EXAMPLE 50. *Calculate the e.m.f. of the cell at 298 K. Cr/Cr^{3+} (0.1 M) || Fe^{2+} (0.01 M)/Fe. Given : $E^{\circ}_{(Cr^{3+}/Cr)} = -0.75\ V$; $E^{\circ}_{(Fe^{2+}/Fe)} = -0.45\ V$.*

(PSEB, 2005, HP Board, 2007, ISC, 2009, CBSE, 2009)

SOLUTION.

Since $E°$ value, – 0.45 *V* > – 0.75 *V*, so we have :

$$Fe^{2+} + 2e^- \rightleftharpoons Fe] \times 3; \qquad E^{\circ} = -0.45\ V$$

$$Cr^{3+} + 3e^- \rightleftharpoons Cr] \times 2; \qquad E^{\circ} = -0.75\ V$$

Subtract: – – – +

$$3Fe^{2+} + 2Cr \rightleftharpoons 3\,Fe + 2Cr^{3+}\ ;\ E^{\circ} = +0.30\ V$$

$$n = 6\ [\because 2e^- \times 3 = 6e^-; 3e^- \times 2 = 6e^-]$$

Using Nernst equation, we have :

$$E_{\text{cell}} = E^{\circ}_{\text{cell}} - \frac{0.0591}{n} \log \frac{[\text{Products}]}{[\text{Reactants}]}$$

$$= 0.30\ \text{V} - \frac{0.0591}{6} \log \frac{[Fe]^3 [Cr^{3+}]^2}{[Fe^{2+}]^3 [Cr]^2}$$

$$= 0.30\ \text{V} - \frac{0.0591}{6} \log \frac{1 \times (0.1)^2}{(0.01)^3 \times 1}$$

$$\begin{bmatrix} \log (0.1)^2 = 2 \log 0.1 = 2 \times -1 = -2 \\ \log (0.01)^3 = 3 \log 0.01 = 3 \times -2 = -6 \end{bmatrix}$$

$$= 0.3\ \text{V} - \frac{0.0591}{6} \times [-2 - (-6) = 4]$$

$$= 0.3\ V - 0.0394 = \mathbf{0.2606\ V} \qquad \textbf{Ans.}$$

EXAMPLE 51. *Calculate the potential for half-cell containing 0.1M $K_2Cr_2O_7$ (aq), 0.20 M Cr^{3+}(aq) and 1.0 × 10^{-4} M H^+(aq). The half-cell reaction is $Cr_2O_7^{2-}$ (aq) + $14H^+$(aq) + $6e^- \longrightarrow$ 2 Cr^{3+}(aq) + $7H_2O$(l) and the standard electrode potential is given as E° = 1.33 V* **(CBSE, 2007, HP Board, 2007, ISC, 2010)**

SOLUTION. To find potential of the half-cell, we use the Nernst equation

$$E_{\text{cell}} = E^{\circ}_{\text{cell}} - \frac{0.0591}{n} \log \frac{[\text{Products}]}{[\text{Reactants}]}$$

$$= 1.33 - \frac{0.0591}{6} \log \frac{[Cr^{3+}]^2 [H_2O]^7}{[Cr_2O_7^{2-}]^1 [H^+]^{14}}$$

$$E_{\text{cell}} = 1.33 - \frac{0.0591}{6} \log \frac{[0.2]^2}{(0.1) \times (10^{-4})^{14}}$$

$$E_{\text{cell}} = 1.33 - \frac{0.059}{6} \log \left[\frac{4}{10^2 \times 10^{-1} \times 10^{-5}} = 4 \times 10^{55} \right]$$

$$= 1.33 - \frac{0.0591}{6}\ [\log 4 + 55 \log 10) = 0.6020 + 55 = 55.6020]$$

$$= 1.33 - \frac{0.0591}{6} \times 55.6020$$

$$= 1.33 - 0.5477 = \mathbf{0.78232}\ V \qquad \textbf{Ans.}$$

EXAMPLE 52. *A copper silver cell is set up. The copper ion concentration in it is 0.10 M. The concentration of silver ion is not known. The cell potential measured is 0.422 V. Determine the concentration of silver ion in the cell. Given, $E^{\circ}_{Ag^+/Ag}$ = + 0.80 V; $E^{\circ}_{Cu^{2+}/Cu}$ = + 0.34 V.* **(DB, 2009, CBSE, 2013)**

SOLUTION. A cell is feasible, if emf of the cell is positive.

Since + 0.80 *V* > + 0.34 *V*, So:

$$Ag^+ + e^- \longrightarrow Ag] \times 2; \quad E^{\circ} = +0.80\ V; n = 2$$

$$Cu^{2+} + 2e^- \longrightarrow Cu; \quad E^{\circ} = +0.34\ V; n = 2$$

Subtracting: – – – –

$$2Ag^+ + Cu \longrightarrow 2Ag + Cu^{2+}; \quad E^{\circ} = +0.46\ V$$

$$E_{\text{cell}} = E^{\circ}_{\text{cell}} - \frac{0.059}{n} \log \frac{[Cu^{2+}]}{[Ag^+]^2}$$

$$0.422 = 0.46 - \frac{0.059}{2}\log\frac{1}{[Ag^+]^2};$$

$$-\frac{0.059}{2}\ \log (Ag^+)^{-2} = 0.46 - 0.422$$

or $-2 \times -\frac{0.059}{2}\ \log [Ag^+] = 0.038\ V; 0.059 \log [Ag^+] = 0.038$

Taking antilog of both sides, we get:

$[Ag^+]$ = antilog 0.038/0.059 = **0.644 M**

Ans.

19.13 TO FIND PARTIAL PRESSURE OF A GAS

Type. To find partial pressure of a gas in a cell reaction, use Nernst equation.

$$E_{cell} = E°_{cell} - \frac{0.0591}{n}\log\frac{[Products]}{[Reactants]}$$

Example 53. *In the cell reaction, $4Cr^{2+}(aq) + O_2(g) + 4H^+(aq) \rightarrow 4Cr^{3}(aq) + 2H_2O(l)$, the concentrations are : $[Cr^{2+}] = 0.1\,M$, $[Cr^{3+}] = 0.082\,M$, $[H^+] = 0.01M$. Find the partial pressure* of O_2 *gas at equilibrium at 25°C. E° Cr^{3+}/Cr^{2+} = – 0.41 V. E° O_2/H_2O = 1.23 V].*

Solution. (*i*) At equilibrium, $E_{cell} = 0.0$ V

(*ii*) $E°\ Cr^{3+}/Cr^{2+} = -0.42\ V$:

$E°O_2/H_2O = 1.23\ V$;

$[Cr^{2+}] = 0.1\ M$; $[Cr^{3+}] = 0.082\ M$;

$[H^+] = 0.01\ M$

(*iii*) $O_2 + 4H^+ + 4e^- \longrightarrow 2H_2O;\qquad E° = +1.23\ V$

$Cr^{3+} + e^- \longrightarrow Cr^{2+}] \times 4;\qquad E° = -0.41\ V$

Subtract: – – – +

$4Cr^{2+} + O_2 + 4H^+ \longrightarrow 4Cr^{3+} + 2H_2O;\qquad E° = 1.64\ V$

So, $n = 4$ from (*iii*) above and $E°_{cell} = 1.64$ V. Applying Nernst equation to given reaction, $4Cr^{2+}(aq) + O_2(g) + 4H^+(aq) \rightarrow 4Cr^{3+}(aq) + 2H_2O(l)$, we have :

$E_{cell} = E°_{cell} - (0.0591/n)$ [log [Products]/(Reactants]. Substituting the values, we get : 0 = 1.64 – (0.0591/4) [log $(Cr^{3+}]^4 [H_2O]^2/[Cr^{2+}]^4 [pO_2] [H^+]^4$ = 1.64 – (0.0591/4) [log $[0.082]^4$ [constant]/$(0.1)]^4[pO_2][0.01]^4]$ = 1.64 – (0.0591/4) [4 log 0.082 + 0 – 4 log 0.1 – logpO_2 – 4 log 0.01] = 1.64 – (0.0591/4)[(4 × –1.0861) – (4 × – 1) – log pO_2 – (4 × – 2)] = 1.64 – (0.0591/4) [– 4.3444 + 4 – logpO_2 + 8] = 1.64 – (0.0591/4) [7.6556 – logpO_2]. **Or** – 1.64 = – 0.1131 + (0.0591/4) logpO_2. **Or** – 1.5269 = (0.0591/4) logpO_2 **Or** (–1.569 × 4/0.0591) = logpO_2. Hence log pO_2 = – 103.3435. **Or** pO_2 = antilog – 103.3434 *i.e.*, $\overline{104}.6566$ = 4.53×10^{-104} atm

Ans.

19.14 TO FIND pH OF A SOLUTION

Type. The pH of an acidic solution in a given cell can be found by firstly using the relation :

$$E = E^{o}_{cell} - \frac{0.0591}{n}\log\frac{[Products]}{[Reactants]}$$

and then :

$$pH = -\log [H^+]$$

Example 54. *Derive a relation to measure the pH of a solution with the help of standard hydrogen electrode.*

Solution. The cell diagram is

Pt | H_2 (1 bar) | $H^+(aq)$, unknown || $H^+(aq)$ (1M) | H_2 (1 bar) | Pt

Reactions.

$H_2(g) + 2H^+(1M) \longrightarrow 2H^+(aq, unknown) + H_2(g)$

$\tfrac{1}{2} H_2(g) + H^+(1M) \longrightarrow H^+(aq, unknown) + \tfrac{1}{2} H_2(g)$ ...(1)

Here, $n = 1$ because $\tfrac{1}{2} H_2 \longrightarrow H^+ + 1e^-$

Using Nernst equation, for equation (1), we have :

$$E_{cell} = E^{o}_{cell} - \frac{0.0591}{n}\log\frac{[Products]}{[Reactants]}$$

$$= 0.0V - \frac{0.0591}{1}\ \log \frac{\left[H^+ (aq, unknown)\right]\left[pH_2\right]^{1/2}}{\left[pH_2\right]^{1/2}\left[H^+\right]}$$

$$= 0.0V - \frac{0.0591 \log \left[H^+ (aq, unknown)\right][1.0]^{1/2}}{1 \times 1}$$

$$= -0.0591 \log [H^+, (aq, unknown)]$$

$\therefore E_{cell}$ = **0.0591 pH** $[\because -\log (H^+) = pH]$

Example 55. *Find the pH of the following acid solution; Pt (H_2 (1 bar) | H^+ (aq, acid) || H^+ (1M) | H_2 (g, 1 bar) | Pt. The measured e.m.f. of the cell* = 0.182 *V.*

Solution. For finding the pH of an unknown acid, using the above cell connected with standard hydrogen electrode, we use the relation :

$$E_{cell} = 0.0591\ pH$$

$$\therefore \qquad pH = \frac{E_{cell}}{0.0591} = \frac{0.182\ V}{0.0591\ V} = \mathbf{3.079}\ \ \textbf{Ans.}$$

Example 56. *The e.m.f. of the following cell Pt | H_2(1atm) | $H^+(aq)$ || $Ag^+(1M)$ | Ag(s) at 25°C is 0.87 V. Calculate the pH of the acid solution.*

E° Ag^+/Ag = 0.80 V ; E° $2H^+/H_2$ = 0.0V

Solution. Reaction :

$2Ag^+ + 2e^- \rightleftharpoons 2Ag(s);\qquad E° = 0.8\ V$

$2H^+ + 2e^- \rightleftharpoons H_2;\qquad E° = 0.0\ V$

Subtract: – – – +

$2Ag^+ + H_2 \rightleftharpoons 2Ag(s) + 2H^+;\qquad E° = 0.8\ V$

Using Nernst equation, we have :

$$E_{cell} = E°_{cell} - \frac{0.0591}{2}\log$$

$$\left[\frac{[Ag(s)]^2\left[H^+\right]^2}{\left[Ag^+\right]^2[pH_2]} = \frac{1 \times (H^+)^2}{(1)^2 \times 1} = \left[H^+\right]^2\right]$$

$$0.87\ V = 0.80\ \text{V} - \frac{0.0591}{2} \times 2\log\left[\text{H}^+\right]$$

$$= 0.80\ V - 0.0591 \log \text{H}^+$$

$$0.87\ V - 0.80\ V = -\log[\text{H}^+] \times 0.0591\ ;$$

$$0.07\ V = \text{pH} \times 0.0591\ V$$

$$\therefore \quad \text{pH} = \frac{0.07\ \text{V}}{0.0591\ \text{V}} = \mathbf{1.184} \qquad \textbf{Ans.}$$

Example 57. *Calculate the equilibrium constant K for the following reaction at 298 K* **(CBSE, 2009, 2013)**

$$\text{Zn}(s) + \text{Cu}^{2+}(aq) \rightleftharpoons \text{Zn}^{2+}(aq) + \text{Cu}(s).$$

Given : $E^\circ_{\text{Zn}^{2+}/\text{Zn}} = -0.76\ \text{V}\ ;\ E^\circ_{\text{Cu}^{2+}/\text{Cu}} = +0.34\ V$

Solution. Since the E° (reduction) value $+ 0.34V > - 0.76\ V$

So, we have :

$$\text{Cu}^{2+} + 2e^- \rightleftharpoons \text{Cu}(s);\ E^\circ = +0.34\ V\ \text{(cathode)}$$

$$\text{Zn}^{2+} + 2e^- \rightleftharpoons \text{Zn}(s)\ ;\ E^\circ = -0.76\ V\ \text{(anode)}$$

Subtract: − − − +

$$\text{Cu}^{2+} + \text{Zn}(s) \rightleftharpoons \text{Cu}(s) + \text{Zn}^{2+}\ ; \qquad E^\circ = 1.10\ V$$

Using Nernst equation, we have :

$$\text{We know} \quad \log K_c = \frac{n\,\text{E}^\circ_{\text{cell}}}{0.0591} = \frac{2 \times 1.1}{0.0591} = 37.22$$

$$\therefore \quad K_c = \text{antilog } 37.22$$

$$= \mathbf{1.66 \times 10^{37}} \qquad \textbf{Ans.}$$

19.15 USE OF ΔG° (OR MAXIMUM WORK OR ELECTRICAL ENERGY)= – nFE°$_{\text{cell}}$ AND ΔG° = – 2.303 RT LOG K$_c$

Example 58. The *equilibrium constant at 25°C for the process*

$$\text{Co}^{3+}(aq) + 6\text{NH}_3(aq) \rightleftharpoons [\text{Co}(\text{NH}_3)_6]^{3+}(aq)$$

is 2.0×10^7. *Calculate the value of* ΔG° *at* 25°C ($R = 8.314\ J\ K^- mol^-$). *In which direction is the reaction spontaneous when the reactants and products are under standard conditions ?* **(DSB, 1999 S)**

Solution. $K_c = 2.0 \times 10^7\ ;\ R = 8.314\ J\ K^-\ \text{mol}^-\ ;$

$$T = 25 + 273 = 298\ K$$

We know that : $\Delta G^\circ = -2.303\ RT \log K_c$

$$= -2.303 \times 8.314\ JK^-\ \text{mol}^- \times 298\ K \log 2.0 \times 10^7$$

$$= -2.303 \times 8.314\ JK^-\text{mol}^- \times 298\ K$$

$$[\log 2 + \log 10^7 = 0.3010 + 7 = 7.301]$$

$$= -2.303 \times 8.314\ JK^-\ \text{mol}^- \times 298\ K \times 7.301$$

$$= -41658\ J\ \text{mol}^-$$

$$\Delta G^\circ = \mathbf{-41.658\ KJ\ mol^-} \qquad \textbf{Ans.}$$

Since ΔG° is negative, the reaction is feasible in the forward direction.

Example 59. *Calculate equilibrium constant for the reaction at* 298 *K* :

$$4\,Br^- + O_2 + 4H^+ \rightleftharpoons 2Br_2 + 2H_2O$$

Given : $E^\circ_{cell} = 0.16\ V$ **(PSEB, 2001)**

Solution. For the given reaction, we have :

$$4\text{H}^+ + 4e^- \rightleftharpoons 2\text{H}_2\ ; \qquad 2\text{Br}_2 + 4e^- \rightleftharpoons 4\text{Br}^-$$

These are four electron change reactions.

So, $n = 4.$

We know that : $E^\circ_{cell} = \dfrac{0.0591}{n} \log K.$

Substituting the values, we get :

$$0.16 = \frac{0.0591}{4} \log K$$

$$\therefore \quad \log K = \frac{0.16 \times 4}{0.0591} = 10.83$$

$$\text{or} \quad K = \text{antilog } 10.83 = \mathbf{6.76 \times 10^{10}}\ \textbf{Ans.}$$

Example 60. *Determine the values of equilibruim constant* (K_c) *and* ΔG° *for the following reaction:*

$$Ni(s) + 2Ag^+(aq) \longrightarrow Ni^{2+}_{(aq)} + 2\,Ag(s); \quad E^\circ = 1.05\ V$$

(1F = 96500 C mol$^-$) **(CBSE Board, 2011)**

Solution. Given $E^\circ = 1.05$ V. At equilibrium, $E_{\text{cell}} = 0$. The given reaction can be written as:

$$\text{Ni}(s) \longrightarrow \text{Ni}^{2+} + 2e^-$$

$$2\text{Ag}^+_{(aq)} + 2e^- \longrightarrow 2\text{Ag}(s)$$

Here, $n = 2$ *i.e;* no. of electrons. Adding:

$$\text{Ni}(s) + 2\text{Ag}^+(aq) \longrightarrow \text{Ni}^{2+} + 2\text{Ag}(s); \qquad E^\circ = 1.05\ V$$

$$\text{But} \quad E_{\text{cell}} = E^\circ - \frac{0.0591}{n} \log \frac{[\text{Ni}^{2+}]}{[\text{Ag}^+]^2}$$

$$= E^\circ - \frac{0.0591}{2} \log \frac{[\text{Ni}^{2+}]}{[\text{Ag}^+]^2}$$

$$0 = 1.05 - (0.059/2) \log K_c$$

$$[\because \text{at equilibrium, } \log [\text{Ni}^{2+}]/[\text{Ag}^+]^2 = K_c]$$

$$\therefore \quad \log K_c = (2 \times 1.05)/0.0591$$

$$= 35.53;$$

$$K_c = \text{antilog } 35.53$$

$$\text{or} \quad K_c = 3.38 \times 10^{35}.$$

Also:

$$\Delta G^\circ = -n\text{F}E^\circ = -2 \times 96500 \times 1.05$$

$$= \mathbf{-202650\ J} \qquad \textbf{Ans.}$$

Note: We can also use, $\log K_c = \Delta G^\circ/-2.303\ RT$ to find K_c; $R = 8.314\ \text{JK}^-\ \text{mol}^-$, $T = 298\ K$.

Example 61. *Calculate* ΔG° *for the reaction :*

$$Cu^{2+}(aq) + Fe(s) \longrightarrow Fe^{2+}(aq) + Cu(s).$$

$$[E^\circ_{Cu^{2+}/Cu} = 0.34\ V;\ E^\circ_{Fe^{2+}/Fe} = -0.44\ V).$$

(DSB, 1999S)

Solution.

Since $E^\circ_{\text{(reduction)}}$ value $+ 0.34\ V > - 0.44\ V$, so we have :

$$\text{Cathode } [\text{Cu}^{2+} + 2e^- \rightleftharpoons \text{Cu}; \qquad E^\circ = +0.34\ V$$

$$\text{Anode } [\text{Fe}^{2+} + 2e^- \rightleftharpoons \text{Fe}; \qquad E^\circ = -0.44\ V$$

Subtract: − − − + −

$$Cu^{2+} + \text{Fe} \rightleftharpoons \text{Cu} + \text{Fe}^{2+}\ ;\ E^\circ = +0.78\ V$$

[Here $n = 2$ as the reaction is of 2 electron change.]

$$\therefore \quad \Delta G^\circ = -nF\,E^\circ_{cell} = -2 \times 96500\ C\ mol^- \times 0.78\ V$$

$$= -150{,}540\ C\ V\ mol^- = -150{,}540\ J\ mol^- \qquad [\because J = CV]$$

$$= -150{,}540\ J\ mol^- \times \frac{1k\,J}{1000\,J}$$

$$= \mathbf{-150.54\ k\ J\ mol^-} \qquad \textbf{Ans.}$$

EXAMPLE 62. *Calculate the maximum electrical work that can be obtained from the following cell under the standard conditions at* 25° *C.* Zn/Zn^{2+} *(aq)* || Fe^{2+} *(aq)*/Fe. *Given that* $E^\circ\ Zn^2(aq)/\ Zn = -0.76\ V$; $E^\circ\ Fe^{2+}\ (aq)/Fe = -0.44\ V$ *and* $F = 96500\ C\ mol^-$. **(CBSE, 1995)**

SOLUTION. Maximum work, $(-\Delta G^\circ) = ?$

Since $E^\circ_{(reduction)}$ value -0.44 V > -0.76 V, so we have:

$$Fe^{2+} + 2e^- \rightleftharpoons Fe; \qquad E^\circ = -0.44\ V\ \text{(cathode)}$$

$$Zn^{2+} + 2e^- \rightleftharpoons Zn; \qquad E^\circ = -0.76\ V\ \text{(anode)}$$

Subtract: – – – +

$$Fe^{2+} + Zn \rightleftharpoons Fe + Zn^{2+}; \qquad E^\circ = 0.32\ V$$

But ΔG° (= maximum work) $= -nF\,E^\circ$cell

$$= -\ 2 \times 96500\ C\ mol^- \times 0.32\ V$$

$$= -61760\ C\ V\ mol^-$$

$$= -61760\ J\ mol^- \qquad [\because CV = J]$$

$$= -61760\,J\,mol^- \times \frac{1k\ J}{1000\ J}$$

$$= \mathbf{-61.76\ k\ J\ mol^-}\ \textbf{Ans.}$$

EXAMPLE 63. *Calculate the value of* ΔG *and* E_{cell} *at* 298 *K for the following cell.* Al/Al^{3+} (0.01M) || Fe^{2+} (0.02)/Fe. *Given that* $E^\circ Al^{3+}/Al = -1.66\ V$ *and* $E^\circ\ Fe^{2+}/Fe = -0.44\ V$ **(CBSE, 2001, 2007)**

SOLUTION. $\Delta G = ?$; $E_{cell} = ?$

The half cell reactions are :

$$Al^{3+} + 3e^- \longrightarrow Al] \times 2$$

$$Fe^{2+} + 2e^- \longrightarrow Fe] \times 3$$

Subtract: – – –

$$2\,Al^{3+} + 3Fe \longrightarrow 2Al + 3Fe^{2+}$$

So, no. of electrons = 6 Or $n = 6$

$$E^\circ_{cell} = E^\circ_{cathode} - E^\circ_{anode}$$

$$= E^\circ Fe^{2+}/Fe - E^\circ\ Zn^{2+}/Zn$$

$$= -0.44 - (-1.66) = 1.22\ V.$$

According to Nernst equation,

$$E_{cell} = E^o_{cell} - \frac{0.0591}{n}\log\ [Fe^{2+}]^3/[Al^{3+}]^2.$$

Or

$$E_{cell} = 1.22 - (0.0591/6)\log\ (0.02)^3/(0.01)^2$$

$$= 1.22 - (0.0591/6)\log 0.08$$

$$= 1.22 - (0.0591/6) \times -1.097$$

$$= 1.22 + 0.0108 = \mathbf{1.2308\ V} \qquad \textbf{Ans.}$$

Also, $\Delta G = -nF\,E_{cell}$

Substituting the values, we get :

$$\Delta G = -6 \times 96500\ C \times 1.2308\ V$$

$$= 712{,}633\ J = \mathbf{712.633\ k\ J}$$

$$[\because \mathbf{1CV = 1J}]\ \textbf{Ans.}$$

EXAMPLE 64. *Determine the equilibrium constant of the reaction at 298 K ;* $2Fe^{3+} + Sn^{2+} \rightarrow 2Fe^{2+} + Sn^{4+}$. *From the obtained value of equilibrium constant, predict whether* Sn^{2+} *ions can reduce* Fe^{3+} *to* Fe^{2+} *quantitatively or not ? Given :* $E^\circ\ Fe^{3+}, Fe^{2+}/Pt = 0.771\ V$; $E^\circ\ Sn^{4+}/Sn^{2+}/Pt = 0.150\ V$. $[R = 8.314\ J\ K^-\ mol^-.]$ **(DSB, 1993S)**

SOLUTION. $E^\circ_{cell} = E^\circ_{cathode} - E^\circ_{anode}$

$$= E^\circ\ Fe^{3+}, Fe^{2+}/Pt - E^\circ\ Sn^{4+}/Sn^{2+}/Pt$$

$$= 0.771\ V - 0.150\ V$$

$$= 0.621\ V.$$

We know, for $Fe^{2+} + 2e^- \rightarrow Fe$ and $Sn^{4+} + 2e^- \rightarrow Sn^{2+}$,

$$n = 2.$$

Also, $\quad -nF\,E^\circ_{cell} = -2.303\,RT\log K_c.$

Or $\quad \log K_c = (-nF\,E^\circ_{cell})/-2.303\,RT$

$$\therefore \quad \log K_c = (-2 \times 96500\ C\ mol^- \times 0.621\ V)/(-2.303 \times 8.314\ J\ K^-\ mol^- \times 298\ K$$

$$= 21.0053. \qquad [\because CV = J]$$

$$\therefore \quad K_c = \text{antilog}\ 21.0053 = \mathbf{1.01 \times 10^{21}}\ \textbf{Ans.}$$

Since the value of K_c is extremely high, the Sn^{2+} ions will reduce Fe^{3+} to Fe^{2+} completely.

EXAMPLE 65. *The standard reduction potential of* Cu^{2+}/Cu *and* Ag^+/Ag *electrodes are* 0.337 *and* 0.799 *volt respectively. Construct a galvanic cell using these electrodes so that its standard e.m.f. is positive. For what concentration of* Ag^+ *will the e.m.f. of the cell at* 25°C *be zero if the concentration of* Cu^{2+} *is* 0.01 *M* ? **(IIT, 1990; CBSE, 2009)**

SOLUTION.

Since $E^\circ_{Ag^+/Ag} > E^\circ_{Cu^{2+}/Cu}$, the half cell Ag^+/Ag will constitute the cathode of the galvanic cell. Hence, the required cell is :

$$Cu/Cu^{2+}\ ||\ Ag^+/Ag$$

Its standard e.m.f. is $E^\circ_{cell} = E^\circ_{Ag^+/Ag} - E^\circ_{Cu^{2+}/Cu}$

$$= 0.799\ V - 0.337\ V = 0.462\ V$$

The cell reaction in

Right half cell : $2Ag^+ + 2e^- \longrightarrow 2Ag$

Left half cell : $Cu \longrightarrow Cu^{2+} + 2e^-$

Net cell reaction is : $2Ag^+ + Cu \longrightarrow 2Ag + Cu^{2+}$

According to Nernst equation

$$E_{cell} = E^o_{cell} - \frac{RT}{2F}\,\text{In}\,\frac{\left[Cu^{2+}\right]}{\left[Ag^+\right]^2}$$

Substituting the given data, we get

$$0 = 0.462\ V - \frac{0.0591\ V}{2}\log\frac{0.01}{\left[Ag^+\right]^2}$$

$$\text{or} \quad \log\frac{0.01}{\left[Ag^+\right]^2} = \frac{2 \times 0.462\ V}{0.0591} = 15.6345$$

or $\log 0.01 - 2\log[Ag^+] = 15.6345$

or $-2 - 15.6345 = 2\log[Ag^+]$

or $\log[Ag^+] = \frac{-2-15.6345}{2} = -8.8173$

$\therefore$ $[Ag^+] = \text{antilog } \bar{9}.1827 = \mathbf{1.523 \times 10^{-9}\ M}$

EXAMPLE 66. *The standard reduction potential for the half-cell.*

$NO_3^-(aq) + 2H^+(aq) + e^- \longrightarrow NO_2(aq) + H_2O(l)$ *is* 0.78 *V*

(*a*) *Calculate the reduction potential in* 8M H^+

(*b*) *What will be the reduction potential of the half-cell in a neutral solution ? Assume all the other species to be at unit concentration.* **(IIT, 1993)**

SOLUTION. For the half-cell reaction,

$NO_3^-(aq) + 2H^+(aq) + e^- \longrightarrow NO_2(aq) + H_2O(l)$

The Nernst equation is

$$E = E^\circ - \frac{RT}{nF}\ln\frac{PNO_2}{[NO_3^-][H^+]^2}$$

(*a*) In 8M H^+, we have

$$E = 0.78\ V - (0.059\ V)\log\frac{1}{(8)^2}$$

[Here, $n = 1$]

$$= 0.78\ V + (0.059\ V)\log 8^2$$
$$= 0.78\ V + (0.059\ V)(1.806)$$
$$= 0.886\ V$$

(*b*) For a neutral solution at 25°C, $[H^+] = 10^{-7}$ M

Hence $$E = 0.78\ V - (0.059\ V)\log\frac{1}{(10^{-7})^2}$$
$$= 0.78\ V - (0.059V)(14) = \mathbf{0.076\ V.}$$

EXAMPLE 67. *The standard reduction potential of the* Ag^+/Ag *electrode at* 298 *K is* 0.799 *V. Given that for AgI,* $K_{sp} = 8.7 \times 10^{-17}$*, evaluate the potential of the* Ag^+/Ag *electrode in a standard solution of AgI. Also calculate the standard reduction potential of the* $I^-/AgI/Ag$ *electrode.* **(IIT, 1994)**

SOLUTION. For $Ag^+ \mid Ag$, half cell involving standard solution of AgI, the cell reaction is:

$$Ag^+(aq) + e^- \longrightarrow Ag(s)$$

Nernst equation is :

$$E_{Ag^+/Ag} = E^\circ_{Ag^+/Ag} - \frac{RT}{nF}\ln\frac{1}{[Ag^+]}$$

The concentration of Ag^+ in the solution can be calculated from the solubility product constant of AgI.

$$AgI(s) \rightleftharpoons |Ag^+(aq)| + |I^-(aq)|$$

Solubility s s

Hence $K_{sp} = [Ag^+][I^-]$

$8.7 \times 10^{-17}\ M^2 = (s)(s)$

or $s = \sqrt{8.7 \times 10^{-17}\ M^2} = 9.33 \times 10^{-9}$ M

Now, from the Nernst equation, we get

$$E_{Ag^+/Ag} = 0.799\ V$$
$$-(0.059\ V)\log\left(\frac{1}{9.33\times10^{-9}}\right)$$
$$= 0.799\ V - (0.059)(8.030)$$
$$= (0.799\ V - 0.475)\ V = 0.324\ V$$

Standard Reduction potential of $I^- \mid AgI \mid Ag$. Consider Ag/AgI electrode dipped in a standard solution of AgI. Its potential may be computed from either of the following two methods:

(*a*) Considering $Ag^+ \mid Ag$ half-cell, we have cell reaction : $Ag^+_{(aq)} + e^- \rightarrow Ag(s)$

Electrode potential :

$$E_{Ag^+/Ag} = E^\circ_{Ag^+/Ag} - \frac{RT}{F}\ln\frac{1}{[Ag^+]} \quad \ldots(i)$$

(*b*) Considering $I^- \mid AgI \mid Ag$ half-cell

Cell reaction :

$$AgI(s) + e^- \rightleftharpoons Ag(s) + I^-(aq)$$

Electrode potential :

$$E_{I^-}\,|AgI|\,Ag = E^\circ_{I}-|AgI|Ag - \frac{RT}{F}\ln[I^-] \ldots(ii)$$

Thus, $Ag^+/Ag = E_{I^-} \mid AgI/Ag$

Equating equation (*i*) and (*ii*), we get

$$E^\circ\ Ag^+|Ag - \frac{RT}{F}\ln\frac{1}{[Ag^+]}$$
$$= E^\circ_{I^-}/AgI/Ag - \frac{RT}{F}\ln[I^-]$$

or $$E^\circ_{I^-} \mid AgI/Ag = E^\circ_{Ag^+/Ag} + \frac{RT}{F}\ln[Ag^+][I^-]$$
$$= E^\circ\ Ag^+/Ag + \frac{RT}{F}\ln Ksp\,(AgI)$$
$$= 0.799\ V + (0.0591V)\log(8.7 \times 10^{-17})$$
$$= 0.799\ V - (0.0591 \times 16.060)\ V$$
$$= (0.799\ V - 0.950\ V) = \mathbf{-0.151\ V}$$

EXAMPLE 68. *An excess of liquid mercury is added to an acidified solution of* 1.0×10^{-3} *M* Fe^{3+}*. It is found that* 5% Fe^{3+} *remains at equilibrium at* 25°C*. Calculate* $E^\circ\ Hg^{2+}/Hg$*, assuming that the only reaction that occurs is* $2Hg + 2Fe^{3+} \longrightarrow Hg_2^{2+} + 2Fe^{2+}$ *(Given* $E^\circ Fe^{3+}/Fe^{2+} = 0.77V$*)* **(IIT, 1995)**

SOLUTION. The reaction involved is

$$2Hg \quad + \quad 2Fe^{3+} \rightleftharpoons Hg_2^{2+} \quad + \quad 2Fe^{2+}$$

Initial conc. 1.0×10^{-3} M

Equb. conc 0.05×10^{-3} $\quad \frac{0.95\times10^{-3}}{2}$ $\quad 0.95 \times 10^{-3}$

$= 0.475 \times 10^{-3}$

According to Nernst equation,

$$E = \left(E^\circ_{Fe^{3+}/Fe^{2+}}\right) - E^\circ_{(Hg_2^{2+}/Hg)}$$
$$- \frac{0.059}{n}\log\frac{[Fe^{2+}]^2[Hg_2^{2+}]}{[Fe^{3+}]^2}$$

At equilibrium, $E = 0$

$$0 = 0.77 - E^\circ_{Hg_2^{2+}/Hg} - \frac{0.059}{2}\log$$

$$\frac{\left(0.95\times10^{-3}\right)^2\left(0.475\times10^{-3}\right)}{\left(0.05\times10^{-3}\right)^2}$$

or $$E^\circ_{Hg_2^{2+}/Hg} = 0.77 - \frac{0.059}{2}\log\frac{0.4287\times10^{-9}}{2.5\times10^{-9}}$$

$$= 0.77 + 0.022 = \mathbf{0.792\ V}$$

EXAMPLE 69. *A cell Ag | Ag^+ || Cu^{2+} | Cu, initially contains 1 M Ag^+ and 1M Cu^{2+} ions. Calculate the change in cell potential after the passage of* 9.65 *A of current for* 1 *h*.**(IIT, 1999)**

SOLUTION. Quantity of electricity passed is

$$Q = At = (9.65\ \text{A})\ (60\times60\text{s})$$
$$= 34740\ \text{C}$$

Amount of electrons = $\frac{34740}{96500}$ moles = 0.36 mol.

The half cell reactions are :

Left half cell : $Ag\,(s) \longrightarrow Ag^+\,(aq) + e^-$

Right half cell : $\frac{1}{2}Cu^{2+}\,(aq) + e^- \longrightarrow \frac{1}{2}Cu(s)$

Net reaction : $Ag(s) + \frac{1}{2}Cu^{2+} \longrightarrow Ag(s) + \frac{1}{2}Cu^{2+}$

According to the given data :

$$Ag(s) + \frac{1}{2}Cu^{2+}\,(aq) \longrightarrow Ag^+(aq) + \frac{1}{2}Cu\,(s)$$

$t = 0$ 1M 1M

After passing the current [1 – (0.36/2) M = 0.82 (1 + 0.36) M

According to the Nernst equation,

$$E = E^\circ - \frac{RT}{nF}\ln\frac{\left[Ag^+\right]}{\left[Cu^{2+}\right]^{1/2}}$$

Substituting the given data,

$$E_1 = E^\circ - (0.059\ \text{V})\log\frac{1\,\text{M}}{(1\,\text{M})^{1/2}}\ E^\circ$$

$$\left[\because n = 1 \text{ for one electron change}\right]$$

$$E_2 = E^\circ - (0.059\ \text{V})\log\frac{1.36}{(0.82)^{1/2}}$$
$$= E^\circ - 0.010\ \text{V}$$
$$\Delta E = E_2 - E_1 = \mathbf{-\,0.010\ V}$$

EXAMPLE 70. *A silver electrode is immersed in a saturated $Ag_2SO_4(aq)$ solution. The potential difference between silver and the standard hydrogen electrode is found to be* 0.711 *V. Determine K_{sp} (Ag_2SO_4). [Given E° (Ag^+ /Ag) = 0.799 V].*

(Roorkee, 2000)

SOLUTION. According to the given values of electrode potentials, Ag^+ | Ag electrode acts as a cathode and the reactions occurring are :

$2Ag^+\,(aq) + 2e^- \longrightarrow 2Ag_{(s)}$ $E^\circ = 0.799\ V$ (Reduction)

$H_{2(g)} \longrightarrow 2H^+ + 2e^-$ $E^\circ = 0.0V$ (Oxidation)

Net cell reaction is :

$$2\,Ag^+\,(aq) + H_2(g) \longrightarrow 2Ag(s) + 2H^+$$
$$E^\circ_{cell} = E^\circ_{(Ag^+\,|Ag)} - E^\circ_{(2H^+\,|\,H_2)}$$
$$= 0.799 - 0.0 = 0.799\ V$$

According to Nernst equation :

$$E = E^\circ - \frac{0.0591}{n}\log.\frac{\left[H^+\right]^2}{\left[Ag^+\right]^2\times pH_2}$$

$$E_{cell} = 0.711\ \text{V}\ ; pH_2 = 1\ \text{atm}\ ;$$
$$[H^+] = 1\ ; n = 2$$

$$\therefore\quad 0.711 = 0.799 - \frac{0.591}{2}\log\frac{1}{\left[Ag^+\right]^2}$$

$$(0.799 - 0.711) = \frac{0.0591}{2}\log\frac{1}{\left[Ag^+\right]^2}$$

or $$\log\frac{1}{\left[Ag^+\right]^2} = \frac{0.088\times2}{0.0591} = 2.978$$

Taking antilogs,

$$\frac{1}{\left[Ag^+\right]^2} = 950.6$$

or $[Ag^+] = 3.24\times10^{-2}$

For Ag_2SO_4, $Ag_2SO_4(s) \rightleftharpoons 2Ag^+ + SO_4^{2-}$

Since $[Ag^+] = 3.24\times10^{-2}$

$$[SO_4^{2-}\ ] = \frac{1}{2}\left[Ag^+\right] = 1.62\times10^{-2}$$

$$\therefore\quad K_{sp} = [Ag^+]^2\,[SO_4^{2-}]$$
$$= (3.24\times10^{-2})^2\,(1.64\times10^{-2})$$
$$= \mathbf{1.72\times10^{-5}}$$

EXAMPLE 71. *A solution containing* 4.5 *mM of $Cr_2O_7^{2-}$ and* 15 *mM of Cr^{3+} shows a pH of* 2.0. *Calculate the potential of half reaction (standard potential of the reaction* **(Roorkee, 2001)** *$Cr_2O_7^{2-} \longrightarrow Cr^{3+}$ is* 1.33 *V).*

SOLUTION. The half reaction may be represented as :

$$Cr_2O_7^{2-} + 14H^+ + 6e^- \longrightarrow 2Cr^{3+} + 7H_2O$$
$$pH = 2\ ; [H^+] = 10^{-2}\ \text{M};$$
$$[Cr_2O_7^{2-}] = 4.5\times10^{-3}\ \text{M}\ ;$$
$$[Cr^{3+}] = 15\times10^{-3}\ \text{M}$$

According to Nernst equation,

$$E = E^\circ - \frac{0.0591}{n}\log\frac{\left[Cr^{3+}\right]^2}{\left[Cr_2O_7^{2-}\right]\left[H^+\right]^{14}}$$

$$= 1.33 - \frac{0.0591}{6}\log\frac{\left(15\times10^{-3}\right)^2}{\left(4.5\times10^{-3}\right)\left(10^{-2}\right)^{14}}$$

$$= 1.33 - \frac{0.0591}{6}\log 5\times10^{26}$$

$$= 1.33 - \frac{0.0591}{6}\left[26 + 0.599\right]$$

$$= 1.33 - 0.263 = \mathbf{1.067\ V}$$

EXAMPLE 72. *The zinc/silver oxide cell is used in hearing aids and electrical watches*

$Zn \rightleftharpoons Zn^{2+} + 2e^-; \qquad E° = 0.76\ V$

$Ag_2O + H_2O + 2e^- \rightleftharpoons 2Ag + 2OH^-; \qquad E° = 0.344\ V$

(a) What is oxidised and reduced

(b) Find E° of the cell and ΔG° in joules.

(HSB,1996 ; PSEB, 1999, CBSE, 2008)

SOLUTION. Since the E°(reduction) value + 0.344 V > – 0.76 V, so we have :

$Ag_2O + H_2O + 2e^- \rightleftharpoons 2Ag + 2OH^-;$

$E° = +\,0.344\ V$ (cathode)

$Zn^{2+} + 2e^- \rightleftharpoons Zn; \qquad E° = -\,0.76 V$ (anode)

Subtract: $- \quad - \qquad - \qquad +$

$Ag_2O + H_2O + Zn \rightleftharpoons 2Ag + 2OH^- + Zn^{2+}$;

$E° = 1.104\ V$ ...(1)

Here, no. of electrons involved = 2. So, $n = 2$. We know that :

$$\Delta_r G° = -nF\,E°_{cell}$$

$= -\,2 \times 96500$ coulomb mol$^-$ $\times\ 1.104\ V$

= 213,072 coulomb volt mol$^-$

= 213,072 J [∵ 1 coulomb volt = 1 Joule]

= 213.072 k J mol$^-$ **Ans.**

EXAMPLE 73. *The E° values at 298 K corresponding to the following two reduction electrode processes are* :

(*i*) $Cu^+/Cu = 0.52\ V$ (*ii*) $Cu^{2+}/Cu^+ = 0.16\ V$

Formulate the galvanic cell for their combination. What will be the cell potential ? Calculate the $\Delta_r G°$ for the cell reaction (F = 96500 C mol$^-$) **(CBSE, 2005)**

SOLUTION. Since anode electrode has less value of E°(reduction), so the galvanic cell obtained by the combination of anode and cathode will be :

Cu^+ (1M)/Cu^{2+} || Cu^+ (1M) /Cu(s)

Since $E°_{(reduction)}$ value, + 0.52 V > + 0.16 V, so we have:

$Cu^+ + 1e^- \rightleftharpoons Cu; \quad E° = +\,0.52\ V$ (cathode)

$Cu^{2+} + e^- \rightleftharpoons Cu^+; \quad E° = +\,0.16\ V$ (anode)

Subtract: $- \quad - \qquad - \qquad -$

$2Cu^+ \rightleftharpoons Cu + Cu^{2+}; \qquad E° = +\,0.36\ V$

Since, the reaction is a one electron change, $n = 1$.

But : $\Delta_r G° = -nF\,E°_{cell}$

$= -\,1 \times 96500\ C \times 0.36\ V$

= 34740 C V = 34740 J[1 C V = 1 J]

$= 34740\ J \times \frac{1\ kJ}{1000\ J} =$ **34.74 k J Ans.**

EXAMPLE 74. *Find the equilibrium constant of the following reaction,*

$Cu^{2+}(aq) + Sn^{2+}(aq) \longrightarrow Cu(s) + Sn^{4+}(aq)$, *at 25°C,*

$E°Cu^{2+}/Cu = 0.34V;\ E°\ Sn^{4+}/Sn^{2+} = 0.155V.$

SOLUTION. $E°_{cell} = E°_{cathode} - E°_{anode}$

$= E°Cu^{2+}/Cu - E°$

$Sn^{4+}/Sn^{2+} = 0.34 - 0.155 = 0.185V$

But $\log k = (n \times E°_{cell})/0.0591.$

Also, $Cu^{2+} + 2e^- \longrightarrow Cu$; So, $n = 2$.

Hence : $\log k = (2 \times 0.185)/0.0591$

$= 6.26.$

Hence k = antilog 6.26.

Or $k = 1.819 \times 10^6$ **Ans.**

EXAMPLE 75. *Calculate the equilibrium constant for the following cell reaction :*

$1/2\ Cl_2(g) + Br^- \longrightarrow 1/2Br_2(l) + Cl^-;\ E° = 0.30\ V$

SOLUTION. $E°_{cell} = 0.30\ V.$

We know, $\log k = (n \times E°_{cell})/0.0591.$

Also, $Br^- \longrightarrow Br + e^-$, so, $n = 1$

Hence, $\log k = (1 \times 0.30)/0.059 = 5$

∴ k = antilog 5 = **10^5**. **Ans.**

EXAMPLE 76. *The Edison storage cell is represented as Fe(s) | FeO(s) | KOH (aq) | Ni_2O_3(s) | Ni(s)*

The half-cell reactions are

$Ni_2O_3(s) + H_2O\ (l) + 2e^- \rightleftharpoons 2NiO(s) + 2OH^-;$

$E° = +\,0.40\ V$

$FeO(s) + H_2O(l) + 2e^- \rightleftharpoons Fe(s) + 2OH^-;$

$E° = -\,0.87\ V$

(*a*) *What is the cell reaction ?*

(*b*) *What is the cell e.m.f. ? How does it depend on the concentration of KOH ?*

(*c*) *What is the maximum amount of electrical energy that can be obtained from one mole of Ni_2O_3?* **(IIT, 1994)**

SOLUTION. (*a*) The cell reaction is obtained by subtracting reduction reaction of left half cell from that of right half cell. Reduction half reactions are :

Right half-cell :

$Ni_2O_3(s) + H_2O_{(l)} + 2e^- \rightleftharpoons 2NiO(s) + 2OH^-$

Left half-cell :

$FeO(s) + H_2O_{(l)} + 2e^- \rightleftharpoons Fe(s) + 2OH^-$

∴ Cell reaction is

$Fe(s) + Ni_2O_3(s) \rightleftharpoons FeO\ (s) + 2NiO(s)$

(After subtraction)

(*b*) The cell e.m.f. $= E°_R - E°_L = 0.40 - (-\,0.87)$

$= 1.27\ V$

The cell e.m.f. is independent of concentration of KOH as no OH^- appears in the cell reaction.

(*c*) Electrical energy produced = $nF\,E_{cell}$

$= 2 \times 96500\ C\ mol^{-1} \times 1.27\ V$

$= 2.4511 \times 10^5$ J

= 245.11 k J mol^{-1}

EXAMPLE 77. *The following electrochemical cell is set up at 25°C.*

$$Zn \mid Zn^{2+} (a = 1) \parallel Cd^{2+} (a = 1) \mid Cd$$

(*a*) *Write the cell reaction.*

(*b*) *Calculate e.m.f. of the cell*

$(E°\ Zn^{2+}/Zn = -0.763\ V,\ E°\ Cd^{2+}/Cd = -0.403\ V)$

(*c*) *Calculate the value of* $\Delta G°$ *for the cell reaction at 25°C. (Given that F = 96500 C).*

(*d*) *Is the reaction spontaneous ? Discuss.* **(BCEE, 2002)**

SOLUTION. (*a*) The cell reaction involved is

$$Zn + 2Cd^{2+} \longrightarrow Zn^{2+} + Cd$$

(*b*) $E°_{cell} = E°_{cathode} - E°_{anode} \qquad [\because a_{Zn}{}^{2+} = a_{Cd}{}^{+2} = 1]$

$$= -0.0403 - [-0.763] = \mathbf{0.36\ V}$$

(*c*) $\Delta G° = -nF\,E° = -2 \times 96500 \times 0.36$

$$= \mathbf{-69480\ volt\ coulomb}$$

or $\Delta G° = \mathbf{-69480\ J}$

(*d*) As $E°_{cell}$ is positive and ΔG is negative, the cell reaction is spontaneous.

EXAMPLE 78. *Find the equilibrium constant for the reaction*

$$Cu^{2+}{}_{(aq)} + In^{2+}{}_{(aq)} \rightleftharpoons Cu^{+}_{(aq)} + In^{3+}_{(aq)}$$

Given that $E°_{Cu^+/Cu} = 0.15\ V;\ E°_{In^{2+}/In^+} = -0.4\ V;$

$E°_{In^{3+}/In^+} = -0.42\ V$ **[IIT, 2004]**

SOLUTION. $Cu^{2+}_{(aq)} + In^{2+}{}_{(aq)} \rightleftharpoons Cu^{+}_{(aq)} + In^{3+}{}_{(aq)}$;

$$E°_{cell} = E°_{Cu^{2+}/Cu^+} - E°_{In^{3+}/In^{2+}}$$

$$E°_{cell} = 0.15 - E°_{In^{3+}/In^{2+}}$$

Now for In^{3+}/In^{2+}

$In^{3+} + 2e^- \longrightarrow In^+; \qquad E° = -0.42\ V$

Add : $In^+ \longrightarrow In^{2+} + e; \qquad E° = 0.40\ V$

$In^{3+} + e^- \longrightarrow In^{2+}; \qquad E° = ?$

Applying $\Delta G° = \Delta G°_1 + \Delta G°_2$

or $-nF\,E° = -2F(-0.42) - 1F(0.40)$

or $-E° = 0.84 - 0.40;\ E°_{In^{3+}/In^{2+}} = -0.44\ V$

$\therefore$ $E°_{cell} = 0.15 + 0.44 = 0.59\ V$

Now $E°_{cell} = \dfrac{2.303\ RT}{nF} \log K_c$

$\therefore$ $0.59 = \dfrac{0.059}{1} \log K_c$

or $\log K_c = 10.\ \ \mathbf{K_c = Antilog\ 10 = 10^{10}}$

EXAMPLE 79. *Calculate the value of equilibrium constant and Gibb's free energy change in the reaction given below :* **[CBSE PMT (Final) 2004]**

$$Cr_2O_7^{2-} + 6I^- + 14H^+ \longrightarrow Cr^{3+} + 3I_2 + 7H_2O$$

Given that :

(*a*) $Cr_2O_7^{2-} + 14H^+ + 6e^- \longrightarrow 2Cr^3 + 7H_2O;$

$$E° = 1.33\ V$$

(*b*) $2I^- \longrightarrow I_2 + 2e^-;$

$$E° = -0.54\ V$$

SOLUTION. Half reactions taking place are :

Oxidation : $2I^- \longrightarrow I_2 + 2e^-; \quad E°_{oxi} = -0.54\ V$

Reduction :

$$Cr_2O_7^{2-} + 14H^+ + 6e^- \longrightarrow 2Cr^{3+} + 7H_2O; E°_{red} = 1.33V$$

Overall Reaction :

$$Cr_2O_7^{2-} + 6I^- + 14H^+ \longrightarrow 2Cr^{3+} + 3I_2 + 7H_2O;$$

$$E° = E°_{oxi} + E°_{red} = -0.54 + 1.33$$

$$= 0.79\ V$$

Now $E°_{cell} = \dfrac{2.303RT}{nF} \log K_c$ (Here $n = 6$)

$\therefore$ $\log K_c = \dfrac{n\,E°}{0.059} = \dfrac{6 \times 0.79}{0.059} = 80.338$

$$K_c = \text{Antilog } 80.338 = \mathbf{2.178 \times 10^{80}}$$

$$\Delta G° = -nFE° = -6 \times 96500\ C \times 0.79\ V$$

$$= 457410\ J = \mathbf{457.41\ k\,J}$$

EXAMPLE 80. *The standard potential of the following cell is 0.23 V at 15°C and 0.21 V at 35° C.*

$$Pt \mid H_2(g) \mid HCl(aq) \parallel AgCl/Ag(s)$$

(*a*) *Write the cell reaction.*

(*b*) *Calculate* $\Delta H°$ *and* $\Delta S°$ *for the cell reaction by assuming that these quantities remain unchanged in the range of 15°C to 35°C.*

(*c*) *Calculate the solubility of AgCl in water at 25°C. Given: The standard reduction potential of* $Ag^+(aq) \mid Ag(s)$ *couple is 0.80 V at 25°C.* **(IIT, 2001)**

SOLUTION. (*a*) The two half cell reactions are :

$$\frac{1}{2}H_2(g) \longrightarrow H^+ + e^- \text{(Oxidation)}$$

$$AgCl_{(s)} + e^- \longrightarrow Ag_{(s)} + Cl^- \text{(Reduction)}$$

Net cell reaction is :

$$\frac{1}{2}H_{2(g)} + AgCl_{(s)} \longrightarrow HCl_{(aq)} + Ag_{(s)}$$

(*b*) $E_{cell} = 0.23\ V$ (at 15°C)

$$-\Delta G° = nF\,E° = 1 \times 96500\ C \times 0.23\ V$$

$$= 22195\ J \text{ (at 15°C)}$$

$$-\Delta G° = 1 \times 96500\ C \times 0.21\ V$$

$$= 20265\ J \text{ (at 35°C)}$$

Also, $\Delta G° = \Delta H° - T\,\Delta S°$

$\therefore$ $-22195 = \Delta H° - 288 \times \Delta S°$

$$-20265 = \Delta H° - 308 \times \Delta S°$$

Subtracting, $-1930 = 20\ \Delta S°$

or $\Delta S° = \mathbf{-96.50\ J\ K^{-1}\ mol^{-1}}$

Now $-22195 = \Delta H° - 288(-96.50)$

or $\Delta H° = -22195 - 27792 = -49987\ J$

$$= \mathbf{-49.987\ k\,J}$$

(*c*) $E°$ at the average temperature of 298 K

$$= \frac{0.23 + 0.21}{2} = 0.22\ V$$

$$E°_{cell} = 0.22 - 0.80 = -0.58\ V$$

$$E° = 0.059 \log K_{sp} = -0.58$$

On usual calculations,

$$K_{sp} = \mathbf{1.48 \times 10^{-10}\ mol^2\ L^{-2}}$$

19.16 FARADAY'S FIRST AND SECOND LAW OF ELECTROLYSIS

Faraday's first law of electrolysis. According to this law, the weight or mass (*w*) liberated or *deposited at* any electrode as a result of electrolysis is directly proportional to the quantity of electricity (Q) passed through the electrolyte.

Mathematically : $W \propto Q$ or $W = ZQ$ ...(1)

where $Q = It$.

Thus $\mathbf{W = Z\,I\,t}$ ...(2)

where I is the current in amperes, *t* is the time in seconds and Z is **the electrochemical equivalent.**

when I = 1 ampere, *t* = 1 second, then $W = Z$. Thus :

Electrochemical equivalent (Z) is equal to the weight of the substance liberated when one ampere current is passed for 1 second.

Note that : (*i*) 1 coulomb of electricity = 1 ampere current × 1 second time.

(*ii*) When 96500 coulomb (or one Faraday) of electricity is passed through an electrolyte then 1 gram equivalent weight of the substance is liberated.

∴ 1 Faraday = 96500 coulomb and wt. of substance liberated when 96500 coulomb electricity is passed = 1 g. equivalent. e.g., when 96500 coulomb of electricity is passed through aluminium chloride solution then wt. of Al (eq.wt. = At. wt/valency = 27/3 = 9) liberated = 9 g.

Thus : Gram equivalent weight = Z × 96500 coulomb

Or $$Z = \frac{\text{Gram eq. wt.}}{96500 \text{ coulomb}}$$

Also : $$Z = \frac{\text{Wt. of substance (W)}}{\text{Quantity of electricity (Q)}}$$

[from relation (1) above]

Unit of $Z = gC^{-}$ where *C* represents coulomb

Faraday's second law of electrolysis. *According* to this law, *when same* quantity of electricity is passed through *different electrolyte* solutions connected in series, the weights of different substances liberated at the electrodes are proportional to their equivlent weights. For example, consider three electrolytic cells containing solutions of $AgNO_3$, $CuSO_4$ and dil. H_2SO_4 which are connected in series and same amount of current is passed for the same time, then:

$$\frac{\text{Wt. of Ag}}{\text{Eq. Wt. of Ag}} = \frac{\text{Wt. of Cu}}{\text{Eq. Wt. of Cu}} = \frac{\text{Wt. of } H_2}{\text{Eq. Wt. of } H_2}$$

To understand the law, consider the following reactions :

(*i*) $H^+ + e^- \longrightarrow H \,;\, H + H \longrightarrow H_2$

(*ii*) $Cu^{2+} + 2e^- \longrightarrow Cu$;

(*iii*) $Al^{3+} + 3e^- \longrightarrow Al$

Suppose that these three reactions take place in three separate electrolytic cells connected in series. When *'a' moles of electrons* are passed through these three cells, the mass of H_2, Cu and Al liberated/deposited are 1a g, 31.75a g and 9a g respectively. Here, 1, 31.75 and 9 are the chemical equivalent weights (*E*) of H, Cu and Al respectively. Thus:

$$W = \textbf{moles of electrons } (a) \times E$$

The charge possessed by one mole (= 6.022×10^{23}) of **electrons** = $1.6 \times 10^{-19} \times 6.022 \times 10^{23}$ = **96500** C. This charge (96500 C) is called one **Faraday**.

This means that by passing one mol of electrons and by passing one Faraday of charge, one gram equivalent weight of the substance will be liberated or deposited

$$\therefore \quad W = \frac{\textbf{Q (in coulomb)}}{\textbf{96500 coulomb}} \times \textbf{Eq. wt.}$$

19.17 FARADAY'S FIRST LAW OF ELECTROLYSIS

Example 81. *Find the weight of chlorine gas produced when one ampere current is passed for 15 minutes through molten sodium chloride. (Atomic mass of chlorine* = 35.5*).* **(PSEB, 1995S)**

Solution. Time (*t*) = 15 minutes = 15 × 60 = 900 seconds; current = 1 ampere. Reaction : $Cl^- - 1\,e^- \longrightarrow 1/2\,Cl_2$. Eq. wt. of Cl_2 = At. wt. of Cl/1 = 35.5/1 = 35.5. Electrochemical equivalent, Z = g.eq.wt. of Cl/96500 C = 35.5/96500. We know, wt = Z × current in amperes × time in seconds = (35.5 × 1 × 15 × 60)/96500) = **0.331 g** **Ans.**

Example 82. *For how long a current of 1.5 amperes has to be passed through the electrolyte in order to deposit 1.5 g of Al when the electrode reaction is*

$$Al^{3+} + 3e^- \longrightarrow Al \quad (\textit{Atomic mass of Al} = 27)$$

Solution. Reaction : $\underset{1\text{ mol}}{Al^{3+}} + \underset{3\text{ mol}}{3e^-} \longrightarrow \underset{1\text{mol } (=27\text{g})}{Al}$

Charge on 3 mol of electrons = 3 × 96500 coulombs :

(*a*) Total charge to deposit 27 g Al = 3 × 96500 C

∴ Charge to deposit 1.5 g Al = (3 × 96500 × 1.5)/27 = 16083.3 C ...(1)

(*b*) **To Calculate time (t).** Current = 1.5 ampere; time (*t*) = ?.

No. of coulombs = ampere × time (in seconds) = 1.5 × *t*. C. ...(2)

Equating (1) and (2), we get : 1.5 *t* = 16083.3

Or *t* = (16083.3)/1.5 sec. **Or** (16083.3)/(1.5 × 60 × 60) = 2.978 hours **Ans.**

Example 83. *A galvanic cell is set up from a zinc bar weighing 100 g and one litre of 1 M $CuSO_4$ solution. Assuming that the cell delivers a steady current of 1.0 ampere, how long the cell would work ?* (at. wt., Zn = 65.38g mol⁻)

Solution. Wt. of Zn = 100 g ;

At wt. of Zn = 65.38 g mol⁻.

So, no. of mol of Zn = $\dfrac{100\text{ g}}{65.38\text{ g mol}^-}$ = 1.58 mol

1 M CuSO = 1 mol $CuSO_4$ per litre.

But $CuSO_4 \rightleftharpoons Cu^{2+} + SO_4^{2-}$

$\therefore$ $Cu^{2+} + 2e^- \longrightarrow Cu$

$\therefore$ One mol of $CuSO_4$ can produce electricity,

Q = 2 × 96500 coulomb

But Q = Current in amperes × time in seconds

$\therefore$ 2 × 96500 coulomb = 1 ampere × time in seconds

$$\therefore \text{Time in seconds} = \frac{2 \times 96500 \text{ ampere second}}{1 \text{ ampere}}$$

($\because$ C = ampere × second)

= 193000 s

$$= 193000\text{s} \times \frac{1\text{min}}{60\text{s}} \times \frac{1\text{hr}}{60\text{min}}$$

= **53.6 hr** **Ans.**

EXAMPLE 84. *How much charge is required for the following reduction of :*

(*a*) 1 *mol of* Al^{3+} *to Al* (*b*) 1 *mol of* Cu^{2+} *to Cu.*

SOLUTION. (*a*) The required reduction is,

$Al^{3+} + 3e^- \longrightarrow Al$ *i.e.*, 1 mole of Al = 3 Faradays as it is a 3 electron change

(*b*) The required reduction is, $Cu^{2+} + 2e^- \rightarrow Cu$ *i.e.*, 1 mole of Cu = 2 Faradays as it is a 2 electron change.

EXAMPLE 85. *Calculate the number of coulombs required to deposit* 5.4 *g of Al when the electrode reaction is :*

$Al^{3+} + 3e^- \longrightarrow Al$:

(*atomic mass of Al* = 27 *g mol*$^-$; *F* = 96500 *mol*$^-$)

(DSB,1994)

SOLUTION. From the reaction, $Al^{3+} + 3e^- \longrightarrow Al$, eq. wt. of Al = At. wt. of Al/3 = 27/3 = 9. Hence electrochemical equivalent, Z = g.eq. wt. of Al/96500 = 9/96500. We know, wt = Z × (current in ampere × time in sec) = Z × no. of coulombs. Substituting the values, we get :

5.4 = (9/96500) × no. of coulombs.

Hence, no. of coulombs = (5.4 × 96500)/9

= **57900 coulombs**. **Ans.**

EXAMPLE 86. *Write anode and cathode reactions for the electrolysis of water. How much charge will be transported for the decomposition of* 3.6 *g of* H_2O ? **(CBSE, 2000S)**

SOLUTION. For the electrolysis of water, the reactions taking place at different electrodes are :

At anode. $2H_2O \longrightarrow O_2 + 4H^+ + 4e^-$ (Oxidation)

2 × 18 = 36 g 4 × 96500 coulombs ...(1)

At cathode. $2H^+ + 2e^- \longrightarrow H_2$ (Reduction) ...(2)

wt. of H_2O = 3.6g.

From reaction (1), we have:

36 g H_2O require for electrolysis

= 4 × 96500 coulombs.

$\therefore$ 3.6 g H_2O require for electrolysis

= (4 × 96500 × 3.6)/36

= **38600 coulombs.** **Ans.**

EXAMPLE 87. *Al_2O_3 is reduced by electrolysis at low potentials and high currents. If 4.0 × 10^4 amperes of current is passed through molten Al_2O_3 for 6 hours, what mass of aluminum is produced? (Assume 100% current efficiency, at. mass of Al = 27g mol$^-$)*

(*a*) *8.1 × 10^4g* (*b*) *2.4 × 10^5g*

(*c*) *1.3 × 10^4 g* (*d*) *9.0 × 10^3 g*

(PSEB, 2007, CBSE-PMT, 2009)

SOLUTION. Eq. wt. of

Al = At. wt of Al/Valency = 27/3 = 9.

Z = Electrochemical equivalent

= g. eq. wt/96500 coulomb

$\therefore$ *g*. eq. wt. of Al = *Z* × 96500 *C*; 9g = *Z* × 96500 *C*

$$\therefore \quad Z = \frac{9g}{96500C}.$$

We know

Mass of Al = *Z* × *I* × *t*;

$$\text{mass of Al} = \frac{9g}{96500C} \times 4 \times 10^4 \text{ amp.} \times 6 \times 60 \times 60 \text{ s}$$

$$= 8.1 \times 10^4 \text{ g.} \frac{\text{amp.s}}{\text{C}} = 8.1 \times 10^4 \text{ g.}$$

So, the correct answer is (*a*).

EXAMPLE 88. *How many coulombs are required for the following reduction ?*

(*a*) 1 *mol of* $C_6H_5NO_2$ to $C_6H_5NH_2$

(*b*) 1 *mol of* MnO_4^- *to* Mn^{2+} **(PSEB, 1999S)**

SOLUTION. (*a*)

$C_6H_5NO_2 + 6H^+ + 6e^- \longrightarrow C_6H_5NH_2 + 2H_2O$

1mol 6mol

6*F*

So, 6*F* = 6 × 96500 C

= **579000 coulombs** **Ans.**

(*b*) $MnO_4^- + 8H^+ + 5e^- \longrightarrow Mn^{2+} + 4H_2O$

1 mol 5 mol

5*F*

So, 5*F* = 5 × 96500 Coulombs

= **482500 Coulombs** **Ans.**

EXAMPLE 89. *How many moles of mercury will be produced by electrolysing 1.0 M Hg(NO$_3$)$_2$ solution with a current of 2.0 A for 3 hours? (Hg = 200.6g mol$^-$).* **(ISC, 2010)**

SOLUTION.

$Hg(NO_3)_2$ (1M) $\rightleftharpoons Hg^{2+}$ (1M) + $2NO_3^-$ (2M)

$Hg^{2+} + 2e^- \longrightarrow Hg$

Charge = current in A × time in second

= 2.0 × 3 × 60 × 60 = 21600 s

At. wt. of Hg = 200.6g mol$^-$. Since at. wt. of Hg is 200.6g mol$^-$, so we require

2F or 2 × 96500 C to deposit

Hg = 200.6 g mol$^-$ = 1 mol

$\therefore$ 21600 C are required to deposit

$$\text{Hg} = \frac{1}{2 \times 96500} \times 21600 = 0.112 \text{ mol.}$$

EXAMPLE 90. *How many coulombs are required for the following oxidation ?*

(*a*) 1 *mol of* H_2O *to* O_2

(*b*) 1 *mol of FeO to* Fe_2O_3. **(PSEB, 1999S)**

SOLUTION. (*a*)

$$\begin{array}{llll} 2H_2O & \longrightarrow 4H^+ + & O_2(g) & + 4e^- \\ 2\text{ mol} & & 1\text{ mol} & 4\text{mol} \\ 1\text{ mol} & & \frac{1}{2}\text{mol} & \frac{4}{2} = 2\text{ mol} = 2 \times 96500 \text{ coulombs} \end{array}$$

(*a*) 1 mol H_2O require charge

$= 2 \times 96500$ coulombs

$=$ **193000 coulombs** **Ans.**

$$\begin{array}{llll} (b) & Fe^{2+} \longrightarrow & Fe^{3+} & + 1e^- \\ & 1\text{ mol} & 1\text{ mol} & 1\text{ F} = 1 \times 96500 \text{ coulombs} \end{array}$$

$\therefore$ 1 mol of FeO require 1 mol electrons *i.e.*, **1 × 96500 coulombs.** **Ans.**

EXAMPLE 91. *A current of* 8.0 *amperes is used to prepare* MnO_2 *by the electrolysis of* $MnSO_4$ *that uses* 85% *of the current passing through the cell. Calculate the time in which* 60 *g of* MnO_2 *can be prepared.*

SOLUTION. The reaction involved is :

$$Mn^{2+}(aq) + 2H_2O(l) \longrightarrow Mn^{4+}O_2(s) + 2H^+(aq) + H_2(g).$$

[At. mass, Mn = 55, O = 16]

Wt. of MnO_2 = 60 g ; eq. wt. of

$$MnO_2 = \frac{55 + (2 \times 16)}{2} = 43.5$$

[$\because Mn^{2+} + 2H_2O \to MnO_2 + 4H^+ + 2e^-$ is a 2 electron change].

Current (I), in amperes

$= 85\%$ of 8 amperes

$$= \frac{8 \times 85}{100} = 6.8 \text{ amperes}$$

But $W = Z\,I\,t.$

So, $t = \dfrac{W}{ZI}$

$$= \frac{60 \times 96500}{43.5 \times 6.8} \text{sec}.$$

$$\left[\because Z = \frac{\text{g. eq. wt. of } MnO_2}{96500} = \frac{43.5}{96500}\right]$$

$$= 19374 \text{ sec} \times \frac{1 \text{ min}}{60 \text{ sec}} \times \frac{1 \text{ hr}}{60 \text{ min}}$$

$=$ **5.437 hours** **Ans.**

EXAMPLE 92. *If the charge on an electron is* 1.6×10^{-19} *coulomb, calculate the value of Avogadro's number.*

(1*F* = 96500 *coulomb*)

SOLUTION. 1 F or 96500 coulomb is charge on electrons = 1 mol

Hence 1.6×10^{-19} coulomb × Avogadro's no.

= 96500 coulomb

$$\therefore \text{ Avogadro's no.} = \frac{96500 \text{ coulomb}}{1.6 \times 10^{-19} \text{ coulomb}}$$

$=$ **6.03 × 10²³** **Ans.**

19.18 FARADAY'S SECOND LAW OF ELECTROLYSIS.

EXAMPLE 93. *An electric current is passed through three cells in series, respectively containing solutions of copper sulphate, silver nitrate and potassium iodide. What weights of silver and iodine will be liberated while* 1.25 *g of copper are being deposited? (at. wt. of Ag* = 108, *I* = 127, *Cu* = 63.5*)*

SOLUTION. Eq. wt. of

$$\text{Ag} = \frac{\text{At. wt. of Ag}}{\text{Valency of Ag}} = \frac{108}{1} = 108\,;$$

$$\text{Eq. wt. of I} = \frac{\text{At. wt. of I}}{\text{Valency of I}} = \frac{127}{1} = 127\,;$$

$$\text{Eq. wt. of Cu} = \frac{\text{At. wt. of Cu}}{\text{Valency of Cu}} = \frac{63.5}{2} = 31.75$$

According to Faraday's second law of electrolysis :

$$\frac{\text{Wt. of Cu}}{\text{Eq. wt. of Cu}} = \frac{\text{Wt. of iodine}}{\text{Eq. wt. of iodine}} = \frac{\text{Wt. of Ag}}{\text{Eq. wt. of Ag}}$$

$$\frac{1.25 \text{ g}}{31.75} = \frac{\text{Wt. of iodine}}{127} = \frac{\text{Wt. of Ag}}{108}$$

$$\therefore \quad \text{Wt. of iodine} = \frac{1.25 \text{ g}}{31.75} \times 127 = \mathbf{5.0 \text{ g}}$$

$$\text{Also,} \quad \text{Wt. of Ag} = \frac{1.25 \text{ g}}{31.75} \times 108 = \mathbf{4.25 \text{ g}}$$

EXAMPLE 94. *When an aqueous solution of sodium chloride was electrolysed, 0.1 g of chlorine was liberated. Calculate the volume of hydrogen measured at 15° C and 745 mm pressure which will be liberated at the same time. (at. wt., Cl = 35.5 : H = 1).*

SOLUTION. Eq. wt. of

$$\text{H} = \frac{\text{At. wt. of H}}{\text{Valency of H}} = \frac{1}{1} = 1$$

$$\text{Eq. wt. of Cl} = \frac{\text{At. wt. of Cl}}{\text{Valency of Cl}} = \frac{35.5}{1} = 35.5$$

According to Faraday's second law of electrolysis :

$$\frac{\text{Wt. of H}}{\text{Eq. wt. of H}} = \frac{\text{Wt. of Cl}}{\text{Eq. wt. of Cl}}\,;\ \frac{\text{Wt. of H}}{1} = \frac{0.1}{35.5}$$

$$\therefore \text{ Wt. of H} = \frac{1}{355} \text{ g}.$$

We know that :

2g (*i.e.*, 1 g. equivalent) of H_2 occupies volume at N.T.P. = 22400 mL

$\frac{1}{355}$ g of H_2 occupies volume at N.T.P.

$$= \frac{22400 \text{ mL}}{2\text{g}} \times \frac{1}{355} \text{g} = \mathbf{31.55 \text{ mL}}$$

Now ; $P_1 = 745$ mm, $V_1 = ?$,

$T_1 = 15 + 273$

$= 288\ K$;

At N.T.P., $P_2 = 760$ mm;

$V_2 = 31.55$ mL, $T_2 = 273\ K$

Using gas equation, we have :

$$\frac{P_1V_1}{T_2} = \frac{P_2\,V_2}{T_2}\,;\; V_1 = \frac{P_2\,V_2}{T_2}\times\frac{T_1}{P_1}$$

$$= \frac{760\text{ mm}\times 31.55\text{ mL}\times 288\text{ K}}{273\text{ K}\times 745\text{ mm}}$$

$\therefore \quad V_1 = \mathbf{33.95\ mL.}$ **Ans.**

Example 95. *A current of electricity was passed through a series of cells containing $AgNO_3$, $CuSO_4$ and H_2SO_4 solutions for a period of 25 minutes. If the silver deposited was 0.5394 g, what would be (a) the weight of copper and (b) the volume of H_2 at N.T.P. liberated by the current ? What was the strength of current assuming that it remained constant ? (at. wt., Ag = 108 ; Cu = 63.57 ; 1 Faraday = 96500 C).*

Solution. (*a*) To find wt. of Cu and volume of H_2 at N.T.P.

According to Faraday's second law of electroysis :

$$\frac{\text{Wt. of Cu}}{\text{Eq. wt. of Cu}} = \frac{\text{Wt. of H}}{\text{Eq. wt. of H}} = \frac{\text{Wt. of Ag}}{\text{Eq. wt. of Ag}}$$

$$\frac{\text{Wt. of Cu}}{63.5/2} = \frac{\text{Wt. of H}}{1} = \frac{0.5394\text{g}}{108}$$

$$\therefore \quad \text{Wt. of Cu} = \frac{63.5}{2}\times\frac{0.5394\text{g}}{108} = \mathbf{0.1586\ Ans.}$$

$$\text{Wt. of H} = 1\times\frac{0.5394\text{g}}{108} = 0.00499\text{ g}$$

$$\left[\begin{array}{l} \text{Eq. wt. of Cu} = \dfrac{\text{At. wt.}}{\text{Valency}} = 63.5/2 \\ \text{Eq.wt. of H} = \dfrac{\text{At. wt.}}{\text{Valency}} = \dfrac{1}{1} = 1 \\ \text{Eq. wt. of Ag} = \dfrac{\text{At. wt.}}{\text{Valency}} = \dfrac{108}{1} \end{array}\right]$$

But 2g (= g. mol. wt of H_2) of H_2 at N.T.P. occupies volume = 22400 mL

0.00499g H_2 occupies volume at N.T.P.

$$= \frac{22400\text{ mL}}{2\text{g}}\times 0.00499\text{ g}$$

$$= \mathbf{55.89\ mL} \qquad \textbf{Ans.}$$

(*b*) 108 g (= 1 g. equivalent of Ag) of Ag is liberated by = 96500 C

0.5394 g of Ag is liberated by

$$= \frac{96500\text{ C}}{108\text{ g}}\times 0.5394\text{g} = \text{Q}$$

But Q = Current in ampere × time in seconds :

$$25\text{ min} = 25\text{ min}\times\frac{60\text{ sec}}{1\text{min}} = 1500\text{s}$$

$$\therefore \quad \text{Current} = \frac{\text{Q}}{\text{time}} = \frac{96500\text{ C}\times 0.5394\text{ g}}{108\text{ g}\times 1500\text{ s}}$$

$$= \mathbf{0.3213\ ampere} \qquad \textbf{Ans.}$$

$$\left[\because \frac{\text{C}}{\text{s}} = \text{ampere}\right]$$

Type. (*a*) When one Faraday (= 96500 coulomb) of electricity is passed then one gram atom (= 6.023 × 10^{23} atoms) of Ag^+ ions (say) are liberated.

(*b*) 1 Coulomb = 3 × 10^9 e.s.u.

