), secondary (2°) or tertiary (3°) depending upon the number of valencies of nitrogen atom satisfied by carbon atoms.

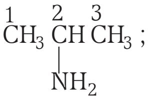
CH_3NH_2	$CH_3—NH—CH_3$	$CH_3—NCH_3—CH_3$
methyl amine	dimethyl amine	trimethyl amine
(primary)	(secondary)	(tertiary)

In the IUPAC system, primary amines are named by replacing the final –e of the parent alkane by amine, *i.e.,*

alkane –e + amine = alkanamine

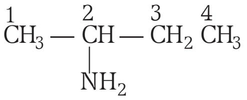
The inclusion of number to indicate the position of $—NH_2$ group is also necessary (except the situation when $—NH_2$ group is attached at terminal position).

$CH_3CH_2NH_2$; ethanamine



$\overset{1}{CH_3}\,\overset{2}{CH}(NH_2)\,\overset{3}{CH_3}$;

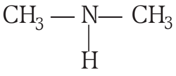
propan-2-amine



$\overset{1}{CH_3}—\overset{2}{CH}(NH_2)—\overset{3}{CH_2}\,\overset{4}{CH_3}$

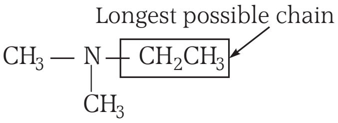
butan-2-amine

The *secondary and tertiary amine are named as N-substituted and N,N-disubstituted amines*. The largest of the alkyl groups attached to nitrogen is chosen as the alkyl group of primary amine. (IUPAC does not considers secondary and tertiary amines as main compounds. According to IUPAC these are the substitution derivatives of primary amine). *e.g.,*



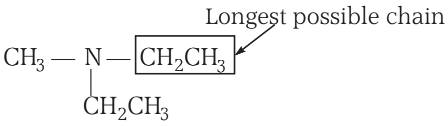
$CH_3—NH—CH_3$

N-methyl methanamine



$CH_3—N(CH_3)—\boxed{CH_2CH_3}$

N,N-dimethyl ethanamine



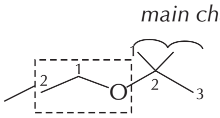
$CH_3—N(CH_2CH_3)—\boxed{CH_2CH_3}$

N-ethyl-N-methyl ethanamine

***Sample* Problem 13** *The systematic name for the given structure is*

(a) *2-ethoxy-2-methyl propane*
(b) *2-methoxy-2-ethoxypropane*
(c) *3-ethoxy-2-methoxypropane*
(d) *3-methoxy-2-ethyl propane*

Interpret (*a*)



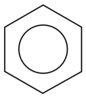
ethoxy group (substituent)

2-ethoxy-2-methyl propane

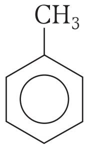
13.9 Nomenclature of Cyclic Compounds

Naming the Aromatic Compounds

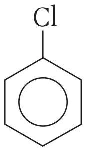
Common trivial names of aromatic compounds are accepted by IUPAC, they do not have separate IUPAC names. Thus,



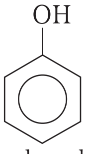
benzene



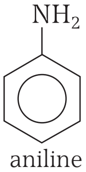
toluene



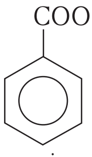
chlorobenzene



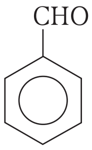
phenol



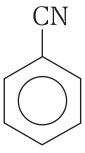
aniline



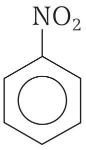
benzoic acid



benzaldehyde

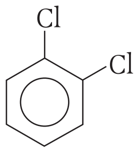


benzonitrile

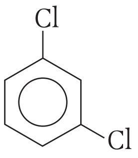


nitrobenzene

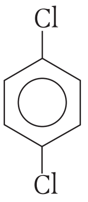
However, the use of *ortho* (*o*-), *meta* (*m*-), or *para* (*p*-) is avoided; instead, they are called 1,2; 1,3 and 1,4. Thus,



1,2-dichlorobenzene

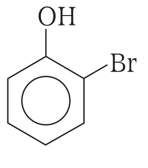


1,3-dichlorobenzene

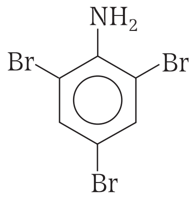


1,4-dichlorobenzene

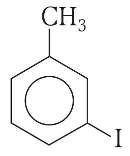
If the two groups attached to benzene ring are different then the main group is treated as the base compound. Thus,



2-bromophenol

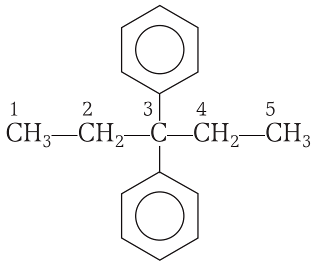


2,4,6-tribromoaniline

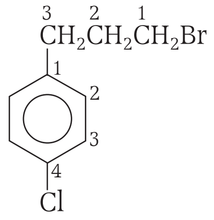


3-iodotoluene

If the aromatic compound has an open chain attached to benzene then this chain gets the main status; ring is treated as substituent. Thus,

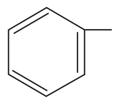


3,3-biphenyl pentane

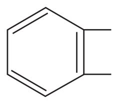


1-bromo-3-(4-chlorophenyl)propane

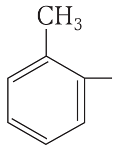
The following names are given to certain aromatic hydrocarbon residues formed by the loss of one or more hydrogen atoms from the parent hydrocarbon :



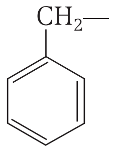
or C_6H_5—
phenyl



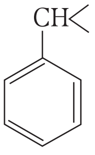
or $C_6H_4<$
o-phenylene



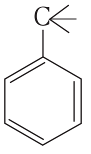
or $CH_3C_6H_4$—
o-tolyl



or $C_6H_5CH_2$—
benzyl or
phenyl methyl

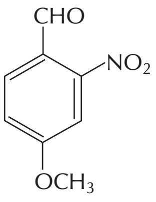


or $C_6H_5CH<$
benzal or
benzylidene



or $C_6H_5C\lessdot$
benzo or
benzylidyne

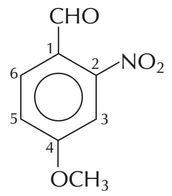
Sample **Problem 14** *What is the correct IUPAC name of*



(a) *4-formyl-3-nitro anisole*
(b) *4-methoxy-2-nitrobenzaldehyde*
(c) *4-methoxy-6-nitrobenzaldehyde*
(d) *2-formyl-5-methoxy nitrobenzene*

Interpret (*b*) The order of preference of given functional groups is

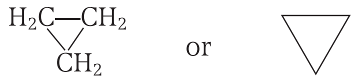
$$—CHO > —NO_2 > —OCH_3$$



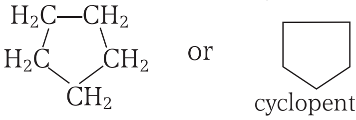
Thus, its IUPAC name is 4-methoxy-2-nitrobenzaldehyde.

Naming the Alicyclic (Monocyclic) Compounds

The alkanes in which carbon atoms are arranged in a ring are called **cycloalkanes.** They are named by attaching the prefix **'cyclo'** to the name of the alkane having the same number of carbons as in the ring.



cyclopropane



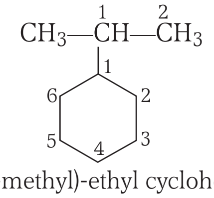
cyclopentane

Cycloalkanes are often represented by simple geometrical figures. It is understood that each corner represents —CH_2 groups. Remember that :

Cyclopropane is represented by a **triangle**
Cyclobutane is represented by a **square**
Cyclopentane is represented by a **pentagon**
Cyclohexane is represented by a **hexagon**

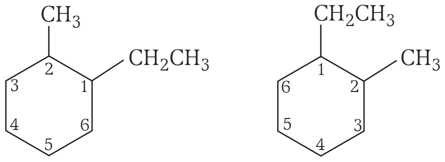
Following rules are considered while naming the alicyclic compounds :

1. Substituted cycloalkanes are named as alkylcycloalkanes. The substituents on the ring are named, and their positions are indicated by number.



1-(1-methyl)-ethyl cyclohexane

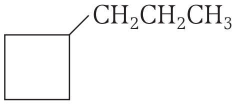
2. While numbering the C-atoms of the ring, the substituent which comes first in alphabetical order is given the lowest number provided that it does not violate the lowest sum rule. Remember there is no restriction in going clockwise or anticlockwise for numbering the C–atoms of ring. *e.g.,*



1-ethyl-2-methylcyclohexane

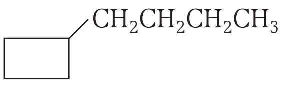
Since, 1-ethyl-2-methyl cyclohexane can have both of above written structures, both the above **written structures are similar.**

3. The alkyl group is designated as a substituent if the alkyl chain contains a lesser or equal number of C-atoms than the ring, *e.g.*,



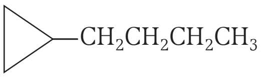
propylcyclobutane

and



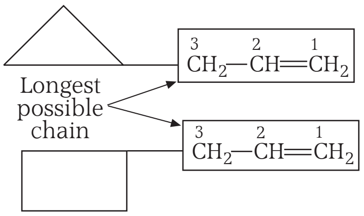
butylcyclobutane

4. The ring is designated as a substituent if the alkyl chain contains a greater number of C-atoms than the ring, *e.g.*,



cyclopropylbutane

5. However, if the side chain contains a multiple bond or a functional group, the ring is treated as a substituent irrespective of the size of ring.

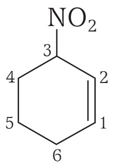


3-cyclopropylprop-1-ene

3-cyclobutylprop -1-ene

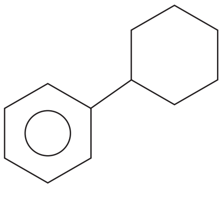
Such an exception is due to the rule *"the multiple bond/functional group if present in the compound should be included in the longest possible chain".*

6. If multiple bond and some other substituent are present in the ring, then the numbering should be done in such a manner so that the multiple bond gets the least possible number, *e.g.*,

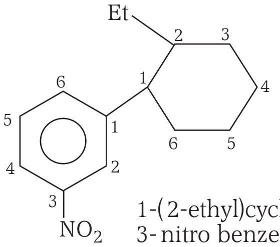


3-nitrocyclohex-1-ene

7. If a compound contains an alicyclic ring directly linked to the benzene ring, it is named as the derivative of benzene, *i.e.,* the compound having lowest state of hydrogenation, *e.g.*,

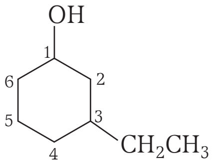


cyclohexyl benzene

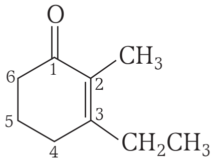


1-(2-ethyl)cyclohexyl 3-nitro benzene

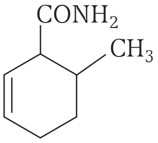
8. If some functional group alongwith other substituent groups are present in the ring, it is indicated by some appropriate prefix or suffix and its position is indicated by numbering the carbon atoms of the ring in such a way that the functional group gets the least possible number, *e.g.*,



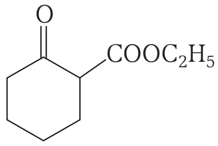
3-ethylcyclohexan-1-ol



3-ethyl-2-methyl cyclohex-2-en-1-one

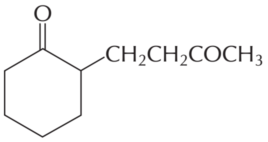


6-methylcyclohex -2-en-1-carboxamide



ethyl (2-oxo) cyclohexane 1-carboxylate

Sample **Problem 15** *The IUPAC name of*



is

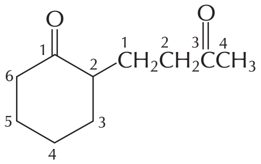
(a) 4-(2-oxobutyl) cyclohexan-1-one

(b) 4-(2-oxocyclohexyl) butan-2-one

(c) 1-(2-oxocyclohexyl) butan-3-one

(d) 2-(3-oxobutyl) cyclohexan-1-one

Interpret (*d*)

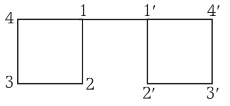


2-(3-oxobutyl) cyclohexan-1-one

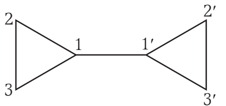
Naming the Bi and Polycyclic Compounds

1. Unbranched Assemblies Consisting of Two Identical Ring Systems

These assemblies are named by placing numerical prefix bi before the name of parent hydride, *e.g.,*



1,1′-bicyclo butane

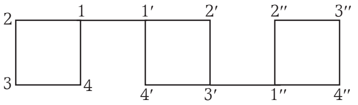


1,1′-bicyclo propane

Such assemblies can be identified by counting the C-atoms in them. The total number of C-atoms in such assemblies will be exactly double of the number of C-atoms present in a single ring.

2. Unbranched Assemblies Consisting of Three or More Identical Ring Systems

These are named by placing an appropriate numerical prefix like ter, quater, quinique etc., before the name of parent hydride corresponding to the repetitive unit, *e.g.,*

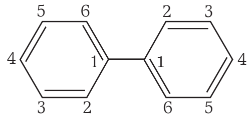


1,1′,3′,1″-tercyclobutane

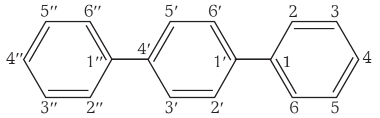
The following multiplying prefixes are used in names for unbranched assemblies of three or more identical repeating units :

2-bi-, 3-ter-, 4-quater-, 5-quiniques-, 6-sexi-, 7-septi-, 8-octi-, 9-novi-, 10-deci-

As exceptions, unbranched assemblies consisting of benzene rings are named by using the appropriate numerical prefix with the substituent prefix name phenyl, *e.g.,*



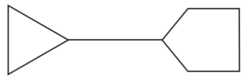
Biphenyl



1,1′4′,1″-terphenyl (preferred to *p*-terphenyl)

3. Unbranched Assemblies Containing Unidentical Rings

In such assemblies the smaller ring will be considered as substituent (written as cycloalkyl) while larger cycle will be considered as main chain, *e.g.,*



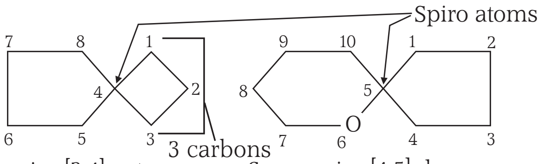
cyclopropyl cyclopentane

4. Spiro Parent Hydrides

A 'spiro union' is a linkage between two rings consisting of a single atom common to both. The common atom is designated as the 'spiro atom'. According to the number of spiro atoms present, the compounds are distinguished as monospiro, dispiro, trispiro, etc., ring systems. The following recommendations apply only to the naming of parent hydrides containing free spiro unions.

Monospiro parent hydrides are the hydrides consisting of two homogeneous saturated monocyclic rings and are named by placing 'spiro' before the name of the acyclic parent hydride with the same total number of skeletal atoms; heteroatoms, if any, in an otherwise hydrocarbon structure. The numbers of skeletal atoms linked to the spiro atom in each ring are indicated by arabic numbers separated by a full stop, cited in ascending order and enclosed in square brackets, this descriptor is placed between the spiro prefix and the name of the parent hydride.

Numbering starts with a ring atom next to the spiro atom and proceeds first through the smaller ring, if one is smaller, and then through the spiro atom and around the second ring, e.g.,

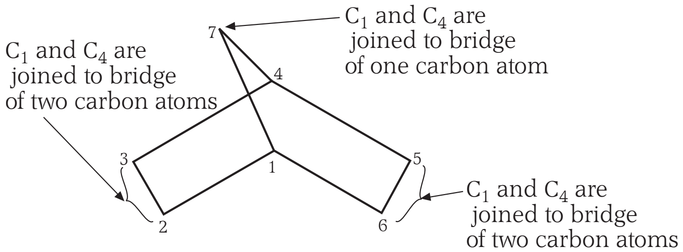


spiro [3.4] octane 6-oxo spiro [4.5] decane

Emphasis on ascending order of numerals was given in 1993 recommondations although it was not there according to 1979 recommondations of IUPAC.

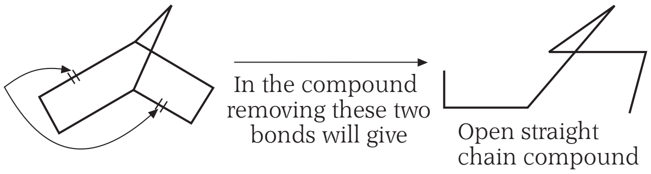
Polycyclic Ring Systems

Saturated homogeneous bicyclic systems having two or more atoms in common, are named by prefixing 'bicyclo-' to the name of the acyclic parent hydride that has the same total number of skeletal atoms. The number of the three acyclic atoms (bridges) connecting the two common atoms (bridgeheads) is given by arabic numbers cited in descending numerical order separated by full stops and enclosed in square brackets.

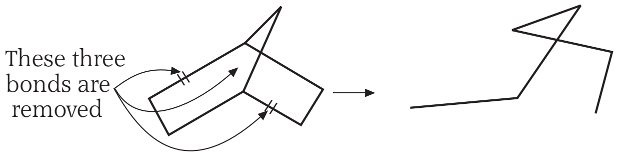


In these cases number or cycles can be guessed by practically observing minimum number of bonds removed so that the compound is converted into a continuous open chain compound.

Practically the minimum number of bonds removed
= Number of cycles present in the compound *e.g.,*



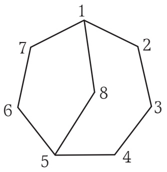
Hence, the above written compound is **bicyclo** (two bonds removed),



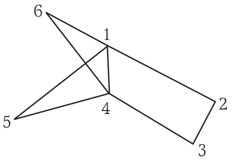
Open straight chain compound

Hence, the above written compound is **tricyclo** (3 bonds have to be removed).

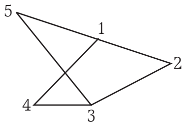
The system is numbered starting with one of the bridgeheads and proceeding through the longest bridge to the second bridgehead, continuing back to the first bridgehead by means of the longer unnumbered bridge, these two bridges constitute the 'main ring' of the system. Numbering is completed by numbering the remaining bridge (the shortest) beginning with the atom next to the first bridgehead, *e.g.,*



bicyclo [3.2.1] octane



bicyclo [2.1.1] hexane



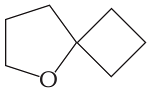
bicyclo [1.1.1] pentane

Sometimes it is difficult to name a compound which looks like simple but show a small deviation from a normal rule. *e.g.,* the compound  can be named as 1,1′ -bicyclo butane, but it is difficult to name:

 as a bivalent bridge is present in it. To name this compound we must know the name of bivalent bridges. In its 1993 recommondations, IUPAC provided the guidelines for such naming also. According to IUPAC the above compound can be named as "methano-1,1′-bicyclobutane". IUPAC gave the guidelines for usage of such simple bivalent bridges as **"such a bridge is named as a prefix derived from the hydrocarbon name by changing the final 'e' to 'o'.** The locant of a double bond, if present, is indicated in square brackets between the hydrocarbon prefix and the ending '–eno' –'dieno' etc. Some of such bridges can be named as :

$—CH_2—$ methano $—CH_2—CH_2—$ ethano
$—CH_2—CH_2—CH_2—$ propano
$—CH_2—CH_2—CH_2—CH_2—$butano
$—CH{=}CH—$ etheno
$—CH{=}CH—CH_2—$ prop[1] eno
$—CH{=}CH—CH_2—CH_2—$ but[1] eno
$—CH_2—CH{=}CH—CH_2—$ but[2] eno
$—CH{=}CH—CH{=}CH—$ buta[1,2] dieno

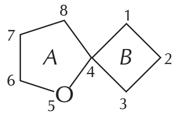
Sample **Problem 16** *The correct IUPAC name of the spiro compound,*



is

(*a*) 5-*oxaspiro* [3. 4] *octane*
(*b*) 1-*oxaspiro* [3. 4] *octane*
(*c*) 5-*oxaspiro* [4. 3] *octane*
(*d*) 1-*oxaspiro* [3. 4] *octane*

Interpret (a)



Number of atoms in ring *A* = 3 + 1 = 4
Number of atoms in ring *B* = 3
Total atoms in ring *A* and ring *B* + bridged *C* atom = 8

Numbering is done from smaller ring followed by spiro (common) carbon and larger ring.

Position of foreign element (O) is = 5

Thus, the IUPAC name of the compound is 5-oxaspiro [3. 4] octane.

13.10 Conversions Used in IUPAC System of Nomenclature

While writing IUPAC name, one should remember the following

1. **Locants** (numerals and/or letters) are placed immediately before the part of the name of which they relate, except in the case of traditional contracted forms. *e.g.,*

   hex-2-ene (formerly, 2-hexene)
   cyclohex-2-en-1-ol (formerly 2-cyclohexen-1-ol)

2. **Commas** are used to separate locants that refer to the same part of a name *i.e.*, locants of a series in names of fused ring systems, *e.g.,*

   1, 2-dichloroethane

3. **Full stops** (periods) separate numerical ring size indicators in names, constructed according to the von Baeyer system and in certain spiro names, *e.g.,*

   bicyclo [3.2.1] octane
4. **Colons** separate related sets of locants; if a higher level of separation is required, semicolons are employed, *e.g.,*

   1, 4, 5, 8-tetrahydro-1, 5 : 5, 8-dimethanoanthracene
5. **Hyphens** separate
   - (i) Locants from the words of syllables of a name.
   - (ii) Adjacent locants referring to different parts of the name (but preferably parentheses should be inserted).
   - (iii) The two parts of the designation for a primary fusion site in a name for a fused ring system.
   - (iv) A stereodescript or / and the name, *e.g.,*

     N-acetyl-N-(2-naphthyl) benzamide

     (preferred to N-acetyl-N-2-naphthyl-benzamide)
6. **Numerical** (multiplicative) **prefixes** are derived from Greek and Latin number names and are the principal method for describing a multiplicity of identical features of a structure in chemical nomenclature.
   - (i) **The simple numerical prefixes** di-, tri-, tetra-, etc., are of Greek derivation (except for nona- and undeca-, which are derived from Latin) and are used to indicate a multiplicity of substituent suffixes, *e.g.,*

     –diol
     –dicarboxylic acid
     –tricyclohexyl-
     –diamidodiaza
     ditetradecane-1, 4-diyl-
     tetra-2-naphthyl-
     dioxime
     ethylenedimino
   - (ii) **The numerical prefixes** 'bis-', 'tris-', 'tetrakis-', etc., which, except for 'bis-' and 'tris-', are derived by adding 'kis-' to the simple numerical prefixes are used to indicate a multiplicity of substituted prefixes or functional modification terms, *e.g.,* bis (2-aminoethyl). Such prefixes are also used when the use of 'di-', 'tri-', etc., is (or could be) ambiguous; this usually happens when an analogue of the term being multiplied begins with a simple numerical prefix.
   - (iii) **The numerical prefixes** 'bi-', 'ter-', 'quater-' etc., are derived from Latin number names and are used mainly in identical ring assembly names, *e.g.,*

     biphenyl, 2, 2' : 6', 2'' : 6'', 2'' -quaterpyridine

Check Point 2

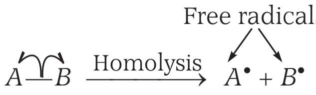
1. Is it always true that molecules with the general formula C_nH_{2n} are alkenes?
2. Write the formula for 1-phenyl-1-butanone. Explain why the designation "1-butanone is somewhat unusual,?
3. Is the name 2-methyl-3-butanol correct? Explain.
4. Which class of compounds is represented by the formula ROR'? Using CH_3 and C_2H_5 as a radical, write formula of three compounds which belong to this class.

13.11 Covalent Bond Fission

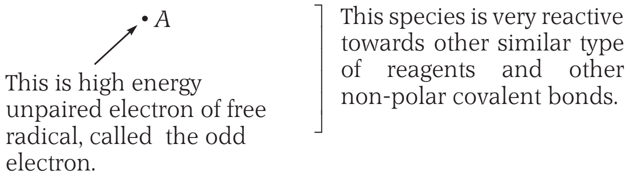
An organic reaction proceed through breaking of bonds and formation of bonds. A reaction is successful when the bond formed in the products are stronger than the bond broken. There are two possible ways through which a covalent bond can cleave.

Homolysis or Symmetrical Fission

If a covalent bond breakes in such a way that each atom takes away one electron of shared pair, the fission is called **homolysis,** *e.g.,*



The neutral chemical species, thus formed is called **free radical** and is represented as



Favourable factors for homolysis The factor which favours homolysis is zero or a small difference in electronegativity between *A* and *B*. Homolytic bond fission takes place in gaseous phase or in the presence of non-polar solvents (CCl_4, CS_2) .

Presence of peroxide, UV light, heat (≥ 500° C), electricity also favour homolysis. This process is known as initiation of free radical reaction.

Heterolysis or Asymmetrical Fission

If a covalent bond breakes in such a way that both the electrons of shared pair are taken away by one of the bonded atoms, the bond fission is called **heterolytic fission**, *e.g.*,

$$X\overset{\curvearrowright}{—}Y \xrightarrow{\text{Heterolysis}} X^+ + Y^-$$

(when X is less electronegative than Y)

$$X\overset{\curvearrowleft}{—}Y \xrightarrow{\text{Heterolysis}} X^- + Y^+$$

(when Y is less electronegative than X)

Such fission results in the formation of cation (positively charged) and anion (negatively charged). If positive charge is present on carbon then cation is termed as **carbocation** or if negative charge is present on carbon then anion is termed as **carbanion.** Cabocation or carbanion is the reaction intermediate.

Heterolysis is seen in polar covalent bonds and is favoured by polar solvents. *The energy required for the heterolytic bond fission is always greater than that for homolytic bond fission due to electrostatic force of attraction between ions.*

Sample Porblem 17 *Heterolysis of propane gives*

(*a*) *methyl and ethyl free radical*
(*b*) *methylium and ethylium ions*
(*c*) *methylium ion and ethyl anion*
(*d*) *methyl anion and ethylium ion*

Interpret (*d*) $CH_3CH_2CH_3 \xrightarrow{\text{Heterolysis}} \underset{\text{ethylium ion}}{CH_3CH_2^+} + \underset{\text{methyl anion}}{CH_3^-}$

or

$\underset{\text{ethyl anion}}{CH_3CH_2^-} + \underset{\text{methylium ion}}{CH_3^+}$

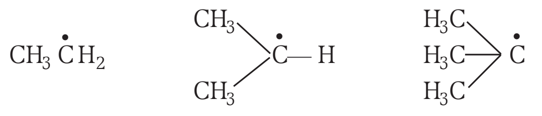
Here, the former products, *i.e.*, $CH_3CH_2^+$ ethylium ion and CH_3^- (methyl anion) are predominant as CH_3 is more electronegative as compared to CH_3CH_2 group.

13.12 Reaction Intermediates

Most of the chemical reactions require certain chemical species to occur. These species are generally short lived, highly reactive and are called **reactive intermediates**. *e.g.*, free radicals, carbocations, carbanions, carbenes, nitrenes etc.

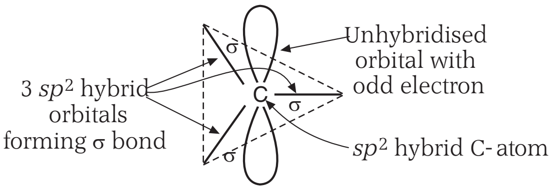
Free Radicals

The free radicals and their odd electron we have already discussed earlier under homolytic fission. These free radicals can be classified as primary (1°), secondary (2°) and tertiary (3°) depending upon the nature of carbon carrying odd electron *e.g.*,



primary or 1° secondary or 2° tertiary or 3°

These free radicals are **planar chemical species, *i.e.*, sp^2 hybridised.** Their unhybridised orbital contains an odd electron as seen below :



The order of the stability of free radicals is

$$(C_6H_5)_3\dot{C} > (C_6H_5)_2\dot{C}H > C_6H_5\dot{C}H_2$$
$$> CH_2 = CH — \dot{C}H_2 > 3° > 2° > 1° > CH_2 = \dot{C}H$$

The stability of free radicals depends upon bond dissociation energies (the energy associated with homolytic cleavage of covalent bond in a molecule). Generally, *lower the bond dissociation energy, more stable is the free radical.*

Reactions Involving Free Radicals

1. Wurtz reaction for alkanes
2. Substitution reactions of alkanes
3. Kolbe's electrolytic method
4. Anti-Markownikoff's addition reactions.

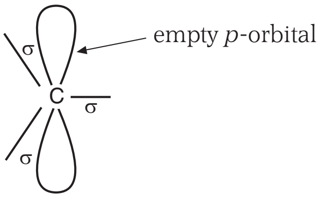
Caution Point *In substituted alkyl radicals, the s-character of these orbitals has been found to increase, thus tending to the pyramidal shape.*

$$\underset{\text{(planar)}}{\dot{C}H_3} < \dot{C}H_3F < \dot{C}H_2 < \underset{\text{(pyramidal)}}{\dot{C}F_3}$$

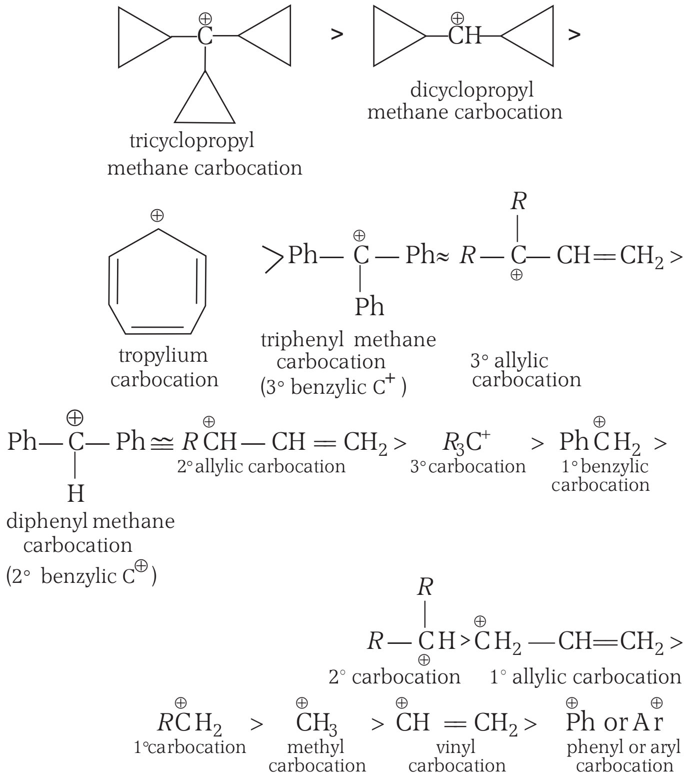
Carbocation

Carbon containing chemical species bearing a positive charge on carbon and carry 6 electrons in its valence shell are called **carbocations**. Just like free radicals these carbocations can also be categorised into primary (1°), secondary (2°) and tertiary (3°), depending upon the nature of carbon carrying positive charge.

Carbocations are also planar chemical species *i.e.*, sp^2 hybridised with an empty p-orbital as seen below



The decreasing order of the stabilities of carbocation

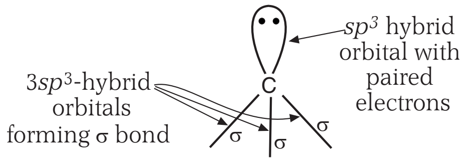


Caution Point $\overset{+}{C}H_5$, *an unusal ion, shares eight electrons among five bonds and is known as carbonium ion.* $\overset{+}{C}H_3, CH_3\overset{+}{C}H_2$ *etc., are termed as carbenium ion. For simplicity, we call both types as carbocations.*

Carbanions

Carbon containing chemical species bearing a negative charge on carbon atom and carrying 8 electrons in its valence shell is called **carbanion.** Just like free radicals and carbocations these can also be categorised into primary (1°), secondary (2°) and tertiary (3°).

The structure of simple carbanions is usually **pyramidal** with C-atom carrying the negative charge in sp^3 hybrid state and can be seen as



The order of stability of carbanions is as

$(C_2H_5)_2CH^- > (C_6H_5)_3\bar{C} > C_6H_5\bar{C}H_2 > \text{allyl} > \bar{C}H_3 >$
(1° > 2° > 3° carbanions)

Caution Point *Carbanions are* sp^3 *hydridised with pyramidal geometry. Due to steric hindrance of three phenyl* (Ph—) *groups, and to acquire pyramidal geometry, lots of energy is required due to which* Ph_3C^- *is less stable than* $Ph_3CH^{\ominus}$.

Reactions Involving Carbanion Intermediate

1. Aldol condensation
2. Cannizzaro reaction
3. Perkin's reaction
4. Knoevenagel reaction

Carbenes

The neutral divalent carbon species in which two non-bonding electrons are present along with 2 bonding pairs are called **carbenes**. These are generally produced either by **photolysis** (photo = light; lysis = breaking) *i.e.,* breaking by light or by **pyrolysis** *i.e.,* breaking by temperature, *e.g.,*

$$CH_2{=}C{=}O \xrightarrow[\text{or } \Delta]{h\nu} :CH_2 + :C{=}O$$

Carbenes are highly reactive chemical species with the tendency to gain electrons (as these have only 6 electrons in their valence shell), **thus behaving as Lewis acids or electrophiles.** These are, infact, neutral electrophiles.

Simplest carbene, *i.e.,* $\ddot{C}H_2$ is known as methylene. Hybridisation of the divalent carbon of carbene may be sp^2 as well as sp.

Carbenes can be categorised to singlet and triplet carbenes, the properties and structure of which is given in the table 13.4.

Table 13.4 **Distinguish Between Singlet and Triplet Carbenes**

S.No.	Singlet	Triplet
1.	With central C-atom sp^2 hybridised. The unhybridised orbital contains no electron and a hybridised orbital contains two electrons as shown below : 	With central C-atom *sp* hybridised. The unhybridised orbitals here contain 1 electron each in them as shown below : 2.	The singlet carbene has bent structure *i.e.,* $\overset{\sigma}{\underset{\sigma}{>}}C\colon$	The triplet carbene has linear structure *i.e.,* $\overset{\sigma}{—}\ddot{C}\overset{\sigma}{—}$
3.	Less stable than triplet carbene.	More stable than singlet carbene.

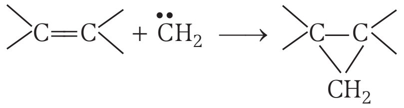
The decreasing order of stability of different types of singlet carbenes is as follows

$$\ddot{C}H_2 > \ddot{C}F_2 > \ddot{C}Cl_2 > \ddot{C}Br_2$$

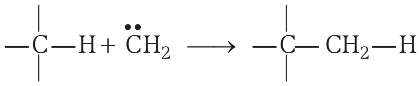
Reactions Given by Carbenes

Carbenes give following reactions.

(i) Addition with alkenes.

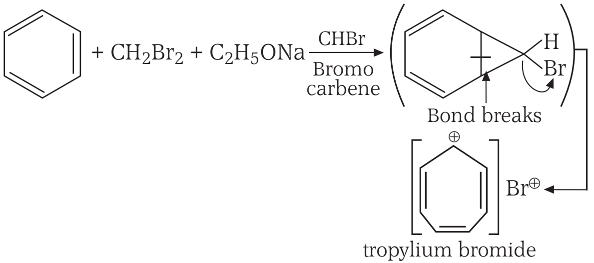


(ii) Insertion reaction between C—H bond.



$$-\overset{|}{\underset{|}{C}}-H + \ddot{C}H_2 \longrightarrow -\overset{|}{\underset{|}{C}}-CH_2-H$$

(iii) Ring expansion reactions *e.g.*, halogenated carbene produced by CHX_3/base adds to (C=C) bond, followed by ring expansion and gives product with one extra C atom ring.



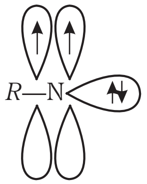
tropylium bromide
(stabilised due to aromatic character)

Nitrenes or Imidogenes

Neutral monovalent nitrogen species in which nitrogen has two unshared pair of electrons with a monovalent atom or group attached is called **nitrenes**, *i.e.*, $\overset{\sigma}{-}\ddot{N}:$

These are produced by thermolysis of azides and are very reactive just like carbenes.

In general, nitrenes obey Hund's rule and are ground state triplet with two degenerate *sp*-orbitals containing a single electron each.



sp-triplet nitrene

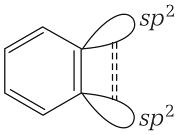
Reactions Involving Nitrene Intermediate

1. Hofmann bromamide rearrangement reaction
2. Lossen rearrangement reaction
3. Curtius rearrangement reaction
4. Schmidt rearrangement reaction

Arynes

A formal carbon-carbon triple bond containing aromatic molecule (in aromatic ring) is called aryne. The best known among these is benzyne.

In benzyne an additional bond is formed between two neighbouring C atoms by side ways overlapping of two sp^2 orbitals. The new bond orbital lies along with side of the ring and has little interaction with the π electron cloud lying above and below the ring. This sideways overlapping is weak and thus, makes the benzyne more reactive.



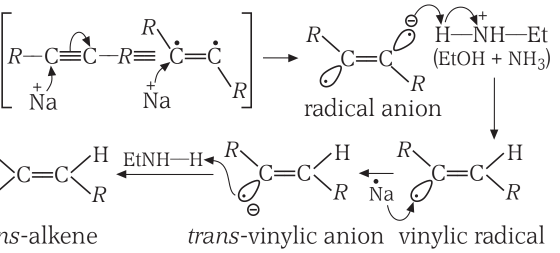
Radical Anions

Species carrying odd electron and negative charge are called radical anion.

These are of two types

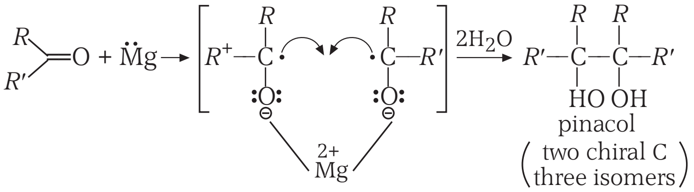
(a) Radical Anions of the Type ($R\dot{C}{=}\overset{\ominus}{\ddot{C}}R$)

These are formed as reactive intermediate in the reduction of (C≡C) bond to *trans* (C=C) bond.



(b) Radical Anions of the Type ($R_2\dot{C}{=}\overset{\ominus}{\ddot{O}}$:) Ketyl

These are formed in bimolecular reduction of carbonyl compounds to pinacol with Mg-Hg/H_2O.



13.13 Attacking Reagent or Species

An attacking reagent may be an organic or inorganic molecule or a part of them, *e.g.*, NaOH, Na in liquid NH_3, $RMgX$ etc. *Just like other organic molecules reagent can also show homolysis and heterolysis resulting in the formation of free radicals and ions respectively.*

The ions formed by heterolysis of a reagent are of utmost importance and can be categorised to

(i) Electrophiles (E^+),

(ii) Nucleophiles (Nu^-)

Electrophiles or **Electrophilic Reagents**

An electrophile is defined as **electron deficient species which attacks on electron rich areas.** Being electron deficient, the electrophiles behave as **Lewis acids**. *e.g.,* H^+, Cl^+, Br^+, I^+, NO_2^+, $\overset{+}{N}O$, $\overset{\oplus}{S}O_3H$ and carbocations.