Example 96. *Calculate the electrostatic charge on Ag^+ ions when one Faraday of electricity is passed through the solution containing these ions.*

Solution. Electrostatic charge on Ag^+ ions

$$= \frac{96500\text{ coulomb}}{6.023\times 10^{23}}$$

($\because$ 1 Faraday = 96500 coulombs)

But 1 coulomb = 3 × 10^9 e.s.u. *i.e.*, electrostatic unit.

$$\therefore \quad \frac{96500\text{ C}}{6.023\times 10^{23}} = \frac{96500\times 3\times 10^9}{6.023\times 10^{23}}\text{ e.s.u.}$$

$$= \mathbf{4.81\times 10^{-10}\ e.s.u.} \qquad \textbf{Ans.}$$

Example 97. *A steady current of 1.8 amperes was passed through three electrolytic cells A, B, and C (connected in series) containing $CuSO_4$, $ZnSO_4$ and $AgNO_3$ solutions respectively till 2.16 g of silver was deposited at the cathode. Calculate the time for which the current was passed Also calculate the weight of copper and zinc deposited.*

Solution. (*i*) Wt. of Ag deposited = 1.7 g, current passed = 1.8 amperes ; quantity of electricity passed, Q = ? ; t = ?

$$\text{Reaction : } \underset{1\text{mol}}{Ag^+} + \underset{\substack{1\text{ mol} \\ = 96{,}500\text{ C}}}{e^-} \longrightarrow \underset{1\text{mol} = 108\text{g}}{Ag}$$

[$\because$ at. wt. of Ag = 108]

108 g Ag is deposited by charge = 96500 coulombs

2.16 g of Ag is deposited by charge

$$= \frac{96500}{108}\times 2.16 = 1930\text{ coulomb}$$

We know Q = current in amperes × time in seconds

$$\therefore \quad t = \frac{\text{Q}}{\text{C}} = \frac{1930\text{ coulombs}}{1.8\text{ amperes}}$$

$$= \mathbf{1072\ seconds} \qquad \textbf{Ans.}$$

(*ii*) $\text{Eq. wt. of Cu} = \dfrac{\text{At. wt.}}{\text{Valency}} = \dfrac{63.5}{2} = 31.75$

Let wt. of Cu deposited = *x* g

$$\text{But} \quad \frac{\text{Wt. of Cu}}{\text{Wt. of Ag}} = \frac{\text{Eq. Wt. of Cu}}{\text{Eq. Wt. of Ag}};$$

$$\frac{x}{2.16} = \frac{31.75}{108}$$

$$\left[\text{Eq. wt. of Ag} = \frac{\text{At. Wt. of Ag}}{\text{Valency}} = \frac{108}{1}\right]$$

$$\therefore \quad x = \mathbf{0.635\ g} \qquad \textbf{Ans.}$$

(*iii*) $\text{Eq. wt. of Zn} = \dfrac{\text{At. wt.}}{\text{Valency}} = \dfrac{65}{2} = 32.5$

Let wt. of Zn = *x* g

$$\text{But} \quad \frac{\text{Wt. of Zn}}{\text{Wt. of Ag}} = \frac{\text{Eq. wt.of Zn}}{\text{Eq. wt. of Ag}};$$

$$\frac{x}{2.16} = \frac{32.5}{108};\; x = \mathbf{0.65\ g} \qquad \textbf{Ans.}$$

EXAMPLE 98. *The amount of electricity which releases 2.6267 g of gold from a gold salt is same as that which dissolves 1.26 g of copper from copper anode during the electrolysis of copper sulphate solution. What is the oxidation number of gold in the gold state ? (At. wts. of Cu = 63.5, Au = 197).* **(W.B.J.E.E., 2003)**

SOLUTION. According to Faraday's second law of electrolysis,

$$\frac{\text{Weight of copper dissolved}}{\text{Weight of gold deposited}} = \frac{\text{Eq. wt. of copper}}{\text{Eq. wt. of gold}} \qquad ...(1)$$

Equivalent weight of an element

$$= \frac{\text{Atomic weight}}{\text{Valency}}$$

$$\text{Eq. wt. of copper} = \frac{63.5}{2} = 31.75\,;$$

$$\text{Eq. wt. of gold} = \frac{197}{x}$$

where x is the oxidation number (or valency) of gold

Substituting the values in equation (1), we get :

$$\frac{1.26}{2.6267} = \frac{31.75x}{197}$$

$$x = \frac{1.26 \times 197}{2.6267 \times 31.75} \simeq \mathbf{3} \qquad \textbf{Ans.}$$

EXAMPLE 99. *A 100 W, 110 V incandescent lamp is connected in series with an electrolytic cell containing $CdSO_4$ solution. What mass of cadmium will be deposited at the cathode after 4 hours of electrolysis ? Calculate gram equivalent of acid that will be formed ? [Cd = 112.2]* **[WBJEE, 2004]**

SOLUTION. 100 W, 110 V bulb sends current

$$= \frac{100}{110} \text{ amp. per second}$$

Electricity passed through the solution in 4 hours

$$= \frac{100}{110} \times 4 \times 60 \times 60 \text{ C}$$

$$= 13091 \text{ C} = 0.1356 \text{ F}$$

$$[\because 1\text{F} = 96500 \text{ C}]$$

Reactions taking place during electrolysis are :

$$CdSO_4 \rightleftharpoons Cd^{2+} + SO_4^{2-}$$

At cathode : $Cd^{2+} + 2e^- \longrightarrow Cd$

At anode : $SO_4^{2-} + H_2O \longrightarrow H_2SO_4 + 1/2\,O_2 + 2e^-$

$\therefore$ 2 × 96500 C produce Cd = 112.2 g

$$13091 \text{ C produce Cd} = \frac{112.2}{2 \times 96500} \times 13091 \text{ g} = 7.61 \text{ g}$$

According to equation,

2F give 1 mol or 2 gram equivalent of acid; or 1F gives 1gram equivalent of acid

$\therefore$ 0.1356 F give acid = 0.1356 g equivalent

EXAMPLE 100. *The density of copper is 8.94 g/c. c. Find out the number of coulombs of electricity needed to plate an area of 10 cm × 10 cm to a thickness of 10^{-2} cm using copper sulphate solution as an electrolyte (Cu = 63.5).*

SOLUTION. Density,

$$d = 8.94 \text{g/c.c.;} \text{ Volume to be plated}$$

$$= 10 \times 10 \times 10^{-2} = 1 \text{c.c.}$$

$$\text{Mass} = d \times V = 8.94 \times 1 = 8.94 \text{ g}$$

$$\underset{\substack{2\text{mol}\\2 \times 96500 \text{ C}}}{Cu^{2+} + 2e^-} \longrightarrow \underset{\substack{1\text{mol}\\63.5 \text{ g}}}{Cu}$$

Number of coulombs required to deposit 63.5 g Cu = 2 × 96500 C

Number of coulombs required to deposit 8.94 g

$$\text{Cu} = \frac{2 \times 96500}{63.5} \times 8.94 = \mathbf{27172\ C\ Ans.}$$

EXAMPLE 101. *A current of 5A is passing through copper wire. Calculate the number of electrons passing through a point per second. ($e = 1.6 \times 10^{-19}$ C).* **(WBJEE, 2003)**

SOLUTION. Current passed = 5A

Coulombs of electricity which pass through the copper wire in one sec = I × t = 5 × 1= 5C

Charge on an electron = 1.6×10^{-19} C

1.6×10^{-19} C of charge is carried by electrons = 1

5C charge is carried by electrons

$$= \frac{1}{1.6 \times 10^{-19}} \times 5$$

$$= \mathbf{3.125 \times 10^{19}\ electrons} \qquad \textbf{Ans.}$$

EXAMPLE 102. *Copper sulphate solution (250 mL) was electrolysed using a platinum anode and a copper cathode. A constant current of 2 mA was passed for 16 minutes. It was found that after electrolysis, the absorbance of the solution was reduced to 50% of its original value. Calculate the concentration of copper sulphate in the solution to begin with.* **(IIT, 2001)**

SOLUTION. Quantity of electricity passed is

$$Q = At = 2 \times 10^{-3} \text{ A} \times (16 \times 60\text{s}) = 1.92$$

Amount of electrons passed

$$= \frac{1.92}{96500} \text{ mol} = 1.98 \times 10^{-5} \text{ mol}$$

$$Cu^{2+} + 2e^- \longrightarrow Cu$$

$\therefore$ No. of moles of Cu^{2+} ions discharged

$$= \frac{1.98}{2} \times 10^{-5} \text{ mol} = 9.9 \times 10^{-6} \text{mol.}$$

Hence initial concentration

$$= 9.9 \times 10^{-6} \times 2 \text{ mol per 250 mL}$$

$$= \frac{9.9 \times 10^{-6} \times 2 \times 1000}{250} \text{M}$$

$$= \mathbf{7.92 \times 10^{-5}\ M} \qquad \textbf{Ans.}$$

EXAMPLE 103. *The following electrochemical cell has been set up :*

$$Pt\,(1) \mid Fe^{3+}, Fe^{2+}{}_{(a\,=\,1)} : Ce^{4+}, Ce^{3+}{}_{(a\,=\,1)} \mid Pt\,(2)$$

$$E°\,(Fe^{3+} \mid Fe^{2+}) = 0.77\ V,\ E°\,(Ce^{4+} \mid Ce^{3+}) = 1.61\ V$$

If an ammeter is connected between two platinum electrodes, predict the direction of flow of current. Will the current increase or decrease with time ? **(IIT, 2000)**

Solution. From the given values of reduction potentials, for the e.m.f. to be positve, the following reaction should occur :

$$Ce^{4+} + Fe^{2+} \longrightarrow Ce^{3+} + Fe^{3+}$$

∴ $Ce^{4+} | Ce^{3+}$ electrode will act as cathode and $Fe^{3+} | Fe^{2+}$ electrode will act as anode

$$E°_{cell} = E°_{cathode} - E°_{anode} = E°(Ce^{4+} | Ce^{3+}) - E°\,(Fe^{3+} | Fe^{2+})$$

$$= \mathbf{1.61 - 0.77 = 0.84\ V}$$

E.M.F. is positive and therefore, reaction is spontaneous.

∴ *Current will flow from Ce electrode to iron electrode and will decrease with time.* (Electrons will flow from iron electrode to Ce electrode)

19.19 MISCELLANEOUS EXAMPLES

Example 104. *Calculate the current required to be passed in the reaction*

$2NH_4HSO_4 \longrightarrow (NH_4)_2S_2O_8 + H_2$ *(electrolytic reaction) to form enough*

$(NH_4)_2S_2O_8 + 2H_2O \longrightarrow H_2O_2 + 2NH_4HSO_4$ *(Steam distilation) intermediate* $(NH_4)_2S_2O_8$, *to yield 50 g of pure hydrogen peroxide per hour. Assume 75% current efficiency in the process.*

Solution. (*a*) Molar mass of

$$H_2O_2 = (2 \times 1) + (2 \times 16) = 34.$$

In NH_4HSO_4, all the oxygen atoms have –2 oxidation state. In $(NH_4)_2S_2O_8$, two oxygen atoms are linked to each other through peroxide linkage. So, these oxygen atoms have –1 oxidation state. It means, two oxygen atoms have got oxidised from –2 to –1state. Thus when two moles of NH_4HSO_4 (given) react, 2 moles of electrons are formed.

Also, 50 g of pure H_2O_2 will be 50/34 moles of H_2O_2. Moles of $(NH_4)_2S_2O_8$ that would have reacted = moles of $(NH_4)_2S_2O_8$ that need to be formed from $NH_4HSO_4 = \frac{50}{34}$.

∴ Moles of NH_4HSO_4 that need to react $= \frac{50}{34} \times 2 = \frac{50}{17}$.

or Moles of electrons given by $\frac{50}{17}$ moles of

$$NH_4HSO_4 = \frac{50}{17}$$

Hence, $\text{charge} = \frac{50}{17} \times 96500$

$$= \mathbf{283823.5\ coulombs.} \qquad \textbf{Ans.}$$

(*b*) **Current with 75% efficiency.**

$$= \frac{283823.5\ C}{60 \times 60\,s} \times \frac{100}{75}$$

$= 105.12$ A *i.e.*, ampere[∵ 1A = Cs^{-}]
∵ 1 hour = 60 × 60 seconds]

Example 105. *During electrolysis of a solution, 125 ampere current was passed for 500 seconds. If one of the electrodes is that of impure copper (containing only Ag , Au and Fe), the mass of the cathode increased by 20.02 g and that of the anode decreased by 20.5 g. Calculate the percentage of copper and iron originally present in the sample.*

Solution. In order to solve this problem, we have to make certain assumptions:

(*a*) *The cathode* should either be an *inert electrode or a pure copper electrode:* It means, anode should be of impure copper. In this situation, metals in impure copper will get oxidised when electric current is passed. This assumption is necessary because, we are to find the percentage of Cu and Fe in the anode. This fact can be related to mass increase of cathode only if the metal from the anode gets deposited on the cathode. Based on their reduction potential values, Fe will be oxidised first and then copper. When Cu is competely oxidised, Ag and Au fall into the electrolyte as anode mud below anode.

(*b*) *Type of electrolyte used.* The electrolyte used should not contain Cu^{2+} ions. The reason is that mass increase of the cathode during the oxidation of Fe to Fe^{2+}, would be due to copper and the mass increase of the cathode, during the oxidation of copper would also be due to copper. Hence percentage of Cu and Fe cannot be determined in the anode. To overcome this difficulty, the electrolyte used should be an acid with an anion having a low standard oxidation potential. It means, H^+ of solution will get reduced to H_2 gas and Fe gets oxidised to Fe^{2+}. Since H_2 is a gas, the mass of cathode does not increase. After Fe, Cu gets oxidised to Cu^{2+} and at this time, it is Cu^{2+} that would be reduced to Cu and mass of the cathode starts increasing.

∴ Decrease in mass of anode = mass of Cu, Ag, Au, Fe = 20.5 g. Increase in mass of cathode = mass of Cu in the anode = 20.02 g.

% age of Cu in impure sample (anode)

$$= \frac{20.02}{20.5} \times 100$$

$$= \mathbf{97.66\ \%} \qquad \textbf{Ans.}$$

Moles of electrons passed

$$= \frac{500 s \times 125\ A}{96500 C} = 0.648$$

Moles of electrons used for

$$Cu = \frac{20.02}{63.5} \times 2 = 0.631$$

[∵ At. wt. of Cu = 63.5 : $Cu^{2+} + 2e^- \rightarrow Cu$]

Moles of electrons used for

$$Fe = 0.648 - 0.631 = 0.017$$

$$\text{Moles of Fe} = \frac{0.017}{2} = 0.0085$$

[∵ $Fe^{2+} + 2e^- \rightarrow Fe$; At. wt. of Fe = 56]

% age of Fe in the anode

$$= \frac{0.0085 \times 56}{20.5} \times 100 = \mathbf{2.32\%} \quad \textbf{Ans.}$$

EXAMPLE 106. *A person is interested to coat a metal surface of 60 cm^2 area with 0.004 mm thick layer of silver. Calculate the time for which he must pass a current of four amperes through a silver nitrate solution ? Atomic weight of Ag is 107.9 g mol$^-$ and density of Ag is 10.5 g cm^{-3}.*

SOLUTION. Let us assume that the Ag–coating has to be done on one side of the metal surface.

Volume of Ag needed for coating

$$= 60\ \text{cm}^2 \times \left(\frac{0.004}{10}\ \text{cm}\right) = 0.024\,\text{cm}^3$$

$$\text{Mass of Ag} = \text{Volume} \times \text{density}$$

$$= 0.024\ \text{cm}^3 \times 10.5\ \text{g cm}^{-3} = 0.252\ \text{g}$$

$$\text{Moles of Ag} = \text{mass/At.wt.} = 0.252/107.9$$

$$= 2.34 \times 10^{-3}$$

$$\text{Moles of electrons} = (2.34 \times 10^{-3}) \times 1$$

$$[\because Ag^+ + 1e^- \rightarrow Ag \text{ is a one electron change}]$$

$$\text{Hence, charge passed} = 2.34 \times 10^{-3} \times 96500$$

$$= \mathbf{225.81\ coulomb's.}$$

$$\therefore \quad \text{Time} = \text{charge passed in coulombs/}$$

$$\text{current in amperes} = \frac{225.81}{4}$$

$$= \mathbf{56.4525\ seconds.\ Ans.}$$

EXAMPLE 107. *When a metal (at. wt., a) salt solution was electrolysed for 100 minutes with 0.2 A of current, 0.696 g of the metal was deposited. Calculate the value of 'a'. Given that specific heat of metal = 0.0566 cal (g)$^-$ °C. Also, according to Dulong and Petit's law, approximate atomic weight = 6.4/specific heat.*

SOLUTION. From the given data :

$$\text{Approximate at. wt.} = \frac{6.4}{\text{sp. heat}} = \frac{6.4}{0.0566} = 113.07$$

To get exact atomic weight, exact equivalent weight must be known. So, we have :

$$\text{Charge passed} = 0.2\ \text{A} \times 100 \times 60\text{s} = 1200\ \text{coulombs}$$

Mass of metal deposited

$$= 0.696\ \text{g}$$

$$\text{Mole of electrons} = \frac{1200\ \text{coulombs}}{96500\ \text{coulombs}} = 0.0124$$

$$\therefore \text{Equivalent weight} = \frac{0.696}{0.0124} = 56.13$$

Approximate valency

$$= \frac{\text{Approximate at. wt.}}{\text{Eq. wt.}}$$

$$= \frac{113.07}{56.13} = 2.014 \approx 2$$

$$\therefore \quad \text{Exact at. wt., } a = \text{Eq. wt.} \times \text{valency}$$

$$= 56.13 \times 2 = \mathbf{112.26} \qquad \textbf{Ans.}$$

EXAMPLE 108. *Given:*

(i) $Cu^{2+} + 2e^- \longrightarrow Cu;\ E° = 0.337\ V$

(ii) $Cu^{2+} + e^- \longrightarrow Cu^+;\ E° = 0.153\ V$

Electrode potential for the reaction, $Cu^+ + e^- \longrightarrow Cu$ will be:

(a) 0.90 V *(b)* 0.30 V

(c) 0.38 V *(d)* 0.52 V

(CBSE-PMT, 2009)

SOLUTION. Given:

(*i*) $Cu^{2+} + 2e^- \longrightarrow Cu;\ E° = 0.337\ V$

(*ii*) $Cu^{2+} + e^- \longrightarrow Cu^+;\ E° = 0.153\ V$

(*iii*) $Cu^+ + e^- \longrightarrow Cu;\ E° = ?$

In order to get equation (*iii*), we have equation (*i*) – equation (*ii*). Thus, we have

(*i*) $Cu^{2+} + 2e^- \longrightarrow Cu;\ E_1^\circ = 0.337\ V;\ n = 2$ due to $2e^-$ s

(*ii*) $Cu^{2+} + e^- \longrightarrow Cu^+;\ E_2^\circ = 0.153\ V;\ n = 1$

$\quad - \quad - \quad\quad -$

---

or (*iii*) $Cu^+ + e^- \longrightarrow Cu;\ E_3^\circ = ?;\ n_3 = 1$

Since the required equation involves an electron; so:

$$n_3E_3^\circ = n_1E_1^\circ - n_2E_2^\circ;$$

$$E_3^\circ = \frac{n_1E_1^\circ - n_2E_2^\circ}{n_3}$$

$$\therefore \quad E_3^\circ = \frac{(2 \times 0.337) - (1 \times 0.153)}{1}$$

$$= (0.674 - 0.153)\text{V}$$

$$= \mathbf{0.521V \approx 0.52\ V.}$$

So, the correct answer is (*d*).

EXAMPLE 109. *An experimental data indicates a linear graph between E_{cell} and log $\frac{[Zn^{2+}]}{[Cu^{2+}]}$ with intercept on E_{cell} axis 1.1 volt. Calculate the E_{cell} for Zn/Zn^{2+} (0.01 M) || Cu^{2+} (0.1 M)/Cu.*

SOLUTION. For the cell reaction $Zn + Cu^{2+} \rightarrow Zn^{2+} + Cu$, the value of $n = 2$ [$\because Zn \rightarrow Zn^{2+} + 2e^-;\ Cu^{2+} + 2e^- \rightarrow Cu$].

$$\therefore \quad E_{\text{cell}} = E^\circ_{\text{cell}} - \frac{0.0591}{n}\log\frac{[Zn^{2+}]}{[Cu^{2+}]}$$

...(1) (Nernst equation)

Comparing equation (1) with $Y = mx + C$ we have :

$$C = E^\circ_{\text{cell}} = 1.1\ \text{V}.$$

Substituting the values in equation (1),

$$\text{we get :} \quad E_{\text{cell}} = 1.1 - \frac{0.0591}{2}\log\frac{0.01}{0.1}$$

$$= 1.1 - \frac{0.0591}{2}(-\log 10)$$

$$= 1.1 + 0.0295 = \mathbf{1.1295}\ \boldsymbol{V} \qquad \textbf{Ans.}$$

EXAMPLE 110. *Calculate the reduction potential at p_{OH} = 14 for the couple $E°_{Cu^{2+}/Cu}$ = 0.34 V. Given that (K_{sp}) $Cu(OH)_2$ = 1.0 × 10^{-19}.*

SOLUTION. Since pOH = 14,

$$\text{pOH} = -\log OH^- = 1\ \text{M}$$

$$\text{or} \quad [OH^-] = 1\ \text{M}.$$

$$\text{But} \quad [Cu^{2+}][OH^-]^2 = K_{sp}.$$

$$\text{Thus} \quad [Cu^{2+}][1]^2 = 1.0 \times 10^{-19}$$

$$\textbf{Or} \quad [Cu^{2+}] = 10^{-19}\text{M}$$

$$\text{Also,} \quad Cu^{2+} + 2e^- \longrightarrow Cu$$

So, using Nernst equation, we have :

$$E_{Cu^{2+}/Cu} = E°_{Cu^{2+}/Cu} - \frac{0.0591}{2}\log\frac{[OH^-]^2}{[Cu^{2+}]}$$

$$= 0.34 - 0.0295\log\frac{(1)^2}{10^{-19}}$$

$$= 0.34 - 0.0295 \times 19 \log 10$$
$$= 0.34 - 0.0295 \times 19$$
$$0.34 - 0.56 = -\mathbf{0.22\ volt} \qquad \textbf{Ans.}$$

EXAMPLE 111. (*i*) *Write the cell reaction for the Edison storage cell which is represented as :*

Fe(s) | FeO (s) | KOH(aq) | $Ni_2O_3(s)$ | Ni(s) ; E° Ni_2O_3/ NiO = 0.40 *V* ; E° *FeO/Fe* = – 0.87 *V*

(*ii*) *Calculate its e.m.f. How does it depend upon the concentration of KOH ?*

(*iii*) *Calculate the maximum amount of electrical energy available from one mole of nickel trioxide.*

SOLUTION. For the given cell, Fe(s) | FeO(s) | KOH(aq) | Ni_2O_3(s) | Ni(s), the half-cell reactions are :

(*i*) $Ni_2O_3(s) + H_2O\,(l) + 2e^- \longrightarrow 2\,NiO(s) + 2OH^-(aq)$ ...(*i*)

$$E° = 0.4\ V$$

$$FeO(s) + H_2O\,(l) + 2e^- \longrightarrow Fe(s) + 2OH^- \quad ...(ii)$$
$$E° = -0.87\ V.$$

Subtracting half-reaction (2) from (1) we get :

$$Ni_2O_3(s) + Fe(s) \longrightarrow FeO(s) + 2NiO(s);$$
$$E°_{cell} = +1.27\ V \qquad \textbf{Ans.}$$

It is the required cell reaction.

(*ii*) Cell e.m.f. = + 1.27 V as shown above. Since the net cell reaction does not involve any OH^- ions, the cell e.m.f. does not depend upon the concentration of KOH solution.

(*iii*) Maximum amount of electrical energy,

$$\Delta G° = -nF\,E°\text{cell}.$$

Substituting the values, we get :

$$\Delta G° = -2 \times 96500\ C \times 1.27\ V$$
$$= 245110\ J\ mol^-$$
$$= \frac{245110}{10^3}\ k\ J\ mol^-$$
$$= \mathbf{245.11\ k\ J\ mol^-} \qquad \textbf{Ans.}$$

EXAMPLE 112. *By mistake, the H^+ ion concentration of a MnO_4^-/Mn^{2+} couple was decreased by a student, from 1 M to 10^{-2} M at 25°C. By how much will the oxidising power of the MnO_4^-/Mn^{2+} couple be decreased. Assume that the concentration of other species does not alter.*

SOLUTION. The reduction reaction of MnO_4^- in acidic medium is represented as :

$$MnO_4^- + 8H^+ + 5e^- \longrightarrow Mn^{2+} + 4H_2O\ ;\ (n = 5)$$

Using Nernst equation,

$$E = E° - \frac{0.0591}{n} \log \frac{[Mn^{2+}][H_2O]^4}{[MnO_4^-][H^+]^8};$$

we have : $E - E° = -\dfrac{0.0591}{5} \log \dfrac{1}{(10^{-2})^8}$

$$= -0.0118 \log 10^{16}$$
$$= -0.0118 \times 16 \log 10$$
$$= -0.0118 \times 16$$
$$= -0.19\ V.$$

Hence, MnO_4^- /Mn^{2+} couple will move to position of less oxidising power by 0.19 V.

EXAMPLE 113. *Calculate K_a of HSO_3^- i.e., for the equilibrium, $HSO_3^- \rightleftharpoons H^+ + SO_3^{2-}$ with the help of following data:*

$E°_{Zn^{2+}/Zn}$ = – 0.76 *V ; e.m.f. of the cell.*

Pt, H_2 (1 atm) | HSO_3^- (0.4 M), SO_3^{2-} (6.4 × 10^{-3} M) || Zn^{2+} (0.3 M) /Zn is –0.46 V.

SOLUTION. The half-cell reactions for the given cell as :

(*a*) $H_2 \longrightarrow 2H^+ + 2e^-;$ $\quad E° = 0.0\ V$

(*b*) $Zn^{2+} + 2e^- \longrightarrow Zn;$ $\quad E° = -0.76\ V$

Adding equations (*a*) and (*b*), we get

$$H_2 + Zn^{2+} \longrightarrow 2H^+ + Zn;\ E° = -0.76\ V ...(1)$$

Applying Nernst equation, we have :

$$E_{cell} = E°_{cell} - \frac{0.0591}{n} \log \frac{[H^+]^2}{[Zn^{2+}][pH_2]}$$

$$-0.46 = -0.76 - \frac{0.0591}{2} \log \frac{[H^+]^2}{(0.3)\times(1)}$$

Or $\quad 0.76 - 0.46 = -0.02955 \log \dfrac{[H^+]^2}{0.3}$

Or $\quad 0.3 = -0.02955 \log \dfrac{[H^+]^2}{0.3}$

∴ $\quad \log \dfrac{[H^+]^2}{0.3} = -10.1523$

Or $\quad \dfrac{[H^+]^2}{0.3} = \text{antilog} - 10.1523$

∴ $\quad \dfrac{[H^+]^2}{0.3} = 7.04 \times 10^{-11}$

Or $\quad (H^+) = (0.3 \times 7.04 \times 10^{-11})^{½}$

$$= 4.6 \times 10^{-6}\ M$$

The given reaction is :

$$\underset{0.4\ M}{HSO_3^-} \rightleftharpoons \underset{4.6 \times 10^{-6}\ M}{H^+} + \underset{6.4 \times 10^{-3}\ M}{SO_3^{2-}}$$

∴ $\quad K_a = \dfrac{[H^+][SO_3^{2-}]}{[HSO_3^-]}$

$$= \frac{(4.6 \times 10^{-6}) \times (6.4 \times 10^{-3})}{0.4}$$
$$= \mathbf{7.36 \times 10^{-8}} \qquad \textbf{Ans.}$$

EXAMPLE 114. *From the following given data, calculate the solubility product of $CdSO_4$.*

$E°_{Cd^{2+}/Cd}$ = – 0.403 V ; e.m.f. of the cell, Cd/$CdSO_4$ | H_2SO_4 (0.01M) | H_2 (1 atm) | Pt = + 0.362 V.

SOLUTION. The half-cell reactions are :

(*a*) $Cd \longrightarrow Cd^{2+} + 2e^-$ (oxidation) ;

$$E° = +0.403\ V$$

(*b*) $2H^+(aq) + 2e^- \longrightarrow H_2$ (reduction) ;

$$E° = 0\ V$$

Adding equations, (*a*) and (*b*) we get :

$$Cd + 2\,H^+(aq) \longrightarrow Cd^{2+} + H_2;$$
$$E° = +0.403\ V.$$

Applyig Nernst equation we have :

$$E_{\text{cell}} = E^{\circ}_{\text{cell}} - \frac{0.0591}{n}\log\frac{[Cd^{2+}][pH_2]}{[Cd][H^+]^2}$$

$$+0.362 = +0.403 - \frac{0.0591}{2}\log\frac{[Cd^{2+}]\times 1}{1\times(0.01\times 2)^2}$$

$$[\because H_2SO_4 \rightleftharpoons \underset{2\times 0.01}{2H^+} + SO_4^{2-}]$$

$$-0.041 = -0.02955\log\frac{[Cd^{2+}]}{4\times 10^{-4}}$$

Or $\log\frac{[Cd^{2+}]}{4\times 10^{-4}} = 1.3875 \quad \therefore \quad \frac{[Cd^{2+}]}{4\times 10^{-4}} = 24.41$

Or $[Cd^{2+}] = 24.41 \times 4 \times 10^{-4}$

$= 97.64 \times 10^{-4}$ M

We know

$$\underset{97.64\times 10^{-4}M}{CdSO_4 \rightleftharpoons Cd^{2+}} + SO_4^{2-}; \qquad H_2SO_4 \rightleftharpoons 2H^+ + \underset{0.01\ M}{SO_4^{2-}}$$

But K_{sp} for $CdSO_4 = [Cd^{2+}][SO_4^{2-}]$

$= (97.64 \times 10^{-4}) \times (0.01)$

$= \mathbf{9.764 \times 10^{-5}}$ **Ans.**

EXAMPLE 115. *When an electric current of 50 microamperes is passed through a solution containing Ag⁺ ions for half an hour using Pt electrodes, a uniform single atom thick layer of Ag is deposited on the cathode surface. If 40% cathode surface is covered by Ag atoms, calculate the total surface of the cathode. Given that 5.4×10^{-16} cm² surface is covered by each Ag–atom. (At. wt. Ag. = 108).*

SOLUTION. Current passed = 50μ A = 50×10^{-6} A ; time = 30 min = 30 × 60 = 1800 seconds. Also, $Ag^+ + 1e^- \rightarrow Ag$. Thus :

(*a*) Total charge passed = 50×10^{-6} A × 1800 s = 0.09 coulomb or C.

(*b*) Total mass of Ag deposited at cathode $= \frac{108\times 0.09}{96500}$ g $= 1.01 \times 10^{-4}$ g

(*c*) Total number of Ag–atoms deposited $= \frac{1.01\times 10^{-4}}{108} \times 6.022 \times 10^{23} = 5.6 \times 10^{17}$

Hence, surface area of cathode covered by Ag–atoms

$= 5.6 \times 10^{17} \times 5.4 \times 10^{-16} = 302.4$ cm².

Thus, total surface area of cathode

$= \frac{302.4\times 100}{40} = \mathbf{756\ cm^2}$ **Ans.**

EXAMPLE 116. *Find the magnitude of equilibrium constant for the reaction, $2H_2O \rightarrow OH^- + H_3O^+$ at 298K. Given that the standard reduction potential at 298 K for the reaction, $2H_2O + 2e^- \rightarrow 2OH^- + H_2$ is – 0.8277 Volt.*

SOLUTION. Given : (*a*) $2H_2O + 2e^- \rightarrow 2OH^- + H_2$; E° = – 0.8277 V. For hydrogen electrode, (*b*) $2H^+ + 2e^- \rightarrow H_2$; E° = 0.0 V

Subtracting reaction (*a*) from (*b*), we get positive value of E°.

Thus : net cell reaction is :

$$2H^+ + 2OH^- \longrightarrow 2H_2O\ ;\ E^\circ = +0.8277\ V$$

Using Nernst equation, we have :

$$E_{\text{cell}} = E^{\circ}_{\text{cell}} - \frac{0.0591}{n}\log\frac{(H_2O)^2}{[H^+]^2[OH^-]^2}$$

$$= 0.8277 - \frac{0.0591}{2}\log\frac{(1)^2}{(K_w)^2}$$

$$= 0.8277 - 2\times\frac{0.0591}{2}\log\frac{1}{K_w}$$

At equilibrium, $E_{\text{cell}} = 0$.

Hence : $0 = 0.8277 - 0.0591\log\frac{1}{K_w}$

or $\log\frac{1}{K_w} = \frac{-0.8277}{-0.0591} = 14.0051$

$\therefore \quad \log K_w = -14.0051$

$\therefore \quad K_w = \text{Antilog} - 14.0051 = \mathbf{9.88 \times 10^{-15}}$

For $2H_2O \rightleftharpoons H_3O^+ + OH^-$, $\quad K_w = [H_3O^+][OH^-]$

$\therefore \quad K_w = \mathbf{9.88 \times 10^{-15}}$ **Ans.**

EXAMPLE 117. *On electrolysis of 9.5 gram of fused stannous chloride using inert electrodes, 0.0595 g of tin was deposited. Calculate the ratio of weights of stannous chloride and stannic chloride after electrolysis. At. Wt. of Sn = 119. Also, no species was given out during electrolysis.*

SOLUTION. $SnCl_2$ ionises as :

$$SnCl_2 \rightleftharpoons Sn^{2+} + 2Cl^-$$

During electrolysis : $2Cl^- \longrightarrow Cl_2 + 2e^-$ (oxidation)

$Sn^{2+} + 2e^- \longrightarrow Sn$ (reduction)

Since no species was given out, Cl_2 will react with $SnCl_2$ to form $SnCl_4$.

$$SnCl_2 + Cl_2 \longrightarrow SnCl_4$$

Thus, g. equivalent of $SnCl_2$ converted to $SnCl_4$ during electrolysis = g. equivalent of Cl_2 formed = g. equivalent of Sn formed.

Hence : g. equivalent of Cl_2 formed $= \frac{0.0595}{(119/2)} = 10^{-3}$

∴ g. equivalent of $SnCl_4$ formed = g. equivalent of $SnCl_2$ lost = 10^{-3}. It means, *total loss of g. equivalent* of $SnCl_2$ lost + g. equivalent of $SnCl_2$ reacted with $Cl_2 = 10^{-3} + 10^{-3} = 2 \times 10^{-3}$

Initial g. equivalent of $SnCl_2 = \frac{\text{Wt. of } SnCl_2}{\text{g. eq. wt. of } SnCl_2}$

$$= \frac{9.5}{(190/2)} = 0.1$$

∴ g. equivalent of $SnCl_2$ left in solution

$= 0.1 - (2 \times 10^{-3})$

$= 0.1 - 0.002 = 0.098$

From above, we find that, g. equivalent of $SnCl_4$ formed

$= 10^{-3}$

Hence, $\dfrac{\text{Wt. of SnCl}_2\text{ left behind}}{\text{Wt. of SnCl}_4\text{ formed}}$

$$= \frac{0.098 \times (190/2)}{10^{-3} \times (261/2)}$$

$$\left[\begin{array}{l}\because \text{g. eq. wt. of SnCl}_4 \\ = \{119 + (4 \times 35.5)\}/2 = 261/2\end{array}\right]$$

$$= \frac{9.31}{0.1305} = \mathbf{71.34\ Ans.}$$

EXAMPLE 118. *Calculate potential of the Ag^+/Ag electrode in a saturated solution and also calculate the standard reduction potential of $I^-/AgI/Ag$ electrode from the following data.*

$E^\circ_{Ag^+/Ag}$ *at 298 K = 0.799 V : Ksp (AgI) = 8.7×10^{-17}*

SOLUTION. (*a*) K_{sp} for AgI(s) $\rightleftharpoons$ $Ag^+(aq) + I^-(aq)$ is given as :

$$K_{sp} = [Ag^+][I^-] = [Ag^+]^2\ [\because (Ag^+) = (I^-)]$$

$$\therefore \quad [Ag^+] = [K_{sp}]^{1/2} = (8.7 \times 10^{-17})^{1/2} = 9.33 \times 10^{-9}$$

For Ag^+/Ag electrode, the reaction is :

$$Ag^+ + e^- \longrightarrow Ag$$

Using Nernst equation, we have :

$$E_{Ag^+/Ag} = E^\circ_{Ag^+/Ag} - \frac{0.0591}{n}\log\frac{1}{[Ag^+]}$$

$$= 0.799 - \frac{0.0591}{1}\log\frac{1}{9.33 \times 10^{-9}}$$

$$= 0.799 - 0.0591 \log 107181136$$

$$= 0.799 - (0.0591 \times 8.0301)$$

$$= 0.799 - 0.475 = \mathbf{0.324} \qquad \textbf{Ans.}$$

(*b*) We know, $Ag \longrightarrow Ag^+ + 1e^-$ (oxidation)

$AgI + e^- \longrightarrow Ag + I^-$ (reduction)

On adding, we get, $AgI \longrightarrow Ag^+ + I^-$

$$\therefore \quad E^\circ_{cell} = \frac{0.0591}{n}\log[Ag^+][I^-]$$

$$= \frac{0.0591}{1}\log K_{sp}$$

$$E^\circ_{Ag/Ag^+} + E^\circ_{I^-/AgI/Ag} = 0.0591 \log 8.7 \times 10^{-17}$$

$$= 0.0591\,[\log 8.7 + \log 10^{-17}]$$

$$-0.799 + E^\circ_{I^-/AgI/Ag} = 0.0591\,[0.9395 - 17]$$

$$= 0.0591\,(-16.0605)$$

$$E^\circ_{I^-/AgI/Ag} = +0.799 - 0.949 = \mathbf{-0.150\ V} \quad \textbf{Ans.}$$

EXAMPLE 119. 2.5 *ampere current was passed for 1.5 hours through one litre of 0.1 M Fe^{3+} solution. Assuming that only Fe^{3+} ions are reduced to Fe ($Fe^{3+} + 3e^- \rightarrow Fe$), calculate the number of moles of Fe, those will be produced.*

SOLUTION. Current passed = 2.5 A, time = 1.5 hr = $1.5 \times 60 \times 60 = 5400$ s. Hence total charge passed = $2.5\text{ A} \times 5400\text{ s} = 13500$ coulombs = $\dfrac{13500}{96500}$ Faraday = 0.140 F.

The reduction of Fe^{3+} to Fe takes place through following steps.

(*i*) $Fe^{3+} + e^- \longrightarrow Fe^{2+}$ (*ii*) $Fe^{2+} + 2e^- \longrightarrow Fe$

The charge used to reduce Fe^{3+} to Fe^{2+} = 0.1 F

[∵ solution is 0.1 M]

∴ Charge left behind which is used to reduce Fe^{2+} to Fe = 0.140 – 0.1 = 0.04 F

Hence the number of moles of Fe those are produced

$$= \frac{1 \times 0.04}{2} = \mathbf{0.02} \qquad \textbf{Ans.}$$

EXAMPLE 120. *Cu^+ disproportionates as, $2Cu^+ \rightleftharpoons Cu^{2+} + Cu(s)$. Calculate standard reduction potential $E^\circ_{Cu^{2+}/Cu}$ if (i) standard reduction potential for $Cu^{2+}/Cu^+ = +0.15$ V and (ii) at equilibrium, the magnitude of $Cu^{2+}/(Cu^+)^2 = 1.8 \times 10^6$.*

SOLUTION. At equilibrium e.m.f. = Zero. Since $E^\circ_{Cu^{2+}/Cu^+} = +0.15$ V, $E^\circ_{Cu^+/Cu^{2+}} = -0.15$ V. The given disproportionate reaction is :

$$2Cu^+ \rightleftharpoons Cu^{2+} + Cu$$

$$E^\circ_{Cu^{2+}/Cu^+} = +0.15\text{ V};\ Cu^{2+}/[Cu^+]^2 = 1.8 \times 10^6$$

$$\text{We know : } \quad E^\circ_{cell} = \frac{0.0591}{n}\log\frac{Cu^{2+}}{[Cu^+]^2}$$

$$\therefore E^\circ_{Cu^+/Cu^{2+}} + E^\circ_{Cu^+/Cu} = \frac{0.0591}{1}\log\frac{[1.8 \times 10^6]}{1}$$

$$[\because Cu^+ + 1e^- \longrightarrow Cu,\ n = 1]$$

$$-0.15\text{ V} + E^\circ_{Cu^+/Cu} = 0.0591\,[\log 1.8 + \log 10^6]$$

$$= 0.0591\,[0.2553 + 6]$$

$$= 0.0591 \times 6.2553 = 0.3697$$

$$\text{Hence,} \quad E^\circ_{Cu^+/Cu} = 0.3697 + 0.15 = \mathbf{0.5197\ V} \qquad \textbf{Ans.}$$

EXAMPLE 121. *The charging and discharging reactions in a lead storage battery are :*

(*a*) *$Pb + SO_4^{2-} \longrightarrow PbSO_4 + 2e^-$ (charging) (b) $PbO_2 + 4H^+ + 2e^- + SO_4^{2-} \longrightarrow PbSO_4 + 2H_2O$ (discharging). H_2SO_4 of density 1.139 g $(mL)^-$ is 20% H_2SO_4 by weight while H_2SO_4 of density 1.294 g $(mL)^-$ is 39% H_2SO_4 by weight. The density of H_2SO_4 during discharge falls from 1.294 to 1.139 g $(mL)^-$. Calculate the number of ampere hours for which the battery has been used if battery holds 3.5 L of acid and volume remains practically constant during the discharge.*

SOLUTION. Given :

(*a*) $\underset{1\text{ mol}}{Pb + SO_4^{2-}} \longrightarrow \underset{1\text{ mol}}{PbSO_4} + 2e^-$ (Charging)

(*b*) $PbO_2 + 4H^+ + SO_4^{2-} + 2e^- \longrightarrow PbSO_4 + 2H_2O$ (discharging)

Adding reactions (*a*) and (*b*), the net reaction is :

(*c*) $Pb + PbO_2 + 2H_2SO_4 \longrightarrow 2\,PbSO_4 + 2H_2O$

We see from reaction (*a*) that one mole of Pb gets oxidised to one mole of Pb^{2+} (in $PbSO_4$). Also, 2 moles of H_2SO_4 are consumed with the consumption of 2 moles of electrons. Hence, number of moles of H_2SO_4 = number of Faradays consumed. Density = 1.294 g (mL^-) = 1.294×10^3 g L^-. Similarly, density 1.139 g mL^- = 1.139×10^3 g L^-.

Before discharge. Mass of sample in 3.5 L of acid

= Volume × density

= $3.5\text{ L} \times 1.294 \times 10^3\text{ g L}^- = 4529$ g.

$$\text{Mass of 39\% } H_2SO_4 = 4529 \times \frac{39}{100} = 1766.31\text{ g}$$

$$\text{Moles of } H_2SO_4 = \frac{\text{Mass}}{\text{Mol. mass}} = \frac{1766.31}{98} = \mathbf{18.02}$$

After discharge. Mass of sample in 3.5 L of acid

$$= \text{Volume} \times \text{density}$$

$$= 3.5\text{ L} \times 1.139 \times 10^3 \text{ g L}^{-} = 3986.5 \text{ g}$$

$$\text{Mass of 20\% } H_2SO_4 = 3986.5 \times \frac{20}{100} = 797.3 \text{ g}$$

$$\text{Moles of } H_2SO_4 = \frac{797.3}{98} = \mathbf{8.136}$$

Number of moles of H_2SO_4 consumed

$$= 18.02 - 8.136 = 9.884$$

∴ Number of Faradays consumed = 9.884 F

Hence total charge = 9.884 × 96500 = 953806 C

But one ampere hour = charge passed by one ampere current in one hour = 1 × 60 × 60 = 3600 C

[∵ 1 hr = 60 × 60 = 3600 seconds]

Hence required number of ampere hours

$$= \frac{953806 \text{ C}}{3600 \text{ C}} = \mathbf{264.95} \qquad \textbf{Ans.}$$

Example 122. *Using K_a value of CH_3COOH (= 1.8×10^{-5}) and K_b value of NH_4OH (= 1.8×10^{-5}), calculate the e.m.f. of the following cell.*

Pt, H_2 (1 atm) | CH_3COOH (0.01 M) | NH_4OH (0.001) | H_2, Pt

Solution. We know that :

$$\frac{1}{2} H_2 \longrightarrow H_a^+ + e^- \text{ (at anode, oxidation)}$$

$$H^+_c + e^- \longrightarrow \frac{1}{2} H_2 \text{ (at cathode, reduction)}$$

$$\therefore \text{ Net reaction is : } H_c^+ \longrightarrow H_a^+$$

Using Nernst equation, we have :

$$E = E° - \frac{0.0591}{n} \log [H_a^+]/[H_c^+] \quad ...(1)$$

At anode :

$$\begin{array}{lcl} CH_3COOH & \rightleftharpoons & CH_3COO^- + H_a^+ \text{ (ionisation)} \\ C - C\alpha & & C\alpha \qquad\quad C\alpha \end{array}$$

(α = degree of ionisation)

$$\therefore \quad (H_a^+) = C\alpha$$

$$= C\sqrt{\frac{K_a}{C}} = \sqrt{K_a C}$$

Or

$$[H_a^+] = (K_a \times [CH_3COOH]))^{1/2}$$

$$= (1.8 \times 10^{-5} \times 0.01)^{1/2}$$

$$= (0.18 \times 10^{-6})^{1/2} = \mathbf{0.424 \times 10^{-3} \ M}$$

At cathode :

$$\begin{array}{lcl} NH_4OH & \rightleftharpoons & NH_4^+ + OH^- \text{ (ionisation)} \\ C - C\alpha & & C\alpha \qquad C\alpha \end{array}$$

(α = degree of ionisation)

$$\therefore \quad [OH^-] = C\alpha = C\left[\frac{K_b}{C}\right]^{1/2} = [K_b C]^{1/2}$$

$$\therefore \quad [H_c^+] = \frac{K_w}{[OH^-]} = \frac{K_w}{[K_b C]^{1/2}}$$

$$= \frac{K_w}{\{K_b \times [NH_4OH]\}^{1/2}}$$

[∵ K_w = [H⁺] [OH⁻]]

$$= \frac{10^{-14}}{(1.8 \times 10^{-5} \times 0.001)^{1/2}}$$

$$= \frac{10^{-14}}{0.01342 \times 10^{-3}} = 7.452 \times 10^{-11} \text{ M}$$

Using Nernst equation, we have :

$$E = E° - \frac{0.0591}{n} \log \frac{[H_a^+]}{[H_c^+]}$$

$$= 0 - \frac{0.0591}{1} \log \frac{0.424 \times 10^{-3}}{7.452 \times 10^{-11}}$$

$$= -0.0591 \log 5689748$$

$$= -0.0591 \times 6.7551 = \mathbf{-0.3992 V} \ \textbf{Ans.}$$

Example 123. *The electrolytic oxidation of sulphuric acid gives the following products, along with O_2, $2H_2SO_4 \rightarrow 2H^+ + 2e^- + H_2S_2O_8$ (perdisulphuric acid). (= 2.56 g) and H_2 (= 0.64 g) as by product at N.T.P. Calculate the weight of $H_2S_2O_8$ formed and also the quantity of current passed for electrolysis.*

Solution. Reactions. At anode :

$$2H_2SO_4 \longrightarrow H_2S_2O_8 + 2H^+ + 2e^- \qquad \text{(oxidation)}$$

$$2H_2O \longrightarrow O_2 + 4H^+ + 4e^- \qquad \text{(oxidation)}$$

At cathode. $2H^+ + 2e^- \longrightarrow H_2$ (reduction).

From above reactions, it is clear that first of all H_2SO_4 oxidises to give $H_2S_2O_8$ and then H_2O to give O_2. At the same time, H_2 is liberated which continues during electrolysis. Thus :

(*a*) Total charge needed to form 2.56 g O_2

$$= \frac{4 (= e^- \text{-charge}) \times 96500 \times 2.56}{32} \text{ C}$$

[∵ Mol. wt. of O_2 = 32]

$$= \mathbf{30880 \ C}$$

(*b*) Total charge needed to form 0.64 g H_2

$$= \frac{2 (= e^- \text{ charge}) \times 96500 \times 0.64}{2} \text{ C}$$

[∵ Mol. wt. of H_2 = 2]

$$= 61760 \text{ C.}$$

∴ Total charge used to get

$$H_2S_2O_8 = 61760 - 30880 = 30880 \text{ C.}$$

$$\text{Hence, weight of } H_2S_2O_8 \text{ generated} = \frac{194 \times 30880}{2 \times 96500}$$

[∵ Mol. wt. of $H_2S_2O_8$ = 194]

$$= \mathbf{31.04 \ g}$$

Example 124. *A given 0.1 M MnO_4^- and 0.8 M H^+ solution when treated with 80% of Fe^{2+}, reduces the whole MnO_4^- to Mn^{2+}. ($MnO_4^- + 8H^+ + 5e^- \rightarrow Mn^{2+} + 4H_2O$; E° = + 1.51 V). Calculate the potential of an indicator electrode versus the standard hydrogen electrode.*

Solution. Consider a Galvanic cell involving MnO_4^- and Mn^{2+}. H_2 (1 atm), Pt | H^+ (1M) || MnO^-_4 (H^+) | Mn^{2+}, Pt.

Reaction at anode :

H_2 (1atm) $\longrightarrow$ $2H^+ + 2e^-$ (oxidation)

At cathode : $MnO_4^- + 8H^+ + 5e^- \longrightarrow Mn^{2+} + 4H_2O$

$$\begin{array}{llll} \text{Initial conc.} & 0.1M & 0.8M & 0.1M \\ \text{After complete oxidation of } Fe^{2+} & \left[\begin{array}{l} 0.1-\dfrac{0.1\times 80}{100} \\ = 0.1-0.08 \\ = 0.02 \end{array}\right] & \left[\begin{array}{l} 0.8-\dfrac{0.1\times 80\times 8}{100} \\ = 0.8-0.64 \\ = 0.16 \end{array}\right] & \left[\begin{array}{l} \dfrac{0.1\times 80}{100} \\ = 0.08 \end{array}\right] \end{array}$$

The electrode potential of indicator electrode is given by the relation :

$$E_{MnO_4^-/Mn^{2+}} = E^\circ_{MnO_4^-/Mn^{2+}} - \frac{0.0591}{n} \log \frac{[Mn^{2+}]}{[MnO_4^-][H^+]^8}$$

$$= +1.51 - \frac{0.0591}{5} \log \frac{0.08}{0.02 \times (0.16)^8}$$

$$= 1.51 - 0.01182 \log \frac{0.08}{8 \times 10^{-9}}$$

$$= 1.51 - 0.01182 \log 10^7$$

$$= 1.51 - 0.01182 \times 7.0$$

$1.51 - 0.0827 = \mathbf{1.427}\ V$ **Ans.**

Example 125. *In order to plate nickel in $NiSO_4$ bath, a student passed a current of 20 amperes. He found that both Ni and H_2 were formed at the cathode (a) What volume of H_2 gas at N.T.P. is formed per hour? Density of Ni is 8.9 g (mL)$^-$ (b) If current efficiency with respect to the formation of nickel is 50%, how many grams of Ni will be plated out in one hour. (c) Also calculate the thickness of the plating of the cathode consisting of a rectangular sheet of metal of length 5cm and breadth 4 cm which is coated on both faces. (At. wt. of Ni = 58.69).*

Solution. Current passed = 20 amperes :

time = 1 hour = 1 × 60 × 60 = 3600 seconds

Hence : Total charge passed in 3600 seconds

= 20 amperes × 3600s

= 72000 coulombs

Since, the current efficiency with respect to Ni is 50%, so :

charge used to deposit Ni

$$= \frac{72{,}000 \times 50}{100} = 36{,}000\ C$$

It means, the rest of charge is used to evolve H_2 gas.

Hence : charge used to evolve

H_2 gas = 72,000 – 36,000 = 36,000 C

But $Ni^{2+} + 2e^- \longrightarrow Ni$

So :Weight of Ni (plated)

$$= \frac{58.69 \times 36000}{2 \times 96500} = 10.95\ g$$

Volume of rectangular Ni sheet required to be coated on both faces = Mass/density

$$= \frac{10.95\ g}{8.9\ g\ (mL)^-} = 1.23\ mL\ (\text{or } cm^3)$$

So, volume of rectangular Ni sheet required to be coated on one face $= \frac{1.23}{2} = 0.615\ cm^3$

But

Volume = Length × breadth × thickeness of plate

∴ $0.615\ cm^3$ = 5 cm × 4 cm × thickness of plate

∴ Thickness of plate

$$= \frac{0.615\ cm^3}{5\ cm \times 4\ cm} = 0.03075\ cm$$

We know $2H^+ + 2e^- \longrightarrow H_2$

Thus, volume of H_2 gas liberated at N.T.P.

$$= \frac{22.4L \times 36000\ C}{2 \times 96500\ C} = \mathbf{4.178\ L}\ \textbf{Ans.}$$

Example 126. *When a cadmium chloride solution was electrolysed in presence of mercury cathode, cadmium amalgam was formed. Calculate the time in minutes for which the electrolysis be done to prepare 10% (by weight) of cadmium amalgam using 4 amperes current and 45 g of mercury. (At. wt. of Cd = 112)*

Solution. 10% by wt. of cadmium amalgam means 10 g Cd and 90 g (100 – 10 = 90) mercury. Thus :

Wt. of Cd in 90 g Hg = 10 g;

Wt. of Cd in 45g

$$\text{Hg} = \frac{10}{90} \times 45 = 5g$$

$$\text{g. eq. wt. of Cd} = \frac{\text{g. At. wt.}}{\text{Valency}} = \frac{112}{2} = 56\ g$$

Charge required to deposit 56 g Cd = 96500 coulombs

Charge required to deposit 5 g Cd

$$= \frac{96500}{56} \times 5 = 8616.07\ C$$

Time in seconds required for electrolysis

$$= \frac{\text{Charge in coulombs}}{\text{Current in amperes}} = \frac{8616.07}{4}$$

$$= 2154.02 \text{ seconds} = \frac{2154.02}{60}$$

= **35.9 min** **Ans.**

Example 127. *Find the value of equilibrium constant for the reaction :*

$$Fe^{2+} + Ag^+ \longrightarrow Fe^{3+} + Ag$$

Given that : $Ag^+ + e^- \longrightarrow Ag;$ $E^\circ = 0.799V;$

$Fe^{3+} + e^- \longrightarrow Fe^{2+};$ $E^\circ = 0.771$ V;

Solution. The given reaction at equilibrium is given as:

$$Fe^{2+} + Ag^+ \rightleftharpoons Fe^{3+} + Ag$$

For reaction at equilibrium, $E_{cell} = 0$.

But $$E^\circ_{cell} = \frac{0.0591}{n} \log K$$

Hence

$$E^\circ_{Fe^{2+}/Fe^{3+}} + E^\circ_{Ag^+/Ag} = \frac{0.0591}{n} \log K$$

$$\left[\begin{aligned}\text{Since } E^\circ_{Fe^{3+}/Fe^{2+}} &= 0.771\,V,\\ E^\circ_{Fe^{2+}/Fe^{3+}} &= -0.771\,V\end{aligned}\right]$$

$$-0.771 + 0.779 = \frac{0.0591}{1}\log K$$

Or $\quad 0.008 = 0.0591 \log K$

∴ $\quad \log K = \dfrac{0.008}{0.0591} = 0.1354$

Or $\quad K = \text{antilog } 0.1354 = \mathbf{1.366}$

EXAMPLE 128. *For the reaction*

$Ag^+(aq) + Cl^-(aq) \longrightarrow AgCl(s)$

Given.

Species	ΔG°*(KJ/mol)*
$Ag^+(aq)$	+ 77
$Cl^-(aq)$	− 129
$AgCl(s)$	− 109

(*i*) *Write the cell representation of the above reaction and*

(*ii*) *Calculate E° at 298 K.*

(*iii*) *Calculate the* $\log_{10} K_{sp}$ *(AgCl) at 298 K.*

(*iv*) *If* 6.539×10^{-2} *g of metallic zinc is added to 100 mL saturated solution of AgCl, find the value of* $\log_{10}\dfrac{[Zn^{2+}]}{[Ag^+]^2}$.

(*v*) *How many moles of Ag will be precipitated in the above reaction? Given that :*

$$Ag^+ + e^- \longrightarrow Ag\,; \qquad E^\circ = -0.80\ V.$$
$$Zn^{2+} + 2e^- \longrightarrow Zn\,; \qquad E^\circ = -0.76\ V.$$

(*at. wt., Zn = 65.39*) **[IIT–JEE (mains), 2005]**

SOLUTION. (*i*) For the given reaction, the cell can be represented as :

Ag(s) | AgCl(s) | Cl^-(aq) || Ag^+(aq) | Ag(s)

(*ii*) ΔG° (reaction) for

$Ag^+(aq) + Cl^-(aq) \longrightarrow AgCl(s)$,

we have :

$$\begin{aligned}\Delta G^\circ \text{ (reaction)} &\longrightarrow \Delta G^\circ_{AgCl} - (\Delta G^\circ_{Ag^+} + \Delta G^\circ_{Cl^-})\\ &= -109 - (77 - 129)\\ &= -109 - 77 + 129 = -57 \text{ k J}\end{aligned}$$

$$\therefore \quad E^\circ_{cell} = \frac{\Delta G^\circ\text{ (reaction)}}{nF} = \frac{57 \times 10^3 \text{ J } (= \text{CV})}{1 \times 96500 \text{ C}} = \mathbf{0.59\ V\ \ Ans.}$$

(*iii*) For cell reaction, $Ag^+(aq) + Cl^-(aq) \longrightarrow AgCl(s)$, we have :

$$\begin{aligned}\Delta G^\circ \text{ (reaction)} &= 2.303\, RT \log K_{sp} \text{ (AgCl)}\\ -57 \times 10^3 \text{ J} &= 2.303 \times 8.314 \text{ J K}^- \times 298 \text{ K} \log K_{sp} \text{ (AgCl)}\end{aligned}$$

$$\therefore \quad \log K_{sp}\text{ (AgCl)} = -\frac{57 \times 10^3 \text{J}}{2.303 \times 8.314 \text{J K}^- \times 298 \text{ K}} \approx -10$$

$$\therefore \quad K_{sp}\text{ (AgCl)} = \text{antilog } (-10) = 10^{-10}\ M^2$$

$$[Ag^+] = [K_{sp}\text{(AgCl)}]^{1/2} = [10^{-10} M^2]^{1/2} = 10^{-5}\ M$$

$$\text{Mol of } Zn^{2+} = \frac{\text{Wt. of } Zn^{2+}}{\text{At. wt. of } Zn^{2+}} = \frac{6.539 \times 10^{-2}\text{ g}}{65.39} = 10^{-3}$$

For the following reaction, applying Nernst equation we have :

$$2\,Ag^+(aq) + Zn^{2+}(aq) \rightleftharpoons 2\,Ag(s) + Zn^{2+}(aq)$$

$$E = E^\circ - \frac{0.059}{2}\log\frac{[Zn^{2+}]}{[Ag^+]^2}$$

At equilibrium, $E = 0$, E° cell $= 1.56V$

$$0 = 1.56 - \frac{0.059}{2}\log\frac{[Zn^{2+}]}{[Ag^+]^2};$$

$$\frac{0.059}{2}\log\frac{[Zn^{2+}]}{[Ag^+]^2} = 1.56$$

$$\therefore \quad \log\frac{[Zn^{2+}]}{[Ag^+]^2} = \frac{1.56 \times 2}{0.059} = 52.88;\ \log Kc = 52.88$$

$$\therefore \quad K_c = \text{antilog } 52.88 = 10^{52.88}$$

Since the value of K_c is very high, the reaction will almost go to completion. Hence mol of Ag precipitated is 10^{-5} (already found).

EXAMPLE 129. *Two students use same stock solution of* $ZnSO_4$ *and a solution of* $CuSO_4$. *The e.m.f. of one cell is 0.03 V higher than the other. The conc. of* $CuSO_4$ *in the cell with higher e.m.f. value is 0.5 M. Find out the concentration of* $CuSO_4$ *in the other cell. (2.302 RT/F = 0.06)* **(IIT, 2003)**

SOLUTION. From the given data, we see that there are two Daniell cells *i.e.*, Zn | Zn^{2+} || Cu^{2+} | Cu. Hence :

(*i*) Zn | $Zn^{2+}(C_1)$ || Cu^{2+}(C = ?) | Cu ; $E_{cell} = E_1$

(*ii*) Zn | $Zn^{2+}(C_2)$ || Cu^{2+}(C = 0.5) | Cu ; $E_{cell} = E_2$ where $E_2 > E_1$

Also, $\quad E_2 - E_1 = 0.03\ V$; $C_1 = C_2$. The cell reaction will be

$$Zn + Cu^{2+} \rightleftharpoons Zn^{2+} + Cu$$

while $\quad Q = \dfrac{[Zn^{2+}]}{[Cu^{2+}]}$

We know that $E_{cell} = E^\circ_{cell} - \dfrac{0.06}{n}\log Q \quad$ or $\quad \dfrac{[Zn^{2+}]}{[Cu^{2+}]}$

Or $\quad E_1 = E_{cell} = E^\circ_{cell} - \dfrac{0.06}{2}\log\dfrac{C_1}{C}$

[∵ for $Zn \rightleftharpoons Zn^{2+} + 2e^-$, $n = 2$]

$$E_2 = E_{cell} = E^\circ_{cell} - \frac{0.06}{2}\log\frac{C_2}{0.5}$$

$$\therefore \quad E_2 - E_1 = -\frac{0.06}{2}\log\frac{C_2}{0.5} - \left(-\frac{0.06}{2}\log\frac{C_1}{C}\right)$$

$$= \frac{0.06}{2}\log\frac{C_1}{C} - \frac{0.06}{2}\log\frac{C_2}{0.5}$$

$$\therefore \quad 0.03 = \frac{0.06}{2}\left[\log\frac{C_1}{C} - \log\frac{C_2}{0.5}\right]$$

$$= 0.03\left[\frac{\log\frac{C_1}{C}}{\log\frac{C_2}{0.5}} \quad \text{Or} \quad \log\frac{C_1}{C}\times\frac{0.5}{C_2}\right]$$

$$0.03 = 0.03\left[\log\frac{0.5}{C}\right] \qquad [\because C_1 = C_2]$$

$$\text{or} \qquad \log\frac{0.5}{C} = 1$$

Taking antilog of both sides, we get :

$$\frac{0.5}{C} = \text{antilog } 1 = 10;$$

$$C = \frac{0.5}{10} = \mathbf{0.05} \qquad \textbf{Ans.}$$

Example 130. *A current of 10 A is passed for 80 min. and 27 seconds through a cell containing dilute sulphuric acid.*

(1) *How many moles of oxygen gas will be liberated at the anode ?*

(2) *Calculate the amount of zinc deposited at the cathode when another cell containing $ZnSO_4$ solution is connected in series (Zn = 65).* **(ISC, 2007)**

Solution. $H_2SO_4 \longrightarrow 2H^+ + SO_4^{2-}$

and $2H_2O \rightleftharpoons H_3O^+ + OH^-$

(1) Current, $C = 10$ A; time, $t = 80$ min. and 27 seconds

$= (80 \times 60 \text{ s}) + 27\text{s} = 4827$ s.

Reaction at anode: $4OH^- \longrightarrow 2H_2O + O_2 + 4e^-$

∴ Eq. wt. of oxygen

$$= \frac{\text{Mol. wt. of } O_2}{\text{no. of } e^{-}\text{s involved}} = \frac{2\times 16}{4} = 8$$

$$\text{But Wt. of oxygen} = \frac{\text{Eq. wt.} \times C \times t}{96500} = \frac{8\times 10\times 4827}{96500}$$

$$= 4 \text{ g}$$

$$\text{no. of mol. of } O_2 = \frac{\text{Wt.}}{\text{Mol. wt.}} = \frac{4}{32} = \mathbf{0.125} \qquad \textbf{Ans.}$$

$$(2) \quad \text{Eq. wt. of Zn} = \frac{\text{At. wt.}}{\text{Valency}} = \frac{65}{2} = 32.5;$$

eq. wt. of oxygen = 8

Wt. of oxygen = 4 g

We know that by second law of electrolysis :

$$\frac{\text{Wt. of Zn}}{\text{Wt. of oxygen}} = \frac{\text{Eq. wt. of Zn}}{\text{Eq. wt. of oxygen}};$$

$$\frac{\text{Wt. of Zn}}{4} = \frac{32.5}{8}$$

$$\therefore \quad \text{Wt. of Zn} = \frac{32.5\times 4}{8} = \mathbf{16.25\ g} \qquad \textbf{Ans.}$$

19.20 AIEEE PATTERN EXAMPLES

Example 131. *If the conductance and specific conductance of a solution is same, then its cell constant is equal to :*

(*a*) *zero* (*b*) *1*

(*c*) *2* (*d*) *3*

Solution. We know that :

Specific conductance = Observed conductance × Cell constant

$$\therefore \quad \text{Cell constant} = \frac{\text{Specific conductance}}{\text{Observed conductance}}$$

When specific conductance

= Observed conductance, then :

Cell constant = 1.

So, the correct answer is, (*b*).

Example 132. *The specific conductance of a salt of 0.01 concentration is 1.061×10^{-4}. Molar conductance will be*

(*a*) *1.061×10^{-4}* (*b*) *1.061*

(*c*) *10.61* (*d*) *106.1*

(Pb PMT, 1993)

Solution. Molar conductance,

$$\Lambda_m = \frac{\text{specific conductance} \times 1000}{\text{concentration}}$$

$$= 1.061 \times 10^{-4} \times \frac{1000}{0.01}$$

$$= \mathbf{10.61}$$

So, the correct answer is (*c*).

Example 133. *Equivalent conductance of NaCl, HCl and C_2H_5COONa at infinite dilution are 126.45, 426.16 and 91 ohm⁻ cm² respectively. The equivalent conductance of C_2H_5COOH* is:

(*a*) *201.28 ohm⁻ cm²* (*b*) *390.71 ohm⁻cm²*

(*c*) *698.28 ohm⁻ cm²* (*d*) *540.48 ohm⁻cm²*

(CBSE, 1997)

Solution. We know that ;

$$\Lambda^\circ_{C_2H_5COOH} = \Lambda^\circ_{C_2H_5COONa} + \Lambda^\circ_{HCl} - \Lambda^\circ_{NaCl}$$

$$= (91 + 426.16 - 126.45)\ \text{Ohm}^{-}\ \text{cm}^2$$

$$= 390.71\ \text{ohm}^{-}\text{cm}^2$$

So, the correct answer is (*b*).

Example 134. *The resistance of a cell (cell constant = 1.1 cm^{-1}) containing $\frac{N}{50}$ KCl was found to be 400 ohms. The equivalent conductivity of KCl at this dilution is :*

(*a*) *68.75 ohm⁻* (*b*) *437.5 ohm⁻*

(*c*) *200 cm⁻* (*d*) *137.5 ohm⁻ cm² (g. equiv)⁻*

Solution. Cell constant = 1.1 cm⁻ ;

R = 400 ohms ; Λ = ? ,

$$\text{normality} = \frac{N}{50}.$$

$$\text{Specific conductance, } K = \frac{1}{R} \times \text{cell consstant}$$

$$= \frac{1}{400 \text{ ohm}} \times 1.1 \text{ cm}^{-}$$

But equivalent conductance,

$$\Lambda = \frac{K \times 1000 \text{ cm}^3}{\text{Normality}}$$

$$= \frac{1}{400 \text{ ohm}} \times \frac{1.1 \text{ cm}^{-} \times 1000 \text{ cm}^3}{(1/50)\text{ g. equiv}}$$

$$= \mathbf{137.5\ ohm^{-}\ cm^{2}\ (g.\ equiv)^{-}}$$

So, the correct answer is (*d*).

EXAMPLE 135. *The specific conductivity of 0.01 N KCl is 0.0014106 ohm*$^{-}$ *cm*$^{-}$ *at 298 K. When a conductivity cell was filled up with the same solution, it offered a resistance of 484 ohm at 298 K. The same cell was then filled with 0.001 N solution of NaCl at the same temperature which gave a resistance of 5496 ohms. The value of equivalent conductivity of 0.001 N NaCl solution is :*

(*a*) *124.2 ohm* (*b*) *124.2 ohm*$^{-}$*cm*^{2}*(g. equiv)*$^{-}$

(*c*) *62.1 cm*$^{-}$ (*d*) *6.21 cm*$^{-}$

SOLUTION. (*a*) Cell constant

$$= K \times \frac{1}{\text{conductance } (=1/R)} = K \times R$$

$$= 0.0014106\ \text{ohm}^{-}\ \text{cm}^{-} \times 484\ \text{ohm}$$

∴ *K* for 0.001 N NaCl

$$= \frac{\text{Cell constant}}{\text{Resistance}}$$

$$= \frac{0.0014106\ \text{ohm}^{-}\ \text{cm}^{-} \times 484\ \text{ohm}}{5496\ \text{ohm}}$$

But
$$\Lambda = \frac{\text{K} \times 1000\ \text{cm}^3}{\text{Normality in (g equiv)}}$$

$$= \frac{0.0014106\ \text{cm}^{-} \times 484}{5496\ \text{ohm}} \times \frac{1000\ \text{cm}^3}{0.001\ \text{g. equiv}}$$

$$= \mathbf{124.2\ ohm^{-}cm^{2}\ (g.\ equiv)^{-}}$$

So, the correct answer is (*b*).

EXAMPLE 136. *Specific conductances of two electrolytic solutions of the 0.1. M concentration of the substances A and B are 8.5 × 10*$^{-3}$ *and 4.5 × 10*$^{-4}$ *ohm*$^{-}$ *cm*$^{-}$ *respectively. The one which offers less resistance for the flow of current and the one which is a stronger electrolyte are :*

(*a*) *A, A* (*b*) *A, B*

(*c*) *B, A* (*d*) *B, B*

SOLUTION. Specfic conductances (*K*) of solution,

$$\text{A} = 8.5 \times 10^{-3}\ \text{ohm}^{-}\ \text{cm}^{-}.$$

∴ Specific resistance offered by solution,

$$\text{A} = 1/(8.5 \times 10^{-3}\ \text{ohm}^{-}\ \text{cm}^{-})$$

$$= 117.65\ \text{ohm cm}.$$

Specific conductance (*K*) of solution,

$$\text{B} = 4.5 \times 10^{-4}\ \text{ohm}^{-}\ \text{cm}^{-}$$

∴ Specific resistance of solution, B = 1/(4.5 × 10^{-4} ohm^{-} cm^{-}) = 2222.2 ohm cm. Since solution A offers less resistance (= 117.65 ohm cm) than B (= 2222.2 ohm cm), A is stronger electerolyte. So, the correct answer is (*a*).

EXAMPLE 137. *For a cell given below Ni/Ni*$^{2+}$ *(0.1 M) ‖ Au*$^{3+}$ *(1M) |Au,* $E°_{\text{Ni/Ni}^{2+}} = +0.25\ V$; $E°_{\text{Au/Au}^{+3}} = +1.5\ V$. *The e.m.f. of the cell will be :*

(*a*) *0.1679 V* (*b*) *– 1.1786 V*

(*c*) *+ 1.779 V* (*d*) *– 1.77955 V*

SOLUTION. Cell reaction is written as :

$$\text{Ni} \longrightarrow \text{Ni}^{2+} + 2e^-] \times 3;\ E° = +0.25\ V$$

$$\text{Au}^{3+} + 3e^- \longrightarrow \text{Au}] \times 2; \qquad E° = +1.5\ V$$

Adding : $3\text{Ni} + 2\text{Au}^{3+} \longrightarrow 3\text{Ni}^{2+} + 2\text{Au};$

$$E° = 0.25 + 1.5 = 1.75\ V$$

Using Nernst equation, we have :

$$E_{\text{cell}} = E^{\circ}_{\text{cell}} - \frac{0.0591}{n} \log \frac{[\text{Ni}^{2+}]^3}{[\text{Au}^{3+}]^2}$$

$$= 1.75 - \frac{0.0591}{6} \log \frac{(0.1)^3}{(1)^2}$$

$$= 1.75 - \frac{0.0591}{6} \log 10^{-3}$$

$$= 1.75 - \frac{0.0591}{6} \times -3$$

$$= 1.75 + 0.02955 = \mathbf{+\,1.779\ V.}$$

So, the corect answer is (*c*).

EXAMPLE 138. *Which represents disproportionation.*

(*a*) $Cu + 2Ag^+ \longrightarrow Cu^{2+} + 2Ag$

(*b*) $Zn + Cu^{2+} \longrightarrow Zn^{2+} + Cu$

(*c*) $3I_2 \longrightarrow 5I^- + I^{5+}$

(*d*) $2Cu^+ \longrightarrow Cu + Cu^{2+}$

SOLUTION. In a disproportionation reaction, one substance is oxidised as well as reduced. I_2 is oxidised to I^{5+} as well as reduced to I^-. Also, Cu^+ is oxidised to Cu^{2+} as well as reduced to Cu. So, the answers are, (*c*) and (*d*).

EXAMPLE 139. *When an electric current is passed through a solution containing* $AgNO_3$, $Hg_2(NO_3)_2$, $Ba(NO_3)_2$ *and* $Cu(NO_3)_2$ *using inert electrode, their cations got liberated at the cathode. With increasing voltage, the sequence of deposition of metals on the electrodes will be :*

(*a*) *Ba, Hg, Cu, Ag* (*b*) *Mg, Ag, Cu, Hg*

(*c*) *Hg, Ag, Cu, Ba* (*d*) *Ag, Hg, Cu.*

$E^{\circ}_{Ba^{2+}/Ba} = -2.90\ V;\ E°_{Hg_2^{2+}/2Hg} = +0.79\ V : E^{\circ}_{Cu^{2+}/Cu} = +0.34\ V$ *and* $E°_{Ag^+/Ag} = +0.779\ V$

SOLUTION. We know that greater the standard reduction potential value, greater is its tendency to undergo reduction. Barium will not be deposited because its standard reduction potential value is negative. The increasing order of standard reduction potential value of Ag, Cu, Hg is Cu < Hg <Ag. So, the sequence of deposition of metals on the electrodes is, Ag, Hg, Cu. Hence, the answer is (*d*).

EXAMPLE 140. *When an electric current is passed through dil.* H_2SO_4, *the gases liberated at anode and cathode are :*

(*a*) H_2 *and* O_2 *respectively*

(*b*) O_2 *and* H_2 *respectively*

(*c*) SO_2 *and* O_2 *respectively*

(*d*) SO_2 *and* H_2 respectively

SOLUTION. The reactions that take place are :

At anode. $2H_2O \longrightarrow O_2 + 4H^+ + 4e^-$

At cathode. $2H^+ + 2e^- \longrightarrow H_2$

Since O_2 is liberated at anode and H_2 at cathode, the answer is (*b*).

EXAMPLE 141. *The standard redox potentials for the reactions, $Mn^{2+} + 2e^- \longrightarrow Mn$ and $Mn^{3+} + e^- \longrightarrow Mn^{2+}$ are –1.18 V and 1.51 V respectively. What is the redox potential for the reaction, $Mn^{3+} + 3e^- \longrightarrow Mn$?*

(*a*) *0.33 V* (*b*) *1.69 V*

(*c*) *–0.28 V* (*d*) *–0.85 V*

(*e*) *0.85 V* **(Kerala PET, 2011)**

SOLUTION. $Mn^{2+} + 2e^- \longrightarrow Mn$ ...(1);

$$\Delta G^\circ = -nFE^\circ = -2F \times -1.18 = 2.36\ F$$

$$Mn^{3+} + e^- \longrightarrow Mn^{2+} \quad ...(2);$$

$$\Delta G^\circ = -nFE^\circ = -1.51\ F$$

By adding equations (1) and (2), we get:

$Mn^{3+} + 3e^- \longrightarrow Mn$; $\Delta G^\circ = 2.36\ F + (-1.51\ F) = 0.85\ F$

$\Delta G^\circ = -nFE^\circ$; $0.85F = -3 \times F \times E^\circ$; $E^\circ = -0.28$ V

So, the correct answer is (*c*).

EXAMPLE 142. *Being unstable, Cu^+ undergoes disproportionation. E° for Cu^+ disproportionation is :*

(*a*) *– 0.367 V* (*b*) *+ 0.377 V*

(*c*) *– 0.726 V* (*d*) *+ 0.666V*

$E^\circ_{Cu^{2+}/Cu^+} = +\ 0.153\ V$; $E^\circ_{Cu^+/Cu} = 0.53\ V.$

SOLUTION. The reaction for disproportionation of Cu^+ is :

$$2Cu^+ \longrightarrow Cu + Cu^{2+}$$

$$E^\circ_{cell} = E^\circ_{Cu^+/Cu^{2+}} + E^\circ_{Cu^+/Cu}$$

Substituting the values, we get :

$$E^\circ_{cell} = -0.153 + 0.53 = \mathbf{+0.377}\ V$$

Hence, the answer is (*b*).