The electrophiles can be seen in the form of neutral molecules also *e.g.,* carbenes ($:CR_2$), nitrenes ($\overset{\cdot\cdot}{N}R$), BF_3 etc. *The neutral electrophiles can be*

(i) All neutral covalent compounds in which central atom has incomplete octet, *e.g.,* $BeCl_2$, BH_3, $ZnCl_2$, AlX_3, FeX_3, $\dot{C}H_3$, $\overset{\cdot\cdot}{C}X_2$ etc.

(ii) All those compounds in which central atom has incomplete or expanded octet or unfilled *d*-subshell, *e.g.,* $SnCl_4$, $SiCl_4$, PCl_5, IF_7, etc.

(iii) All those compounds in which central atom is bonded by two or more than two electronegative atoms, *e.g.,* BX_3, AlX_3, FeX_3, PCl_3, PCl_5, etc.

Nucleophiles or Nucleophilic Reagents

A **nucleophile** or nucleophilic reagent is infact **an electron rich species that attacks on electron deficient areas.** Being electron rich, the nucleophiles behave as **Lewis bases.** *e.g.,* H^-, Cl^-, Br^-, I^- carbanions, etc., along with $\bar{O}H$, $\bar{O}R$, $\bar{S}R$. Nucleophiles can also be seen in the form of neutral molecules. Neutral covalent compounds in which central atom, has complete octet, has at least one lone pair of electrons and all atoms present on central atom are not be electronegative, is **neutral nucleophile**. *e.g.,*

$$H_2\underset{\cdot\cdot}{\overset{\cdot\cdot}{O}},\ \overset{\cdot\cdot}{N}H_3,\ R\overset{\cdot\cdot}{N}H_2,\ R\underset{\cdot\cdot}{\overset{\cdot\cdot}{O}}H,\ R\underset{\cdot\cdot}{\overset{\cdot\cdot}{S}}H,\ R\underset{\cdot\cdot}{\overset{\cdot\cdot}{O}}H, \text{etc.}$$

Organic compounds containing carbon-carbon multiple bonds behave as the nucleophile, *e.g.,* alkene, alkyne, benzene, $CH_2{=}CH{-}CH{=}CH_2$, $CH_2{=}CH{-}C{\equiv}CH$, etc.

Sample Problem 18 *Choose the correct match of the underlined reagent with their nature (electrophile or nucleophile)* **[NCERT]**

(a) $CH_3COOH + \underline{HO^-} \longrightarrow CH_3COO^- + H_2O$ *Electrophile*

(b) $CH_3COCH_3 + \underline{CN^-} \longrightarrow (CH_3)_2C(CN)(OH)$ *Nucleophile*

(c) $C_6H_6 + \underline{CH_3CO^+} \longrightarrow C_6H_5COCH_3$ *Nucleophile*

(d) *All the above are correct*

Interpret (*b*) In the reaction given in option (a), OH^- carries negative charge and is an electron rich species so behaves as a nucleophile.

In the reaction given in option (b), CN^- carries negative charge and is also an electron rich species, so it is also a nucleophile.

In the reaction given in option (c), CH_3CO^+ carries positive charge and is an electron deficient species, so it acts as an electrophile.

Hot Spot 2

NUCLEOPHILICITY

It is a very important topic for JEE Main examination. By just following a few rules, you can answer questions based on nucleophilicity, which is more important and sometimes create confusion. So learn these rules and do practice.

Nucleophilicity is the theory of an element in a molecule/ion/species to donate its lone pair to an electrophile.

Following rules are considered while comparing the nucleophilicities of different nucleophiles.

(I) In case of same nucleophilic site, nucleophilicity parallels basicity, *i.e.,* as the basicity of nucleophile increases, its strength also increases. *e.g.,* the order of nucleophilicity is

$$RO^- > OH^- < ArO^- \quad (\text{Here, } R \neq CH_3)$$

This is because in all these, nucleophilic site is O. In RO^-, R group, being electron releasing, makes the O site more nucleophilic. OH^- is less nucleophilic because of the absence of any such group whereas ArO^- is least nucleophilic because of the presence of electron withdrawing Ar group.

The conjugate acid of above bases have the following order of acidity.

$$ROH > H_2O < ArOH$$

Hence, the order of basicity of their base is just opposite because conjugate base of a strong acid is weak or *vice-versa.*

Caution Points

(*i*) *Methanol is a stronger acid than* H_2O *but other alcohols are weaker than it.*

(*ii*) *If attacking atoms are different, nucleophilicity varies inversely with electronegativity. e.g., the order of nucleophilicity of halide ion is*

$$I^- > Br^- > Cl^- > F^-$$

(*this order is solvent dependent*)

Similary, sulphur being less electronegative than oxygen, is more nucleophilic. Similar is true in case of P *and* N.

The overall decreasing order of nucleophilicity for S_N2 *reaction in protic solvent is as follows.*

$$RS^- > ArS^- > I^- > CN^- > OH^- > N_3^- > Br^- > ArO^- > Cl^-$$

$$> \text{pyridine} > CH_3COO^- > H_2O$$

(III) A nucleophile carrying negative charge is more powerful nucleophile as compared to its conjugate acid *e.g.*, OH^- is a strong nucleophile as compared to H_2O and NH_2^- is strong nucleophile than NH_3.

***Sample* Problem 19** *The decreasing order of nucleophilicity of the following is*

I. CH_3S^- *II.* CH_3O^-
III. OH^- *IV.* EtO^-

(*a*) *IV > III > II > I*
(*b*) *I > II > III > IV*
(*c*) *IV > III > I > II*
(*d*) *II > I > III > IV*

Interpret (*c*) In II, III and IV nucleophilic site is same, so nucleophilicity follows the same order as basicity. The order of acidic character of conjugate acid of these base is

$$EtOH < H_2O < CH_3OH$$

So, the order of basicity of their base is opposite *i.e.*,

$$EtO^- > OH^- > CH_3O^-$$

Between I and II, CH_3S^- is more nucleophilic as S is less electronegative as compared to O. So the order of nucleophilicity is

$$\underset{IV}{EtO^-} > \underset{III}{OH^-} > \underset{I}{CH_3S^-} > \underset{II}{CH_3O^-}$$

Comparison between Electrophiles and Nucleophiles

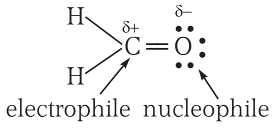
Electrophiles and nucleophiles differ in several aspects which are tabulated below.

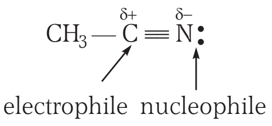
Table 13.5 **Comparison between Electrophiles and Nucleophiles**

S. No.	Electrophile	Nucleophile
1.	These are electron deficient species, usually cations.	These are electron rich species, usually anions.
2.	They possess an empty orbital in which they can accomodate an electron pair, thus behaves as Lewis acids.	They possess an unshared pair of electrons which they can donate easily, thus behaves as Lewis bases.
3.	They attack at the regions of high electron density.	They attack at the regions of low electron density.
4.	They are represented as E^+.	They are represented as $Nu\!:$.

Ambiphiles

Some molecules behave like both electrophiles and nucleophiles. These are called **ambiphiles.** Generally organic compounds containing a multiple bond between carbon and a more electronegative atom can act as ambiphiles. *e.g.*,





Isocyanides although cannot behave in these ways as their structure is

$$-\overset{+}{N}\equiv\overset{-}{C}\!:\longleftrightarrow -N=C\leftarrow \text{(bivalent)}$$

It is attacked by Nu as well as E^+.

Check Point 3

1. Propane on heterolysis gives methyl anion and ethyl carbocation but not ethyl carbocation. Explain.
2. Benzyne has following structure  the C_1 and C_2 are attached through triple bond but are sp^2 hybridised. Explain.
3. In between C and N atoms of isocyanides, multiple bond is present but they do not behave like ambiphiles. Explain.
4. Which one is more stable: singlet carbene or triplet carbon. Give reason.

13.14 Electronic Displacement in a Covalent Bond

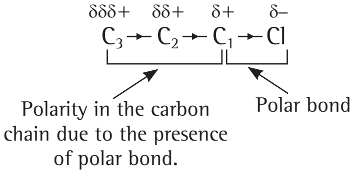
Presence of some atom or group in a molecule or presence of attacking reagent may lead to electronic displacement in a covalent bond. As a consequence of which, centres of different electron densities are generated. These centres are susceptible to attack by the reagents. The factors that create the centres of different electron densities are discussed below.

Hot Spot 3

INDUCTIVE Effect

It is the most important topic of the chapter for JEE Main examination. Questions are generally based on the application of inductive effect and their difficulty level is generally moderate (average).

The **inductive effect** is defined as **polarity produced in a molecule due to the presence of a polar bond.** *e.g.,* In a chain of carbon atoms with a chlorine atom joined to the last C-atom, due to higher electronegativity of chlorine atom, the electron distribution varies as



This induction of polarity due to the presence of polar bond in an organic molecule is called inductive effect.

The inductive effect is

(i) a permanent effect

(ii) operate through σ bonds

(iii) decreases in magnitude as we move away from the cause of polarity (*i.e.,* polar bond)

(iv) generally observed in saturated compounds.

For practical purpose the inductive effect is ignored after the second C-atom. It must be born in mind that the electron pairs although permanently displaced but they do not leave their valence shells.

Positive and Negative Inductive Effects

For measurement of relative inductive effects, atoms or groups having greater electron affinity than hydrogen are said to have $-I$ effect **(electron attracting).** Similarly, atoms or groups having smaller electron affinity than hydrogen are said to have $+I$ effect **(electron releasing or repelling).** Actually $-I$ group produce partial positive charge (*i.e.,* decrease in electron density due to more attracting power) while $+I$ groups produce partial negative charge (*i.e.,* increase in electron density due to less attracting power) on the carbon chain.

Some of the $-I$ effect producing groups in decreasing order of inductive effect are

$$R_3\overset{+}{N} > \overset{+}{N}H_3 > NO_2 > CN > SO_3H > CHO > CO > COOH >$$
$$COCl > COOR > CONH_2 > F > Cl > Br >$$
$$I > OH > OR > NH_2 > C_6H_5 > H$$

$-I$ power in decreasing order with respect to H

On the other hand alkyl groups, O and COO$^-$ are $+I$ groups. The $+I$ effect of different alkyl groups is as

$—O^- > —COO^- >$ tertiary alkyl group > secondary alkyl group > primary alkyl group $> —CH_3 > H$

$+I$ power of same type of alkyl groups varies directly with the number of C-atoms in the alkyl group *i.e.,*

$+I$ power $\propto$ number of C-atoms in same type of alkyl group

[The terminology ($+I$ and $-I$) is due to **Ingold,** while **Robinson** has suggested opposite signs. To avoid confusion, we shall use Ingold terminology throughout.]

Applications of Inductive Effect

The applications of inductive effect include

1. **In determining the stability of free radicals, carbocations and carbanions** following relationships are considered

(i) Stability of carbocation or free radical

$$\propto +I \text{ power of the group}$$
$$\propto \frac{1}{-I \text{ power of the group}}$$

Thus, the stability order for carbocations and free radicals is

$$1° < 2° < 3°$$

(ii) Stability of carbanions $\propto -I$ power of the group

$$\propto \frac{1}{+I \text{ power of the group}}$$

and the stability order for carbanions is

$$1° > 2° > 3°$$

2. **In determining the strength of acids and bases following relationships are considered**

(i) Strength of an acid $\propto K_a \propto \dfrac{1}{pK_a} \propto$ stability of acid anion

As stability of acid anion (or conjugate base)

$$\propto -I \text{ power of group present}$$
$$\propto \frac{1}{+I \text{ power of group present}}$$

Thus, **strength of acid increases with the attachment of group showing $-I$ effect and decreases with the attachment of group showing $+I$ effect.**

Although Ph group is $-I$ effect showing group, HCOOH (formic acid) is more acidic than benzoic acid (PhCOOH). This is because of $+R$ (resonance effect) of phenyl (Ph or C_6H_5) group.

(ii) Similarly strength of a base $\propto +I$ power of group present in the base $\propto K_b \propto \dfrac{1}{pK_b}$

$$\propto \frac{1}{-I \text{ power of group present in the base}}$$

However, this relation is not true for amines in their aqueous solutions as here the basicity is decided by combined effect of inductive effect, solvation effect and steric hindrance. The order of some of the amines are as

R of amine	Relative basic sterngth
CH_3—	2°>1°>3°> NH_3
C_2H_5—	$R_2NH > R_3N > RNH_2 > NH_3$
Me_2CH—	$RNH_2 > NH_3 > R_2NH > R_3N$
Me_3C—	$NH_3 > RNH_2 > R_2NH > R_3N$

The above two relations can be summarised as

Acid/Base	Group with +*I* effect	Group with –*I* effect
Acidic strength of acid	Decreases with this group	Increases with this group
Basic strength of base	Increases with this group	Decreases with this group

3. **In determining the reactivities of carbonyl compounds towards nucleophilic reagent** following relationship is considered

$$\text{Reactivity of carbonyl compound} \propto -I \text{ power of the group}$$
$$\propto \frac{1}{+I \text{ power of the group}}$$

4. Reactivity of alkyl halides is also determined by considering *I* effects.

Reactivity of alkyl halide towards S_N1 reaction is

$$3° > 2° > 1° \ \textit{i.e.}, \propto +I$$
$$\propto \frac{1}{-I}$$

Reactivity of alkyl halides towards S_N2 reactions follows reverse order of S_N1 reaction.

Sample Problem 20 *What is the correct order of decreasing stability of the following cations?*

$\underset{I}{CH_3—\overset{\oplus}{C}H—CH_3}$ $\underset{II}{CH_3—\overset{\oplus}{C}H—OCH_3}$

$\underset{III}{CH_3—\overset{\oplus}{C}H—CH_2—OCH_3}$ **[NCERT Exemplar]**

(a) *II* > *I* > *III* (b) *II* > *III* > *I*
(c) *III* > *I* > *II* (d) *I* > *II* > *III*

Interpret (a) $CH_3\overset{+}{C}H$ is same in all the cations, thus stability is affected by *Y* group in $CH_3\overset{+}{C}HY$

Stability of carbocation ∝ + *I* showing group.

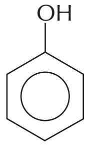
Order of + *I* effect of *Y* group is

$$—OCH_3 > —CH_2OCH_3 > —CH_3$$

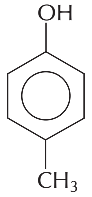
Thus, order of stability is

$$\underset{II}{CH_3\overset{+}{C}H\,OCH_3} > \underset{III}{CH_3\overset{+}{C}H\,CH_2OCH_3} > \underset{I}{CH_3\overset{+}{C}H\,CH_3}$$

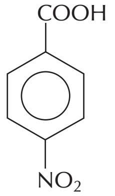
Sample Problem 21 *The acidic strength of the following compounds is in the order*



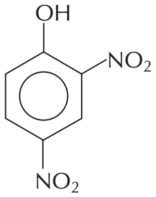
(*I*)



(*II*)



(*III*)



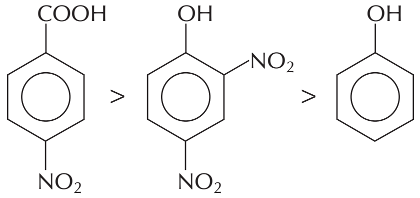
(*IV*)

(a) (*II*) > (*I*) > (*III*) > (*IV*) (b) (*III*) > (*IV*) > (*I*) > (*II*)
(c) (*I*) > (*IV*) > (*III*) > (*II*) (d) (*IV*) > (*III*) > (*I*) > (*II*)

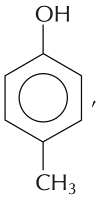
Interpret (*b*) Presence of electron withdrawing group, *i.e.*, the group showing –*I* effect, results in increased acidity while presence of electron releasing groups, *i.e.*, the group showing + *I* effect results in decreased acidity. —COOH, $—NO_2$, —OH all are electron withdrawing groups and the order of their –*I* effect is

$$—NO_2 > —COOH > —OH$$

Thus, the order of acidity is



(III) (IV) (I)



, however, is less acidic among the given compounds due to the presence of electron releasing $—CH_3$ group. Hence, the order of acidity is

III > IV > I > II

Sample Problem 22 *Arrange the following compounds in increasing order of acidity.*

I. $CH_3CH(Br)CH_2COOH$ *II*. $CH_3CH_2\,CH(Br)\,COOH$
III. $CH_3CH_2\,C(Br)_2\,COOH$ *IV*. $CH_3Br\,CH_2\,CH_2\,COOH$

(*a*) *II* > *III* > *I* > *IV*
(*b*) *III* > *IV* > *I* > *II*
(*c*) *III* > *II* > *I* > *IV*
(*d*) *III* > *I* > *II* > *IV*

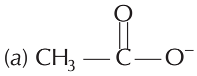
Interpret (*c*) As we know inductive effect decreases as we move away from the cause of polarity. Here Br group is the cause of polarity, so as the distance between Br and COOH increases inductive effect as well as acidity decreases. Thus, the order of acidity is

III > II > I > IV

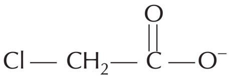
more -I group

Remember! as the distance between +*I* showing group and —COOH increases, acidity increases.

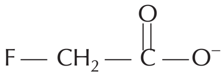
Sample **Problem 23** *Ionic species are stabilised by the dispersal of charge. Which of the following carboxylate ion is the most stable?* **[NCERT** Exemplar]

(*a*)


$CH_3—\overset{\overset{O}{\|}}{C}—O^-$

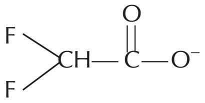
(*b*)


$Cl—CH_2—\overset{\overset{O}{\|}}{C}—O^-$

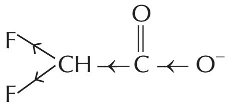
(*c*)


$F—CH_2—\overset{\overset{O}{\|}}{C}—O^-$

(*d*)



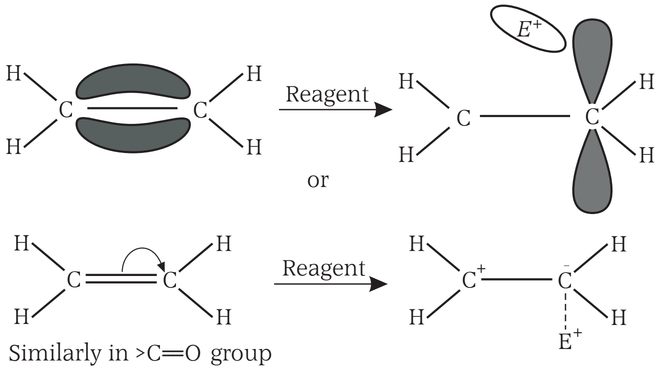
Interpret (*d*) Presence of two electron withdrawing – F atoms in $CF_2H – COO^-$ ion, makes the $\overset{\overset{O}{\|}}{C}—O^-$ carbon more electron deficient and hence, help in dispersal of negative charge.



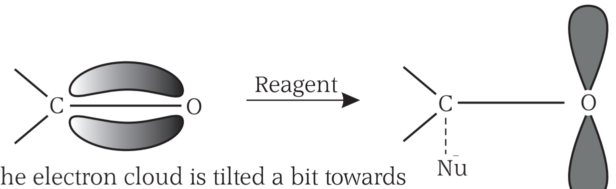
Electromeric Effect

The electromeric effect can be defined as *"Polarity produced in a multiple bonded compound as a reagent approaches it"* When a π bond is exposed to a reagent, the two π electrons are completely transferred to any of the one atom forming such a bond, thus producing polarity. *This is a temporary effect and brought into play only in the presence of attacking reagent.*

If π and σ bond both are present in a compound, the reagent always attacks the π electron cloud first because π electron cloud is always much more exposed than a σ electron cloud. *e.g.,* in ethylene molecule when an electrophile part of the reagent attacks the π bond, the symmetry of molecular orbital is disturbed as



Similarly in >C=O group



The electron cloud is tilted a bit towards oxygen due to its high electronegativity

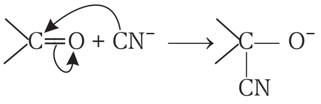
It is a strong effect because of the involvement of weak π bonds.

The electromeric effect is represented by means of a *curved arrow beginning at original position of the electron pair and denoting where the pair has migrated.* This effect may be of +*E* type or of – *E* type.

(1) If the electrons of the π-bond are transferred to that atom of the double bond to which the reagent gets finally attached, it is known as + *E* effect.

$CH_3—CH=CH_2 + H^+ \longrightarrow CH_3—\overset{+}{C}H—CH_3$

(2) If the electrons of the double bond are transferred to an atom of the double bond other than the one to which the reagent gets finally attached, the effect is known as – *E* effect.



Caution Point *In cases where inductive and electromeric effect both occur together, these may be aiding or opposing each other. Here it is not worthy that when these two effects are working in opposite directions, it is the electromeric effect that usually overcomes the inductive effect.*

Conjugation

A given atom or group is said to be in **conjugation** with an unsaturated system if it satisfies following two conditions

1. It has either π bond or any charge or odd electron or lone pair of electron.
2. It is directly linked to one of the atoms of multiple bond through a single bond. *e.g.,*

(i) $CH_2=CH—CH=CH_2$
(conjugation between 2π bonds)

(ii) $CH_2=CH—C\equiv N$
(conjugation between 2π bonds; one between 2 C-atoms and one between C and N)

(iii) $CH_2=\overset{+}{C}H—CH_2$
(conjugation between a π bond and a charge)

(iv) $CH_2=CH—\ddot{N}H_2$
(conjugation between a π bond and a lone pair)

Atoms or groups in conjugation with π electron should be at alternate position and in the same plane and at the same angle with each other.

Types of Conjugation

Conjugation can be of following types

(i) π-π conjugation
(ii) π and charge conjugation

(iii) π and odd electron conjugation
(iv) π and lone pair conjugation
(v) Lone pair and charge or odd electron conjugation

Consequences of Conjugation

Conjugation results in delocalisation of electrons which is visible through following observation

(i) Improper bond length, *i.e.,* bond length will not be as per expectations
(ii) The compound containing conjugated system will show extra stability (with antiaromatic compounds as exception).
(iii) As the compound will be extra stable that means its heat of formation will be greater than expected.

Conjugation in a Molecule

While looking for conjugation one must keep following points in mind

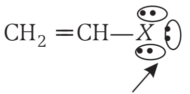
(i) **If any conjugate position has more than one π bond then only one π bond participates in conjugation** (See example (ii) above)

or in $CH_2{=}CH-C{\equiv}CH$

Here only one π bond out of two participates takes part in conjugation.

(ii) If any conjugate position has more than one lone pairs then only one lone pair participates in conjugation.

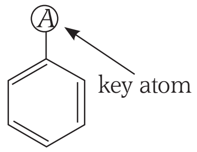
e.g.,



Here out of 3 lone pairs of halogen only one participates in conjugation.

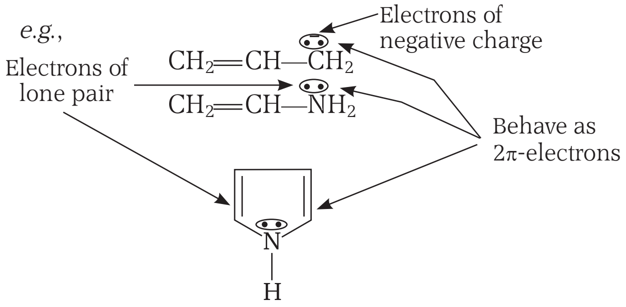
(iii) Key atom (atom other than hydrogen which is bonded with benzene ring) on aromatic ring will be in conjugate position if it has one of the following :

(i) A π bond
(ii) A charge
(iii) A lone pair
(iv) An odd electron

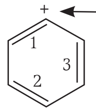


(iv) **Electrons of negative charge** or **lone pair** behaves as 2π electrons if these are in conjugation with 2π electrons.

e.g.,

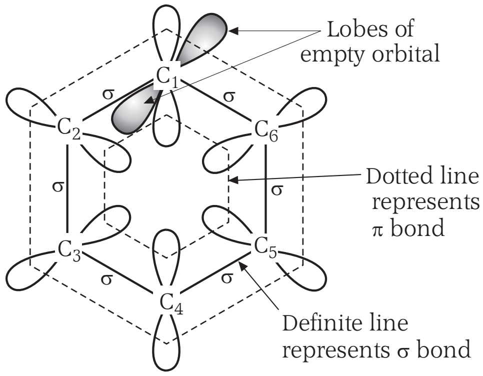


(v) Always remember alternate position and same plane with same angles for conjugation *e.g.,*



This charge does not conjugate with π bond as both of them are not in the same plane although the charge is in alternate position with π-bond number 3.

(Here, alternate position does not work but **same plane with same angle works.** Actually real conditions for conjugation are same plane with same angle while the alternate position is an assumption because these two conditions are normally fulfilled by this assumption.)



The orbitals of all the C-atoms with definite line are participating in conjugation (are in the same plane) while orbital with positive charge (empty orbital) of C_1 atom (here shown with dotted lines) cannot participates as it lies in different plane.

Resonance

Occassionally no reasonable electronic picture can be drawn for a molecule which could satisfactorily account for its observed properties. In such a condition, we assume several structures of the compound each one of which contribute to some of its observed properties but none of these structures satisfactorily account for all of its observed properties. The structure of such a compound is said to be resonance hybrid and the phenomenon is called resonance.

Thus, *"When several structures may be assumed to contribute to the true structure of the molecule but no one of them can be said to represent it uniquely, the molecule is referred to as a resonance hybrid and the phenomenon is termed as resonance". Such several structures are called canonical forms or resonating structures.*

It is hoped that the following crude functional similarity will help the reader to grasp the concept of resonance. "The mule is a hybrid of the jackass and the mare". It has inherited characteristics from both the parents, *e.g.,* it can carry load like an ass, and run faster like a mare. However when we look at the mule, we do not see a jackass at one glance and a mare at another, we see a mule always. In the similar way a resonance hybrid does not oscillate between its canonical forms. Its properties are fixed and these are the properties of the actual hybrid structure. It is hoped that you must have understood the meaning of word resonance. Now what are the chief conditions of resonance *i.e.,* in which conditions we can say that this hypothetical process is working. *The process of resonance can be said to occur only in one condition and that is when we are unable to explain all the observed properties of a compound with a single structure.*

In resonance,

1. *The arrangement of atoms must be identical or almost same in every formula.*
2. *The energy content of all the canonical forms must be nearly the same.*
3. *Each canonical form must have the same number of unpaired electrons.*

In a compound known to show resonance,

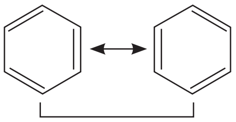
1. Heat of formation of resonance hybrid is abnormally high, *e.g.,* the observed heat of formation of CO_2(= 1590 kJ / mol) is greater than the calculated value (= 1464 kJ/mol) of the heat of formation of its most stable structure. The difference in heat of formation, *i.e.,*

   $$\underset{\text{(observed)}}{\text{Heat of formation}} - \underset{\text{(calculated)}}{\text{Heat of formation}}$$

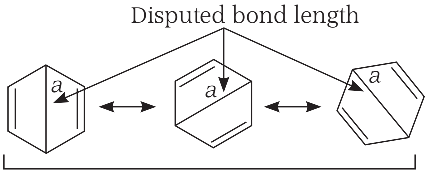
   is called the **resonance energy,** which is assumed to be the energy lost when a molecule acquires resonance hybrid formula.
2. The bond length in resonance hybrid is variable as compared to bond length in canonical forms.
3. The resonance hybrid is always stable than any of its canonical forms. *e.g.,*
   (i) CO_2 is said to have following canonical forms

   $$O{=}C{=}O \longleftrightarrow O^- — C{\equiv}O^+ \longleftrightarrow \overset{+}{O}{\equiv}C — O^-$$

   (ii) Benzene may be represented by following structures



Kekule structures



Dewar structures

In both the above examples the actual structure of CO_2 or benzene is more stable than either of the structures described.

(Later on Dewar structures were discarded as there one double bond (marked *a* in the figure above) is lengthy. Any π bond between 2 carbon atoms cannot have such length.)

Stability of a Canonical Form

Among the canonical forms the most stable canonical form can be judged by following rules

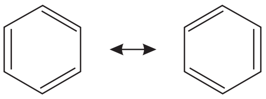
1. Among all the canonical forms **the form without charges will be the most stable one.**
2. Among the **charged forms**
   - (i) The structure with maximum number of covalent bonds is most stable one.
   - (ii) The structure with maximum charge separation comes second in number.
   - (iii) The structure with **conventionally correct charges** comes at third place (Here convention means the reason because of which charge arise)

Relation between Resonance and Bond Order

In compounds exhibiting resonance, bond order can be given by the formula

$$\text{Bond order} = \frac{\text{Total number of bonds between two atoms}}{\text{Total number of resonating structures}}$$

e.g., In benzene molecule with following canonical forms



$$\text{Bond order} = \frac{2+1}{2} = 1.5$$

Misconceptions Associated with Resonance

1. The canonical forms have no real existence.
2. There is no equilibrium between the canonical forms.
3. The molecule does not exist for a certain fraction of time in one canonical form and for other fractions of time in other canonical forms.

Sample **Problem 24** *Which of the following resonating structures of 1-methoxy-1,3-butadiene is least stable?*

(*a*) $\overset{\ominus}{C}H_2—CH{=}CH—CH{=}\overset{\oplus}{O}—CH_3$

(*b*) $CH_2{=}CH_2—\overset{\ominus}{C}H—CH{=}\overset{\oplus}{O}—CH_3$

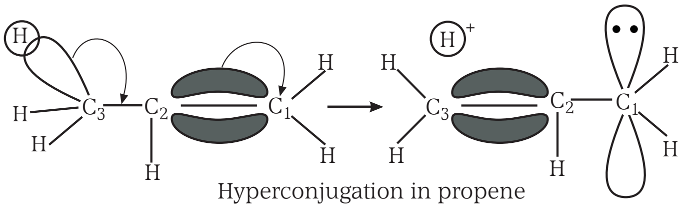
(*c*) $\overset{\ominus}{C}H_2—\overset{\oplus}{C}H—CH{=}CH—O—CH_3$

(*d*) $CH_2{=}CH—\overset{\ominus}{C}H—\overset{\oplus}{C}H—O—CH_3$

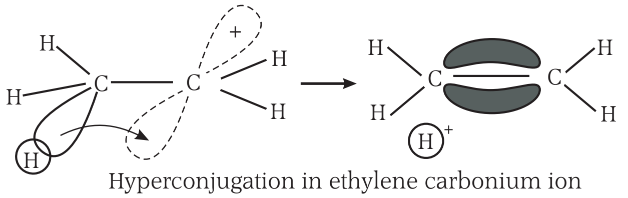
Interpret (c), In structures given in option (a) and (b), all the atoms have their complete octet. Moreover, these have more number of covalent bonds as compared to structure (c) and (d). In structure (d), the lone pair of electrons of adjacent oxygen atom compensates the electron deficiency of positively charged carbon whereas such neighbouring group support is not available in structure (c). Hence, it is the least stable resonating structure.

Hyperconjugation

It is shown by heat of hydrogenation data that alkenes are stabilized not only by conjugation but also by the presence of alkyl groups. Greater the number of alkyl groups attached to the doubly bonded carbon atoms, the more stable is the alkene, *e.g.*, propylene is more stable than ethylene. *Stabilization by alkyl group has been attributed to delocalisation of electrons due to overlapping between a π orbital and a σ bond orbital of the alkyl group* (C—H bond basically). *Such an overlapping is called hyperconjugation* which results to actually **no bond resonance.** This phenomenon is also helpful in stabilising carbonium ions and free radicals, *e.g.*,

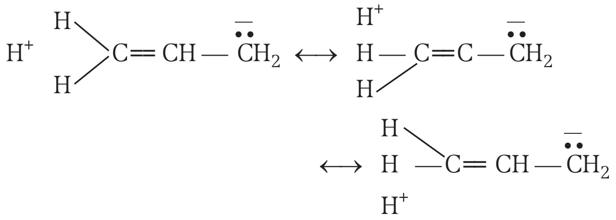


Hyperconjugation in propene

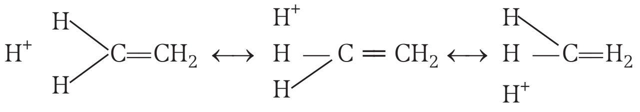


Hyperconjugation in ethylene carbonium ion

As in both the cases a methyl group is present near to the π bond (in propene) or (+)ve charge (in ethyl carbonium ion), all the three C—H bonds of it have equal probability of showing hyperconjugation. Thus, both of them have three hyperconjugative structures as



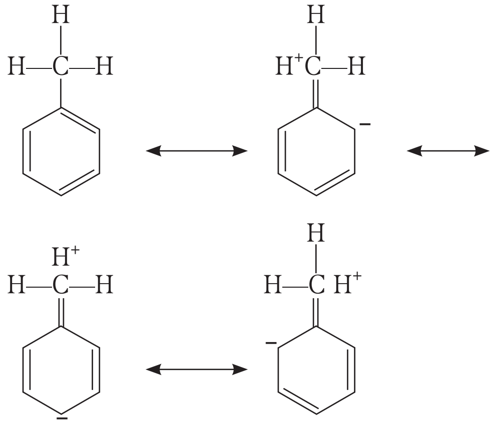
Hyperconjugative structures of propene



Hyperconjugative structures of ethyl carbonium ion

In both the above cases it is seen clearly that C—H bond of alkyl group possess a partial ionic character due to resonance *i.e.*, C—H covalent bond is not seen in resonating structure that's why the process is also called **no bond resonance** or **Baker Nathan effect**.

Hyperconjugation can also be seen in toluene as follows



Structure Requirements for Hyperconjugation

These are as follows

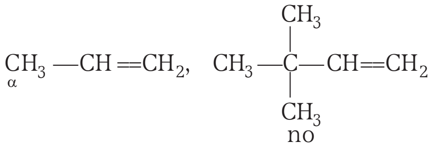
(i) Compound should have at least one sp^2 hybrid carbon of either alkene, alkyl carbocation or alkyl free radical.

(ii) α-carbon with respect to sp^2 hybrid carbon should have at least one hydrogen. *More the number of* H—C *bonds attached to the unsaturated system, more stable will be the alkene.*

Types of Hyperconjugation

Hyperconjugation is of three types

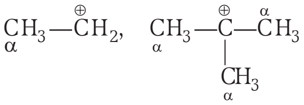
(i) **(C — H), π-conjugation** → This type of conjugation occurs in alkenes.



$$\underset{\alpha}{CH_3}-CH{=}CH_2,\quad CH_3-\overset{CH_3}{\underset{CH_3}{C}}-CH{=}CH_2$$

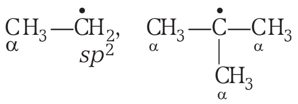
no hyperconjugation here

(ii) **(C — H), positive charge conjugation** → This type of conjugation occurs in alkyl carbocations.



$$\underset{\alpha}{CH_3}-\overset{\oplus}{C}H_2,\quad \underset{\alpha}{CH_3}-\overset{\oplus}{\underset{\underset{\alpha}{CH_3}}{C}}-\overset{\alpha}{CH_3}$$

(iii) **(C — H), odd electron conjugation** → This type of conjugation occurs in alkyl free radicals.



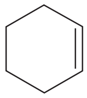
$$\underset{\alpha}{CH_3}-\underset{sp^2}{\dot{C}H_2},\quad \underset{\alpha}{CH_3}-\overset{\bullet}{\underset{\underset{\alpha}{CH_3}}{C}}-\underset{\alpha}{CH_3}$$

Applications of Hyperconjugation

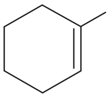
Following are the important applications of hyperconjugation.

(i) **The stability of alkene** can be determined on the basis of hyperconjugative structures. Always remember the more hyperconjugating structures an alkene possess, the more stable it is.

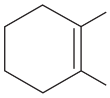
e.g., Out of



I



II

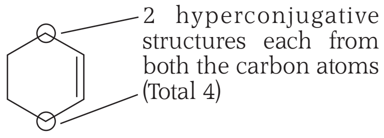


III

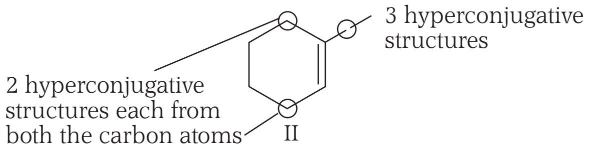
The stability order will be written as

$$\underset{\text{most stable}}{\text{III}} > \text{II} > \underset{\text{least stable}}{\text{I}}$$

The reason being I has minimum number of hyperconjugative structures (*i.e.,* 4) while 2nd have (7) and IIIrd have maximum number of hyperconjugative structures (*i.e.,* 10) as

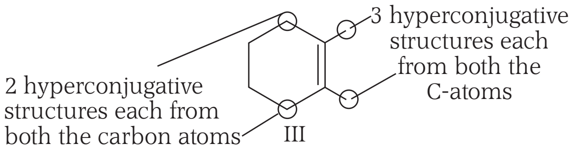


I



II

Total 4 + 3 = 7 structures

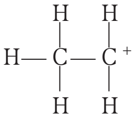


III

Total 6 + 4 = 10 structures

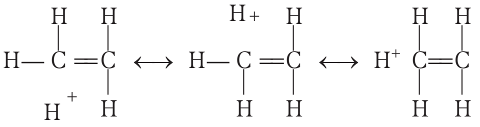
(ii) **Stability of alkyl free radicals and carbocations**

The stability of alkyl free radicals and carbocations can also be explained on the basis of hyperconjugation. Just like alkenes, *more the number of hyperconjugative structures seen in a free radical or carbonium ion more stable it is e.g.,* ethyl carbonium ion has following 3 hyperconjugative structures.



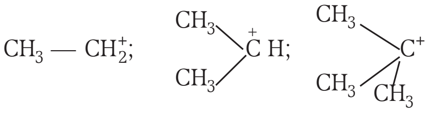
$$H-CH_2-\overset{+}{C}H_2$$

ethyl carbonium ion



hyperconjugative structures

Now, when we compare the stability of following ions



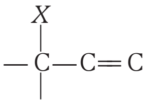
I II III

The I structure has 3 hyperconjugative structures, the II has 6 and the III has 9 hyperconjugative structures hence, the stability order of above three ions will be

$$\underset{\text{most stable}}{(CH_3)_3C^+} > (CH_3)_2CH^+ > \underset{\text{least stable}}{CH_3CH_2^+}$$

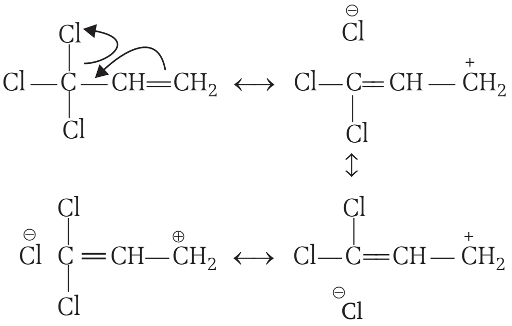
Reverse Hyperconjugation

The phenomenon of hyperconjugation is also observed in the system given below.



$$-\overset{X}{\underset{|}{\overset{|}{C}}}-C=C$$

In such system, the effect operates in the reverse direction. Hence, the hyperconjugation in such system is known as reverse hyperconjugation.