EXAMPLE 143. *Following are given two half-cell reactions along with their standard reduction potential values at 25°C.*

$$Mg^{2+} + 2e^- \longrightarrow Mg \ ; \ E^\circ = -2.37\ V$$

$$Zn^{2+} + 2e^- \longrightarrow Zn \ ; \ E^\circ = -0.76\ V$$

Some zinc dust is now added to $MgCl_2$ solution. Predict :

(*a*) *Zinc dissolves in solution*

(*b*) *$ZnCl_2$ is formed*

(*c*) *No reaction takes place*

(*d*) *Mg gets precipitated.*

SOLUTION. Reaction. $Zn + Mg\ Cl_2 \longrightarrow ZnCl_2 + Mg$

But $E^\circ_{cell} = E^\circ_{anode} + E^\circ_{cathode}$

$$= E^\circ_{Zn/Zn^{2+}} + E^\circ_{Mg^{2+}/Mg} = +0.76 - 2.37$$

$$= \mathbf{-1.61\ V}$$

Since E°_{cell} is negative , reaction will not take place.

Hence, the answer is (*c*)

EXAMPLE 144. *Stronger the oxidant, greater will be the :*

(*a*) *Ionic character*

(*b*) *Standard reduction potential value*

(*c*) *Standard oxidation potential value*

(*d*) *None of these*

SOLUTION. We know that species having higher value of standard reduction potential are stronger oxidants. Hence, the answer is (*b*).

EXAMPLE 145. *The reductant H_2 will reduce :*

(*a*) *Heated aluminium oxide*

(*b*) *Heated lead (II) oxide*

(*c*) *Heated ferric oxide*

(*d*) *Heated cupric oxide.*

$E^\circ_{2H^+/H_2} = 0.0V$; $E^\circ_{Fe^{3+}/Fe^{2+}} = +\ 0.771\ V$;

$E^\circ_{Al^{3+}/Al} = -\ 1.66\ V$

$E^\circ_{Cu^{2+}/Cu} = +\ 0.34\ V$; $E^\circ_{Pb^{2+}/Pb} = -\ 0.126\ V$.

SOLUTION. An element with lower reduction potential value can reduce element with higher reduction potential value. Since the reduction potential value of Cu and Fe is greater than that of H_2, the latter will reduce their oxides.

$$Fe_2O_3 + H_2 \longrightarrow 2FeO + H_2O\ ;$$

$$CuO + H_2 \longrightarrow Cu + H_2O$$

Hence, the answers are (*c*) and (*d*)

EXAMPLE 146. *During the discharge of lead storage battery, which one of the following is true?*

(*a*) *Lead is formed* (*b*) *$PbSO_4$ is consumed*

(*c*) *H_2SO_4 is consumed* (*d*) *SO_2 is liberated*

SOLUTION. Following reactions take place in lead storage battery.

At anode :

$$Pb + H_2SO_4 \longrightarrow PbSO_4 + 2H^+ + 2e^- \quad \text{(oxidation)}$$

At cathode :

$$PbO_2 + H_2SO_4 + 2H^+ + 2e^- \longrightarrow PbSO_4 + H_2O \quad \text{(reduction)}$$

Net reaction.

$$Pb + PbO_2 + 2H_2SO_4 \longrightarrow 2PbSO_4 + 2H_2O$$

From the net discharge reaction, we see that only H_2SO_4 is consumed during discharging. So, (*c*) is true.

EXAMPLE 147. *Three electrolytic cells containing Ag^+, Cu^{2+} and Al^{3+} ions are connected to-gether in series. Now a current of three Faraday was passed. The molar ratio in which the above three metal ions are liberated at the electrodes is :*

(*a*) *2 : 3 : 6* (*b*) *6 : 3 : 2*

(*c*) *1 : 2 : 3* (*d*) *2 : 3 : 6*

SOLUTION. According to second law of electrolysis :

$$\frac{\text{Wt. of element}}{\text{Eq. wt. of element}} = \text{Constant}$$

Thus : g. Eq. wt. of Ag^+

= g. Eq. wt. of Cu^{2+}

= g. eq. wt. of Al^{3+} = *a* (suppose)

(*a*) Mole of Ag^+ = *a* [$\because Ag^+ + e^- \rightarrow Ag$]

(*b*) Mole of $Cu^{2+} = \frac{a}{2}$ [$\because Cu^{2+} + 2e^- \rightarrow Cu$]

(*c*) Mole of $Al^{3+} = \frac{a}{3}$ [$\because Al^{3+} + 3e^- \rightarrow Al$]

Hence, molar ratio of Ag^+, Cu^{2+}, Al^{3+}

$$= \frac{a}{1} : \frac{a}{2} : \frac{a}{3}$$

$$= \frac{6:3:2}{6\,(=\text{LCM})} \quad \textit{i.e.,} \quad 6:3:2$$

Hence, true answer is (*b*).

EXAMPLE 148. *Standard reduction electrode potentials of three metals A, B and C are respectively +0.5V, – 3.0 V and – 1.2 V. The reducing powers of these metals are :*

(*a*) $A > C > B$ (*b*) $B > C > A$

(*c*) $A > B > C$ (*d*) $C > B > A$

(AIEEE, 2003)

SOLUTION. We know that as the value of standard reduction electrode potential decreases, the power of these elements to act as reducing agent increases. Since – 3.0 V < – 1.2 V < + 0.5V, the reducing power of these metals decreases as : B > C > A. So, the correct answer is (*b*).

EXAMPLE 149. *For a cell reaction involving a two electron change, the standard e.m.f. of the cell is found to be 0.295 V at 25°C. The equilibrium constant of the reaction at 25°C will be :*

(*a*) 1×10^{10} (*b*) 1×10^{-10}

(*c*) 29.5×10^{-2} (*d*) 10 **(AIEEE, 2003)**

SOLUTION. Given, $n = 2$ because reaction is of two electron change.

$$E^\circ_{\text{cell}} = 0.0295 \text{ V}; \; \log K = ?$$

We know that : $E^\circ_{\text{cell}} = \dfrac{0.0591}{n} \log \text{K}$

$$\therefore \qquad \log K = \frac{n \times E^\circ_{\text{cell}}}{0.059} = \frac{2 \times 0.295}{0.059} = \mathbf{10}$$

So, the correct answer is (*d*).

EXAMPLE 150. *A solution contains Fe^{2+}, Fe^{3+} and I^- ions. This solution was treated with iodine at 35°C. E° for Fe^{3+}/Fe^{2+} is + 0.77 V and E° for $I_2/2I^-$ = 0.536 V. The favourable redox reaction is:*

(*a*) *I_2 will be reduced to I^-.*

(*b*) *There will be no redox reaction*

(*c*) *I^- will be oxidised to I_2*

(*d*) *Fe^{2+} will be oxidised to Fe^{3+}*

(AIPMT, 2011)

SOLUTION. Greater the value of reduction potential, greater will be its tendency to get reduced. Since the reduction potential value of Fe^{3+}/Fe^{2+} (= + 0.77 V) is greater than that of $I_2/2I^-$ (= 0.536 V), Fe^{3+} will be reduced to Fe^{2+} and I^- will be oxidised to I_2. So, the correct answer is (*c*).

EXAMPLE 151. *Conductance (unit siemen's S) is directly proportional to area of the vessel and the concentration of the solution in it and is inversely proportional to the length of the vessel, then the unit of constant of proportionality is :*

(*a*) *$Sm\,mol^-$* (*b*) *$S^2m^2\,mol^{-2}$*

(*c*) *$Sm^{-2}\,mol^-$* (*d*) *$S^{-2}\,m^2\,mol.$*

(AIEEE, 2002)

SOLUTION. Given : Conductance, $C \;\alpha\; a \times \text{concentration} \times \dfrac{1}{l}$

or $\qquad C = K \times a \times \text{conc.} \times \dfrac{1}{l}$

where $\qquad K$ = Constant called conductivity

$$\therefore \qquad K = \frac{Cl}{a \times \text{Conc}} = \frac{\text{S} \times m \times \text{m}^{-3}}{\text{m}^2 \times \text{mol}}$$

$$= \mathbf{Sm^{-2}\,mol^{-}}$$

So, the correct answer is (*c*).

EXAMPLE 152. *The equivalent conductances at infinite dilutions ($\wedge_o$) for electrolytes BA and CA are 140 and 120 S cm² eq⁻. The equivalent conductance at infinite dilution for BX is 198 S cm² eq⁻. The $\wedge_o$ (in S cm² eq⁻) of CX is :*

(*a*) *218* (*b*) *198*

(*c*) *178* (*d*) *130*

SOLUTION. We know

$$\wedge^\circ_{CX} = \wedge^\circ_{C} + \wedge^\circ_{X} = \wedge^\circ_{CA} - \wedge^\circ_{BA} + \wedge^\circ_{BX}$$

$$= 120 - 140 + 198 = \mathbf{178\ S\ cm^2\ eq^-}$$

So, the correct answer is (*c*).

Note : $\wedge^\circ_{CA} = \wedge^\circ_{C} + \wedge^\circ_{A}\,;\; \wedge^\circ_{BA} = \wedge^\circ_{B} + \wedge^\circ_{A}\,;\; \wedge^\circ_{BX} = \wedge^\circ_{B} + \wedge^\circ_{X}$

EXAMPLE 153. *The equilibrium constant (K) for the reaction $Cu\,(s) + 2\,Ag^+(aq) \longrightarrow Cu^{2+}\,(aq) + 2Ag(s)$ will be :*

(*a*) *K_c = Antilog 4.5*

(*b*) *K_c = Antilog 42.2*

(*c*) *K_c = Antilog 9.5*

(*d*) *K_c = Antilog 15.6; (E°_{cell} = 0.46 V)*

SOLUTION. We know,

$$E^\circ_{\text{cell}} = \frac{0.059}{n} \log K_c \qquad \text{...(1)}$$

In the given reactions,

$$\text{Cu(s)} \rightleftharpoons \text{Cu}^{2+} + 2e^-$$

$$2\text{Ag}^+ + 2e^- \rightleftharpoons 2\text{Ag},$$

there is two electron change.

So, $\qquad n = 2$

Substituting the values, in (1) we get :

$$0.46 = \frac{0.0591}{2} \log K_c$$

or $\qquad \log K_c = \dfrac{2 \times 0.46}{0.059} = 15.6$

or $\qquad K_c$ = **Antilog 15.6**

So, the correct answer is (*d*).

EXAMPLE 154. *The equilvalent conductance at infinite dilution of the salt AB is 160.84 ohm⁻ cm² (eq)⁻. If the transport number of A^+ is 0.40, the ionic mobility of B^- in cm²s⁻ V⁻ is :*

(*a*) *8.9×10^{-5}* (*b*) *4.5×10^{-3}*

(*c*) *1.0×10^{-3}* (*d*) *6.9×10^{-4}*

SOLUTION. We know that, *ionic conductance of an ion*

= Transport number of that ion.

$\therefore$ B $\wedge^\circ_{\text{eq}}$ of strong electrolyte containing that ion

$$= (1 - 0.40) \times 160.84$$

$$= 0.6 \times 160.84 = 96.504$$

$$\therefore \quad \text{Ionic mobility} = \frac{\text{Ionic conductance}}{96500}$$

$$= \frac{96.504}{96500} = \mathbf{1.0 \times 10^{-3}}$$

So, the correct answer is (*c*).

Example 155. *Given standard electrode potentials :*

$Fe^{3+} + 3e^- \longrightarrow Fe\ ;\ E° = -0.036\ V;$

$Fe^{2+} + 2e^- \longrightarrow Fe\ ;\ E° = -0.440\ V$

The standard electrode potential,

$E°$ for $Fe^{3+} + e^- \longrightarrow Fe^{2+}$ is :

(*a*) *0.02 V* (*b*) *0.0277 V*

(*c*) *0.772 V* (*d*) *– 0.772 V*

(AIEEE, 2009)

Solution. Given :

$$Fe^{3+} + 3e^- \longrightarrow Fe\ ;\ E° = -0.036\ V \quad ...(1)$$

$$Fe^{2+} + 2e^- \longrightarrow Fe\ ;\ E° = -0.440\ V \quad ...(2)$$

For reaction (1), $\Delta G = -nF\,E°_{cell} = -3F\,(-0.036)$

$$= 0.108\ F \quad ...(3)$$

For reaction (2), $\Delta G = -nF\,E°_{cell} = -2F\,(-0.440)$

$$= 0.88\ F \quad ...(4)$$

Subtracting reaction (2) from (1) and their ΔG values, we have :

$$Fe^{3+} + e^- \longrightarrow Fe^{2+}\ ;$$

$$\Delta G = 0.108\ F - 0.88\ F = -0.772\ F$$

$$\therefore E° \text{ of the reaction} = -\frac{\Delta G}{nF} = -\frac{(-0.772F)}{1F} = \mathbf{+0.772\ V}$$

So, the correct answer is (*c*).

Example 156. *How many coulombs of electricity are consumed when a 100 mA current is passed through a solution of $AgNO_3$ for half an hour during an electrolysis experiment ?*

(*a*) *80 C* (*b*) *180 C*

(*c*) *360 C* (*d*) *3600C*

Solution. $1mA = 10^{-3}$ ampere

$\therefore \quad 100mA = 100 \times 10^{-3} A$

Time = ½ hr = ½ × 60 × 60 = 1800 second

∴ Quantity of electricity to be passed

= Current in amperes × time in seconds

$= 100 \times 10^{-3}\ A \times 1800\ s = 180 As$

= 180 C

So, the correct answer is (*b*).

Example 157. *Three Faradays of electricity are passed through molten Al_2O_3, aqueous solution of $CuSO_4$ and molten NaCl taken in three different electrolytic cells. Then the mole ratio of Al, Cu and Na deposited on cathode will be:*

(*a*) *3 : 4 : 6* (*b*) *2 : 1 : 6*

(*c*) *3 : 2 : 1* (*d*) *2 : 3 : 6*

(J and K-CET, 2011)

Solution. The required reduction reactions are:

(*i*) $Al^{3+} + 3e^- \longrightarrow Al$

(*ii*) $Cu^{2+} + 2e^- \longrightarrow Cu$

(iii) $Na^+ + e^- \longrightarrow Na$

Since 3 Faradays of electricity is passed, so, the amount of Al, Cu and Na deposit in mole will be:

$$\text{Al: Cu : Na or } \frac{3}{3} : \frac{3}{2} : \frac{3}{1} \text{ or } 1 : 1.5 : 3 \text{ i.e.,}$$

$$1 : \frac{3}{2} : 3 \text{ or } (1 \times 2) : \left(\frac{3}{2} \times 2\right) : 3 \times 2 = 2 : 3 : 6.$$

So, the correct answer is (*d*).

Example 158. *A current of 9.65 ampere flowing for 10 minutes deposits 3.0 g of the metal which is monovalent. The atomic mass of the metal is :*

(*a*) *150* (*b*) *100*

(*c*) *50* (*d*) *5.0*

Solution. Wt. of metal deposited = 3.0 g ;

quantity of electricity passed,

Q = Current in amperes × time in seconds

= 9.65 A × (10 × 60s)

= 9.65 A × 600s

= 5790 As = 5790 C.

$$\text{But Eq. wt. of metal} = \frac{\text{Wt. of metal}}{Q} \times 96500$$

$$= \frac{3.0}{5790} \times 96500 = 50$$

Valency of metal = 1 (given)

∴ Atomic weight = Eq. wt. × Valency

or At. wt. = 50 × 1 = **50**

So, the correct answer is (*c*).

Example 159. *The standard e.m.f. of a galvanic cell involving two moles of electrons in its redox reaction is 0.59 V. The equilibrium constant for a redox reaction of the cell is:*

(*a*) 10^{20} (*b*) 10^5

(*c*) *10* (*d*) 10^{10}

(Karnataka CET, 2011)

Solution. Galvanic cell is represented as:

$$Zn(s) + Cu^{2+}(aq) \rightleftharpoons Zn^{2+}(aq) + Cu(s)$$

$$[Zn \rightleftharpoons Zn^{2+} + 2e^-;\ n = 2.]$$

At equilibrium, $E_{cell} = 0$. But equilibrium constant K_C is found from the relation:

$$E°_{cell} = \frac{0.059}{n} \log K_C$$

$$0.59 = \frac{0.059}{2} \log K_C;$$

$$\log K_C = \frac{2 \times 0.59}{0.059} = 20;$$

$$\therefore \quad K_C = \text{antilog } 20 = 10^{20}.$$

So, the correct answer is (*a*).

EXAMPLE 160. *The volume of H_2 gas at N.T.P. obtained by passing 4 amperes through acidified H_2O for 30 minutes is :*

(*a*) *0.0836 L*	(*b*) *0.0432L*
(*c*) *0.1672 L*	(*d*) *0.836 L*

(DCE, 2005)

SOLUTION. Time, *t* in seconds

$$= 30 \text{ min} \times \frac{60 \text{ sec}}{1 \text{ min}} = 1800s$$

$$\text{Current, C} = 4 \text{ amperes}$$

$$\therefore \quad Q = 4 \text{ amperes} \times 1800 \text{ s}$$

$$= 7200 \text{ amperes} = 7200 \text{ Coulomb}$$

$$= 7200 \text{ C}$$

Reaction. $H_2O \longrightarrow H_2 + 1/2\, O_2$;

$$\underset{2 \times 96500 \text{ C}}{2H^+ + 2e^-} \longrightarrow \underset{1 \text{ mol } i.e., 22400 \text{ mL at N.T.P.}}{H_2}$$

$$2 \times 96500 \text{ C will give } H_2 = 22400 \text{ mL}$$

$$\therefore \quad 7200 \text{ C will give } H_2 = \frac{22400 \text{ mL} \times 7200 \text{ C}}{2 \times 96500 \text{ C}}$$

$$= 835.64 \text{ mL} = \mathbf{0.836\ L}$$

So, the correct answer is (*d*).

EXAMPLE 161. *The standard electrode potential of Ag^+ / Ag is +0.08 V and Cu^{2+} / Cu = 0.34 V. These electrodes are connected through a salt bridge and if*

(*a*) *Copper electrode acts as a cathode, then $E°_{cell}$ is +0.46V*
(*b*) *Silver electrode acts as anode, then $E°_{cell}$ is –0.34 V*
(*c*) *Copper electrode acts as anode, then $E°_{cell}$ is +0.46 V*
(*d*) *Silver electrode acts as a cathode then $E°_{cell}$ is –0.34 V*
(*e*) *Silver electrode acts as anode and $E°_{cell}$ is +1.14 V*

(Kerala PET, 2005)

SOLUTION. The cell reaction is

$$Cu(s) + 2Ag^+ \longrightarrow Cu^{2+} + 2Ag$$

The two half-cell reactions are :

$$Cu(s) \rightleftharpoons Cu^{2+} + 2e^- \text{ (oxidation, anode)}$$

$$Ag^+ + e^- \rightleftharpoons Ag \quad \text{(Reduction, cathode)}$$

$$\therefore \quad E°_{\text{cell}} = E_{\text{ox}} + E_{\text{red}} = -\,0.34 + 0.80$$

$$= +\,0.46\ V.$$

Since *E*° is positive, the reaction is feasible. So, the correct answer is (*c*).

EXAMPLE 162. *Aluminium oxide may be electrolysed at 1000°C to furnish aluminium metal (at. mass = 27 amu; 1 Faraday = 96,500 coulombs). The cathode reaction is $Al^{3+} + 3e^- \to Al°$. To prepare 5.12 kg of aluminium metal by this method would require.*

(*a*) *5.49×10^7 C of electricity*
(*b*) *1.83×10^7C of electricity*
(*c*) *5.49×10^4 C of electricity*
(*d*) *5.49×10^1 C of electricity.*

(AIEEE, 2005)

SOLUTION. Reaction.

$$\underset{3 \times 96500 \text{ C}}{Al^{3+} + 3e^-} \longrightarrow \underset{27 \text{ g}}{Al}$$

$$\text{wt. of Al} = 5.12 \text{ kg} = 5.12 \times 1000 = 5120 \text{ g}$$

27 g Al require electricity = 3 × 96500 C

5120g Al require electricity

$$= \frac{3 \times 96500}{27} \times 5120 = \approx \mathbf{5.49 \times 10^7 C}$$

So, the correct answer is (*a*).

EXAMPLE 163.

Electrolyte	*KCl,*	*KNO_3,*	*HCl,*	*NaOAC,*	*NaCl*
$\wedge^\infty$(S cm^2 mol$^-$)	*149.4*	*145*	*426.2*	*91.0*	*126.5*

Calculate $\wedge^\infty_{\text{HOAC}}$ using appropriate molar conductances of the electrolytes listed above at infinite dilution in H_2O at 25°C.

(*a*) 517.2	(*b*) 552.7
(*c*) 390.7	(*d*) 217.5

SOLUTION. $\wedge^\infty_{\text{HOAC}} = \wedge^\infty_{\text{NaOAC}} + \wedge^\infty_{\text{HCl}} - \wedge^\infty\text{NaCl}$

$$= 91 + 426.2 - 126.5$$

$$= \mathbf{390.7\ S\ cm^2\ mol^-}$$

So, the correct answer is (*c*).

EXAMPLE 164. *9.65 coulombs of electric current is passed through fused anhydrous $MgCl_2$. The Mg metal thus obtained is completely converted into a Grignard reagent. The number of moles of Grignard reagent obtained is:*

(*a*) *5×10^{-4}*	(*b*) *1×10^{-4}*
(*c*) *5×10^{-5}*	(*d*) *1×10^{-5}*

(Karnataka CET, 2011)

SOLUTION. Eq. wt. of Mg = At. wt./valency = 24/2 = 12g mol$^-$.

We know that:

96500 coulombs of electric current deposits Mg = 12g

9.65 coulombs of electric current deposit Mg.

$$= \frac{12}{96500} \times 9.65 = 1.2 \times 10^{-3} \text{ g of Mg.}$$

$$\text{But } MgCl_2 \rightleftharpoons Mg^{2+} + 2Cl^-$$

$$Mg^{2+} + 2e^- \longrightarrow Mg$$

∴ Number of moles of Grignard reagent obtained

$$= \frac{1.2 \times 10^{-3}}{24} = 5 \times 10^{-5} \text{ mol.}$$

So, the correct answer is (*c*).

EXAMPLE 165. *The two Pt electrodes fitted in a conductance cell are 1.5 cm apart while the crossectional area of each electrode is 0.75 cm^2. What is the cell constant ?*

(*a*) *1.125*	(*b*) *0.5 cm*
(*c*) *2.0 cm$^-$*	(*d*) *0.2 cm$^-$*

(PUCET, 1989)

SOLUTION. Cell constant

$$= \frac{\text{length}}{\text{area}} = \frac{1.5 \text{ cm}}{0.75 \text{ cm}^2} = \mathbf{2.0\ cm^-}$$

So, the correct answer is (*c*).

EXAMPLE 166. *How much silver will be displaced by that quantity of current which displaces 5.6 L of H_2 :*

(*a*) *13.5 g* (*b*) *20 g*
(*c*) *54 g* (*d*) *168 g*

(Pb PMT, 1993)

SOLUTION. 22.4 L volume is occupied by H_2 = 1 mol

5.6 L volume is occupied by H_2

$$= \frac{1}{22.4} \times 5.6 = 0.25 \text{ mol}$$

$$= 0.25 \text{ mol} \times \frac{2 \text{ g. equivalent}}{1 \text{ mol}}$$

$$= 0.5 \text{ g equivalent}$$

∴ Wt. of silver displaced = 0.5 × 108 g = 54g

[∵ eq. wt. of Ag = 108)

So, the correct answer is (*c*).

EXAMPLE 167. *What is the number of coulombs required for the conversion of one mol of* MnO_4^- *to one mol of* Mn^{2+} *?*

(*a*) *96500* (*b*) *96500 × 3*
(*c*) *96500 × 5* (*d*) *96500 × 7*

(Orissa, MBBS, 1993)

SOLUTION.

Reaction : $MnO_4^- + 8H^+ + 5e^- \longrightarrow Mn^{2+} + 4H_2O$

The reaction involves 5 electrons :

∴ Coulombs required = 5 × 96500 coulombs.

So, the correct answer is (*c*).

EXAMPLE 168. *A 0.05 M NaOH solution offered a resistance of 31.6 ohm in a conductivity cell. If the cell constant of a conductivity cell is 0.378 cm⁻, determine the molar conductivity of sodium hydroxide solution at this temperature.* **(ISC, 2008)**

SOLUTION. Resistance,

$$R = 316 \text{ ohm};$$

$$\text{Molarity} = 0.05 \text{ M};$$

$$\text{cell constant} = 0.378 \text{ cm}^-;$$

$$\text{conductance} = \frac{1}{R} = \frac{1}{31.6} \text{ohm}^-.$$

Specific conductance (K) = Conductance × cell constant

$$= \frac{1}{31.6} \text{ ohm}^- \times 0.378 \text{ cm}^-$$

$$= 0.0119 \text{ ohm}^- \text{ cm}^-$$

$$\therefore \text{ Molar conductance} = \frac{\text{K} \times 1000 \text{ cm}^3}{\text{Molarity}}$$

$$= \frac{0.0119 \text{ ohm}^- \text{ cm}^- \times 1000 \text{ cm}^3}{0.05 \text{ mol}}$$

$$= \mathbf{238 \text{ ohm}^- \text{ cm}^2 \text{ mol}^-}.$$

EXAMPLE 169. *When electricity is passed through aqueous solution of aluminium chloride, 13.5 g of Al are deposited. The number of Faradays of electricity passed must be :*

(*a*) *2.0* (*b*) *1.5*
(*c*) *1.0* (*d*) *0.5*

(Pb CET, 1994)

SOLUTION. $AlCl_3 \rightleftharpoons Al^{3+} + 3Cl^-$;

$$Al^{3+} + 3e^- \rightleftharpoons Al$$

3F 27 g

(∵ At. wt. of Al = 27)

27g Al is deposited from faradays = 3

$$13.5 \text{ g Al is deposited from faradays} = \frac{3}{27} \times 13.5 = \mathbf{1.5}$$

So, the correct answer is (*b*).

EXAMPLE 170. *2.5 Faradays of electricity is passed through a solution of* $CuSO_4$*. The number of gram equivalents of copper deposited at cathode are :*

(*a*) *1* (*b*) *2*
(*c*) *2.5* (*d*) *1.25*

(CPMT, 1996)

SOLUTION. $CuSO_4 \rightleftharpoons Cu^{2+} + SO_4^{2-}$;

$$Cu^{2+} + 2e^- \longrightarrow Cu$$

2F 1g. eq.

2F electricity deposits Cu = 1 g. equivalent

$$2.5 \text{ F electricity deposits Cu} = \frac{1\text{g. equivalent} \times 2.5}{2}$$

$$= \mathbf{1.25 \text{ g equivalent}}$$

So, the correct answer is (*d*).

EXAMPLE 171. *An electrolytic cell contains a solution of* Ag_2SO_4 *and has Pt electrodes. A current is passed till 1.6g* O_2 *has been liberated at anode. The amount of silver deposited at cathode will be.*

(*a*) *107.88 g* (*b*) *1.6 g*
(*c*) *0.8 g* (*d*) *21.60 g*

(CPMT, 1996)

SOLUTION. wt. of O_2 = 1.6 g ; wt. of Ag deposited = ? ;

eq. wt. of oxygen = 8, eq. wt. of Ag = 108

We know :

$$\frac{\text{Wt. of Ag}}{\text{Wt. of } O_2} = \frac{\text{Eq. wt. of Ag}}{\text{Eq. wt. of } O_2}$$

$$\text{Hence } \frac{\text{Wt. of Ag}}{1.6 \text{ g}} = \frac{108}{8} \text{ Or}$$

$$\text{Wt. of Ag deposited} = \frac{108 \times 1.6}{8} = \mathbf{21.60 \text{ g}}$$

So, the correct answer is (*d*).

EXAMPLE 172. *In a solution of* $CuSO_4$*, how much time will be required to precipitate 2 g copper by 0.5 ampere current ?*

(*a*) *12157.48 sec* (*b*) *102 sec*
(*c*) *510 sec* (*d*) *642 sec.*

(BIT Ranchi, 1996)

SOLUTION. Wt. of Cu = 2g ;

Current, I = 0.5 ampere ; t = time is sec = ?;

Z (= electrochemical equivalent)

$$= \frac{\text{g. eq. wt. of Cu}}{96500}$$

$$\text{or} \quad Z = \frac{63.5}{2 \times 96500}$$

According to Faraday's first law of electrolysis :

$$W = ZIt\ ;\ t = \frac{W}{ZI}$$

$$t = \frac{2\text{ g} \times 2 \times 96500\text{ C}}{63.5\text{ g} \times 0.5\text{ ampere}}$$

$$= \mathbf{12157.48\ sec.}$$

So, the correct answer is (*a*).

EXAMPLE 173. *What would be the weight of deposited silver on passing 965 coulombs of electricity in a solution of silver nitrate ?*

(*a*) *1.08 g* (*b*) *2.16 g*

(*c*) *0.54 g* (*d*) *0.27 g*

(MP CET, 1998)

SOLUTION. Reaction

$$Ag^+ + \underset{96500C}{1e^-} \longrightarrow \underset{108\text{ g}}{Ag}$$

96500 C electricity deposits

$$Ag = \text{g. eq. wt. of Ag} = 108\text{ g}$$

$$965\text{ C electricity deposits Ag} = \frac{108}{96500} \times 965 = 1.08\text{ g}$$

So, the correct answer is (*a*).

EXAMPLE 174. *What is the amount of chlorine evolved when 2 amperes of current is passed for 30 minutes in an aqueous solution of NaCl ?*

(*a*) *66 g* (*b*) *1.32 g*

(*c*) *33 g* (*d*) *99 g* **(BHU 1998)**

SOLUTION. Charge (Q) passed = Current (I) in amperes × time (t) in seconds

$$= 2\text{ amperes} \times 30\text{ min} \times \frac{60\text{ sec}}{1\text{ min}}$$

$$= 3600\text{ coulombs}$$

($\because$ Ampere × sec = Coulomb).

$$NaCl \rightleftharpoons Na^+ + Cl^-$$

$$Cl^- \rightleftharpoons \underset{\substack{1/2 \times (2 \times 35.5) \\ = 35.5\text{ g}}}{1/2Cl_2} + \underset{96500C}{1e^-}$$

96500 C produce chlorine

= 35.5 g (= g. equivalent of chlorine)

3600 C produce chlorine

$$= \frac{35.5\text{ g}}{96500\text{ C}} \times 3600\text{C} = \mathbf{1.32\ g}$$

So, the correct answer is (*b*).

EXAMPLE 175. *When $CuCl_2$ solution was electrolysed, the mass of the cathode increased by 3.175 g. What occurred at the copper anode ?*

(*a*) *0.01 mol of Cu^{2+} passed into solution*

(*b*) *0.05 mol of Cu^{2+} passed into solution*

(*c*) *1.1L Cl_2 was produced*

(*d*) *1.1 L O_2 was produced*

SOLUTION. $CuCl_2 \rightleftharpoons Cu^{2+} + 2\,Cl^-$

The mass of cathode increased by 3.175 g. It is due to the deposition of Cu^{2+} ions at cathode. As a result, the Cl^- ions would dissolve same amount of Cu from anode *i.e.*, 3.175 g of copper. Thus :

63.5 g Cu that passed into solution = 1 mol

$$3.175\text{ g Cu that passed into solution} = \frac{3.175\text{ g}}{63.5}$$

$$= \mathbf{0.05\ mol}$$

So, the correct answer is (*b*).

EXAMPLE 176. *A galvanic cell was set up from zinc rod (= 100 g) and 1L of 1 M $CuSO_4$ solution. If the cell delivers a steady current of one ampere, the time for whch the cell would work is:*

(*a*) *5.36 hr* (*b*) *2.68 hr*

(*c*) *26.8 hr* (*d*) *53.6 hr.*

SOLUTION. No. of mol of Zn

$$= \frac{\text{Wt. of Zn}}{\text{at. wt. of Zn}} = \frac{100}{65} = 1.54\text{ mol}$$

Also, 1L of 1M $CuSO_4$ = 1 mol $CuSO_4$

$$CuSO_4 \rightleftharpoons Cu^{2+} + SO_4^{2-}\ ;$$

$$\underset{1\text{ mol}}{Cu^{2+}} + \underset{2 \times 96500\text{ C}}{2e^-} \longrightarrow Cu$$

$\therefore$ 1 mol of $CuSO_4$ produces electricity,

$$Q = 2 \times 96500\text{ C}$$

But Q = Current in amperes × time in seconds

$\therefore$ 2 × 96500 C = 1 ampere × time in seconds

[$\because$ 1 ampere sec = 1C]

$$\therefore \text{Time in seconds} = \frac{2 \times 96500\text{ ampere sec}}{1\text{ ampere}}$$

$$= 2 \times 96500\text{ seconds}$$

$$= 2 \times 96500\text{ sec} \times \frac{1\text{ min}}{60\text{ sec}} \times \frac{1\text{ hr}}{60\text{ min}}$$

$$= \mathbf{53.6\ hr}$$

So, the correct answer is (*d*).

EXAMPLE 177. *Calculate the weight of copper that would be deposited at the cathode in the electrolysis of 0.2 M solution of copper sulphate when a quantity of electricity equal to that required to liberate 2.24 L of hydrogen from 0.1 M equeous sulphuric acid, is passed. Atomic mass of Cu = 63.5.*

(*a*) *1.59 g* (*b*) *3.18g*

(*c*) *6.35 g* (*d*) *12.7 g*

(ISM Dhanbad, 1994)

SOLUTION. Eq.wt. of $H_2 = \dfrac{\text{Mol. wt. of } H_2}{2}$

We know : 22.4 L H_2 = 1 mol H_2 at N.T.P.

$$\therefore\ \frac{22.4}{2}\text{ L } H_2 = 1\text{ g. equivalent of } H_2 \text{ at N.T.P.}$$

$$= 96500\text{ C}$$

$$2.24\text{ L } H_2 = 2.24 \times \frac{2}{22.4}$$

$$= 0.2\text{ g equivalent of } H_2$$

$$= 0.2 \times 96500\text{ C}$$

Also, $$\underset{2 \times 96500\ C}{Cu^{2+} + 2e^-} \longrightarrow \underset{63.5\ g}{Cu}$$

$$\therefore \quad 0.2 \times 96500\ C = \frac{63.5}{2 \times 96500} \times 0.2 \times 96500$$
$$= 6.35\ g\ Cu$$

So, the correct answer is (*c*).

EXAMPLE 178. *How many grams of copper will be deposited from a solution of $CuSO_4$ by passing 0.5 F of electric current ?*

(*a*) *31.75* (*b*) *63.5*
(*c*) *15.875* (*d*) *127*

(EAM, CET, 1994)

SOLUTION. $$CuSO_4 \rightleftharpoons Cu^{2+} + SO_4^{2-}$$

Hence : $$\underset{\substack{2 \times 96500\ C \\ = 2F}}{Cu^{2+} + 2e^-} \longrightarrow \underset{63.5\ g}{Cu}$$

$$\text{2F electric current produces Cu} = 63.5\ g$$
$$\therefore \quad \text{0.5 F electric current produces Cu} = \frac{63.5}{2} \times 0.5$$
$$= 15.875\ g$$

So, the correct answer is (*c*).

EXAMPLE 179. *How many electrons are in one coulomb ?*

(*a*) *6.023×10^{23}* (*b*) *1.64×10^{-24}*
(*c*) *6.24×10^{18}* (*d*) *6.24×10^{-24}*

(Bihar, CEE, 1995)

SOLUTION. 1 mol of electrons = 6.02×10^{23} electrons = 96500 C

Hence : 96500 C contain electrons = 6.02×10^{23}
1 C contain electrons

$$= \frac{6.02 \times 10^{23}}{96500} = 6.24 \times 10^{18}$$

So, the correct answer is (*c*).

EXAMPLE 180. *Electrolysis of dilute aqueous NaCl solution was carried out by passing 10 milli-ampere current. The time required to liberate 0.01 mol of H_2 gas at the cathode is (1 Faraday = 96500 C mol$^-$)*

(*a*) *9.65×10^4 sec* (*b*) *19.3×10^4 sec*
(*c*) *28.95×10^4 sec* (*d*) *38.6×10^4 sec*

(IIT-JEE, 2008)

SOLUTION. We know $Q = It$. I = 10 milliampere = 10×10^{-3} ampere

So, $Q = 10 \times 10^{-3}$ ampere $\times\ t$ (is seconds). ...(1)

Reaction : $$\underset{2 \times 0.01F = 0.02F}{2H_2O + 2e^-} \longrightarrow H_2 + 2OH^-$$

0.1 mol H_2 is liberated by charge (= 0.02 Faraday),
Q = 0.02 × 96500 C ...(2)

From (1) and (2), we have; $10 \times 10^{-3}\ t = 0.02 \times 96500$ C

$$\therefore \quad t = \frac{0.02 \times 96500\ C}{10 \times 10^{-3} C s^-} = 19.3 \times 10^4\ s$$

(ampere = C s^-)

So, the correct answer is (*b*).

EXAMPLE 181. *If $\lambda°_{H^+} = 349.8$ ohm$^-$ cm^2, $\lambda°_{OH^-} = 198.5$ ohm$^-$ cm^2 and specific conductance (K) of water at 298 K is 5.54×10^{-8} ohm$^-$ cm$^-$, then ionic product (kw) of water is :*

(*a*) *10^{-13}* (*b*) *10^{-10}*
(*c*) *10^{-9}* (*d*) *1.02×10^{-14}*

SOLUTION. We know that

$$\Lambda°_m = \frac{K(\text{in ohm}^- \text{cm}^-) \times 1000\ \text{cm}^3\ \text{L}^-}{\text{Molarity}(\text{in mol L}^-)}$$

So, molarity *i.e.*, $[H^+][OH^-]$

$$= \frac{K(\text{in ohm}^- \text{cm}^-) \times 1000\ \text{cm}^3\ \text{L}^-}{\Lambda°_m(= \lambda°_{H^+} + \lambda°_{OH^-})}$$

$$\therefore \quad \text{Molarity} = \frac{5.54 \times 10^{-8}\ \text{ohm}^- \text{cm}^- \times 1000\ \text{cm}^3\ \text{L}^-}{349.8 + 198.5 = 548.3\ \text{ohm}^- \text{cm}^2}$$
$$= 1.01 \times 10^{-7}\ \text{g ion L}^-$$

$$\therefore \quad K_w = [H^+][OH^-]$$
$$= (1.01 \times 10^{-7}) \times (1.01 \times 10^{-7})$$
$$= 1.02 \times 10^{-14}$$

So, the correct answer is (*d*).

EXAMPLE 182. *Calculate the standard free energy change for the reaction $2Ag + 2H^+ \rightarrow H_2 + 2Ag^+$, given that E° for $Ag^+ + e^- \rightarrow Ag$ is 0.8 V.*

(*a*) *+ 154.4 k J* (*b*) *+ 308.8 k J*
(*c*) *– 154.4 k J* (*d*) *– 308.8 k J*

(ISM Dhanbad, 1994)

SOLUTION. Since E°Ag^+/Ag = + 0.8 V, the value of E°Ag/Ag^+ of the given reaction is –0.8V. But for $2Ag^+ + 2e^- \rightarrow 2Ag$, n = 2. So :

$$\Delta G° = -n E°F,$$
So, $$\Delta G° = -2 \times -0.8\ V \times 96500\ C$$
or $$\Delta G° = 154{,}400\ VC = 154{,}400\ J \quad (\because C\ V = J)$$
$$= 154{,}400\ J \times \frac{k\ J}{1000\ J} = \mathbf{154.4\ k\ J}$$

Hence, the correct answer is (*a*).

EXAMPLE 183. *The emf of a cell involving the following reaction, $2Ag^+ + H_2 \longrightarrow 2\ Ag + 2H^+$ is 0.80 volt. The standard oxidation potential of silver electrode is:*

(*a*) *–0.80 volt* (*b*) *0.80 volt*
(*c*) *0.40 volt* (*d*) *– 0.40 volt*

[AMU (engg, 2011)]

SOLUTION. For the cell reaction, $H_2 \mid 2H^+ \mid\mid 2Ag^+/2Ag$.

$$H_2 \longrightarrow 2H^+ + 2e^- \text{ and}$$
$$Ag^+ + e^- \longrightarrow \text{A. Given, emf.} = 0.8V.$$

Since $E°_{\text{reduction}}$ for Ag^+/Ag is + 0.80 V, the oxidation potential will be –0.80 V. So, the correct answer is (*a*).

EXAMPLE 184. *The e.m.f. of a particular cell is 1.1 volts. If the value of Faraday is 96500 coulombs per mole, the change in free energy in k J. is :*

(*a*) *212.30* (*b*) *–212.30*
(*c*) *106.5* (*d*) *–106.50 (n = 2)*

(Pb CET, 1995)

SOLUTION. n = 2 ; F = 96500 C, E = 1.1 V

We know that : $\Delta G = -n\ F\ E = -2 \times 96500\ C \times 1.1\ V$
$= 212{,}300\ CV = 212{,}300$ J

$$[\because 1\,\text{CV} = 1\,\text{J}]$$

or $\quad \Delta G = (212,300/1000)\ \text{kJ} = \mathbf{212.3\ kJ}$

So, the correct answer is (*a*).

Example 185. *The standard e.m.f. for the cell reaction, $Zn + Cu^{2+} \rightleftharpoons Cu + Zn^{2+}$ is 1.10 V at 25°C. The e.m.f. for the cell reaction, when 0.1 M Cu^{2+} and 0.1 M Zn^{2+} solutions are used at 25°C is:*

(*a*) 1.10 V (*b*) 0.110V

(*c*) –1.10 V (*d*) – 0.110 V

(MLNR, 1994)

Solution. E° for $Zn + Cu^{2+} \rightleftharpoons Zn^{2+} + Cu$ is 1.10 *V*.

The Nernst equation for this reaction is :

$$E_{\text{cell}} = E^{\circ}_{\text{cell}} - \frac{0.0591}{n} \log \frac{[\text{Products}]}{[\text{Reactants}]}$$

Since $\quad Zn \rightleftharpoons Zn^{2+} + 2e^-$ is 2 electron change, $n = 2$

$$\therefore \quad E_{\text{cell}} = E^{\circ}_{\text{cell}} - \frac{0.0591}{2} \log \frac{[Zn^{2+}][Cu(s)]}{[Zn(s)][Cu^{2+}]} \text{ or } \frac{[Zn^{2+}]}{[Cu^{2+}]}$$

$$= 1.10\,V - \frac{0.0591}{2} \log \frac{0.1}{0.1}$$

$$= 1.10\,V - \frac{0.0591}{2} \log 1$$

$$= 1.10\,V - \frac{0.0591}{2} \times 0 = \mathbf{1.10\ V}$$

So, the correct answer is (*a*).

Example 186. *The value of potential of a hydrogen electrode, pH = 10 is :*

(*a*) 0.4 V (*b*) –0.4 V

(*c*) – 0.3V (*d*) – 0.591 V

Solution. $\quad pH = -\log [H^+]\,;\ [H^+] = 10^{-pH} = 10^{-10}$

Since, $\quad H^+ + 1e^- \longrightarrow \frac{1}{2} H_2, \qquad n = 1.$

Using Nernst equation, we have :

$$E = E^{\circ} - \frac{0.0591}{n} \log \frac{[\text{products}]}{[\text{reactants}]}$$

$$= 0 - \frac{0.0591}{1} \log \frac{[H_2]^{1/2}}{[H^+]}$$

$$= -0.0591 \log \frac{1}{[H^+]}$$

$$= -0.0591 \log \frac{1}{10^{-10}}$$

$$= -0.0591 \times [\log 1 - \log 10^{-10}]$$

$$= -0.0591[0 - (-10)]$$

$$= \mathbf{-0.591\ V}$$

So, the correct answer is (*d*).

Example 187. *The E° value at 298 K of $Cl_2(g) + 2\,Br^-(aq) \longrightarrow 2\,Cl^-(aq) + Br_2$ is 0.29 V. The e.m.f. of the cell when $[Cl^-] = [Br_2] = [Br^-] = 0.015$ M and $Cl_2(g)$ is at 1 atmospheric pressure will be:*

(*a*) 0.172 V (*b*) 0.172 V

(*c*) 0.344 V (*d*) – 0.344 V

Solution. For the reaction, $Cl_2\,(g) + 2Br^-\,(aq) \rightarrow 2\,Cl^-\,(aq) + Br_2$, the Nernst equation, will be :

$$E = E^{\circ} - \frac{0.0591}{n} \log \frac{[Cl^-(aq)]^2\,[Br_2]}{[Cl_2(g)]\,[Br^-(aq)]^2}$$

$$\left[\begin{array}{l} Cl_2\,(g) + 2e^- \rightleftharpoons 2\,Cl^-\,(aq) \\ \therefore\ n = 2 \end{array}\right]$$

$$E = 0.29 - \frac{0.0591}{2} \log \frac{(0.015)^2 \times (0.015)}{1 \times (0.015)^2}$$

$$= 0.29 - \frac{0.0591}{2} \log 0.015$$

$$= 0.29 - \frac{0.0591}{2} \times -1.824$$

$$= 0.29 + 0.054 = \mathbf{0.344V}$$

So, the correct answer is (*c*).

Example 188. *The potential of the cell containing two hydrogen electrodes as represented below*

$$Pt\,;\ \tfrac{1}{2}\,H_2(g)\,|\,H^+\,(10^{-8}\,M)\,|\,|\,H^+\,(0.001\,M)\,|\ \tfrac{1}{2}\,H_2(g);\,Pt,$$

is:

(*a*) 0.296 V (*b*) – 0.295 V

(*c*) 0.13 V (*d*) – 0.13 V

Solution. At anode :

$$\frac{1}{2}\,H_2 \longrightarrow H^+\,(10^{-8}\,M) + e^-\,;$$

(n = 1, since electron change = 1)

At Cathode : $\quad H^+\,(0.001\,M) + e^- \longrightarrow \frac{1}{2}\,H_2\,(g)$

Cell reaction : $\quad H^+\,(0.001\,M) \longrightarrow H^+\,(10^{-8}\,M)$

Applying Nernst equation, we have :

$$E = E^{\circ} - \frac{0.0591}{n} \log \frac{[\text{Products}]}{[\text{Reactants}]}$$

$$= 0 - \frac{0.0591}{1} \log \frac{10^{-8}}{0.001 \text{ or } 10^{-3}}$$

$$= -0.0591 \log 10^{-8+3}$$

or $\quad E = -0.0591[-5 \log 10 = -5];$

$$E = \mathbf{0.296\ V}$$

So, the correct answer is (*a*).

Example 189. *Consider the following cell reaction $2Fe(s) + O_2(g) + 4\,H^+_{(aq)} \longrightarrow 2Fe^{2+}_{(aq)} + 2H_2O(l)$; E° = 1.67 V. If $(Fe^{2+}) = 10^{-3}$M, $P(O_2) = 0.1$ atm and pH = 3, the cell potential at 25°C is:*

(*a*) 1.47 V (*b*) 1.77 V

(*c*) 1.87 V (*d*) 1.57 V

(IIT-JEE, 2011)

Solution. (*i*) $Fe(s) \longrightarrow Fe^{2+} + 2e^-] \times 2$ $\quad$ At anode

$O_2 + 4H^+ + 4e^- \longrightarrow 2H_2O$ $\quad$ At cathode

no. of e^-s involved, $n = 4$

Adding: $2Fe(s) + O_2 + 4H^+ \longrightarrow 2Fe^{2+} + 2H_2O$

$$\therefore \quad Q = \frac{[Fe^{2+}]^2}{[H^+]^4 \times P_{O_2}} = \frac{(10^{-3})^2}{(10^{-3})^4 \times 0.1} = 10^7$$

$$\text{(ii)} \quad E_{cell} = E^\circ - \frac{0.0591}{n} \log Q$$

$$= 1.67 - \frac{0.0591}{4} \log 10^7$$

$$= 1.67 - \frac{0.0591}{4} \times [7 \log 10 = 7]$$

$$= 1.57 \text{ V}$$

So, the correct answer is (*d*).

Example 190. *When 9.65 coulombs of electricity is passed through a solution of silver nitrate (at. mass of Ag = 108 amu), the amount of silver deposited is :*

(*a*) *10.8 mg*	(*b*) *5.4 mg*
(*c*) *16.2 mg*	(*d*) *21.2 mg*

(Karnataka, CET, 2000, BET, 2003)

Solution. 96500 coulomb electricity deposit Ag

= g. eq. wt. of Ag = 108 g

∴ 9.65 coulomb of electricity deposit Ag

$$= \frac{108 \text{ g}}{96500} \times 9.65 = 0.0108 \text{ g}$$

$$= 0.0108 \times 1000 = \mathbf{10.8\ mg}$$

So, the correct answer is (*a*).

Example 191. *1A current is supplied for 30 minutes through NaCl. How much chlorine will be liberated ?*

(*a*) *0.66 gm*	(*b*) *0.66 mol*
(*c*) *0.33 g*	(*d*) *0.33 mol*

(IMS – BHU, 2003)

Solution. Total charge suppplied

= current in ampere × time in seconds

= 1 A × 30 × 60s

= 1800 As = 1800 coulombs

$$NaCl \rightleftharpoons Na^+ + \underset{35.5\text{ g}}{Cl^-}$$

96500 coulombs liberate

Cl_2 = Eq. wt. of Cl_2 = 35.5 g

∴ 1800 coulombs liberate

$$Cl_2 = \frac{35.5 \times 1800}{96500} = \mathbf{0.66\ g}$$

∴ The correct answer is (*a*).

Example 192. *4.5 g of aluminium (at. mass 27 amu) is deposited at cathode from Al^{3+} solution by a certain quantity of electric charge. The volume of hydrogen produced at S.T.P. from H^+ ions in solution by the same quantity of electric charge will be :*

(*a*) *44.8 L*	(*b*) *22.4 L*
(*c*) *11.2 L*	(*d*) *5.6 L*

(CBSE - PMT (Prelims) – 2005)

Solution. Eq. wt. of Al (Valency = 3)

$$= \frac{\text{at. wt.}}{\text{Valency}} = \frac{27}{3} = 9$$

According to Faraday's first law :

1 Faraday charge liberates Al = Eq. wt. of Al = 9

$$\therefore \quad \text{No. of Equilvalent of Al} = \frac{\text{wt. of Al}}{\text{eq. wt. of Al}}$$

$$= \frac{4.5}{9} = 0.5$$

∴ No. of equivalent of H_2 produced = 0.5

But volume occupied by 1 equivalent of

$$H_2 = \frac{22.4 \text{ L}}{2} = 11.2 \text{ L}$$

∴ Volume occupied by 0.5 equivalent of

$$H_2 = (11.2 \times 0.5) \text{ L}$$
$$= 5.6 \text{ L. at STP.}$$

So, the correct answer is (*d*).

Example 193. *100 mL of a neutral solution containing 0.2 g copper was electrolysed till the whole of copper was deposited. The current strength was maintained at 1.2 amperes and the volume of solution was maintained at 100 mL. Assuming 100% current efficiency, the time it would take to deposit copper will be :*

(*a*) *253 sec*	(*b*) *506 sec*
(*c*) *1012 sec*	(*d*) *2024 sec*

(at. wt. of Cu = 63.5)

Solution. Eq.wt. of

$$Cu = \frac{\text{at. wt.}}{\text{Valency}} = \frac{63.5}{2} = 31.75$$

$$Z \text{ for Cu} = \frac{\text{g. eq. wt.}}{96500 \text{ C}} = \frac{31.75 \text{ g}}{96500 \text{ C}}$$

But, $\quad$ wt., $w = Z \times I \times t$

or $\quad t = \dfrac{w}{Z \times I}$

$$= \frac{0.2 \text{ g} \times 96500 \text{ C}}{31.75 \text{ g} \times 1.2 \text{ amp}}; \ \mathbf{506\ seconds}$$

[∵ C = amp. × sec

So, the correct answer is (*b*).

Example 194. *The current strength in amperes that is required to liberate 10 g of iodine from KI solution in 1 hour will be :*

(*a*) *1.05*	(*b*) *2.1*
(*c*) *13.9*	(*d*) *1.12*

(at. wt. of I = 127)

Solution. Eq. wt. of

$$I = \frac{\text{At. wt. of I}}{\text{Valency of I}} = \frac{127}{1} = 127$$

127 g (= 1 g. equivalent of I) of iodine is liberated by

= 96500 C

∴ 10g of iodine is liberated by

$$= \frac{96500 \text{ C}}{127 \text{ g}} \times 10 \ g = Q$$

But Q in coulomb = Current in ampere × time in seconds

where $$t = 1\text{ hr} \times \frac{60\text{ min}}{1\text{ hr}} \times \frac{60\text{ sec}}{1\text{ min}} = 3600\text{ s}$$

$$\therefore \quad \text{Current} = \frac{Q}{\text{time}} = \frac{96500 \times 10}{127}\text{ C} \times \frac{1}{3600\text{s}}$$
$$= \mathbf{2.1\ amp} \qquad [\because \text{C} = \text{amp.} \times \text{sec}]$$

So, the correct answer is (*b*).

EXAMPLE 195. *Tollen's reagent is used for the detection of aldehyde. When a solution of $AgNO_3$ is added to glucose with NH_4OH, then gluconic acid is formed.*

$$2Ag^+ + C_6H_{12}O_6 + H_2O \longrightarrow 2Ag(s) + C_6H_{12}O_7 + 2H^+$$
$$Ag^+ + e^- \longrightarrow Ag\ ;\ E^\circ_{red} = 0.8\ V\ ;$$
$$C_6H_{12}O_6 + H_2O \longrightarrow \text{gluconic acid} + 2H^+ + 2e^-\ ;$$
$$E^\circ_{red} = -0.05\ V$$

Find ln K of this reaction.

(*a*) *66. 13* (*b*) *58.45*
(*c*) *28.30* (*d*) *46.29*

(IIT - JEE, 2006)

SOLUTION. $$\text{Ag}^+ + e^- \longrightarrow \text{Ag(s)}] \times 2\ ;\ E^\circ_{red} = 0.8\ V$$
$$\text{C}_6\text{H}_{12}\text{O}_6 + \text{H}_2\text{O} \longrightarrow \text{gluconic acid} + 2\text{H}^+ + 2e^-;$$
$$E^\circ_{red} = -0.05\ V$$

Add :

$$2\ \text{Ag}^+ + \text{C}_6\text{H}_{12}\text{O}_6 + \text{H}_2\text{O} \longrightarrow 2\text{Ag(s)} + \text{C}_6\text{H}_{12}\text{O}_7 + 2\text{H}^+;$$
$$E^\circ = 0.8 - 0.05 = 0.75\ V$$

Here, number of electrons = 2. So, $n = 2$

Using $2.303\dfrac{RT}{F} = 0.0591$, we have $\dfrac{RT}{F} = \dfrac{0.0591}{2.303}$

But $$E^\circ_{\text{cell}} = \frac{RT}{nF}\ln K\ ;\ 0.75 = \frac{0.0591}{2 \times 2.303}\ln K$$

$$\therefore \quad \ln K = \frac{0.75 \times 2 \times 2.303}{0.0591} = \mathbf{58.45}$$

So, the correct answer is (*b*).

EXAMPLE 196. *When ammonia is added to the solution, pH is raised to 11. Which half-cell reaction is affected by pH and by how much ?*

(*a*) E°_{oxd} *wil increase by a factor of 0.65 from* E°_{oxd}
(*b*) E°_{oxd} *will decrease by a factor of 0.65 from* E°_{oxd}
(*c*) E°_{red} *wil increase by a factor of 0.65 from* E°_{red}
(*d*) E°_{red} *will decrease by a factor of 0.65 from* E°_{red}

[IIT, JEE 2006]

SOLUTION. Since on the addition of NH_3 to the solution, the pH, 11 is reached, it means the concentration of H^+ should decrease.

$$E_{\text{red}} = E^\circ_{\text{red}} - \frac{0.0591}{n}\log(\text{H}^+)$$
$$= 0 - \frac{0.0591}{1}\log 10^{-11}$$
$$= -0.0591 \times -11\log 10$$
$$= -0.0591 \times -11 \times 1 = \mathbf{+0.65}$$

So, the correct answer is (*c*).

EXAMPLE 197. *The reduction potential of hydrogen half cell will be negative if*

(*a*) *$p(H_2)$ = 1 atm and $[H^+]$ = 2.0 M*
(*b*) *$p(H_2)$ = 1 atm and $[H^+]$ = 1.0 M*
(*c*) *$p(H_2)$ = 2 atm and $[H^+]$ = 1.0 M*
(*d*) *$p(H_2)$ = 2 atm and $[H^+]$ = 2.0 M*

(AIEEE, 2010)

SOLUTION. $2\text{H}^+(aq) + 2e^- \longrightarrow \text{H}_2(g)$

$$E_{\text{red}} = E^\circ_{\text{red}} - \frac{0.0591}{n}\log\frac{\text{pH}_2}{[\text{H}^+]^2}$$

where n = no. of electrons involved

$$E_{\text{red}} = 0 - \frac{0.0591}{2}\log\frac{2}{(1)^2} \qquad \ldots(1)$$

From equation (1), it is clear that E_{red} will be negative only if $\text{pH}_2 > [\text{H}^+]$. So, the correct answer is (*c*).

EXAMPLE 198. *The equivalent conductance at infinite dilution of HCl and NaCl are 426.15 and 126.15 mho cm^2 g eq^- respectively. It can be said that the mobility of*

(*a*) *H^+ ions is much more than that of Cl^- ions.*
(*b*) *Cl^- ions is much more than that of H^+ ions.*
(*c*) *H^+ ions is much more than that of Na^+ ions.*
(*d*) *Na^+ ions is much more than that of H^+ ions.*

(Gujrat CET, 2006)

SOLUTION. We know that ionic conductances (λ) are proportional to the ionic mobilities (μ) of the ions. At infinite dilution:

$$\lambda c = k\,\mu c\ ;\ \lambda a = k\,\mu a$$

where λc and λa are the ionic conductances of cations and anions respectively. Value of k = 1 Faraday. μc and μa are the ionic mobilities of cations and anions respectively. Thus higher the value of λ, higher will be the value of μ. So, the correct answer is (*c*).

EXAMPLE 199. *The molar conductivities Λ°_{NaOAC} and Λ°_{HCl} at infinite dilution in water at 25°C are 91.0 and 426.2 S cm^2/mol respectively. To calculate Λ°_{HOAC}, the additional value required is :*

(*a*) $\Lambda^\circ_{H_2O}$ (*b*) Λ°_{KCl}
(*c*) Λ°_{NaOH} (*d*) Λ°_{NaCl}

(AIEEE, 2006)

SOLUTION. $\text{CH}_3\text{COONa} + \text{HCl} \longrightarrow \text{NaCl} + \text{CH}_3\text{COOH}$

From this reaction, we find that :

$$\Lambda^\circ_{\text{CH}_3\text{COONa}} + \Lambda^\circ_{\text{HCl}} \longrightarrow \Lambda^\circ_{\text{NaCl}} + \Lambda^\circ_{\text{CH}_3\text{COOH}} \text{ or } \Lambda^\circ_{\text{HOAC}}$$

So, to calculate $\Lambda^\circ_{\text{HOAC}}$, we need $\Lambda^\circ_{\text{NaCl}}$ because $\Lambda^\circ_{\text{CH}_3\text{COONa}}$ and $\Lambda^\circ_{\text{HCl}}$ are given. So, the correct answer is (*d*).

EXAMPLE 200. *The limiting molar conductivities of HCl, CH_3COONa and NaCl are respectively 425, 90 and 125 mho cm^2 mol^- at 25°C. The molar conductivity of 0.1M CH_3COOH solution is 7.8 mho cm^2 mol^- at the same temperature. The degree of dissociation of 0.1 M acetic acid solution at the same temperature is:*

(*a*) 0.10 (*b*) 0.02

(*c*) 0.15 (*d*) 0.03

(*e*) 0.20 **(Kerala PET, 2011)**

Solution. We know that:

$$\Lambda^\circ_{(CH_3COOH)} = \lambda^\circ_{Na^+} + \lambda^\circ_{CH_3COO^-} + \lambda^\circ_{H^+} + \lambda^\circ_{Cl^-} - \lambda^\circ_{Na^+} - \lambda^\circ_{Cl^-}$$
$$= \lambda^\circ_{CH_3COO^-} + \lambda^\circ_{H^+} \cdots\cdots\cdots \quad (1)$$

Substituting the values in equation (1), we get:

$$\Lambda^\circ_{(CH_3COOH)} = 90 + 425 - 125$$
$$= 390 \text{ mho cm}^2 \text{ mol}^-$$

∴ Degree of dissociation,

$$\alpha = \frac{\Lambda^c_m}{\Lambda^\circ_m} = \frac{7.8}{390} = 0.02$$

So, the correct answer is (*b*).

Example 201. *Given the data at 25°C*

$$Ag + I^- \longrightarrow AgI + e^- \ ; \quad E^\circ = 0.152 \text{ V}$$
$$Ag \longrightarrow Ag^+ + e^- \ ; \quad E^\circ = -0.800 \text{ V}$$

What is the value of $\log K_{sp}$ *for* AgI? $\left[2.303\frac{RT}{F} = 0.059V\right]$

(*a*) − 8.12 (*b*) + 8.612

(*c*) − 37.83 (*d*) − 16.11

(AIEEE, 2006)

Solution. $AgI(s) + e^- \longrightarrow Ag(s) + I^-\ ;\ E^\circ = -0.152 \text{ V}$

$$Ag(s) \longrightarrow Ag^+ + e^-\ ;\ E^\circ = -0.8 \text{ V}$$

Add : $AgI(s) \longrightarrow Ag^+ + I^-\ ;\ E^\circ = -0.952 \text{ V}$

But $E^\circ_{cell} = \frac{0.0591}{n}\log K_{sp}$

So, $-0.952 = \frac{0.0591}{1}\log K_{sp}$

∴ $\log K_{sp} = -\frac{0.952}{0.0591} = \mathbf{-16.11}$

So, the correct answer is (*d*).

Example 202. *Resistivity of a conductivity cell filled with a solution of an electrolyte of concentration 0.1 M is 100 Ω. The conductivity of this solution is 1.29 S m⁻. Resistance of the same cell when filled with 0.2 M of the same solution is 520 Ω. The molar conductivity of 0.02 M solution of the electrolyte will be:*

(*a*) 124×10^{-2} S m² mol⁻ (*b*) 1240×10^{-4} S m² mol⁻

(*c*) 1.24×10^{-4} S m² mol⁻ (*d*) 12.4×10^{-4} S m² mol

(AIEEE, 2006)

Solution. Conductivity,

$$K = \frac{1}{R}\left(\frac{l}{a}\right);$$
$$1.29 = \frac{1}{100}\left(\frac{l}{a}\right)$$

∴ $\frac{l}{a} = 1.29 \times 100 = 129 \text{ m}^-$

Also, $K = \frac{1}{R}\left(\frac{l}{a}\right) = \frac{1}{520} \times 129$

$R = 520\Omega$ for 0.2 M, C = 0.02 M

∴ $\Lambda_m = K \times \frac{1000}{\text{Molarity}}$

$$= \frac{1 \times 129}{520} \times \frac{1000}{0.02} \times 10^{-6} \text{ m}^3$$
$$= \mathbf{124 \times 10^{-2} \text{ S m}^2 \text{ mol}^-}.$$

So, the correct answer is (*a*).

EXAMPLE 203. *The molar conductivities at infinite dilution (*Λ°_m*) for* $Ba(OH)_2$ *= 457.6 Ω⁻cm² mol⁻;* $BaCl_2$ *= 240.6 Ω⁻ cm² mol⁻ and* NH_4Cl *= 129.8 Ω⁻cm² mol⁻. The* Λ°_m *value for* NH_4OH *is Ω⁻cm² mol⁻ will be :*

(*a*) 828 (*b*) 417

(*c*) 238.3 (*d*) 303.2

Solution. $\Lambda^\circ_m\ Ba(OH)_2 = \lambda^\circ_{Ba^{2+}} + 2\lambda^\circ(OH^-);$

457.6 Ω⁻ cm² mol⁻ ...(*i*)

$\Lambda^\circ_m\ BaCl_2 = \lambda^\circ_{Ba^{2+}} + 2\lambda^\circ\ Cl^-;$

240.6 Ω⁻ cm² mol⁻ ...(*ii*)

$\Lambda^\circ_m\ NH_4Cl = \lambda^\circ_{NH_4^+} + \lambda^\circ\ Cl^-;$

129.8 Ω⁻ cm² mol⁻ ...(*iii*)

$\Lambda^\circ_m\ NH_4OH = \lambda^\circ_{NH_4^+} + \lambda^\circ\ (OH^-)$ ...(*iv*)

In order to get equation (*iv*), we have :

$$\Lambda^\circ_m\ NH_4OH = \left[\frac{1}{2}\times\text{equation } (i)\right] - \frac{1}{2}$$

[equation (*ii*)] + Equation (*iii*)

$$= \left[\frac{1}{2}\overset{\circ}{\lambda}_{Ba^{2+}} + \frac{1}{2}\times 2\,\overset{\circ}{\lambda}_{OH^-}\ ;\ \frac{1}{2}\times 457.6\ \Omega^-\text{cm}^2\text{ mol}^-\right]$$
$$-\frac{1}{2}\overset{\circ}{\lambda}_{Ba^{2+}} - \frac{1}{2}\times 2\overset{\circ}{\lambda}_{Cl^-}\ ;\ -\frac{1}{2}\times 240.6\ \Omega^-\text{cm}^2\text{ mol}^-\Big]$$
$$+\left[\overset{\circ}{\lambda}_{NH_4^+} + \overset{\circ}{\lambda}_{Cl^-}\ ;\ +129.8\ \Omega^-\text{cm}^2\text{ mol}^-\right]$$
$$= \overset{\circ}{\lambda}_{NH_4^+} + \overset{\circ}{\lambda}_{OH^-}\ ;$$

(228.8 – 120.3 + 129.8 = 238.3 Ω⁻ cm² mol⁻)

∴ $\overset{\circ}{\Lambda}_m(NH_4OH) = 238.3\ \Omega^-\text{ cm}^2\text{ mol}^-$

So, the correct answer is (*c*).

Example 204. *The conductivity of a saturated solution of AgCl at 288 K is found to be* 1.382×10^{-6} *ohm⁻ cm⁻. If ionic conductances of* Ag^+ *and* Cl^- *ions at infinite dilution are 61.9 ohm⁻ cm² mol⁻ and 76.3 ohm⁻ cm² mol⁻ respectively, then its solubility in g L⁻ will be :*

(*a*) 0.7×10^{-3} (*b*) 1.435×10^{-3}

(*c*) $0.7 \times 10^{+3}$ (*d*) 2.87×10^{-6}

(molar mass of AgCl = 143.5 g mol⁻)

Solution.

$$\Lambda^\circ_m(AgCl) = \lambda^\circ_{Ag^+} + \lambda^\circ_{Cl^-} = 61.9 + 76.3$$
$$= 138.2 \text{ ohm}^- \text{ cm}^2 \text{ mol}^-$$

$$\text{Solubility} = \frac{K(\text{in ohm}^-\text{cm}^-) \times 1000 \text{ cm}^3 \text{ L}^-}{\overset{\circ}{\Lambda}_m(\text{in ohm}^-\text{cm}^2\text{mol L}^-)}$$

$$= \frac{1.382 \times 10^{-6}\text{ohm}^-\text{cm}^- \times 1000 \text{ cm}^3 \text{ L}^-}{138.2 \text{ ohm}^-\text{cm}^2\text{mol}^-.\text{ mol L}^-}$$

$= 10^{-5}\ \text{mol}^-$

$= 10^{-5} \times 143.5\ \text{g}\ L^- = 1.435 \times 10^{-3}\text{g}\ L^-$

So, the correct answer is (*b*).

Example 205. *Out of Na^+, K^+, H^+ and Li^+ cations, the one with highest ionic mobility and another with lowest ionic mobility respectively are :*

(*a*) H^+, K^+
(*b*) H^+, Li^+
(*c*) Li^+, Na^+
(*d*) H^+, K^+

Solution. According to Grothus mechanism, H^+ cation has the maximum ionic mobility. On the other hand, Li^+ has the maximum charge density. So, it is most hydrated ion among all the given cations. So, Li^+ cation has the least ionic mobility. So, the true answer is (*b*)

Example 206. *Specific conductance has the unit*

(*a*) *Ohm⁻ cm*
(*b*) *Ohm⁻cm²*
(*c*) *Ohm⁻ cm⁻*
(*d*) *Ohm cm.*

Solution. Specific conductance

$$= \text{Observed conductance} \times \frac{l}{a}$$

$$= \text{Ohm}^- \times \frac{\text{cm}}{\text{cm}^2} = \mathbf{Ohm^-\ cm^-}$$

So, the correct answer is (*c*).

Example 207. *Specific conductance of 0.01 M NaCl solution is p ohm⁻ cm⁻. When conductivity cell is filled with the above solution, the observed conductance is q ohm⁻. When the same cell is filled with 0.01 M H_2SO_4, the observed conductance was r ohm⁻ cm⁻. So, the specific conductance of 0.01 M H_2SO_4 is :*

(*a*) pq
(*b*) qr
(*c*) $\frac{r}{pq}$
(*d*) $\frac{pr}{q}$

Solution. Specific conductance of 0.01 MH_2SO_4

$$= \text{Observed conductance} \times \text{cell constant} \qquad \text{... (1)}$$

$$\text{But Cell constant} = \frac{\text{Specific conductance}}{\text{Observed conductance}}$$

$$= \frac{p}{q}\ \text{cm}^- \qquad \text{...(2)}$$

Substituting the value of cell constant from (2) in (1), we get ;

Specific conductance of 0.01 MH_2SO_4

$$= r\ \text{ohm}^- \times \frac{p}{q}\ \text{cm}^- = \frac{rp}{q}\ \text{ohm}^-\ \text{cm}^-$$

Hence, the true answer is (*d*).

Example 208. *The value of equivalent conductance of 1M CH_3COOH is 12 ohm⁻ cm² (equiv)⁻ and that at infinite dilution is 240 ohm⁻ cm² (equiv)⁻. The percent ionisation of CH_3COOH will be :*

(*a*) 2
(*b*) 3
(*c*) 4
(*d*) 5.

Solution. We know that : Percent ionisation,

$$\mu = \frac{\Lambda_c}{\Lambda_\infty} \times 100 = \frac{12}{240} \times 100 = \mathbf{5}$$

So, the true answer is (*d*).

Example 209. *Given below are a set of half-cell reactions (acidic medium) along with their E° (V with respect to normal hydrogen electrode) values.*

$I_2 + 2e^- \longrightarrow 2I^-, E° = 0.54;\ Cl_2 + 2e^- \longrightarrow 2Cl^-, E° = 1.36;$
$Mn^{3+} + e^- \longrightarrow Mn^{2+}, E° = 1.50;\ Fe^{3+} + e^- \longrightarrow Fe^{2+}, E° = 0.77;$

$$O_2 + 4H^+ + 4e^- \longrightarrow 2H_2O, E° = 1.23V$$

Using above data, among the following, identify the correct statement.

(*a*) *Chloride ion is oxidised by O_2*
(*b*) *Fe^{2+} is oxidised by iodine*
(*c*) *Iodide ion is oxidised by chlorine*
(*d*) *Mn^{2+} is oxidised by chlorine.* **(IIT-JEE, 2007)**

Solution.

$$\begin{array}{lrcll}
(a) & O_2 + 4H^+ + 4e^- & \longrightarrow & 2H_2O; & E° = 1.23\ V \\
\textbf{Add:} & 2Cl^- & \longrightarrow & Cl_2 + 2e^-] \times 2; & E° = -1.36\ V \\
\hline
 & O_2 + 4Cl^- + 4H^+ & \longrightarrow & 2H_2O + 2Cl_2; & E° = -0.13\ V
\end{array}$$

Since E° is negative, reaction is not feasible.

$$\begin{array}{lrcll}
(b) & Fe^{2+} & \longrightarrow & Fe^{3+} + 1e^-] \times 2; & E° = -0.77\ V \\
\textbf{Add:} & I_2 + 2e^- & \longrightarrow & 2I^-; & E° = +0.54\ V \\
\hline
 & 2Fe^{2+} + I_2 & \longrightarrow & 2Fe^{3+} + 2I^-; & E° = -0.23\ V
\end{array}$$

Since E° is negative, reaction is not feasible.

$$\begin{array}{lrcll}
(c) & Cl_2 + 2e^- & \longrightarrow & 2Cl^-; & E° = 1.36\ V \\
 & I_2 + 2e^- & \longrightarrow & 2I^-; & E° = 0.54\ V \\
\textbf{Subtract:} & - \quad - & & - & - \\
\hline
 & Cl_2 + 2I^- & \longrightarrow & 2Cl^- + I_2; & E° = +0.82\ V
\end{array}$$

Since E° is positive, reaction is feasible.

$$\begin{array}{lrcll}
(d) & Mn^{2+} & \longrightarrow & Mn^{3+} + 1e^-] \times 2; & E° = -1.50\ V \\
\textbf{Add:} & Cl_2 + 2e^- & \longrightarrow & 2Cl^-; & E° = +1.36\ V \\
\hline
 & 2Mn^{2+} + 2Cl_2 & \longrightarrow & 2Mn^{3+} + 2Cl^-; & E° = -0.14\ V
\end{array}$$

Since E° is negative, the reaction is not feasible.

Hence, the correct answer is (*c*).

Example 210. *Using E° data given in example 209, while Fe^{3+} is stable, Mn^{3+} is not stable in acidic solution because*

(*a*) *O_2 oxidises Mn^{2+} to Mn^{3+}*
(*b*) *O_2 oxidises both Mn^{2+} to Mn^{3+} and Fe^{2+} to Fe^{3+}*
(*c*) *Fe^{3+} oxidises H_2O to O_2*
(*d*) *Mn^{3+} oxidises H_2O to O_2.* **(IIT-JEE, 2007)**

Solution.

$$\begin{array}{lrcll}
(a) & O_2 + 4H^+ + 4e^- & \longrightarrow & 2H_2O; & E° = 1.23\ V \\
\textbf{Add:} & Mn^{2+} & \longrightarrow & Mn^{3+} + e^-] \times 4; & E° = -1.50\ V \\
\hline
 & O_2 + 4Mn^{2+} + 4H^+ & \longrightarrow & 2H_2O + 4Mn^{3+}; & E° = -0.27\ V
\end{array}$$

Since E° is negative, the reaction is not feasible.

$$\begin{array}{lrcll}
(b) & O_2 + 4H^+ + 4e^- & \longrightarrow & 2H_2O; & E° = 1.23\ V \\
\textbf{Add:} & Fe^{2+} & \longrightarrow & Fe^{3+} + 1e^-] \times 4; & E° = -0.77\ V \\
\hline
 & O_2 + 4Fe^{2+} + 4H^+ & \longrightarrow & 2H_2O + 4Fe^{3+}; & E° = +0.46\ V
\end{array}$$

Since E° is positive, this reaction is feasible. But O_2 does not oxidise Mn^{2+} to Mn^{3+} [See (*a*) above].

$$\begin{array}{lrcll}
(c) & Fe^{3+} + 1e^- & \longrightarrow & Fe^{2+}] \times 4; & E° = +0.77\ V
\end{array}$$

$$\begin{array}{lrl} \textbf{Add:} & 2H_2O & \longrightarrow O_2 + 4H^+ + 4e^-; E^\circ = -1.23\ V \\ \hline & 4Fe^{3+} + 2H_2O & \longrightarrow 4Fe^{2+} + O_2 + 4H^+; \\ & & \qquad E^\circ = -0.46\ V \end{array}$$

Since E° is negative, the reaction is not feasible.

$$\begin{array}{lrl} (d) & Mn^{3+} + e^- & \longrightarrow Mn^{2+}] \times 4; \quad E^\circ = 1.50\ V \\ \textbf{Add:} & 2H_2O & \longrightarrow O_2 + 4H^+ + 4e^-; E^\circ = -1.23\ V \\ \hline & 4Mn^{3+} + 2H_2O & \longrightarrow 4Mn^{2+} + O_2 + 4H^+; \\ & & \qquad E^\circ = +\ 0.27\ V \end{array}$$

Since E° is positive, the reaction is feasible. Hence, the correct answer is (*d*).