Check Point 4

1. Why is electromeric effect considered as a strong effect whereas *I* effect as a weak effect.
2. Why does a reagent attack first on the electron cloud as compared to σ electron clouds?
3. Explain why,
   (i) The central carbon-carbon bond in 1,3-butadiene is shorter than that of *n*-butane?
   (ii) Anilinium ion does not show mesomeric effect while aniline does?
4. Arrange the following in increasing order of their basic strength : $(C_6H_5)_3N$, $C_6H_5NH_2$, NH_3, RNH_2, R_3N, R_2NH, C_6H_5NHR, $C_6H_5CH_2NH_2$, $C_6H_5NHC_6H_5$.
5. Why benzyl carbocation is more stable than ethyl carbocation?
6. Which CX_2 (where, $X =$ F, Cl, Br, I) is the most stable singlet as compared to the corresponding triplet?

13.15 Common Types of Organic Reactions

The organic reactions can be categorised into following five categories

1. Substitution reactions
2. Addition reactions
3. Elimination reactions
4. Addition-elimination reactions
5. Rearrangement reactions

1. Substitution Reactions

A substitution reaction is that which involves the direct replacement (displacement or substitution) of an atom or a group of atoms in an organic molecule by another atom or group of atoms without any change in the remaining part of the molecule. The product obtained as a result of substitution is called the **substitution product** and the new atom or group of atoms which enters the molecule is called a **substituent,** *e.g.,*

$$R{-}CH_3 + X_2 \xrightarrow[520\text{–}670\text{ K}]{h\nu \text{ or}} \underbrace{R{-}CH_2\overset{\text{Substituent}}{\boxed{X}}}_{\text{substitution product}} + HX$$

Substitution reactions can further be classified into three categories on the basis of intermediate species which begins the reaction. These are

(i) Free Radical Substitution

Substitution reaction brought about by free radicals are called **free radical substitutions.** The best example of this kind of reactions is **halogenation of alkanes** in the presence of sunlight or heat *i.e.,*

$$\underset{\text{substrate-1}}{R{-}CH_3} + \underset{\substack{\text{substrate-2}\\ \text{or reagent}}}{X_2} \xrightarrow[\text{heat}]{\text{Sunlight}} \underset{\text{product-1}}{RCH_2X} + \underset{\text{product-2}}{HX}$$

Halogenation reactions are mainly given by those hydrocarbons which have at least one hydrogen on sp^3 hybrid carbon.

Free radical reactions run under following three steps (These reactions are infact chain reactions).

Step I **Chain initiation step** It involves the formation of free radicals from the reagent *i.e.,*

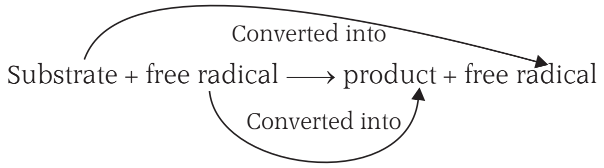
$$\text{Reagent} \xrightarrow[h\nu \text{ or free radical initiators}]{\text{Heat or}} \text{two free radicals}$$

e.g., for the above halogenation reaction

$$X_2 \xrightarrow[\text{free radical initiators}]{\text{Heat or } h\nu \text{ or}} X^{\bullet} + X^{\bullet}$$

This step can be recognised by the fact that free radicals are present on the product side i.e., after the arrow.

Step II **Chain propagation step** It Involves attack of radicals formed in step I on the substrate *i.e.,*



e.g., in the above reaction.

$$\underset{\text{substrate-1}}{R{-}CH_3} + \underset{\text{free radical}}{X^{\bullet}} \longrightarrow \underset{\text{free radical}}{R\dot{C}H_2} + \underset{\text{product-2}}{HX}$$

The free radical obtained continues the process as follows

$$\underset{\text{free radical}}{R{-}\dot{C}H_2} + \underset{\substack{\text{substrate-2}\\ \text{or reagent}}}{X_2} \longrightarrow \underset{\text{product-1}}{RCH_2X} + \underset{\text{free radical}}{X^{\bullet}}$$

This free radical formed further attacks on substrate-1

Thus, the steps continue repeating till one of the substrates is finished.

(*This step can be recognised by the presence of free radicals on both the sides of arrows.*)

Step III **Chain termination step** This step comes into action only when one of the substrates is finished. Here, the free radicals which are present combine at random, resulting to various kinds of products in traces *i.e.,* For the above reaction :

$$\dot{X} + \dot{X} \longrightarrow X_2$$

$$R{-}\dot{C}H_2 + R{-}\dot{C}H_2 \longrightarrow R{-}CH_2{-}CH_2{-}R$$

$$R{-}\dot{C}H_2 + \dot{X} \longrightarrow R{-}CH_2X$$

(*This step can be recognised by the presence of free radicals before the arrow only*)

Following is the decreasing order of reactivity of halogens (on the basis of electronegativity)

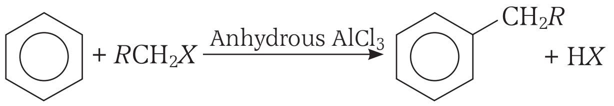
$$F_2 > Cl_2 > Br_2 > I_2$$

Following is the decreasing order of ease of abstraction of different kinds of hydrogens (on the basis of hyperconjugation and + *I* effect)

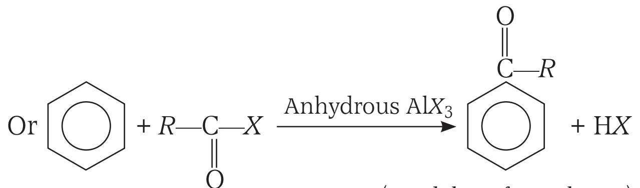
$$3^\circ \text{ hydrogen} > 2^\circ \text{ hydrogen} > 1^\circ \text{ hydrogen} > CH_3{-}H.$$

(ii) Electrophilic Substitution Reactions

The substitution reactions which are initiated by electrophiles, are called electrophilic substitution reactions. *These reactions are characteristics of aromatic compounds, e.g.,*



(Friedel Crafts' alkylation)



(Friedel-Crafts acylation)

Any electrophilic substitution reaction involves following three steps

***Step I* Liberation of electrophile from reagent**

$$[E^+Nu^-] + \text{catalyst} \longrightarrow \text{catalyst } Nu^-\text{complex} + E^+$$

Note This reagent can be any compound which is broken heterolytically

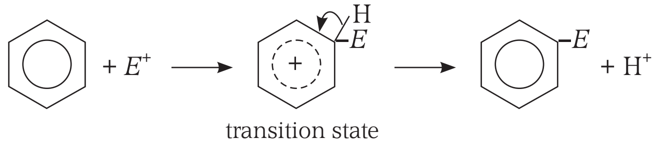
Note This can be any Lewis acid, *i.e.,* electron deficient compound

Thus, for the above reaction

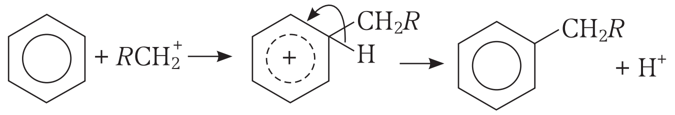
$$R\text{—}CH_2X + AlX_3 \longrightarrow \underset{\substack{Nu^- \text{ catalyst}\\ \text{complex}}}{AlX_4^-} + \underset{\text{electrophile}}{RCH_2^+}$$

***Step II* Attack of electrophile on benzene ring**

The electrophile formed in step I then attacks on the benzene ring as follows



Thus, in the above reaction



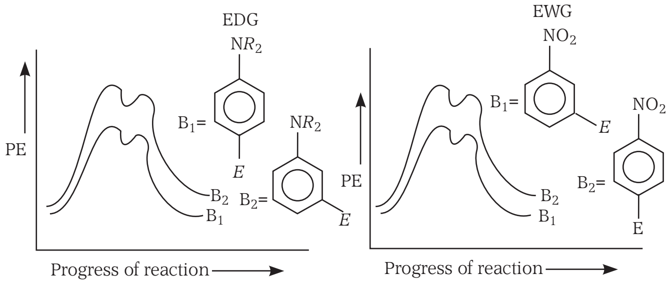
***Step III* Liberation of catalyst from catalyst Nu^- complex** The H^+ formed in step II attacks on catalyst Nu^- complex as

$$\text{Catalyst } Nu^- \text{ complex} + H^+ \longrightarrow H^+Nu^- + \text{catalyst}$$

Thus, in the above reaction

$$AlX_4^- + H^+ \longrightarrow HX + \underset{\text{catalyst}}{AlX_3}$$

Electron donating groups favour electrophilic substitution reactions whereas electron withdrawing groups disfavour them. Energy level diagram for such reactions is



Lower energy path for *p*-substitution
(a)

Lower-energy path for *m*-substitution
(b)

Fig. 13.1 Energy level diagram with (a) electron donating group (b) electron withdrawing group

Hot Spot 4

NUCLEOPHILIC Substitution Reactions

It is also an important topic for JEE Main examination point of view. Generally questions based on mechanism type and favourable factors are asked in the examination. The level of questions may vary from easy to difficult.

The reactions involving substitution which begins with attack of nucleophile are called **nucleophilic substitution reactions.** These are usually written as S_N (S-substitution, N = nucleophile) and are of two types, *i.e.,* **unimolecular** (shown as S_N1) and **bimolecular** (shown as S_N2)

These reactions are generally seen in alkyl halides and alcohols, *e.g.,*

$$RX + KOH(aq) \longrightarrow ROH + KX$$

1. **Bimolecular nucleophilic substitution (S_N2)** reaction is seen in primary alkyl halides and alcohols. The term bimolecular means, here, the rate of reaction depends upon the concentration of two molecule *i.e.,*

   Rate expression can be given as

   $$\text{Rate} \propto [A][B] \text{ for the reaction}$$

   $$A + B \longrightarrow C + D$$

   In specific words, we can say that the rate of reaction depends upon the concentration of substrate as well as of nucleophile and can be shown as

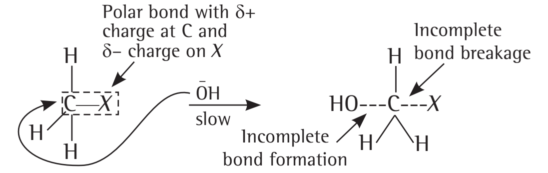
$$\text{Rate of reaction} \propto [\text{Substrate}]\,[Nu^-]$$

Let us consider the hydrolysis of any primary alkyl halide (say CH_3X) with aqueous KOH, *i.e.,*

$$CH_3X + KOH(aq) \longrightarrow CH_3OH + KX$$

The reaction is a multistep reaction and proceeds as

Step I

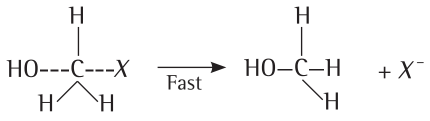


Here, C–X bond is polar thus negatively charged (electron dense) nucleophile is attracted towards δ+ carbon atom as shown

Transition state with incomplete C—OH bond formation and incomplete C—X bond breakage (both seen with dotted lines)

In this step, the OH^- cannot attack from the front side due to the przesence of electron rich *X* (halogen atom) on the front side which can repel OH^- and the transition state have all the C—H bonds in same plane.

Step II



transition state

product
Here the C—*X* bond gets fully broken and HO—C bond is fully formed

The alcohol formed here have opposite configuration to that of the parent alkyl halide (or has been inverted as an umbrella turns inside out in a high wind). This change in configuration is called **Walden's inversion.**

The step 1 of this reaction is slower step *i.e.,* formation of transition state is the rate determining step of this reaction. In the reaction step, involvement of both substrate and nucleophile (involvement can be judged by the presence of both in the transition state) suggest that

$$\text{Rate} \propto [\text{Alkyl halide}][\bar{O}H]$$

Hence, the reaction is considered as bimolecular.

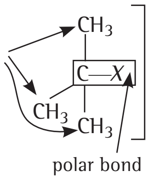
S_N2 **reactions are both stereospecific and stereoselective.** Some important facts related to this mechanism are

1. The order of reactivity of alkyl halide towards S_N2 mechanism is Me > 1° > 2° > 3°.
2. S_N2 reactions is catalysed by phase transfer catalysts *e.g.*, $R_4N^+X^-$ and by crown ethers.
3. If Nu (nucleophile) and reactant are uncharged, the rate increases with increase in solvent polarity.
4. If either one or both Nu and reactant are charged, the rate decreases with increase in solvent polarity.
5. In polar aprotic solvent the rate increases (DMSO >DMF > acetone), since such solvents leave the most reactive nucleophile free.
6. Rate of such reactions depends upon nucleophilicity. Greater the nucleophilicity, faster is the rate of reaction.

2. Unimolecular Nucleophilic Substitution

This reaction is the characteristic of tertiary alkyl halides and alcohols. In these molecules S_N2 reaction is not possible due to **steric hindrance** (steric = structure). Presence of three electron releasing alkyl groups along with an electron rich halide group or hydroxyl group hinders the reaction to occur through S_N2 pathway. This will be more clear if we examine a tertiary alkyl halide.

+*I* effect of these three groups reduces the $\delta+$ charge on C-atom attached to *X*.

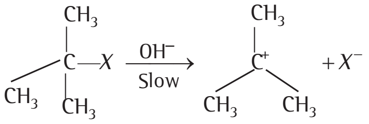


Target C-atoms for nucleophile, Note
1. Presence of $4e^-$ rich groups repel Nu^- to attack.
2. Reduced positive charge on C-atoms also does not favour S_N2 mechanism.
3. Alkyl groups being larger covered the target C-atom from sides.

Thus, in such cases the structure hinders the process to occur in accordance with S_N2 pathway that's why the reaction proceeds through another pathway, called S_N1 pathway or polar mechanism.

Here, the multistep reaction proceeds as

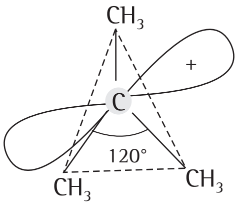
Step I



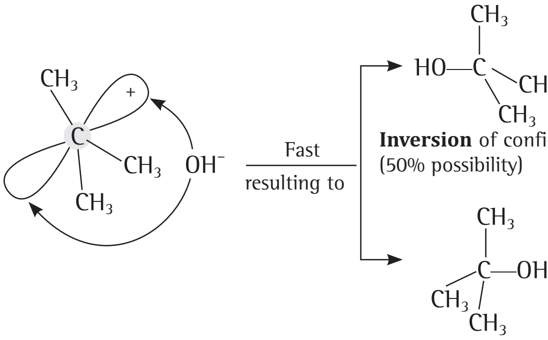
The C—*X* bond is broken due to the presence of nucleophile resulting to formation of a tertiary carbonium ion and X^- instead of transition state *i.e.*, ions are developed due to heterolysis in place of transition state.

During this step following changes take place

1. The bond angle between three alkyl groups come to 120° from 109°·28′ (in alkyl halide).
2. The empty orbital present in carbonium ion seems to present perpendicular to the plane of alkyl groups (as carbonium ion is sp^2 hybridised).



Step II The OH^- attacks on empty orbital as



Inversion of configuration (50% possibility)

Retention of configuration (50% possibility)

The alcohol formed here can have two possibilities

(i) 50% chances are there of *retention* in configuration.
(ii) 50% chances are there of *inversion* in configuration.

The rate determining step *i.e.,* step 1 of this reaction involves one molecule only *i.e.,* alkyl halide, hence,

$$\text{Rate of reaction} \propto [\text{Alkyl halide}]$$

S_N1 **reaction is non-stereospecific and non-stereoselective** as the attack of nucleophile is not specific and the products are a mixture of enantiomers.

Some Important facts about this mechanism are

(i) The order of reactivity of halides towards S_N1 reactions is

benzyl > allyl > 3°>2°>1°>Me

(ii) These reactions are catalysed by heavy metal ions, Lewis and Bronsted acids.

(iii) The rate of such reactions increases in polar solvents, *i.e.*, rate $\propto \alpha$-H bonding ability of solvent and dielectric constant.

(iv) The rate of such reactions remain unaffected by the concentration of nucleophile.

Caution Points

(*i*) *Secondary alcohols can proceed through either of these mechanisms.*

(ii) *Rearrangement of the carbocation (formed in S_N1 reaction) leading to more stable carbocation is also observed in S_N1 reaction.*

(iii) *High concentration of the nucleophile favours S_N2 reaction while low concentration favours S_N1 reaction.*

(iv) $(CH_3)_3CCH_2Br$ *shows S_N2 reaction with $C_2H_5O^-$, but S_N1 reaction with C_2H_5OH.*

Sample **Problem 25** *Under S_N1 conditions the hydrolysis of neo-pentyl bromide gives*

(*a*) $CH_3-\underset{CH_3}{C}=CH-CH_2OH$

(*b*) $CH_3-\overset{CH_3}{\underset{OH}{C}}-CH_2CH_3$

(*c*) $CH_3-\overset{CH_3}{\underset{CH_3}{C}}-CH_2OH$

(*d*) *None of these*

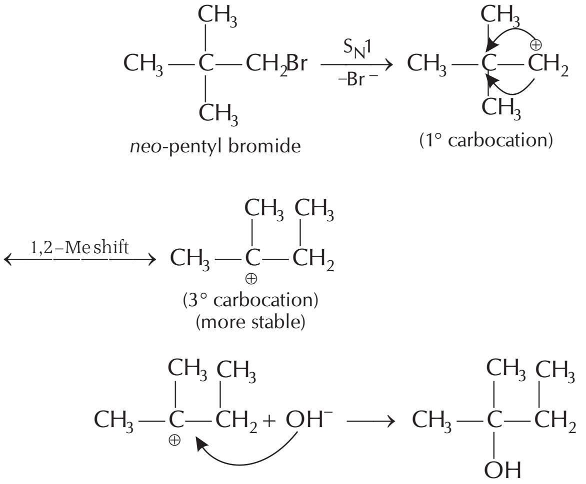
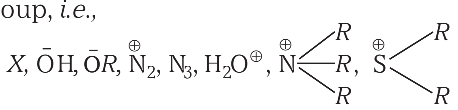
Interpret (*b*) $CH_3-\overset{CH_3}{\underset{OH}{C}}-CH_2CH_3$ is the major product of this reaction. The formation of the unexpected product is due to the rearrangement of the first formed 1°carbocation to the 3° carbocation as



---

2. Elimination Reactions

An elimination reaction is one that involves the loss of two atoms or groups of atoms from the same or adjacent atoms of a substance leading to the formation of a multiple (double or triple) bond. Elimination reaction is given by those compounds which have a nucleophile as leaving group, *i.e.*,



$X, \bar{O}H, \bar{O}R, \overset{\oplus}{N}_2, N_3, H_2O^{\oplus}, \overset{\oplus}{N}R_3, \overset{\oplus}{S}R_2$

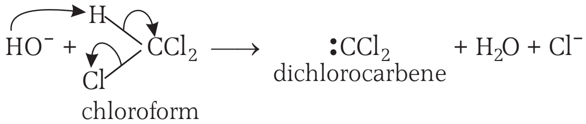
These reactions are generally endothermic and take place on heating. Moreover, **these are very common in alcohols and alkyl halides.**

In these reactions, there is loss of two σ bonds and gain of one π-bond, consequently, the product of such reactions is usually less stable than the reactant.