EXAMPLE 211. *A 4.0 molar aqueous solution of NaCl is prepared and 500 mL of this solution is electrolysed. This leads to the evolution of chlorine gas at one of the electrodes (at. mass : Na = 23; Hg = 200; 1 Faraday = 96500 coulombs)*

(*i*) *The total number of moles of chlorine gas evolved is :*

(*a*) *0.5* (*b*) *1.0*

(*c*) *2.0* (*d*) *3.0*

(*ii*) *If the cathode is a Hg electrode, the maximum weight (g) of amalgam formed from this solution is :*

(*a*) *200* (*b*) *225*

(*c*) *400* (*d*) *446*

(*iii*) *The total charge (coulombs) required for complete electrolysis is :*

(*a*) *24125* (*b*) *48250*

(*c*) *96500* (*d*) *193000*

(IIT-JEE, 2007)

SOLUTION. (*i*) NaCl = 4 mol. L⁻. Thus : 1000 mL solution contain NaCl = 4 mol

$$\therefore \text{ 500 mL solution contain NaCl} = \frac{4}{1000} \times 500 = 2 \text{ mol}$$

$$\begin{array}{lccc} & NaCl & \rightleftharpoons Na^+ & + Cl^- \\ \text{No. of mol} & 2 & 2 & 2 \end{array}$$

$$\therefore \text{no. of mol of } Cl_2 \text{ gas formed} = 1 \left[\begin{array}{lcr} \because 2NaCl & \equiv & Cl_2 \\ 2\text{ mol} & & 1\text{ mol} \end{array}\right]$$

So, the correct answer is (*b*).

(*ii*) From (*i*) above, we see that, no. of mol of Na⁺ = 2.

$$\begin{array}{lccc} \text{Also} & 2NaCl \equiv 2\,Na & & \\ \text{and} & Na\ +\ Hg & \rightleftharpoons & Na/Hg\ (\text{amalgam}) \\ \text{no. of mol} & 2 \qquad 2 & & 2 \\ \text{Maximum wt.} & 2\times23 \quad 2\times200 & & (2\times23) + (2\times200) \\ \text{of Na/Hg} & = 46\text{ g} \quad = 400\text{ g} & & = 446\text{ g} \end{array}$$

∴ The correct answer is (*d*).

$$\begin{array}{lccc} (iii) & Na^+ + e^- & \rightleftharpoons & Na \\ \text{no. of mol} & 2 \qquad 2 & & 2 \end{array}$$

[See part (*i*) above]

∴ Total charge required = 2 Faraday

[∵ no. of electrons required = 2 mol]

= 2 × 96500 coulomb

= 193000 coulomb.

∴ The correct answer is (*d*).

EXAMPLE 212. *The current is passed through two cells connected in series. The first cell contains $X(NO_3)_3 .X(aq)$ and the second cell contains $Y(NO_3)_2$ (aq). The relative atomic masses of X and Y are in the ratio 1 : 2. What is the ratio of the liberated mass of X to that of Y?*

(a) 3 : 2 *(b) 1 : 2* *(c) 1 : 3* *(d) 3 : 1*

(e) 2 : 1 **(Kerala PMT, 2011)**

SOLUTION. In $X(NO_3)_3$ (aq), oxidation state of X = + 3. In Y $(NO_3)_2$ (*aq*), the oxidation state of Y = + 2. The ratio of given atomic masses is 1 : 2. Hence, the ratio of equivalent masses is $\frac{1}{3} : \frac{2}{2}$ or $\frac{1}{3}$: 1 or 1 : 3. So, the correct answer is (*c*).

EXAMPLE 213. *Consider two half-cells based on the reaction, $Ag^+_{(aq)} + e^- \longrightarrow Ag(s)$*

The left half-cell contain Ag⁺ ions at unit concentration, and the right half-cell initially had the same concentration of Ag⁺ ions, but just enough NaCl(aq) had been added to completely precipitate the Ag⁺(aq) as AgCl. If the emf of the cell is 0.29 V, then $\log_{10} K_p$ would have been:

(*a*) *9.804* (*b*) *–9.804*

(*c*) *–4.907* (*d*) *10.004*

(AMU (medical), 2012)

SOLUTION. We know that:

Electrode potential is :

$$E_{Cl^-/AgCl/Ag} = E^\circ_{Cl^-/AgCl/Ag} + \frac{0.0591}{1}\log\frac{1}{[Cl^-]}$$

$$E_{Cl^-/AgCl/Ag} = E^\circ_{Ag^+/Ag} + \frac{0.0591}{1}\log K_{sp}/AgCl;$$

$$0.29 = 0 + \frac{0.0591}{1}\log K_{sp/AgCl}$$

$$\therefore \log K_{sp}\,(AgCl) = \frac{-0.29}{0.0591} = -\,4.907.$$

So, the correct answer is (*c*).

EXAMPLE 214. *Consider the cell,*

$Pt/H_2(g, 1\ atm) \mid H^+_{(aq)}, 1\ M) \mid\mid Fe^{3+}_{(aq)}, Fe^{2+}_{(aq)} \mid Pt_{(s)}$

Given that $E^\circ_{Fe^{3+}/Fe^{2+}} = 0.771V$, the ratio of concentration of $Fe^{2+}_{(aq)}$ to $Fe^{3+}_{(aq)}$ is, when the cell potential is 0.830 V.

(*a*) *0.101* (*b*) *0.924*

(*c*) *0.120* (*d*) *none of these*

(AMU (medical), 2012)

SOLUTION. We know that for oxidation-reduction in half-cell:

Pt/Fe²⁺, Fe³⁺, the half-cell is, $Fe^{3+}_{(aq)} + e^- \longrightarrow Fe^{2+}_{(aq)}$

$$\therefore\ E_{Fe^{3+}/Fe^{2+}} = E^\circ_{Fe^{3+}/Fe^{2+}} - \frac{0.0591}{1}\log\frac{[Fe^{2+}]}{[Fe^{3+}]}$$

$$0.83 = 0.771 - \frac{0.0591}{1}\log\frac{[Fe^{2+}]}{[Fe^{3+}]};$$

$$-\frac{0.0591}{0.0591} = \log\frac{[Fe^{2+}]}{[Fe^{3+}]}; -1 = \log\frac{[Fe^{2+}]}{[Fe^{3+}]}; \frac{[Fe^{2+}]}{[Fe^{3+}]}$$

$$= \text{antilog} - 1 = 0.1$$

So, the correct answer is (*a*).

EXAMPLE 215. *In the button cell, widely used in watches, the following reaction takes place.*

$$Zn_{(s)} + Ag_2O_{(s)} + H_2O_{(l)} \longrightarrow Zn^{2+}_{(aq)} + 2Ag_{(s)} + 2OH^-_{(aq)}.$$

Determine E° and ΔG° for the reaction.

(Given $E^\circ_{Ag^+/Ag} = +0.80\ V; E^\circ_{Zn^{2+}/Zn} = -0.76V$ *)*

(CBSE, 2012)

SOLUTION. Given: $E^\circ_{Ag^+/Ag} = +0.80$ V;

$E^\circ_{Zn^{2+}/Zn} = -0.76$V.

But $E^\circ_{cell} = E^\circ_{cathode} - E^\circ_{anode}$

$= 0.80 - (-0.76) = 1.56\ V$

Also, $\Delta G^\circ = -nFE^\circ = -2 \times 96500 \times 1.56$

$[\because Zn^{2+} + 2e^- \longrightarrow Zn$; For $2e^-$ s, $n = 2]$

$= -301080$ J mol$^-$

$= -301.08$ kJ mol$^-$ **Ans.**

EXAMPLE 216. *The conductance of a conductivity cell containing 0.001 M KCl solution at 298 K is 1500 Ω. What is the cell constant if the conductivity of 0.001 M KCl solution at 298 K is 0.146 × 10*$^{-3}$*S cm*$^-$ *?* **(CBSE, 2012)**

SOLUTION. Given conductivity, $K = 0.146 \times 10^{-3}$ S cm$^-$

Resistance, $R = 1500$ ohm. But:

$$\text{Cell constant} = \frac{\text{Conductivity }(K)}{\text{Conductance }(G)}$$

= Conductivity (K) × Resistance, R

$\therefore$ Cell constant $= 0.146 \times 10^{-3}$ S cm$^-$ × 1500 ohm

$= 0.219$ cm$^-$ **Ans.** $(\because S = \text{ohm}^-)$

EXAMPLE 217. *A weak electrolyte having the limiting equivalent conductance of 400 S cm*^{2} *g. equivalent at 298 K is 2% ionised in its 0.1 N solution. The resistance of this solution (in ohms) in an electrolytic cell of cell constant 0.4 cm*$^{-1}$ *at this temperature is:*

(a) *200* *(b)* *300*

(c) *400* *(d)* *500*

(e) *600* **(Kerala PET, 2012)**

SOLUTION. Degree of ionisation,

$\alpha = \frac{2}{100}$; $\Lambda_\infty = 400\ S\ \text{cm}^2 g\ eq^-$

But $\alpha = \frac{\Lambda_m}{\Lambda_\infty}$. So, $\Lambda_m = \alpha \times \Lambda_\infty = \frac{2}{100} \times 400 = 8$

$$\text{Also, } \Lambda_m = \frac{K \times 1000}{\text{Normality}} = \frac{1}{R} \times \frac{\text{Cell constant} \times 1000}{\text{Normality}}$$

$$\left[\because K = \frac{1}{R} \times \text{cell constant}\right]$$

$$\therefore R = \frac{\text{cell constant} \times 1000}{\Lambda_m \times \text{normality}} = \frac{0.4 \times 1000}{8 \times 0.1} = 500 \text{ ohm.}$$

So, the correct answer is (*d*).

EXAMPLE 218. *The solubility product (*K_{sp}*; mol*^{3} *dm*$^{-9}$*) of* MX_2 *at 298K based on the information available for the given concentration cell (*$[M^{2+}] = 0.001$*) is : (take 2.303 × R × 198/F = 0.059 V)*

(a) 1×10^{-15} *(b)* 4×10^{-15}

(c) 1×10^{-12} *(d)* 4×10^{-12}

(IIT-JEE, 2012)

SOLUTION. $MX_2 - 2e^- \rightleftharpoons M^{2+} + 2X^-; C_1 = ?, C_2 = 0.001$
0.001 M

$$\text{But } E_{cell} = \frac{0.0591}{n}\log\frac{C_2}{C_1}; 0.059 = \frac{0.0591}{2}\log\frac{0.001}{C_1}$$

$\therefore \log\frac{0.001}{C_1} = \frac{2 \times 0.059}{0.0591} = 2.$ Taking antilog of both sides,

we get:

$$\frac{0.001}{C_1} = \text{antilog } 2 = 100; \therefore C_1 = \frac{0.001}{100} = 10^{-5}$$

$$\underset{\text{Solubility}}{MX_2} \rightleftharpoons \underset{S}{M^{2+}} + \underset{2S}{2X^-}$$

$\therefore K_{sp} = [M^{2+}][X^-]^2 = S \times (2S)^2 = 4S^3 = 4 \times (10^{-5})^3$

$= 4 \times 10^{-15}$ mol^3 dm^{-9}

So, the correct answer is (*b*).

EXAMPLE 219. *The conductivity of 0.2 M KCl solution is 3 × 10*$^{-2}$ *ohm*$^-$ *cm*$^-$*. Calculate the molar conductance.*

(ISC, 2012)

SOLUTION. Conductivity, $K = 3 \times 10^{-2}$ ohm$^-$ cm$^-$

Molarity = 0.2 mol L$^-$

Λ_m = Molar conductance = ?

$$\text{We know } \Lambda_m = \frac{K \times \frac{1000\text{ cm}^3}{L}}{\text{Molarity}}$$

$$= \frac{3 \times 10^{-2}\text{ ohm}^-\text{cm}^- \times 1000\text{ cm}^3}{0.2\text{ mol L}^- \times \text{L}} = 150\text{ ohm}^-\text{cm}^-\text{mol}^-$$

Ans.

EXAMPLE 220. *The value of ΔG (kJ mol*$^-$*) for the given cell is (take 1F = 96500 C mol*$^-$*,* $M - 2e^- \rightarrow M^{2+}$*)*

(a) *– 5.7* *(b)* *5.7*

(c) *11.4* *(d)* *–11.4*

(IIT-JEE, 2012)

SOLUTION. In $M - 2e^- \longrightarrow M^{2+}$, $n = 2$ due to 2 electron change.

But $\Delta G = -nFE$. Substituting the value, we get:

$\Delta G = -2 \times 96500 \times 0.059 = -11387$ J mol$^-$ = –11.387 kJ mol$^-$

≃ – 11.4 kJ mol$^-$. So the correct answer is (*d*).

EXAMPLE 221. *On passing C amperes of current for time, t sec through one litre of 2 M* $CuSO_4$ *solution (at. wt of Cu = 63.5), the amount (m) of Cu (in g) deposited on cathode will be:*

(a) $m = \frac{Ct}{63.5 \times 96500}$ *(b)* $m = \frac{Ct}{31.25 \times 96500}$

(c) $m = \frac{Ct}{31.25 \times t}$ *(d)* $m = \frac{31.75 \times C \times t}{96500}$

(W.B. JEE, 2012)

Solution. We know, $m = ZCt$ (Faraday's law) ...(1)

Where Z = Eq. wt. of metal/96500.

Eq. wt. of Cu = At. wt./Valency = 63.5/2 = 31.75

$\therefore Z = \dfrac{31.75}{96500}$. Substituting the value in equation (1),

We get:

$m = \dfrac{31.75}{96500} \times C \times t$. So, the correct answer is (*d*).

Example 222. *Given that the standard reduction potential for M⁺/M and N⁺/N electrodes at 298 K are 0.52 V and 0.25 V respectively. Which of the following is correct in respect of the following electrochemical cell?*

$M/M^+ \,||\, N^+/N$

(*a*) *The overall cell reaction is a spontaneous reaction*

(*b*) *The standard emf of the cell is – 0.27 V*

(*c*) *The standard emf of the cell is + 0.77V*

(*d*) *The standard emf of the cell is – 0.77 V*

(*e*) *The standard emf of the cell is + 0.27 V*

(Kerala PET, 2012)

Solution. $E^\circ_{\text{cell}} = E^\circ_{\text{cathode}} - E^\circ_{\text{anode}}$

$= E^\circ_{\text{Right}} - E^\circ_{\text{Left}}$

$= 0.25 - 0.52 = -0.27\ V$. So, the correct answer is (*b*).

Example 223. *The quantity of electricity required to deposit 1.15g of sodium from molten NaCl (Na = 23, Cl = 35.5) is:*

(*a*)	*1F*	(*b*)	*0.5F*
(*c*)	*0.05F*	(*d*)	*1.5F*

(ISC, 2012)

Solution. NaCl (molten) $\rightleftharpoons Na^+ + Cl^-$

At cathode: $\underset{1F}{Na^+ + e^-} \longrightarrow \underset{23g}{Na}$

To deposit 23 g Na, quantity of electricity needed = 1 F

To deposit 1.15 g Na, quantity of electricity needed $= \dfrac{1F}{23\,g} \times 1.15\,g = 0.05\,F$

So, the correct answer is (*c*).

Example 224. *In a plot of log K vs 1/T, the slope is:*

(*a*)	$-E_a/2.303$	(*b*)	$E_a/2.303R$
(*c*)	$E_a/2.303$	(*d*)	$-E_a/2.303R$

(ISC, 2012)

Solution. According to Arrhenius law:

$\log k = \log A - \dfrac{E_a}{2.303\,R} \times \dfrac{1}{T}$

So, the correct answer is (*d*).

Example 225. *From the following data at 25°C,*

(i) $Cr^{3+}_{(aq)} + e^- \longrightarrow Cr^{2+}_{(aq)}\,;\ E^\circ = -0.424V$

(ii) $Cr^{2+}_{(aq)} + 2e^- \longrightarrow Cr\ (s)\ ;\ E^\circ = -0.90\ V$

Find E° at 25°C for the reaction, $Cr^{3+} + 3e^- \longrightarrow Cr(s)$ ...(1)

(*a*)	*– 0.741V*	(*b*)	*–1.324V*
(*c*)	*–0.476V*	(*d*)	*+ 0.741V*

(AMU. Engg., 2012)

Solution. $Cr^{3+}_{(aq)} + e^- \longrightarrow Cr^{2+}_{(aq)}\ ;\ -1 \times F \times -0.424 = +0.424\ F$ ...(*i*)

$Cr^{2+}_{(aq)} + 2e^- \longrightarrow Cr(s)\ ;\ -2 \times F \times -0.90 = +1.8\ F$ ...(*ii*)

Adding equations (*i*) and (*ii*), we get:

$$Cr^{3+} + 3e^- \longrightarrow Cr(s); E^\circ = -\left[\frac{0.424\,F + 1.84F}{(1+2)F}\right] = 0.741\,V$$

So, the correct answer is (*a*).

Example 226. *The approximate time duration in hours to electroplate 30 g of calcium from molten calcium chloride using a current of 5 amp. is:*

(*a*)	*8*	(*b*)	*80*
(*c*)	*10*	(*d*)	*16*

(Karnataka, CET 2012)

Solution. We know: $W = ZCt$ ...(1)

Where W = wt. of Ca deposited = 30 g; Z = Electrochemical equivalent, C = current in amperes and t = time in seconds. Here:

Z = Eq. wt. of Ca/96500 coulomb = 20/96500. Substituting the values in equation (1), we get:

$$30 = \frac{40}{96500} \times 5 \times t;\ t = \frac{30 \times 96500}{40 \times 5}\ \text{seconds}$$

$$= \frac{30 \times 96500}{20 \times 5 \times 60 \times 60}\ \text{hr.}$$

Or $t = 8.04 \simeq 8$ hours. So, the correct answer is (*a*).

Example 227. *Molar conductivities* (Λ°_m) *at infinite dilution of NaCl, HCl and* CH_3COONa *are 126.4, 425.9 and 91.0 Scm² mol⁻ respectively.* (Λ°_m) *for* CH_3COOH *will be:*

(*a*)	*425.5 S cm² mol⁻*	(*b*)	*180.5 S cm² mol⁻*
(*c*)	*290.8 S cm² mol⁻*	(*d*)	*390.5 S cm² mol⁻*

(AIPMT, Mains, 2012)

Solution. Given : $\Lambda^\circ_{NaCl} = 126.4\ S\ cm^2\ mol^-$; $\Lambda^\circ_{HCl} = 425.9\ S\ cm^2\ mol^-$; $\Lambda^\circ_{CH_3COONa} = 91.0\ S\ cm^2\ mol^-$. Thus:

$\Lambda^\circ_{CH_3COOH} = \Lambda^\circ_{HCl} + \Lambda^\circ_{CH_3COONa} - \Lambda^\circ_{NaCl}$

$= 425.9 + 91.0 - 126.4 = 390.5\ S\ cm^2\ mol^-$.

So, the correct answer is (*d*).

Example 228. *A current strength of 3.86 amp. was passed through molten calcium oxide for 41 minutes and 40 seconds. The mass of calcium in grams deposited at the cathode is (atomic mass of Ca is 40g/mol, 1F = 96500 C).*

(*a*)	*4*	(*b*)	*2*
(*c*)	*6*	(*d*)	*8*
(*e*)	*1*		

(Kerala, PMT, 2012)

Solution. Current, $I = 3.86$ amp; $t = 41$ min. 40 sec. = (41 × 60) + 40 = 2500 seconds, eq. wt. of Ca = At. wt./valency = 40/2 = 20

$\therefore$ Z = Eq. wt./96500 = 20/96500. But:

Mass deposited = ZIt = $\frac{20}{96500} \times 3.86 \times 2500 = 2g$.

So, the correct answer is (*b*).

Example 229. *The electrode potential ($E_{Zn^{2+}/Zn}$) of a zinc electrode at 25°C with an aquoes solution of 0.1 M $ZnSO_4$ is ($E_{Zn^{2+}/Zn} = -0.76V$. Assuming $\frac{2.303\ RT}{F} = 0.06$ at 298K)*

(*a*) + 0.73 (*b*) – 0.79

(*c*) – 0.82 (*d*) – 0.70

(*e*) + 0.79

(**Kerala PMT, 2012**)

Solution. For $Zn^{2+} + 2e^- \longrightarrow Zn$, $n = 2$. But

$$E_{Zn^{2+}/Zn} = E^\circ_{Zn^{2+}/Zn} - \frac{2.303\ RT}{nF} \log \frac{[Zn]}{[Zn^{2+}]}$$

$$= -0.76 - \frac{0.06}{2} \log \frac{1}{0.1 \text{ or } 10^{-1}} = -0.76 - 0.03 \log 10$$

= – 0.76 – 0.03 × 1 = – 0.79 V. So, the correct answer is (*b*).

Example 230. *The E° values of the following reduction reactions are given:*

$Fe^{3+}_{(aq)} + e^- \longrightarrow Fe^{2+}_{(aq)}$; $E^\circ = 0.771V$; $Fe^{2+}_{(aq)} + 2e^- \longrightarrow Fe_{(s)}$; $E^\circ = -0.447V$.

What will be the free energy change for the reaction?

$Fe^{3+}_{(aq)} + 3e^- \longrightarrow Fe_{(s)}$; 1F = 96485 C mol$^-$

(*a*) + 18.51 kJ mol$^-$ (*b*) + 11.87 kJ mol$^-$

(*c*) – 8.10 kJ mol$^-$ (*d*) – 10.41 kJ mol$^-$

(**AMU (medical), 2012**)

Solution. We know that $\Delta G^\circ = -nFE^\circ_{cell}$

(*i*) $Fe^{3+}_{(aq)} + e^- \longrightarrow Fe^{2+}_{(aq)}$; $\Delta G^\circ_1 = -F \times 0.771$

(*ii*) $Fe^{2+}_{(aq)} + 2e^- \longrightarrow Fe_{(s)}$; $\Delta G^\circ_2 = -2 \times F \times -0.447 = +0.894\ F$

(*iii*) $Fe^{3+} + 3e^- \longrightarrow Fe_{(s)}$; $\Delta G^\circ_3 = ?$

But $\Delta G^\circ_3 = \Delta G^\circ_1 + \Delta G^\circ_2$; $\Delta G^\circ_3 = -0.771\ F + 0.894\ F$

= + 0.123 *F* = 0.123 × 96485 = 11867.6 ≃ 11.87 kJ mol$^-$.

So, the correct answer is (*b*).

Example 231. *A current of 10.0 A is passed through 1.0 L of 1.0 M HCl solution for 965 seconds. The pH at the end of the experiment is:*

(*a*) 0 (*b*) 0.2

(*c*) 0.8 (*d*) none of these

(**AMC (medical), 2012**)

Solution. 1 L of 1.0 M HCl solution contain HCl = 1mol

$$H^+ + e^- \longrightarrow \frac{1}{2}H_2$$

$\therefore$ 1 Faraday produce $H_2 = \frac{1}{2} \times 1 = 0.5$ mol

$$\frac{965 \times 10}{96500} \text{ Faraday produce } H_2 = \frac{0.5 \times 965 \times 10}{96500} = 0.05 \text{ mol } H_2$$

$\therefore$ 0.05 mol H_2 contain H^+ = 0.1 mol

So, H^+ ions left in solution = 1 – 0.1 = 0.9 mol.

$\therefore$ pH = – log (H^+) = – log 0.9 = (–) × – 0.0457 = + 0.0475.

So, the correct answer is (*d*).

Example 232. *Calculate the maximum work that can be obtained from the given electrochemical cell constructed with two metals, M and N. ($E^\circ_{M^{2+}/M} = -0.76V$; $E^\circ_{N^{2+}/N} = +0.34$ V). The cell reaction is, $M + N^{2+} \longrightarrow M^{2+} + N$.*

(**ISC, 2012**)

Solution.

$$\begin{array}{ll} & N^{2+} + 2e^- \longrightarrow N\ ;\ E^\circ = +0.34\text{ V} \\ & M^{2+} + 2e^- \longrightarrow M\ ;\ E^\circ = -0.76\text{ V} \\ \text{Subtract} & -\quad -\quad\quad -\quad\quad + \\ \hline & M + N^{2+} \longrightarrow M^{2+} + N\ ;\ E^\circ = 1.10\text{ V} \end{array}$$

But the maximum work = – *nFE*°. ...(1)

Since the reduction process involves two electrons change, so, *n* = 2; F = 96500 coulombs; *E*° = 1.10 V. Substituting the values in equation (1), we get:

Maximum work = – 2 × 96500 C × 1.10 V

= – 221300 CV = – 221300 J

[∵ 1 CV = I J]

= – 221.3 kJ **Ans.**

Example 233. *The standard reduction potential for Zn^{2+}/Zn, Ni^{2+}/Ni and Fe^{2+}/Fe are – 0.76, – 0.23 and – 0.44V respectively. The reaction, $X + Y^{2+} \longrightarrow X^{2+} + Y$ will be spontaneous when:*

(*a*) X = Ni, Y = Zn (*b*) X = Fe, Y = Zn

(*c*) X = Zn, Y = Ni (*d*) X = Ni, Y = Fe

(**AIEEE, 2012**)

Solution. A reaction is spontaneous, if E° of the reaction is positive. But $E^\circ = E^\circ_{reduction}$ (higher value) – $E^\circ_{reduction}$ (lower value). Since – 0.23 V > – 0.44 > – 0.76 V, we see that in order to get + ve value, *X* must be Zn (∵ Zn^{2+}/Zn = – 0.76). So, using data of (*c*), we have:

E° = – 0.23 – (– 0.76) = +0.53 V.

So, the correct answer is (*c*).

Example 234. *Standard electrode potential of half-cell reactions are given below:*

$Cu^{2+} + 2e^- \longrightarrow Cu$; $E^\circ = 0.34$ V

$Zn^{2+} + 2e^- \longrightarrow Zn$; $E^\circ = -0.76$ V

What is the emf of the cell ?

(*a*) *+ 1.10 V* (*b*) *– 1.10 V*

(*c*) *– 0.42 V* (*d*) *+ 0.42 V*

(J&K– CET, 2012)

SOLUTION. Subtracting reduction reaction with less E° value from reduction reaction with more E° value, we have:

$$Cu^{2+} + 2e^- \longrightarrow Cu\ ;\ E° = +0.34\ \text{V}$$
$$Zn^{2+} + 2e^- \longrightarrow Zn\ ;\ E° = -0.76\ \text{V}$$
$$-\quad -\qquad -\qquad +$$
$$\text{Zn} + \text{Cu}^{2+} \longrightarrow \text{Zn} + \text{Cu}\ ;\ E° = +1.10\ \text{V}$$

So, the correct answer is (*a*).

EXAMPLE 235. *The equilibrium constant for the reaction* $A_{(s)} + 2B^+_{(aq)} \rightleftharpoons A^{2+}_{(aq)} + 2B_{(s)};\ E°_{cell} = 0.0295V$ *is:* $\left[\dfrac{2.303\,RT}{F} = 0.059\right]$*:*

(*a*) *10* (*b*) 2×10^2

(*c*) 3×10^2 (*d*) 2×10^5

(Karnataka, CET, 2012)

SOLUTION. In the reaction, $\text{A}_{(s)} + 2\text{B}^+_{(aq)} \rightleftharpoons \text{A}^{2+}_{(aq)} + 2\text{B}_{(s)}$ the $\text{A}_{(s)} \rightleftharpoons \text{A}^{2+}_{(aq)} + 2e^-$ has $n = 2$ ($\because$ of $2e^-$ change)

But $\log K_c = \dfrac{n \times E^\circ_{\text{cell}}}{0.059}$; $\log K_c = \dfrac{2 \times 0.0295}{0.059} = 1$

$\therefore K_c = \text{antilog } 1 = 10.$

So, the correct answer is (*a*).

PROBLEMS FOR PRACTICE

1. A cell with parallel electrodes (area = 1.88 cm^2) has a solution of specific conductance 1.51×10^{-2} ohm^{-} cm^{-}. If resistance of solution is 170.5 ohms, find the distance between the electrodes and cell constant.

[Hint and Ans. Distance, $l = k\,R\,a = 1.5 \times 10^{-2}\ \text{ohm}^{-}\ \text{cm}^{-} \times 170.5\ \text{ohm} \times 1.88\ \text{cm}^2 = 4.81\ \text{cm}$; cell constant $= l/a = k\,R = 1.5 \times 10^{-2}\ \text{ohm}^{-}\ \text{cm}^{-} \times 170.5\ \text{ohm}$ = **2.558 cm^{-}** **Ans.]**

2. The resistance of a cell containing N/10 AgNO_3 solution and N/10 KCl solution was 362.62 ohms and 337.62 ohms respectively. The specific conductance of N/10 KCl is 0.01286 S cm^{-}. Calculate the equivalent conductance of N/10 AgNO_3 and the cell constant.

[Hint and Ans. Cell constant = 0.01286 × 337.62 = 4.342 cm^{-} ; Λ_{eq} of N/10 AgNO_3 = (observed conductivity × cell constant × 1000)/Normality

$$= \frac{1}{362.65} \times \frac{4.342 \times 1000}{1/10}$$

= **119.73 ohm^{-} cm^2 (g. equiv)$^{-}$Ans.]**

3. The equivalent conductivity of centinormal solution of HCl, NaCl, CH_3COO Na and CH_3COOH are 369.3, 101.7, 71.7 and 14.3 respectively. Calculate the degree of dissociation and H^+ ion concentration of centinormal acid assuming that other electrolytes are completely ionised. Also, calculate the dissociation constant of the acid.

[Hint and Ans. $\Lambda_{\text{CH}_3\text{COOH}} = (\lambda_{\text{H+}} + \lambda\text{Cl}^-) + (\lambda_{\text{CH}_3\text{COO}^-} + \lambda\ \text{Na}^+) - (\lambda\ \text{Na}^+ + \lambda\ \text{Cl}^-) = 369.3 + 71.7 - 101.7 = 339.3$ mhos ; Degree of dissociation, $\alpha = \lambda_c/\lambda° = 14.3/339.3$ **= 0.042 or 4.2 %** **Ans.]**

$$[\text{H}^+] = \text{C}\,\alpha = \frac{1}{100} \times 0.042$$

= 0.00042 g ion L^{-} **Ans.**

$$K_c = \frac{C\,\alpha^2}{1-\alpha} \simeq C\,\alpha^2 = 0.01 \times (0.042)^2$$

= 1.764 ×10^{-5} mol L^{-} **Ans.**

4. Equivalent conductivities at infinite dilution of KCl, HCl and CH_3COOK are 0.01301, 0.03794 and 0.00956 Ω^{-} m^2 (g.eq)$^{-}$ respectively at 291 K. If specific conductivity of 0.001 N CH_3COOH at 291 K is 4.09×10^{-3} Ω^{-} m^{-}, find its degree of dissociation.

[Hint and Ans.

(*i*)
$$\Lambda_{eq} = \frac{K}{C\,(\text{g. eq}/\text{m}^3)}$$
$$= \frac{4.09 \times 10^{-3}\ \Omega^{-}\ \text{m}^{-}}{0.001 \times 10^3\ \text{g. eq m}^{-3}}$$
$$= 4.09 \times 10^{-3}\ \Omega^{-}\ \text{m}^2\ (\text{g. eq.})^{-}$$

(*ii*) $\Lambda°\ (\text{CH}_3\text{COOH}) = \Lambda°\ (\text{CH}_3\text{COOK}) + \Lambda°\ (\text{HCl}) - \Lambda°\ (\text{KCl})$

$= (0.00956 + 0.03794 - 0.01301)$

$= 0.03449\ \Omega^{-}\ \text{m}^2\ (\text{g. eq})^{-}$.

Hence, degree of dissociation

$$\alpha = \frac{4.09 \times 10^{-3}\ \Omega^{-}\ \text{m}^2\ (\text{g. eq.})^{-}}{0.03449\ \Omega^{-}\ \text{m}^2\ (\text{g. eq.})^{-}}$$

= 0.1186 **Ans.]**

5. Calculate the molar conductivity of 0.00241 M CH_3COOH if its conductivity is 7.896×10^{-5} ohm^{-} cm^{-}. If $\Lambda°$ (CH_3COOH) is 390.5 ohm^{-} cm^2 mol^{-}, find its dissociation constant.

[Hint and Ans. $\Lambda = (7.896 \times 10^{-5} \times 1000)/0.00241 = 32.76\ \text{ohm}^{-}\ \text{cm}^2\ \text{mol}^{-}$; $\alpha = 32.76/390.5 = 0.084$; $K = C\,\alpha^2/1 - \alpha = 0.00241 \times (0{,}084)^2/1 - 0.084$ **= 1.85 × 10^{-5}** **Ans.]**

6. In a Co – Zn cell, $E°_{\text{Zn}^{2+}/\text{Zn}} = -0.76\ V$ and $E°_{\text{Co}^{2+}/\text{Co}} = -0.28\ V$. Name the anode and cathode.

[Ans. Zn is anode : Co is cathode]

7. Find the pH of the following acid solution Pt | H_2(1bar) | H^+(*aq.* acid) || $H^+(g)$ 1 bar| Pt. The measured e.m.f. of the cell is 0.178 V.

[Hint and Ans. pH = $\dfrac{E_{cell}}{0.0591} = \dfrac{0.178}{0.159}$ = **3.012 Ans.]**

8. Calculate the maximum work that can be obtained from the following cell Zn/Zn^{2+} (*aq*) || Ag^+(*aq*)/Ag. Given that $E°$ Zn^{2+}/Zn = – 0.76 *V* and $E°$ Ag^+/Ag = 0.80 *V* **(PSEB, 1999)**

[Hint: Maximum work = – $nE°F$ = – 2 × 1.56 = 96500 = 301.08] **Ans. 301.08 kJ]**

9. How many hours does it take to reduce 3 mol of Fe^{3+} to Fe^{2+} with 2 ampere current? **(DSB, 1997)**

[Hint and Ans. $Fe^{3+} + 1e^- \rightarrow Fe^{2+}$. To reduce 3 mol Fe^{3+}, quantity of electricity required = 3 F = 3 × 96500 C; time in hour = ?. But Q = current in amp × time in seconds. So, time in seconds = (3 × 96500)/2 = 144750 sec = 144750 sec × $\dfrac{1\text{ hr}}{3600\text{ sec}}$ = **40.2 hr Ans.]**

10. How many coulombs are required to produce (*a*) 20.0g of calcuim from molten $CaCl_2$? (*b*) 40.0g of aluminium from molten Al_2O_3 ? **(HSB, 1998)**

[Hint and Ans.

$$\begin{array}{cccc} Ca^{2+} & + \ 2e^- & \longrightarrow & Ca \\ 1\text{ mol} & 2\text{mol} & & 1\text{mol} \\ 1\text{mol} & 2F & & 40g \\ \frac{1}{2}\text{mol} & \frac{2}{2} = 1\text{ F} & & \frac{40}{2} = 20\text{ g} \end{array}$$

∴ To produce 20g Ca, charge required

= 1 F = **1 × 96500 coulombs Ans.**

(*b*)

$$\begin{array}{cccc} Al^{3+} & + \ 3e^- & \longrightarrow & Al \\ 1\text{ mol} & 3\text{ mol} & & 1\text{mol} \\ 1\text{mol} & 3\text{ F} & & 27\text{ g} \end{array}$$

27 g Al is formed from charge = 3 F = 3 × 96500 coulombs

40 g Al is formed from charge

$$= \frac{3 \times 96500}{27} \times 40$$

= **428, 888.9 Coulombs Ans.]**

11. A current of 0.67 ampere when passed through a solution of $CuSO_4$ ($Cu^{2+} + 2e^- \rightarrow Cu$) for 5 hours, 7.9 g Cu was deposited. (*a*) How many coulombs will be used to deposit 1 mol of Cu and (*b*) how many moles of Cu are deposited ?

[Hint and Ans.

$$\begin{array}{ccc} Cu^{2+} & + \ 2e^- \longrightarrow & Cu \\ 1\text{mol} & 2\text{mol} = 2F & 1\text{mol} \end{array}$$

From the reaction, it is clear that :

(*i*) One mol of copper is deposited from coulombs = 2 × 96500 = **193000 Ans.]**

(*ii*) Coulombs of electricity passed = Current in amperes × (time in seconds)

$$= 0.67\text{amp} \times 5\text{hr} \times \frac{60\text{ min}}{1\text{ hr}} \times \frac{60\text{ sec}}{1\text{ min}}$$

= 12060 Coulombs

But 2 × 96500 coulomb deposit

Cu = 1 mol

12060 coulomb deposit

$$Cu = \frac{1}{2 \times 96500} \times 12060$$

= **0.06249 mol Ans.]**

12. On passing electric current through acidulated water and solution of copper sulphate, 0.571 g of copper and 203 mL of H_2 at N.T.P. are liberated. Calculate the equivalent weight of copper .

[Hint and Ans. wt. of 203 mL H_2 at N.T.P. = 0.00009 g × 203 = 0.01827 g

∵ 1mL H_2 at N.T.P. weighs = 0.00009g.

But $\dfrac{\text{Wt. of Cu}}{\text{Wt. of }H_2} = \dfrac{\text{Eq. wt. of Cu}}{\text{Eq. wt. of }H_2}; \dfrac{0.571}{0.01827} = \dfrac{E}{1.008};$

***E* = 31.5 Ans.]**

13. A graph between E_{cell} and log $\dfrac{[Cu^{2+}]}{[Ag^+]^2}$ was linear with intercept on E_{cell} axis 0.46 V. Calculate E_{cell} for Cu/Cu^{2+} (0.1 M) || Ag^+(0.01M)/Ag. **Ans. 0.383 V**

14. Calculate the reduction potential at p_{OH} = 14 for the couple

$E°_{Zn^{2+}/Zn} = -0.76$ V.

Given that

$(K_{sp})_{Zn(OH)_2} = 1.0 \times 10^{-15}$ **Ans. – 1.2025 Volt**

15. In the electrolysis of acidulated water, it is desired to obtain 1.12 cc. of hydrogen per second under S.T.P. condition. The current to be passed is:

(*a*) 9.65 A (*b*) 19.3 A

(*c*) 0.965 A (*d*) 1.93 A

(Karnataka CET, 2009)

SOLUTION. Number of moles of

$$H_2 = \frac{\text{Volume of } H_2}{22400\text{ cc.}} = \frac{1.12}{22400}$$

∴ Number of equivalents of

$$H_2 = \frac{1.12}{22400} \times 2 = 10^{-4}$$

Hence no. of Faradays needed = 10^{-4}

∴ Current to be passed in 1 sec = 96500 × 10^{-4} = 9.65 A. So, the correct answer is (*a*).

16. Which represents disproportionation.

(*a*) $3HNO_2 \longrightarrow 2NO + HNO_3 + H_2O$

(*b*) $Zn + 2Ag^+ \longrightarrow Zn^{2+} + 2Ag$

(*c*) $3Ni + 2\,Au^{3+} \longrightarrow 3\,Ni^{2+} + 2Au$

(*d*) None. **Ans. (*a*)**

17. Given $E°_{Cr^{3+}/Cr} = -0.74$ V; $E°_{MnO_4^-/Mn^{2+}} = 1.51$ V; $E°_{Cr_2O_7^{2-}/Cr^{3+}} = 1.33$ V; $E°_{Cl/Cl^-} = 1.36$ V. Based on the data given above, strongest oxidising agent will be:

1. Cr^{3+} 2. Mn^{2+}
3. MnO_4^- 4. Cl^-

(JEE Main, 2013)

Solution: A stronger oxidising agent is that whose reduction potential value is more. Out of the given data, the reduction potential, E° is maximum for $E°_{MnO_4^-/Mn^{2+}}$ = 1.55 V. So, the correct answer is (3).

18. The same current was passed through two electrolytic cells (connected in series) containing $AgNO_3$ and $ZnSO_4$ solution respectively. The concentration of two solutions is in the ratio 1 : 2. The ratio of weights of Ag and Zn deposited on Pt electrode is :

(*a*) 107.9 : 65 (*b*) 65 : 107.9
(*c*) 107.9 : 32.5
(*d*) 32.5 : 107.9; At. wt. Ag = 107.9 ; Zn = 65. **Ans.** (*c*)

Hint: Consult example, 93.

19. The equivalent conductance of monobasic acid at infinite dilution is 438 $ohm^- cm^2 eq^{-1}$. If the resistivity of the solution containing 15 g of acid (mol. wt. = 49) in 1L is 18.5 ohm cm, what is the degree of dissociation of acid?

(*a*) 12.2% (*b*) 20.2%
(*c*) 30.2% (*d*) 40.3% **Ans.** (*d*)

20. When 0.1 milli Faraday of electricity was passed through molten Al_2O_3, the weight of Al deposited at the cathode was:

(*a*) 1.23 mg (*b*) 19.3 mg
(*c*) 24.7 mg (*d*) 0.9 mg

Ans. (*d*)

21. If the 0.05 molar solution of M^+ is replaced by a 0.0025 M molar M^+ solution, then the magnitude of cell potential would be: ($E_{cell\ (1)}$ = 70 mV)

(*a*) 35 mV (*b*) 70 mV
(*c*) 140 mV (*d*) 700 mV

(IIT-JEE, 2010) Ans. (*c*)

22. A certain current liberates 0.504 g of hydrogen in 2 hours. How many grams of oxygen can be liberated by the same current in same time?

(*a*) 2.0 g (*b*) 0.4 g
(*c*) 4.0 g (*d*) 8.0 g

(J and K CET, 2010) Ans. (*c*)

23. The number of Faradays required to deposit 1 mol of Cu from a solution of $CuSO_4$ will be:

(*a*) 0.1 (*b*) 0.2
(*c*) 1 (*d*) 2

(Bihar CECE, 2009) Ans. (*d*)

24. At 18°C, the conductance of H^+ and CH_3COO^- at infinite dilution are 315 and 35 mho cm^2 eq^- respectively. The equivalent conductivity of CH_3COOH at infinite dilution is ...... mho cm^2 eq^-:

(*a*) 350 (*b*) 280
(*c*) 30 (*d*) 315

(AFMC, 2010) Ans. (*a*)

25. One Faraday of electricity is passed through Al_2O_3, aqueous solution of $CuSO_4$ and molten NaCl taken in three different electrolytic cells connected in series. The mole ratio of Al, Cu and Na deposited at the respective cathode is:

(*a*) 2 : 3 : 6 (*b*) 6 : 2 : 3
(*c*) 6 : 3 : 2 (*d*) 1 : 2 : 3
(*e*) 3 : 6 : 2 **(Kerala PET, 2010) Ans. (*a***

26. The value of equivalent conductance of 1.1 M CH_3COOH is 14 ohm^- cm^2 $(equiv)^-$ and that at infinite dilution is 238 ohm^- cm^2 eq^-. The percent ionisation of CH_3COOH will be:

(*a*) 5.9 (*b*) 10
(*c*) 1.2 (*d*) 15

Ans. (*a*)

27. For how long a current of 2.5 ampere has to be passed through the electrolyte in order to deposit 2.0 g of copper when electrode reaction is $Cu^{2+} + 2e^- \longrightarrow Cu$. **Ans. 0.844 hrs**

28. Calculate the electrostatic charge on Na^+ ions when one Faraday of electricity is passed through the solution containing these ions.

Ans. 4.8×10^{-10} e s u.

29. Silver is electrodeposited on a metallic vessel of total surface 500 cm^2 by a current of 0.5 ampere for two hours. Calculate the thickness of silver deposited (density of silver = 10.5 g cm^{-3}, at. wt. of Ag = 108 amu, *F* = 96500 C mol^-) **(CBSE (AI), 2006)**

Hint: $W = ZIt = \frac{108}{96500} \times 0.5 \times 2 \times 60 \times 60 = 4.029$ g;

Volume, *V* = mass/density = 4.029 g/10.5 g cm^{-3} = 0.3837 cm^3. But volume = Area × thickness. So, Thickness = (Volume/area) = (0.3837/500) = 7.67×10^{-4} cm.

20
CHAPTER

Chemical Kinetics

20.1 RATE OF REACTION

It is defined as the quantity of a reactant species consumed or the quantity of a product species formed in unit time. It is also defined as the '*rate of change of concentration of the reactants with time*'.

Mathematically :

$$\text{Rate of reaction} = \frac{\text{Amount of substances transformed}}{\text{Time taken in transformation}}$$

(*i*) For a reaction, A → B

$$\text{Rate of reaction} = -\frac{\Delta[\text{A}]}{\Delta t} \quad \textbf{or}$$

$$\text{Rate of reaction} = +\frac{\Delta[\text{B}]}{\Delta t}$$

$$\text{In general, rate of reaction} = -\frac{dx}{dt} \ or \ +\frac{dx}{dt}$$

(*ii*) For a general reaction : $a\text{A} + b\text{B} \rightarrow c\text{C} + d\text{D}$

$$\text{Rate of reaction} = -\frac{1}{a}\frac{d[A]}{dt} = -\frac{1}{b}\frac{d[B]}{dt}$$

$$= +\frac{1}{c}\frac{d[C]}{dt} = +\frac{1}{d}\frac{d[D]}{dt}.$$

For the **formation of a compound,** rate of reaction is given a **positive sign** while for the **disappearance of a compound,** the rate of reaction is given a **negative** sign.

20.2 RATE OF DISAPPEARANCE OF A COMPOUND

Type : Rate of disappearance of a compound, is given a negative sign while rate of formation of a compound is given a positive sign. For $a\text{A} + b\text{B} \rightleftharpoons c\text{C} + d\text{D}$.

$$\text{Rate of reaction,} \quad r = -\frac{1}{a}\frac{d[A]}{dt} = -\frac{1}{b}\frac{d[B]}{dt}$$

$$= +\frac{1}{c}\frac{d[C]}{dt} = +\frac{1}{d}\frac{d[D]}{dt}.$$

EXAMPLE 1. *Nitrogen dioxide (NO_2) reacts with fluorine (F_2) to yield nitryl fluoride (NO_2F)*

$$2\,NO_2(g) + F_2(g) \rightarrow 2\,NO_2F(g).$$

Write the rate of reaction in terms of (i) rate of formation of NO_2F, (ii) rate of disappearance of NO_2 (iii) rate of disappearance of F_2.

SOLUTION. Given : $2\text{NO}_2(g) + \text{F}_2(g) \rightarrow 2\,\text{NO}_2\text{F}(g)$. (*i*) For the formation of a compound, rate of reaction is given a positive sign while for the disappearance of a substance, there is decrease in concentration and rate is given a negative sign. Hence :

(*i*) Rate of formation of

$$\text{NO}_2\text{F} = +\frac{1}{2}\frac{\Delta[\text{NO}_2\text{F}]}{\Delta T}$$

(*ii*) Rate of disappearance of

$$\text{NO}_2 = -\frac{1}{2}\frac{\Delta[\text{NO}_2]}{\Delta T}$$

(*iii*) Rate of disappearance of

$$\text{F}_2 = -\frac{\Delta[\text{F}_2]}{\Delta T}.$$

EXAMPLE 2. *Consider the following reaction which proceeds in a closed vessel. 3X → 2Y + Z. The rate of disappearance of X, $-\frac{\Delta[X]}{\Delta t}$ is found to be 0.075 mol^{-} L^{-} s^{-}. Calculate $\frac{\Delta[Y]}{\Delta t}$ and $\frac{\Delta[Z]}{\Delta t}$.*

SOLUTION. The reaction 3X → 2Y + Z can be written as: $\text{X} \rightarrow \frac{2}{3}Y + \frac{1}{3}Z$. Since $-\frac{\Delta[X]}{\Delta t}$ = 0.075 mol^{-} L^{-} s^{-}, we have,

$$(i) \qquad \frac{\Delta[Y]}{\Delta t} = \frac{2}{3} \times 0.075 = 0.05 \text{ mol L}^{-}\text{ s}^{-} \qquad \textbf{Ans.}$$

$$(ii) \qquad \frac{\Delta[Z]}{\Delta t} = \frac{1}{3} \times 0.075 = 0.025 \text{ mol L}^{-}\text{ s}^{-} \qquad \textbf{Ans.}$$

EXAMPLE 3. *For the straight reaction, $X_2(g) + 2Y_2(g) \rightarrow 2XY_2(g)$, write the rate equation in terms of disappearance of Y_2.* **(AISB, 1992, PSEB 1999 S, HSB, 1996)**

SOLUTION. The equation in terms of disappearance of Y_2 in the rate equation.

$X_2(g) + 2Y_2(g) \longrightarrow 2XY_2(g)$ is : rate $= -\frac{1}{2}\frac{d[Y_2]}{dt}$ **Ans.**

Example 4. *How will you express the rate of following reactions : (i) $N_2 + 3H_2 \rightarrow 2NH_3$ in terms of disappearance of H_2 (ii) $H_2 + I_2 \rightleftharpoons 2HI$.* **(CBSE, 2007)**

Solution. (*i*) For $N_2 + 3H_2 \rightleftharpoons 2NH_3$, rate in terms of disappearance of $H_2 = -\frac{1}{3}\frac{d[H_2]}{dt}$

(*ii*) For $H_2 + I_2 \rightleftharpoons 2HI$;

$$\text{rate} = \frac{-d[H_2]}{dt} = \frac{-d[I_2]}{dt} = +\frac{1}{2}\frac{d[HI]}{dt}$$

20.3 AVERAGE RATE OF REACTION

Type : Average rate of reaction = $\frac{-[R_2 - R_1]}{t_2 - t_1}$ *i.e.*, rate $= -\frac{\Delta[R]}{\Delta t}$ where R_1 = rate of reaction at time t_1 and R_2 is the rate of reaction at t_2; $t_2 > t_1$; $R_1 > R_2$.

Example 5. *The concentration of a reactant changes from 0.03 M to 0.02 M in 25 minutes. Calculate the average rate of reaction during units of time both in minutes and seconds.*

Solution. For the reaction, R $\rightarrow$ products

$R_1 = 0.03$ M; $R_2 = 0.02$ M; $t_1 = 0$ min; $t_2 = 25$ min.

But average rate of reaction

$$= -\frac{(R_2 - R_1)}{t_2 - t_1} = -\frac{(0.02 - 0.03)\,\text{mol L}^{-}}{(25 - 0)\,\text{min}}$$

$$= \frac{0.01\,\text{mol L}^{-}}{25\,\text{min}} = 4 \times 10^{-4} \text{ or}$$

0.4×10^{-3} mol L^{-} min^{-} **Ans.**

$$= \frac{0.01\text{ mol L}^{-}}{25 \times 60s} = 6.67 \times 10^{-6}\text{ s}$$ **Ans.**

Example 6. *The decomposition of N_2O_5 in CCl_4 solution at 318 K has been studied by monitoring the concentration of N_2O_5 in the solution. Initially, the concentration of N_2O_5 is 2.33 M and after 184 minutes, it is reduced to 2.08 M. The reaction takes place according to the equation :*

$$2N_2O_5 \rightarrow 4NO_2 + O_2$$

Calculate the average rate of this reaction in terms of hours, minutes and seconds. What is the rate of production of NO_2 during this period ?

Solution. For the reaction, $2N_2O_5 \rightarrow 4NO_2 + O_2$;

$$\text{Rate} = -\frac{1}{2}\frac{\Delta[N_2O_5]}{\Delta T}$$

$$= \frac{-1}{2}\frac{[2.08 - 2.33]\,\text{mol L}^{-}}{(184 - 0)\,\text{min}} = \frac{-1}{2}\left(\frac{-0.25}{184}\right)$$

$$= \frac{6.8 \times 10^{-4}\,\text{mol L}^{-}}{\text{min}}$$

$$= 6.8 \times 10^{-4}\,\frac{\text{mol L}^{-}}{\text{min}} \times \frac{60\text{ min}}{1\text{h}}$$

$$= \frac{4.08 \times 10^{-2}\text{ mol L}^{-}}{\text{hr}}$$ **Ans.**

Also, $$\text{Rate} = \frac{6.08 \times 10^{-4}\text{mol L}^{-}}{\text{min} \times 1\text{ min}/60\text{sec}}$$

$$= \frac{1.13 \times 10^{-5}\text{ mol L}^{-}}{\text{s}}$$ **Ans.**

Also, $$\text{Rate} = \frac{1}{4}\frac{d[NO_2]}{dt}.$$

Or $$\frac{6.8 \times 10^{-4}\text{mol L}^{-}}{\text{min}} = \frac{1}{4}\frac{d[NO_2]}{dt}$$

Hence, $$\frac{d[NO_2]}{dt} = \frac{4 \times 6.8 \times 10^{-4}\text{mol L}^{-}}{\text{min}}$$

$$= \frac{2.72 \times 10^{-3}\text{ mol L}^{-}}{\text{min}}$$ **Ans.**

Example 7. *From the concentration of reactant A at different times given below, calculate the average rate of reaction $A \rightarrow B$ during different intervals of time.*

t/s	0	5	10	20	30
[A] × 10^3 mol L^{-}	160	80	40	10	2.5

Solution. (*i*) For time $t_1 = 0$ and $t_2 = 5$, the rate $R_1 = 160 \times 10^3$ and $R_2 = 80 \times 10^3$.

$$\text{So, average rate} = \frac{[-(R_2 - R_1) \times 10^3]}{t_2 - t_1}$$

$$= \frac{(-80 + 160) \times 10^3}{5 - 0} = 16 \times 10^3.$$

(*ii*) For time $t_1 = 5$, $t_2 = 10$, the rate $R_1 = 80 \times 10^3$ and $R_2 = 40 \times 10^3$.

$$\text{So, average rate} = \frac{[-(R_2 - R_1) \times 10^3]}{t_2 - t_1}$$

$$= -\frac{(40 - 80) \times 10^3}{10 - 5} = 8 \times 10^3$$ **Ans.**

(*iii*) For time $t_1 = 10$, $t_2 = 20$, the rate $R_1 = 40 \times 10^3$, $R_2 = 10 \times 10^3$.

$$\text{So, average rate} = \frac{-(R_2 - R_1) \times 10^3}{t_2 - t_1}$$

$$= \frac{[-(10 - 40) \times 10^3}{20 - 10} = 3 \times 10^3$$ **Ans.**

(*iv*) Try your self. **Ans.** 0.75×10^3.

Example 8. *8 mol L^{-} of $BaCO_3$ are heated. After 4 seconds, the concentration of $BaCO_3$ left is 4 mol L^{-}. Calculate the rate of reaction.*

Solution. Time = 4 seconds; no. of moles of $BaCO_3$ consumed = 8 – 4 = 4 mol L^{-}. But rate of reaction = no. of moles per litre of reactant consumed / Time taken = 4 mol/ 4 seconds = 1 mol s^{-} **Ans.**

Example 9. *When 50 mL of 2 M solution of N_2O_5 was heated, 0.28 L of O_2 at NTP was formed after 30 minutes. Calculate the concentration of unreacted N_2O_5 at that time and also find the average rate of reaction.*

Solution. N_2O_5 decomposes as

$$\underset{1\,\text{mol}=(2\times14+5\times16=108\,\text{g})}{N_2O_5} \longrightarrow N_2O_4 + \underset{\frac{1}{2}\text{mol}=\frac{1}{2}\times32=16\,\text{g}}{1/2O_2} \quad ...(i)$$

(*i*) To find wt. of O_2 formed. 22.4 L O_2 weighs = 32 g.

0.28 L O_2 weighs

$$= \frac{(32\times0.28)}{22.4} = 0.4\,g.$$

From relation (*i*), we have;

16 g O_2 is formed from N_2O_5 = 108 g

∴ 0.4 g O_2 is formed from N_2O_5

$$= \frac{(108\times0.4)}{16} = 2.7\text{ g}$$

= wt, of N_2O_5 decomposed.

(*ii*) To find total wt. of N_2O_5 present in 50 mL of 2M N_2O_5;

$$\text{Molarity} = \frac{(\text{wt. of }N_2O_5\times1000)}{\text{g. Mol. wt. of }N_2O_5\times\text{Vol. of }N_2O_5\text{ in mL}}$$

$$\text{or} \qquad 2 = \frac{\text{wt. of }N_2O_5\times1000}{108\times50}$$

or Wt. of N_2O_5 = 10.8 g

Hence, wt. of N_2O_5 left unreacted

= 10.8 – 2.7 = 8.1. g.

Hence, molarity or concentration of N_2O_5 unreacted

$$= \frac{(\text{wt.}\times1000)}{\text{g.mol.wt.of }N_2O_5\times\text{Vol.of }N_2O_5}$$

$$\text{or} \qquad \text{Molarity} = \frac{(8.1\times1000)}{(108\times50)} = \mathbf{1.5\,M} \qquad \textbf{Ans.}$$

(*iii*) Average rate of reaction.

$$\frac{(2\text{M} - 1.5\text{M})}{(\text{Time in seconds})}$$

$$= \frac{0.5\text{ M}}{(30\times60\text{ seconds}) - 0\text{ second}}$$

$$= \frac{0.5\text{ M}}{1800\text{ second}} = 0.000278\text{ Ms}^- \quad \textbf{Ans.}$$

Example 10. *For the reaction $2X + Y + Z \rightarrow X_2YZ$, the rate equation is, Rate = $k[X][Y]^2$ with $k = 3.0 \times 10^{-6}$ mol^{-2} L^2s^-. If [X] = 0.1 mol L^-, [Y] = 0.2 mol L^- and [Z] = 0.7 mol L^-, determine (i) the initial rate of reaction and also (ii) the rate after 0.02 mol of X has been reacted.*

Solution. The given rate equation is rate, = $k[X]\,[Y]^2$ and $k = 3.0 \times 10^{-6}$ mol^{-2} L^2s^-

[X] = 0.1 mol L^-; [Y] = 0.2 mol L^- and

[Z] = 0.7 mol L^-

∴ Initial rate = $(3.0 \times 10^{-6}\text{ mol}^{-2}\text{ L}^2\text{ s}^-)\ (0.1\text{ mol L}^-)\ (0.2\text{ mol L}^-)^2$

= $\mathbf{12 \times 10^{-9}\ mol\ L^-\ s^-}$

Concentration of X after 0.02 mole has been reacted

[X] = 0.1 – 0.02 = 0.08 mol L^-

From the given reaction it is clear that when 2 moles of X are consumed then one mole of Y gets consumed.

∴ moles of Y consumed when 0.02 moles of X have been consumed

$$= 0.02\times\frac{1}{2} = 0.01\text{ mole}$$

∴ [Y] = 0.2 – 0.01 = 0.19 mol L^-

Rate = $(3.0 \times 10^{-6}\text{ mol}^{-2}\text{L}^2\text{s}^{-2})\ (0.08\text{ mol L}^-)\ (0.19\text{ mol L}^{-1})^2$

= $\mathbf{8.66 \times 10^{-9}\ mol\ L^-\ s^-}$.

Type : Calculation of rate of reaction when concentration is given. Rate = *k* × conc. of reactants.

Example 11. *The rate of 1st order reaction when conc. of reactants is 10^{-2} mol L^- is 3×10^{-4} mol L^-s^-. What will be the rate of reaction when conc. of the reactant is 10^{-4} mol L^-?*

Solution. (*i*) $r = k\,[A]$

$$\therefore \qquad k = \frac{r}{[A]} = \frac{3\times10^{-4}}{10^{-2}} = 3\times10^{-2}s^-$$

(*ii*) $r = k[A] = 3 \times 10^{-2} \times 10^{-4}$

$= 3 \times 10^{-6}$ mol L^-s^-.

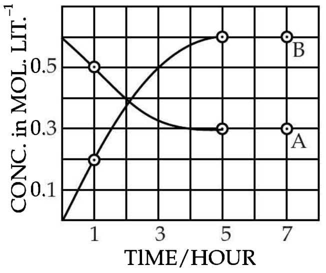
Example 12. *The progress of the reaction $A \rightleftharpoons nB$, with time is presented in the figure. Determine*

(*i*) *the value of n,*

(*ii*) *the equilibrium constant, K, and*

(*iii*) *the initial rate of conversion of A.* **(IIT,1994)**

Solution. (*i*) According to Fig. below, the concentration of reactant and products becomes constant after 5 hours indicating the establishment of equilibrium. In the time span of 4 hours (1 to 5) concentration of A falls from 0.5 to 0.3 M (0.5 – 0.3 = 0.2) and that of B increases from 0.2 M to 0.6 M (0.6 – 0.2 = 0.4). Thus increase in concentration of B in a given time is twice $\left(\frac{0.4}{0.2} = 2\right)$ the decrease in concentration of A. Hence $n = 2$.



(*ii*) Equilibrium reaction can be represented as :

$$A \rightleftharpoons 2B$$

$$\therefore \qquad K = \frac{[B]^2}{[A]} = \frac{(0.6)^2}{0.3} = 1.2M$$

(*iii*) In the time interval 0 to 1 hour, the plot of [A] and [B] are almost linear. Hence the initial rate of conversion of A may be evaluated over this time interval.

$$\text{Initial rate} = -\frac{d[A]}{dt} = \frac{(0.6-0.5)\,M}{1\,\text{hour}} = \mathbf{0.1\ mol\ L^{-1}s^{-1}}$$

Example 13. *The gases X and Y are enclosed in a cubical container. Write down the effect of following changes on the reaction rate between the gases :*

(i) the pressure is doubled

(ii) the temperature is lowered at constant volume

(iii) the number of molecules of gas Y are doubled.

Solution. (*i*) When the pressure is increased, the volume would decrease. Hence concentration will increase and the rate of reaction would become doubled.

(*ii*) When the temperature is lowered, the kinetic energy of the molecules would decrease and the reaction will slow down.

(*iii*) On increasing the number of molecules of Y, the rate of reaction will increase.

Example 14. *The decomposition of N_2O_5 in CCl_4 was studied by measuring the oxygen gas evolved from it. In one hour, 24 ml of the gas was evolved while 35 ml of the gas were evolved when no more oxygen was coming out. Calculate the fraction of N_2O_5 that decomposed in one hour.*

Solution. Here concentration of oxygen gas increases with time. Since 35 mol is the total volume of the gas evolved and 24 mol gas was evolved in one hour, so :

Fraction of N_2O_5 that decomposed in one hour

$$= \frac{24}{35} = \mathbf{0.686.}$$

Example 15. *An experiment was performed on the study of decomposition of H_2O_2 by titration with $KMnO_4$ solution. At the initial stage, 5 ml of the reaction mixture required 46.0 ml of $KMnO_4$ solution. After 5 minutes, the same volume of the reaction mixture needed 37.0 ml of $KMnO_4$ solution. Calculate the fraction of H_2O_2 that decomposed in five minutes.*

Solution. Here concentration of H_2O_2 decreases with time.

Let, initial concentration of H_2O_2 = 1 mol L^-

Fraction of concentration of H_2O_2 at 5 minutes

$$= \frac{37}{46} = 0.804$$

$\therefore$Fraction of H_2O_2 that decomposed in 5 minutes

$$= 1 - 0.804 = \mathbf{0.196.}$$

Example 16. *$PCl_{5(g)}$ (initial pressure 150 mm, Hg) was heated to get $PCl_{3(g)}$ and $Cl_2(g)$ and the final pressure recorded was 350 mm Hg. Calculate the fraction of $PCl_{5(g)}$ that remained unchanged when the pressure was 200 mm Hg.*

Solution. (*i*) For complete change of PCl_5 to PCl_3 and Cl_2 :

Change of pressure = 350 – 150 = 200 mm Hg.

(*ii*) For fractional change, change of pressure = 200 – 150 = 50 mm Hg

$$\therefore \qquad \text{Fraction changed} = \frac{50}{200} = 0.25$$

Hence fraction unchanged = 1 – 0.25 = **0.75 Ans.**

Example 17. *A reactant R was allowed to decompose. After 20 minutes, it was found that its concentration changed from 0.05 M to 0.025 M. Calculate the average rate of the reaction during these 20 minutes.*

Solution. We know that :

$$\text{rate} = -\frac{\Delta[R]}{\Delta t} = -\frac{(0.05-0.025)}{20\ \text{min mol L}^-}$$

$$= -\frac{0.025}{20}$$

$$= \mathbf{-1.25 \times 10^{-3}\ mol\ L^-\ min^-}$$

Example 18. *Consider the following reaction*

$$2\,NO_{(g)} + 2H_2 \longrightarrow N_{2(g)} + 2H_2O$$

Following rate law has been observed for it experimentally

$$R = k\,[NO]^2\,[H_2]^1$$

Predict the reaction rate change, if the following changes are made in the concentration of the reactants.

(i) [NO] is doubled but the concentration of other reactant is kept constant.

(ii) $[H^+]$ is doubled but the concentration of other reactant (NO) is kept constant.

(iii) [NO] is halved but $[H^+]$ is kept constant.

(iv) The concentration of NO as well as H_2 are doubled.

Solution. (*i*) The rate of reaction would become four times because it is proportional to power two of the molar concentration of $NO_{(g)}$.

(*ii*) The reaction rate would become double because it is proportional to single power of the molar concentration of H_2.

(*iii*) The reaction rate would be reduced to one fourth as it is proportional to power two of the molar concentration of $NO_{(g)}$.

(*iv*) The reaction rate would become six times, four times for $NO_{(g)}$ and two times for $H_{2(g)}$.

Example 19. *The following reaction was carried out in H_2O*

$$Cl_2 + 2I^- \rightarrow I_2 + 2Cl^-$$

The initial concentration of I^- was 0.25 mol L^- and concentration after 10 min. is 0.23 mol L^-. Calculate rate of disappearance of I^- and appearance of I_2.

Solution.

$$-\frac{1}{2}\frac{\Delta[I^-]}{\Delta t} = +\frac{\Delta[I_2]}{\Delta t}$$

$$\Delta[I^-] = [I^-]_{\text{final}} - [I^-]_{\text{initial}}$$

$$= 0.23 - 0.25$$

$$= -0.02\ \text{mol L}^-$$

$$\Delta t = 10 - 0 = 10\ \text{min}$$

$$\therefore \text{Rate of disappearance of } I^- = -\frac{1}{2}\frac{\Delta[I^-]}{\Delta t} = -\frac{1}{2}\frac{-0.02}{10}$$

$$= 0.001\ \text{mol L}^-\ \text{min}^-$$

$$\text{Also, rate of appearance of } I_2 = \frac{\Delta[I_2]}{\Delta t} = -\frac{1}{2}\frac{\Delta[I^-]}{\Delta t}$$

$$= 0.001 \text{ mol L}^- \text{ min}$$

20.4 ORDER OF REACTION-FIRST ORDER EQUATION

It is defined as the sum of the *exponents (powers)* to which the molar concentration are *raised in the* rate law or rate equation.

For a general reaction, $lA + mB \rightarrow$ Products,

$$\text{Rate,} \quad r = \frac{-dx}{dt} = k[A]^a[B]^b$$

where $a = l$ or $a \neq l$;

$b = m$ or $b \neq m$.

∴ order of reaction $= a + b$.

First order reaction : *These are* the reactions in which the rate of reaction is determined by the variation of one concentration term only. For a reaction; A → Products :

$$r = -\frac{dx}{dt} = \frac{-d[A]}{dt} = k[A]$$

or

$$\frac{dx}{dt} = k(a - x)$$

On solving, we get: $k = \dfrac{2.303}{t}\log\dfrac{a}{a-x}$

or $k = \dfrac{2.303}{t}\log\dfrac{No}{N}$ First order equation

when, $x = \dfrac{a}{2}$;

$$k = \frac{2.303}{t} \times \log \frac{a}{a - a/2 \, (= a/2)}$$

$$= \frac{2.303}{t_{0.5} \text{ or } t_{1/2}} \log 2$$

$$\therefore \quad k = \frac{2.303 \times 0.310}{t_{0.5}}$$

$$k = \frac{0.693}{t_{0.5}}$$

where $t_{0.5}$ or $t_{1/2}$ = half-change time. a or No = Initial concentration; $a - x$ or N = concentration after time, t.

∴ ***For first order reaction.*** $k = \dfrac{2.303}{t}\log\dfrac{a}{a-x}$;

$$t_{0.5} = \frac{0.693}{k}$$

Second order reaction. These are the reactions in which the rate of reaction is determined by the variation of two concentration terms only.

For second order reaction, $k = \dfrac{1}{t} \times \dfrac{x}{a(a-x)}$ when initial concentration of reactants are equal. When initial concentration of reactants are not equal, then :

$$k = \frac{2.303}{t(a-b)}\log\frac{b(a-x)}{a(b-x)}$$

Third order reaction. These are the reactions in which the rate of reaction is determined by the variation of three concentration terms only.

$$\text{For third order reaction, } k = \frac{1}{t} \times \frac{x(2a-x)}{2a^2(a-x)^2}$$

20.5 UNITS OF RATE CONSTANT

The unit of a rate constant is different for different order of reactions (n). For

$$nA \longrightarrow \text{Products}$$

$$\text{Rate} = k[A]^n; \; k = \frac{\text{Rate}}{[A]^n}$$

(*i*) ***For non-gaseous substances,***

$$k = \frac{\text{Concentration}}{\text{time}} \times \frac{1}{[A]^n}$$

or

$$k = \frac{(\text{mol L}^-)^1}{\text{time}} \times \frac{1}{(\text{mol L}^-)^n}$$

$$= \mathbf{(mol\ L^-)^{1-n}\ time^-}.$$

Since **L$^-$ = dm^{-3}, unit of *k* =** (mol dm^{-3})$^{1-n}$ time$^-$.

(*ii*) ***For gaseous substances,***

$$k = \frac{\text{Concentration}}{\text{time}} \times \frac{1}{[A]^n}$$

or

$$k = \frac{(\text{atm})^1}{\text{time}} \times \frac{1}{(\text{atm})^n}$$

$$= (\text{atm})^{1-n} \text{ time}^-$$

∴ For zero order reaction ($n = 0$), k = (mol L$^-$)$^{1-0}$ time$^-$ = mol L$^-$ time$^-$. When time is in seconds, k = **mol L$^-$s$^-$.**

Also, k = (atm)$^{1-0}$ time$^-$ = atm time$^-$. When time is in seconds, ***k* = *atm s*$^-$**. Similarly

order of reaction	*Unit of rate constant*
0	mol L$^-$ time$^-$ or atm time$^-$
1	time$^-$
2	L mol$^-$ time$^-$ or atm$^-$ time$^-$
3	L^2 mol^{-2} time$^-$ or atm^{-2} time$^-$

Type : To know the order of a reaction from the units of rate constant. For this purpose, use the following relation.

k = (mol L$^-$)$^{1-n}$s$^-$ (*i.e.*, time$^-$)

or k = (mol dm^{-3})$^{1-n}$s$^-$ (*i.e.*, time$^-$)

k = (atm)$^{1-n}$s$^-$ *i.e.*, time$^-$

EXAMPLE 20. *Identify the order of a reaction if the units of its rate constant are* (*i*) L$^-$ mol s$^-$ (*ii*) L mol$^-$ s$^-$

(ISC, 2010, CBSE 2012)

SOLUTION. k = (mol L$^-$)$^{1-n}$s$^-$ where n is the order of reaction.

(*a*) Put $n = 0$; k = (mol L$^-$)$^{1-0}$s$^-$ = mol L$^-$s$^-$

So, the reaction

(*i*) is of zero order

(*b*) Put $n = 1$; $k = (\text{mol L}^{-})^{1-1}\text{s}^{-} = \text{s}^{-}$.

So, order of reaction in not 1.

(*c*) Put $n = 2$; $k = (\text{mol L}^{-})^{1-2}\text{s}^{-} = \text{L mol}^{-}\text{s}^{-}$.

So, order of reaction for the units given in (*ii*) is two.

EXAMPLE 21. *Find the order of a reaction if the units of its rate constant is* $L^2\ mol^{-2}\ sec^{-}$.

SOLUTION. We know that, $k = (\text{mol L}^{-})^{1-n}\text{s}^{-}$ where n is the order of reaction.

(*i*) Put $n = 0, k = \text{mol L}^{-}\ \text{s}^{-}$

(*ii*) Put $n = 1, k = (\text{mol L}^{-})^0\text{s}^{-} = \text{s}^{-}$

(*iii*) Put $n = 2, k = (\text{mol L}^{-})^{1-n}\text{s}^{-}$

$= (\text{mol L}^{-})^{1-2}\text{s}^{-} = (\text{mol L}^{-})^{-1}\text{s}^{-}$

$= \text{mol}^{-}\text{L s}^{-}$

(*iv*) Put $n = 3, k = (\text{mol L}^{-})^{1-n}\text{s}^{-}$

$= (\text{mol L}^{-})^{1-3}\ \text{s}^{-} = (\text{mol L}^{-})^{-2}\text{s}^{-}$

$= \text{mol}^{-2}\ \text{L}^2\ \text{s}^{-}$.

$\therefore$ order of reaction $= 3$.

EXAMPLE 22. *The time for half-life of a certain reaction A → products is 1 hour. When the initial concentration of the reactant, A is 2.0 mol L*$^{-}$*, how much time does it take for its concentration to come from* 0.50 *to 0.25 mol L*$^{-}$*, if it is a zero order reaction.*

(*a*) 1 hr (*b*) 4 hr (*c*) 0.5 hr (*d*) 0.25 hr

(AIEEE, 2010)

SOLUTION. For zero order reaction, $t_{1/2} = [A_0]/2k$; $k = [A_0]/2\,t_{1/2} = 2\text{mol}/2 \times 1\text{ hr} = 1\text{ mol L}^{-}\text{hr}^{-}$. The integrated rate law for zero order reaction is:

$[A] = -kt + [A_0]$. So, $0.25 = -1 \times t + 0.5$.

Hence, $t = 0.25$ hr.

So, the correct answer is (*d*)

EXAMPLE 23. *The unit of rate constant for a zero order reaction is:*

(*a*) $\text{mol L}^{-}\ \text{s}^{-}$ (*b*) $\text{L mol}^{-}\ \text{s}^{-}$ (*c*) $\text{L}^2\ \text{mol}^{2-}\ \text{s}^{-}$ (*d*) s^{-}

(AIPMT, 2011)

SOLUTION. Unit of rate constant, $k = (\text{mol L}^{-})^{1-n}$ time^{-}. For zero order reaction, $n = 0$. Thus, the unit of k is : $k = (\text{mol L}^{-})^{1-0}\ \text{s}^{-} = (\text{mol L}^{-})^1\ \text{s}^{-} = \text{mol L}^{-}\ \text{s}^{-}$.

So, the correct answer is (*a*).

EXAMPLE 24. *Find the units of rate constant for second order oreation if :*

(*i*) *reactants and products are in aqueous state*

(*ii*) *reactants and products are in gaseous state*

SOLUTION. (*i*) For aqueous state, units of

$k = (\text{mol L}^{-})^{1-n}\text{s}^{-}$

Since order of reaction, $n = 2$

$\therefore$ $k = (\text{mol L}^{-})^{1-2}\text{s}^{-}$

$= (\text{mol L}^{-})^{-1}\text{s}^{-} = \text{L mol}^{-}\text{s}^{-}$

(*ii*) For gaseous state, unit of

$k = (\text{atm})^{1-n}\text{s}^{-}$

Since order of reaction, $n = 2$

$\therefore$ $k = (\text{atm})^{1-2}\text{s}^{-} = \text{atm}^{-}\text{s}^{-}$.

EXAMPLE 25. *Find the order of a reaction if the units of its rate constant is atm*$^{-}$ *sec*$^{-}$.

SOLUTION. We know, unit of $k = (\text{atm})^{1-n}\text{s}^{-}$

(*i*) Put $n = 0$, $k = (\text{atm})^{1-0}\ \text{s}^{-} = \text{atm . s}^{-}$

(*ii*) Put $n = 1$, $k = (\text{atm})^{1-1}\ \text{s}^{-} = (\text{atm})^0\text{s}^{-} = \text{s}^{-}$

(*iii*) Put $n = 2$, $k = (\text{atm})^{1-2}\ \text{s}^{-} = (\text{atm})^{-1}\text{s}^{-} = \text{atm}^{-}\text{s}^{-}$

$\therefore$ Order of reaction = 2

Type : *To find order of reaction* from the various steps given for a complete reaction or to find order of reaction from rate equation.

(*a*) The slowest step in the rate determining step.

(*b*) Sum of exponents in a rate equation or rate law is the order of reaction.