Elimination reactions are of two types

(i) α-elimination Reactions or 1,1-elimination Reactions

In these reactions, the loss of two atoms or groups occurs from the same atom of the substrate molecule, *e.g.*, base-catalysed dehydrohalogenation of chloroform to form dichlorocarbene



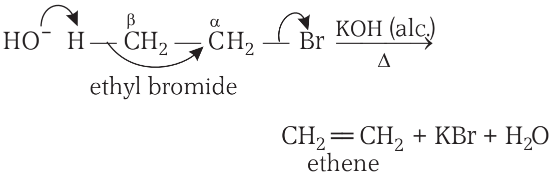
Dichlorocarbene is the reactive intermediate involved in carbylamine reaction and Reimer-Tiemann reaction.

(ii) β-elimination Reactions

In these reactions, the loss of two atoms or groups occurs from the adjacent atoms of the substrate molecule, *e.g.*, acid-catalysed dehydration of alcohols and base-catalysed dehydrohalogenation of alkyl halides

Acid-catalysed dehydration of alcohols

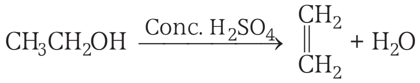
Base-catalysed dehydrohalogenation of alkyl halides



The β-elimination reactions proceed through two pathways just like nucleophilic substitutions. These are infact E_1 and E_2 pathways *i.e.*, unimolecular elimination and bimolecular elimination respectively.

(i) **Bimbolecular elimination (E_2) reactions are characteristic of primary alkyl halides and alcohols.** Just like S_N2 reaction pathway, here also a transition state is formed.

e.g., in the reaction



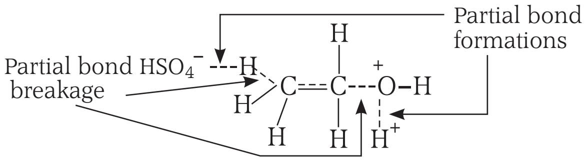
$$CH_3CH_2OH \xrightarrow{\text{Conc. } H_2SO_4} \begin{matrix} CH_2 \\ \| \\ CH_2 \end{matrix} + H_2O$$

The reaction proceeds as

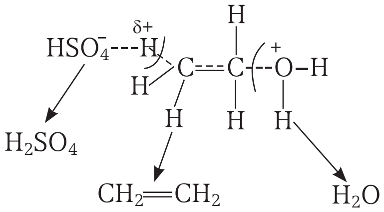
Step I H_2SO_4 gives H^+ and HSO_4^- as

$$H_2SO_4 \rightleftharpoons H^+ + HSO_4^-$$

Step II H^+ attacks on the oxygen of —OH group while HSO_4^- attacks on the H atom of adjacent C–atom to form the transition state. The transition state formed is explained with the help of hyperconjugation.



Step III The transition stage shows lysis as



In the above reaction as the transition state involves the participation of both alcohol and H_2SO_4 thus

$$\text{Rate of reaction} \propto [\text{alcohol}]\,[H_2SO_4]$$

Another example of such a reaction is dehydrohalogenation of primary alkyl halides.

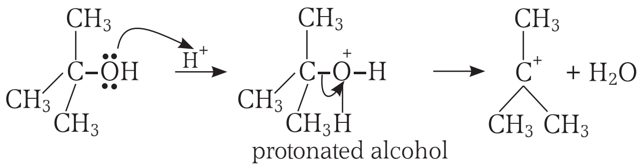
(ii) **Unimolecular elimination** (E_1) pathway is seen in tertiary alkyl halides and alcohols due to steric hindrance.

The unimolecular elimination proceeds as

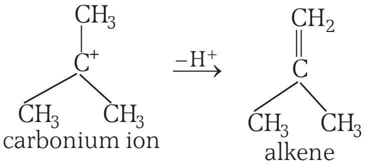
Step I H_2SO_4 dissociates as

$$H_2SO_4 \rightleftharpoons H^+ + HSO_4^-$$

Step II H^+ attacks on alcohol as



Step III The carbonium ion generated in step II stabilises itself with hyperconjugation to form alkene as



(This process is exactly as that of S_N1 pathway till the step II. The difference lies only in step III which involves substitution in S_N1 and elimination here in E_1.)

Substitution *Vs* Elimination Product

A good base favours elimination whereas a good nucleophile favours substitution reactions. The proportion of elimination and substitution products depends upon the following factors

(a) Nature of Substrate

The proportion of elimination increases with increase in the branching of carbon chain, *i.e.*, 1°→2°→3° because the alkenes formed on elimination are stabilised by hyperconjugation. Also the steric strain due to crowding is relieved on the formation of alkenes, whereas on substitution, the strain is reintroduced. Moreover, the substituted groups such as (C=C) and (Ph) in the substrate (which can stabilise the developing alkene) favour elimination. Thus, C_2H_5Br gives about 1% alkene while $PhCH_2CH_2Br$ gives about 99% $PhCH{=}CH_2$ (styrene).

(b) Nature of Base

1. Strong base favours elimination over substitution (in particular E2 over E1.
2. In low base concentration and in polar solvents, S_N1 reaction is favoured over E1.
3. High concentration of base in non-polar solvents favour E2 over S_N2. That's why alcoholic KOH favours elimination and aqueous KOH favours substitution.
4. Strong nucleophiles but weak bases promote substitution over elimination, whereas strong bases but weak nucleophiles promote elimination over substitution.
5. A large nucleophile favours elimination.

(c) Nature of Solvent

A more polar solvent increases the rate of S_N1 reactions and decreases S_N2 reactions. A less polar solvent although favours E2 over S_N2.

The change of hydroxylic solvents to aprotic solvents increases the base strength because the solvent layer around the base by H-bonding is absent. Thus, $Cl^{\ominus}$, $OH^{\ominus}$, $OR^{\ominus}$, etc., are very strong bases in DMF (dimethyl formamide) or DMSO (dimethyl sulphoxide).

The use of aprotic solvents may sometimes change the pathway from E1 to E2. *e.g.*, the nucleophilicity order increases with the decreasing basicity of elements. The nucleophilicity order of the halides is $I^{\ominus} > Br^{\ominus} > Cl^{\ominus} > F^{\ominus}$, but in aprotic solvents such as DMF or DMSO, the order is reversed, *i.e.*, $F^{\ominus} > Cl^{\ominus} > Br^{\ominus} > I^{\ominus}$.

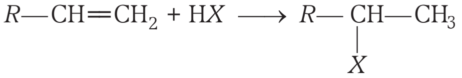
(d) Effect of Temperature

In elimination, the strong (C—H) bond has to break, hence high activation energy is required for elimination. High temperature favours elimination rather than substitution.

Caution Point *In general, elimination increases with strong base of high concentration, low polarity of solvent and high temperature. Substitution increases with the weak base of low concentration, high polarity of solvent, and low temperature.*

3. Addition Reactions

Reactions which involve combination between two reacting molecules to give a single molecule of the product are called addition reactions. Such reactions are typical of compounds containing multiple (double and triple) bonds, *e.g.*,



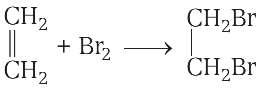
$$R—CH{=}CH_2 + HX \longrightarrow R—\underset{\displaystyle X}{\underset{|}{CH}}—CH_3$$

or $$R—CH{=}CH_2 + H_2 \xrightarrow{Ni-250°C} R—CH_2CH_3$$

Addition reactions can be further classified into following three categories on the basis of the intermediate species which begins the reaction.

(i) Electrophilic Addition Reactions

Here, the electrophilic part of reagents initiates the reaction, *e.g.*,

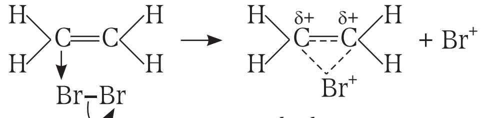


$$\begin{matrix} CH_2 \\ \| \\ CH_2 \end{matrix} + Br_2 \longrightarrow \begin{matrix} CH_2Br \\ | \\ CH_2Br \end{matrix}$$

The reactions are normally seen in those compounds **where π electron cloud is evenly distributed** *i.e.,* alkenes and alkynes etc., (when π bonds is formed between two atoms of same or almost same electronegativity).

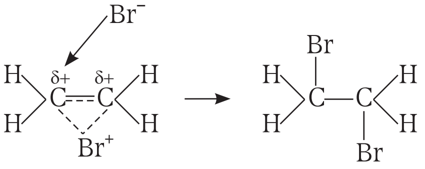
The reaction proceeds *via* the formation of a cyclic intermediate as under

Step I



cyclic bromonium ion

Step II Br^- attacks on either of the δ + charge containing carbonium ions as

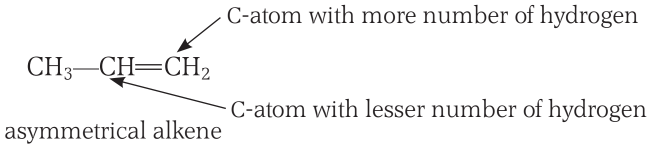


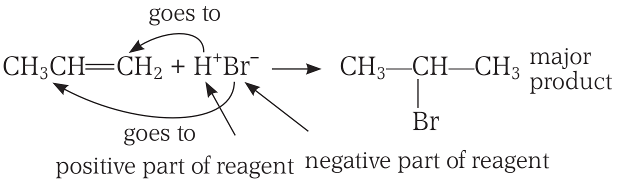
Caution Points

(*i*) *In anti addition like halogenation, cis alkene gives d and l products. trans alkene gives meso form.*

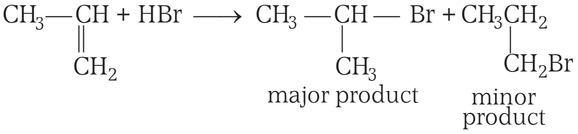
(*ii*) *In syn addition like hydrxylation cis alkene gives meso product trans alkene gives d and l products.*

Markownikoff's rule is useful in such conditions when an asymmetrical reagent is added to an asymmetrical alkene and says that in such additions positive part of reagent goes to that C–atom which have more number of hydrogens or negative part of reagent goes to that C–atom which have lesser number of hydrogens, In case, number of hydrogens are same, negative part goes to the carbon having more number of alkyl groups. If number of alkyl groups are also same then addition occur but this rule is not followed *e.g.,*





The Markownikoff's addition of HBr to propene also involves electrophilic addition and can be seen as



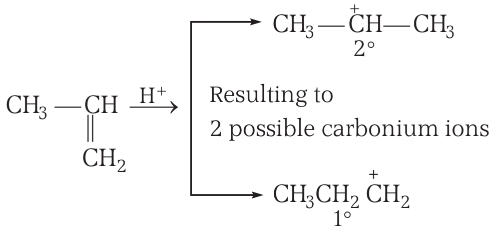
$$CH_3—\underset{\displaystyle CH_2}{\underset{\|}{CH}} + HBr \longrightarrow \underset{\text{major product}}{CH_3—\underset{\displaystyle CH_3}{\underset{|}{CH}}—Br} + \underset{\text{minor product}}{CH_3\underset{\displaystyle CH_2Br}{\underset{|}{CH_2}}}$$

The above reaction can be explained as

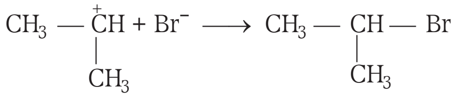
Step I HBr gives a H^+ and a Br^- ion, *i.e.*,

$$H—Br \longrightarrow H^+ + Br^-$$

Step II The H^+ attacks the π bond of propene to form carbonium ion as

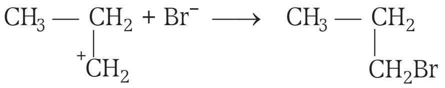


The 2° carbonium ion is more stable, thus



$$CH_3—\overset{+}{C}H(CH_3) + Br^- \longrightarrow CH_3—CH(CH_3)—Br$$

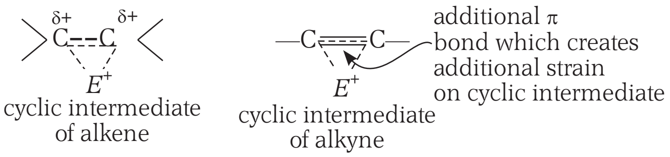
major product



$$CH_3—CH_2—\overset{+}{C}H_2 + Br^- \longrightarrow CH_3—CH_2—CH_2Br$$

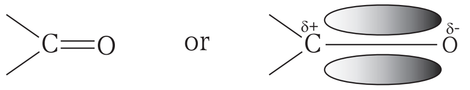
minor product

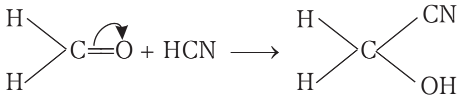
Alkenes are more reactive than alkynes as far as electrophilic additions are concerned although latter has more unsaturation than former. The reason for such a difference is more strained (less stable) cyclic intermediate in the case of alkynes due to the presence of additional π bond as



(ii) Nucleophilic Addition Reactions

In these reactions the nucleophilic part of reagent initiates the reaction. These additions are seen in those compounds which have unevenly distributed electron cloud, *i.e.*, have a π bond between two atoms of different electronegativity, *e.g.*, πe^- cloud in aldehydes and ketones, *i.e.*,





$$H_2C{=}O + HCN \longrightarrow H_2C(CN)(OH)$$

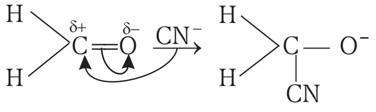
cyanohydrin

The reaction proceeds as follows

Step I HCN gives H^+ and CN^- as

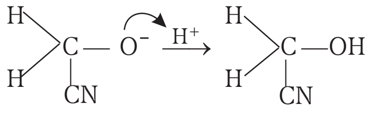
$$HCN \longrightarrow H^+CN^-$$

Step II CN^- attacks on carbon atom of carbonyl group to form corresponding anion as



$$H_2\overset{\delta+}{C}{=}\overset{\delta-}{O} \xrightarrow{CN^-} H_2C(CN)—O^-$$

Step III The proton attacks on anion to form the addition product as



$$H_2C(CN)—O^- \xrightarrow{H^+} H_2C(CN)—OH$$

The reactivity of aldehydes and ketones towards **nucleophilic additions** follows the order

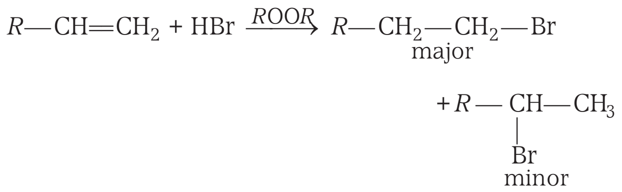
HCHO > other aldehydes > ketones

The reactivity in actual sense depends upon the magnitude of δ+ charge on the C-atom of >C═O group *i.e.*,

In  , C-atom bears maximum possible charge as in higher homologues, the magnitude of charge decreases due to the +*I* effect of an alkyl group attached in place of H. The magnitude further decreases in ketones as there the second hydrogen atom of HCHO is also replaced by another alkyl group.

(iii) Free Radical Addition Reactions

As addition reactions are commonly found in unsaturated compounds, the free radical additions involve additions through free radicals. The most common example of this type of reaction is addition of HBr to any asymmetric alkene in the presence of peroxide, *i.e.*,



$$R—CH{=}CH_2 + HBr \xrightarrow{ROOR} \underset{\text{major}}{R—CH_2—CH_2—Br} + \underset{\text{minor}}{R—CH(Br)—CH_3}$$

The reaction commonly called **Kharasch effect** or **peroxide effect** or **anti Markownikoff's** addition *i.e.*, here addition occurs opposite to Markownikoff's rule.

The free radical addition pathway in above written reaction proceeds as

Step I Initiation step

$$R—O—O—R \xrightarrow{h\nu \text{ or high temperature}} 2RO^\bullet$$

Step II Propagation steps

(i) $RO^\bullet + HBr \longrightarrow ROH + Br^\bullet$

(Homolytic fission of HBr by $RO^\bullet$ free radical)

(ii) 
Out of these two free radicals 2° free radical is more stable than 1° free radical.

(iii) 
$$CH_3\underset{\underset{Br}{|}}{CH}—\dot{C}H_2 + HBr \longrightarrow CH_3\underset{\underset{Br}{|}}{CH}CH_3 + Br^{\bullet}$$

(1°)less stable — minor product

$$CH_3 — \underset{\underset{Br}{|}}{\dot{C}H} — CH_2 + HBr \longrightarrow CH_3 — CH_2CH_2Br + Br^{\bullet}$$

(2°)more stable — major product

The stable intermediates give more product (major product) always due to following two reasons

(i) These lower the activation energy of the reaction.

(ii) These stay for a longer duration in the reaction.

Caution Point *The reaction is true for* HBr *only among halogen acids. The reason is* HF *and* HCl *bonds are so strong that their homolytic breakage is not possible with* $RO^{\bullet}$ *while* H—I *bond breakes easily but iodine free radicals are very unstable and generally combine to form* I_2 *molecule thus reducing the possibility of completion of reaction in this manner.*

4. Addition-Elimination Reactions

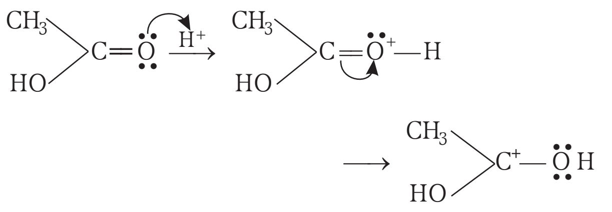
These reactions involve addition of two molecules with elimination of smaller molecules like H_2O. The best example of such a type of reaction is **esterification** *i.e.*,

$$C_2H_5OH + CH_3COOH \overset{H^+}{\rightleftharpoons} CH_3COOC_2H_5 + H_2O$$

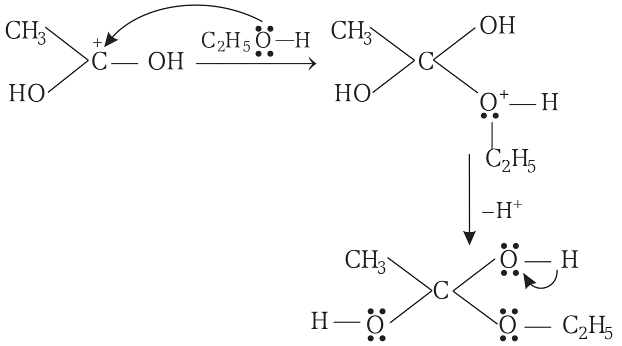
The reaction is said to proceed through **"nucleophilic addition-elimination"** and gives best result in the presence of mineral acids.

The **nucleophilic addition-elimination pathway with acid catalysed condition** for esterification can be said to proceed as follows

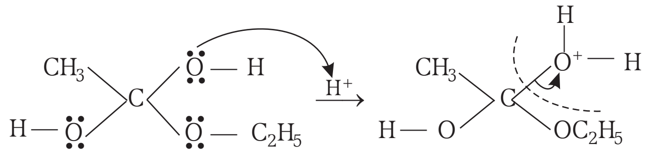
Step I Initially the H^+ of mineral acid attacks on O-atom of carbonyl part of —COOH group. Such an attack is said to create unit positive charge on C-atom of this group so that nucleophile can attack on it easily as



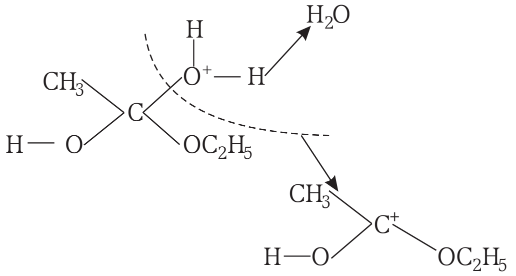
Step II Now the oxygen of alcohol donates its lone pair to positively charged C-atom of carbonium ion as



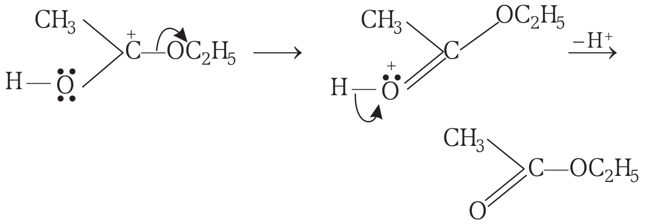
Step III The H^+ liberated in step II attacks on the oxygen of —OH group, taking the lone pair from it, thus



This results in liberation of water molecule and formation of another carbonium ion as



This carbonium ion stabilises itself as



(In this process the oxygen of alcohol remains intact and seen in ester itself. The process given above was fully worked out by **Fischer** in 1920, hence also called **Fischer Spierer** method commonly.)

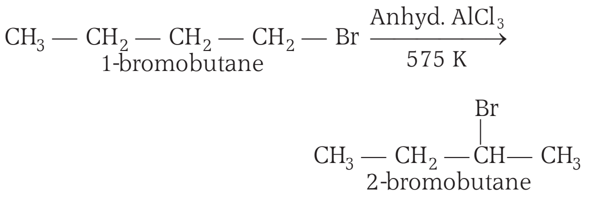
Two H^+ are used in the process and two are eliminated thus showing that H^+ is working as a catalyst **(During the reaction the concentration of catalyst remain unchanged).**

Other common examples of addition elimination reaction are addition of ammonia derivatives to aldehydes and ketones.

5. Rearrangement Reactions

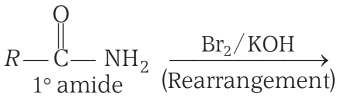
Reactions involving the migration of an atom or a group from one atom to another within the same molecule are called **rearrangement reactions,** *e.g.,*

(i) 1-bromobutane rearranges to 2-bromobutane in the presence of anhydrous $AlCl_3$ at 575 K.

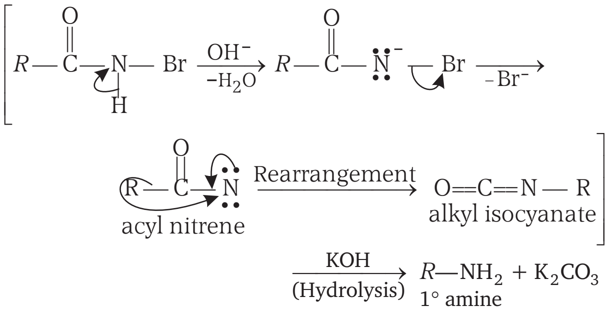


$$\underset{\text{1-bromobutane}}{CH_3—CH_2—CH_2—CH_2—Br} \xrightarrow[575\text{ K}]{\text{Anhyd. }AlCl_3} \underset{\text{2-bromobutane}}{CH_3—CH_2—\overset{Br}{\overset{|}{C}H}—CH_3}$$

(ii) **Hofmann bromamide reaction** involving the conversion of 1° amides to 1° amines on treatment with Br_2 in the presence of KOH.

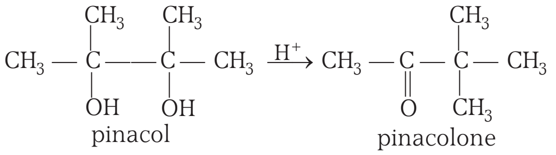


$$\underset{1°\text{ amide}}{R—\overset{O}{\overset{\|}{C}}—NH_2} \xrightarrow[\text{(Rearrangement)}]{Br_2/KOH}$$

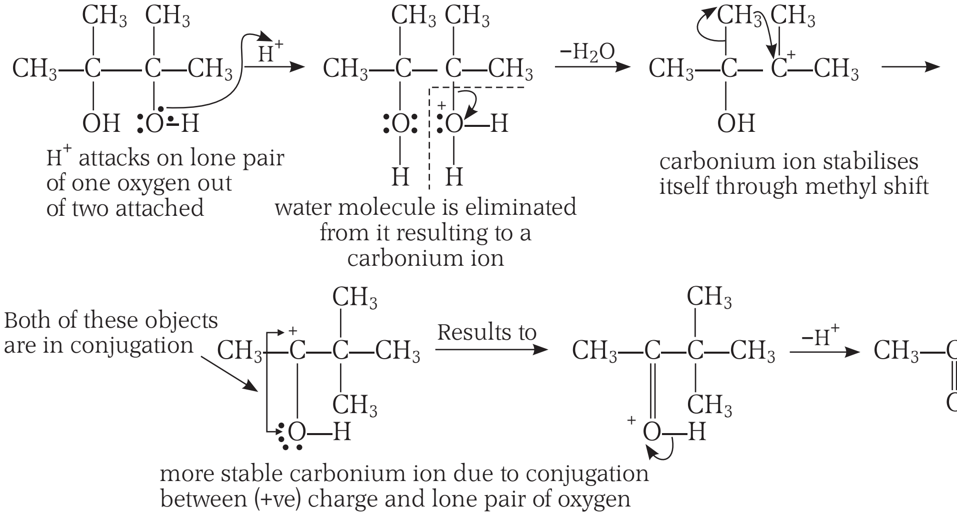


In this rearrangement reaction, the group *R* migrates from carbon to nitrogen to first give an alkyl isocyanate which upon hydrolysis gives a 1° amine with one carbon atom less than the original amide.

(iii) Another example of rearrangement reaction is a very common **pinacol-pinacolone** rearrangement which can be seen as



The reaction proceeds as

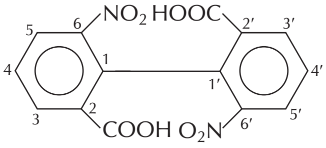


Check Point 5

1. Why allyl halides are more reactive than alkyl halides for S_N1 reaction?
2. Explain why carboxylic acids do not undergo substitution reaction under basic conditions?
3. Arrange benzene, toluene, methoxybenzene and chlorobenzene in increasing order of reactivity towards sulphonation.
4. Choose the reagent which will not give addition reactions with $CH_3—CH{=}CH_2$ and why?
   Br_2, HOCl, NaCl/HOH, NaOH, H_2, H*X*.
5. Arrange the following in increasing order of their nucleophilicity in a polar solvent. $\bar{N}_3$, $\bar{C}N$, OH^-, CH_3COO^-, Cl^-, H_2O. Also give the reason.

WORKED OUT Examples

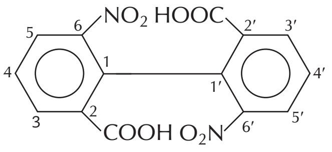
Example 1 *The IUPAC name of*



is

(*a*) 2, 2′-*dinitrodiphenic acid*
(*b*) 6, 6′-*dinitrodiphenic acid*
(*c*) 6, 6′-*dinitrophenyl*-2, 2′-*dicarboxylic acid*
(*d*) 2, 2′-*dinitrophenyl*-6, 6′-*dicarboxylic acid*

Solution (*c*)



6,6′-dinitrophenyl-2,2′-dicarboxylic acid

Example 2 *Consider the following compounds :*

(*i*) 1,2-*dichloroethene* (*ii*) *benzene*
(*iii*) 1,3-*butadiene* (*iv*) 1,3,5-*hexatriene*

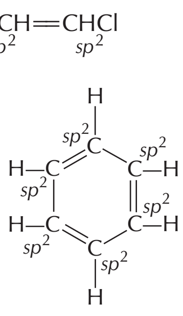
All the carbon atoms are sp^2 *hybridised in*

(*a*) (*i*), (*ii*), (*iii*) *only*
(*b*) (*i*), (*ii*) *only*
(*c*) (*i*) (*iii*), (*iv*) *only*
(*d*) *All of the above*

Solution (*d*) If a carbon atom forms three σ bonds, *i.e.*, attached through double bond, the hybridisation of the carbon is sp^2.

(i) $\underset{sp^2}{ClCH}=\underset{sp^2}{CHCl}$

(ii)



(iii) $\overset{sp^2}{CH_2}=\overset{sp^2}{CH}-\overset{sp^2}{CH}=\overset{sp^2}{CH_2}$

(iv) $\overset{sp^2}{CH_2}=\overset{sp^2}{CH}-\overset{sp^2}{CH}=\overset{sp^2}{CH}-\overset{sp^2}{CH}=\overset{sp^2}{CH_2}$

Example 3 *Which of the following is correctly connected for x and y ?*

$$\underset{\text{Bond length x Å}}{\underset{\downarrow}{CH_3-CH_2-\ddot{\underset{..}{Cl}}:}} \qquad \underset{\text{Bond length y Å}}{\underset{\downarrow}{CH_2=CH-\ddot{\underset{..}{Cl}}:}}$$

(*a*) $x = y$
(*b*) $x > y$
(*c*) $y > x$
(*d*) $x = 3y$

Solution (*b*) CH_3CH_2Cl is a non-conjugated compound, hence C—Cl bond will be pure single bond. $CH_2=CHCl$ is a conjugated compound, hence resonance effect works and a partial double bond character is developed between C and Cl and the bond length of a double bond is shorter as compared to that of a single bond. Thus, $x > y$.

Example 4 *Which of the following is the strongest nucleophile?*

(*a*) $CH_3-CH_2^-$
(*b*) $HC\equiv C^-$
(*c*) NH_2^-
(*d*) $H_2C=CH^-$

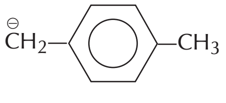
Solution (*a*) In case of same nucleophilic site, nucleophilicity parallels the basicity while in case of different sites, nucleophilicity varies inversely with electronegativity. Order of electronegativity, N > C.

Thus, the order of nucleophilicity C > N

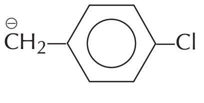
Among, $CH_3CH_2^-$, $HC\equiv C^-$ and $H_2C=CH^-$, $CH_3CH_2^-$ is the strongest nucleophile, as it is less electronegative (due to least *s*-character).

Example 5 *Which one of the following is most stable?*

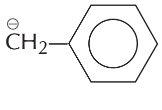
(*a*)



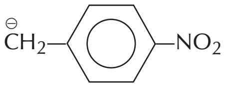
(*b*)



(*c*)



(*d*)



Solution (*d*) –*R* group present at *ortho* or *para* position increases the stability of carbanion.

Example 6 *Dichlorocarbene is generated by the action of potassium-1-butoxide on chloroform. This is an example of*

(*a*) *α-elimination reaction*
(*b*) *β-elimination reaction*
(*c*) *addition reaction*
(*d*) *rearrangement reaction.*

Solution (*a*) $\underset{\text{chloroform}}{CHCl_3} \xrightarrow{K(t\text{-butoxide})} \underset{\text{dichlorocarbene}}{:CCl_2}$

Since, the eliminating group, *i.e.,* hydrogen and chlorine,here are lost from the same carbon atom, it is an example of α-elimination reaction.

Example 7 *Which of the following is correctly matched?*

(*a*) CH_3CH_2OH	*Thermal elimination*
(*b*) $(CH_3)_3C\cdot OH$	*E*1 *reaction*
(*c*) $CH_3—CH_2—CH_2OH$	*$E1_{cb}$ reaction*
(*d*) *All of the above*	

Solution (*b*) Tertiary alcohols usually favour *E*1 reactions.

Example 8 *Which alcohol will be most reactive for dehydration?*

(*a*) $CH_3—\overset{OH}{\overset{|}{C}}H—CH_2—CN$

(*b*) $CH_3—\overset{OH}{\overset{|}{C}}H—CH_2—NO_2$

(*c*) $CH_3—\overset{OH}{\overset{|}{C}}H—CH_2—COCH_3$

(*d*) $CH_3—\overset{OH}{\overset{|}{C}}H—CH_2—CHO$

Solution (*b*) More is the acidity of β-hydrogen, more will be the reactivity of alcohol for dehydration. Presence of electron withdrawing group increases the acidity, thus $CH_3CH(OH)CH_2NO_2$ is most reactive for dehydration.

Start Practice for JEE Main

Round I (Topically Divided Problems)

General Terms and Classification of Organic Compounds

1. The first organic compound prepared in the laboratory was
(a) acetic acid (b) acetylene
(c) urea (d) methane

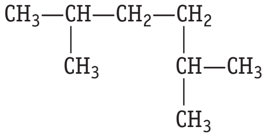
2. The huge number of organic compounds is due to the fact that
(a) carbon is tetravalent
(b) carbon possesses property of catenation
(c) carbon compounds exhibits polymerisation
(d) Both (a) and (b)

3. The alkane which has only primary hydrogen atom is
(a) pentane (b) *iso*-pentane
(c) *neo*-pentane (d) 2,2-dimethyl butane

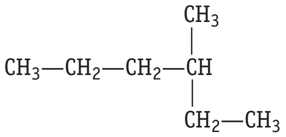
4. Alicyclic compounds are
(a) aromatic cyclic compounds
(b) aliphatic cyclic compounds
(c) Both (a) and (b)
(d) None of the above

5. The number of tertiary C-atoms in 2,2,4,4-tetra methyl pentane is
(a) 1 (b) 2
(c) 3 (d) 4

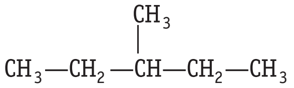
6. Which of the following structure contain 9 primary and 6 secondary hydrogen atoms?

(a)


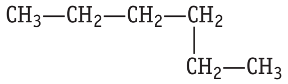
$CH_3-\underset{\underset{\displaystyle CH_3}{|}}{CH}-CH_2-\underset{\underset{\displaystyle \underset{\underset{\displaystyle CH_3}{|}}{CH}-CH_3}{|}}{CH_2}$

(b)


$CH_3-CH_2-CH_2-\overset{\overset{\displaystyle CH_3}{|}}{\underset{\underset{\displaystyle CH_2-CH_3}{|}}{CH}}$

(c)


$CH_3-CH_2-\overset{\overset{\displaystyle CH_3}{|}}{CH}-CH_2-CH_3$

(d)


$CH_3-CH_2-CH_2-\underset{\underset{\displaystyle CH_2-CH_3}{|}}{CH_2}$

7. Which of the following is a heterocyclic compound?
(a) Phenanthrene (b) Thiophene
(c) Phenol (d) Aniline

Bonding and Hybridisation in Organic Compounds

8. Which of the following represents the given mode of hybridisation $sp^2 - sp^2 - sp\text{-}sp$ from left to right?
(a) $CH_2{=}CH{-}C{\equiv}CH$ (b) $HC{\equiv}C{-}C{\equiv}N$
(c) $CH_2{=}C{-}C{=}CH_2$ (d)

9. How many sigma and pi bonds are there in the molecule of dicyanoethene $(CN{-}CH{=}CH{-}CN)$?
(a) 3 sigma and 3 pi (b) 5 sigma and 2 pi
(c) 7 sigma and 5 pi (d) 2 sigma and 3 pi

10. The enolic form of acetone contains
(a) 8σ bonds, 2π-bonds and 1 lone pair
(b) 9σ bonds, 1π-bond and 2 lone pairs
(c) 9σ bonds, 2π-bonds and 1 lone pair
(d) 10σ bonds, 1π-bond and 1 lone pair

11. In the dehydration reaction,

$CH_3CONH_2 \xrightarrow{P_2O_5} CH_3C{\equiv}N$, the hybridisation state of carbon changes from
(a) sp^3 to sp^2 (b) sp to sp
(c) sp^2 to sp (d) sp to sp^3

12. The shape of the π electron cloud in acetylene is
(a) linear (b) planar
(c) cylindrical (d) doughtnut

13. Electronegativity of carbon atoms depends upon their state of hybridisation. In which of the following compounds, the carbon marked with asterisk is most electronegative? **[NCERT Exemplar]**

(a) $CH_3—CH_2—{}^*CH_2—CH_3$
(b) $CH_3—{}^*CH{=}CH—CH_3$
(c) $CH_3—CH_2—C{\equiv}{}^*CH$
(d) $CH_3—CH_2—CH{=}{}^*CH_2$

14. The C—H bond distance is longest in

(a) C_2H_2
(b) C_2H_4
(c) C_2H_6
(d) $C_2H_2Br_2$

15. The maximum number of carbon atoms arranged linearly in the molecule, $CH_3—C{\equiv}C—CH{=}CH_2$ is

(a) 5
(b) 4
(c) 2
(d) 3

16. The basic strength of

$$\underset{\text{I}}{CH{\equiv}\bar{C}},\ \underset{\text{II}}{CH_2{=}\bar{C}H},\ \underset{\text{III}}{CH_3\bar{C}H_2}$$

will be in order

(a) I < II < III
(b) II < III < I
(c) III < II < I
(d) III < I < II

17. In the given structure, which carbon atom is most electronegative?

$$\underset{\text{(I)}}{CH_3}—\underset{\text{(II)}}{CH_2}—\underset{\text{(III)}}{CH}{=}\underset{\text{(IV)}}{\overset{\oplus}{C}H}$$

(a) (I)
(b) (II)
(c) (III)
(d) (IV)

Nomenclature of Organic Compounds

18. The incorrect statement for IUPAC system of nomenclature is

(a) in an organic compound, the longest carbon chain is always selected for assigning the root word
(b) there is no compound with the name 3-ethyl pentane
(c) out of $—NH_2$ and $—OH$ groups present in an organic compound, $—NH_2$ is treated as substituent
(d) different alkyl groups are written alphabetically while writing the IUPAC name

19. Which one is not correct for homologous series?

(a) All members are represented by same general formula
(b) All members have same chemical properties
(c) All members have same physical properties
(d) All members have same functional group

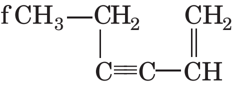
20. The correct statement related to IUPAC nomenclature is

(a) if two or more chains of equal length are seen in the compound then the chain with minimum number of side chains will be preferred
(b) if double and triple bonds are at symmetrical positions in a compound then triple bond gets lower preference
(c) correct IUPAC name of $CH_3COC_2H_5$ is ethyl methyl ketone
(d) as far as possible, the IUPAC name of a compound is written as a single word

21. Choose the option which show correct preferential order of groups among the following

(a) $—COOH, —CHO, —OH, —NH_2$
(b) $—NH_2, —OH, —CHO, —COOH$
(c) $—COOH, —OH, —NH_2, —CHO$
(d) $—COOH, —NH_2, —CHO, —OH$

22. The correct name of

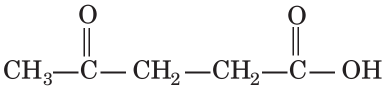


$$CH_3—CH_2—C{\equiv}C—CH{=}CH_2$$

is

(a) hex-3-yn-5-ene
(b) hex-5-en-3-yne
(c) hex-3-yn-1-ene
(d) hex-1-en-3-yne

23. The IUPAC name for

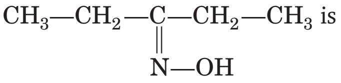


$$CH_3—\overset{\overset{\large O}{\|}}{C}—CH_2—CH_2—\overset{\overset{\large O}{\|}}{C}—OH$$

is **[NCERT Exemplar]**

(a) 1-hydroxypentane-1,4-dione
(b) 1, 4-dioxopentanol
(c) 1-carboxybutan-3-one
(d) 4-oxopentanoic acid

24. The IUPAC name of the compound

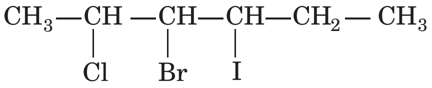


$$CH_3—CH_2—\underset{\underset{\large N—OH}{\|}}{C}—CH_2—CH_3$$

is

(a) N-hydroxy-3-aminopentane
(b) N-hydroxyaminopentane
(c) N-hydroxy-3-iminopentane
(d) None of the above