EXAMPLE 26. *For the reaction*

$$2NO_2(g) + F_2(g) \longrightarrow 2NO_2F(g)$$

the following mechanism is suggested.

(*i*) $NO_2 + F_2 \longrightarrow NO_2F + F$ (*slow*)

(*ii*) $NO_2 + F \longrightarrow NO_2F$ (*fast*)

What is the predicted rate law ? **(PSEB, 2007)**

SOLUTION. We know that slow step is the rate determining step. So, the rate law for the slow reaction (*i*) is :

Rate = $[NO_2]\,[F_2]$ Ans.

EXAMPLE 27. *What is the rate of reaction and the order of the reaction if the mechanism of reaction is :*

$2NO + H_2 \longrightarrow N_2 + H_2O_2$ (*slow*)

followed by $2H_2O_2 \longrightarrow 2H_2O + O_2$ (*fast*)

SOLUTION. Rate equation is, rate $= k\,[\text{NO}]^2\,[\text{H}_2]^1$ (for slow reaction only)

$\therefore$ order of reaction $= 2 + 1 = 3$

EXAMPLE 28. *Decomposition of* N_2O_5 *is expressed by the equation :*

$$N_2O_5 \longrightarrow 2NO_2 + \frac{1}{2}O_2$$

If during a certain time interval, the rate of decomposition of N_2O_5 *is* 1.8×10^{-3} *mol L*$^{-}$ *min*$^{-}$*, what will be the rate of formation of* NO_2 *and* O_2 *during the same interval.*

SOLUTION. Rate expression for decomposition of N_2O_5:

$$-\frac{\Delta[\text{N}_2\text{O}_5]}{\Delta t} = \frac{1}{2}\frac{\Delta[\text{NO}_2]}{\Delta t} = 2\frac{\Delta[\text{O}_2]}{\Delta t}$$

$\therefore$ Rate of formation of NO_2 is :

$$\frac{1}{2}\frac{\Delta[\text{NO}_2]}{\Delta t} = -\frac{\Delta[\text{N}_2\text{O}_5]}{\Delta t}$$

$$\therefore \quad \frac{\Delta[\text{NO}_2]}{\Delta t} = 2 \times -\frac{\Delta[\text{N}_2\text{O}_5]}{\Delta t}$$

$$= 2 \times 1.8 \times 10^{-3}\ \text{mol L}^{-}\ \text{min}^{-}$$

and

$$\frac{\Delta[\text{O}_2]}{\Delta t} = -\frac{\Delta[\text{N}_2\text{O}_5]}{\Delta t} \times \frac{1}{2}$$

$$= 1.8 \times 10^{-3} \times \frac{1}{2}\ \text{mol L}^{-}\text{min}^{-}$$

20.6 HALF-LIFE PERIOD

Relation between half-life period (or half-change time), $t_{1/2}$ and initial concentration (a) of a reaction. $t_{1/2}$ and a are related as :

(*i*) $\mathbf{t_{1/2} = 1/a^{n-1}}$ where n = order of reaction.

∴ For zero order, first order, second order and third order reactions :

$$t_{1/2} = \frac{1}{a^{-1}}, \frac{1}{a^{0}} \text{ or } \frac{1}{1} \text{ or } 1, \frac{1}{a} \text{ and } \frac{1}{a^{2}} \text{ respectively.}$$

(*ii*) Number of half-life periods

$$= \frac{\text{Total time}}{\text{Time of half-life period}}$$

(*iii*) Quantity of reactant life after '*n*' half-life period

$$= \left(\frac{1}{2}\right)^{n} \times \text{Initial amount of reactant.}$$

(*iv*) $t_{1/2}$ or $t_{0.5} = \dfrac{0.693}{k}$

EXAMPLE 29. *The half-life period of first order reaction $A \longrightarrow B$ is 600 sec. What percent of A remains after 30 minutes? Also, find its rate constant.* **(PSEB, 1999, ISC, 2013)**

SOLUTION. Half-life period = 600 sec = 10 min.

[∵ 1 min = 60s]

Let a = initial amount of reactant.

Number of half-lives in 30 min.

$$= \frac{30}{10} = 3$$

Amount of A left after three half-lives

$$= \frac{a}{2^3} = \frac{a}{8} = \frac{a}{8} \times 100$$

$$= \mathbf{12.5 \text{ of } a \ \%.}$$

$$k = \frac{0.693}{t_{1/2}} = \frac{0.693}{600\,s} = 1.16 \times 10^{-3} s$$

EXAMPLE 30. *The half-life of a substance in certain enzyme catalyzed reaction is 138* s. *The time required for the concentration of the substance to fall from 1.28 mg L^{-} to 0.04 mg L^{-} is:*

(*a*) 414 s (*b*) 552 s (*c*) 690 s (*d*) 276 s

(AIPMT, 2011)

SOLUTION. n = no. of half-life periods is given as:

$$\frac{0.04 \text{ mg L}^{-}}{1.28 \text{ mg L}^{-}} = \frac{1}{32}; \left(\frac{1}{2}\right)^{n} = \left(\frac{1}{2}\right)^{5} \quad \text{or} \quad n = 5$$

∴ Time required = $n \times t_{1/2} = 5 \times 138$ s = 690 s.

So, the correct answer is (*c*)

EXAMPLE 31. *Identify the reaction order from each of the following rate constants.*

(*i*) $k = 5 \times 10^{-5}\ s^{-}$, (*ii*) $k = 9 \times 10^{-4}\ mol^{-}litre\ s^{-}$,

(*iii*) $k = 6 \times 10^{-2}$ *litre* $mol^{-}s^{-}$.

SOLUTION. The unit of rate constant, k is given as : $k = (\text{mol L}^{-})^{1-n}\text{s}^{-}$ where n is the order of the reaction. Using this relation, the unit of rate constant is found and compared with the units of k given. Thus, order of reaction can be decided.

For example :

(*a*) When $n = 0, k = (\text{mol L}^{-})^{1-n}s^{-}$

$= (\text{mol L}^{-})^{1-0}s^{-} = \text{mol L}^{-}s^{-}$.

(*b*) When $n = 1, k = (\text{mol L}^{-})^{1-n} . s^{-} = (\text{mol L}^{-})^{1-1}s^{-}$

$= (\text{mol L}^{-})^{0}s^{-} = s^{-}$

So, reaction (*i*) is of first order.

(*c*) When $n = 2, k = (\text{mol L}^{-})^{1-n} . s^{-} = (\text{mol L}^{-})^{1-2}s^{-}$

$= (\text{mol L}^{-})^{-}s^{-} = \text{mol}^{-} \text{Ls}^{-}$.

So, reactions (*ii*) and (*iii*) are of second order ($n = 2$).

EXAMPLE 32. *The rate equation for a reaction, $A \rightarrow B$ is $r = k\ (A)^0$. If the initial concentration of the reactant is a mol dm^{-3}, the half-period of the reaction is:*

(*a*) $k/2$ (*b*) a/k (*c*) $2a/k$ (*d*) $a/2k$

(Karnataka CET, 2009)

SOLUTION. Given: rate = $k[\text{A}]^0$. So order of reaction is zero. For a zero order reaction, $t_{1/2} \propto a$

∴ $t_{1/2} = \dfrac{a}{2k}$. So, the correct answer is (*d*).

EXAMPLE 33. *Carbonyl chloride gas decomposes to give carbon monoxide gas and chlorine gas.*

$$COCl_2(g) \longrightarrow CO(g) + Cl_2(g)$$

It follows the rate law : rate = k $[COCl_2]^{3/2}$. Calculate the units of its rate constant.

SOLUTION. Given : Rate = $k\ [\text{COCl}_2]^{3/2}$. Hence order of reaction, $n = \dfrac{3}{2}\cdot$ To find units of rate constant, k, we have: $k = (\text{mol L}^{-})^{1-n}. \text{s}^{-}$. Substituting the value of $n = \dfrac{3}{2}$, we get $k = (\text{mol L}^{-})^{1-3/2} . \text{s}^{-} = (\text{mol L}^{-})^{1/2}\text{s}^{-}$. So, unit of k = $(\text{mol L}^{-})^{-1/2}.\text{s}^{-}$. **Ans.**

Type : Order of a reaction in which rate = $k\ [\text{A}]^a[\text{B}]^b$ (slowest step reaction) = Sum of exponents = $a + b$; k = rate constant or specific reaction rate.

EXAMPLE 34. *Cyclopropane rearranges to form propene*

$$\longrightarrow \text{CH}_3 - \text{CH} = \text{CH}_2$$

This follows first order kinetics. The rate constant is 2.714 × 10^{-3} sec^{-}. The initial concentration of cyclopropane is 0.29 M. What will be the concentration of cyclopropane after 100 sec?

(*a*) 0.035 *M* (*b*) 0.22 *M* (*c*) 0.145 *M* (*d*) 0.0018 *M*

(Orissa JEE, 2009)

SOLUTION. Rate constant, $k = 2.714 \times 10^{-3}$ sec^{-}, initial concentration $a = 0.29\ M$; concentration left after 100 sec, $(a - x)$ = ? We know that: rate constant,

$$k = \frac{2.303}{t} \log \frac{a}{a-x}.$$

Thus 2.714×10^{-3} sec

$$= \frac{2.303}{100 \text{ sec}} \log \frac{0.29}{a-x};$$

$$\frac{0.27}{2.303} = \log \frac{0.29}{a-x}; 0.117 = \log \frac{0.29}{a-x}.$$

Taking antilog, we get

$$\text{Anti log } 0.117 = \frac{0.29}{a-x}; a-x = \frac{0.29}{1.3091} = 0.22\,M.$$

So, the correct answer is (*b*).

EXAMPLE 35. *Consider the following first order reaction*

$$2H_2O_2(aq) \xrightarrow{I^-(aq)} 2H_2O(l) + O_2(g)$$

If the rate constant of the reaction is 1.01×10^{-2} *min*$^{-}$ *(i) what concentration of* H_2O_2 *would give rate of* 1.12×10^{-2} *mol L*$^{-}$ *min*$^{-}$*? (ii) Calculate rate of reaction when* $[H_2O_2] = 0.5$ *mol L*$^{-}$*.*

SOLUTION. (*i*) For first order reaction, rate = $k[H_2O_2]$. Substituting the values, we get,

$$1.12 \times 10^{-2} \text{ mol L}^{-} \text{ min}^{-} = 1.01 \times 10^{-2} \text{ min}^{-} [H_2O_2].$$

Hence,
$$[H_2O_2] = \frac{1.12 \times 10^{-2} \text{ mol L}^{-} \text{ min}^{-}}{1.01 \times 10^{-2} \text{ min}^{-}}$$
$$= 1.11 \text{ mol L}^{-}$$

(*ii*) rate = $k[H_2O_2]$.

Substituting the values, we get;

$$\text{rate} = 1.01 \times 10^{-2} \text{ min}^{-} \times 0.5 \text{ mol L}^{-}$$
$$= 5.05 \times 10^{-3} \text{ mol L}^{-} \text{ min}^{-}$$ **Ans.**

EXAMPLE 36. *The decomposoition of*

$$N_2O_{5(g)} \longrightarrow NO_2(g) + NO_{3(g)}$$

proceeds as a first order reaction with a half-life period of 30 seconds at a certain temperature. If the initial concentration $[N_2O_5] = 0.4$ *M, what is the rate constant of the reaction?*

(*a*) 0.00924 sec (*b*) 0.0231 sec (*c*) 75 sec (*d*) 12 sec

(Orissa JEE, 2009)

SOLUTION. Given $t_{1/2} = 30$ sec. For a first order reaction: rate constant, $k = 0.693/t_{1/2}$. Thus, $k = 0.693/30$ sec = 0.0231 sec. So, the correct answer is (*b*).

Type : To find rate law, rate constant, order of reaction and half-life period from *k*.

(*i*) $$\text{Rate} = -\frac{\Delta x}{\Delta t} = k\,[\text{reactant}]$$

∴ $$\text{Numerical value of } k = \frac{\Delta x}{\Delta t[\text{Reactant}]}$$

(*ii*) $$\text{Half-life period, } t_{1/2} = \frac{0.693}{k}$$

(*iii*) If a reaction is *y*% complete in time, *t*, then:

$a = 100; a - x = 100 - y$

(*iv*) If it takes time, *t* for *y* % of a reactant (initial concentration = *a*) to be decomposed, Then, $a - x = a - (a \times y/100)$

EXAMPLE 37. *The experimental data for the decomposition of* N_2O_5 *in gaseous phase at 318 K is as follows :*

$$2\,N_2O_5 \longrightarrow 4\,NO_2(g) + O_2(g)$$

Time (seconds)	*[N$_2$O$_5$] mol L^{-}*	*Time (sec)*	*[N$_2$O$_5$] mol L^{-}*
0	1.36×10^{-2}		
400	1.36×10^{-2}	1600	0.78×10^{-2}
800	1.14×10^{-2}	2000	0.64×10^{-2}
1200	0.95×10^{-2}	2400	0.53×10^{-2}

Calculate rate law, rate constant, order of reaction and half life period.

SOLUTION. Rate law :

$$\text{rate} = -\frac{\Delta x}{\Delta t} = k[N_2O_5] \therefore\ k = \frac{\Delta x}{\Delta t[N_2O_5]}$$

(*i*) $$k = \frac{(1.63 - 1.36) \times 10^{-2}}{(400 - 0) \times 1.36 \times 10^{-2}}$$
$$= 4.9632 \times 10^{-4} \text{ s}^{-}$$

(*ii*) $$k = \frac{(1.36 - 1.14) \times 10^{-2}}{(800 - 400) \times 1.14 \times 10^{-2}}$$
$$= 4.8246 \times 10^{-4} \text{s}^{-}$$

(*iii*) $$k = \frac{(1.14 - 0.95) \times 10^{-2}}{(1200 - 800) \times 0.95 \times 10^{-2}}$$
$$= 5.0 \times 10^{-4} \text{s}^{-}$$

(*a*) Since the value of *k* is constant, rate = $k\,[N_2O_5]^1$.

(*b*) Mean value of rate constant,

$$k = \frac{(4.9632 \times 10^{-4} + 4.8246 \times 10^{-4} + 5.0 \times 10^{-4})\text{s}^{-}}{3}$$
$$= 4.9293 \times 10^{-4} \text{ s}^{-}.$$

(*c*) Order of reaction = 1.

(*d*) Half life period,

$$t_{1/2} = \frac{0.693}{k} = \frac{0.693}{4.9293 \times 10^{-4} \text{s}^{-}}$$
$$\simeq \mathbf{1406\ s}$$ **Ans.**

EXAMPLE 38. *Decomposition of a gas is of first order. It takes 80 minutes for 80% of the gas to be decomposed when its initial concentration is* 8×10^{-3} *mole/litre. Calculate the specific reaction rate.*

SOLUTION. We know, $$t = \left(\frac{2.303}{k}\right)\log\frac{a}{a - x}$$

where,
$$a = 8 \times 10^{-3} \text{mol L}^{-},$$
$$x = 8 \times 10^{-3} \times \left(\frac{80}{100}\right);$$
$$= 6.4 \times 10^{-3};$$
$$t = 80 \text{ minutes.}$$

Substituting the values, we get :

$$80 = \left(\frac{2.303}{k}\right)\log\frac{(8 \times 10^{-3})}{(8 \times 10^{-3} - 6.4 \times 10^{-3})}$$
$$= \left(\frac{2.303}{k}\right)\log\frac{(8 \times 10^{-3})}{1.6 \times 10^{-3}}$$
$$= \left(\frac{2.303}{k}\right)\log 5$$
$$= 2.303 \times 0.6989$$

or
$$k = \frac{(2.303 \times 0.6989)}{80 \text{ min.}}$$
$$= 0.02012 \text{ min}^{-}$$ **Ans.**

EXAMPLE 39. *The rate constant of a first order reaction is* 4.5×10^{-2} *sec*$^{-}$*. What will be the time required for the initial* *concentration of 0.4 m of the reactant to be reduced to 0.2 m.* **(ISC, 2008)**

SOLUTION. $k = 4.5 \times 10^{-2}\ s^{-}$. Since the initial concentration (0.4 m) is to be reduced to one half (= 0.2 m), the time required will be equal to half-life period, $t_{0.5}$. For a first order reaction:

$$t_{0.5} = \frac{0.693}{k} = \frac{0.693}{4.5 \times 10^{-2} s^{-}}$$

$$= \mathbf{15.4s}$$ **Ans.**

EXAMPLE 40. *A first order reaction is 20% complete in 10 min. Calculate (i) the time taken for the reaction to go to 75% completion (ii) specific reaction rate.* **(IIT, 1983)**

SOLUTION. (*i*) Here, $k = \frac{2.303}{t_{20\%}} \log \frac{a}{a-x}$

$$= \frac{2.303}{10} \log \frac{100}{100-20}$$

$$= 0.022\ \text{min}^{-}.$$

(*ii*) $$k = \frac{2.303}{t_{75\%}} \log \frac{a}{a-x}$$

$$= \frac{2.303}{t_{75\%}} \log \frac{100}{100-75=25} \text{ or } \log 4.$$

$$\therefore \quad 0.022\ \text{min}^{-} = \frac{2.303}{t_{75\%}} \log 4;$$

$$\therefore t_{75\%} = \frac{2.303}{0.022} \log 4 \text{ or } 0.6021 = 63 \text{ min.}$$

EXAMPLE 41. *A reaction is of second order with respect to a reactant. How will rate of reaction be affected if the concentration of this reactant is (i) doubled (ii) reduced half.* **(CBSE, 2009).**

SOLUTION. We know that for a second order reaction, rate = $k[A]^2$. Let [A] = a. So, rate = ka^2

(*i*) If [A] = $2a$, rate = $k(2a)^2 = 4k\,a^2$ = 4 times

(*ii*) If [A] = $a/2$, rate = $k(a/2)^2 = 1/4\ k\,a^2$ = 1/4 th.

EXAMPLE 42. *The thermal decomposition of HCO_2H is a first order reaction with a rate constant of $2.4 \times 10^{-3} s^{-}$ at a certain temperature. Calculate how long will it take for three fourths of initial quantity of HCO_2H to decompose (log 0.25 = – 0.6021)* **(CBSE, 2007; ISC, 2010)**

SOLUTION. 3/4 = 0.75; $k = 2.4 \times 10^{-3} s^{-}$. We know that:

$$t_f = \frac{2{\cdot}303}{k} \log \frac{1}{1-f}$$

where f is fraction of reactant that is left behind after a given time.

$$\therefore \quad t_{0.75} = \frac{2{\cdot}303}{2{\cdot}4 \times 10^{-3} s^{-}} \log \frac{1}{1-0{\cdot}75\,(=0.25)}$$

$$= \frac{2{\cdot}303}{2{\cdot}4 \times 10^{-3} s^{-}} [\log 1 - \log 0.25]$$

$$= \frac{2{\cdot}303}{2{\cdot}4 \times 10^{-3} s^{-}} [0 - (-0.6021) = +0.6021]$$

$$= \mathbf{577.8s}$$ **Ans.**

EXAMPLE 43. *What will be the initial rate of a first order reaction with initial concentration, 0.2 mol dm^{-3}, if its rate constant is 10^{-3} min^{-1} and how much of the reactant will be converted into the products in 200 minutes ?* **(Roorkee, 1992)**

SOLUTION. Rate constant, $k = 10^{-3}$ min^{-1}

∴ Reaction is a first order reaction

$$\text{Initial rate} = k[A] = 10^{-3}\ \text{min}^{-1} \times 0.2\ \text{mol dm}^{-3}$$
$$= 2.0 \times 10^{-4}\ \text{mol dm}^{-3}\ \text{min}^{-1}$$

For a first order reaction,

$$k = \frac{2.303}{t} \log \frac{a}{(a-x)}$$

$$\text{or} \quad \log \frac{a}{(a-x)} = \frac{kt}{2.303} = \frac{10^{-3} \times 200}{2.303} = 8.684 \times 10^{-2}$$

Taking antilog we have,

$$\frac{a}{(a-x)} = \text{antilog } 8.684 \times 10^{-2}$$

$$\text{or} \quad \frac{a}{(a-x)} = 1.221$$

$$\therefore \quad a = 1.221\,a - 1.221\,x;\ 1.221\,x = 0.221\,a$$

$$x = \frac{0.221}{1.221} a = 0.181a$$

∴ Percentage conversion

$$= \frac{0.181a}{a} \times 100 = \mathbf{18.1\%}.$$

EXAMPLE 44. *The decomposition of N_2O_5 according to the equation.*

$$2\,N_2O_5(g) \rightleftharpoons 4\,NO_2(g) + O_2(g)$$

is a first order reaction. After 30 min. from the start of the decomposition in a closed vessel, the total pressure developed is found to be 284.5 mm of Hg and on complete decomposition, the total pressure is 584.5 mm of Hg. Calculate the rate constant of the reaction.

SOLUTION. Dissociation of N_2O_5 is represented as :

$$2\,N_2O_5(g) \rightleftharpoons 4\,NO_2(g) + O_2(g)$$

From the equation, we find that two moles of N_2O_5 on decomposition give a total of five moles of gaseous species (4 mol NO_2 and 1 mol O_2).

$$\text{Hence, initial pressure of } N_2O_5 = \frac{584.5 \times 2}{5} = 233.8 \text{ mm Hg}$$

Let x be the amount of N_2O_5 decomposed after 30 minutes.

∴ After 30 min.

$$\text{Pressure due to } N_2O_5 = 233.8 - x$$
$$\text{Pressure due to } NO_2 = 2x$$
$$\text{Pressure due to } O_2 = \frac{x}{2}$$

Total pressure after 30 minutes = 284.5 mm Hg

$$\therefore \quad (233.8 - x) + 2x + \frac{x}{2} = 284.5$$

$$\therefore \quad x = \frac{284.5 - 233.8}{1.5}$$

$$= 33.8 \text{ mm Hg}$$

Hence pressure of N_2O_5 after 30 minutes

$$= 233.8 - 33.8$$

$$= 200 \text{ mm Hg}$$

$$\therefore \quad k = \frac{2.303}{t}\log\frac{a}{(a-x)}$$

$$= \frac{2.303}{30}\log\frac{233.8}{200}$$

$$= \frac{2.303}{30} \times 0.0678$$

$$= 5.20 \times 10^{-3} \text{ min}^{-1}.$$

Example 45. *The reaction, $SO_2Cl_2 \longrightarrow SO_2 + Cl_2$ is a first order reaction. What percentage of SO_2Cl_2 is decomposed on heating it for 90 minutes ($k = 2.2 \times 10^{-5}\ s^{-}$ at 595 K).*

Solution. Let initial concentration (a) of SO_2Cl_2

$$= 100 \text{ mol L}^{-}$$

Degree of dissociation of $SO_2Cl_2 = x$ mol L^{-} (say)

Using the first order equation

$$t = \frac{2.303}{k}\log\frac{a}{a-x}$$

We have,

$$90 \times 60 = \frac{2.303}{2.2 \times 10^{-5}}\log\frac{100}{100-x}$$

$$[\because 90 \text{ min} = 60 \times 90\text{s} = 5400 \text{ s}]$$

$$5400 = \frac{2.303}{2.2 \times 10^{-5}}\log\frac{100}{100-x}$$

$$\log\frac{100}{100-x} = \frac{5400 \times 2.2 \times 10^{-5}}{2.303}$$

$$= 0.0516$$

Taking antilogs of both sides, we get

$$\frac{100}{100-x} = \text{antilog } 0.0516 = 1.126$$

$$\therefore \quad \mathbf{x = 11.19.}$$

Example 46. *Show that the time required for the completion of 75% of a reaction of first order is twice the time required for the completion of 50% of the reaction.* **(ISC, 2010)**

Solution. (*i*) $t_{1/2} = \dfrac{2\cdot303}{k}\log\dfrac{1}{1-0.5}$

$$[\because 50\% = 50/100 = 0.5 = 1/2\,]$$

or

$$t_{1/2} = \frac{2\cdot303}{k}\log\frac{1}{0\cdot5} = \frac{2\cdot303}{k}\log 2$$

(*ii*)

$$t_{0.75} = \frac{2\cdot303}{k}\log\frac{1}{1-0\cdot75}$$

$$= \frac{2\cdot303}{k}\log\frac{1}{0.25} = \frac{2\cdot303}{k}\log 4$$

Dividing (*i*) and (*ii*), we get $\dfrac{t_{0.75}}{t_{0.5}} = \dfrac{\log 4}{\log 2}$

$$= \frac{0\cdot6020}{0\cdot3010} = \mathbf{2}$$

Ans.

Example 47. *The half change time for the thermal decomposition of N_2O_5 at 303 K is 4.2 hours. Using this date, calculate the following :*

(i) how much of N_2O_5 will be left behind after 16 hours if initial concentration of N_2O_5 is 100 g.

(ii) If the number of molecules of N_2O_5 present initially are 5×10^{20}, after what time, the number of molecules left behind would be 10^{18} ?

Solution. Hint. Find $(a - x) = 0.9822$ g; $t = 21.5$ hrs.

Example 48. *Show that for a unimolecular reaction, the time needed for 99.9% of the reaction to take place is ten times as needed for half of the reaction.*

Solution. Let initial concentration of reactant = 1 mol L^{-}.

Using first order equation, we have :

(*i*) For 99.9% of the reaction to take place, we have.

$$t_{99.9\%} = \frac{2.303}{k}\left[\log\frac{1}{1-\dfrac{99.9}{100}} \textit{ or } \frac{100}{0.1} = \log 1000 = \log 10^3 = 3\right]$$

$$t_{99.9\%} = \frac{2.303}{k} \times 3 \qquad ...(i)$$

For half *i.e.*, 50% of the reaction to take place, we have :

$$t_{50\%} = \frac{2.303}{k}\left[\log\frac{1}{1-\dfrac{50}{100}} \text{ or } \frac{100}{50} = \log 2 = 0.301\right]$$

$$= \frac{2.303}{k} \times 0.301 \qquad ...(ii)$$

Dividing equation (*i*) by (*ii*), we get :

$$\frac{t_{99.9\%}}{t_{50\%}} = \frac{2.303}{k} \times 3 \times \frac{k}{2.303 \times 0.301} \simeq 10$$

$\therefore$ Time taken for 99.9% is 10 times the time taken for half of the reaction.

Type : (*i*) Half life $t_{1/2}$ or $t_{0.5} = \dfrac{0.693}{k}$.

Example 49. *The first order reaction is found to have a rate constant $k = 7.39 \times 10^{-5}$ sec^{-}. Find the half life of this reaction.*

(CBSE, 1981, 2013, DSB., 1973, AISB, 1987, HSB and PSEB 1989)

Solution. Given: half-life $t_{1/2} = 7.39 \times 10^{-5}$ sec^{-}

We know, rate constant,

$$k = \frac{0.693}{t_{1/2}} = \frac{0.693}{7.39 \times 10^{-5} s^{-}}$$

$$= 9377.54 s^{-}$$

$$= \left(\frac{9377.54}{60 \times 60}\right) \text{ hours}$$

$$= 2.6 \text{ hours}$$

Ans.

Example 50. *For which order reaction, unit of rate is equal to unit of rate constant?* **(AIPMT, 2009)**

Solution. We know that rate constant, $k = (\text{mol L}^{-})^{1-n}$ time^{-} where n is the order of reaction.

Put $n = 0$ (i.e; zero order reaction) in $k = (\text{mol L}^{-})^{1-n}$ time^{-}, we get:

$k = (\text{mol L}^{-})^{1-0}$ time^{-} = **mol L^{-} time^{-}**.

Also for zero order reaction, rate = $\frac{dx}{dt} = k[\text{A}]^0 = k$ *i.e.,* rate constant.

Hence, unit of rate = unit of rate constant = mol L^{-} time^{-}.

Example 51. *If half life of a 1st order reaction in A is 2 min (a) How long will it take [A] to reach 25% of its initial concentration, or 1/4 of the reactant to be left behind. (b) 10% of its initial conc.* **(PSEB, 2013)**

Solution. $t_{1/2} = \frac{0.693}{k} \quad \therefore \quad k = \frac{0.693}{t_{1/2}}$ or

$$k = \frac{0.693}{2} = 0.3465\,\text{min}^{-}$$

(*a*) Let initial conc.,

$$a = 100 \text{ mol L}^{-}. \quad \therefore \quad a - x = 25 \text{ mol L}^{-}.$$

But $\quad k = \frac{2.303}{t}\log\frac{a}{a-x}$ or

$$0.3465 = \frac{2.303}{t}\log\frac{100}{25}$$

$$t = \frac{2.303}{0.3465}\log 4 = \frac{2.303}{0.3465} \times 0.6020$$

$$= 4 \text{ min}$$

(*b*) Let initial conc., $a = 100$ mol L^{-}. $\therefore$ $a - x = 10$ mol L^{-}

But, $\quad k = \frac{2.303}{t}\log\frac{a}{a-x}$

$$\therefore \quad 0.3465 = \frac{2.303}{t}\log\frac{100}{10} \text{ or } 10$$

$$\therefore \quad t = \frac{2.303}{0.3465} \times 1 = 6.65\,\text{min}.$$

Example 52. *Benzene diazonium chloride decomposes as* $C_6H_5N_2Cl \rightarrow C_6H_5Cl + N_2$. *The volume of* N_2 *evolved at different intervals was measured and following results were obtained.*

Time (min)	*0*	*20*	*70*	*∞*
Vol. of N2 (mL)	*0*	*10*	*32*	*162*

Show that reaction is of first order.

Solution. Here $a \propto V_\infty$ and $x \propto V_t \quad \therefore a - x \propto V_\infty - V_t$

At 20 min, $\quad k = \frac{2.303}{t}\log\frac{a}{a-x}$

$$= \frac{2.303}{20}\log\frac{162}{162-10} = 3.186 \times 10^{-3}$$

At 70 min $\quad k = \frac{2.303}{t}\log\frac{a}{a-x}$

$$= \frac{2.303}{70}\log\frac{162}{162-32} = 3.144 \times 10^{-3}$$

Example 53. *A reaction that is of 1st order w.r.t. reactant A has a rate constant 6 min*$^{-}$. *If we start with [A] = 5 mol L*$^{-}$, *when would [A] reach the value of 0.05 mol L*$^{-}$ *?*

Solution. $\quad t = \frac{2.303}{k}\log\frac{a}{a-x}$

$$\therefore \quad t = \frac{2.303}{6}\log\frac{5}{0.05} \quad \therefore \quad t = 0.768 \text{ min.}$$

Example 54. *The rate of a first-order reaction is 0.04 mol L*$^{-}$ *s*$^{-1}$ *at 10 minutes and 0.03 mol L*$^{-}$*s*$^{-1}$ *at 20 minutes after initiation. Find the half-life of the reaction.* **(IIT, 2001)**

Solution. For a first order reaction, A $\longrightarrow$ Products.

$$\text{rate} = -\frac{d[\text{A}]}{dt} = k[\text{A}]$$

or $\quad -\frac{d[\text{A}]}{[\text{A}]} = k\,dt$

$$\text{Integrating} \; -\int_{[\text{A}]_1}^{[\text{A}]_2}\frac{d[\text{A}]}{\text{A}} = k\int_{t_1}^{t_2} dt$$

i.e., $\quad \ln\frac{[\text{A}]_1}{[\text{A}]_2} = k(t_2 - t_1)$

Hence, $\quad \ln\frac{(\text{rate})_1}{(\text{rate})_2} = k(t_2 - t_1)$

or $\quad k = \frac{\ln[(\text{rate})_1/(\text{rate})_2]}{(t_2 - t_1)}$

$$= \frac{\ln(0.04/0.03)}{(20-10)\,\text{min}}$$

$$= 2.88 \times 10^{-2}\,\text{min}^{-1}$$

For a first order reaction, $t_{0.5} = \frac{0.693}{k}$

$$= \frac{0.693}{2.88 \times 10^{-2}\,\text{min}^{-}}$$

$$= \mathbf{24.06\ min.}$$

Example 55. *In an experiment when the initial concentrations of A and B are 0.1 M each, the initial rate is 1.0 × 10*$^{-4}$ *M per minute. In the second experiment when the initial concentrations of A and B are 0.1 M and 0.30 M respectively, the initial rate is 9.0 × 10*$^{-4}$ *M per minute. In the third experiment when the initial concentrations of both A and B are 0.30 M, the initial rate is 2.7 × 10*$^{-3}$ *M per minute.*

(a) Write the rate law for this reaction.

(b) Calculate the value of specific rate constant for this reaction. **(Roorkee, 1987)**

Solution. Let the order of the reaction with respect to A and B be a and b respectively.

Now according to rate law, $\frac{dx}{dt} = k[\text{A}]^a[\text{B}]^b$

According to the given data

(*i*) $1.0 \times 10^{-4}\,\text{M min}^{-1} = k\,[0.1\,\text{M}]^a\,[0.1\,\text{M}]^b$

(*ii*) $9.0 \times 10^{-4}\,\text{M min}^{-1} = k\,[0.1\,\text{M}]^a\,[0.3\,\text{M}]^b$

(*iii*) $2.7 \times 10^{-3}\,\text{M min}^{-1} = k\,[0.3\,\text{M}]^a\,[0.3\,\text{M}]^b$

For calculating the value of b, divide (ii) by (i)

$$\frac{9.0\times10^{-4}}{1.0\times10^{-4}} = \frac{[0.3M]^b}{[0.1M]^b}$$

or $$9 = (3)^b \text{ or } (3)^2 = (3)^b \therefore b = 2$$

Similarly, for calculating 'a' divide (iii) by (ii)

$$\frac{2.7\times10^{-3}}{9\times10^{-4}} = \frac{[0.3\text{M}]^a}{[0.1\text{M}]^a} \text{ or } (3)^1 = (3)^a$$

$$\therefore \qquad a = 1$$

Thus the required rate law is $\frac{dx}{dt} = k[A][B]^2$

(b The value of k can be obtained by substituting the values of a and b in either of the three equations.

For example,

$$1.0\times10^{-4}\text{ M min}^{-1} = k\,[0.10\text{ M}]\,[0.10\text{ M}]^2$$

$$\therefore \qquad k = \frac{1.0\times10^{-4}\text{M min}^{-1}}{[0.10\text{M}]^3}$$

$$= 1.0\times10^{-1}\text{ M}^{-2}\text{ min}^{-1}$$

$$= \mathbf{0.10\ M^{-2}\ min^{-1}}$$

$$= \mathbf{0.10\ L^2\ mol^{-2}\ min^{-}}.$$

EXAMPLE 56. *The experimental data for the reaction :*

$$2A + B_2 \longrightarrow 2AB \text{ is :}$$

Experiment No.	*[A]*	*[B]*	*rate (mol^{-1} s^{-})*
1.	*0.50*	*0.50*	*1.6×10^{-4}*
2.	*0.50*	*1.00*	*3.2×10^{-4}*
3.	*1.00*	*1.00*	*3.2×10^{-4}*

Write the most probable rate equation for the reaction giving reasons for your answer. **(Roorkee, 1991)**

SOLUTION. (i) According to the given data, rate of reaction gets doubled when concentration of B_2 is doubled keeping that of A constant.

$$\therefore \qquad \text{rate} \propto [B_2]^2$$

(ii) Rate of reaction does not change if the conc. of A is doubled keeping that of B constant.

$$\therefore \qquad \text{rate} \propto [A]^0$$

$$\therefore \qquad \text{Rate law is : } \frac{dx}{dt} = k[B_2]^1.$$

Type : When amount or percentage of the reactant that will be left after a given time t is to be found then use :

(i) $t_{1/2} = \frac{0.693}{k}$ and

(ii) $t_f = \frac{2.303}{k}\log\frac{1}{1-f}$ where f is the fraction of the reactant that is left behind after a given time.

(iii) When time is to be found out for y% of the reactant to be decomposed, then $f = \frac{y}{100}$

EXAMPLE 57. *The half-life of a first order reaction is 30 min. (i) Calculate the specific rate constant of the reaction. (ii) What fraction of the reactant remains after 70 min ? (iii) How long would be required for 25% of the reactant to be decomposed ?*

SOLUTION. We know, half life, $t_{1/2} = \frac{0.693}{k}$; $t_{1/2} = 30$ min. Substituting the values,

we get : $$30\text{ min} = \frac{0.693}{k}$$

or $$k = \frac{0.693}{30\text{ min}}$$

$$= 0.0231\text{ min}^{-} \qquad \textbf{Ans.}$$

(ii) $$t = 70\text{ min},$$

$$k = 0.0231\text{ min}^{-}.$$

We know, $$t = \left(\frac{2.303}{k}\right)\log\left(\frac{a}{af}\text{ or }\frac{1}{f}\right)$$

$$= \left(\frac{2.303}{k}\right)\log(-f).$$

Substituting the values, we get :

$$70\text{ min.} = \frac{2.303\log - f}{0.0231\text{min}^{-}}$$

or $$\log(-f) = \frac{(70\text{min}\times0.0231\text{min}^{-})}{2.303}$$

$$= 0.7021$$

Taking antilog of both sides, we get :

or $$f = \text{antilog}\,(-0.7021)$$

$$= -1 - 0.7021 + 1$$

$$= \bar{1}.2979 = 0.1985.$$

Hence fraction of the reactant left after 70 minutes = 0.1985 or 0.1985 × 100 = **19.85%.**

(iii) We know, $$t_{25\%} = \frac{2.303}{k}\log\frac{1}{1-f}$$

$$= \left(\frac{2.303}{k}\right)\log\frac{1}{1-0.25}$$

or $$\frac{1}{0.75}\text{or } 1.333$$

Substituting the values, we get :

$$t_{25\%} = \left(\frac{2.303}{0.0231}\right)\log 1.333$$

or $$t_{25\%} = \left(\frac{2.303}{0.0231}\right)\times 0.1248$$

$$= 12.44\text{ min} \qquad \textbf{Ans.}$$

EXAMPLE 58. *A first order reaction (A $\longrightarrow$ Products) has a specific reaction rate of 2.1×10^{-3} sec^{-}. How much time will it take for 99% of A to be consumed ?* **(PSEB, 1988 S)**

Solution. We know that, $t_f = \frac{2.303}{k}\log\frac{1}{1-f}$

For f = 99% or 0.99,

$$t_{0.99} = \frac{2.303}{2.1\times10^{-3}\ \text{sec}^{-}}$$

$$\log\frac{1}{1-0.09} = \frac{2.303}{2.1\times10^{-3}\ \text{sec}^{-}}$$

log 1/0.01 or 10^2)

$$= \frac{2.303}{2.1\times10^{-3}\ \text{sec}^{-}}\times 2$$

= 2.19 × 10^3 sec **Ans.**

Example 59. *For the decomposition of a compound AB at 600 K, the following data were obtained.*

	[AB] mol dm^{-3}	*Rate of decomposition of AB in mol dm^{-3}s^{-}*
(*i*)	0.20	2.75 × 10^{-8}
(*ii*)	0.40	11.0 × 10^{-8}
(*iii*)	0.60	24.75 × 10^{-8}

The order for the decomposition of AB is:

(a) 0 *(b) 1* *(c) 2* *(d) 1.5*

(Karnataka CET, 2009)

Solution. We know that, rate = $k[AB]^n$ (rate equation)

For

Case (*i*), $2.75\times10^{-8} = k[0.2]^n$

Case (*ii*), $11.0\times10^{-8} = k[0.4]^n$

Case (*iii*), $24.75\times10^{-8} = k[0.6]^n$

Dividing (*ii*) by (*i*), we get,

$$\frac{11\cdot0\times10^{-8}}{2\cdot75\times10^{-8}} = \frac{k[0.4]^n}{k[0.2]^n}$$

or $4 = 2^n;\ 2^2 = 2^n$ or $n = 2$.

Similarly, n = 2 when case (*iii*) is divided by case (*i*). So, order of reaction is 2 and the correct answer is (*c*).

Example 60. *For a first order reaction, calculate the ratio between the time taken for the completion of three fourth of the reaction and the time taken for the completion of half the reaction.*

Solution.(*i*) $t_{0.5} = \frac{2.303}{k}\log\frac{1}{1-0.5}$

$$= \frac{2.303}{k}\log 2$$

(*ii*) $t_{0.75} = \frac{2.303}{k}\log\frac{1}{1-0.75}$

$$= \frac{2.303}{k}\log 4 \quad \left[\because \frac{3}{4} = 0.75\right]$$

$$\therefore \quad \frac{t_{0.75}}{t_{0.5}} = \frac{\log 4}{\log 2} = \frac{0.6020}{0.3010} = \frac{2}{1}.$$

Example 61. *A first order reaction is 20% complete in 20 minutes. Calculate the time taken for the reaction to go to 80% completion.* **(IIT, 1979 modified, CBSE, 1999)**

Solution. $t_{20\%} = \frac{2.303}{k}\log\frac{100}{100-20}$

$$\therefore \quad 20 = \frac{2.303}{k}\log\frac{5}{4}$$

$$\therefore \quad k = \frac{2.303}{20}\log\frac{5}{4}$$

$$t_{80\%} = \frac{2.303}{k}\log\frac{100}{100-80}$$

i.e., $5 = 5 = \frac{20\log 5}{\log 5/4} = \frac{20\times0.6990}{\log 5-\log 4}$

$$= \frac{20\times0.6990}{0.6990-0.6021}$$

= 144.27 minutes.

Example 62. *(a) Derive a general expression for the time taken for the reactant to reduce to nth fraction (b) The rate constant of first order reaction is 60 s^{-}. How much time will it take to reduce the initial concentration of the reactant to its 1/16th value?* **(NCERT)**

Solution. (*a*) $t = \frac{2.303}{k}\log\frac{a}{a-x}$.

Put $a - x = \frac{a}{n}$ and we have :

$$t = \frac{2.303}{k}\log\frac{a}{a/n} \quad \text{or}$$

$$t = \frac{2.303}{k}\log n.$$

(*b*) $t = \frac{2.303}{k}\log\frac{a}{a-x}$

(first order equation); $a - x = \frac{a}{16}$

Substituting the values of k and $a - x$ in above equation, we get :

$$t = \frac{2.303}{60\,s^{-}}\log\frac{a}{a/16}$$

$$= \frac{2.303}{60\,s^{-}}\log 16 = \frac{2.303}{60\,s^{-}}\times 1.2041$$

t = **4.62 × 10^{-2} s** **Ans.**

Example 63. *A first order reaction undergoes 25% completion in 20 minutes. How much percent will it complete in one hour 40 minutes ?*

Solution. Using first order equation :

$$t = \frac{2.303}{k}\log\frac{a}{a-x}$$

We have, $t_{25\%} = \frac{2.303}{k}\log\frac{100}{100-25} = \frac{2.303}{k}\log\frac{100}{75}$

$$= \frac{2.303}{k}[\log 100 - \log 75]$$

$$= \frac{2.303}{k} \times 0.1249 \qquad ...(i)$$

$$100 = \frac{2.303}{k}\log\frac{100}{100-x} \qquad ...(ii)$$

[x = percent completed; 1 hr. 40 min = 100 min.]

Dividing (*ii*) by (*i*), we get

$$\frac{100}{t_{25\%}} = \frac{\frac{2.303}{k}\log\frac{100}{100-x}}{\frac{2.303}{k}\times 0.1249}$$

$$0.1249 \times \frac{100}{20} = \log\frac{100}{100-x}$$

$$= \log 100 - \log(100 - x)$$

$$= 2 - \log(100 - x)$$

$$0.6245 = 2 - \log 100 - x$$

$$\log 100 - x = 2 - 0.6245 = 1.3755$$

Taking antilog of both sides, we get

$$\therefore \quad 100 - x = \text{antilog } 1.3755 = 23.74$$

$$\therefore \quad x = 100 - 23.74$$

$$= \mathbf{76.26\%}$$

EXAMPLE 64. *Using the following data prove that the decomposition of H_2O_2 in aqueous solution is a first order reaction.*

't' (minuts)	*0*	*10*	*20*
'n' (ml)	*22.8*	*13.8*	*8.2*

Where n represents the number of ml of $KMnO_4$ required to decompose a definite volume of H_2O_2.

SOLUTION. (*i*) $t = 0$, the initial concentration (a) of H_2O_2 is proportional to 22.8 ml of $KMnO_4$.

(*ii*) At $t = 10$ minutes, the concentration $(a - x)$ of H_2O_2 is proportional to 13.8 ml of $KMnO_4$.

(*iii*) At $t = 20$ minutes, the concentration $(a - x)$ of H_2O_2 is proportional to 8.2 ml of $KMnO_4$.

Using first order equation

$$t = \frac{2.303}{k}\log\frac{a}{a-x}$$

We have, (1)

$$10 \times 60\, s = \frac{2.303}{k}\log\frac{22.8}{13.8}$$

[$\therefore$ 10 minutes = 10 × 60 seconds]

$$\therefore \quad k = \frac{2.303}{600\,s}[\log 22.8 - \log 13.8]$$

$$= \frac{2.303}{600\,s}[1.358 - 1.140]$$

$$= = \frac{2.303}{600} \times 0.218 = \mathbf{8.37 \times 10^{-4} s^{-}}$$

(2)

$$20 \times 60\, s = \frac{2.303}{k}\log\frac{22.8}{8.2}$$

[$\therefore$ 20 minutes = 20 × 60 seconds]

$$\therefore \quad k = \frac{2.303}{1200\,s}[\log 22.8 - \log 8.2]$$

$$= \frac{2.303}{1200\,s}[1.358 - 0.914]$$

$$= \frac{2.303}{1200} \times 0.444 = \mathbf{8.52 \times 10^{-4}\ s^{-}}$$

$$\text{Average value of } k = \frac{8.37 \times 10^{-4} + 8.52 \times 10^{-4}}{2}$$

$$= \mathbf{8.45 \times 10^{-4} s^{-}}$$

Since the value of k is almost same in all the experiments, the reaction is of first order.

EXAMPLE 65. *The half-life for first order reaction $PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$ is 10 minutes. In what period of time would the concentration of PCl_5 be reduced to 10% of the original concentration?*

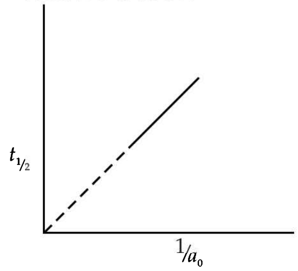
SOLUTION. (*i*) $k = \frac{0.693}{t_{1/2}} = \frac{0.693}{10\,\text{min}} = 0.0693\,\text{min}^{-}$

(*ii*) $t = \frac{2.303}{k}\log\frac{a}{a-x} = \frac{2.303}{0.0693\,\text{min}^{-}}$

$$\left[\log\frac{100}{10} = \log 10 = 1\right]$$

$$t = \frac{2.303}{0.0693\,\text{min}^{-}} = 33.23\,\text{min} \quad \textbf{Ans.}$$

EXAMPLE 66. *The following graph shows how $t_{1/2}$ (half life) of a reactant, R changes with the initial reactant concentration, a_0. The order of the reaction will be:*



(*a*) 0 (*b*) 1 (*c*) 2 (*d*) 3 **(West Bangal JEE, 2009)**

SOLUTION. We know that half-life period $t_{1/2} \propto \frac{1}{a_0^{n-1}}$ or $a_0^{n-1} = a_0^1$ (given) where a_0 = initial reactant concentration.

$\therefore \quad n - 1 = 1$. Hence, $n = 1 + 1 = 2$,

where n is the order of reaction. So, the correct answer is (*c*).

EXAMPLE 67. *For the reaction, $SO_2 + \frac{1}{2}O_2 \rightleftharpoons SO_3$, if we write $K_p = K_c(RT)^x$, then x becomes:*

(*a*) –1 (*b*) $-\frac{1}{2}$ (*c*) $\frac{1}{2}$ (*d*) 1 **(West Bengal, JEE, 2009)**

SOLUTION. Given:

$$SO_2(g) + \frac{1}{2}O_2(g) \rightleftharpoons SO_3(g)$$

$$1\text{mol} \qquad \frac{1}{2}\text{mol} \qquad 1\text{mol};\ \Delta n_g = 1 - \left(1 + \frac{1}{2}\right) = \frac{-1}{2}$$

Since $K_p = K_c\,(RT)^x$, we have $x = \Delta n_g = \frac{-1}{2}$ explained above. So, the correct answer is (*b*).

Example 68. *The half life period of a first order reaction is 60 minutes. What percentage of the reactant will be left after 120 minutes ?*

Solution. $t_{0.5} = 60$ min. Total time = 120 min.

$\therefore \quad n =$ no. of half lives $= \frac{120 \text{ min}}{60 \text{ min}} = 2$

$\therefore$ Amount of substance left after n (= 2) half lives

$$= \frac{A_0}{2^n} = \frac{A_0}{2^2} = \frac{A_0}{4} \times 100 = 25\ \%\ \text{of}\ A_0$$

(= initial amount).

Example 69. *The following rate data were obtained at 300 K for the reaction 2A + B → C + D.*

Experiment No.	*[A] mol L$^-$*	*[B] mol L$^-$*	*Rate of formation of D mol L$^-$ min$^-$*
1	0.1	0.1	5.0×10^{-3}
2	0.3	0.2	6.0×10^{-2}
3	0.3	0.4	2.4×10^{-1}
4	0.4	0.1	2.0×10^{-2}

Calculate (1), the order with respect to A and B for the reaction (2) Rate constant for the reaction and (3) the rate of formation of D when : [A] = 0.5 mol L$^-$ and [B] = 0.2 mol L$^-$.

(CBSE, 1996; ISC, 2011)

Solution. Rate of reaction is given as : Rate = $k\,[A]^x[B]^y$.

(*i*) For experiment 1, $\quad 5.0 \times 10^{-3} = k(0.1)^x(0.1)^y$

(*ii*) For experiment 2, $\quad 6.0 \times 10^{-2} = k(0.3)^x\,(0.2)^y$

(*iii*) For experiment 3, $\quad 2.4 \times 10^{-1} = k(0.3)^x\,(0.4)^y$

(*iv*) For experiment 4, $\quad 2.0 \times 10^{-2} = k(0.4)^x\,(0.1)^y$

Determination of *x*. Dividing equation (*i*) and (*iv*), we get :

$$\frac{5.0\times10^{-3}}{2.0\times10^{-2}} = \frac{k\ (0.1)^x(0.1)^y}{k\ (0.4)^x(0.1)^y} \quad \text{or} \quad \left(\frac{1}{4}\right)^1 = \left(\frac{1}{4}\right)^x.$$

Hence, **x = 1.**

Determination of *y*. Dividing equation (*ii*) by (*iii*), we get :

$$\frac{6\times10^{-2}}{2.4\times10^{-}} = \frac{k}{k}\,\frac{(0.3)^x\,(0.2)^y}{(03)^x\,(0.4)^y}$$

$$\text{or} \quad \frac{1}{4} = \left(\frac{1}{2}\right)^2 = \left(\frac{1}{2}\right)^y.$$

Hence, $\quad$ **y = 2**

From experiment (*i*), we see that

$$5 \times 10^{-3} = k(0.1)^{x\,=\,1}\,(0.1)^{y\,=\,2}$$

$$\text{Thus,} \quad k = \frac{5\times10^{-3}}{0.1\times0.1\times0.1} = 5$$

$$\text{Hence,} \quad \text{rate} = k(\text{A})^x\,(\text{B})^y = 5 \times (0.5)^1(0.2)^2$$

$$= 0.1\ \text{mol L}^-\ \text{min}^-.$$

Example 70. *Nitrogen pentoxide decomposes according to the equation,*

$$2N_2O_5(g) \longrightarrow 4NO_2(g) + O_2(g).$$

This first order reaction was allowed to proceed at 40°C and the data below were collected.

[N_2O_5]M	*Time (min)*
0.400	*0.00*
0.289	*20.0*
0.209	*40.0*
0.151	*60.0*
0.109	*80.0*

(*a*) *Calculate the rate constant. Include units with your answer.*

(*b*) *What will be the concentration of N_2O_5 after 100 minutes?*

(*c*) *Calculate the initial rate of reaction.* **(CBSE, 2011)**

Solution. (*a*) a = Initial concentration of N_2O_5, [N_2O_5] = 0.400 M; [N_2O_5] after 20 minutes (t) = 0.289 M (= $a - x$). But rate constant (k) is:

$$k = \frac{l}{t}\ln\frac{a}{a-x} = \frac{1}{20\,\text{min}}\log\frac{0\cdot400}{0\cdot289}\times 2\cdot303$$

$$= \frac{1}{20}\ [\log 400 - \log 289] \times 2\cdot303$$

$$= \frac{1}{20}\ [(2.6020 - 2.4609) \times 2.303]$$

$$= 0.0162\ \text{min}^-$$

$\therefore$ Rate constant,

$k = 0.0162\ \text{min}^-$ **Ans.**

(*b*) When t = 100 minutes, let concentration after 100 min = $a - x'$

$$\text{Thus:} \quad k = \frac{1}{t}\ln\frac{a}{a-x},$$

$$0.0162 = \frac{1}{100}\times 2.303\log\frac{0.400}{a-x'}$$

$$\text{or} \quad \frac{0.0162\times100}{2.303} = \log 0.400 - \log\,(a-x');$$

$$0.7034 = -\,0.3979 - \log\,(a - x')$$

$$\therefore \quad \log\,(a - x') = -\,1.1013;$$

$$a - x' = \text{antilog}\,(-1.1013) = \mathbf{0.07919\ M}$$

$\therefore$ Concentration of N_2O_5 after 100 minutes = 0.07919 M.

(*c*) We know,

Initial rate = rate constant, (k) × initial concentration of N_2O_5.

Here: Initial rate = 0.0162 × 0.400

$$= \mathbf{6.48 \times 10^{-3}\ mol\ dm^{-3}\ min^{-1}}$$ **Ans.**

Example 71. *Rate of reaction A + B ⟶ products is given below as a function of different initial concentrations of A and B.*

[A] (mol/L)	*[B] (mol/L)*	*Initial rate (mol $L^{-}min^{-}$)*
0.01	0.01	0.005
0.02	0.02	0.010
0.01	0.02	0.005

Determine the order of the reaction with respect to A and with respect to B. What is the half life of A in the reactions ?

(IIT, 1982)

Solution. Let the rate r of a reaction between A and B be given by $r = k\,[A]^a[B]^b$.

According to the given data, initial rate becomes twice when the concentration of A is increased to double its value. Hence, the order of reaction with respect to A *i.e.,* a is equal to 1. However, the rate remains constant when the concentration of B is doubled. Thus, the order of reaction with respect to B *i.e., b* is equal to zero.

Total order = 1 + 0 = 1.

As the initial rate is equal to 0.005 mol L^{-} when concentration of A and B is equal to 0.01 mol L^{-}.

$$\therefore \qquad 0.005 = k[0.01]^1\,[0.01]^0$$

$$\text{or} \qquad k = \frac{0.005}{0.01} = \mathbf{0.5\ min^{-1}}$$

$$\therefore \qquad \text{Half life of A} = \frac{0.693}{0.5} = \mathbf{1.386\ min.}$$

Example 72. *For the reaction A + B → Products, it is observed that:*

(i) On doubling the initial concentration of A only, the rate of reaction is also doubled.

(ii) On doubling the initial concentration of both A and B, there is a change by a factor of 8 in the rate of the reaction. The rate of reaction is given by:

(*a*) rate = $k[A][B]^2$ (*b*) rate = $k\,[A]^2[B]^2$

(*c*) rate = $k[A][B]$ (*d*) rate = $k[A]^2[B]$

(CBSE-PMT, 2009)

Solution. We know that, rate,

$$R = k\,[A]^m[B]^n \qquad ...(i)$$

$$\text{But} \qquad 2R = k[2A]^m[B]^n \qquad ...(ii)$$

$$\text{and} \qquad 8R = k[2A]^m\,[2B]^n \qquad ...(iii)$$

Dividing equation (*i*) by (*ii*), we get:

$$\frac{R}{2R} = \frac{k \times [A]^m \times [B]^n}{k \times 2^m \times [A]^m \times [B]^n};$$

$$\frac{1}{2^1} = \frac{1}{2^m}.\ \text{So, } m = 1$$

Dividing equation (*ii*) by (*iii*), we get

$$\frac{2R}{8R} = \frac{k \times 2^m \times [A]^m \times [B]^n}{k \times 2^m \times [A]^m \times 2^n \times [B]^n};$$

$$\frac{1}{4} = \frac{1}{2^n};\ \frac{1}{2^2} = \frac{1}{2^n};\ \boldsymbol{n = 2}$$

Thus, rate = $k\,[A][B]^2$. So the correct answer is (*a*).

Example 73. *The kinetics of hydrolysis of methyl acetate in excess of hydrochloric acid solution at 298 K were followed by withdrawing 2 mL of the reaction mixture at intervals of time (t), adding 50 mL of water and titrating against baryta-water. The following results were obtained :*

t (min)	*0*	*10*	*28*	*58*	*115*	*∞*
Titre (mL)	*18.5*	*19.1*	*20.1*	*21.65*	*24.6*	*34.8*

Determine the velocity constant of the hydrolysis.

Solution. Initial concentration, a = 34.8 – 18.5 = 16.3. At time 10 min, $a - x$ = 34.8 – 19.1 = 15.7; at time 28 min., $a - x$ = 34.8 – 20.1 = 14.7; at time 58 min., $a - x$ = 34.8 – 21.6 = 13.2 and at time 115 min., $a - x$ = 34.8 – 24.6 = 10.2. We know,

$$k = \left(\frac{2.303}{10}\right)\log\frac{a}{a-x} \qquad ...(i)$$

(*a*) At time, 10 min.

$$k = \left(\frac{2.303}{10}\right)\log\frac{16.3}{15.7}$$

$$= 0.2303 \log 1.0382 = 0.2303 \times 0.01628$$

$$= 3.749 \times 10^{-3}$$

(*b*) At time, 28 min.,

$$k = \left(\frac{2.303}{28}\right)\log\frac{16.3}{14.7}$$

$$= \frac{2.303}{28}\log 1.1088$$

$$= \left(\frac{2.303}{28}\right) \times 0.04485 = 3.689 \times 10^{-3}$$

(*c*) At time, 58 min.

$$k = \frac{2.303}{58}\log\frac{16.3}{13.2} = \left(\frac{2.303}{58}\right)\log 1.2348$$

$$= \left(\frac{2.303}{58}\right) \times 0.0916 = 3.637 \times 10^{-3}$$

(*d*) At time 115 min,

$$k = \frac{2.303}{115}\log\frac{16.3}{10.2}$$

$$= \left(\frac{2.303}{115}\right)\log 1.5980 = \left(\frac{2.303}{115}\right)$$

$$= 0.2035 = 4.07 \times 10^{-3}$$

Average value of

$$k = (3.749 \times 10^{-3} + 3.689 \times 10^{-3} + 3.637 \times 10^{-3} + 4.07 \times 10^{-3})/4$$

$$= 0.003786$$

Ans.

Type : (*i*) In rate = $k[A]^a[B]^b$, order, $n = a + b$

Example 74. *The rate of reaction,* $2NO + Cl_2 \longrightarrow 2NOCl$ *is doubled when concentration of* Cl_2 *is doubled and it becomes 8 times when concentration of both NO and* Cl_2 *are doubled. Deduce the order of this reaction.* **(CBSE, 2000S)**

Solution. The rate of reaction is given as :

$$\text{Rate} = k[NO]^x[Cl_2]^y. \qquad ...(A)$$

Given :

Experiment No.	*[NO]*	*[Cl_2]*	*Rate*
1	0.1	0.1	1 (say)
2	0.1	0.2	2 (given)
3	0.2	0.2	8 (given)

(*i*) For experiment 1, $1 = k(0.1)^x(0.1)^y$

(*ii*) For experiment 2, $2 = k(0.1)^x(0.2)^y$

(*iii*) For experiment 3, $8 = k(0.2)^x(0.2)^y$

Determination of y. Dividing equations (*i*) and (*ii*), we get :

$$\frac{1}{2}=\frac{k(0.1)^x(0.1)^y}{k(0.1)^x(0.2)^y} \text{ or } \left(\frac{1}{2}\right)^1=\left(\frac{1}{2}\right)^y. \text{ Hence, } y=1$$

Determination of x. Dividing equations (*ii*) and (*iii*), we get :

$$\frac{2}{8}=\frac{k(0.1)^x(0.2)^y}{k(0.2)^x(0.2)^y} \text{ or } \left(\frac{1}{2}\right)^2=\left(\frac{1}{2}\right)^x. \text{ Hence, } x=2.$$

Substituting the values of x and y in equation (A), we get, Rate = $k[NO]^2[Cl_2]^1$. Hence order of reaction = 2 + 1 = 3

Ans.

EXAMPLE 75. *Three experimental runs were carried out for the reaction between Cl_2 and NO.*

$$Cl_2(g) + 2NO(g) \rightarrow 2NOCl(g)$$

The following rate data were obtained

Run	*· Initial concentration*		*Initial Rate (mol L^-s^-)*
	[Cl_2](mol L^-)	*[NO](mol L^-)*	
1	0.020	0.01	2.40×10^{-4}
2	0.020	0.030	2.16×10^{-3}
3	0.040	0.030	4.32×10^{-3}

Determine (i) the order w.r.t. Cl_2 and NO (ii) the rate law and (iii) the rate constant.

SOLUTION. Rate of reaction is given as :

Rate = $k[Cl_2]^x[NO]^y$ ...(A)

(*i*) For experiment 1, $2.40 \times 10^{-4} = k(0.02)^x(0.01)^y$

(*ii*) For experiment 2, $2.16 \times 10^{-3} = k(0.02)^x(0.03)^y$

(*iii*) For experiment 3, $4.32 \times 10^{-3} = k(0.04)^x(0.03)^y$

Determination of x. Dividing equation (*ii*) by (*iii*), we get :

$$\frac{2.16\times10^{-3}}{4.32\times10^{-3}} = =\frac{k(0.02)^x(0.03)^y}{k(0.04)^x(0.03)^y} \text{ or}$$

$$\left(\frac{1}{2}\right)^1 = \left(\frac{1}{2}\right)^x. \text{ Hence, } x=1$$

Determination of y. Dividing equation (*i*) by (*ii*), we get :

$$\frac{2.40\times10^{-4}}{2.16\times10^{-3}} = \frac{k(0.02)^x(0.01)^y}{k(0.02)^x(0.03)^y} \text{ or}$$

$$\frac{1}{9} = \left(\frac{1}{3}\right)^y \text{ or } \left(\frac{1}{3}\right)^2=\left(\frac{1}{3}\right)^y. \text{ or } y=2.$$

Substituting the value of x and y in equation (A), the rate equation is : rate = $k[Cl_2][NO]^2$; order of reaction w.r.t. Cl_2 = 1, w.r.t. NO = 2.

Determination of k. From experiment 1, we see that

$$2.40 \times 10^{-4} = k(0.02)^x(0.01)^y = k(0.02)\,(0.01)^2$$

$$\textbf{or} \quad k = \frac{(2.40\times10^{-4})}{(0.02\times0.01\times0.01)} = 120 \quad \text{or}$$

$$1.2 \times 10^2 \text{ mol}^{-2}\text{L}^2\text{s}^-$$ **Ans.**

EXAMPLE 76. *The following results were obtained for the decomposition of nitrous acid in contact with gold surface at 900C.*

t (minutes)	*15*	*30*	*45*	*65*	*80*
% decomposed	*17*	*32*	*44.5*	*57*	*65*

Show that order of reaction is unity.

SOLUTION. Initial concentration, a = 100 (say). x = 17, 32, 44.5, 57 and 65. So, $a - x$ = 100 – 17 = 83; 100 – 32 = 68; 100 – 44.5 = 55.5; 100 – 57 = 43; 100 – 65 = 35. We know that

$$k = \left(\frac{2.303}{t}\right)\log\frac{a}{a-x}.$$

(a) At time 15 min.,

$$k = \frac{2.303}{15}\log\frac{100}{83} = \left(\frac{2.303}{15}\right)\log 1.2048 = \left(\frac{2.303}{15}\right)\times 0.0809 = 0.0124$$

(b) At time 30 min.,

$$k = \frac{2.303}{30}\log\frac{100}{68} = \left(\frac{2.303}{30}\right)\log 1.4705 = \left(\frac{2.303}{30}\right)\times 0.1674 = 0.01285$$

(c) At time 45 min.,

$$k = \left(\frac{2.303}{45}\right)\log\frac{100}{55.5} = \left(\frac{2.303}{45}\right)\log 1.8018 = \left(\frac{2.303}{45}\right)\times 0.2557 = 0.01308$$

(d) At time 65 min.,

$$k = \left(\frac{2.303}{65}\right)\log\frac{100}{43} = \left(\frac{2.303}{65}\right)\log 2.3255 = \left(\frac{2.303}{65}\right)\times 0.3665 = 0.01298$$

(e) At time 80 min.,

$$k = \left(\frac{2.303}{80}\right)\log\frac{100}{35} = \left(\frac{2.303}{80}\right)\log 2.8571 = \frac{2.303}{80}\times 0.4559 = 0.01312$$

Since the value of k is almost same in all experiments, considering first order equation, the order of reaction is unity.

EXAMPLE 77. *In the following second order reaction, $2NO_2 \longrightarrow 2NO + O_2$ the rate of decomposition of NO_2 having 0.5 M concentration was found to be 1.4×10^{-3} mol L^- min^-. Find the rate of decomposition of NO_2 when the concentration of NO_2 is 0.75 M.*

SOLUTION. (*i*) Rate = 1.4×10^{-3} mol L^- min^-; $[NO_2] = 0.5$ M. For second order reaction, rate = $k[NO_2]^2$.

So $k = \text{rate}/[NO_2]^2$. Substituting the values, we get :

$$k = \frac{(1.4 \times 10^{-3})}{(0.5)^2} = 5.6 \times 10^{-3}$$

(*ii*) Also, rate = $k[NO_2]^2$

Substituting the values, we get :

$$\text{rate} = 5.6 \times 10^{-3} \times 0.75 \times 0.75$$
$$= 3.15 \times 10^{-3} \text{ mol L}^- \text{ min}^-$$ **Ans.**

EXAMPLE 78. *Calculate the order of the reaction with respect to the reactant A, and also the rate constant from the following data.*

$[A_0]_1 = 2 \times 10^{-3}$ M; $[r_0]_1 = 2.40 \times 10^{-4}$ Ms^-};

$[A_0)]_2 = 1 \times 10^{-3}$ M; $[r_0]_2 = 0.60 \times 10^{-4}$ Ms^-.

SOLUTION. We know,

$$r_0 = k[A_0]^a. \text{ Thus, } \frac{[r_0]_1}{[r_0]_2} = \left\{\frac{[A_0]_1}{[A_0]_2}\right\}^a$$

Taking logs, we get

$$\log\left\{\frac{[r_0]_1}{[r_0]_2}\right\} = \log\left\{\frac{[A_0]_1}{[A_0]_2}\right\}^a$$

or
$$a = \frac{\log\left[\frac{(r_0)_1}{(r_0)_2}\right]}{\log[(A_0)_1/[A_0)_2]}$$

$$= \frac{\left[\log\left(\frac{2.4 \times 10^{-4}}{(0.6 \times 10^{-4})}\right)\right]}{\left[\log\frac{(2 \times 10^{-3})}{(1 \times 10^{-3})}\right]}$$

$$= \left[\frac{\log 2.4 + \log 10^{-4} - \log 0.6 - \log 10^{-4}}{\log 2 + \log 10^{-3} - \log 1 - \log 10^{-3}}\right]$$

$$= 0.3802 - 4 - (-0.2218)$$
$$+ 4/0.3010 - 3 - 0 + 3 = \frac{0.602}{0.301} = 2.$$

So, the reaction is of second order.

But : rate constant, $k = \dfrac{\text{rate}}{[A]^2}$ or $k = \dfrac{2.4{\times}10^{-4}\text{mol L}^{-}\text{s}^-}{(2{\times}10^{-4}\text{mol L}^-)^2}$

$$= 6 \times 10^3 \text{ or } 0.6 \times 10^4 \text{ mol}^- \text{ Ls}^-$$ **Ans.**

EXAMPLE 79. *The initial rate of reaction, $A + 5B + 6C \longrightarrow 3D + 3E$ has been determined by measuring the rate of disappearance of A under the following conditions*

Experiment	*Initial concentration (mol L^-)*			*Initial rate*
	A	*B*	*C*	
I	0.02	0.02	0.02	2.08×10^{-3}
II	0.01	0.02	0.02	1.04×10^{-3}
III	0.02	0.04	0.02	4.16×10^{-3}
IV	0.02	0.02	0.04	8.32×10^{-3}

(i) Determine the order of reaction with respect to each reactant and overall order of the reaction (ii) What is the rate constant (iii) Calculate the initial rate of the reaction when concentration of all the reactants is 0.01 M (iv) Calculate the initial rate of change in concentration of B and D.

SOLUTION. The general rate expression is,

$$r = k[A_0]^a[B_0]^b[C_0]^c$$

(*i*) In experiment I and II,

$$[A_0] = [B_0] = [C_0] = 0.02 = k_0[A_0]^a.$$

Hence : $$\frac{(r_0)_1}{(r_0)_2} = \frac{2.08 \times 10^{-3}}{1.04 \times 10^{-3}}$$

$$= \frac{[A_0]_1^a}{[A_0]_2^a} = \frac{(0.02)^a}{(0.01)^a} \quad \text{or} \quad (2)^a = (2)^1$$

or $a = 1$ *i.e*,

order with respect to A = 1.

Similarly, $$\frac{(r_0)_3}{(r_0)_1} = \frac{4.16 \times 10^{-3}}{2.08 \times 10^{-3}} = \frac{(B_0)_3^b}{(B_0)_1^b} = \frac{(0.04)^b}{(0.02)^b}$$

or $(2)^b = (2)^1$ or $b = 1$ *i.e.*,

order with respect to B = 1.

Similarly, $$\frac{(r_0)_4}{(r_0)_1} = \frac{8.32 \times 10^{-3}}{2.08 \times 10^{-3}} = \frac{(C_0)_4^c}{(C_0)_1^c} = \frac{(0.04)^c}{(0.02)^c}$$

or $(2)^c = (2)^2$ or $c = 2$ *i.e*,

order with respect to $c = 2$. Hence overall order of reaction = 1 + 1 + 2 = **4** **Ans.**

We know, $$k = \frac{r}{[A_0]^a[B_0]^b[C_0]^c} = \frac{r}{[A_0][B_0][C_0]^2}$$

Using the data of set I, we have

$$k = \frac{2.08{\times}10^{-3}\text{ M min}^-}{16{\times}10^{-8}\text{M}^4}$$

$$= 1.3 \times 10^4 \text{ M}^{-3} \text{ min}^-$$ **Ans.**

Rate of reaction when $[A_0] = [B_0] = [C_0] = 0.01$ M, $r = k\,[A_0][B_0][C_0]^2 = 1.3 \times 10^4\ M^{-2}\ min^-$ (0.01 M) (0.01 M) $(0.01 \text{ M})^2 = 1.3 \times 10^{-4}$ M min^- **Ans.**

But $$r = \frac{-d[B]}{5dt} = \frac{1}{3} \cdot \frac{d[D]}{dt} = 1.3 \times 10^{-4} \text{ Mmin}^-$$

thus, $$\frac{d[B]}{dt} = -5 \times 1.3 \times 10^{-4} \text{ M min}^-$$

$$= -6.5 \times 10^{-4} \text{ M min}^-$$

Similarly, $$\frac{d[D]}{dt} = 3 \times 1.3 \times 10^{-4} \text{ M min}^-$$

$$= 3.9 \times 10^{-4} \text{ M min}^-$$ **Ans.**

Example 80. *In presence of an acid, N-chloroacetanilide changes slowly into p-chloroacetanilide. The former substance liberates I_2 from KI and not the latter and hence the progress of reaction can be measured by titrating the iodine liberated with $Na_2S_2O_3$ solution. The results obtained are :*

t(hours)	*0*	*1*	*2*	*4*	*6*	*8*
(a – x) i.e., Volume of hypo in mL ($Na_2S_2O_3$)	*45*	*32*	*22.5*	*11.3*	*5.7*	*2.3*

Show that the reaction is of first order and find out the fraction of N-chloroacetanilide decomposed after three hours.

Solution. $a = 45$, at time 1 hr, $a - x = 32$; at 2 hr, $a - x = 22.5$; at 4 hrs. $a - x = 11.3$; at 6 hrs. $a - x = 5.7$; at 8 hrs, $a - x = 2.3$. Using the relation, $k = \left(\frac{2.303}{t}\right)\log\frac{a}{a-x}$, we have :

(*a*) At time 1 hr,

$$k = \left(\frac{2.303}{1}\right)\log\frac{45}{32} = 2.303\log 1.4062$$

$$= 2.303 \times 0.1480 = 0.3408.$$

(*b*) At time 2 hr,

$$k = \left(\frac{2.303}{2}\right)\log\frac{45}{22.5} = 1.1515\log 2$$

$$= 1.1515 \times 0.3010 = 0.3466.$$

(*c*) At time 4 hrs,

$$k = \left(\frac{2.303}{4}\right)\log\frac{45}{11.3} = \left(\frac{2.303}{4}\right)\log 3.9823$$

$$= \left(\frac{2.303}{4}\right) \times 0.6001 = 0.3455$$

(*d*) At time 6 hrs,

$$k = \frac{2.303}{6}\log\frac{45}{5.7} = \left(\frac{2.303}{6}\right)\log 7.8947$$

$$= \left(\frac{2.303}{6}\right) \times 0.8973 = 0.3973 = 0.3444$$

(*e*) At time 8 hrs,

$$k = \left(\frac{2.303}{8}\right)\log\frac{45}{2.3} = \left(\frac{2.303}{8}\right)\log 19.5652$$

$$= \left(\frac{2.303}{8}\right) \times 1.2914 = 0.3717$$

Average value of

$$k = \frac{(0.3408 + 0.3466 + 0.3455 + 0.3444 + 0.3717)}{5}$$

$$= 0.3498$$

Let x = fraction of N-chloroacetanilide decomposed after 3 hours. Hence we have :

$$k = \frac{2.303}{t}\log\frac{a}{a-x} \quad \textbf{or}$$

$$0.3498 = \left(\frac{2.303}{3}\right)\log\frac{45}{45-x}$$

or $\frac{(0.3498 \times 3)}{2.303} = \log 45 - \log(45 - x)$

or $0.4556 = 1.6532 - \log(45 - x)$

or $\log(45 - x)$

$= 1.6532 - 0.4556 = 1.1976$

or $45 - x = \text{antilog } 1.1976 = 15.7615$

or $x = 45 - 15.7615 = 29.24$ **Ans.**

Type : $t_{1/2} \propto a$ *i.e.,* initial concentration.

Example 81. *The half-life period of a substance is 50 minutes at a certain concentration. When the concentration is reduced to one half of the initial concentration, the half-life period is 25 minutes. Calculate the order of the reaction.*

Solution. On reducing the concentration to one half, the value of half-life ($t_{0.5}$) becomes one half the original value Or $t_{0.5}$ is directly proportional to the initial concentration. Hence the reaction is a zero order reaction.

Type : (*i*) $\frac{(t_{1/2})_1}{(t_{1/2})_2} = \left(\frac{P_2}{P_1}\right)^{n-1}$ where n = order of reaction and P_1 and P_2 are the pressures at half-lives $(t_{1/2})_1$ and $(t_{1/2})_2$ respectively.

(*ii*) For y% hydrolysis in a given time t, $k = \frac{2.303}{t}\log\frac{a}{a-x}$ where $a = 100$, $a - x = y$.

(*iii*) If $t_{1/2}$ values are almost same irrespective of the initial pressure or concentration, reaction is of first order *i.e.,* $n = 1$.

Example 82. *At a certain temperature, the half-life period for the decomposition for the substance A is as follows :*

P(mm)	*500*	*700*	*900*
Half-life period	*18*	*17.9*	*18*

What is the order of reaction ?

Solution. Since the half-life periods are almost same irrespective of the initial concentration *i.e.,* pressure, the reaction is of **first order**.

Example 83. *Following data were obtained for the catalytic decomposition of ammonia.*

Initial pressure (mm)	*50*	*100*	*200*
Half-life (hrs)	*3.52*	*1.92*	*1.00*

Find the order of reaction.