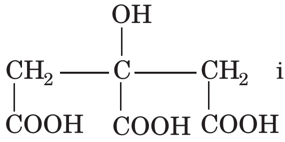
25. The correct IUPAC name of the compound is



$$CH_3—\underset{\underset{\large Cl}{|}}{CH}—\underset{\underset{\large Br}{|}}{CH}—\underset{\underset{\large I}{|}}{CH}—CH_2—CH_3$$

(a) 4-bromo-5-chloro-3-iodohexane
(b) 3-bromo-2-chloro-4-iodohexane
(c) 3-bromo-4-iodo-2-chlorohexane
(d) 2-chloro-3-bromo-4-iodohexane

26. The correct IUPAC name of

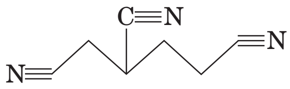


$$\begin{array}{ccccc} & & OH & & \\ & & | & & \\ CH_2 & — & C & — & CH_2 \\ | & & | & & | \\ COOH & & COOH & & COOH \end{array}$$

is

(a) 2-hydroxypropane-1, 2, 3-tricarboxylic acid
(b) 3-carboxy-3-hydroxypentane-1,5-dioic acid
(c) 2-carboxy-4 hydroxypentane-1,5-dioic acid
(d) 3-carboxy-3-hydroxyhexane-1,6-dioic acid

27. The IUPAC name of compound



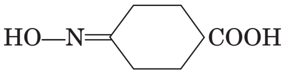
is

(a) hexane-1,2,5-tricarbonitrile
(b) hexane-1,3,6-tricarbonitrile
(c) butane-1,2,4-tricarbonitrile
(d) butane-1,3,4-tricarbonitrile

28. The IUPAC name of the compound  is

(a) butane-2-aldehyde
(b) 2-methylbutanal
(c) 2-ethylpropanal
(d) None of the above

29. The IUPAC name of



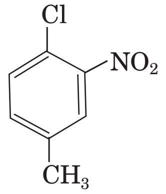
is

(a) 4-hydroxy amino benzene carboxylic acid
(b) 4-(N-hydroxy) imino benzene carboxylic acid
(c) 4-hydroxy imino cyclohexanoic acid
(d) 4-(N-hydroxy) imino cyclohexane-1-carboxylic acid

30. The correct IUPAC name of tartaric acid is

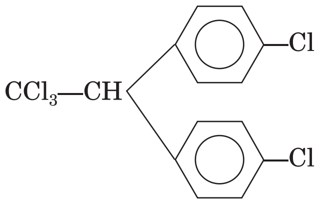
(a) 1,4-dicarboxy-2,3-dihydroxyethane
(b) α, α'-dihydroxybutane-1,4-dioic acid
(c) 1,4-dihydroxybutane-2,3-dioic acid
(d) 2,3-dihydroxybutane-1,4-dioic acid

31. The IUPAC name for **[NCERT Exemplar]**



(a) 1-chloro-2-nitro-4-methylbenzene
(b) 1-chloro-4-methyl-2-nitrobenzene
(c) 2-chloro-1-nitro-5-methylbenzene
(d) *m*-nitro-*p*-chlorotoluene

32. Correct IUPAC name of

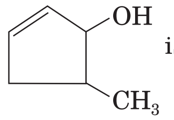


is

(a) gammexane
(b) dichloro diphenyl trichloroethane
(c) diparachlorophenyl trichloroethane
(d) 1,1,1-trichloro-2,2-bis (4-chlorophenyl) ethane

33. The compound 2,2′-bipyridine has the structure

(a) 
(b) 
(c) 
(d) 
34. The IUPAC name of the compound

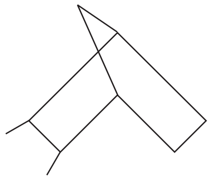


is

(a) 4-methylcyclopent-1-en-3-ol
(b) 5-methylcyclopent-2-en-1-ol
(c) 2-methylcyclopent-4-en-1-ol
(d) 3-methylcyclopent-1-en-2-ol

35. Which is the structure of compound 2-(1-cyclobutenyl)- 1-hexene?

(a) 
(b) 
(c) 
(d) 
36. Write the IUPAC name of the compound



(a) 5,6-dimethyl bicyclo [2.2.1] heptane
(b) 2,3-dimethyl bicyclo [2.2.1] heptane
(c) 2,3-dimethyl bicyclo[1.2.2] heptane
(d) 3,4-dimethyl bicyclo [2.1.2] heptane

Bond Fission and Reaction Intermediates

37. Covalent bond can undergo fission in two different ways. The correct representation involving a heterolytic fission of CH_3 — Br is **[NCERT Exemplar]**

(a) $CH_3—Br \longrightarrow \overset{\oplus}{C}H_3 + \overset{\ominus}{Br}$

(b) $CH_3—Br \longrightarrow \overset{\oplus}{C}H_3 + \overset{\ominus}{Br}$

(c) $CH_3—Br \longrightarrow \overset{\ominus}{C}H_3 + \overset{\oplus}{Br}$

(d) $CH_3—Br \longrightarrow \overset{\bullet}{C}H_3 + \overset{\bullet}{Br}$

38. Heterolysis of $CH_3CH_2CH_3$ results in the formation of

(a) $\overset{\oplus}{C}H_3$ and $\bar{C}_2H_5$ (b) $\overset{\bullet}{C}H_3$ and $\overset{\bullet}{C}_2H_5$

(c) $\bar{C}H_3$ and $\overset{\oplus}{C}_2H_5$ (d) CH_3 and C_2H_5

39. Which of the following is an electrophile?

(a) $:CCl_2$ (b) CO_2

(c) H_2O (d) NH_3

40. Which of the following is not a nucleophile?

(a) BF_3 (b) CN^- (c) OH^- (d) NH_3

41. Among the following the strongest nucleophile is

(a) C_2H_5SH (b) CH_3COO^-

(c) CH_3NH_2 (d) $NCCH_2^-$

42. Which behaves both as a nucleophile as well as an electrophile?

(a) CH_3OH (b) CH_3NH_2

(c) CH_3CN (d) CH_3Cl

43. Correct order of nucleophilicity is

(a) $I^- > Br^- > Cl^- > F^-$ (b) $F^- > Cl^- > Br^- > I^-$

(c) $Cl^- > F^- > Br^- > I^-$ (d) $I^- > Cl^- > Br^- > F^-$

44. The stability of a carbonium ion depends upon

(a) the bond angle of the attached group

(b) the substrate with which it reacts

(c) the inductive effect and hyper-conjugative effect of the attached group

(d) None of the above

45. The most stable carbonium ion among the following is

(a) $C_6H_5CH_2\overset{+}{C}H_2$ (b) $CH_3\overset{+}{C}H_2$

(c) $C_6H_5\overset{+}{C}HC_6H_5$ (d) $C_6H_5\overset{+}{C}H_2$

46. The stability of the free radicals; allyl, benzyl, 3°, 2°, 1° and CH_3 is in the order

(a) benzyl > allyl > 3° > 2° > 1° > CH_3

(b) allyl > 3° > benzyl > 2° > 1° > CH_3

(c) 3° > 2° > 1° > CH_3 > allyl > benzyl

(d) 3° > 2° > 1° > CH_3 > allyl = benzyl

47. The most stable carbocation is

(a) 
(b) 
(c) 
(d) 
48. Arrange the following carbocations in order of stability

I. benzyl, II. allyl, III. methyl, IV. vinyl

(a) IV > III > II > I (b) I > II > III > IV

(c) II > IV > III > I (d) III > II > I > IV

49. Correct order of stability is

(a) $HC{\equiv}\bar{C} > CH_2{=}\bar{C}H > CH_3{—}\bar{C}H_2$

(b) $CH_3{—}\bar{C}H_2 > CH_2{=}\bar{C}H > CH{\equiv}\bar{C}$

(c) $CH_3{—}\bar{C}H_2 > CH{\equiv}CH \cong CH_2{=}\bar{C}H$

(d) All are equally stable

50. Consider the following carbanions

I.  II. 

III. 
Correct order of stability is

(a) I > II > III (b) III > II > I

(c) II > III > I (d) I > III > II

51. Which of the two : $O_2NCH_2CH_2O^-$ or $CH_3CH_2O^-$ is expected to be more stable? **[NCERT]**

(a) $O_2NCH_2CH_2O^-$

(b) $CH_3CH_2O^-$

(c) Both are equally stable

(d) Cannot say anything

52. State the hybridisation of carbon present in triplet carbene.

(a) sp^3 (b) sp^2

(c) sp (d) None of these

53. The order of stability of the following carbanion is

$CH_3\overset{\ominus}{C}H_2$   
I II III IV

(a) I > II > III > IV (b) I > III > II > IV

(c) IV > III > II > I (d) III > IV > I > II

54. With a change in hybridisation of the carbon bearing the charge, the stability of a carbanion increase in the order

(a) $sp < sp^3 < sp^2$ (b) $sp < sp^2 < sp^3$

(c) $sp^2 < sp < sp^3$ (d) $sp^3 < sp^2 < sp$

Electronic Displacement in Organic Compounds

55. The inductive effect

(a) implies the atom's ability to cause bond polarization

(b) increases with increase of distance

(c) implies the transfer of lone pair of electrons from more electronegative atom to the lesser electronegative atom in a molecule

(d) implies the transfer of lone pair of electrons from lesser electronegative atom to the more electronegative atom in a molecule

56. In which of the following compounds, the carbon marked with asterisk is expected to have greatest positive charge? **[NCERT Exemplar]**

(a) $^*CH_3—CH_2—Cl$ (b) $^*CH_3—CH_2—Mg^+Cl^-$

(c) $^*CH_3—CH_2—Br$ (d) $^*CH_3—CH_2—CH_3$

57. Hyperconjugation involves overlap of the following orbitals

(a) σ-σ (b) σ-*p*

(c) *p*-*p* (d) π-π

58. Alkyl groups act as electron donors when attached to a π-system because of **[NCERT]**

(a) resonance (b) mesomeric effect

(c) hyperconjugation (d) Both (b) and (c)

59. Which of the following orders is not correct regarding the –*I* effect of the substituents?

(a) $—I < —Cl < —Br < —F$ (b) $—\overset{+}{N}R_3 < —\overset{+}{O}R_2$

(c) $—\overset{+}{N}R_2 < —OR < —F$ (d) $—SR < —OR < —\overset{+}{O}R_2$

60. Which of the following orders is correct regarding the acidity of carboxylic group?

(a) $CH_3CH_2CH(Cl)COOH > CH_3CH(Cl)CH_2COOH > ClCH_2CH_2CH_2COOH$

(b) $CH_3CH_2CH(Cl)COOH < CH_3CH(Cl)CH_2COOH < ClCH_2CH_2CH_2COOH$

(c) $CH_3CH_2CH(Cl)COOH > CH_3CH(Cl)CH_2COOH < ClCH_2CH_2CH_2COOH$

(d) $CH_3CH_2CH(Cl)COOH < CH_3CH(Cl)CH_2COOH > ClCH_2CH_2CH_2COOH$

61. Correct gradation of basic character is

(a) $NH_3 > CH_3NH_2 > NF_3$ (b) $CH_3NH_2 > NH_3 > NF_3$

(c) $NF_3 > CH_3NH_2 > NH_3$ (d) $CH_3NH_2 > NF_3 > NH_3$

62. The order of stability of the alkenes is

$$\underset{\text{I}}{R_2C{=}CR_2},\ \underset{\text{II}}{R_2C{=}CHR},\ \underset{\text{III}}{R_2C{=}CH_2},$$

$$\underset{\text{IV}}{RCH{=}CHR},\quad \underset{\text{V}}{RCH{=}CH_2}$$

(a) I > II > IV > III > V (b) I = II > III > IV > V

(c) II > I > IV > III > V (d) V > IV > III > I > II

63. Which of the following does not show electromeric effect?

(a) Alkenes (b) Ethers

(c) Aldehyde (d) Ketones

64. Stability of which intermediate is not governed by hyperconjugation?

(a) Carbon cation (b) Carbon anion

(c) Carbon free radical (d) None of these

65. Delocalised electrons are present in

(a) 1, 3-butadiene (b) C_6H_6

(c) 1, 3, 5-hexatriene (d) All of these

66. Resonance energy is more for

(a) C_6H_6 (b) cyclohexene

(c) cycloheptene (d) cyclohexa-1,2,3-triene

67. In which of the following molecules, the resonance effect is not present?

(a) 
(b) 
(c) 
(d) 
68. Polarisation of electron in acrolein may be written as

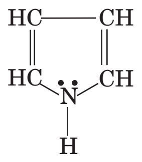
(a) $\overset{-\delta}{C}H_2{=}CH—\overset{+\delta}{C}H{=}O$

(b) $\overset{-\delta}{C}H_2{=}CH—CH{=}\overset{+\delta}{O}$

(c) $\overset{-\delta}{C}H_2{=}\overset{+\delta}{C}H—CH{=}O$

(d) $\overset{+\delta}{C}H_2{=}CH—CH{=}\overset{-\delta}{O}$

69. How many delocalised π-electrons are there in the compound



(a) 8 (b) 2

(c) 4 (d) 6

70. Among the following, the least stable resonance structure is

(a) 
(b) 
(c) 
(d) 
71. One of the stable resonating forms of methyl vinyl ketone is

(a) 
$\overset{+}{C}H_2 - \overset{-}{\ddot{C}}H - \overset{:\ddot{O}:}{\overset{\|}{C}} - CH_3$

(b) 
$\overset{+}{C}H_2 - CH = \overset{:\ddot{O}:^-}{\overset{|}{C}} - CH_3$

(c) 
$\overset{-}{\ddot{C}}H_2 = CH - \overset{:\ddot{O}:}{\overset{\|}{C}} - CH_3$

(d) 
$CH_2 = CH - \overset{:\ddot{O}:^-}{\overset{|}{C}} - CH_3$

72. The oxygen atom in phenol
(a) exhibits only inductive effect
(b) exhibits only resonance effect
(c) has more dominating resonance effect than inductive effect
(d) has more dominating inductive effect than the resonance effect

Types of Organic Reaction

73. The addition of HCl to an alkene proceeds in two steps. The first step is the attack of H^+ ion to $>C=C<$ portion which can be shown as **[NCERT Exemplar]**

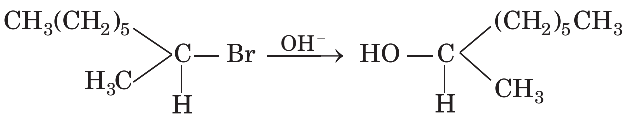
(a) 
(b) 
(c) 
(d) All of these

74. Electrophilic addition reactions proceed in two steps. The first step involves the addition of an electrophile. Name the type of intermediate formed in the first step of the following addition reaction.

$H_3C - HC{=}CH_2 + H^+ \longrightarrow ?$ **[NCERT Exemplar]**

(a) 2° carbanion
(b) 1° carbocation
(c) 2° carbocation
(d) 1° carbanion

75. The following reaction is described as



(a) S_E2
(b) S_N2
(c) S_N1
(d) S_N0

76. Which one is least reactive in a nucleophilic substitution reaction?
(a) CH_3CH_2Cl
(b) $CH_2{=}CHCH_2Cl$
(c) $CH_2{=}CHCl$
(d) $(CH_3)_3CCl$

77. *t*-butyl chloride reacts with OH^- by S_N1 mechanism and rate $\propto$ [*t*-butyl chloride]. One of the reasons for this is that
(a) stereochemical inversion takes place
(b) *t*-butyl carbocation is first formed which is more stable
(c) the product *t*-butyl alcohol is more stable
(d) the intermediate *t*-butyl carbocation is stabilized by solvation

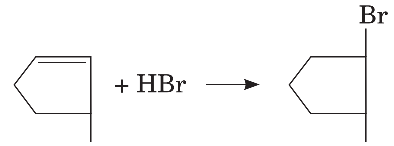
78. Which one of the following explain, why does propene undergo electrophilic addition with HBr, but not with HCN ?
(a) Br^- is better nucleophile than CN^-
(b) HBr being better source of proton as it is stronger acid than HCN
(c) HCN attacks preferentially *via* lone pair of nitrogen
(d) The C—Br bond being stronger is formed easily as compared to C—CN bond

79. Which of the following is most reactive towards elimination reaction?
(a) $RCOO^-$
(b) CN^-
(c) NO_3^-
(d) RO^-

80. Examine the following statements regarding S_N2 reaction
(1) The rate of reaction is independent of concentration of nucleophile
(2) The nucleophile attacks the carbon atom on the side of molecule opposite to the group being displaced
(3) The reaction proceeds with simultaneous bond formation and rupture

Which of the above written statements are correct?
(a) 1, 2
(b) 1, 3
(c) 1, 2, 3
(d) 2, 3

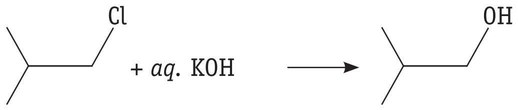
81. The reaction,



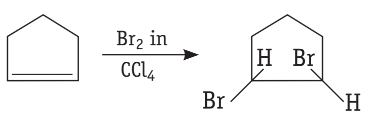
is an example of
(a) nucleophilic substitution
(b) electrophilic addition
(c) elimination reaction
(d) nucleophilic addition

82. The addition reaction among the following is

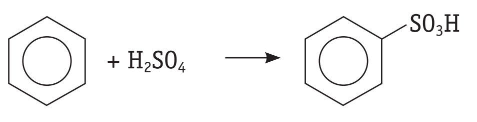
(a)



(b)



(c)



(d) All of the above

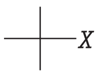
83. Consider the following reaction

$$>C{=}O + H_2NOH \longrightarrow >C{=}NOH + H_2O$$

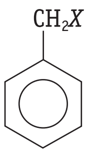
It is an example of
(a) substitution
(b) elimination
(c) addition
(d) addition-elimination

84. Which of the following cannot show S_N1 reaction?

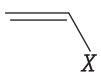
(a)



(b)



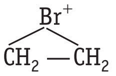
(c)



(d)

85. Which of the following types of reaction occurs when a substituent has got a double bond with evenly distributed π electron cloud ?
(a) Electrophilic addition
(b) Nucleophilic addition
(c) Any of the (a) and (b)
(d) None of the above

86. During addition of bromine on ethene, the first species formed is

(a)


$\overset{Br^+}{CH_2—CH_2}$

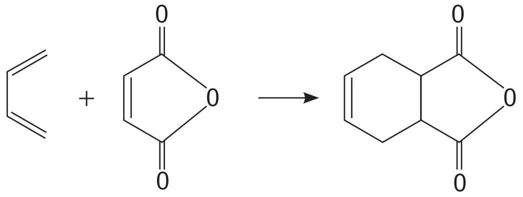
(b) $C_2H_4OH^+$

(c) $\overset{+}{C}H_2CH_2Br$

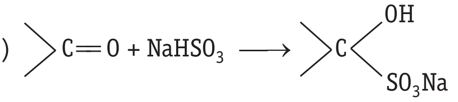
(d) $C_2H_5^+$

87. The substitution reaction among the following is

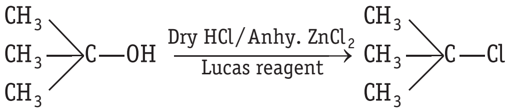
(a)

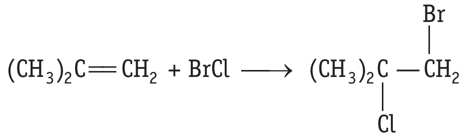


(b)



(c)



(d)


$(CH_3)_2C{=}CH_2 + BrCl \longrightarrow (CH_3)_2\underset{Cl}{C}—\overset{Br}{CH_2}$

88. The reaction,