Solution. We know, $\frac{(t_{1/2})_1}{(t_{1/2})_2} = \left(\frac{P_2}{P_1}\right)^{n-1}$

Substituting the values for the given data we have :

(*i*) $\frac{(t_{1/2})_1}{(t_{1/2})_2} = \left(\frac{P_2}{P_1}\right)^{n-1}$

$$\text{or} \qquad \left(\frac{3.52}{1.92}\right) = \left(\frac{100}{50}\right)^{n-1}$$

Taking logs, we get,

$$\log 3.52 - \log 1.92 = (n-1)\log 2$$

$$\text{or} \qquad 0.5440 - 0.2833 = (n-1) \times 0.301$$

$$\text{or} \qquad 0.2607 = 0.301\,(n-1)$$

$$\text{Thus,} \qquad n-1 = \frac{0.2607}{0.301} = 0.866.$$

$$\text{Hence,} \qquad n = 1 + 0.866 = 1.866 \approx 2.$$

$$(ii) \qquad \frac{(t_{1/2})_1}{(t_{1/2})_2} = \left(\frac{P_2}{P_1}\right)^{n-1}$$

$$\text{or} \qquad \left(\frac{1.92}{1}\right) = \left(\frac{200}{100}\right)^{n-1}$$

Taking logs, we get, $\log 1.92 = \log (2)^{n-1}$;

$$\log 1.92 = (n-1)\log 2$$

$$0.2833 = 0.301\,(n-1);$$

$$n-1 = \frac{0.2833}{0.301} = 0.941.$$

$$\text{Hence,} \qquad n = 1 + 0.941 = 1.941 \approx 2.$$

The order, n in both cases is 2.

EXAMPLE 84. *It was found that a solution of canesugar was hydrolysed to the extent of 25% in one hour. Calculate the time that would be taken for the sugar to be 50% hydrolysed assuming that the reaction is of first order.*

SOLUTION. Let initial concentration, $a = 100$; $x = 25$; $t = 1$ hour $= 60$ minutes. For first order reaction,

$$k = \frac{2.303}{t}\log\frac{a}{a-x}$$

Substituting the values, we get :

$$k = \left(\frac{2.303}{60}\right)\log\frac{100}{100-25}$$

$$= \frac{92.303}{60}\log\frac{100}{75}$$

$$= \left(\frac{2.303}{60}\right)\log 1.3333$$

$$= \left(\frac{2.303}{60}\right) \times 0.1249 = 0.00479$$

Let t = time to hydrolyse sugar;

$a = 100$; $x = 50$.

$$\text{We know,} \qquad k = \left(\frac{2.303}{t}\right)\log\frac{a}{a-x}$$

Substituting the values, we get,

$$0.00479 = \left(\frac{2.303}{t}\right)\log\frac{100}{100-50} = \left(\frac{2.303}{t}\right)\log 2$$

$$= (2.3031 \times 0.3010)/t$$

$$\text{or} \qquad t = \frac{(2.303 \times 0.3010)}{0.00479} = 144.7\,\text{min}. \quad \textbf{Ans.}$$

EXAMPLE 85. *Pressure of a gas decomposing at the surface of a solid catalyst has been measured at different times and the results are given below :*

t/s	*0*	*100*	*200*	*300*
p/Pa	*4.0 × 10^3*	*3.50 × 10^3*	*3.00 × 10^3*	*2.5 × 10^3*

Determine the order of reaction, its rate constant and half-life period.

SOLUTION. (*i*) For time interval 0 to 100*s*,

$$\text{rate} = \frac{-(3.5-4.0)10^3\text{Pa}}{(100-0)\,\text{s}}$$

$$= \frac{0.5{\times}10^3\text{Pa}}{100} = 5\text{Pas}^-$$

(*ii*) For time interval 100s to 200*s*,

$$\text{rate} = \frac{-(3.0-3.5)10^3\text{Pa}}{(200-100)\text{s}}$$

$$= \frac{0.5{\times}10^3}{100} = 5\text{Pas}^-$$

(*iii*) For time interval 200*s* to 300*s*, rate

$$= \frac{-(2.5-3.0)10^3\text{Pa}}{(300-200)\text{s}} = 5\ \text{Pas}^-.$$

Since the rate remains constant, the reaction is of zero order because for the units Pas$^-$ of rate constant, the order is zero.

(*iv*) Since k = rate = 5 Pas$^-$,

$$t_{0.5} = \frac{\text{(Initial concentration or pressure)}}{2k}$$

$$\text{Thus,} \qquad t_{0.5} = \frac{4.0{\times}10^3\text{Pa}}{2{\times}5\text{Pas}^-} = 400\text{s} \qquad \textbf{Ans.}$$

EXAMPLE 86. *The gas phase decomposition of dimethyl ether follows first order kinetics :*

$$CH_3 - O - CH_3(g) \rightarrow CH_4(g) + H_2(g) + CO(g)$$

The reaction is carried out in a constant volume container at 500°C and has a half life of 14.5 minutes. Initially only dimethyl ether is present at a pressure of 0.40 atmosphere. What is the total pressure of the system after 12 minutes ? Assume ideal gas behaviour. **(IIT,1993)**

SOLUTION. $CH_3 - O - CH_3 \longrightarrow CH_4(g) + H_2 + CO$

Initial state	p_0	0	0	0	*Total pressure,* p_0
After 12 min.	$p_o - p$	p	p	p	$p_0 + 2p$

For a first order reaction

$$k = \frac{0.693}{t_{1/2}} = \frac{0.693}{14.5} = 4.78 \times 10^{-2}\,\text{min}^{-1}$$

$$k = \frac{2.303}{t}\log\frac{a}{(a-x)}$$

In the present case $a \propto p_0$ and $(a - x) \propto p_0 - p$

$$\therefore \qquad k = \frac{2.303}{t}\log\frac{p_0}{(p_0 - p)}$$

$$\text{or} \quad \log\frac{p_0}{(p_0 - p)} = \frac{kt}{2.303}$$

$$\text{or} \quad \log\frac{p_0 - p}{p_0} = -\frac{kt}{2.303} = -\frac{4.78 \times 10^{-2} \times 12}{2.303}$$

$$= -0.249$$

$$\text{or} \quad \frac{p_0 - p}{p_0} = \text{Antilog}\ (-0.249) = 0.564$$

$$\text{or} \quad p = p_0 - 0.564\, p_0 = p_0\,(1 - 0.564)$$

$$= (0.40\ \text{atm})\ (0.436) = 0.1744\ \text{atm}$$

Hence, total pressure of the system is

$$p_0 + 2p = (0.40 + 2 \times 0.1744)\ \text{atm}$$

$$= \mathbf{0.7488\ atm.}$$

Example 87. *Some $PH_3(g)$ is introduced into flask at 600°C containing an inert gas. PH_3 proceeds to decompose into $P_4(g)$ and $H_2(g)$ and the reaction goes to completion. The total pressure is given below as a function of time. Find the order of reaction and calculate the rate constant.*

Time	*0*	*60*	*120*	*∞*
P(mm)	*262.40*	*272.90*	*275.51*	*276.40*

(Roorkee, 2001)

Solution. Total increase in pressure due to complete decomposition of $PH_3 \propto$ Initial conc. of PH_3 *i.e.,* $a \propto P_\infty - P_0$ or $a \propto (276.40 - 262.40)$ or $a \propto 14.0$

Increase in pressure at any time $\propto$ amount of PH_3 decomposed at that time.

i.e., $\quad P_t - P_0 \propto x$

∴ $\quad (a - x) \propto (P_\infty - P_0) - (P_t - P_0)$

i.e., $\quad (a - x) \propto (P_\infty - P_t)$

If the reaction follows first order rate law,

$$k = \frac{2.303}{t}\log\frac{a}{(a - x)}$$

$$= \frac{2.303}{t}\log\frac{P_\infty - P_0}{P_\infty - P_t}$$

$$\text{At } t = 60s, \quad k_t = \frac{2.303}{650}\log\frac{(276.4 - 262.4)}{(276.4 - 272.90)}$$

$$= \frac{2.303}{60}\log\frac{14}{3.5} = 2.31 \times 10^{-2}\, s$$

$$\text{At } t = 120s, \quad k_2 = \frac{2.303}{120}\log\frac{276.4 - 262.4}{276.4 - 275.51}$$

$$= \frac{2.303}{120}\log\frac{14}{0.89} = 1.967 \times 10^{-2} s^{-}$$

Since k comes out to be nearly constant, reaction is a first order reaction.

$$k = \frac{k_1 + k_2}{2} = \frac{2.31 + 1.967}{2} \times 10^{-2} s^{-}$$

$$= 2.138 \times 10^{-2} s^{-}$$ **Ans.**

Example 88. *While studying the decomposition of gaseous N_2O_5, it is observed that a plot of logarithm of its partial pressure versus time is linear. What kinetic parametres can be obtained from this observation ?* **(IIT, 1985)**

Solution. As the graph of logarithm of partial pressure versus time is linear, the reaction is of first order. Thus :

$$k = \frac{2.303}{t}\log\frac{p_0}{p}$$

$$\text{or} \qquad \log\frac{p_0}{p} = \frac{kt}{2.303};\ \log p_0 - \log p = \frac{kt}{2.303}$$

$$\text{or} \qquad \log p = \log p_0 - \frac{kt}{2.303}$$

Therefore, the slope of the line obtained by plotting $\log p$ against time, t will be $\frac{-k}{2.303}\cdot$ Thus, the value of rate constant k can be calculated from the slope. Hence the kinetic parameters that can be obtained from the graph are: (*i*) specific reaction rate (*ii*) order of reaction.

Example 89. *The vapour pressure of two miscible liquids A and B are 300 and 500 mm of Hg respectively. In a flask, 10 mol of A is mixed with 12 mol of B. However as soon as B is added, A starts polymerising into a completely insoluble solid. This polymerisation follows first order kinetics. After 100 minutes, 0.525 mol of a solute is dissolved which arrests the polymerisation completely. The final vapour pressure of the solution is 400 mm of Hg. Estimate the rate constant of the polymerisation reaction. Assume negligible volume change on mixing and polymerisation and ideal behaviour for the final solution.* **(IIT, 2001)**

Solution. Let the number of moles of A left after 100 min be Z.

∴ Total number of moles after 100 min

$$= Z + 12 + 0.525 = Z + 12.525$$

$$\text{Mole fraction of } A,\ x_A = \frac{Z}{Z + 12.525}$$

$$\text{Mole fraction of } B,\ x_B = \frac{12}{Z + 12.525}$$

$P°_A$ = Vapour pressure of pure A = 300 mm

$P°_B$ = Vapour pressure of pure B = 500 mm

According to Raoult's law.

$$P_{\text{mix}} = x_A \times P°_A + x_B \times P°_B$$

$$= \left(\frac{Z}{Z + 12.525} \times 300\right) + \left(\frac{12}{Z + 12.525} \times 500\right)$$

$$\therefore \qquad 400 = \frac{300\,Z}{(Z + 12.525)} + \frac{12 \times 500}{(Z + 12.525)}$$

$$= \frac{6000 + 300Z}{Z + 12.525}$$

This on solving gives, Z = 9.9 mol

According to first order rate law, $k = \dfrac{2.303}{t}\log\dfrac{[A_0]}{A}$

where $[A]_0 = 10$ mol., $[A] = 9.9$ mol and $t = 100$ min.

$$\therefore \quad k = \frac{2.303}{100\,\text{min}}\log\frac{10}{9.9}$$

$$= \mathbf{1.005 \times 10^{-4} min^{-1}}.$$

Example 90. *The rate constant for an isomerisation reaction, $A \to B$ is 4.5×10^{-3} min^{-1}. If the initial concentration of A is 1M, calculate the rate of reaction after one hour.* **(IIT, 1999; CBSE, 2009)**

Solution. From the units of rate constant (min^{-1}), it is clear that the given reaction is a first order reaction. Thus,

$$k = \frac{2.303}{t}\log\frac{a}{(a-x)}$$

$$k = 4.5 \times 10^{-3}\ \text{min}^{-1}, a = 1\text{M}, (a-x) = ?$$

$$t = 1\text{hr} = 60\ \text{min}.$$

$$\therefore \quad 4.5 \times 10^{-3} = \frac{2.303}{60}\log\frac{1}{a-x}$$

$$\log\frac{1}{(a-x)} = \frac{4.5 \times 10^{-3} \times 60}{2.303} = 0.1172$$

$$\frac{1}{a-x} = \text{antilog}\ 0.1172$$

$$\text{or} \quad \frac{1}{(a-x)} = 1.310$$

$$\text{or} \quad (a-x) = 0.7634\ M$$

$\therefore$ Rate of reaction after 1 hr

$$= k[A] = 4.5 \times 10^{-3} \times 0.7634$$

$$= \mathbf{3.44 \times 10^{-3}\ mol\ L^{-1}\ min^{-1}}.$$

Example 91. *1.0 cm^3 of ethyl acetate was added to 25 cm^3 of 0.5 NHCl. 2.0 cm^3 of the mixture were withdrawn from time to time during the progress of the hydrolysis of ester and titrated against standard NaOH solution. The amount of NaOH required for titration at various intervals is given below.*

Time (min)	*0*	*20*	*75*	*119*	*∞*
NaOH added (cm^3)	*20.24*	*21.73*	*25.20*	*27.60*	*43.95*

The value of ∞ time was obtained by completing the hydrolysis on boiling. Show that it is a reaction of first order.

Solution. For pseudo first order reaction *e.g.*, hydrolysis of esters, $k = \dfrac{2.303}{k}\log\dfrac{V_\infty - V_0}{V_\infty - V_t}$.

Amount of NaOH used at $t = 0$ ($=V_0$) $\propto$ HCl present

Amount of NaOH used at any time, t (V_t) $\propto$ [HCl present + CH_3COOH formed]

$\therefore$ CH_3COOH formed at any time $\propto$ ethyl acetate reacted; $V_t - V_0 \propto x$.

Amount of NaOH used at time, $t = \infty$ ($= V_\infty$) $\propto$ [HCl present + maximum acetic acid formed]

But maximum CH_3COOH formed $\propto$ initial conc. of ethyl acetate *i.e.*, $V_\infty - V_0 \propto a$. For first order reaction :

$$k = \frac{2.303}{t}\log\frac{a}{a-x}; k = \frac{2.303}{t}\log\frac{V_\infty - V_0}{V_\infty - V_t}$$

t(min) 0	V_t 20.24	$V_\infty - V_t$ 43.95 – 20.24 = 23.71	$k = \dfrac{2.303}{t}\log$ $\dfrac{V_\infty - V_0}{V_\infty - Vt}$
20	21.73	43.95 – 21.73 = 22.22	$\therefore k = \dfrac{2.303}{20}\log\dfrac{23.71}{22.22}$ $= \dfrac{2.303}{20}$ log 23.71 – log 22.22 $= \dfrac{2.303}{20}$ (1.3749 – 1.3467 = 0.02816) = 0.00324 min^{-}
75	25.20	43.95 – 25.20 = 18.75	$k = \dfrac{2.303}{75}\log\dfrac{23.71}{18.75}$ = 0.000313 min^{-}
119	27.60	43.95 – 27.60 = 16.35	$k = \dfrac{2.303}{119}\log\dfrac{23.71}{16.35}$ = 0.00312 min^{-}

Since the value of k is almost constant, the reaction is of first order.

20.7 ZERO ORDER REACTIONS

Example 92. (*i*) *During the decomposition of a gas on the surface of a solid catalyst, the pressure of the gas at different times was observed to be as follows :*

t/s	*0*	*100*	*200*	*300*
p/Pa	*5.0 × 10^3*	*4.2 × 10^3*	*3.4 × 10^3*	*2.6 × 10^3*

Calculate the order of the reaction.

(*ii*) *The decomposition on platinum surface,*

$$2NH_3(g) \xrightarrow{Pt} N_2(g) + 3H_2(g)$$

is a zero order reaction with k = 2.5 × 10^{-4} ms^{-}. What are the rate of production of N_2 and H_2? **(CBSE, 2007)**

Solution. (*i*) In order to get the order of reaction, let us first of all calculate the rate of reaction during different intervals of time.

Interval	**Rate of reaction**
0 to 100 s	$-\dfrac{(4.2-5)\times 10^3\,\text{Pa}}{100\ -\ 0} = \dfrac{0.8\times 10^3\,\text{Pa}}{100\ \text{s}} = 8\ \text{Pa s}^{-}$
100 to 200 s	$-\dfrac{(3.4-4.20)\times 10^3\,\text{Pa}}{200\ -\ 100} = \dfrac{0.8\times 10^3\,\text{Pa}}{100\ \text{s}} = 8\ \text{Pa s}^{-}$

$$200 \text{ to } 300 \text{ s} - \frac{(2.6-3.4)\times 10^3 \text{ Pa}}{300\ -\ 200} = \frac{0.8\times 10^3 \text{ Pa}}{100 \text{ s}} = 8 \text{ Pa s}^{-}$$

From above it is found that, as the rate of reaction remains constant through out, so the order of reaction is **zero.**

(*ii*) Reaction: $2NH_3(g) \xrightarrow{Pt} N_2(g) + 3H_2(g)$

$$\text{Rate} = -\frac{1}{2}\frac{d[NH_3]}{dt} = \frac{d[N_2]}{dt}$$
$$= \frac{1}{3}\frac{d[H_2]}{dt}$$

For a zero order reaction, rate does not depend upon the concentration of reactants. Hence :

$$r = k[NH_3]^{\circ} = k \times 1 = k$$

Thus : (*i*)
$$\frac{d[N_2]}{dt} = \frac{1}{2}\times\frac{d[NH_3]}{dt}$$
$$= \frac{1}{2}\times k = \frac{1}{2}\times 2.5\times 10^{-4} \text{ms}^{-}$$
$$= 1.25 \times 10^{-4} \text{ ms}^{-}$$ **Ans.**

(*ii*)
$$\frac{d[H_2]}{dt} = \frac{3}{2}\times\frac{d[NH_3]}{dt}$$
$$= \frac{3}{2}\times k = \frac{3}{2}\times 2.5\times 10^{-4} \text{ms}^{-}$$
$$= 3.75 \times 10^{-4}$$ **Ans.**

Note. For zero order reaction, $t_{\frac{1}{2}} = \frac{a}{2k}$ while for first order reaction $t_{\frac{1}{2}} = 0.693/k$ where a is initial concentration and k is rate constant **(AIPMT, 2009)**

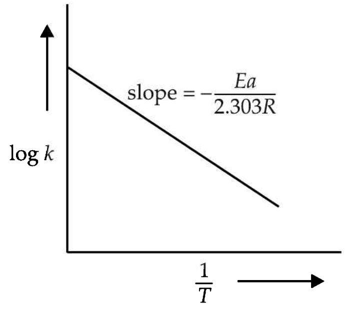
20.8 ARRHENIUS LAW

Effect of temperature on rate constant – Arrhenius equation. According to Arrhenius equation :

$$k = Ae^{-Ea/RT} \qquad ...(i)$$

where A = constant called frequency factor, Ea = energy of activation, R is gas constant and T is absolute temperature.

Calculation of *Ea*. *First method.* Taking logs of equation (*i*), we get,



$$\ln k = \ln A + \ln e^{-Ea/RT}; \ln k = \ln A - \frac{Ea}{RT}$$

$$2.303 \log k = 2.303 \log A - \frac{Ea}{RT}$$

$$\therefore \quad \log k = \log A - \frac{Ea}{2.303R}\times\frac{1}{T}$$

When a graph is drawn between log k and $\frac{1}{T}$, we get a straight line having slope = $-\frac{Ea}{2.303R}$.

Hence, **Ea = – 2.303 R × slope.**

Second method. Let k_1 and k_2 are the rate constants at temperatures T_1 and T_2 respectively. Hence by using Arrhenius equation, we have :

$$\log k_1 = \log A - \frac{Ea}{2.303RT_1} \qquad ...(i)$$

$$\log k_2 = \log A - \frac{Ea}{2.303RT_2} \qquad ...(ii)$$

Subtracting equation (*i*) from (*ii*), we get :

$$\log k_2 - \log k_1 = \frac{Ea}{2.303R}\left[\frac{1}{T_1} - \frac{1}{T_2}\right]$$

or
$$\log\frac{k_2}{k_1} = \frac{Ea}{2.303R}\left[\frac{T_2 - T_1}{T_1T_2}\right]$$
$$= \frac{Ea}{2.303R}\left[\frac{T_2 - T_1}{T_1T_2}\right]$$

$$\therefore \quad E_a = \left(\log\frac{k_2}{k_1}\right)\times\frac{2.303R(T_1T_2)}{T_2 - T_1}$$

Activation energy of forward reaction (E_a^f) and activation energy of backward reaction (E_a^r) are related to enthalpy of reaction ($\Delta_r H^0$) by the equation :

$$\Delta_r H^0 = E_a^f - E_a^r$$

Example 93. *For a chemical reaction, A → B, the rate of the reaction is* 2×10^{-3} *mol dm*$^{-3}$*s*$^{-}$*, when the initial concentration is 0.25 mol dm*$^{-3}$*. The rate of the same reaction is* 1.6×10^{-2} *mol dm*$^{-3}$*s*$^{-}$ *when the initial concentration is* 0.1 *mol dm*$^{-3}$*. The order of the reaction is:*

(*a*) 0 (*b*) 3 (*c*) 1 (*d*)2. **(Karnataka, CET, 2009)**

Solution. We know that, rate = $k[A]^n$ where R is rate constant, n is order of reaction and [A] is concentration of reactant.

Given: $\text{Rate}_I = 2 \times 10^{-3} \text{ mol dm}^{-3}\text{s}^{-}; [A_0] = 0.05 \text{ mol dm}^{-3}$
$\text{Rate}_{II} = 1.6 \times 10^{-2} \text{ mol dm}^{-3}\text{s}^{-}; [A_0] = 0.1 \text{ mol dm}^{-3}$
$\therefore \quad 2 \times 10^{-3} = k[0.05]^n$ —(1); $1.6 \times 10^{-2} = k[0.1]^n$ ...(2)

Dividing (1) by (2), we get; $\frac{2\times 10^{-3}}{1.6\times 10^{-2}} = \left(\frac{0.05}{0.10}\right)^n$

or $\frac{(0.05)^n}{(0.05)^n \times 2^n}$ or $\frac{1}{2^n} = \frac{1}{8}$ or $\frac{1}{2^3}$. Hence, n = 3.

So, the correct answer is (*b*).

Example 94. *For a first order reaction, A → P, the temperature (T) dependent rate constant (k) was found to follow the equation, log k* = –(2000) $\frac{1}{T}$ + *6.0. The pre-exponential factor, A and the activation energy, Ea respectively are:*

(*a*) $1.0 \times 10^6 s^{-}$ and 9.2 J mol^{-} (*b*) $6.0 s^{-}$ and 16.6 J mol^{-}

(*c*) $1.0 \times 10^6 s^{-}$ and 16.6 kJ mol^{-} (*d*) $1.0 \times 10^6 s^{-}$ and 38.3k J mol^{-} **(IIT-JEE, 2009)**

Solution. Given $\log k = -(2000)\dfrac{1}{T} + 6.0$ ...(*i*)

But $\log k = \log A - \dfrac{Ea}{2.303RT}$ ...(*ii*) (Arrhenius equation)

Comparing equations (*i*) and (*ii*), we get:

$\log A = 6$; $A = 1 \times 10^6 s^{-}$ and

$$\frac{-E_a}{2.303RT} = -\frac{2000}{T};\ E_a = 2000 \times 2.303 \times 8.314\ \text{J}$$

$(\because R = 8.314\ \text{J})$

or $E_a = 38294\ \text{J} \simeq 38.3\ k\text{J mol}^{-}$. So, the correct answer is (*d*).

Example 95. *The bacterial growth follows the rate low, $\dfrac{dN}{dt} = kN$, where k is a constant and N is the number of bacterial cell at anytime. If the population of bacteria (no. cells) is doubled in 5 minutes, find the time by which the population will be eight times of the initial one* **(WB-JEE, 2011)**

Solution. Given $dN/dt = kN$; $N = N_0\, e^{kt}$. Also: in 5 minutes, $N_0 = 2N_0$. So, $k = \dfrac{2.303}{t} \log N/N_0$

$$= (2.303/5)\log\frac{2N_0}{N_0} = \frac{2.303}{5}\log 2 = \frac{2.303}{5} \times 0.3010 = 0.138$$

$$\text{For } 8\,N_0,\ t = \frac{2.303}{0.138}\log\frac{8N_0}{N_0} = \frac{2.303}{0.138}\log 8$$

$$= \frac{2.303}{0.138} \times 0.9030$$

$\simeq$ 15 minutes. **Ans**

Example 96. *The value of rate constant for a second order reaction is 6.7×10^{-5} mol^{-} Ls^{-} at 298 K and 1.64×10^{-4} mol^{-}Ls^{-} at 313 K. Find the Arrhenius frequency factor A and activation energy of the reaction.*

Solution. Given : Rate constant, $k_1 = 6.7 \times 10^{-5}$ mol^{-} Ls^{-}; $T_1 = 298\ K$; $k_2 = 1.64 \times 10^{-4}$ mol^{-} $L\ s^{-}$; $T_2 = 313\ K$; Arrhenius frequency, A = ?; activation energy, E_a = ?; $R = 8.314$ JK^{-} mol^{-}. We know that (*a*),

$$E_a = \left(\frac{2.303RT_1T_2}{T_2 - T_1}\right)\log\frac{k_2}{k_1}$$

Substituting the values we get :

$$E_a = \frac{(2.303 \times 8.314 \times 313}{(313 - 298)}\log\frac{(1.64 \times 10^{-4})}{(6.7 \times 10^{-5})}$$

$= 119{,}062.03 \times \log 2.4477$

$= 119{,}062.03 \times 0.3887$

$= 46{,}279.4$ J = 46.2794 kJ **Ans.**

(*b*) $\log k_1 = \log A - E_a/(2.303\ RT_1)$; $\log 6.7 \times 10^{-5} = \log A - 46279.4/8.314 \times 298)$; $\log 6.7 + \log 10^{-5} = \log A - 18.679$; $0.826 - 5 = \log A - 18.679$; $\log A = 0.826 - 5 + 18.679 = 14.505$. Hence, A = antilog of $14.505 = 3.19 \times 10^{14}$ at 298 K **Ans.**

Example 97. *The rate constant for a reaction is 1.6×10^{-5} and $6.36 \times 10^{-3} s^{-}$ at 600 K and 700 K respectively. Calculate the activation energy for the reaction.* **(PSEB, 1995, HSB, 2002)**

Solution. Rate constant, $k_1 = 1.6 \times 10^{-5}$; $k_2 = 6.36 \times 10^{-3} s^{-}$; $T_1 = 600\ K$; $T_2 = 700\ K$; activation energy, E_a = ? $R = 8.314$ J K^{-} mol^{-}. We know that,

$$E_a = \left(\frac{2.303RT_1T_2}{T_2 - T_1}\right)\log\frac{k_2}{k_1}$$

Substituting the values, we get :

$$E_a = \left[\frac{2.303 \times 8.314 \times 600 \times 700}{700 - 600}\right]\log\frac{(6.36 \times 10^{-3})}{(1.6 \times 10^{-5})}$$

$= 80418 \times \log 397.5$

$= 80418 \times 2.5993 = 209030$ J

$= 209.03\ k$J **Ans.**

Example 98. *Calculate the activation energy of a reaction whose reaction rate at 27°C get doubled for 10°C rise in temperature. (R = 8.314 JK^{-} mol^{-}, log 2 = 0.301)* **(JEE Main, 2013)**

Solution. Activation energy, E_a = ?; $T_1 = 27 + 273 = 300\ K$; $T_2 = 300 + 10 = 310\ K$; $\dfrac{k_2}{k_1} = 2$

We know that : $E_a = \left(\dfrac{2.303RT_1T_2}{T_2 - T_1}\right)\log\dfrac{k_2}{k_1}$

Substituting the values, we get :

$$E_a = \left[\frac{2.303 \times 8.314 \times 300 \times 310}{(310 - 300)}\right]\log 2$$

$= 178068.4 \times 0.3010 = 53599$ J

$= 53.599\ k$J mol^{-} **Ans.**

Example 99. *If a first order reaction has activation energy of 25000 cal and a frequency factor of 5×10^{12} sec^{-1}, at what temperature will the reaction rate have a half life of 1 minute ?*

Solution. Activation energy, E_a = 25000 cal = 25000 × 4.1846 J (*i*) $t_{1/2}$ = 1 minute = 60 seconds; A = $5 \times 10^{12} s^{-}$; temperature, T = ?; (*ii*) $t_{1/2}$ = 80 days = 80 × 24 × 60 × 60 seconds = 6912000 seconds. We know that rate constant,

$$k = \frac{0.693}{t_{1/2}} = \frac{0.693}{60} = 0.01155.$$

But, $\log k = \log A - \left[\dfrac{E_a}{2.303RT}\right]$

where, $R = 8.314$ JK^{-} mol^{-}

Substituting the values, we get :

$$\log 0.01155 = \log 5 \times 10^{12} - \left[\frac{25000 \times 4.1846}{2.303 \times 8.314 \times T}\right]$$

$$-1.9374 = \log 5 + \log 10^{12} - \left[\frac{5463.7}{T}\right]$$

$$-1.9374 = 0.6989 + 12 - \left(\frac{5463.7}{T}\right)$$

$$-1.9374-0.6989-12=\left[\frac{-5463.7}{T}\right]$$

$$-14.6363=\frac{-5463.7}{T} \quad \text{or} \quad T=\frac{-5463.7}{-14.6363}$$

$$=373.2K \qquad \textbf{Ans.}$$

EXAMPLE 100. *Rate constant k of a reaction varies with temperature according to equation : log k = constant – E_a/2.303 RT. What is the activation energy for the reaction ? When a graph is plotted for log k versus 1/T, a straight line with a slope – 6670 K is obtained. Calculate energy of activation for this reaction. (R = 8.314 JK^{-} mol^{-}).*

SOLUTION. Activation energy, E_a = ? ; R = 8.314 JK^{-} mol^{-}; slope = –6670 K. We know, E_a = – 2.303 R × slope. Substituting the values, we get :

$$E_a=-2.303\times 8.314\times -6670$$

$$=127711\text{ J}=127.711\text{ kJ} \qquad \textbf{Ans.}$$

EXAMPLE 101. *The following values for the first order rate constant were obtained for a certain reaction.*

Temperature (K)	*k(sec)$^{-}$*
298	*3.46×10^{-5}*
308	*13.50×10^{-5}*

Calculate the activation energy. R = 8.314 J K^{-} mol^{-}.

(AISB, 1990 comptt., 1991 Comptt.)

SOLUTION. T_1 = 298 K; T_2 = 308 K; $k_1=3.46\times 10^{-5}s^{-}$; $k_2=13.50\times 10^{-5}s^{-}$. Activation energy, E_a = ? ; R = 8.314 JK^{-} mol^{-}. We know that,

$$E_a=\left(\frac{2.303RT_1T_2}{T_2-T_1}\right)\log\frac{k_2}{k_1}$$

Substituting the values, we get :

$$E_a=\left[\frac{2.303\times 8.314\times 298\times 308}{308-298}\right]\log\left(\frac{13.50\times 10^{-5}}{3.46\times 10^{-5}}\right)$$

$$=175740.1\log 3.9=175740.1\times 0.591$$

$$=103862.4\text{ J}=103.8624\,k\text{J} \qquad \textbf{Ans.}$$

EXAMPLE 102. *The no. of flashes of a fire fly changes with temperature as follows :*

t°C	*No. of flashes per minute*
25	*7*
28	*10*

Calculate the energy of activation for the chemical reaction that leads to the flash.

SOLUTION. $k_1=7\text{ min}^{-}$; $k_2=10\text{ min}^{-}$; $T_1=273+25=298$K; $T_2=273+28=301$ K; R = 8.314 JK^{-} mol^{-}.

$$\therefore \quad \log\frac{10}{7}=\frac{E_a}{2.303\times 8.314}\left[\frac{301-298}{301\times 298}\right]$$

$$\therefore \quad E_a=88.678\text{ kJ mol}^{-}.$$

EXAMPLE 103. *The slope of the line in the graph of log k (k = rate constant) Vs $\frac{1}{T}$ for a reaction is – 5841 K. Calculate the energy of activation for this reaction (R = 8.314 JK^{-} mol^{-}].*

SOLUTION. Slope = $\dfrac{-E_a}{2.303R}$

$$\therefore \quad -5841\,K=\frac{-E_a}{2.303\times 8.314\,\text{JK}^{-}\text{mol}^{-}}$$

$$\therefore \quad E_a=\mathbf{111838\ kJ\ mol^{-}}.$$

EXAMPLE 104. *The experimental data for the decomposition of nitrogen pentoxide in the gaseous phase at 300 K is as follows :*

E_a = 100 kJ mol^{-}, A (frequency constant) = $10^{10}s^{-}$. What is the half life period of the reaction at 300 K ?

SOLUTION. (1)

$$\log k=\log A-\frac{E_a}{2.303RT}$$

$$=\log 10^{10}-\frac{100000}{2.303\times 8.314\times 300}$$

$$=-7.409$$

$$=-1+1-7.409=\bar{8}.591$$

Antilog of .591 is 3.899.

$$\therefore \quad k=\text{antilog }\bar{8}.591=3.899\times 10^{-8}s^{-}$$

$$(2) \quad t_{0.5}=\frac{0.693}{3.899\times 10^{-8}s^{-}}=1.8\times 10^{7}s$$

EXAMPLE 105. *The specific rate constant for a reaction increases by a factor 4 if the temperature is changed from 27°C to 47°C. Find the activation energy for the reaction.*

(IIT, Advance entrance, 1980, CBSE, 1991, PSEB, 1999)

SOLUTION. 27°C = 27 + 273 = 300 K

47°C = 47 + 273 = 320 K

Using Arrhenius equation (relating rate constant and activation energy),

$$\text{We have : }\log\frac{k_2}{k_1}=\frac{E_a}{2.303R}\left(\frac{T_2-T_1}{T_1T_2}\right)$$

$$\log\frac{4k_1}{k_1}=\frac{E_a}{2.303\times 1.98}\left(\frac{320-300}{300\times 320}\right)$$

[∵ R = 1.98 cal.]

$$\log 4=\frac{E_a}{2.303\times 1.98}\left(\frac{20}{96000}\right)$$

$$0.6021=\frac{E_a\times 20}{2.303\times 1.98\times 96000}$$

$$\therefore \quad E_a=\frac{0.6021\times 2.303\times 1.98\times 96000}{20}$$

$$=13179\text{ cal}=\mathbf{13.179\ k\ cal.}$$

EXAMPLE 106. *The following data were obtained during the first order decomposition of $2A_{(g)}\rightarrow B_{(g)}+C_{(s)}$ at a constant volume and at a particular temperature. The rate constant in min^{-1} is:*

(*a*) 0.0693 (*b*) 69.3 (*c*) 6.93 (*d*) 6.93×10^{-4}

(Karnataka CET, 2011)

S. No.	*Time*	*Total pressure in pascal*
1	*At the end of 10 minutes*	*300*
2	*After completion*	*200*

SOLUTION. $2A_{(g)} \rightarrow B_{(g)} + C_{(s)}$

At the end of 10 min.$2(1-x)$ $\quad x$

$2-2x$

Total number of moles $= 2 - 2x + x = 2 - x$

At the end of reaction, 1 mol of gas present has pressure $= 200$ pascal

$\therefore$ 2 mol of gas has pressure

$= 200 \times 2 = 400$ pascal

$\therefore \quad 400 - x = 300; x = 400 - 300 = 100$

Pressure due to $2 - 2x$ mol of

$A = 400 - 200 = 200$ pascal

$\therefore$ Rate constant,

$$k = \frac{2.303}{10}\log\frac{a}{a-x} = \frac{2.303}{10}\log\frac{400}{200}$$

or
$$k = \frac{2.303}{10}\log 2$$

$$= \frac{2.303}{10} \times 0.3010 = 0.0693 \text{ min}^{-}.$$

So, the correct answer is (*a*)

EXAMPLE 107. *A hydrogenation reaction is carried out at 500 K. If the same reaction is carried out in the presence of a catalyst at the same rate, the temperature required is 400 K. Calculate the activation energy of the reaction if the catalyst lowers the activation barrier by 20 kJ mol^{-1}.* **(I.I.T., 2000)**

SOLUTION. According to the Arrhenius equation,

$$K = Ae^{-Ea/RT}.$$

Let E_a of the reaction in absence of catalyst $= x$ kJ mol^{-1}.

$\therefore \quad E_a$ in presence of catalyst $= x - 20$ kJ mol^{-1}

Therefore, the Arrhenius equation in the two conditions is :

$$K = Ae^{-\frac{x}{R\times 500}} \qquad ...(i)$$

$$K = Ae^{-\frac{x-20}{R\times 400}} \qquad ...(ii)$$

Dividing equation (*i*) by (*ii*), we get :

$$e^{-\frac{x}{500R}} = e^{-\frac{x-20}{400R}}$$

or
$$\frac{x}{500} = \frac{x-20}{400}$$

$\therefore \quad x = 100$ kJ mol^{-1}

EXAMPLE 108. *At 380°C, the half-life period for the first order decomposition of H_2O_2 is 360 min. The energy of activation of the reaction is 200 kJ mol^{-1}. Calculate the time required for 75% decomposition at 450°C.*

SOLUTION. $T_1 = 380 + 273 = 653$ K;

$T_2 = 450 + 273 = 723$ K

$t_{1/2}$ at 653 K $= 360$ min

$$k_{653} = \frac{0.693}{t_{1/2}} = \frac{0.693}{360} = 1.925 \times 10^{-3}\text{ min}^{-1}$$

Calculation of k_{723}

$$E_a = 200 \text{ kJ mol}^{-1} = 200 \times 10^3 \text{ J mol}^{-1}$$

According to Arrhenius law

$$\log\frac{k_{723}}{k_{635}} = \frac{E_a}{2.303R}\frac{[T_2 - T_1]}{T_1T_2}$$

or
$$\log\frac{k_{723}}{1.925\times10^{-3}\text{ min}^{-1}} = \frac{200\times10^3}{2.303\times8.314}\frac{[723-653]}{723\times653}$$

$$\log\frac{k_{723}}{1.925\times10^{-3}\text{ min}^{-1}} = 1.5487$$

or
$$\frac{k_{723}}{1.925\times10^{-3}} = \text{Antilog } 1.5487 = 35.376$$

or
$$k_{723} = 35.376 \times 1.925 \times 10^{-3}$$

$$= \mathbf{6.81 \times 10^{-2}\ min^{-1}}$$

Calculation of time required for 75% completion. For a first order reaction,

$$t = \frac{2.303}{k}\log\frac{a}{(a-x)}$$

$$= \frac{2.303}{6.81\times10^{-2}}\log\frac{100}{(100-75)}$$

$$= \frac{2.303}{6.81\times10^{-2}}\log 4 = 33.817 \times 06020$$

$$= \mathbf{20.35\ min.}$$

EXAMPLE 109. *A first order reaction, $A \longrightarrow B$ requires activation energy of 70 kJ mol^{-1}. When a 20% solution of A was kept at 25°C for 25 minutes, 25% decomposition took place. What will be the percentage decomposition in the same time in a 30% solution maintained at 40°C ? Assume that activation energy remains constant in this range of temperature.* **(IIT, 1993)**

SOLUTION. Calculation of rate constant at 25°C (298 K), k_1

Here, $a = 100$, $(a - x) = 100 - 25 = 75$, $t = 20$ min.

$$\therefore \quad k_1 = \frac{2.303}{20}\log\frac{100}{75} = 0.014386\text{ min}^{-1}$$

Calculation of rate constant at 40°C (313 K), k_2. According to Arrhenius equation :

$$\log\frac{k_2}{k_1} = \frac{E_a}{2.303R}\left[\frac{1}{T_1} - \frac{1}{T_2}\right]$$

$$\therefore \log\frac{k_2}{0.014386} = \frac{70\times10^3}{2.303\times8.314}\times\left[\frac{1}{298} - \frac{1}{313}\right]$$

$$= \frac{70\times10^3\times15}{2.303\times8.314\times298\times313} = 0.587$$

$$\frac{k_2}{0.014386} = \text{Antilog } 0.587$$

$$= 3.8636;$$

$$k_2 = 0.014386 \times 3.8636$$

$$= 0.05558$$

Calculation of percentage decomposition at 40°C. Let the % decomposition in this case = x.

Thus here $a = 100$, $(a - x) = 100 - x$.

$$t = 20 \text{ min}; k_2 = 0.05558.$$

Substituting the values in the first order rate equation

$$k_2 (= 0.05558) = \frac{2.303}{20} \log \frac{100}{100 - x}$$

$$= \frac{0.0558 \times 20}{2.303} = \log \frac{100}{(100 - x)}$$

$$\log \frac{100}{(100 - x)} = 0.48458 \quad \frac{100}{(100 - x)}$$

$$= \text{Antilog } 0.48458 = 3.052$$

$$100 - x \times 3.052 = 100 ; 305.2 - 3.052x = 100$$

$$\text{or} \quad 3.052x = 305.2 - 100 = 205.2;$$

$$x = 67.2346 = 67.23\%.$$

EXAMPLE 110. *Two reactions (i) A $\longrightarrow$ Products (ii) B $\longrightarrow$ Products follow first order kinetics. The rate of the reaction (i) is doubled when the temperature is raised from 300 K to 310 K. The half life for this reaction at 310 K is 30 minutes. At the same temperature B decomposes twice as fast as A. If the energy of activation for the reaction (ii) is half that of reaction (i), calculate the rate constant of the reaction (ii) at 300 K.*

(IIT, 1992)

SOLUTION. $T_1 = 300$ K. Let k_1 and k_2 be the rate constants for reaction (*i*) at temperature T_1 and T_2 respectively.

According to Arrhenius equation,

$$\log \frac{k_2}{k_1} = \frac{E_a}{2.303R}\left[\frac{1}{T_1} - \frac{1}{T_2}\right]$$

$$= \frac{E_a}{2.303R}\left[\frac{T_2 - T_1}{T_1 T_2}\right]$$

$$\therefore \quad E_a = \log \frac{k_2}{k_1} \times \frac{2.303R(T_1 T_2)}{T_2 - T_1}$$

$$= \log 2 \times \frac{2.303 \times 300 \times 310 \times R}{(310 - 300)}$$

$$= \frac{0.301 \times 2.303 \times 8.314 \times 300 \times 310}{10} \text{ J}$$

$$= 53598.593 \text{ J}$$

$$E_a = \mathbf{53.598 \text{ kJ}}$$

Activation energy for second reaction,

$$E_a = \frac{53.598}{2} = \mathbf{26.799 \text{ kJ}}$$

$t_{1/2}$ for first reaction at 310 K = 30 min.

Rate constant for first reaction at 310 K (k_2)

$$= \frac{0.693}{t_{1/2}} = \frac{0.693}{30} = 0.0231 \text{min}^{-1}$$

Rate constant for second reaction at 310 K (k_2)

$$= 0.0231 \times 2 = 0.0462 \text{ min}^{-1}$$

Now according to Arrhenius equation,

$$\log \frac{k_2}{k_1} = \frac{E_a}{2.303R} \frac{[T_2 - T_1]}{T_1 T_2}$$

$$= \frac{26799}{2.303 \times 8.314} \times \frac{(310 - 300)}{310 \times 300}$$

$$\log \frac{k_2}{k_1} = 0.1504$$

$$\text{or} \quad \log 0.0462 - \log k_1$$

$$= 0.1504$$

$$\log k_1 = \log 0.0462 - 0.1504$$

$$= \bar{2}.6646 - 0.1504$$

$$\log k_1 = \bar{2}.5142$$

$$\therefore \quad k_1 = \text{antilog } \bar{2}.5142 = 0.03267.$$

EXAMPLE 111. *The activation energy of a reaction is 75.2 kJ mol^{-} in the absence of a catalyst and 50.14 kJ mol^{-} with a catalyst. How many times will the rate of reaction grow in the presence of the catalyst if the reaction proceeds at 25°C ? (R = 8.314 JK^{-} mol^{-}).* **(CBSE,2005)**

SOLUTION. Let k_1 and k_2 are the rate constants. Let E_1 = activation energy in the absence of a catalyst. E_2 = activation energy in the presence of a catalyst. T = 25 + 273 = 298 K.

$$\ln k_1 = \ln A - \frac{E_1}{RT} \quad \text{...(1)}$$

$$\ln k_2 = \ln A - \frac{E_2}{RT} \quad \text{...(2)}$$

Subtracting equation (1) from (2), we get :

$$\ln k_2 - \ln k_1 = \frac{E_1}{RT} - \frac{E_2}{RT} ; \ln \frac{k_2}{k_1} = \frac{1}{RT}[E_1 - E_2]$$

$$\textbf{or} \quad \log \frac{k_2}{k_1} = \frac{1}{2.303RT}[E_1 - E_2]$$

$$= \frac{(75.2 - 50.14) \times 1000 \text{ J mol}^{-}}{2.303 \times 8.314 \text{ JK}^{-}\text{mol}^{-} \times 298 \text{ K}}$$

$$= \frac{25.06 \times 1000}{2.303 \times 8.314 \times 298} = 4.392$$

$$\therefore \quad \frac{k_2}{k_1} = \text{antilog } 4.392 = 24660$$

Hence, the rate of reaction increases by 24660 times.

Ans.

EXAMPLE 112. *$N_2O_5(g)$ decomposes at 473 K as $N_2O_5(g) \longrightarrow N_2O_4(g) + \frac{1}{2}O_2(g)$. If the initial pressure is 114 mm and after 25 minute of reaction, total pressure of gaseous* *mixture is 133 mm, calculate the average rate of reaction in (a) atm min^{-} (b) mol L^{-}.*

SOLUTION. (*a*) Let p = decrease in pressure of N_2O_5 in 25 minutes, then

$$N_2O_5\,(g) \longrightarrow N_2O_4\,(g) + \frac{1}{2}O_2(g)$$

Initial pressure	114 mm	0	0
Pressure after 25 min.	$114 - p$	p	$\frac{1}{2}p$

$$\text{Total pressure} = 114 - p + p + \frac{1}{2}p = 114 + \frac{p}{2}.$$

So, $\quad 114 + p/2 = 133$ mm (given)

$\therefore \quad p = 2 \times (133 - 114 = 19\text{ mm})$

$= 38$ mm or $(38/760)$ atm.

$$\therefore \text{ Average rate of reaction} = \frac{(38/76)\text{ atm}}{25\text{ min}}$$

$= \mathbf{0.002\ atm\ min^{-}}$ **Ans.**

(*b*) Applying $pV = nRT$ *i.e.*, $\frac{n}{V} = \frac{p}{RT}$;

decrease in molar concentration

$$= \frac{(38/760)\text{ atm}}{0.0821\text{ L atm K}^{-}\text{ mol}^{-} \times 473\text{ K}}$$

$= \mathbf{0.0012875\ mol\ L^{-}}$ **Ans.**

EXAMPLE 113. *The rate constants of a reaction at 700 K and 760 K are 0.011 M^{-}s^{-} or L mol^{-}s^{-} and 0.105 M^{-} s^{-} or L mol^{-} s^{-} respectively. Calculate the values of E_a and frequency factor, A.* **(DB 2009)**

SOLUTION. $k_1 = 0.011$ M^{-}s^{-}; $k_2 = 0.105$ M^{-}s^{-}; $T_1 = 700$ K; $T_2 = 760$ K; E_a = ?

We know that :

(*i*) $$\log\frac{k_2}{k_1} = \frac{E_a}{2.303R}\left[\frac{T_2 - T_1}{T_1T_2}\right]$$

$$\log k_2 - \log k_1 = \frac{E_a}{2.303R}\left[\frac{T_2 - T_1}{T_1T_2}\right]$$

$\log 0.105 - \log 0.011$

$$= \frac{E_a}{2.303 \times 8.314\text{ JK}^{-}\text{mol}^{-}}\left[\frac{760 - 700}{760 \times 700}\right]\text{K}^{-}$$

$[-0.9788 - (-1.9586)]$ *i.e.*, 0.9798

$$= \frac{E_a}{2.303 \times 8.314\text{ J mol}^{-}}\left[\frac{60}{760 \times 700}\right]$$

$$\therefore \quad E_a = \frac{0.9798 \times 2.303 \times 8.314\text{ J mol}^{-} \times 760 \times 700}{60}$$

$= 166342$ J mol^{-}

(*ii*) $$\log k = \log A - \frac{E_a}{2.303R} \times \frac{1}{T}$$

$$\log 0.011 = \log A - \frac{166342\text{ J mol}^{-}}{2.303 \times 8.314\text{ J K}^{-}\text{mol}^{-}} \times \frac{1}{700\text{ K}}$$

$-1.9586 = \log A - 12.41;$

$\log A = 12.41 - 1.9586 = 10.4514$

$\therefore \quad A = \text{antilog } 10.4514 = 2.82 \times 10^{10}$ **Ans.**

EXAMPLE 114. *In a pseudo first order hydrolysis of ester in water, the following results are obtained.*

t in second	*0*	*30*	*60*	*90*
(Ester)M	*0.55*	*0.31*	*0.17*	*0.085*

Calculate the average rate of reaction between the time interval 30 to 60 seconds. **(ISC, 2011)**

SOLUTION. For first order reaction, rate constant

$$k = \frac{2.303}{t}\log\frac{a}{a - x} \qquad \ldots(1)$$

When $t = 0, a = 0.55$; $t = 30, a - x = 0.31$; $t = 60$, $a - x = 0.17$; $t = 90, a - x = 0.085$. Substituting these values is equation (1), one by one, we get:

(*i*) $$k = \frac{2.303}{30}\log\frac{0.55}{0.31} = \frac{2.303}{30}$$

$[\log 55 - \log 31 = 1.7404 - 1.4914 = 0.249]$

$$= \frac{2.303}{30} \times 0.249 = 0.0191$$

(*ii*) $$k = \frac{2.303}{60}\log\frac{0.55}{0.17} = \frac{2.303}{60}$$

$[\log 55 - \log 17 = 1.7404 - 1.2304 = 0.51]$

$$= \frac{2.303}{60} \times 0.51 = 0.0191$$

(*iii*) $$k = \frac{2.303}{90}\log\frac{0.550}{0.085}$$

$= \frac{2.303}{90}$ $[\log 550 - \log 85 = 2.7404 - 1.9294 = 0.811]$

$$= \frac{2.303}{90} \times 0.811 = 0.02$$

$\therefore$ Average rate of reaction

$= (0.0191 + 0.0191 + 0.02)/3 = 0.0194$

EXAMPLE 115. *At 310 K, in presence of a catalyst, the activation energy of a reaction is lowered by 2 k cal. Calculate how much rate of reaction will increase. ($R = 2 \times 10^{-3}$ k cal mol^{-} K^{-})*

SOLUTION. $$\log k = \log A - \frac{E_a}{2.303\,RT} \qquad \ldots(i)$$

In presence of catalyst, let rate constant = k' ;

$E_a = E_a - 2$

$$\therefore \quad \log k' = \log A - \frac{E_a - 2}{2.303\,RT} + \frac{2k\text{ cal mol}^{-}}{2.303\,RT} \qquad \ldots(ii)$$

Subtracting equation (*i*) from equation (*ii*), we get :

$$\log k' - \log k = \frac{2k\text{ cal mol}^{-}}{2.303\,RT}$$

$$\log\frac{k'}{k} = \frac{2k \text{ cal mol}^{-}}{2.303\times 2\times 10^{-3}\, k \text{ cal mol}^{-}\ \text{K}^{-}\times 300\ \text{K}}$$

$$\log\frac{k'}{k} = 1.4474;\ \frac{k'}{k} = \text{antilog } 1.4474 = 28;$$

$k' = 28\,k$. *i.e.*, rate of reaction will increase 28 times.

EXAMPLE 116. *At constant temperature and volume, X decomposes as :*

$$2X(g) \longrightarrow 3Y(g) + 2Z(g)$$

Px is the partial pressure of X :

Observation No.	*Time (in minute)*	*Px (in mm of Hg)*
1	*0*	*800*
2	*100*	*400*
3	*200*	*200*

What is the order of reaction with respect to X ?

(i) Find the rate constant.

(ii) Find the time for 75% completion of the reaction.

(iii) Find the total pressure when pressure of X is 700 mm of Hg. **(IIT-JEE(mains), 2005)**

SOLUTION. For first order reaction, $k = \frac{2.303}{t}\log\frac{P_0}{P_t}$

Or
$$k_1 = \frac{2.303}{100}\log\frac{800}{400}$$
$$= \frac{2.303}{100}\log 2 = \frac{2.303}{100}\times 0.301$$
$$= 6.932\times 10^{-3}\ \text{min}^{-}$$

Similarly,
$$k_2 = \frac{2.303}{t}\log\frac{P_0}{P_1} = \frac{2.303}{200}\log\frac{800}{200}$$
$$= \frac{2.303}{200}\log 4$$
$$= \frac{2.303}{200}\times 0.602 = 6.932\times 10^{-3}\ \text{min}^{-}.$$

From above we see that the value of k_1 = value of k_2. So, the reaction is of first order and hence :

Order of reaction with respect to X = 1 **Ans.**

(*i*) Rate constant, $k = 6.932\times 10^{-3}$ min^{-} (found above) **Ans.**

(*ii*) To find time for 75% completion of reaction; $a = 100$, $a - x = 100 - 75 = 25$.

$$\therefore\ 6.932\times 10^{-3} = \frac{2.303}{t}\log\frac{100}{25} = \frac{2.303}{t}\log 4$$

$$6.932\times 10^{-3} = \frac{2.303}{t}\times 0.602$$

$$\therefore\quad t = \frac{2.303\times 0.602}{6.932\times 10^{-3}} = \mathbf{200\ min.}$$ **Ans.**

(*iii*) For reaction :	$2X(g)$	$\longrightarrow$	$3Y(g)$	+	$2Z(g)$
Initial pressure	800		0		0
After time, t	800 – 2P		3P		2P

When pressure of X is 700 mm of Hg, then :

$$800 - 2P = 700;\ 2P = 100;$$
$$P = \frac{100}{2} = 50 \text{ mm of Hg.}$$

$$\text{Total pressure} = 800 - 2P + 3P + 2P$$
$$= 800 + 3P \textit{ i.e.}, 800 + (3\times 50)$$
$$= \mathbf{950\ mm\ of\ Hg}$$ **Ans.**

EXAMPLE 117. *The value of rate constant of a reaction increases by 9% when its temperature is raised from 27°C to 28°C while the equilibrium constant increases by 4%. Calculate the activation energy of the forward and backward reaction.*

SOLUTION. (*a*) $T_1 = 27 + 273 = 300$ K; $T_2 = 28 + 273 = 301$ K.

Let rate constant at 300 K = k; k_1 = rate constant at 301 K.

$$= k + \frac{k\times 9}{100} = k + 0.09k = 1.09k = k_2$$

Using Arrhenius equation, we have :

$$\log\frac{k_2}{k_1} = \frac{E_a^f}{2.303R}\left[\frac{T_2 - T_1}{T_1T_2}\right];$$

$$\log\frac{1.09}{1} = \frac{E_a}{2.303\times 8.314}\left[\frac{301-300}{300\times 301}\right]$$

$$0.0374 = \frac{E_a^f}{2.303\times 8.314}\left[\frac{1}{300\times 301}\right]$$

$$E_a^f = 0.0374\times 2.303\times 8.314\times 300\times 301$$

[$\because$ R = 8.314 JK^{-} mol^{-}]

$$\therefore\quad E_a^f = 64664 \text{ J mol}^{-} = 64.664 \text{ kJ mol}^{-}.$$

(*b*) At 300 K, equilibrium constant, k_1 = K

At 301 K, equilibrium constant, $k_2 = \text{K} + \frac{4\text{K}}{100} = 1.04\,\text{K}$

Using Arrhenius equation, we have :

$$\log\frac{k_2}{k_1} = \frac{\Delta_r\text{H}^\circ}{2.303R}\left[\frac{T_2 - T_1}{T_1T_2}\right];$$

$$\log\frac{1.04}{1} = \frac{\Delta_r\text{H}^\circ}{2.303\times 8.314}\left[\frac{301-300}{300\times 301}\right]$$

$$0.017 = \frac{\Delta_r\text{H}^\circ}{2.303\times 8.314}\left[\frac{1}{300\times 301}\right]$$

$$\therefore\quad \Delta_r\text{H}^\circ = 0.017\times 2.303\times 8.314\times 300\times 301$$
$$= 29393 \text{ J mol}^{-} = 29.393 \text{ kJ mol.}$$

But, $\Delta_r\text{H}^\circ = E_a^f - E_a^r$.

Hence
$$E_a^r = E_a^f - \Delta_r\text{H}^\circ$$
$$= 64.664 \text{ kJ mol}^{-} - 29.393 \text{ kJ mol}^{-}$$
$$= 35.271 \text{ kJ mol}^{-}.$$

For endothermic reaction, $\Delta_r\text{H}^\circ > 0$. Hence $E_a^r < E_a^f$.

For exothermic reaction $\Delta_r\text{H}^\circ < 0$. Hence $E_a^r > E_a^f$.

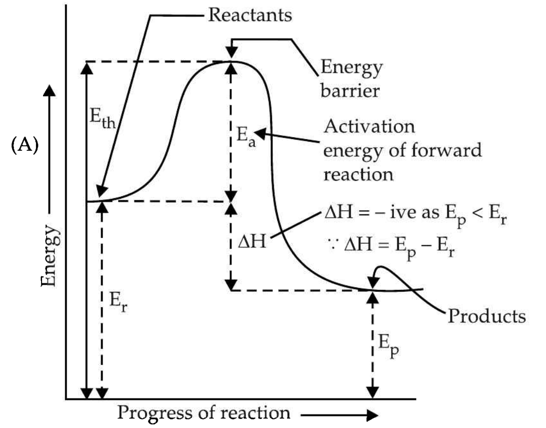
20.9 THRESHOLD ENERGY, ACTIVATION ENERGY ETC.

Type : Calculation of threshold energy, activation energy, energy of reactants and products, enthalpy change (ΔH) from exothermic and endothermic reactions.

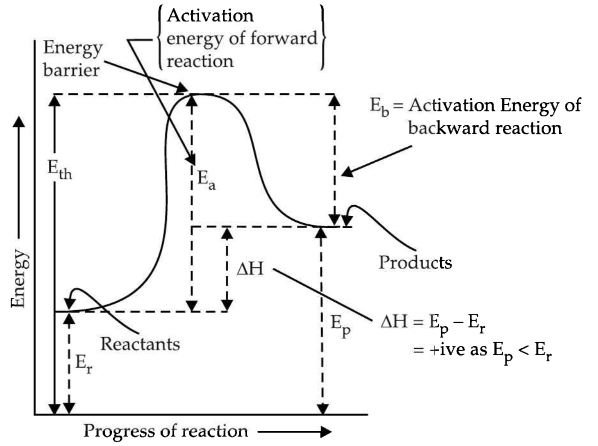
(*i*) $\left.\begin{array}{l}\text{Threshold energy for}\\ \text{forward reaction } (E_{th})\end{array}\right] = \text{Energy of reactants } (E_R) + \text{Activation energy } (E_a)$

(*ii*) $\left.\begin{array}{l}\text{Threshold energy for}\\ \text{backward reaction } (E_{th})\end{array}\right] = \text{Energy of products } (E_P) + \text{Activation energy of backward reaction } (E_b)$

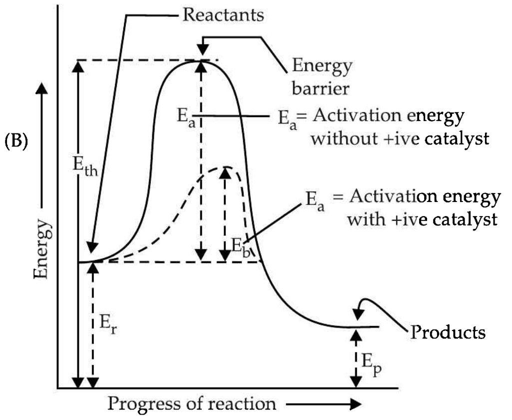
(*iii*) Energy level diagram for endothermic, exothermic, catalysed and uncatalysed reactions.

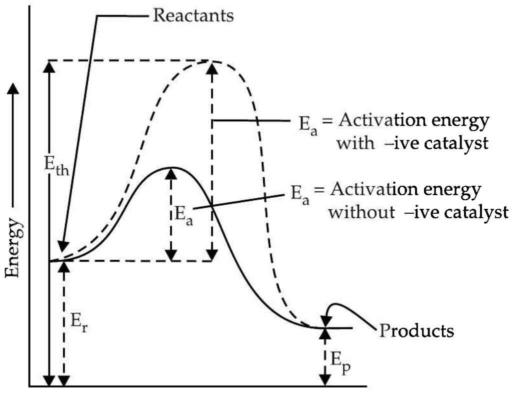


(Exothermic reaction, ΔH = –ive)



(Endothermic reaction, ΔH = +ive)





Example 118. *For a hypothetical reaction, the mean potential energies of reactants and products are 40 and 25 k cal mol⁻. Calculate the activation energies of the forward and reverse reactions if the threshold energy is 65 k cal. Also, calculate the heat of reaction.*

Solution. (*i*) Activation energy of the forward reaction,

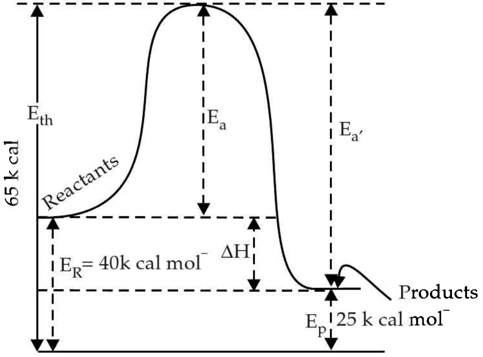
$$E_a = E_{th} - E_R = 65 - 40 = 25\ k\ \text{cal.} \qquad \textbf{Ans.}$$

(*ii*) Activation energy of the backward reaction,

$$E_{a'} = E_{th} - E_P = 65 - 25 = 40\ k\ \text{cal.} \qquad \textbf{Ans.}$$

(*iii*) $\Delta H = E_P - E_R = 25 - 40 = -15\ k$ cal.

Ans. (see figure)



Example 119. *From the data of the reaction $A \to B$, $\Delta H = +\ 20\ k$ cal mol⁻, $E_{act} = 30\ k$ cal mol⁻. Find the value of ΔH and E_{act} of the reverse reaction, $B \to A$.*

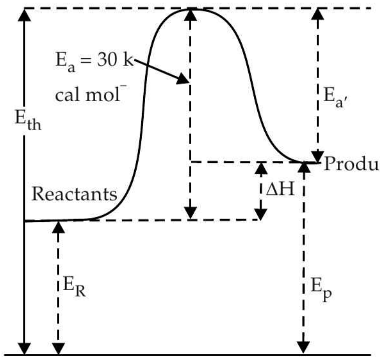
Solution. (*i*) $\Delta H = E_P - E_R$; $20 = E_P - E_R$.

ΔH for the reverse reaction, $E_P - E_R = -20\ k$ cal mol⁻.

(*ii*) Activation energy of the reverse reaction,

$$E'_a = E_a - \Delta H = 30 - (+\ 20) = 10\ k\ \text{cal.}$$

Ans. (see figure).

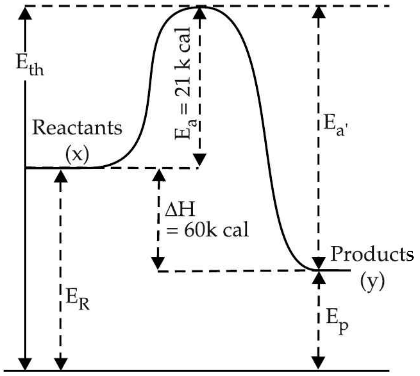


Example 120. *An exothermic reaction, $x \rightarrow y$ has an activation energy of 21.0 k cal mol^{-} of x and heat of reaction is 60 k cal. Find the activation energy of the reaction, $y \rightarrow x$.*

Solution. Activation energy of the backward reaction,

$$E'_a = E_a + \Delta H = 21 + 60$$

$$= 81\ k\ \text{cal.}$$ **Ans.**



Example 121. *The reaction, $A + B \rightarrow C + D + 40$ kJ has an activation energy of 18 kJ. Then the activation energy for the reaction, $C + D \rightarrow A + B$ is:*

(*a*) 58 kJ (*b*) –40 kJ (*c*) –18 kJ (*d*) 22 kJ

(J and K-ECT, 2011)

Solution. Activation energy of products

= ΔH + Activation energy of reactants

= 40 + 18 = 58 kJ

So, the correct answer is (*a*).

Example 122. *The activation energy of a reaction at a given temperature is found to be 2.303 RTJ mol^{-}. The ratio of rate constant to the Arrhenius factor is:*

(*a*) 0.01 (*b*) 0.1 (*c*) 0.02 (*d*) 0.001

(Karnataka CET, 2011)

Solution. Let E_a = activation energy, *k* is rate constant and *A* is Arrhenius factor. We know that:

$$\log\frac{k}{A} = \frac{-E_a}{2.303\,RT};\ \log\frac{k}{A} = -\frac{2.300\,RT}{2.303\,RT} = -1;$$

$$\frac{k}{A} = \text{antilog}(-1) \text{ or } \frac{k}{A} = 0.1.$$

So, the correct answer is (*b*).

20.10 AIEEE PATTERN EXAMPLES

Example 123. *The rate law for a reaction between the substance A and B is given by, Rate = $k[A]^n[B]^m$. On doubling the concentration of A and halving that of B, the ratio of the new rate to the earlier rate of reaction will be as :*

(*a*) $2^{(n-m)}$; (*b*) $\frac{1}{2^{(m+n)}}$; (*c*) $(m + n)$; (*d*) $(n - m)$.

(AIEEE, 2003)

Solution. Given : $R = k[A]^n[B]^m$ ....(1)

New concentration of A = $(2A)^n$;

New concentration of B = $\left(\frac{B}{2}\right)^m$

$$\therefore \quad \text{New rate, } R_1 = k[2A]^n\left[\frac{B}{2}\right]^m \quad ...(2)$$

Dividing relation (2) by (1), we get :

$$\frac{R_1}{R} = \frac{k\,2^n[A]^n[B]^m}{k[A]^n[B]^m 2^m}$$

$$= 2^n \times 2^{-m} = 2^{(n-m)}.$$

Hence, the answer is (*a*).

Example 124. *For the gaseous reaction $2A + B \rightarrow C + D$, the rate is given by K [A] (B]. The volume of the container containing the reaction mixture is suddenly reduced to one fourth of its original volume. With respect to the original rate, now the rate would be :*

(*a*) $\frac{1}{16}$ *times* ; (*b*) *12 times;*

(*c*) *4 times;* (*d*) $\frac{1}{4}$ *times.*

Solution. Since the volume of the container is reduced to one fourth of its original volume, the concentration and hence rate would become four times. So, the correct answer is (*c*).

Example 125. *Under the same reaction conditions, initial concentration of 1.386 mol dm^{-3} of a substance becomes half in 40 seconds and 20 seconds through first order and zero order kinetics, respectively. Ratio (k_1/k_0) of the rate constant for first order (k_1) and zero order (k_0) of the reactions is:*

(*a*) *0.5 mol^{-} dm^3* (*b*) *1.0 mol dm^{-3}*

(*c*) *1.5 mol dm^{-3}* (*d*) *2.0 mol^{-} dm^{-3}* **(IIT–JEE, 2008)**

Solution. (*i*) For zero order reaction,

$$t_{1/2} = \frac{A_0}{2k_0}$$

$$\therefore \quad k_0 = \frac{A_0}{2 \times t_{1/2}} = \frac{1.386\,\text{mol dm}^{-3}}{2 \times 20\,s} \quad ...(1)$$

(*ii*) For first order reaction,

$$k_1 = \frac{2.303}{t_{1/2}}\log\frac{a}{0.5a}$$

$$= \frac{2.303}{t_{1/2}}\log 2 = \frac{2.303}{t_{1/2}} \times 0.301 = \frac{0.693}{t_{1/2}}$$

$$\therefore \quad k_1 = \frac{0.693}{40\,s} \quad ...(2)$$

From equations (1) and (2), we have

$$\frac{k_1}{k_0} = \frac{0.693}{40s} \times \frac{2 \times 20s}{1.386\ \text{mol dm}^{-3}} = 0.5\ \text{mol}^{-}\,\text{dm}^3$$

So, the correct answer is (*a*).

Example 126. *The rate law for the reaction, $xA + yB \rightarrow mP + nQ$ is rate = $k[A]^c[B]^d$. What is the total order of reaction?*

(*a*) $x + y$ (*b*) $m + n$ (*c*) $c + d$ (*d*) x/y (*e*) two

(Kerala PMT, 2011)

Solution. Rate = $k[A]^c[B]^d$. So, order of reaction = sum of exponents = $c + d$.

So, the correct answer is (*c*).

EXAMPLE 127. *The rate of reaction,* $2N_2O_5 \rightarrow 4NO_2 + O_2$ *can be written is three ways:*

$$\frac{-d[N_2O_5]}{dt} = k[N_2O_5];\ \frac{d[NO_2]}{dt}$$

$$= k'[N_2O_5];\ \frac{d(O_2)}{dt} = k''[N_2O_5].$$

The relationship between k and k' and between k and k'' are

(*a*) $k' = 2k,\ k'' = k$; (*b*) $k' = 2k;\ k'' = k/2$;

(*c*) $k' = 2k;\ k = 2k$; (*d*) $k' = k;\ k'' = k$

(AMU, 2010; AIPMT, 2011)

SOLUTION. For the reaction, $2N_2O_5 \rightarrow 4NO_2 + O_2$:

$$-\frac{1}{2}\frac{d[N_2O_5]}{dt} = +\frac{1}{4}\frac{d[NO_2]}{dt} = +\frac{d[O_2]}{dt}$$

Rate constant: k k' k''

∴ $1/2\,k = 1/4\,k' = k''$. Hence, $k' = 2k$; $k'' = 1/2k$. So, the correct answers is (*b*).

EXAMPLE 128. *The rate of reaction, A + B → products is given by the equation, r = k [A] [B]. If B is taken in large excess, the order of reaction would be :*

(a) 1.5; *(b) 2.5;*

(c) 1; *(d) unpredictable.*

SOLUTION. It is given that concentration of B is in large excess. So, the reaction will follow first order kinetics because in such a case, the rate will not depend upon the concentration of B. So, order of reaction = 1. Thus, the correct answer is (*c*).

EXAMPLE 129. *In a reaction,* $N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$, *the rate of appearance of ammonia is* 2.5×10^{-4} *mol* $L^{-}s^{-}$, *the rate of disappearance of* H_2 $\frac{-d[H_2]}{dt}$ *will be:* **(CBSE-PMT, 2009)**

(a) Cannot be predicted; *(b)* 375×10^{-9};

(c) 2.1×10^{-9}; *(d)* 3.00×10^{-4}.

SOLUTION. Given reaction : $N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$. For one mol of NH_3, we have :

$$\frac{1}{2}N_2(g)+\frac{3}{2}H_2(g) \rightleftharpoons NH_3(g) \quad \text{[After dividing by 2]}$$

∴ Rate of disappearance of H_2

$$= \frac{3}{2} \times \text{Rate of appearance of } NH_3$$

$$= \frac{3}{2} \times 2.5 \times 10^{-4}$$

$$= 3.75 \times 10^{-4}\ \text{mol}\ L^{-}s^{-}$$

So, the correct answer is, (*d*).

EXAMPLE 130. *For a first order reaction A → B, the reaction rate at reactant concentration of 0.01 M is found to be* 2.0×10^{-5} *mol* $L^{-}s^{-}$. *The half-life period of the reaction is :*

(a) 30s; *(b) 220s;* *(c) 300s;* *(d) 347s.*

[CBSE–PMT (Prelims), 2005]

SOLUTION. In A → B reaction, rate of reaction = 2×10^{-5} mol $L^{-}s^{-}$. Order of reaction, $n = 1$ (given). But rate = $k\,[A]^n$.

Where k = rate (or velocity) constant ; [A] = 0.01 M.

$$\therefore \quad \text{Rate} = k\,[A]^1$$

$$\text{or} \quad k = \frac{\text{rate}}{[A]} = \frac{2\times10^{-5}\ \text{mol}\,L^{-}s^{-}}{0.01\,\text{mol}\,L^{-}}$$

$$\text{or} \quad k = 2 \times 10^{-3}s^{-}$$

$$\text{But, half-life } t_{0.5} = \frac{0.693}{k}$$

$$\therefore \quad t_{0.5} = \frac{0.693}{2\times10^{-3}s^{-}} \approx 347\,s$$

So, the correct answer is (*d*).

EXAMPLE 131. *The time required for 100% completion of a zero order reaction is:*

(*a*) *a k* (*b*) *a*/2 *k* (*c*) *a*/*k* (*d*) 2*k*/*a*

[Karnataka CET, 2011]

SOLUTION. Time needed for 100% completion of reaction is the time at which the concentration of A i.e.; [A] = 0

$$\therefore \quad t_{\text{completion}} = \frac{[A]_0}{k} = \frac{a}{k}.$$

So, the correct answer is (*c*).

EXAMPLE 132. *For reaction,* $2NOCl(g) \longrightarrow 2NO(g) + Cl_2(g)$, K_C *at 427°C is* 3×10^{-6} *L mol*$^{-}$. *The value of* K_p *is nearly :*

(a) 7.5×10^{-5}; *(b)* 2.5×10^{-5};

(c) 2.5×10^{-4}; *(d)* 1.72×10^{-4}. **(AIIMS – 2005)**

SOLUTION. $K_C = 3 \times 10^{-6}$ L mol^{-}; $T = 427 + 273 = 700$ K, $R = 0.0821$ L atm K^{-} mol^{-}.

For the reaction :

$$\underset{2\,\text{mol}}{2NOCl(g)} \rightarrow \underset{2\,\text{mol}}{2NO(g)} + \underset{1\,\text{mol}}{Cl_2(g)}$$

$$\Delta n = n_p - n_R = (2 + 1) - 2 = 1\ \text{mol}$$

We know that ;

$$K_p = K_c\,(RT)^{\Delta n} = 3.0 \times 10^{-6}\ L\ \text{mol}^{-} \times (0.0821\ L\ \text{atm}\ \text{mol}^{-}\ K^{-} \times 700\ K)^1$$

$$\therefore \quad k_p = 1.72 \times 10^{-4}\ L^2\ \text{mol}^{-2}\ \text{atm}.$$

So, the correct answer is (*d*).

EXAMPLE 133. *The rate of reaction between two reactants A and B decreases by a factor of 4 if the concentration of reactant B is doubled. The order of this reaction with respect to reactant B is:*

(a) 2; *(b) –2;* *(c) 1;* *(d) –1*

[CBSE – PMT (Prelims), 2005]

SOLUTION. Let a = order of reaction with respect to A

b = order of reaction with respect to B

But rate of reaction = $k\,[A]^a[B]^b$; [B] = [2B].

$$\text{So,} \quad \frac{r_1}{r_2} = \frac{k[A_0]^a[B]^b}{k[A_0]^a[2B]^b}$$

$$4 = \left(\frac{1}{2}\right)^b$$

Taking logs of both sides, we get :

$$\log 4 = b \log\left(\frac{1}{2}\right)$$

$$0.602 = b \times -0.301;\ b = \frac{0.602}{-0.301} = -2$$

So, the correct answer is (*b*).

Example 134. *The rate of a chemical reaction doubles for every 10°C rise in temperature. If the temperature is raised by 50°C, the rate of reaction increases by about:*

(a) 10 times (b) 24 times; (c) 32 times (d) 64 times

[AIEEE, 2011]

Solution. Since rate of a reaction becomes 2 times for every 10°C, we have;

Rate of reaction at 50°C $= 2^{50/10} = 2^5 = 32$ times.

So, the correct answer is (*c*).

Example 135. *The rate constant k_1 and k_2 for two different reactions are $10^{16}.e^{-2000/T}$ and $10^{15}.\ e^{-1000/T}$ respectively. The temperature at which $k_1 = k_2$ is :*

(a) 2000 K (b) $\frac{1000}{2.303}K$ (c) 1000 K (d) $\frac{2000}{2.303}K$

(CBSE–PMT, 2008 Prelims)

Solution. Given : $k_1 = 10^{16}.\ e^{-2000/T};\ k_2 = 10^{15}.\ e^{-1000/T}$

The temperature at which $k_1 = k_2$ will be :

$$10^{16}.\ e^{-2000/T} = 10^{15}.\ e^{-1000/T};\ \text{or}\ \frac{10^{15}}{10^{16}} = \frac{e^{-2000/T}}{e^{-1000/T}}$$

$$\text{or} \qquad 10^{-1} = e^{-1000/T}$$

$$\log_e e^{-1000/T} = \log_e 10^{-1};$$

$$2.303 \log_{10} e^{-1000/T} = 2.303 \log_{10} 10^{-1}$$

$$\text{or} \quad -\frac{1000}{T}\log_{10} e = -1.\ \text{So,}\ T = \frac{1000}{2.303}K.$$

Hence the correct answer is (*b*).

Example 136. *For the reaction : $2N_2O_5(g) \longrightarrow 4NO_2(g) + O_2(g)$ if the concentration of NO_2 increases by 5.2×10^{-3} M in 100 seconds, then the rate of reaction is :*

(a) $1.3 \times 10^{-5}\ Ms^{-}$; (b) $5 \times 10^{-4} Ms^{-}$

(c) $7.6 \times 10^{-4} Ms^{-}$; (d) $2 \times 10^{3}\ Ms^{-}$; (e) $2.5 \times 10^{-5}\ Ms^{-}$.

(Kerala PET, 2005)

Solution. $2N_2O_5(g) \rightarrow 4NO_2(g) + O_2(g)$

∴ Rate of reaction with respect to NO_2 will be :

$$\text{rate} = \frac{1}{4}\frac{d(NO_2)}{dt} = \frac{1}{4} \times \frac{5.2 \times 10^{-3} M}{100 s}$$

$$= \mathbf{1.3 \times 10^{-5}\ Ms^{-}}.$$

So, the correct answer is (*a*).

Example 137. *$t_{1/4}$ can be taken as the time taken for the concentration of a reactant to drop to 3/4 of its initial value. If the rate constant for the first order reaction is k, the $t_{1/4}$ can be written as :*

(a) $\frac{0.10}{k}$; (b) $\frac{0.29}{k}$; (c) $\frac{0.69}{k}$; (d) $\frac{0.75}{k}$.

(AIEEE, 2005)

Solution. We know that for first order reaction :

$$t = \frac{2.303}{k}\log\frac{a}{a-x}$$

Substituting the values, we get :

$$t_{1/4} = \frac{2.303}{k}\log\left(\frac{1}{3/4}\ \text{or}\ \frac{4}{3}\right)$$

$$= \frac{2.303}{k}[\log 4 - \log 3]$$

$$= \frac{2.303}{k}[0.602 - 0.477]$$

$$= \frac{2.303 \times 0.125}{k} = \frac{0.29}{k}.$$

So, the correct answer is (*b*).

Example 138. *For a first order reaction, the time taken to reduce the initial concentration by a factor of 1/4 is 20 minutes. The time required to reduce initial concentration by a factor of 1/16 is*

(a) 20 min (b) 10 min (c) 80 min (d) 40 min

(e) 5 min

(Kerala PMT, 2011)

Solution. The various steps to reduce the initial concentration are

$$\xrightarrow[\text{half-life}]{\text{first}} \frac{1}{2} \xrightarrow[\text{half-life}]{\text{Second}} \frac{1}{4} \xrightarrow[\text{half-life}]{\text{Third}} \frac{1}{8}$$

$\xrightarrow[\text{half-life}]{\text{Fourth}} \frac{1}{16}$. So 1/16 is four half-lives. Also, 1/4 is 2 half-lives. Since time taken for 2 half-lives is 20 minutes, the time taken for four half-lives will be 40 minutes. So, the correct answer is (*d*).

Example 139. *Consider an endothermic reaction $X \longrightarrow Y$ with the activation energies E_b and E_f for the backward and forward reactions respectively. In general,*

(a) $E_b < E_f$; (b) $E_b > E_f$; (c) $E_b = E_f$;

(d) There is no definite relation between E_b and E_f.

(AIEEE, 2005)

Solution. For an endothermic reaction, ΔH = positive.

∴ $\Delta H = E_f - E_b$ or $E_b + \Delta H = E_f$ *i.e.*, $E_b < E_f$.

So, the correct answer is (1).

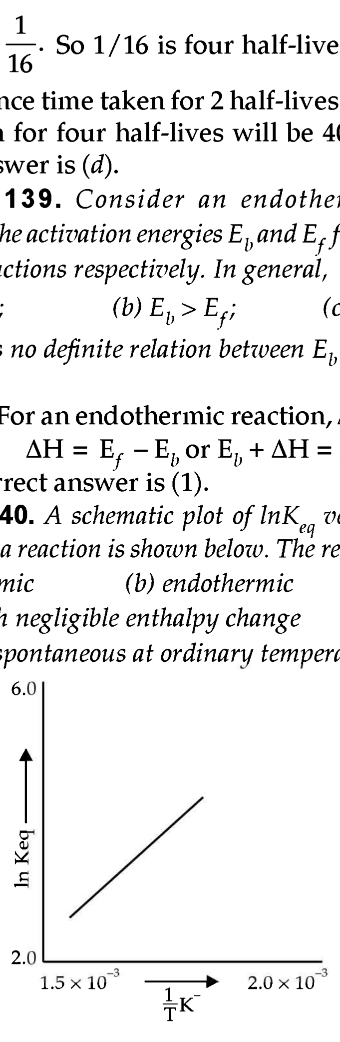
Example 140. *A schematic plot of $\ln K_{eq}$ versus inverse of temperature for a reaction is shown below. The reaction must be :*

(a) exothermic (b) endothermic

(c) one with negligible enthalpy change

(d) highly spontaneous at ordinary temperature.

(AIEEE, 2005)



Solution. From the diagram, it is clear that, $k_1 = 2.0$ and $k_2 = 6$; $\frac{1}{T_1} = 1.5 \times 10^{-3}$, $\frac{1}{T_2} = 2.0 \times 10^{-3}$.

But, $$\ln\frac{k_2}{k_1} = \frac{\Delta H}{R}\left[\frac{1}{T_1}-\frac{1}{T_2}\right]$$

$$\frac{2.303\log k_2}{2.303\log k_1} = \frac{\Delta H}{R}[1.5\times10^{-3}-2.0\times10^{-3}]$$

$$\log\frac{6}{2} = \frac{\Delta H}{R}(-0.5\times10^{-3})$$

$$\therefore \qquad \Delta H = \frac{(-\log 3)\times R}{0.5\times10^{-3}} = -\text{ive}$$

Since the value of ΔH is negative, the reaction is exothermic. So, the correct answer is (*a*).

Example 141. *For a spontaneous reaction, the ΔG, equilibrium constant (K) and $E°_{cell}$ will be respectively.*

(*a*) –*ive*, >1, +*ive*, (*b*) +*ive*, >1, –*ive*,

(*c*) –*ive*, < 1, –*ive*, (*d*) –*ive*, > 1, –*ive*.

(AIEEE, 2005)

Solution. The conditions for a spontaneous reaction are, ΔG = – ve, K > 1 and $E°_{cell}$ = +ive. So, the correct answer is (*a*).

Example 142. *For the reaction, A ⟶ B, the rate of reaction is quadrupled when the concentration of A is doubled. The rate expression of the reaction is $r = k[A]^n$ when the value of n is :*

(*a*) 1 (*b*) zero (*c*) 3 (*d*) 2

(P.U., PET 1983 CPMT, 1988)

Solution. The rate expression for the reaction which becomes 4 times on doubling the concentration can be written as :

(*i*) $r = k[A]^n$; (*ii*) $4r = k\,[2A]^n$]

Dividing (*ii*) by (*i*), we get,

$$\frac{4r}{r} = \frac{k[2A]^n}{k[A]^n} \text{ or } 4 = (2)^n \textbf{ or } (2)^2 = (2)^n.$$

Hence, $n = 2$. Hence rate = $k\,[A]^2$. So, the correct answer is (*d*).

Example 143. *For a first order reaction, we have k = 100 sec⁻. The time for completion of 50% (or half life time for completion) reaction is:*

(*a*) 1m sec; (*b*) 4 m sec; (*c*) 7m sec; (*d*) 10m sec.

(U.P.S.E., 1991, CBSE-PMT, 2009)

Solution. Time for completion of 50% reaction, $t_{1/2} = \frac{0.693}{k}$ for a first order reaction.

or $t_{1/2} = \frac{0.693}{100\,\text{sec}^-} \approx \frac{0.7}{100} = 7\times10^{-3}$ seconds = 7 milliseconds **or** 7 m sec. So, the correct answer is (*c*).

Example 144. *The half-life period of a first order chemical reaction is 6.93 minutes. The time required for the completion of 99% of the chemical reaction will be (log 2 = 0.301)*

(*a*) 230.3 minutes (*b*) 23.03 minutes

(*c*) 46.06 minutes (*d*) 460.6 minutes

(AIEEE, 2009)

Solution. $t_{1/2}$ = 6.93 minutes. For first order reaction:

$$\lambda = \frac{0.693}{t_{1/2}};\ \lambda = \frac{0.693}{6.93}$$

For a first order kinetic reaction, $t = \frac{2.303}{\lambda}\log\frac{[A_0]}{[A]}$

Where $[A_0]$ and [A] are initial concentration and concentration at time, *t* respectively. For 99% reaction complete, $\frac{[A_0]}{A} = \frac{100}{1}$. Hence, $t = \frac{2.303}{0.693}\times 6.93\times\log 100$

∴ $t = 23.03 \times 2 = 46.06$ minutes.

So, the correct answer is (*c*)

Example 145. *The rate of reaction between reactants A and B is expressed as Rate = k [A] [B]². On doubling the concentrations of both the reactants A and B, the rate is increased by a factor of :*

(*a*) 4; (*b*) 3; (*c*) 8; (*d*) 6.

(SCRA, 2000)

Solution. Given : $\text{Rate}_1 = k\,[A]\,[B]^2$. New concentrations of A and B are 2A and 2B respectively. Hence,

$\text{Rate}_2 = k\,[2A]\,[2B]^2 = k \times 2 \times 2^2\,[A]\,[B]^2 = 8k\,[A]\,[B]^2$.

∴ $\text{Rate}_2 = 8 \times \text{Rate}_1$. So, the correct answer is (*c*).

Example 146. *If a plot of $\log_{10}(t_{1/2})$ Vs $\log_{10}a$ gives a straight line with a slope of –1, the order of reaction would be :*

(*a*) 0; (*b*) 1; (*c*) 2; (*d*) 3

(SCRA, 2000)

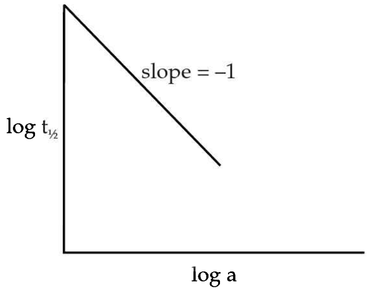
Solution. We know that for a second order reaction $t_{1/2} = K\cdot\frac{1}{a}$ where *a* = initial concentration of the reactants.

$$\therefore \qquad t_{1/2} = K\,.\,a^{-1}.$$

Taking logs of both sides, we get,

$$\log t_{1/2} = \log K + \log a^{-1}$$
$$\log t_{1/2} = \log K - \log a.$$

So, from the following graph we find the slope = – 1. So, the correct answer is (*c*).



Example 147. *Plot of log C (concentration) as a function of time gives a straight line for a first order reaction. The slope of this line gives :*

(*A*) *k*; (*B*) 1/*k*; (*c*) –*k*; (*d*) –1/*k*.

(BET, 2003)

SOLUTION. For a reaction, A $\longrightarrow$ Products.

$$\text{Rate} = -\frac{\Delta A}{\Delta t} = kt \,;\ \ln[A] = -kt + \ln[A_0]$$

or $$kt = \ln[A_0] - \ln[A]$$
$$= 2.303 \log[A_0] - 2.303 \log[A]$$

or $2.303 \log[A] = -kt + 2.303 \log[A_0]$ ...(1)

But $Y = mx + C$ is an equation of a straight line. So comparing this equation with (1), we can say that : a plot of Y (= log A) versus X (= t) is a straight line with slope, m (= $-k$) and intercept, C (= log A_0). So, for first order reaction, slope = $-k$ and the correct answer is, (*c*).

EXAMPLE 148. *A plot of ln k against 1/T (abscissa) is expected to be a straight line with intercept on the ordinate axis :*

(a) $\Delta S°/2.303\ R$ *(b) $\Delta S°/R$*

(c) $-\Delta S°/R$ *(d) $R \times \Delta S°$* **(WB-JEE, 2011)**

SOLUTION. We know: $\Delta G° = -RT \ln k$

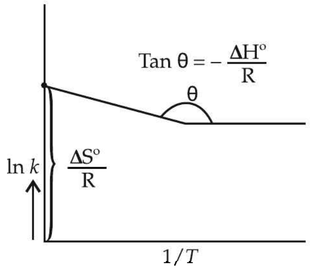
or $\Delta H° - T\Delta S° = -RT \ln k$

$$\therefore \quad \ln k = \frac{-\Delta H°}{RT} + \frac{\Delta S°}{R} \quad \text{...(1)}$$

But $y = mx + C$ ...(2) (equation of a straight line)

Comparing (1) and (2), we get:

Intercept, $y = \Delta S°/R$. So, the correct answer is (*b*)



EXAMPLE 149. *A reaction following zero order kinetics is 50% complete in 10 minutes. If the initial concentration of the reactants is 1×10^3 mol dm^{-3}, the rate constant of the reaction is :*

(a) 5 mol dm^{-3}min^{-}; *(b) 50 mol dm^{-3} min^{-};*

(c) 250 mol dm^{-3} min^{-}; *(d) 500 mol dm^{-3}min^{-}.*

(BET, 2003)

SOLUTION. For zero order reaction, $[A] = -kt + [A_0]$ ...(1)

But [A] = 50% *i.e.*, $= [A_0] \times \frac{50}{100} = \frac{[A_0]}{2}$; t = 10 min.

Substituting the values in (1), we get:

$$\frac{[A_0]}{2} = -kt + [A_0];$$

$$kt = [A_0] - \frac{[A_0]}{2} = \frac{[A_0]}{2}; k = \frac{[A_0]}{2t}$$

$$\therefore \quad k = \frac{1 \times 10^3 \text{mol dm}^{-3}}{2 \times 10 \text{min}}$$

$$= 50 \text{ mol dm}^{-3} \text{ min}^{-}$$

So, the correct answer is (*b*).

EXAMPLE 150. *$r = k\,[NO]^2[O_2]$. Rate constant can be increased by :*

(1) Increasing concentration of NO; (2) Increasing concentration of O_2; (3) Increasing temperature; (4) Decreasing temperature. **(IMS–BHU, 2003)**

SOLUTION. Since rate constant (r) depends upon temperature, it can be increased by increasing the temperature. So, the correct answer is (3).

EXAMPLE 151. *A reaction that is of first order with respect to reactant A has rate constant 6 min^{-}. If we start with [A] = 0.5 mol L^{-}, when would [A] reach the value 0.05 mol L^{-} ?*

(a) 0.15 min; *(b) 0.384 min;*

(c) 3.84 min; *(d) 3 min.* **(Karnataka – CET, 2000)**

SOLUTION. k = 6 min^{-}, initial concentration, N_0 = 0.5 mol L^{-}. Final concentration of A, N = 0.05 mol L^{-}. We know that :

$$t = \frac{2.303}{k} \log \frac{N_0}{N};$$

$$t = \frac{2.303}{6 \text{ min}^{-}} \log \frac{0.5}{0.05} = \frac{2.303}{6 \text{min}^{-}} \log 10$$

or $$t = \frac{2.303}{6 \text{ min}^{-}} \times 1 = 0.384 \text{min}.$$

So, the correct answer is (*b*).

EXAMPLE 152. *A reaction was found to be of second order with respect to the concentration of carbon monoxide. If the concentration of carbon monoxide is doubled with everything else kept the same, the rate of reaction will :*

(a) remain unchanged; *(b) be tripled;*

(c) increase by a factor of 4; *(d) be doubled.*

(AIEEE, 2006)

SOLUTION. Since the reaction is of second order, we have :

$$\text{Rate} = \frac{dx}{dt} = k[CO]^2.$$

Hence, according to rate law expression, doubling the concentration of CO increases the rate by a factor of 4. So, the correct answer is (*c*).

EXAMPLE 153. *The following mechanism has been proposed for the reaction of NO with Br_2 to form NOBr.*

$$NO(g) + Br_2(g) \rightleftharpoons NOBr_2(g)$$
$$NOBr_2(g) + NO(g) \longrightarrow 2NOBr(g)$$

If the second step is the rate determining step, the order of the reaction with respect to NO(g) is :

(a) 1; *(b) 0;*

(c) 3; *(d) 2.* **(AIEEE, 2006)**

SOLUTION. Given : $NO(g) + Br_2(g) \rightleftharpoons NOBr_2(g)$ ...(*i*)

$NOBr_2(g) + NO(g) \rightleftharpoons 2NOBr(g)$ ...(*ii*)

Since second step is the rate determining step, we have,

Rate of reaction, $r = K\,[NO]\,[NOBr_2]$

But, $$K_C = \frac{[NOBr_2]}{[NO][Br_2]} \text{ (from first step)}$$

$$\therefore \quad [NOBr_2] = K_C\,[NO]\,[Br_2]$$

$$\therefore \quad r = K[NO] \times K_C\,[NO]\,[Br_2]$$

$$= KK_C\,[NO]^2[Br_2]$$

So, the order of reaction with respect to NO = 2. So, the correct answer is (*d*).

Example 154. *For the reaction $N_2O_5 \longrightarrow 2NO_2 + 1/2\ O_2$*

$$\frac{d\,[N_2O_5]}{dt} = k_1\,[N_2O_5]; \frac{d[NO_2]}{dt} = k_2\,[N_2O_5]; \frac{d[O_2]}{dt} = k_3[N_2O_5]$$

the relation between k_1, k_2, and k_3 is:

(a) $2k_1 = k_2 = 4k_3$ *(b) $k_1 = k_2 = k_3$*
(c) $2k_1 = 4k_2 = k_3$ *(d) none of these.*

(AMU (engg), 2011)

Solution. For the given equation, $N_2O_5 \rightarrow 2NO_2 + 1/2\ O_2$; $\dfrac{-d[N_2O_5]}{dt} = \dfrac{1}{2}\dfrac{d[NO_2]}{dt} = \dfrac{2d[O_2]}{dt}$. Hence, after comparing with given data in question, $k_1 : k_2 : k_3$ ratio is $1 : \frac{1}{2} : 2$ or $(2 \times 1) : (2 \times \frac{1}{2}) : (2 \times 2)$ or $2 : 1 : 4$ *i.e.*, $2k_1 = k_2 = 4k_3$. So, the correct answer is (*a*).

Example 155. *The inversion of cane sugar was studied in IN HCl at 298 K. The following polarimeter readings were obtained at different intervals of time.*

Time (min)	*0*	*7.18*	*18.0*	*27.05*	*∞*
Reading (degree)	*+ 24.09*	*+ 21.41*	*+ 17.74*	*+ 15.00*	*– 10.74*

The reaction of inversion of cane sugar is :

(a) Unimolecular *(b) bimolecular*
(c) trimolecular *(d) tetramolecular*

Solution. For inversion of sugar, $k = \dfrac{2.303}{t} \log \dfrac{r_0 - r_\infty}{r_t - r_\infty}$

where r_0, r_t and r_∞ are readings of polarimeter at zero time, any time, *t* and at infinite time respectively.

time (min)	r_t	$r_t - r_\infty$	$k = \dfrac{2.303}{t} \log \dfrac{r_0 - r_\infty}{r_t - r_\infty}$
7.18	+ 21.41	21.41 – (– 10.74) = 32.15	$k = \dfrac{2.303}{7.18} \times \log \dfrac{24.09 - (-10.74) = 34.83}{32.15}$ $= \dfrac{2.303}{7.18\text{ min}} \times [\log 34.83 - \log 32.15]$ $= \dfrac{2.303}{7.18\text{ min}} \times [1.5419 - 1.5072 = 0.0347]$ $= 0.01113$
18.0	+ 17.74	17.74 – (– 10.74) = 28.48	$k = \dfrac{2.303}{18} \log \dfrac{34.83}{28.48} = 0.01118$
27.05	+ 15.0	15.0 – (– 10.74) = 25.74	$k = \dfrac{2.303}{27.05} \log \dfrac{34.83}{25.74} = 0.01118$

Since the value of *k* is almost same, the reaction is of first order. So, the correct answer is (*a*).

Example 156. *Consider a reaction a G + b H → Products. When concentration of both the reactants G and H is doubled, the rate increases eight times. However, when concentration of G is doubled, keeping the concentration of H fixed, the rate is doubled. The overall order of the reaction is:*

(a) 0 *(b) 1* *(c) 2* *(d) 3*

(IIT-JEE, 2007)

Solution. Reaction: $a\,\text{G} + b\,\text{H} \longrightarrow \text{Products}$

$$\therefore \quad \text{Rate, } r = k[\text{G}]^x\,[\text{H}]^y \qquad ...(i)$$

Given

Expt. no.	*[G] mol L^{-}*	*[H] mol L^{-}*	*Rate, r in mol L^{-} time^{-}*
1	*a*	*b*	*r*
2	2*a*	2*b*	8*r*
3	2*a*	*b*	2*r*

But $\quad 8\,r = k[2\text{G}]^x\,[2\text{H}]^y \qquad$ (expt. no. 2)

$$8\,r = k \cdot 2^x \times 2^y \cdot [\text{G}]^x\,[\text{H}]^y \qquad ...(ii)$$

Substituting the value of *r* from equation (*i*) in equation (*ii*), we get

$$8\,k[\text{G}]^x\,[\text{H}]^y = k \times 2^x \times 2^y \cdot [\text{G}]^x\,[\text{H}]^y$$

$$\therefore \quad 2^{x+y} = 8; \quad 2^{x+y} = (2)^3.$$

Hence $x + y = 3$. So, the order of reaction is 3. Hence the correct answer is (*d*).

Example 157. *The rate of a reaction A → products, at the initial concentration of 3.24×10^{-2} M, is nine times its rate at another initial concentration of 1.2×10^{-3} M. The order of the reaction is:*

(a) 1/2 *(b) 3/4* *(c) 3/2*
(d) 2/3 *(e) 1/3* **(Kerala PET, 2011)**

Solution. Let α = order of reaction and *r* is the rate of reaction

(*i*) For initial rate (*r*) of reaction, $r = k(1.2 \times 10^{-3})^\alpha$ ...(1)

(*ii*) For initial rate (9*r*) of reaction, $9r = k\,(3.24 \times 10^{-2})^\alpha$ ...(2)

Dividing equations (1) and (2) we get:

$$\frac{9r}{r} = \frac{k(3.24 \times 10^{-2})}{k(1.2 \times 10^{-3})^\alpha};$$

$$9 = (27)^\alpha; 3^2 = 3^{3\alpha}; 3\,\alpha = 2 \text{ or } \alpha = \frac{2}{3}$$

So, the correct result is (*d*).

Example 158. *The initial rates of reaction, 3A + 2B + C products at different initial concentrations are given below.*

Initial rate, Ms^{-}	$[A]_0$M	$[B]_0$M	$[C]_0$ M	
5.0×10^{-3}	0.010	0.005	0.010	...(*i*)
5.0×10^{-3}	0.010	0.005	0.015	...(*ii*)
1.0×10^{-2}	0.010	0.010	0.010	...(*iii*)
1.25×10^{-3}	0.005	0.005	0.010	...(*iv*)

The order with respect to the reactants, A, B and C are respectively.

(*a*) 3, 2, 0 (*b*) 3, 2, 1
(*c*) 2, 2, 0 (*d*) 2, 2, 1
(*e*) 2, 1, 0 **(Kerala PMT, 2011)**

SOLUTION. (1) Consider first and second sets of data. Both have same rate with change in the concentration of C. So, **order** with respect to C = **zero**.

(2) Consider first and third sets of data. Divide equation (*i*) by (*iii*).

$$\frac{5.0\times10^{-3}}{1.0\times10^{-2}} = \left(\frac{0.005}{0.010}\right)^x;$$
$$(0.5)^1 = (0.5)^x; x = 1.$$

So, **order** with respect to *B* is **1**

(3) Consider first and fourth sets of data. Divide equation (*iv*) by (*i*).

$$\frac{1.25\times10^{-3}}{5.0\times10^{-3}} = \left(\frac{0.005}{0.010}\right)^y \text{ or}$$
$$0.25 = (0.5)^y; (0.5)^2 = (0.5)^y; y = 2.$$

So, order with respect to A is **2**. Thus the order with respect to *A*, *B* and *C* is 2, 1 and 0. Hence the correct answer is (*e*).

EXAMPLE 159. *For the reaction,* $2NH_3 \longrightarrow N_2 + 3H_2$

$$\frac{-d[NH_3]}{dt} = k_1\,[NH_3];$$
$$\frac{d[N_2]}{dt} = k_2[NH_3]; \frac{d[H_2]}{dt} = k_3[NH_3].$$

Then, the relation between k_1, k_2, and k_3 is:

(*a*) $k_1 = 4\,k_2 = 5k_3$ (*b*) $1.5\,k_1 = 3\,k_2 = k_3$
(*c*) $10\,k_1 = k_2 = 0.3\,k_3$ (*d*) $k_1 = 2k_2 = 3k_3$.

SOLUTION. For $2NH_3 \longrightarrow N_2 + 3H_2$,

$$-\frac{1}{2}\frac{d[NH_3]}{dt} = +1\,\frac{d[N_2]}{dt} = \frac{+1}{3}\frac{d[H_2]}{dt} \qquad ...(1)$$

Comparing (1) with given data in question, we have:

$$k_1 : k_2 : k_3 = \frac{1}{2} : 1 : \frac{1}{3} = 3 : 6 : 2$$

or $$k_1 : k_2 : k_3 = \frac{3}{2} : \frac{6}{2} : \frac{2}{2}$$
$$= 1.5 : 3 : 1$$

Hence $1.5\,k_1 : 3k_2 : k_3$.

So, correct answer is (*b*)

EXAMPLE 160. *In the following reaction,* $aA \longrightarrow bB$

$$\log\frac{-d[A]}{dt} = \log\frac{d[B]}{dt} + 0.3$$ *where negative sign indicates rate of disappearance of the reactant.*

Thus; a : b is:

(*a*) 2 : 1 (*b*) 3 : 1
(*c*) 3 : 10 (*d*) 1 : 2

SOLUTION. $$\log\frac{d[A]}{dt} - \log\frac{d[B]}{dt} = 0.3 \qquad ...(1)$$

For $$aA = bB, \frac{1}{a}\frac{[-dA]}{dt} = \frac{1}{b}\frac{[dB]}{dt}.$$

Taking logs of both sides: $$\log\frac{1}{a} + \log\frac{[-dA]}{dt}$$
$$= \log\frac{1}{b} + \log\frac{dB}{dt} \qquad ...(2)$$

$$\therefore \log\frac{[-dA]}{dt} - \log\frac{[dB]}{dt} = \log\frac{1}{b} - \log\frac{1}{a} \qquad ...(2)$$

Comparing equations (1) and (2), we get,

$$\frac{\log\frac{1}{b}}{\log 1/a} = 0.3$$

or $$\frac{1/b}{1/a} = \frac{0.3}{1} = \frac{3}{10} \text{ or } a : b = 3 : 10.$$

So, correct answer is (*c*)

EXAMPLE 161. *A study of chemical kinetics of the reaction A + B ⟶ Products gave the following data at 25°C.*

Experiment	*[A]*	*[B]*	$\frac{d\,[Products]}{dt}$
1	*1.0*	*0.15*	4.20×10^{-6}
2	*2.0*	*0.15*	8.40×10^{-6}
3	*1.0*	*0.20*	5.60×10^{-6}

Find:

(1) The order of reaction with respect to A
(2) The order of reaction with respect to B
(c) The rate law **(ISC, 2012)**

SOLUTION. Rate law = $k\,[A]^x\,[B]^y$

$4.2\times10^{-6} = k\,[1]^x\,[0.15]^y$ ...(1)
$8.4\times10^{-6} = k\,[2]^x\,[0.15]^y$ ...(2)
$5.6\times10^{-6} = k\,[1]^x\,[0.2]^y$ ...(3)

(*a*) Dividing equation (1) by (2), we get:

$$\frac{4.2\times10^{-6}}{8.4\times10^{-6}} = \frac{k\,[1]^x\,[0.15]^y}{k\,[2]^x\,[0.15]^y}; \left(\frac{1}{2}\right)^1 = \left(\frac{1}{2}\right)^x; \text{ so, } x = 1$$

(*b*) Dividing equation (1) by (3), we get:

$$\frac{4.2\times10^{-6}}{5.6\times10^{-6}} = \frac{k\,[1]^x\,[0.15]^y}{k\,[1]^x\,[0.2]^y}; \left(\frac{3}{4}\right)^1 = \left(\frac{3}{4}\right)^y; \text{ so, } y = 1$$

∴ Order with respect to *A* = 1

Order with respect to *B* = 1

Rate law = $k\,[A]^1\,[B]^1 = k\,[A]\,[B]$. **Ans.**

EXAMPLE 162. *A first order reaction is 60% complete in 20 minutes. How long will the reaction take to be 84% complete?*

(a) 54 mins. *(b) 68 mins.*

(c) 40 mins. *(d) 76 mins.*

(Karnataka, CET, 2012)

Solution. For first order reaction:

$$k=\frac{2.303}{t}\log\frac{a}{a-x} \qquad ...(1)$$

Since the reaction is 60% complete, it means, $a = 100$; $a - x = 100 - 60 = 40$; $t = 20$ mins. Substituting the values in equation (1), we get:

$$k=\frac{2.303}{20}\log\frac{100}{40}(=2.5).\text{ Thus}:$$

$$k=\frac{2.303}{20}\times 0.3979=0.0458$$

Also, $a = 100$; $a - x = 100 - 84 = 16$; $t = ?$ Substituting these values in equation (1), we get:

$$0.0458=\frac{2.303}{t}\log\frac{100}{16}(=6.25)$$

$$\therefore\ t=\frac{2.303}{0.0458}\times 0.7959=40.02\simeq 40,\text{ mins.}$$

So, the correct answer is (*c*).

Note: y % complete reaction means, $a = 100$; $a - x = 100 - y$

Example 163. *A given sample of milk turns sour at room temperature (27°C) in 5 hours. In a refrigerator at –3°C, it can be stored 10 times longer. The energy of activation of souring of milk is:*

(a) 2.303 × 10R kJ mol^{-} *(b) 2.303 × 5R kJ mol*$^{-}$

(c) 2.303 × 3R kJ mol^{-} *(d) 2.303 × 2.7R kJ mol*$^{-}$

(Karnataka, CET, 2012)

Solution. $T_1 = 273 + 27 = 300\ K$; $T_2 = 273 - 3 = 270\ K$; Let rate constant at 27°C is k_1 and at – 3°C is k_2.

$$(i)\ \text{At } 27°\text{C}, k_1=\frac{2.303}{t}\log\frac{a}{a-x}=\frac{2.303}{5}\log\frac{a}{a-x} \qquad ...(1)$$

$$(ii)\ \text{At } -3°\text{C}, k_2=\frac{2.303}{5\times10}\log\frac{a}{a-x}=\frac{2.303}{50}\log\frac{a}{a-x} \qquad ...(2)$$

$$\text{Thus: } \frac{k_2}{k_1}=\left[\frac{2.303}{50}\log\frac{a}{a-x}\right]\times\frac{5}{2.303\log a/a-x}=10^{-1}$$

$$\text{But } \log\frac{k_2}{k_1}=\frac{E_a}{2.303\,R}\times\left[\frac{T_2-T_1}{T_1T_2}\right]=\frac{E_a}{2.303R}\times\left[\frac{270-300}{270\times300}\left(=-\frac{1}{2700}\right)\right]$$

$$\therefore\ \log 10^{-1}=\frac{E_a}{2.303\,R}\times-\frac{1}{2700};\ -1=\frac{E_a}{2.303\,R}\times\frac{-1}{2700};$$

$E_a = 2.303R \times 2700$ J mol^{-}

Or $Ea = 2.303\ R \times 2.7$ kJ mol^{-}. So, the correct answer is (*d*).

Example 164. *In the following reaction, the initial concentrations of the reactant and initial rate at 298 K are given:*

$$2A \longrightarrow C + D$$

$[A]_0$ mol^{-}	*Initial rate in mol L^{-} s^{-}*
0.01	*5.00×10^{-5}*
0.02	*2.0×10^{-4}*

The value of rate constant of this reaction at 298 K is:

(a) 0.01s^{-} *(b) 5×10^{-3} mol L^{-} s^{-}*

(c) 2.0×10^{-2} mol^{-} L s^{-} *(d) 5×10^{-1} mol^{-} L s^{-}*

(e) 5.0×10^{-1} mol L^{-} s^{-} **(Kerala PET, 2012)**

Solution. Let a = order of reaction with respect to A

Rate = $k\,[A]^a$

$5.0\times10^{-5}=k\,[0.01]^a$ ...(*i*)

Also: $2.0\times10^{-4}=k\,[0.02]^a$ ...(*ii*)

Dividing (*ii*) by (*i*), we get:

$$\frac{2\times10^{-4}}{5\times10^{-5}}=\frac{k\,[0.02]^a}{k\,[0.01]^a};\ 4=(2)^a;\ (2)^2=(2)^a;\ a=2$$

Substituting $a = 2$ in equation (*i*) we get:

5.0×10^{-5} mol L^{-} s^{-} = k [0.01 mol L^{-}]^2

$$\therefore\ k=\frac{5.0\times10^{-5}\text{ mol }L^{-}s^{-}}{0.01\text{ mol }L^{-}\times0.01\text{ mol }L^{-}}=5\times10^{-1}\text{ mol}^{-}\ L\,s^{-}$$

So, the correct answer is (*d*).

Example 165. *In a first order reaction, the concentration of the reactant is reduced to 1/8 of the initial concentration in 75 minutes at 298 K. What is the half-life period of the reaction in minutes?*

(a) 50 *(b) 15*

(c) 45 *(d) 25*

(e) 30 **(Kerala PMT, 2012)**

Solution. Here initial concentration, $a = 1$, $a - x = 1/8$, $t = 75$ minutes. For first order reaction:

$$k=\frac{2.303}{t}\log\frac{a}{a-x}=\frac{2.303}{75}\log\frac{1}{1/8}$$

$$=\frac{2.303}{75}\log 8=\frac{2.303\times0.903}{75}\text{ min}^{-}$$

For first order reaction:

$$\text{Half life, } t_{1/2}=\frac{0.693}{k}=\frac{0.693\times75}{2.303\times0.903}=24.99\simeq 25\text{ min.}$$

So, the correct answer is (*d*).

Example 166. *In the Arrhenius plot of ln k vs 1/T, a linear plot is obtained with a slope of – 2×10^4 K. The energy of activation of the reaction (in kJ mol*$^{-}$*) is (R value is 8.3 J K*$^{-}$ *mol*$^{-}$*)*

(a) 83 *(b) 166*

(c) 249 *(d) 332*

(e) 830 **(Kerala PMT, 2012)**

Solution. Arrhenius equation is: $k = A\, e^{-E_a/RT}$ Or

$\ln k = \log A - \frac{E_a}{RT}$. For $\ln k$ *vs* $1/T$.

Intercept = $\ln A$; slope = $\frac{-E_a}{R} = -2\times 10^4 K$

$\therefore\ E_a = (-)\,(-)\,2\times 10^4\, K \times R = 2\times 10^4\, K \times 8.3\ \text{J K}^{-}\text{mol}^{-}$

$= 16.6\times 10^4\ \text{J mol}^{-}$ or $16.6\times 10^4 \times 10^{-3}\ \text{kJ mol}^{-}$

$= 166\ \text{kJ mol}^{-}$

So, the correct answer is (*b*).

Example 167. *For the reaction*

$$2\,NO(g) + Cl_2(g) \longrightarrow 2NOCl(g)$$

the following data were collected. All the measurements were taken at 263 K.

Experiment no.	*Initial [NO] (M)*	*Initial [Cl_2] (M)*	*Initial rate of disapperance of Cl_2 (M/Min)*
1	0.15	0.15	0.60
2	0.15	0.30	1.20
3	0.30	0.15	2.40
4	0.25	0.25	?

(a) Write the expression for rate law.

(b) Calculate the value of rate constant and specify its units.

(c) What is the initial rate of disappearance of Cl_2 in exp. 4?

(CBSE, 2012)

Solution. (*a*) Suppose, rate law = $k\,[\text{NO}]^x\,[\text{Cl}_2]^y$

From expt. 1; $0.60 = k\,[0.15]^x\,[0.15]^y$ ...(1)

From expt. 2; $1.20 = k\,[0.15]^x\,[0.30]^y$ ...(2)

From expt. 3; $2.40 = k\,[0.30]^x\,[0.15]^y$ ...(3)

Dividing equation (2) and (1), we get:

$$2 = \frac{k\,[0.15]^x\,[0.30]^y}{k\,[0.15]^x\,[0.15]^y} = (2)^y;\ (2)^1 = (2)^y,\ \text{so } y = 1$$

Dividing equation (3) by (1), we get:

$$4 = \frac{k\,[0.30]^x\,[0.15]^y}{k\,[0.15]^x\,[0.15]^y} = 2^x;\ (2)^2 = (2)^x;\ \text{so, } x = 2$$

(*b*) Using equation (1), we have:

$$0.60 = k\,[0.15]^2\,[0.15]^1;\ k = \frac{0.60}{0.15\times 0.15\times 0.15}$$

$= 177.77\ \text{mol}^{-2}\ \text{L}^2\ \text{min}^{-1}$

[$\because$ Unit of k for $n = 3$ is $(\text{mol } L^{-})^{1-n}\ \text{min}^{-}$

$= (\text{mol } L^{-})^{1-3=2}\ \text{min}^{-} = \text{mol}^{-2}\ L^2\ \text{min}^{-}$]

(*c*) Rate = $k\,[\text{NO}]^2\,[\text{Cl}_2]^1$

$= 177.77 \times (0.25)^2 \times 0.25 = 2.77\ \text{mol } L^{-}\ \text{min}^{-}$ **Ans.**

Example 168. *At 300K, a gaseous reaction, $A \to B + C$, was found to follow first order kinetics. Starting with pure A, the total pressure at the end of 20 minutes was 100 mm of Hg. The total pressure after the completion of the reaction is 180 mm of Hg. The partial pressure of A (in mm of Hg) is:*

(a) 100 *(b) 90*

(c) 180 *(d) 80*

(Karnataka, CET, 2012)

Solution. Given $A \longrightarrow B + C$ ...(1)

From equation (1), we find that 1 mol of A decomposes to give a total of 2 mol (1 mol of B + 1 mol of C) of gases.

$\therefore$ Initial pressure of $A = \frac{180\times 1}{2} = 90$ mm.

Let x = Amount of A decomposed after 20 minutes.

$\therefore$ Pressure due to $A = 90 - x$. Also, pressure due to $B = x$ and due to $C = x$.

Total pressure after 20 minutes = 100 m.m.

$\therefore\ 90 - x + x + x = 100;\ x = 10$ m.m.

$\therefore$ Pressure of A after 20 minutes = 90 – 10 = 80 m.m.

So, the correct answer is (*d*).

Example 169. *The initial rate, $-\frac{d\,[A]}{dt}$ at t = 0 was found to be 2.6×10^{-2} mol $L^{-}\,s^{-}$ for the reaction, $A + 2B \longrightarrow$ products. The initial rate, $-\frac{d\,[B]}{dt}$ at t = 0 is*

(a) 0.1 mol $L^{-}\,s^{-}$ *(b) 2.6×10^{-2} mol $L^{-}\,s^{-}$*

(c) 5.2×10^{-2} mol $L^{-}\,s^{-}$ *(d) 6.5×10^{-3} mol $L^{-}\,s^{-}$*

(AMU, Engg. 2012)

Solution. For $A + 2B \longrightarrow$ Products:

$$-\frac{d\,[A]}{dt} = -\frac{1}{2}\frac{d\,[B]}{dt}$$

$$2.6\times 10^{-2}\ \text{mol } L^{-}\,s^{-} = -\frac{1}{2}\frac{d\,[B]}{dt}$$

$$\therefore\ -\frac{d\,[B]}{dt} = 2\times 2.6\times 10^{-2} = 5.2\times 10^{-2}\ \text{mol } L^{-}\,s^{-}.$$

So, the correct answer is (*c*).

Example 170. *For the reaction $A + B \longrightarrow C + 2D$, experimental results were collected for three trials and the data obtained are given below:*

Trial	*[A], M*	*[B], M*	*Initial rate, M s^{-}*
1	0.40	0.20	5.5×10^{-4}
2	0.80	0.20	5.5×10^{-4}
3	0.40	0.40	2.2×10^{-3}

the correct rate law of the reaction is:

(a) rate = $k\,[A]^0\,[B]^2$ *(b) rate = $k\,[A]\,[B]^2$*

(c) rate = $k\,[A]\,[B]$ *(d) rate = $k\,[A]\,[B]^0$*

(d) rate = $k\,[A]^0\,[B]$

(Kerala PMT, 2012)

Solution. Let rate law = $k\,[A]^x\,[B]^y$. From experiments, we have:

$$5.5\times10^{-4}=k\,[0.4]^x\,[0.2]^y \qquad ...(i)$$

$$5.5\times10^{-4}=k\,[0.8]^x\,[0.2]^y \qquad ...(ii)$$

$$2.2\times10^{-3}=k\,[0.4]^x\,[0.4]^y \qquad ...(iii)$$

From equations (*i*) and (*ii*), we have:

$$\frac{5.5\times10^{-4}}{5.5\times10^{-4}}=\frac{k[0.4]^x\,[0.2]^y}{k[0.8]^x\,[0.2]^y};1=\left[\frac{0.4}{0.8}\right]^x=\left(\frac{1}{2}\right)^x;\left(\frac{1}{2}\right)^0=\left(\frac{1}{2}\right)^x.$$

So, $x = 0$.

From equation (*i*) and (*iii*), we have:

$$\frac{5.5\times10^{-4}}{2.2\times10^{-3}}=\frac{k\,[0.4]^x\,[0.2]^y}{k\,[0.4]^x\,[0.4]^y};\frac{1}{4}=\left(\frac{1}{2}\right)^y;\left(\frac{1}{2}\right)^2=\left(\frac{1}{2}\right)^y.$$

So, $y = 2$.

Substituting these values in rate law, we get:

rate law: $k\,[A]^0\,[B]^2$. So, the correct answer is (*a*).

Example 171. *If first order reaction is 60% completed in 60 minutes, then 50% reaction completes in:*

(a) 40 min *(b) 45 min*

(c) 60 min *(d) 50 min*

(AFMC, 2012)

Solution. For a given reaction, $a = 100; a - x = 100 - 60 = 40; t = 60$ min. For second reaction, $a = 100, a - x = 100 - 50 = 50$. We know that:

$$(i)\ k=\frac{2.303}{t}\log\frac{a}{a-x}=\frac{2.303}{60}\log\frac{100}{40}=\frac{2.303}{60}\log 2.5.$$

$$=\frac{2.303}{60}\times0.3979=0.0153$$

$$(ii)\ k=\frac{2.303}{t}\log\frac{a}{a-x};t=\frac{2.303}{0.0153}\log\frac{100}{50}=\frac{2.303}{0.0153}\log 2$$

$$=\frac{2.303}{0.0153}\times0.3010\ =45.31\text{ min}\simeq45\text{ min.}$$

So, the correct answer is (*b*).

Example 172. *For a reaction: A + B ⟶ Products, the rate of the reaction at various concentrations are given below:*

Experiment no.	*[A]*	*[B]*	*Rate (mol $dm^{-3}\,s^{-}$)*
1	0.2	0.2	2
2	0.2	0.4	4
3	0.2	0.4	36

The rate law for the above reaction is:

(a) $r = k\,[A]^2\,[B]$ *(b)* $r = k\,[A]\,[B]^2$

(c) $k\,[A]^3\,[B]$ *(d)* $k\,[A]^2\,[B]^2$

(Karnataka, CET, 2012)

Solution. (*i*) For experiment, 1; $2 = k\,[A]^x\,[B]^y = k\,[0.2]^x\,[0.2]^y$

(*ii*) For experiment, 2; $4 = k\,[0.2]^x\,[0.4]^y$

(*iii*) For experiment, 3; $36 = k\,[0.6]^x\,[0.4]^y$

Dividing (*i*) and (*ii*), we get: $\left(\frac{2}{4}\right)=\left(\frac{0.2}{0.4}\right)^y;\left(\frac{1}{2}\right)^1=\left(\frac{1}{2}\right)^y$

$y = 1$

Dividing (*ii*) and (*iii*), we get:

$$\frac{4}{36}=\left(\frac{2}{6}\right)^x;\left(\frac{1}{3}\right)^2=\left(\frac{1}{3}\right)^x;x=2$$

∴ $r = [A]^x\,[B]^y = [A]^2\,[B]^1$. So, the correct answer is (*a*).

Example 173. *The rate constant for a first order reactions is doubled when the temperature is increased from 20°C to 25°C. How many times the rate constant will increases if the temperature is raised from 20°C to 40°C ?*

(a) 4 *(b) 8*

(c) 16 *(d) 32*

(e) 64 **(Kerala, PET, 2012)**

Solution. (*i*) Increase in temperature = 25 – 20 = 5°C.

(*ii*) Increase in temperature = 40 – 20 = 20°C.

5°C increase causes increase in rate constant = 2 times

20°C increase will cause increase in rate constant = $(2)^{20/5} = 2^4 = 16$. So, the correct answer is (*c*).

Example 174. *For a first order reaction, A ⟶ products, the concentration of A changes from 0.1 M to 0.025 M in 40 minutes. The rate of reaction when the concentration of A is 0.01 M is:*

(a) 3.47×10^{-4} *M/min* *(b)* 3.47×10^{-5} *M/min*

(c) 1.73×10^{-4} *M/min* *(d)* 1.73×10^{-5} *M/min.*

(AIEEE, 2012)

Solution. $a = 0.1\,M, a - x = 0.025\,M, t = 40$ minutes. For the first order reaction:

$$k=\frac{2.303}{t}\log\frac{a}{a-x}=\frac{2.303}{40}\log\frac{0.1}{0.025}$$

$$=\frac{2.303}{40}\log4=\frac{2.303}{40}\times0.602=0.0347\text{ min}^{-}$$

For the given reaction, rate = $k\,[A] = 0.0347\text{ min}^{-} \times 0.01$ M

∴ Rate = 3.47×10^{-4}. So, the correct answer is (*a*).

Example 175. *The decomposition of ammonia on tungstan surface at 500 K follows zero order kinectics. The half-life period of this reactions is 45 minutes, when the initial pressure is 4 bar. The half-life period (minutes) of the reaction when the initial pressure is 16 bar at the same temperature is:*

(a) 120 *(b) 60*

(c) 240 *(d) 180*

(e) 300

(Kerala PMT, 2012)

Solution. For zero order reaction, $t_{1/2} = a_0$ (initial concentration of pressure). So:

$$(t_{1/2}) = P_1 \,;\, (t_{1/2})_2 = P_2 \,;\, \frac{(t_{1/2})_2}{(t_{1/2})_1} = \frac{P_2}{P_1}.$$

$\therefore \ \frac{(t_{1/2})_2}{45} = \frac{16}{4}; (t_{1/2})_2 = 4 \times 45 = 180$ minutes. So, the correct answer is (*d*).

Example 176. *In a zero order reaction, for every 10°C rise of temperature, the rate is doubled. If the temperature is increased from 10°C to 100°C, the rate of the reaction will become:*

(a) 256 times *(b) 512 times*
(c) 64 times *(d) 128 times.*

(AIPMT, Pre. 2012)

Solution. Since rate of reaction increases 2 times for every 10°C, so we have:

$$\frac{r_{100°C}}{r_{10°C}} = 2^{\left[\frac{100-10}{10}\right]} = 2^9 = 512 \text{ times.}$$

So, the correct answer is (*b*).

Example 177. *A reacts to form P. A plot of the reciprocal of the concentration of A vs time is a straight line. When the initial concentration of A is 1.0 × 10^{-2} M, its half-life is found to be 20 min. When initial concentration of A is 3.0 × 10^{-3} M, the half life will be:*

(a) 20 min *(b) 40 min*
(c) 56 min *(d) 67 min*

(AMC (medical) 2012)

Solution. Given $A \longrightarrow P$. A plot of $1/[A]$ *vs* time is a straight line. It indicates second order reaction. For second order, $t_{1/2} \propto 1/k[A]_0$.

$[A]_0$ = Initial concentration of *A*.

(*i*) When $[A]_0 = 1.0 \times 10^{-2}\,M$, $t_{1/2} = 20$ min;

$$20 = \frac{1}{k\,(10^{-2})}; k = \frac{1}{20} \times 10^{-2} \quad ...(1)$$

(*ii*) When $[A]_0 = 3.0 \times 10^{-3}\,M$, $t_{1/2} = \frac{1}{k\,(3 \times 10^{-3})}$ ...(2)

Substituting of *k* from (1) in (2), we get:

$$t_{1/2} = \frac{20 \times 10^{-2}}{3 \times 10^{-3}} = 6.66 \times 10 \simeq 67 \text{ min.}$$

So, the correct answer is (*d*).

Example 178. *A first order reaction has a rate constant, k = 3.01 × 10^{-3}/s. How long it will take to decompose half of the reaction?*

(a) 2.303 s *(b) 23.03 s*
(c) 230.3 s *(d) 2303 s*

(J&K, CET, 2012)

Solution. For first order reaction:

$$k = \frac{2.303}{t} \log \frac{a}{a-x} \text{ Or } t = \frac{2.303}{k} \log \frac{a}{a-x}$$

Given $x = a/2$ and $k = 3.01 \times 10^{-3}\,s^{-}$. Substituting the values we get:

$$t = \frac{2.303}{3.01 \times 10^{-3}\,s^{-}} \log\left[\frac{a}{a - a/2} = \frac{a}{a/2} = 2\right]$$

$$= \frac{2.303}{3.01 \times 10^{-3} s^{-}} \times 0.3010 = 230.3\,s$$

So, the correct answer is (*c*).

Example 179. *In a reaction, A + B ⟶ product, rate is doubled when the concentration of B is doubled, and rate increase by a factor of 8 when the concentration of both the reactants (A and B) are doubled. The rate law for the reaction can be written as:*

(a) rate = k [A] $[B]^2$ *(b) rate = k $[A]^2$ $[B]^2$*
(c) rate = k [A] [B] *(d) rate = k $[A]^2$ [B].*

(AIPMT, Pre. 2012)

Solution. For reactants *A*, *B* and rate, *R*, we have:

A	*B*	rate	
a	*b*	*R*	...(*i*)
a	2*b*	2*R*	...(*ii*)
2*a*	2*b*	8*R*	...(*iii*)

Let rate law is : rate = $k\,[A]^x\,[B]^y$

From (*i*) $(a)^x\,(b)^y = R$ ...(*iv*)

From (*ii*) $(a)^x\,(2b)^y = 2R$ ...(*v*)

From (*iii*) $(2a)^x\,(2b)^y = 8R$ ...(*vi*)

Dividing equation (*v*) by (*iv*), we get,

$$\frac{(a)^x\,(2b)^y}{(a)^x\,(b)^y} = \frac{2R}{R}; 2^y = 2^1$$

$\therefore y = 1$

Dividing (*vi*) by (*v*), we get,

$$\frac{(2a)^x\,(2b)^y}{(a)^x\,(2b)^y} = \frac{8R}{2R}; 2^x = 2^2; x = 2$$

Substituting $x = 2$ and $y = 1$ in rate = $k\,[A]^x\,[B]^y$, we get: rate: $k\,[A]^2\,[B]$. So, the correct answer is (*d*).

Example 180. *An organic compound undergoes first order decomposition. The time taken for decomposition to 1/8 and 1/10 its initial concentration are $t_{1/8}$ and $t_{1/10}$ respectively. What is the value of $\frac{[t_{1/8}]}{[t_{1/10}]} \times 10$? (take $\log_{10}^{2} = 0.3$)* **(IIT-JEE, 2012)**

Solution. Let a_0 = initial concentration, a = concentration after sometime, *t*. We know that:

$$k = \frac{2.303}{k} \log \frac{a_0}{a}; a = a_0/8 \text{ at } t_{1/8}$$

$$\therefore t_{1/8} = \frac{2.303}{k} \log \frac{a_0}{a_0/8} = \frac{2.303}{k} \log 8 \quad ...(i)$$

$$k = \frac{2.303}{t} \log \frac{a_0}{a}; a = a_0/10 \text{ at } t_{1/10}$$

$$\therefore t_{1/10} = \frac{2.303}{k} \log \frac{a_0}{a_0/10} = \frac{2.303}{k} \log 10 \quad ...(ii)$$

From equation (*i*) and (*ii*), we have

$$\frac{[t_{1/8}]}{[t_{1/10}]}\times 10 = \frac{2.303}{k}\log 8 \times \frac{k}{2.303\log 10}\times 10$$

$$= \frac{\log 2^3}{\log 10}\times 10 = \frac{3\log 2}{1}\times 10 = 3\times 0.3\times 10 = 9.$$

Example 181. *For the reaction given below:*

$5\,Br^-(aq) + BrO_3^-(aq) + 6\,H^+ \longrightarrow 3Br_2(aq) + 3H_2O(l)$

the rate of formation of bromine is related to rate of consumption of Br^- *by the following relation.*

(*a*) $\frac{d[Br_2]}{dt} = \frac{-5}{3}\frac{d[Br^-]}{dt}$ (*b*) $\frac{d[Br_2]}{dt} = \frac{-d[Br^-]}{dt}$

(*c*) $\frac{d[Br_2]}{dt} = \frac{5}{3}\frac{d[Br^-]}{dt}$ (*d*) $\frac{d[Br_2]}{dt} = -\frac{3}{5}\frac{d[Br^-]}{dt}.$

(AMU. Engg., 2012)

Solution. For the reaction:

$5Br^-(aq) + BrO_3^-(aq) + 6H^+ \longrightarrow 3Br_2(aq) + 3H_2O(l)$

We have:

$$\frac{1}{3}\frac{d[Br_2]}{dt} = -\frac{1}{5}\frac{d[Br^-]}{dt} \text{ Or } \frac{d[Br_2]}{dt} = -\frac{3}{5}\frac{d[Br^-]}{dt}.$$

So, the correct answer is (*d*).

Type. Fraction of original amount of reactant that remains undecomposed after time, $t = \frac{a-x}{a}$.

Example 182. *Decomposition of phosphine* (PH_3) *at 120°C proceeds according to the equation:*

$4PH_3(g) \longrightarrow P_4(g) + 6H_2(g)$

It is found that this reaction follows the following rate equation.

Rate = $k\,[PH_3]$

The half-life of PH_3 *is 37.9 s at 120°C.*

(a) How much time will be required for 3/4 of PH_3 *to decompose?*

(b) What fraction of original amount of PH_3 *will remain undecomposed after one minute?* **(CBSE (F), 2012)**

Solution. $t_{1/2} = 37.9\ s$; $k = 0.693/t_{1/2} = 0.693/37.9\ s^-$; $k = 0.01828\ s^-$

$$(i)\ t_{3/4} = \frac{2.303}{k}\log\frac{a}{a-x};\ t_{3/4} = \frac{2.303}{0.01828}\log\frac{1}{1-3/4} = 4$$

$$\therefore\ t_{3/4} = \frac{2.303}{0.01828}\times 0.602 = \mathbf{75.84}\ s \qquad \textbf{Ans.}$$

(*ii*) Fraction of original amount of PH_3 that will remain undecomposed = $\frac{a-x}{a}$. So:

$$k = \frac{2.303}{t}\log\frac{a}{a-x};\ 0.01828 = \frac{2.303}{1\times 60\ s}\log\frac{a}{a-x};$$

$$\log\frac{a}{a-x} = 0.4762$$

$$\therefore\ \log\frac{a-x}{a} = -0.4762;\ \frac{a-x}{a} = \text{antilog} - 0.4762 = \mathbf{0.334}$$

Ans.

Type. For $pA(g) \longrightarrow q\,B(g) + r\,C(g)$ reaction, when only pressure are given as concentrations, then in the first order reaction:

$$k = \frac{2.303}{t}\log\frac{a}{a-x}.\ \text{Use:}$$

(*i*) $a = Ci$ = Initial pressure at time, $t = 0$ (given). If $t = 0$ not given, then:

$a = Ci$ = [Total pressure after complete decomposition of A] × $\frac{p}{q+r}$

(*ii*) Ct = Pressure at time, t (given). So:

$a - x = Ci - p\left[\frac{Ct - Ci}{q+r-p}\right]$ where p, q and r are the number of moles of A, B and C in the given reaction.

Example 183. *The following data were obtained during the first order thermal decomposition of* $N_2O_5\,(g)$ *at constant volume.*

$2N_2O_5(g) \longrightarrow 2N_2O_4(g) + O_2(g)$

Calculate the rate constant.

S. No.	Time/s	Total pressure in atm.
1	0	0.5
2	100	0.512

Solution. Using formula given in above type, we have: $p = 2$ (of N_2O_5), $q = 2$ (of N_2O_4) and $r = 1$ (for O_2).

$a = Ci = 0.5$ atm; $a - x = Ci - p\left[\frac{Ct - Ci}{q+r-p}\right]$ where, C_t at 100 s = 0.512 atm.

$$\therefore\ a - x = 0.5 - 2\left[\frac{0.512 - 0.5}{2+1-2=1}\right] = 0.5 - 0.024 = 0.476$$

atm.

$$\therefore\ k = \frac{2.303}{t}\log\frac{a}{a-x};\ k = \frac{2.303}{100}\log\frac{0.5}{0.476} = 1.05042$$

$$\therefore\ k = \frac{2.303}{100}\times 0.02136 = 4.92\times 10^{-4} s$$

Example 184. *In hydrogenation reaction at 25°C, it is observed that hydrogen gas pressure falls from 2 atm. to 1.2 atm. in 50 minutes. Calculate the rate of reaction in molarity per second.* (*R* = *0.0 821 L atm degree*$^-$ *mol*$^-$)

(Haryana School board, 2013)

Solution. (*i*) Rate $= \frac{dp}{dt} = \frac{(2-1.2)\text{ atm}}{50\times 60\ s}$

$= 2.666\times 10^{-4}$ atm s^-.

$$(ii)\ PV = nRT;\ \frac{P}{\text{sec}} = \left(\frac{n}{V}\right)\frac{RT}{\text{sec}};\ \left(\frac{n}{V}\right)\times\frac{1}{\text{sec}} = \frac{p}{\text{sec}}\times\frac{1}{RT}$$

∴ Rate (molarity/sec)

$$= \frac{2.666\times 10^{-4}\text{ atm s}^-}{0.0821\text{ L atm deg}^-\text{ mol}^-\times 298\text{ degree}}$$

$= 1.09\times 10^{-5}$ mol L^- s^- **Ans.**

EXAMPLE 185. *A drop of a solution (volume 0.05 mL) contains 3×10^{-6} mol H^+ ions. If the rate of disappearance of H^+ ions is 1×10^{7} mol L^- sec^-, how long would it take for H^+ ions in the drop to disappear ?* **(H.P. Board, 2013)**

SOLUTION. Concentration of drop

$$= \frac{\text{mol}}{\text{volume in mL}} \times 1000\ (\text{mL})\text{L}^-$$

$$= \frac{3 \times 10^{-6}\ \text{mol}}{0.0\,5} \times 1000\ \text{L}^- = 0.06\ \text{mol}\ \ \text{L}^-$$

$$\therefore \text{ Rate of disappearance} = \frac{\text{Concentration change}}{\text{time}}$$

$$1 \times 10^{-7}\ \text{mol L}^- = \frac{0.06\ \text{mol L}^-}{\text{time}}\text{; time} = \frac{0.06}{1 \times 10^{-7}}$$

$$= 6 \times 10^{-9}\ \text{sec. } \textbf{Ans.}$$

EXAMPLE 186. *A compound A decomposes in acid solution to give B and C according to first order rate law, with $t_{1/2} = 3$ hours. What fraction of A remains after 6 hours.*

SOLUTION. $t_{1/2} = 3$ hours. $\therefore k = \dfrac{0.693}{t_{1/2}} = \dfrac{0.693}{3} = 0.231\ hr^-$

We know: $k = \dfrac{2.303}{t} \log \dfrac{a}{a-x}$. Since fraction of A **left behind** is to be found, it means, $\dfrac{a-x}{a}$ is to be found.

$$\therefore 0.231\ hr^- = \frac{2.303}{6} \log \frac{a}{a-x}; \log \frac{a}{a-x} = \frac{0.231 \times 6}{2.303}$$
$$= 0.6018$$

$$\therefore \frac{a}{a-x} = \text{antilog } 0.6018 = 3.9976.$$

Hence, $\dfrac{a-x}{a} = \dfrac{1}{3.9976} = 0.25$ **Ans.**

EXAMPLE 187. *For a reaction $A \rightarrow B$ with $k = 1.9 \times 10^{-2}$ s^-, find the concentration of A left behind after 90 s if the initial concentartion of A is 1.0 mol L^-.*

SOLUTION. Units of *k* shows the reaction as first order. So:

$$k = \frac{2.303}{t} \log \frac{a}{a-x}; 1.9 \times 10^{-2} s^- = \frac{2.303}{90} \log \frac{1.0}{a-x}$$

or $\log a - x = -0.7425$; $\therefore a - x = \text{antilog} - 0.7425 = 0.1809$ mol L^- **Ans.**

EXAMPLE 188. *The following data was obtained during the first order thermal decomposition of SO_2Cl_2 at a constant volume.*

$SO_2Cl_2\,(g) \longrightarrow SO_2\,(g) + Cl_2(g)$

Calculate the rate of reaction when total pressure is 0.65 atm.

Experiment	Time, in s^-	Total pressure in atm
1	0	0.5
2	100	0.6

SOLUTION. $\underset{1\ \text{mol}}{SO_2Cl_2(g)} \longrightarrow \underset{1\ \text{mol}}{SO_2(g)} + \underset{1\ \text{mol}}{Cl_2(g)}$

(*i*) $a = 0.5; a - x = 0.5 - 1\left[\dfrac{0.6-0.5}{1+1-1}\right] = 0.4; t = 100\ s$. So:

$$k = \frac{2.303}{t} \log \frac{a}{a-x} = \frac{2.303}{100\ s} \log \frac{0.5}{0.4} = 2.23 \times 10^{-3} s^- \textbf{ Ans.}$$

(*ii*) Rate $= k \times p_{SO_2Cl_2(g)}$

$= 2.23 \times 10^{-3}\ s^- \times 0.35$ atm

$= 7.805 \times 10^{-4}$ atm s^- **Ans.**

$$\left[\begin{array}{l} \because p_{SO_2Cl_2\,(g)} = C_t - [C_t - C_i] \\ \qquad\qquad = 0.65 - [0.65 - 0.5] \\ \qquad\qquad = 0.35\ \text{atm} \\ \because C_t = \text{Total pressure} \\ \quad C_i = \text{Initial pressure} \end{array}\right]$$

EXAMPLE 189. *For the reaction $2A + B \rightarrow A_2B$, rate = k [A] $[B]^2$ with $k = 2.0 \times 10^{-6}$ mol^{-2} L^2 s^-. Find the initial rate of the reaction when [A] = 0.1 mol L^- and [B] = 0.2 mol L^-. Also, find the rate of reaction after [A] is reduced to 0.06 mol L^-.*

SOLUTION. (*a*) Initial rate $= k\,[A]\,[B]^2 = 2.0 \times 10^{-6}\ \text{mol}^{-2}\ \text{L}^2\ s^- \times 0.1\ \text{mol L}^- \times (0.2\ \text{mol L}^-)^2$

$= 8 \times 10^{-9}$ mol L^- s^- **Ans.**

(*b*) $2A + B \rightarrow A_2B \quad \therefore \quad A + \dfrac{1}{2}B \rightarrow \dfrac{1}{2}A_2B$

As given that [*A*] is reduced to 0.06 mol L^-, so reactant *A* = 0.1 – 0.06 = 0.04. Since *B* reacts with *A*, therefore, reacted $B = \dfrac{1}{2} \times 0.04 = 0.02$ mol L^-.

$\therefore [B] = 0.2 - 0.02 = 0.18$ mol L^-

Hence, Rate $= k\,[A]\,[B]^2 = 2.0 \times 10^{-6}\ \text{mol}^{-2}\ \text{L}^2\ s^- \times 0.06\ \text{mol L}^- \times (0.18\ \text{mol L}^-)^2 = 3.89 \times 10^{-9}\ \text{mol L}^- s^-$.

EXAMPLE 190. *The energy of activation of a reaction is 150 kJ mol^-. Presence of a catalyst lowers the energy of activation by 60%. What will be the effect on rate of reaction at 25°C if all other things remain same?*

(*a*) $\dfrac{r_2}{r_1}$ *[r_1 = without catalyst; r_2 = with catalyst].*

(*b*) $\dfrac{r_2}{r_1} = 5.97 \times 10^{15}$

(*c*) $r_1 = r_2$

(*d*) $\dfrac{r_1}{r_2} = 6$ **(IIT-JEE, modified)**

SOLUTION. We know, $k = A\,e^{-Ea/RT}$.

Hence, $k_1 = Ae^{-150/RT}$ ...(1)

$k_2 = Ae^{-60/RT}$ ...(2)

From (1) and (2), we get $\dfrac{k_1}{k_2} = \dfrac{e^{-150/RT}}{e^{-60/RT}}$.

Taking logs of both sides, we get:

$$\log_e \frac{k_1}{k_2} = \frac{\log_e e^{-150/RT}}{\log_{\in} e^{-150/RT}} = -150 - (-60)/RT = -\frac{90}{RT}$$

$$\therefore \ \text{loge} \ \frac{k_1}{k_2} = \frac{90 \times 10^3 \text{ J mol}^-}{8.314\ J\ K^-\ \text{mol}^- \times 298\ K} = 36.325$$

$[\because T = 25 + 273 = 298\ K]$

Or $\frac{k_1}{k_2}$ = antilog 36.325 = 5.97×10^{15}.

For *n*th order reaction, *n* and [ ] *i.e.*, concentrations are same for both reactions. Thus:

$\frac{r_2}{r_1} = \frac{k_2}{k_1} = 5.97 \times 10^{15}$. So, the correct answer is (*b*).

Example 191. *The composition of a compound follows the equation* $k = (4.4 \times 10^{11}\ s^-)\ e^{-25000\ K/T}$. *Calculate* E_a.

Solution. According to Arrhenius equation,

$$k = Ae^{-E_a/RT}$$

$$\therefore \ -\frac{E_a}{RT} = \frac{-25000\ K}{T} \quad \text{or } E_a = 25000\ K \times R$$

$= 25000 \text{ K} \times 8.314 \text{ JK}^- \text{ mol}^- = 207850 \text{ JK}^- \text{ mol}^-$

$= 207.85 \text{ kJ mol}^-$.

PROBLEMS FOR PRACTICE

1. An exothermic reaction, $y \rightarrow z$ has an activation energy of 20 k cal mol$^-$ of *y*. The heat of reaction is 38 *k* cal. Calculate the activation energy of the reverse reaction. **Ans.** 58 k cal.

2. The threshold energy of a reaction A → B is 60 k cal. If the activation energy of the forward reaction is 25 k cal, find the energy of the reactants. **Ans.** 35 k cal.

3. If the activation energy for the forward reaction is 150 kJ mol$^-$ and that of the reverse reaction is 260 kJ mol$^-$, what is the enthalpy change for the reaction?

(*a*) 410 kJ mol$^-$ (*b*) –110 kJ mol$^-$

(*c*) 110 kJ mol$^-$ (*d*) –410 kJ mol$^-$

(*e*) 90 kJ mol$^-$

(Kerala PET, 2010)

Ans. (*b*)

4. The reaction, $2\ A(g) + B(g) \rightleftharpoons 3C(g) + D(g)$ is begun with the concentration of A and B both at an initial value of 1.0 M. When equilibrium is reached, the concentration of D is measured and found to be 0.25 M. The value for the equilibrium constant for this reaction is given by:

(*a*) $[(0.75)^3\ (0.25)] + [(1.0)^2\ (1.0)]$

(*b*) $[(0.75)^3\ (0.25)^2]/(0.5)^2\ (0.75)$

(*c*) $[(10.75)^2\ (0.25)] + [(0.5)^2\ (0.25)]$

(*d*) $[(0.75)^3\ (0.25)] + [(0.75)^2\ (0.25)]$

(CBSE, PMT, 2010)

Ans. (*b*)

5. The first order reaction is 50% complete in 69.3 minutes. The time required for 90% completion for this reaction is:

(*a*) 100 minutes (*b*) 230 minutes

(*c*) 2303 minutes (*d*) 125 minutes

(Orissa JEE, 2010)

Ans. (*b*)

6. For a reaction $A + 2(B) \longrightarrow C$, the amount of C formed by starting the reaction with 5 moles of A and 8 moles of B is

(*a*) 5 moles (*b*) 8 moles

(*c*) 16 mole (*d*) 4 moles

(*e*) 1 mole

(Kerala PMT, 2010)

Ans. (*d*)

7. For an isomerisation reaction $A \longrightarrow B$, the rate constant is 4.5×10^{-3} min$^-$. If the initial concentration of A is 1M, calculate the rate of reaction after 1 hour.

Ans. 3.4354×10^{-3}

8. The rate of a first order reaction is 0.08 mol L$^-$ at 15 minutes and 0.06 mol L$^-$ at 25 minutes from the start of reaction. Find the half-life of reaction.

Ans. 24.06 min.

9. If the rate constant for the decomposition of a reaction is given by log *k* (s$^-$) = 12.14 – (1.41 × 10^4/T), then (*i*) calculate the energy of activation and (*ii*) value of *k* at 800 K.

(**Ans.** (*i*) E_a = 269.97 kJ; (*ii*) $k = 3.27 \times 10^{-6}$)

10. The rate constant for a first order reaction, $X \longrightarrow Y$ is 0.03465 min$^-$. Find the rate (*i*) at the beginning and (*ii*) after 40 minutes if initial concentration of *X* is 2.0 M.

Ans. 0.017325

11. If the rate constant for the decomposition of a certain compound at 20°C is 3.0×10^{-3} mol$^-$ s$^-$ and at 45° C is 1.2×10^{-2} mol$^-$ s$^-$, then calculate the values of Arrhenius parameters of the reaction.

Ans. 3.5×10^{14}

12. A catalyst lowers the activation energy of a reaction from 30 *k*J mol$^-$ to 20 *k*J mol$^-$. The temperature at which the uncatalysed reaction will have the same rate as that of the catalysed at 25°C is:

(*a*) 500 K (*b*) 447 K

(*c*) 600 K (*d*) 700 K

Ans. (*b*)

13. The activation energy for the reaction,

$2HI(g) \rightarrow H_2(g) + I_2(g)$ is 209.5 kJ mol$^-$ at 581 K. Calculate the fraction of molecules of reactants having energy equal to or greater than activation energy.

Hint. Fraction of molecules,

$$x = \frac{n}{N} = e^{-E_a/RT}; \log x = \frac{-E_a}{2.303\ RT}$$

$$\left[\because \log e^{-E_a/RT} = \frac{-E_a}{2.303\ RT}\right]$$

$$\therefore \log x = -\frac{209.5 \times 1000\ J\ \text{mol}^-}{2.303 \times 8.314\ J\ K^-\ \text{mol}^- \times 581\ K}$$

$= -18.8323 = -18 - 1 + 1 - 0.8323$

$= \overline{19}.1677; x = \text{antilog}\ \overline{19}.1677 = 1.471 \times 10^{-19}$ **Ans.**

14. Tha rate constant for the decomposition of a hydrocarbon is $2.418 \times 10^{-5}\ s^-$ at 546 K. If the energy of activation is 179.9 kJ mol$^-$, find the value of pre-exponential factor.

Hint. $k = 2.418 \times 10^{-5}\ s^-$, $E_a = 179.9$ kJ mol$^-$, $T = 546\ K$, $R = 8.314$ JK$^-$ mol$^-$.

Putting the value of k, E_a and T in, $\log k = \log A - \frac{E_a}{2.303\ RT}$ and solving, $A = 3.912 \times 10^{12}\ s^-$. **Ans.**

15. The half-life for a decay of a radioactive ^{14}C is 5730 years. An archaeological artefact containing wood has only 80% of the ^{14}C activity as found in living trees. Calculate the age of the artefact. **(CBSE, D, 2012)**

Hint. $k = \frac{0.693}{5730\ yr} = 1.209 \times 10^{-4}\ yr^-; t = \frac{2.303}{1.209 \times 10^{-4}}$

$\log \frac{100}{80} = 1847.7$ Yrs. **Ans.**

2nd Method: $\left(\frac{1}{2}\right)^n = \frac{80}{100}$ or $\frac{8}{10}; \left(\frac{2}{1}\right)^n = \frac{10}{8};$

$\log 2^n = \log 10 - \log 8; n \log 2 = 1 - 0.9031;$

$n \times 0.301 = 0.0970; n = 0.0970/0.301; t = n \times t_{1/2}$

$= (0.0970/0.301) \times 5730$ yrs. $= 1846.5$ yrs.

21

CHAPTER

Nuclear Chemistry

21.1 NUCLEAR CHEMISTRY

A reaction in which nucleus of an atom undergoes a change is called a ***nuclear reaction*** and *the branch* of chemistry which deals with the study of nuclear *reactions* is called ***nuclear chemistry***.

Nucleons. The nuclei of atoms contain ***protons*** and ***neutrons*** which are collectively called ***nucleons***.

Some notations of particles

(*i*) Proton = $^{1}_{1}\text{H}$

(*ii*) Neutron = $^{1}_{0}n$

(*iii*) Electron or beta (β) particle = $^{0}_{-1}e$ or $^{0}_{-1}\beta$

(*iv*) Positron = $^{0}_{+1}e$

(*v*) Alpha particle, a = $^{4}_{2}\text{He}$

(*vi*) Gamma rays, $\gamma = {}^{0}_{0}\gamma$

21.2 BALANCING OF NUCLEAR EQUATIONS

In the notation of particles (say $^{4}_{2}\text{He}$), the superscript (*i.e.*, 4) represents *mass number* while the subscript (*i.e.*, 2) represents the atomic number or charge. The nuclear reactions are balanced by the addition or elimination of particles like, $^{4}_{2}\text{He}$, $^{o}_{-1}e$, $^{0}_{0}\gamma$, $^{1}_{0}n$, $^{0}_{1+}e$, $^{1}_{1}\text{H}$ (proton), $^{2}_{1}\text{D}$ or $^{2}_{1}\text{H}$ (deuterium), $^{3}_{1}\text{T}$ or $^{3}_{1}\text{H}$ (tritium) etc.

α – decay means, $-{}^{4}_{2}\text{He}$; β – decay means, $-{}^{0}_{-1}e$.

Type. To balance nuclear equations, the **sum of mass numbers** on the reactant side should be equal to that on product side. Similarly, ***sum of atomic numbers or charges*** on the reactant side should be equal to that on the product side. There is conservation of both atomic number and mass number in the equation of a nuclear reaction.

A balanced equation (say, $^{23}_{11}\text{Na} + {}^{1}_{1}\text{H} \rightarrow {}^{23}_{12}\text{Mg} + {}^{1}_{0}n$) can also be represented as, $^{23}_{11}\text{Na}({}^{1}_{1}\text{H}, {}^{1}_{0}n){}^{23}_{12}\text{Mg}$ or $^{23}_{11}\text{Na}$ $(p, n){}^{23}_{12}\text{Mg}$.

EXAMPLE 1. *Balance the following nuclear reaction.*

$$^{238}_{92}U + {}^{1}_{0}n \rightarrow {}^{239}_{92}U + ?$$

SOLUTION. (*i*) $^{238}_{92}\text{U} + {}^{1}_{0}n \rightarrow {}^{239}_{92}\text{U} + ?$. Let unknown particle is $^{a}_{b}\text{A}$.

$\therefore$ $^{238}_{92}\text{U} + {}^{1}_{0}n \rightarrow {}^{239}_{92}\text{U} + {}^{a}_{b}\text{A}$. Thus equating mass numbers of both sides, we have :

$$238 + 1 = 239 + a; a = 238 + 1 - 239 = 0.$$

Equating the atomic numbers of both sides, we have

$92 + 0 = 92 + b$; $b = 92 + 0 - 92 = 0$.

So, the particle is $^{0}_{0}\text{A}$ *i.e.*, $^{0}_{0}\gamma$. So, the required balanced equation is :

$$^{238}_{92}\text{U} + {}^{1}_{0}n \rightarrow {}^{239}_{92}\text{U} + {}^{0}_{0}\gamma \qquad \textbf{Ans.}$$

EXAMPLE 2. *Balance the following nuclear reactions.*

$^{14}_{7}N(?, \gamma){}^{15}_{8}O$ **(MP PMT, 2000)**

SOLUTION. (*i*) $^{14}_{7}\text{N} + ? \rightarrow {}^{15}_{8}\text{O} + {}^{0}_{0}\gamma$. Let unknown particle is $^{a}_{b}\text{A}$.

$\therefore$ $^{14}_{7}\text{N} + {}^{a}_{b}\text{A} \rightarrow {}^{15}_{8}\text{O} + {}^{0}_{0}\gamma$. Equating the mass numbers of both sides, we have :

$$14 + a = 15 + 0; a = 1$$

Equating the atomic numbers of both sides, we have :

$$7 + b = 8 + 0; b = 8 - 7 = 1$$

So, the particle is $^{1}_{1}\text{A}$ *i.e.*, $^{1}_{1}\text{H}$. Hence :

$$^{14}_{7}\text{N} + {}^{1}_{1}\text{H} \rightarrow {}^{15}_{8}\text{O} + {}^{0}_{0}\gamma \qquad \textbf{Ans.}$$

EXAMPLE 3. *Complete and balance the following nuclear reactions.*

(*i*) $^{234}_{92}\text{U} \rightarrow \ldots\ldots + {}^{4}_{2}\text{H}$, (*ii*) $^{2}_{1}\text{H} + {}^{3}_{1}\text{H} \rightarrow \ldots\ldots + {}^{1}_{0}n$ + energy.

(BIT, Mesra; Ranchi 1989, Pb. PMT, 1990)

SOLUTION. (*i*) $^{234}_{92}\text{U} \rightarrow \ldots\ldots + {}^{4}_{2}\text{H}$. Let the missing element is $^{a}_{b}\text{A}$.

$$^{234}_{92}\text{U} \rightarrow {}^{a}_{b}\text{A} + {}^{4}_{2}\text{He}$$

Equating the mass numbers of both sides, we have : $234 = a + 4$; $a = 230$

Equating the atomic numbers of both sides, we have : $92 = b + 2$; $b = 90$

So, the missing element is $^{230}_{90}\text{A}$ *i.e.*, $^{230}_{90}\text{Th}$.

(*ii*) $^{2}_{1}\text{H} + {}^{3}_{1}\text{H} \rightarrow \ldots\ldots + {}^{1}_{0}n$. Let the missing element is $^{a}_{b}\text{A}$. So, we have :

$$^{2}_{1}\text{H} + {}^{3}_{1}\text{H} \rightarrow {}^{a}_{b}\text{A} + {}^{1}_{0}n + \text{energy}$$

Equating the mass numbers of both sides, we have : $2 + 3 = a + 1$; $a = 4$

Equating the atomic numbers of both sides, we have :

$$1 + 1 = b + 0; b = 2$$

∴ Missing element is ${}_{2}^{4}$A *i.e.*, ${}_{2}^{4}$He **Ans.**

Example 4. *${}_{98}^{246}Cf$ was emitted along with neutrons when an unknown radioactive substance was bombarded using ${}_{6}^{12}$C as projectile. Predict the unknown radioactive substance (at. wt. 238) and the type of nuclear reaction.*

(CBSE Sample Paper, 1991)

Solution. Let the unknown element is ${}_{Z}^{A}$X. So, we have : ${}_{Z}^{A}X + {}_{6}^{12}C \rightarrow {}_{98}^{246}Cf + x\,{}_{0}^{1}n$

Equating atomic numbers on both sides of the equation, we have :

$$Z + 6 = 98 + 0; Z = 92 \text{ or uranium element}$$

But at. wt. of unknown element is 238, so we have :

$$A + 12 = 246 + x; 238 + 12 = 246 + x; x = 4$$

∴ ${}_{92}^{238}U + {}_{6}^{12}C \rightarrow {}_{98}^{246}Cf + 4\,{}_{0}^{1}n$. Type of reaction is ${}_{6}^{12}$C, ${}_{0}^{1}n$.

Example 5. ${}_{92}^{234}X \xrightarrow[-6\beta]{-7\alpha} Y$. *Find the atomic number, mass number of Y and identify it.* **(I.I.T., 2004)**

Solution. Decrease in mass number by the loss of 7 α-particles = 7 × 4 = 28.

∴ Mass number of Y

$$= 234 - 28 = 206$$

Decrease in atomic number by the loss of 7α-particles

$$= 7 \times 2 = 14$$

Increase in atomic number by the loss of 6 β-particles

$$= 6 \times 1 = 6.$$

Net decrease in atomic number

$$= 14 - 6 = 8.$$

∴ Atomic number of

$$Y = 92 - 8 = \mathbf{84}$$

Thus Y is ${}_{84}^{206}$Po.

Type. To calculate the atomic number, mass number and electron configuration of daughter element.

(*i*) Write the balanced nuclear reaction and

(*ii*) Write the electron configuration of the new element or daughter element.

Example 6. *A radioactive element A, mass number 32 that emits a beta particle has electron configuration $1s^22s^22p^63s^23p^3$. What will be the atomic number, mass number and electron configuration of the daughter element.*

Solution. The element with given electron configuration, $1s^22s^22p^63s^23p^3$ has electrons = 2 + 2 + 6 + 2 + 3 = 15.

Since in a neutral atom, at. no. = no. of electrons.

So, at. no. = 15, *i.e.*, phosphorus atom.

Since mass number of element = 32.

∴ nucleide = ${}_{15}^{32}$P.

When ${}_{15}^{32}$P loses a beta particle (${}_{-1}^{0}e$), we have : ${}_{15}^{32}P \rightarrow {}_{16}^{32}S + {}_{-1}^{0}e$

For ${}_{16}^{32}$S, at. no. of S = 16 and mass no. = 32.

∴ Electron configuration of daughter element

$${}_{16}S = 1s^22s^22p^63s^23px^23py^13pz^1.$$

21.3 π-MESONS

These are nuclear particles which are responsible for the interconversion of nuclear particles into one another. Three types of π-mesons are, positive meson (π^+), negative meson (π^-) and neutral meson (π).

To solve problems regarding π-meson, proceed as follows :

(*i*) proton → neutron + π^+ ; neutron + π^+ → proton.

(*ii*) neutron → proton + π^- ; proton + π^- → neutron

(*iii*) neutron 1 → neutron′ 1 + π^0; neutron 2 + π^0 → neutron′ 2

Example 7. *Fill in the blanks. (i) proton → neutron + ?, (ii) proton + ? → neutron.*

Solution. (*i*) proton → neutron + ?

∴ proton → neutron + π^+

(*ii*) proton + ? → neutron

∴ proton + π^- → neutron.

Example 8. *Predict the missing particles.*

(i) neutron 1 → neutron′ 1 + ?, (ii) neutron 2 + ? → neutron′ 2.

Solution. (*i*) neutron 1 → neutron′ 1 + ? ∴ neutron 1 → neutron′ 1 + π^0.

(*ii*) neutron 2 + ? → neutron′ 2,

∴ neutron 2 + π^0 → neutron′ 2.

Type. To find fraction of the atom that is occupied by a nucleus, use the relation :

$$\text{Volume of nucleus} = \frac{4}{3}\pi r^3$$

$$\text{Atomic volume} = \frac{4}{3}\pi r^3$$

Example 9. *Nuclear radius is of the order of 10^{-13} cm while atomic radius is of the order of 10^{-8}cm. Assuming the nucleus and the atom to be spherical, what fraction of the atom is occupied by a nucleus.* **(DSB, 1979)**

Solution. Radius of nucleus,

$$r = 10^{-13} \text{ cm}$$

Volume of nucleus

$$= \frac{4}{3}\pi r^3 = \frac{4}{3}\pi \times \left(10^{-13}\text{cm}\right)^3$$

$$= \frac{4}{3}\pi \times 10^{-39}\text{cm}^3 \qquad \text{...(1)}$$

Radius of atom,

$$r = 10^{-8} \text{ cm}$$

Atomic volume

$$= \frac{4}{3}\pi r^3 = \frac{4}{3}\pi (10^{-8}\text{ cm})^3$$

$$= \frac{4}{3}\pi \times 10^{-24}\text{cm}^3 \qquad \text{...(2)}$$

Dividing (1) and (2), we get :

Volume occupied by nucleus as compared to that of the atom as a whole

$$= \frac{\frac{4}{3}\pi \times 10^{-39}\text{cm}^3}{\frac{4}{3}\pi \times 10^{-24}\text{cm}^3} = 10^{-39+24} = \mathbf{10^{-15}}$$

Ans.

21.4 RADIUS OF NUCLEUS

Type. To calculate the radius of the nucleus of an atom having mass number, A. For this purpose, use the relation : Radius = $R_0\,(A)^{1/3}$ where R_0 is a constant = 1.4×10^{-13}cm = 1.4×10^{-15} m.

Radius = $(A)^{1/3}$ (1.4×10^{-13} cm) = $(A)^{1/3}$ (1.4×10^{-15} m).

Where A = mass number of the given element.

Example 10. *Find the radius of the nucleus of $^{40}_{19}K$.*

Solution. A = mass number of K = 40.

∴ Radius of nucleus of 40

$$K = (40)^{1/3}\,(1.4 \times 10^{-13}\text{ cm})$$

To solve $(40)^{1/3}$, take logs.

$$\therefore \quad \log (40)^{1/3} = \frac{1}{3}\log 40 = \frac{1}{3} \times 1.602 = 0.534.$$

Taking antilog of 0.534, we have : antilog 0.534 = 3.4198.

∴ Radius of nucleus of ^{40}K = $3.4198 \times 1.4 \times 10^{-13}$ cm = 4.79×10^{-13} cm **Ans.**

Type. Calculation of radius of nucleus.

Use : Area (A) of circle = πr^2.

Example 11. *What will be the effective neutron capture radius of nucleus having a cross- section of 1.0 barn ?*

Solution.

$$1.0\text{ barn} = 1.0 \times 10^{-24}\text{ cm}^2$$

Area (A) of a circle = πr^2;

$$r = \left(\frac{A}{\pi}\right)^{1/2} = \left(\frac{10^{-24}\text{cm}^2 \times 7}{22}\right)^{1/2}$$

Taking logs of both sides, we get :

$$\begin{aligned}\log r &= \frac{1}{2}[\log 10^{-24} + \log 7 - \log 22]\\ &= \frac{1}{2}[-24\log 10 + 0.8451 - 1.3424]\\ &= \frac{1}{2}[-24 \times 1 + 0.8451 - 1.3424]\\ &= -12.2486\\ \therefore \quad r &= \text{antilog} - 12.2486\\ &= \text{antilog} - 12 - 1 + 1 - 0.2486\\ &\qquad (= \overline{13}.7514)\\ &= \mathbf{5.64 \times 10^{-13}\ cm}\end{aligned}$$

Ans.

Type. Calculation of coulombic repulsion energy (or coulombic barrier, V). Such energy between any two nuclei having atomic numbers Z_1 and Z_2 respectively can be calculated by using the relations :

(*i*) $r = R_0\,(A)^{1/3}$ where r = radius, R_0 is a constant = 1.4 × 10^{-13}cm. A = at. wt. of atom.

(*ii*) $V = \dfrac{Z_1Z_2(e)^2}{d}$ where e = protonic charge = 4.8 × 10^{-10} esu and d = distance between the two nuclei.

Example 12. *Calculate the coulombic repulsion energy between an α-particle and $^{232}_{90}Th$ assuming that the distance between them is equal to the sum of their radii. ($R_0 = 1.4 \times 10^{-13}$cm).*

Solution. For $^{232}_{90}$Th Z_1 = 90, A = 232; r_1 = radius, $R_0 = 1.4 \times 10^{-13}$, $r_1 = R_0\,(A)^{1/3} = 1.4 \times 10^{-13} \times (232)^{1/3} = 1.4 \times 10^{-13} \times 6.1446 = 8.6 \times 10^{-13}$. For α-particle, $^4_2$He, Z_2 = 2, A = 4, r_2 = radius, $R_0 = 1.4 \times 10^{-13}$, $r_2 = R_0\,(A)^{1/3} = 1.4 \times 10^{-13} \times (4)^{1/3} = 1.4 \times 10^{-13} \times 1.5874 = 2.22 \times 10^{-13}$.

$$\therefore r_1 + r_2 = 8.6 \times 10^{-13} + 2.22 \times 10^{-13} = 10.82 \times 10^{-13} = \boldsymbol{d}.$$

Coulombic repulsion energy

$$\begin{aligned}(V) &= \frac{Z_1Z_2(e)^2}{d} = \frac{90 \times 2 \times (4.8 \times 10^{-10})^2}{10.82 \times 10^{-13}}\\ &= 3.83 \times 10^{-5}\text{ erg} = 3.83 \times 10^{-5}\text{erg}\\ &\quad \times \frac{1eV}{1.602 \times 10^{-12}\text{erg}} \times \frac{1\text{MeV}}{10^6\,eV}\\ &= \mathbf{23.9\ MeV}\end{aligned}$$

Ans.

21.5 CALCULATION OF α AND β PARTICLES

Example 13. *$_{90}Th^{234}$ emits 7 alpha particles and 6 beta particles. What will be the atomic number and mass number of the resulting atom?* **(ISC, 2007)**

Solution.

Since $^{234}_{90}$Th loses 7α ($^4_2$He) and 6β ($^0_{-1}e$)particles, so the resulting atom (^d_cY, say)can be written as:

$$^{234}_{90}\text{Th} \longrightarrow 7\,^4_2\text{He} + 6\,^0_{-1}e + {}^d_c\text{Y}$$

(*i*) Mass no. of reactants = Mass no. of products

$$\therefore \quad 234 = (7 \times 4) + (6 \times 0) + d;$$

$$d = 234 - 28 = \mathbf{206 = mass\ no.}$$ **Ans.**

(*ii*) At. no. of reactants = At. no. of products

$$\therefore \quad 90 = (7 \times 2) + 6(-1) + c\,;$$

$$c = 90 - 14 + 6 = \mathbf{82 = at.\ no.}$$ **Ans.**

Example 14. *In a radioactive emission, actinium loses an α-particle and the product loses another α-particle followed by the product (the new radioactive element) losing one β-particle. Calculate (i) Mass number and (ii) Atomic number of the finally formed element (Atomic number of actinium = 89, mass number of actinium = 227).* **(CBSE, Sample Paper, 1997)**

Solution. Given $^{227}_{89}$Ac. (*a*) On loss of α-particle ($^4_2$He) we have $^{227}_{89}\text{AC} \rightarrow {}^4_2\text{He} + {}^{223}_{87}\text{A}$ (where A = new element); $^{223}_{87}\text{A} \rightarrow {}^4_2\text{He} + {}^{219}_{85}\text{B}$ (where B = new element); $^{219}_{85}\text{B} \rightarrow {}^{219}_{86}\text{C} + {}^0_{-1}\beta$. Hence (*i*) mass no. = 219 and (*ii*) at. no. of finally formed element = 86 [∵ 85 = 86 – 1] **Ans.**

Example 15. *A radioactive element $^{227}_{89}Ac$ undergoes a series of disintegrations and finally yields $^{207}_{82}Pb$. What is the minimum number of α and β-particles involved in this disintegration ?* **(WBJEE 2000)**

Solution. $^{227}_{89}\text{Ac} \rightarrow {}^{207}_{82}\text{Pb} + x.\,^4_2\text{He} + y\,^0_{-1}e.$

Equating mass numbers, we have:

$$227 = 207 + 4x + 0y\,;\, 4x = 20 \text{ or } x = \frac{20}{4} = 5.$$

$\therefore$ Number of α-particles emitted = 5.

Equating charge number or atomic number

$$89 = 82 + 2 \times 5 - y\,;\, 89 = 92 - y$$

or $\quad y = 92 - 89 = 3.$

$\therefore$ Number of β-particles emitted = 3.

EXAMPLE 16. *$^{238}_{92}$U is radioactive and it emits α and β-particles to form $^{206}_{90}$Pb. Calculate the number of α and β-particles emitted in the conversion. An ore of $^{238}_{92}$U is found to contain $^{238}_{92}$U and $^{206}_{82}$Pb in the mass ratio of 1 : 0.1. The half-life period of $^{238}_{92}$U is 4.5 × 10^9 years. Calculate the age of the ore.*

(IIT, 2000)

SOLUTION. The emission of an α-particle causes :

(*i*) Decrease in atomic number = 2.

(*ii*) Decrease in mass number = 4.

The emission of β-particle causes :

(*i*) Increase in atomic number = 1.

(*ii*) Decrease in mass number = zero.

Decrease in mass number when $^{238}_{92}$U changes to

$$^{206}_{82}\text{Pb} = 238 - 206 = 32.$$

Since the mass number changes only due to the emission of α-particles, the number of α-particles emitted = $\frac{32}{4} = 8$

The decrease in atomic number due to the loss of 8 α-particles = 2 × 8 = 16.

Actual decrease in atomic number = 92 – 82 = 10.

Increase in atomic number due to loss of β-particles = 16 – 10 = 6.

$\therefore$ Number of β-particles emitted = 6.

Half-life period = 4.5 × 10^9 years.

Disintegration constant.

$$\lambda = \frac{0.693}{t_{1/2}} = \frac{0.693}{4.5 \times 10^{9}\text{year}}$$

$$= 1.54 \times 10^{-10}\ \text{year}^{-1}$$

See section 21.11.

Assuming atomic mass equal to mass number, we will have :

	U	:	Pb
Mass ratio	1	:	0.1
Mole ratio	$\frac{1}{238}$	:	$\frac{0.1}{206}$ *i.e.,*
	4.202 × 10^{-3}	;	4.854×10^{-4}

Original amount of

$$\text{U, [U]}_0 = \text{[U]} + \text{[Pb]}$$

$$= (4.202 \times 10^{-3} + 4.854 \times 10^{-4})\ \text{mol}$$

$$= 4.687 \times 10^{-3}\ \text{mol}$$

Present amount of

$$\text{U, [U]} = 4.202 \times 10^{-3}\ \text{mol}$$

Now, $$t = \frac{2.303}{\lambda}\log\frac{[\text{U}_0]}{[\text{U}]} = \frac{2.303}{1.54 \times 10^{-10}\text{year}}\log\frac{4.687 \times 10^{-3}}{4.202 \times 10^{-3}}$$

$$= \mathbf{7.09 \times 10^{8}\ year}$$

EXAMPLE 17. *Thorium $^{232}_{90}$Th emits one α-particle and two β-particles. What will be the daughter element ?*

SOLUTION. α-particles = 1; β-particles = 2. For the transformation of $^{b}_{a}\text{X} \rightarrow {}^{d}_{c}\text{Y}$, we have : For $^{232}_{90}$Th (*i*) no. of α-particles = $b - d/4$ **Or** $1 = (232 - d)/4$ or $4 = 232 - d$.

$\therefore d = 232 - 4 = 228$. (*ii*) no. of β-particles = $[c + (b - d/2) - a$. Thus $2 = [c + (232 - 228/2)] - 90$; $2 = c + 2 - 90$ or $c = 90$. Hence daughter element = $^{228}_{90}$Th.

21.6 SODDY-FAJAN-RUSSEL'S GROUP DISPLACEMENT LAW

According to this law :

(*i*) The emission of an α-particles ($^4_2$He) from a radioactive element decreases the mass number of the nucleide by four units and atomic number by two units resulting in the formation of a daughter element which lies two groups to the left in the periodic table. *e.g.,*

$$\underset{\text{group 16}}{^{215}_{84}\text{Po}} \rightarrow \underset{\text{group 14}}{^{211}_{82}\text{Pb}} + \underset{\alpha\text{-particle}}{^{4}_{2}\text{He}}$$

(*ii*) The emission of *a* β-particle ($^{0}_{-1}e$) does not change the mass number but increases the atomic number by one. The resulting nucleide lies one group to the right of the parent nucleide in the periodic table *e.g.,*

$$\underset{\text{group 14}}{^{211}_{82}\text{Pb}} \rightarrow \underset{\text{group 15}}{^{211}_{83}\text{Bi}} + \underset{\beta\text{-particle}}{^{0}_{-1}e}$$

Isotopes. *Different* atoms of the same element having same atomic number but different mass numbers are called isotopes of each other.

Isobars. *Atoms of different* elements having same mass number but different atomic numbers are called *isobars.*

α-decay or – ($^4_2$He). It is a process in which the daughter element has mass number less by 4 units and atomic number less by 2 units from the parent element *e.g.,*

$$^{a}_{b}\text{A} \xrightarrow[\text{or } -\alpha]{-(^{4}_{2}\text{He})} {}^{a-4}_{b-2}\text{B}$$

β-decay or – ($^{0}_{-1}\beta$ or $^{0}_{-1}e$). It is a process in which the daughter element has mass number same but atomic number more by one unit from that of parent element. *e.g.,*

$$^{a}_{b}\text{A} \xrightarrow[-(^{0}_{-1}\beta)]{-(^{0}_{-1}e)\text{or}} {}^{a}_{b+1}\text{A}$$

Type. To calculate atomic mass, atomic number and group number of daughter nucleus from parent nucleus $^{A}_{Z}$X by the emission of α and β particles respectively, use the relation:

$$\underset{\substack{\text{Group no. (say, N)}\\ \text{of periodic table}}}{^{A}_{Z}\text{X}} \xrightarrow[-(^{4}_{2}\text{He})]{-\alpha-\text{particle}} \underset{\substack{\text{N}-[\text{Z}-(\text{Z}-2)]\\ =\text{N}-2}}{^{A-4}_{Z-2}\text{X}_1} \xrightarrow[-(^{0}_{-1}e)]{-\beta-\text{particle}} \underset{\substack{=\text{Z}-1\\ \text{N}-[\text{Z}-(\text{Z}-1)]\\ =\text{N}-1}}{^{A-4}_{Z-2+1}\text{X}_2}$$

EXAMPLE 18. *A radioactive atom A, changes to B by emitting one alpha particle. B changes to C by losing one beta particle and further to D by emitting another beta particle. If the mass number of A is 214 and the atomic number of A is 84, what are the mass numbers of B, C and D ? If A belongs to a group VI of the periodic table, what are the groups to which B, C and D belong ?* **(ISC, 1987)**

SOLUTION. Mass no. of A = 214, at. no. of A = 84. So, A is ${}^{214}_{84}\text{A}$ Hence :

$$ {}^{214}_{84}\text{A} \xrightarrow[\text{or}-{}^{4}_{2}\text{He}]{-\alpha-\text{particle}} {}^{214-4}_{84-2}\text{B} \text{ or } {}^{210}_{82}\text{B} \xrightarrow[\text{or }-({}^{0}_{-1}e)]{-\beta-\text{particle}} {}^{210-0}_{82+1}\text{C} $$

$$ \text{or } {}^{210}_{83}\text{C} \xrightarrow[\text{or }-({}^{0}_{-1}e)]{-\beta-\text{particle}} {}^{210-0}_{83+1}\text{D} \text{ or } {}^{210}_{84}\text{D} $$

$$ \underset{\text{Group}}{\text{Or}} \quad \underset{\text{VI}}{{}^{214}_{84}\text{A}} \xrightarrow{-{}^{4}_{2}\text{He}} \underset{\text{VI}-(84-82)=\text{IV}}{{}^{210}_{82}\text{B}} \xrightarrow{-({}^{0}_{-1}e)} \underset{\text{VI}-(84-83)=\text{V}}{{}^{210}_{83}\text{C}} $$

$$ \xrightarrow{-({}^{0}_{-1}e)} \underset{\text{VI}-(84-84)=\text{VI}}{{}^{210}_{84}\text{D}} $$

EXAMPLE 19. *If a radioactive nucleide of group 15 undergoes β-particle emission, in which group will the daughter element be found ?* **(NCERT Textbook Problem)**

SOLUTION. Let group 15 nucleide is ${}^{a}_{b}\text{A}$. With the emission of β-particle $-({}^{0}_{-1}e)$ we have :

$$ \underset{\text{Group15}}{{}^{a}_{b}\text{A}} \rightarrow \underset{\text{Group16}}{{}^{a}_{b+1}\text{B}} + {}^{0}_{-1}e1 $$

Since the daughter element has at. no. more by one unit, the daughter element will belong to group 16.

EXAMPLE 20. *Write nuclear equation for the following reaction. ${}^{218}_{85}$At undergoesα-decay.* **(NCERT text book)**

SOLUTION. Since α (or ${}^{4}_{2}\text{He}$) decay involves loss of mass number by 4 units and loss of atomic number by 2 units, so the reaction will be :

$$ {}^{218}_{85}\text{Al} \longrightarrow {}^{218-4}_{85-2}\text{X} + {}^{4}_{2}\text{He} \text{ or } \left({}^{214}_{83}\text{X} + {}^{4}_{2}\text{He}\right) $$

EXAMPLE 21. ${}^{238}_{92}$U *undergoes one α, two β and one α-decays in succession. Choose the isotopes formed.*

SOLUTION.

$$ {}^{238}_{92}\text{U} \xrightarrow{-({}^{4}_{2}\text{He})} {}^{234}_{90}\text{A} \xrightarrow{-({}^{0}_{-1}e)} {}^{234}_{91}\text{B} \xrightarrow{-({}^{0}_{-1}e)} {}^{234}_{92}\text{C} $$

$$ \xrightarrow{-({}^{4}_{-2}\text{He})} {}^{230}_{90}\text{D} $$

Out of above elements formed.

(*i*) ${}^{234}_{90}\text{A}$ and ${}^{230}_{90}\text{D}$ are isotopes of each other.

(*ii*) ${}^{238}_{92}\text{U}$ and ${}^{234}_{92}\text{C}$ are isotopes of each other because both have same at. no. but different mass numbers.

EXAMPLE 22. ${}^{211}_{82}$*Pb undergoes one beta decay. Whether the daughter element will be isotope or isobar of the parent element?*

SOLUTION. *Reaction* : $\underset{\substack{\text{Parent}\\\text{element}}}{{}^{211}_{82}\text{Pb}} \longrightarrow {}^{0}_{-1}e + \underset{\substack{\text{Daughter}\\\text{element}}}{{}^{211}_{83}\text{X}}$

Since the parent element and daughter element have same mass number but different atomic numbers, both the elements are isobars of each other.

Type. *The emission* of a positron (β⁺) or ${}^{0}_{+1}e$ from the nucleus decreases the atomic number by one unit but does not change the mass number. The resulting nucleide is shifted one group to the left of the original position of the parent nucleide in the periodic table.

EXAMPLE 23. ${}^{23}_{12}$*Mg of group 2 undergoes emission of positron. To which group will the new element belong ?*

SOLUTION. *Reaction* : $\underset{\text{Group2}}{{}^{23}_{12}\text{Mg}} \longrightarrow \underset{\text{Positron}}{{}^{0}_{+1}e} + \underset{\text{Group}(2-1)=1}{{}^{23}_{11}\text{Na}}$

So, the daughter element belongs to group 1.

EXAMPLE 24. ${}^{210}_{82}$*Pb is a β-emitter and* ${}^{226}_{88}$*Ra is an alpha emitter radioactive element. What will be the atomic masses and atomic numbers of the daughter elements of these radioactive elements? Predict the position of daughter elements in the periodic table.* **(HSB, 1995)**

SOLUTION. (*a*) Let daughter element of ${}^{210}_{82}\text{Pb}$ = A. Thus, ${}^{210}_{82}\text{Pb} \rightarrow {}^{210}_{83}\text{A} + {}^{0}_{-1}\beta.1$ Hence at no. of A = 83, mass number = 210.

(*b*) Let daughter element of ${}^{226}_{88}\text{Ra}$ = B. Thus, ${}^{226}_{88}\text{Ra} \rightarrow {}^{222}_{86}\text{B} + {}^{4}_{2}\text{He}$. Hence at. no. of B = 86, mass no. 222. Since group no. of ${}_{82}\text{Pb}$ $[(\text{Xe})^{54}4f^{14}5d^{10}6s^{2}6p^{2}$ (group no. = 2 of *s* + 10 of *d* + 2 of *p* = 14] is 14 that of A will be 15. Similarly, group no. of ${}_{88}\text{Ra}$ $[(\text{Rn})^{86}7s^{2}]$ being 2, then that of ${}_{86}\text{B}$ will be 0(*i.e.*, 2–2= 0) or 18.

EXAMPLE 25. ${}^{40}_{19}$*K (group 1) undergoes electron capture. To which group the daughter element will belong ?*

SOLUTION. *Reaction* : $\underset{\text{Group1}}{{}^{40}_{19}\text{K}} + {}^{0}_{-1}e \rightarrow \underset{\text{group zero}(i.e., 1-1=0)}{{}^{40}_{18}\text{Ar} + \text{X} - \text{rays}}$

So, the daughter element ${}^{40}_{18}\text{Ar}$ belongs to zero group or group 18 of the periodic table.

Type. Neutron absorption or emission changes the mass number of a nucleide by unity while the atomic number remains the same. Thus, the group number in the periodic table remains the same.

EXAMPLE 26. *Write the isotopes or isobars along with the group number of the daughter element in the periodic table.*

$$ \underset{\text{group3}}{{}^{238}_{92}\text{U}} + {}^{1}_{0}n \rightarrow {}^{239}_{92}\text{U} $$

SOLUTION. (*i*) $\underset{\text{group3}}{{}^{238}_{92}\text{U}} + {}^{1}_{0}n \rightarrow \underset{\substack{\text{group3}\\(\text{Daughter element})}}{{}^{239}_{92}\text{U}}$

Since there is no change in atomic number of the ${}^{238}_{92}\text{U}$, the group number of daughter element will be the same *i.e.*, 3. Also, the atomic numbers of parent and daughter elements are same, so both are ***isotopes*** of each other.

21.7 CALCULATION OF PACKING FRACTION

Type. To calculate **packing fraction**, use the relation :

$$ \text{Packing fraction} = \frac{\text{Isotopic mass} - \text{mass no.}}{\text{mass no.}} \times 10^{4} $$

EXAMPLE 27. *Calculate the packing fraction, mass defect and energy released in the formation of ${}^{98}_{42}$Mo. Isotopic mass of molybdenum = 97.906, proton = 1.007825; neutron = 1.008665.*

Solution. (*i*) Mass no. = 98 a.m.u.; isotopic mass = 97.906 a.m.u.

$$\therefore \text{Packing fraction} = \frac{\text{Isotopic mass} - \text{mass no.}}{\text{mass no.}} \times 10^4$$

$$= \frac{97.906 - 98}{98} \times 10^4 = \frac{-0.094}{98}$$

$$= \mathbf{-9.5918} \qquad \textbf{Ans.}$$

(*ii*) In ${}^{98}_{42}\text{Mo}$, no. of protons = 42; no. of neutrons = 98 – 42 = 56.

Total mass of 42 protons + 56 neutrons = (42 × 1.007825 + 56 × 1.008665) a.m.u. = 42.32865 + 56.48524 = 98.81389 a.m.u.

Isotopic mass of

Mo = 97.906 a.m.u

∴ Mass defect,

$$\Delta m = 98.81389 - 97.906$$

$$= \mathbf{0.90789\ a.m.u.} \qquad \textbf{Ans.}$$

(*iii*) But 1 a.m.u. = 931 MeV. Hence :

Energy released = 0.90789 × 931 MeV

$$= 45.23559 \simeq 845.24\ \mathbf{MeV} \qquad \textbf{Ans.}$$

21.8 MASS DEFECT, Δm

Type. Energy released in a reaction = mC^2 *or* ΔmC^2 where Δm or m = mass consumed in a reaction.

= Sum of masses of reactant species – Sum of masses of product species.

C = Velocity of light = $3.0 \times 10^8\ ms^-$; m_u means a.m.u.

1 a.m.u. = 1.66×10^{-27} kg; J = kg m^2s^{-2}; 1 *e*V = 1.6×10^{-19} J; 1 MeV = 10^6 *e*V.

1 g = 2.15×10^{10} k cal.

Example 28. *Calculate the energy released (i) in Joules in the following nuclear reaction* ${}^{2}_{1}H + {}^{2}_{1}H \rightarrow {}^{3}_{2}He + {}^{1}_{0}n$. *(ii) in MeV in the following nuclear reaction:* ${}^{2}_{1}H + {}^{3}_{1}H \rightarrow {}^{4}_{2}He + {}^{1}_{0}n$

Given masses in amu of ${}^{2}_{1}H = 2.0141, {}^{3}_{2}He = 3.0160, {}^{1}_{0}n = 1.0087, {}^{3}_{1}H = 3.0160, {}^{4}_{2}He = 4.0026.$

(MLNR, 1997, Kerala-PET, 2005)

Solution. (*i*) Mass of ${}^{2}_{1}\text{H}$ = 2.0141 a.m.u., ${}^{3}_{2}\text{He}$ = 3.016 a.m.u. and ${}^{1}_{0}n$ = 1.0087 a.m.u. *Reaction* : ${}^{2}_{1}\text{H} + {}^{2}_{1}\text{H} \rightarrow {}^{3}_{2}\text{He} + {}^{1}_{0}n.$

Energy released = ΔmC^2 ...(1)

where, Δm = [masses of $({}^{2}_{1}\text{H} + {}^{2}_{1}\text{H})$] – [masses of $({}^{3}_{2}\text{He} + {}^{1}_{0}n)$]

= (2.0141 + 2.0141) – (3.016 + 1.0087)

= 4.0282 – 4.0247 = 3.5×10^{-3} a.m.u.

= $3.5 \times 10^{-3} \times 1.66 \times 10^{-27}$ kg

C = $3.0 \times 10^8\ ms^-$

[∵ 1 a.m.u. = 1.66×10^{-27} kg]

∴ Energy released = $\Delta mC^2 = 3.5 \times 10^{-3} \times 1.66 \times 10^{-27}\text{kg} \times (3.0 \times 10^8\ ms^-)^2$

= 5.229×10^{-13} kg m^2s^{-2} ≃ 5.2×10^{-3}J

[∵ J = kg m^2s^{-2}]

(*ii*) *Reaction* : ${}^{2}_{1}\text{H} + {}^{3}_{1}\text{H} \rightarrow {}^{4}_{2}\text{He} + {}^{1}_{0}n$.

Energy released = ΔmC^2 ; C = $3.0 \times 10^8\ ms^-$

Δm = [Masses of $[{}^{2}_{1}\text{H} + {}^{3}_{1}\text{He}]$

$- \left[\text{Masses of } \left({}^{4}_{2}\text{H} + {}^{1}_{0}n\right)\right]$

= (2.0141 + 3.0160) – (4.0026 + 1.0087)

= 5.0301 – 5.0113 = 0.0188 a.m.u.

= $0.0188 \times 1.66 \times 10^{-27}$kg

[∵ 1 a.m.u. = 1.66×10^{-27}kg]

∴ Energy released = $0.0188 \times 1.66 \times 10^{-27}\text{kg} \times (3.0 \times 10^8\ ms^-)^2$

= 2.81×10^{-12} kg m^2s^{-2} = 2.81×10^{-12} J

[∵ J = kg m^2s^{-2}]

$$= 2.81 \times 10^{-12}\text{J} \times \frac{1eV}{1.6 \times 10^{-19}\text{J}}$$

[∵ 1 *e*V = 1.6×10^{-19} J]

$$= 2.81 \times 10^{-12}\ \text{J} \times \frac{1eV}{1.6 \times 10^{-19}\text{J}} \times \frac{1\,\text{MeV}}{10^6 eV}$$

[∵ 1 MeV = 10^6 *e*V]

= 17.6 MeV.

Example 29. *Calculate the energy released in k.cal during the fission of one mol of* ${}^{239}_{94}Pu$ *as given below :*

$${}^{239}_{94}Pu + {}^{1}_{0}n \rightarrow {}^{146}_{58}Ce + {}^{90}_{38}Sr + 2\,{}^{0}_{-1}e + 4\,{}^{1}_{0}n.$$

Given. *Observed mass of different isotopes are* ${}^{239}_{94}\text{Pu}$ = *239.0006,* ${}^{146}_{58}\text{Ce}$ = *145.8865,* ${}^{90}_{38}\text{Sr}$ = *89.8864;* ${}^{0}_{-1}e$ = *0.000549,* ${}^{1}_{0}n$ = *1.00867.*

Solution. *Reaction* : ${}^{239}_{94}\text{Pu} + {}^{1}_{0}n \rightarrow {}^{146}_{58}\text{Ce} + {}^{90}_{38}\text{Sr} + 2\,{}^{0}_{-1}e + 4\,{}^{1}_{0}n.$

Energy released =

= ΔmC^2 ; C = $3.0 \times 10^8\text{ms}^-$

Δm = Masses of reactants – masses of products.

= (masses of ${}^{239}_{94}\text{Pu} + {}^{1}_{0}n$)

– (masses of ${}^{146}_{58}\text{Ce} + {}^{90}_{38}\text{Sr} + 2\,{}^{0}_{-1}e + 4\,{}^{1}_{0}n$)

= (239.0006 + 1.00867) – (145.8865 + 89.8864 + (2 × 0.000549 + 4 × 1.00867)

= 240.00927 – (145.8865 + 89.8864 + 0.001098 + 4.03468)

= 240.00927 – 239.80868 = 0.20059 g.

But 1g = 2.15×10^{10} k cal.

∴ Energy released = 0.20059 × 2.15×10^{10} = 4.31×10^9 k cal. **Ans.**

Example 30. *$^{235}_{92}$U on bombardment with neutrons liberated $^{98}_{42}$Mo and $^{136}_{54}$Xe. Write down the elementary particles released. Also, calculate the energy liberated in the reaction. Isotopic masses of ^{235}U, ^{98}Mo, ^{136}Xe, $^{0}_{-1}e$ and $^{1}_{0}n$ are 235.044, 97.906, 135.907, 0.005486 and 1.0086 a.m.u. respectively.*

Solution. *Reaction* :

$$\underbrace{^{235}_{92}\text{U}+^{1}_{0}n}_{\text{Reactants}} \rightarrow \underbrace{^{98}_{42}\text{Mo}+^{136}_{54}\text{Xe}+2\,^{1}_{0}n+4\,^{0}_{-1}e}_{\text{Products}}$$

∴ Elementary particles liberated are neutrons and electrons

Energy liberated = ($\Delta m \,.\, C^2$) **or** Δm a.m.u. *i.e.*, $\Delta m \times 931$ MeV (∵ 1 a.m.u. = 931 MeV).

$$\begin{aligned}\Delta m &= \text{(Mass of reactants)}\\ &- \text{(Mass of poducts) a.m.u.}\\ &= (235.044 + 1.0086) - [97.906 + 135.907\\ &\quad + 2\,(1.0086) + 4\,(0.005486)\text{ a.m.u.}\\ &= 236.0526 - (97.906 + 135.907 + 2.0172\\ &\quad + 0.021944)\\ &= 236.0526 - 235.852144\\ &= 0.200456 \text{ a.m.u.}\end{aligned}$$

Enegy released = Δm a.m.u. = 0.200456 × 931 MeV

[∵ 1 a.m.u. = 931 MeV]

= **186.62 MeV** **Ans.**

Example 31. *Calculate the nuclear binding energy of $^{4}_{2}$He. (Proton = 1.00813 a.m.u., neutron = 1.00898 a.m.u., atomic mass of He = 4.00387 a.mu., 1 a.m.u. = 931 MeV).*

(UP Board, 1989)

Solution. In $^{4}_{2}$He . (*i*) no. of protons = 2, (*ii*) no. of neutrons = 4 – 2 = 2.

∴ Mass of $^{4}_{2}$He = Mass of 2 protons + mass of 2 neutrons

= (2 × 1.00813) + (2 × 1.00898) a.m.u.

= 2.01626 + 2.01796 = 4.03422 a.m.u.

Atomic mass of

$^{4}_{2}$He = 4.00387 a.mu.

∴ Mass defect,

Δm = 4.03422 – 4.00387 = 0.03035 a.m.u.

∴ Binding energy

= 0.03035 × 931 MeV

(∵ 1 a.m.u. = 931 MeV)

= **28.26 MeV** **Ans.**

Example 32. *Calculate the energy released (in joules) in the fusion reaction per atom of helium formed ($^{2}_{1}H+^{3}_{1}H \rightarrow ^{4}_{2}He+^{1}_{0}n$) . Given $^{2}_{1}H$ = 2.014 a.m.u.; $^{3}_{1}H$ = 3.016 a.m.u; $^{4}_{2}He$ = 4.003 a.m.u; $^{1}_{0}n$ = 1.009 a.m.u.; 1 a.m.u. = 931.5 MeV ; 1 MeV = 1.622 × 10^{-13} J.* **(DSB, 2001, CBSE, 2003)**

Solution. *Reaction is* : $^{2}_{1}H+^{3}_{1}H \rightarrow ^{4}_{2}He+^{1}_{0}n.$

Mass of reactants = 2.014 + 3.016 = 5.030

Mass of products = 4.003 + 1.009 = 5.012.

Mass defect, Δm = 5.030 – 5.012 = 0.018 m_u

∴ Energy released = 931.5 Δm MeV

= 931.5 × 0.018 MeV.

But 1 MeV = 1.622 × 10^{-13}J. So, energy released = 931.5 × 0.018 × 1.622 × 10^{-13} = 2.72 × 10^{-12}J **Ans.**

Example 33. *Calculate the binding energy per nucleon for ^{12}C and ^{16}O and comment on their relative magnitudes. Masses of proton and neutron are 1.0078 and 1.0087 m_u (1m_u = 931 MeV).*

Solution. Mass of proton = 1.0078; mass of neutron = 1.0087.

(*i*) For $^{12}_{6}$C, protons = 6, neutrons = 12 – 6 = 6. So, mass of 6 protons = 6 × 1.0078 = 6.0468; mass of 6 neutrons = 6 × 1.0087 = 6.0522. Sum total of masses of 6 protons and 6 neutrons = 6.0468 + 6.0522 = 12.099. Hence mass defect, Δm = 12.099 – 12 = 0.099. Hence binding energy for 12 nucleons = 931 Δm MeV = 931 × 0.099 = 92.169. So, binding energy per nucleon = 92.169/12 = 7.68075 MeV **Ans.**

(*ii*) For $^{16}_{8}$O, protons = 8, neutrons = 16 – 8 = 8. So, mass of 8 protons = 8 × 1.0078 = 8.0624; mass of 8 neutrons = 8 × 1.0087 = 8.0696. Sum total of masses of 8 protons and 8 neutrons = 8.0624 + 8.0696 = 16.132. Hence mass defect, Δm = 16.132 – 16 = 0.132. Hence binding energy for 16 nucleons = 931 Δm MeV = 931 × 0.132 = 122.892. So, binding energy per nucleon = 122.892/16 = 7.68075 MeV **Ans.** Since binding energy per nucleon is the same, the relative stability of all the nucleides is also of same order.

Example 34. *Naturally occurring boron consists of two isotopes whose atomic weights are 10.01 and 11.01. The atomic weight of natural boron is 10.81. Calculate the percentage of each isotope in natural boron.* **(IIT, 1982, BIT, 1989, MLNR, 1994)**

Solution. Let %age of boron isotope with at.wt. 10.01 = x.

%age of boron isotope with at.wt. 11.01 = 100 – x

$$\text{But} \qquad \text{at. wt.} = \frac{(12.00\times x)+[13.00334\times(100-x)}{100}$$

∴ 10.81 × 100 = [10.01x + 1101 – 11.01x]; x = 20

∴%age of boron with

at.wt. 10.01 = 20% **Ans.**

%age of boron with

at.wt. 11.01 = 100 – 20 = 80% **Ans.**

21.9 K.E. AND VELOCITY OF PARTICLES

Type. To calculate the ***velocity of particles emitted***, firstly find kinetic energy of particles emitted by the relation :

K.E. of emitted particle = Disintegration energy – K.E. of product *i.e.*, K.E. retained by nucleus.

Now use, $\text{K.E.} = \frac{1}{2} m\text{V}^2$ or $\text{V} = \left(\frac{2\text{K.E}}{m}\right)^{1/2}$ where

$$m = \frac{\text{g. at. wt. of particle}}{6.023 \times 10^{23}}\text{g}$$

$$1\ \text{MeV} = 1.6 \times 10^{-6}\ \text{erg.}$$

Example 35. *The energy of alpha particle emitted by $^{218}_{84}Po$ (radio active isotope of Po) is 6.11 MeV. If the energy retained by the product nucleus is about 1.49% of the energy, what would be the velocity of the emitted alpha particle ?*

Solution. We know that :

K.E. of α-particle = Disintegration energy – K.E. of the product *i.e.,* K.E. retained by the nucleus.

$$= 6.11\ \text{MeV} - \left(\frac{6.11 \times 1.49}{100}\right)$$

$$\text{MeV} = 6.11\ \text{MeV} - 0.091\ \text{MeV} = 6.019\ \text{MeV}$$

$$= 6.019\,\text{MeV} \times \frac{1.6 \times 10^{-6}\text{erg}}{1\text{MeV}}$$

$$= 9.6 \times 10^{-6}\ \text{erg} = 9.6 \times 10^{-6}\ \text{g cm}^2 s^{-2}$$

$$(\because 1\ \text{erg} = \text{g cm}^2 s^{-2})$$

$$m = (\text{mass of } \alpha\text{-particle, } ^4_2\text{He})$$

$$= \frac{\text{at. wt. of He}}{\text{Avog. no.}} = \frac{4}{6.023 \times 10^{23}}$$

$$= 6.64\ 5\ 10^{-24}\ \text{g}$$

But $\text{K.E.} = \frac{1}{2} m\text{V}^2$

$$\therefore\ \text{V} = \left(\frac{2\text{K.E.}}{m}\right)^{1/2} = \left(\frac{2.96 \times 10^{-6}\text{g cm}^2\ \text{s}^{-2}}{6.64 \times 10^{-24}\text{g}}\right)^{1/2}$$

$$= (2.89 \times 10^{18}\ \text{cm}^2 s^{-2})^{1/2}$$

$$= 1.7 \times 10^9\ \text{cm}\ s^{-}\quad \textbf{Ans.}$$

Example 36. *With what velocity should an α-particle travel towards the nucleus of a copper atom so as to arrive at a distance of 10^{-13} metre from the nucleus of the copper atom ?* **(IIT, 1997)**

Solution. Mass of α-particle, $^4_2\text{He} = 4$ a.m.u. $= 4 \times 1.674 \times 10^{-27}$g. ($\because$ 1 a.m.u. $= 1.674 \times 10^{-27}$ g); charge on electron, $e = 1.6 \times 10^{-19}$ coulomb. Z for Cu = 29, $r = 10^{-13}$ metre; in $_2$He, e^-s = 2.

Kinetic energy of α-particle

$$= \frac{1}{2} m\text{V}^2 \qquad \text{...(1)}$$

Electrostatic energy

$$= \frac{\text{K(Ze)}(2e)}{r} \qquad \text{...(2)}$$

Equating (1) and (2), we get :

$$\frac{1}{2} m\text{V}^2 = \frac{\text{K(Ze)}(2e)}{r}; \text{V}^2 = \frac{2\text{K(Ze)}(2e)}{mr}$$

$$\therefore\quad V = \left[\frac{2\text{K(Ze)}(2e)}{mr}\right]^{1/2}$$

$$= \left[\frac{2 \times (9 \times 10^9)(29 \times 1.6 \times 10^{-19} \times 2 \times 1.6 \times 10^{-19}}{4 \times 1.674 \times 10^{-27} \times 10^{-13}}\right]^{1/2}$$

$$= \left(3.99 \times 10^{13}\right)^{1/2} = \left(3.99 \times 10^{13} \times \frac{10^{-1}}{10^{-1}}\right)^{1/2}$$

$$= (39.9 \times 1012)^{1/2}$$

$$= 6.32 \times 10^6\ \text{ms}^{-} \qquad \textbf{Ans.}$$

Example 37. *Helium has mass number 4 and atomic number 2. Calculate its binding energy and nuclear binding energy per nucleon. (neutron = 1.00893 a.m.u., proton = 1.00814 a.m.u., He = 4.0039 a.m.u., and mass of electron is negligible).*

(UP Board, 1981)

Solution. No. of protons = at. no. of He = 2; no. of neutrons = mass no. – no. of protons = 4 – 2 = 2; no. of electrons = no. of protons = 2. But mass of electrons is negligible.

∴ Total mass of 2 protons + 2 neutrons = (2 × 1.00814) + (2 × 1.00893) a.m.u.

$$= (2.01628 + 2.01786)\ \text{a.m.u.}$$

$$= 4.03414\ \text{a.m.u.}$$

Isotopic mass of

$$\text{He} = 4.0039\ \text{a.m.u.}$$

∴ Mass defect,

$$\Delta m = 4.03414 - 4.0039 = 0.03024\ \text{a.m.u.}$$

∴ Binding energy

$$= 0.03024 \times 931\ \text{MeV}$$

$$[\because 1\ \text{a.m.u.} = 931\ \text{MeV}]$$

$$\text{No. of nucleons} = \text{no. of protons} + \text{no. of neutrons}$$

$$= 2 + 2 = 4.$$

∴ Binding energy for nucleon

$$= \frac{\text{Binding energy}}{\text{no. of nucleons}}$$

$$= \frac{0.03024 \times 931\,\text{MeV}}{4}$$

$$= \mathbf{7.038\ MeV} \qquad \textbf{Ans.}$$

Example 38. *The spectrographic mass of isotope is 12.01112 a.m.u. If the mass of a proton = 1.00732 a.m.u. and that of neutron = 1.00865 a.m.u., what will be the binding energy per nucleon in MeV. How much energy will be released during the formation of one mol of $^{12}_{6}C$ atoms from protons and neutrons (1 MeV = 1.602 × 10^{-6} erg, 1 a.m.u. = 1.66 × 10^{-24}g).*

SOLUTION. No. of protons = 6, no. of neutrons = mass no. – no. of protons = 12 – 6= 6.

∴ Total mass of 6 protons + 6 neutrons

$$= (6 \times 1.00732) + (6 \times 1.00865)\ \text{a.m.u.}$$

$$= (6.04392 + 6.05190)\ \text{a.m.u.}$$

$$= 12.09582\ \text{a.m.u.}$$

Spectrographic mass of isotope

$$= 12.01112\ \text{a.m.u.}$$

∴ Mass defect,

$$\Delta m = 12.09582 - 12.01112 = 0.0847\ \text{a.m.u.}$$

$$= 0.0847 \times 1.66 \times 10^{-24}\ \text{g}$$

$$[\because 1 \text{ a.m.u.} = 1.66 \times 10^{-24}\text{g}]$$

$$\text{Binding energy} = \Delta m C^2 = 0.0847 \times 1.66 \times 10^{-24}\text{g} \times (3.0 \times 10^{10}\text{cms}^{-})^2$$

Total number of nucleons

$$= \text{no. of protons} + \text{no. of neutrons}$$

$$= 6 + 6 = 12.$$

∴ Binding energy per nucleon

$$= \frac{\text{Binding energy}}{\text{no. of nucleons}}$$

$$= \frac{0.0847 \times 1.66 \times 10^{-24}\text{g} \times 9 \times 10^{20}\text{cm}^2\text{s}^{-2}}{12}$$

$$= 1.05 \times 10^{-5} \text{ g cm}^2\text{s}^{-2} = 1.05 \times 10^{-5} \text{ erg}$$

$$[\because \text{erg} = \text{g cm}^2\text{s}^{-2}]$$

$$= \frac{1.05 \times 10^{-5}\text{erg}}{1.602 \times 10^{-6}\text{erg}}\text{MeV} = 6.55 \text{ MeV}$$

$$[\because 1 \text{ MeV} = 1.602 \times 10^{-6} \text{ erg}]$$

Now, energy released in the formation of per atom = mass no. of C × binding energy per nucleon. = 12 × 6.55 MeV = 78.60 MeV

Hence energy released in the formation of per mol

$$= 78.6 \times 6.023 \times 10^{23} \text{ MeV}$$

$$(\because 1 \text{ mol} = 6.023 \times 10^{23})$$

$$= \mathbf{4.73 \times 10^{25} \text{ MeV}}$$ **Ans.**

21.10 RADIOACTIVITY AND ITS UNITS

Radioactivity. The phenomenon of spontaneous emission of some invisible radiations by elements like uranium is called ***radioactivity***. The elements which emit such radiations are called ***radioactive elements***. It can be natural or artificial radioactivity.

Units of radioactivity :

(*i*) ***Becqueral (Bq).*** It is SI unit of radioactivity. It is defined as the quantity of any radioactive substance which gives one disintegration per second (*dps* or *ds*⁻).

(*ii*) ***Rutherford (rd).*** It is the quantity of any radioactive substance which gives ***10⁶ dps.***

i.e., ***Rutherford (rd). 1 rd = 10⁶ dps***

Millirutherford (mrd). 1 mrd = 10³ dps Micro-rutherford (μrd). 1 μrd = 1 dps.

(*iii*) ***Curie (C or Ci).*** It is the quantity of any radioactive substance which gives 3.7 × 10¹⁰dps or which gives the measure of the rate of disintegration of one gram of radium.

∴ ***Curie (C or Ci) : 1C or Ci***

$$= 3.7 \times 10^{10} \text{ dps} = 3.7 \times 10^4\text{rd}$$

$$[\because 1 \text{ rd} = 10^6 \text{ dps}]$$

$$= 2.22 \times 10^{12} \text{ dpm}$$

(*i.e.,* disintegration per minute)

Millicurie (mc)

$$\mathbf{1mc} = 3.7 \times 10^7 \text{ dps} = 2.22 \times 10^9 \text{ dpm}$$

Microcurie

$$(\mu c) = 1\ \mu\text{c} = \frac{3.7 \times 10^{10}\text{dps}}{10^6\text{dps}} = 3.7 \times 10^4\text{dps}$$

Specific activity. It may be given in terms of :

(*i*) Curies per gram (cg⁻).

(*ii*) millicuries per milligram [mc (mg)⁻]

(*iii*) millicuries per mol (mc mol⁻)

(*iv*) disintegration per minute per millimol [dp min (m.mol)⁻]

(*v*) counts per minute per micromol [cpm (μ.mol)⁻]

Radioactive equilibrium. For A → B → C.

At equilibrium, rate of formation of B = rate of decay of B

$$\therefore \quad \lambda_1 N_1 = \lambda_2 N_2 \text{ or } \lambda_A N_A = \lambda_B N_B$$

21.11 ACTIVITY OR RATE OF DISINTEGRATION – HALF-LIFE PERIOD

Activity or rate of disintegration at time t, is given as:

$$\frac{-dN}{dt} = \lambda N$$

and rate of radioactive decay (λ) is given as

$$\lambda = \frac{2.303}{t}\log\frac{No}{N}$$

or

$$\lambda = \frac{2.303}{t}\log\frac{a}{a-x}.$$

where ***No or a*** = the number of atoms of radioactive substance taken initially and

N or (a – x) = number of atoms at any time, *t*. λ = Disintegration (or decay) constant.

This equation indicates radioactive decay constant (λ) which always follows ***first order kinetics.***

Unit of disintegration constant, λ = (time)⁻ like sec⁻, min⁻, hour⁻, year⁻ etc.

Half-life period, $t_{1/2}$ or $t_{0.5}$. The *time* required for the disintegration of one half of the original amount of the *radioactive* substance is called the half-life period.

$$t_{1/2} = \frac{\mathbf{0.693}}{\boldsymbol{\lambda}} \quad \textbf{or} \quad \lambda = \frac{0.693}{t_{1/2}}$$

> **Note.** If initial amount of radioactive substance = No or *a*, then :

(*i*) Amount of substance left after one half-life period

$$= \text{No} \times \left(\frac{1}{2}\right)^1.$$

(*ii*) Amount of substance left after two half life periods

$$= \frac{\text{No}}{4} = \text{No} \times \left(\frac{1}{2}\right)^2.$$

(*iii*) Amount of substance left after three half-life periods

$$= \frac{\text{No}}{8} = \text{No} \times \left(\frac{1}{2}\right)^3$$

Where *n* = number of half-lives.

Also, total time *= n × $t_{1/2}$ and*

Total amount used in half-lives

$$= \text{No} - \frac{\text{No}}{2''} = \text{No}\left(1 - \frac{1}{2''}\right) = \text{No}\left(\frac{2''-1}{2''}\right)$$

Average life period, $\tau = \frac{1}{\lambda}$ or $\frac{1}{k}$ where λ or *k* is decay constant.

$$\therefore \qquad \tau = \frac{t_{1/2}}{0.693} = \mathbf{1.44 \times half\text{-}life\ period.}$$

Type. To calculate number of particles emitted per second (activity) when half-life period $t_{1/2}$ is given, proceed as follows ;

(*i*) Firstly find λ from,

$$\lambda = \frac{0.693}{t_{1/2}}.$$

(*ii*) Number of particles emitted per second,

$$\frac{dN}{dt} = \lambda \text{No}.$$

$$\text{where No} = \frac{\text{Avogadro's number} \times \text{weight of sample}}{\text{Mass number of sample}}.$$

EXAMPLE 39. *$^{232}_{90}Th$ is an α-particle emitter with a half-life of 1.41 × 10^{10} years. Given a 0.25g sample of this thorium. How many α-particles will it emit per second ? (Avogadro number, N_A = 6.02 × 10^{23} mol^{-}).*

SOLUTION. Since the α-particles emitted per second are required, so $t_{1/2}$ is changed to seconds.

$$\therefore \qquad t_{1/2} = 1.41 \times 10^{10}\text{years} \times \frac{365 \text{ days}}{1 \text{ year}} \times \frac{24 \text{ hours}}{1 \text{ day}} \times \frac{60 \text{ min}}{1 \text{ hour}} \times \frac{60 \text{ sec.}}{1 \text{min.}}$$

$$\text{But} \qquad \lambda = \frac{0.693}{t_{1/2}},$$

$$\text{so} \qquad \lambda = \frac{0.693}{1.41 \times 10^{10} \times 365 \times 24 \times 60 \times 60s}$$

∴ No. of particles emitted per second

$$= \lambda \times \frac{\text{Avogadro no.} \times \text{wt. of sample}}{\text{Mass no. of sample}}$$

$$= \frac{0.693}{1.41 \times 10^{10} \times 365 \times 24 \times 60 \times 60 s} \times \frac{6.02 \times 10^{23}\text{mol}^{-} \times 0.25\text{g}}{232\text{g mol}^{-}}$$

$$= \mathbf{1011\ s^{-}} \qquad \textbf{Ans.}$$

EXAMPLE 40. *Calculate the number of disintegrations which 1 g of ^{226}Ra ($t_{1/2}$ = 1600 years) would undergo per second. What quantity of $^{24}_{11}Na$ (half-life = 15 hr) would undergo the same disintegrations per unit time ?*

SOLUTION. Mass number of radium = 226; no. of atoms in 226 g of Ra = 6.02 × 10^{23}. Hence (*i*) no. of atoms in 1 g Ra = (6.02 × 10^{23} × 1)/226. But λ = 0.693/$t_{1/2}$ = 0.693/1600 × 365 × 24 × 60 × 60 seconds. Hence no. of disintegrations per second = (0.693 × 6.02 × 10^{23} × 1/1600 × 365 × 24 × 60 × 60 = 3.658 × 10^{10} *dps* **Ans.**

(*ii*) no. of disintegrations per second (*dps*) = 3.658 × 10^{10} *dps*; no. of atoms present in 24g Na = 6.02 × 10^{23}. Hence no. of atoms (No) in *x* g of Na = 6.02 × 10^{23} × *x*)/24; λ = 0.693/$t_{1/2}$ = 0.693/15 hr = 0.693/15 × 60 × 60*s*. Hence no. of *dps* = λ × No **Or** 3.658 × 10^{10} = (0.693/15 × 60 × 60) × (6.02 × 10^{23} × *x*/24). Hence, *x* = (3.658 × 10^{10} × 24 × 15 × 60 × 60)/0.693 × 6.02 × 10^{23} = 1.136 × 10^{-7}g **Ans.**

EXAMPLE 41. *^{235}U gives 4770 dps mg^{-1}. Calculate its half life and disintegration constant (1 year = 3.15 × 10^7s).*

SOLUTION. Atoms disintegrating in unit time = λA = 4770/sec. ...(*i*)

$$\text{A = total number of atoms} = 1\text{mg} \times \frac{1\text{g}}{1000\,\text{mg}} \times \frac{1\text{mol}}{235\text{g}} \times \frac{6.02 \times 10^{23}\text{atoms}}{1\,\text{mol}} = 2.56 \times 10^{18}.$$

Substituting the value of A in (*i*), we get, λ = (4770/sec)/2.56 × 10^{18} = 1.86 × 10^{-15} sec^{-} = 1.86 × 10^{-15} sec^{-} × $\frac{60\,\text{sec}}{1\,\text{min}} \times \frac{60\,\text{min}}{1\,\text{hr}} \times \frac{24\,\text{hr}}{1\text{day}} \times \frac{365\,\text{day}}{1\text{year}}$ = 5.86 × 10^{-8} yr^{-} **Ans.** Also, half-life, $t_{1/2}$ = 0.693/λ. Substituting the value of λ, we get : $t_{1/2}$ = 0.693/(5.86 × 10^{-8} yr^{-}) = 11825938 yr ≈ 1.18 × 10^7 year.

EXAMPLE 42. *Half-life period of ^{90}Sr, a β-emitter, is 28 years. Find out the activity of a 1g sample of ^{90}Sr.* **(CBSE, 1999S)**

SOLUTION. Activity indicates no. of particles emitted per second or number of disintegrations per second (dps).

Since the disintegrations are required per second, so, $t_{1/2}$ is changed to seconds.

$$\therefore \qquad t_{1/2} = 28\,\text{years} \times \frac{365\,\text{days}}{1\text{year}} \times \frac{24\,\text{hr}}{1\text{day}} \times \frac{60\,\text{min}}{1\,\text{hr}} \times \frac{60\,\text{s}}{1\text{min}}$$

$$\text{But,} \qquad \lambda = \frac{0.693}{t_{1/2}}.$$

$$\text{So,} \qquad \lambda = \frac{0.693}{28 \times 365 \times 24 \times 60 \times 60s}$$

∴ Activity (or no. of disintegrations per second)

$$= \lambda \times \frac{\text{Avogadro no.} \times \text{wt. of sample}}{\text{Mass no. of sample}}$$

$$= \frac{0.693}{28 \times 365 \times 24 \times 60 \times 60s} \times \frac{6.02 \times 10^{23}\text{mol}^{-} \times 1\text{g}}{90\,\text{g mol}^{-}}$$

$$= \mathbf{5.25 \times 1012\ dps} \qquad \textbf{Ans.}$$

EXAMPLE 43. *The half-life of a radioactive isotope is 10 hours. How many atoms of this isotope will be left after 4 hours if initially 1 g mole of the radioactive isotope was taken?*

(ISC, 2007)

SOLUTION. (*a*) $t_{1/2} = 10$ hours; $a = 1$ g mol; $a - x = ?$

$$\text{We know} \quad t_{1/2} = \frac{0.693}{\lambda};\ \lambda = \frac{0.693}{t_{1/2}} = \frac{0.693}{10\text{ hr}}$$

$$= 0.0693\text{ hr}^{-}$$

(*b*)
$$t = \frac{2.303}{\lambda}\log\frac{a}{a-x};$$

$$4\text{ hr} = \frac{2.303}{0.0693\text{ hr}^{-}}\log\frac{1}{a-x}$$

$$\therefore \quad \log\frac{1}{a-x} = \frac{4 \times 0.0693}{2.303}$$

$$\log 1 - \log(a-x) = 0.1204;\ 0 - \log(a-x) = 0.1204$$

$$\therefore \quad \log(a-x) = -0.1204 = -1 + 1 - 0.1204 = \bar{1}.8796$$

Taking antilog of both sides, we get :

$$a - x = \text{antilog } \bar{1}.8796 = 7.578 \times 10^{-1}$$

$$= 0.7578 \text{ mol}$$

We know that:

$$1 \text{ mol atoms} = 6.02 \times 10^{23} \text{ atoms}$$

$$\therefore \quad 0.7578 \text{ mol} = 6.02 \times 10^{23} \times 0.7578$$

$$= \mathbf{4.56 \times 10^{23}\ atoms} \qquad \textbf{Ans.}$$

Type. (*i*)
$$\lambda = \frac{2.303}{t}\log\frac{a}{a-x} = \frac{2.303}{t}\log\frac{No}{N}$$

(*ii*) %age activity left behind after time, $t = a - x\%$ when $a = 100$. (or = N % when No = 100).

EXAMPLE 44. *The half-life of cobalt is 5.26 years. Calculate its percentage activity remaining after 4 years.*

SOLUTION. $t_{1/2} = 5.26$ years. But

$$\lambda = \frac{0.693}{t_{1/2}} \cdot So,\ \lambda = \frac{0.693}{5.26\text{ years}}$$

We know that,

$$\lambda = \frac{2.303}{t}\log\frac{a}{a-x} \qquad ...(1)$$

Here $t = 4$ years; $a = 100$; $a - x = ?$ Substituting the value in equation (1), we get :

$$\frac{0.693}{5.26\text{ years}} = \frac{2.303}{4\text{ years}}\log\frac{100}{a-x};$$

$$\log\frac{100}{a-x} = \frac{0.693 \times 4}{5.26 \times 2.303} = 0.229.$$

Or $\log 100 - \log(a-x)$

$$= 0.229;\ 2 - \log(a-x) = 0.229$$

$$\therefore \quad \log(a-x) = 2 - 0.229 = 1.771$$

$$\therefore \quad a - x = \text{antilog } 1.771 = 59$$

∴ %age activity left behind after 4 years = **59%** **Ans.**

Type. When activitiy of a radioactive substance becomes or reduced to y% of its original value, then : $a = 100$; $a - x = y$.

EXAMPLE 45. *The half-life period of a radioactive element is 1.4×10^{10} years. Calculate the time in which the activity of the element is reduced to or becomes 90% of its original value.*

(PSEB, 2000)

SOLUTION. $t_{1/2} = 1.4 \times 10^{10}$ years;

$a = 100$, $a - x = 90$; $t = ?$

(*i*)
$$\lambda = \frac{0.693}{t_{1/2}} = \frac{0.693}{1.4 \times 10^{10}\text{years}}$$

(*ii*)
$$t = \frac{2.303}{\lambda}\log\frac{a}{a-x}$$

$$= \frac{2.303 \times 1.4 \times 10^{10}\text{years}}{0.693}\log\frac{100}{90}$$

$$= \frac{2.303 \times 1.4 \times 10^{10}\text{years}}{0.693} \times 0.0458$$

$$\simeq \mathbf{2.13 \times 10^{9}\ years.}$$

$$\left[\because \log\frac{100}{90} = \log 100 - \log 90 = 2.0 - 1.9542 = 0.0458\right]$$

EXAMPLE 46 *The half-life period of a radioactive element is 27.96 days. Calculate the time taken by a given sample to reduce to 1/8th of its activity.* **(PSEB, 2000)**

SOLUTION. Hint. $a = 1$, $a - x = {}^{1}/_{8}$; 83.92 days **Ans.**

Type. When time is to be calculated for the activity of a known weight (w) to fall to y% then :

$$\text{No or} \qquad a = \text{wg; N or } a - x = \text{w} \times \frac{y}{100}\text{g.}$$

EXAMPLE 47. *Two microgram of phosphorus-32 was injected into a living system for a biological tracer studies. The half-life period of $^{32}_{15}P$ is 14.3 days. How long will it take the radioactivity to fall to 20%.*

SOLUTION. $t_{1/2} = 14.3$ days; $a = 2$ microgram; $a - x = 2$ microgram $\times \frac{20}{100} = 0.4$ microgram; $t = ?$

(*i*)
$$\lambda = \frac{0.693}{t_{1/2}} = \frac{0.693}{14.3\text{ days}}$$

(*ii*)
$$t = \frac{2.303}{\lambda}\log\frac{a}{a-x}$$

$$= \frac{2.303 \times 14.3\text{ days}}{0.693}\log\frac{2\text{ microgram}}{0.4\text{ microgram}}$$

$$t = \quad \text{or} \quad t = \mathbf{33.22\ days} \qquad \textbf{Ans.}$$

Type. Total time = $n \times t_{1/2}$ where n = number of half-lives *i.e.*, after n half-lives, the amount of substance left behind $= \text{No}\left(\frac{1}{2}\right)^{n}$ where No = initial amount of substance.

EXAMPLE 48. *Three quarters of Sr^{90}, a radioactive element, disappeared in 56 years. What is the half-life period of the radioactive decay ? What is the rate constant for the decay of strontium?*

(I.S.C., 1996)

SOLUTION.

Total time = 56 years; Three quarters of

$$Sr^{90} = \frac{3}{4} = 3 \times \left(\frac{1}{2}\right)^2 .$$

So, n = no. of half-lives, $t_{1/2} = 2$.

But, total time = $n \times t_{1/2}$; 56 years = $2 \times t_{1/2}$

$$\therefore \quad t_{1/2} = \frac{56}{2} = 28\,\text{years}$$

∴ Rate constant,

$$\lambda = \frac{0.693}{t_{1/2}} = \frac{0.693}{28\ \text{years}}$$

$$= \mathbf{0.02475\ yr^{-}} \qquad \textbf{Ans.}$$

EXAMPLE 49. *1.0 g of Sr – 90 was reduced to 0.953 g after two year. Calculate the half-life period of Sr – 90.*

(PSEB, 2006, ISC, 2009)

SOLUTION. Initial amount, a = 1.0 g ; Amount left after 2 years (= $a - x$) = 0.953 g. But :

$$\lambda = \frac{2.303}{t} \log \frac{a}{a - x}$$

$$= \frac{2.303}{2} \log \frac{1.0}{0.953} = \frac{2.303}{2} \log 1.0493$$

$$= \frac{2.303}{2} \times 0.0209 = 0.02406\ \text{yr}^{-}$$

$$\therefore \text{Half-life,}\ t_{1/2} = \frac{0.693}{\lambda} = \frac{0.693}{0.02406\ \text{yr}^{-}} = 28.80\ \text{years}$$

EXAMPLE 50. *The half-life of ${}_{53}I^{125}$ is 60 days. What percent of the original radioactivity would be present after 180 days ?*

(PSEB, 2006)

SOLUTION. Initial concentration,

$$a = 100; a - x \text{ or } 100 - x = ?\ t_{1/2} = 60\ \text{days.}$$

$$\lambda = \frac{0.693}{t_{1/2}} = \frac{0.693}{60\ \text{days}} = 0.01155\ (\text{days})^{-}$$

$$t = \frac{2.303}{\lambda} \log \frac{a}{a - x};$$

$$180\ \text{days} = \frac{2.303}{0.01155\,(\text{days})^{-}} \log \frac{100}{100 - x}$$

$$\therefore \quad \log \frac{100}{100 - x} = \frac{180\,\text{days} \times 0.01155\,(\text{days})^{-}}{2.303}$$

$\log 100 - \log (100 - x)$

$= 0.9027$ **Or** $2.0 - \log (100 - x)$

$= 0.9027$

$\log (100 - x) = 2 - 0.9027 = 1.0973$

$\therefore \quad 100 - x$ = antilog 1.0973 = 12.5

∴ %age of original radioactivity present after 180 days = **12.5%** **Ans.**

Second Method : $t_{1/2}$ = 60 days. Total time = 180 days.

∴ no. of half-lives

$$= \frac{\text{Total time}}{t_{1/2}} = \frac{180}{60} = 3$$

∴ %age of radioactivity left after 3 half-lives

$$= \frac{\text{No}}{2^n} = \frac{100}{2^3} = \frac{100}{8} = \mathbf{12.5\%} \qquad \textbf{Ans.}$$

Type. (*i*) If initial amount (w) of a radioactive substance is given along with the amount (w_1) of this substance after decay, then

Initial amount, a = w; Amount after decay, $w_1 = a - x$.

(*ii*) If initial amount of a radioactive substnace is not given but amount of the same substance left behind equal to 'y' times its initial amount is given, then : Initial amount, $a = 1$; $a - x = y \times 1 = y$.

EXAMPLE 51. *A radioactive substance decays at such a rate that after 46 days, only 0.25 of its original amount is left behind. Calculate the disintegration constant and half-life period.*

(PSEB, 2002)

SOLUTION. t = 46 days; $a = 1$; $a - x = 0.25 \times 1 = 0.25$; λ =?

$$(i) \qquad \lambda = \frac{2.303}{t} \log \frac{a}{a - x} = \frac{2.303}{46\,\text{days}}$$

$$\log \frac{1}{0.25} = \frac{2.303}{46\,\text{days}} \log 4$$

$$\lambda = \frac{2.303}{46\,\text{days}} \times 0.6020 = \mathbf{0.03\ day^{-}} \quad \textbf{Ans.}$$

$$(ii) \qquad t_{1/2} = \frac{0.693}{\lambda} = \frac{0.693}{0.03\,\text{day}^{-}} = \mathbf{23.1\ day}\ \textbf{Ans.}$$

EXAMPLE 52. *After an hour, the amount of a radioactive substance disintegrated was 15/16th of the original amount. What is the half-life of the radioactive substance ?*

(PSEB, 2002)

SOLUTION. Time, $t = 1\ \text{hr} = 1 \times 60 \times 60 = 3600s$; let initial concentration $a = 1$ and hence $x = 1 \times 15/16 = 15/16$. We know, $k = (2.303/t) \log a/a - x$. Substituting the values, we get $k = 2.303/3600) \log 1/1 - 15/16)$. Or $k = (2.303/3600) \times 1.2041 = 7.7029 \times 10^{-4}$. But half-life $t_{1/2} = 0.693/k$. Substituting the values, we get : $t_{1/2} = 0.693/(7.7029 \times 10^{-4}) = 899.7s$ $= 899.7/60 = 15$ min. **Ans.**

EXAMPLE 53. *A wood piece obtained from an archaeological source shows a ${}^{14}C$ activity which is 10% of the activity found in green wood. Calculate the age of the wood piece. ($t_{1/2}$ ${}^{14}C$ = 5770 years).*

SOLUTION. (*i*) $t_{1/2}$ = 5770 years. Thus $\lambda = \dfrac{0.693}{5770\,\text{yrs}}$ = 1.2× × 10^{-4} yr^{-}

$$(ii) \qquad t = \frac{2.303}{\lambda} \log \frac{a}{a - x} \qquad \ldots(1)$$

Here t = age of wood = ?; Initial activity, $a = a$ suppose.

$\therefore \quad a - x$ (= activity left behind)

$$= a \times \frac{10}{100} = 0.1a$$

Substituting the values in equation (1), we get:

$$t = \frac{2.303}{1.2 \times 10^{-4}\,\text{yr}^{-}} \log \frac{a}{0.1a}$$

$$= \frac{2.303}{1.2 \times 10^{-4}\,\text{yr}^{-}} \log 10$$

$$= \frac{2.303}{1.2 \times 10^{-4}\,\text{yr}^{-}} \times 1$$

t = **19191.7 years = age of wood** **Ans.**

Example 54. *A piece of charred bone found in the ruins of a village has the ^{14}C to ^{12}C ratio 0.72 times found in living organisms. Calculate the age of the bone piece. ($t_{1/2}$ for ^{14}C decay = 5.73×10^3 years).*

Solution. t = age of charred bone piece.

Initial concentration,

$$a = a \text{ (say)}$$

$\therefore$ $a - x = 0.72 \times a$; $t_{1/2} = 5.73 \times 10^3$ years

(*i*) $$\lambda = \frac{0.693}{t_{1/2}};\ \lambda = \frac{0.693}{5.73 \times 10^3\,\text{yrs}}$$

(*ii*) $$t = \frac{2.303}{\lambda} \log \frac{a}{a-x}$$

$$= \frac{2.303 \times 5.73 \times 10^3\,yrs}{0.693} \log \frac{a}{0.72a}$$

Or $$t = \frac{2.303 \times 5.73 \times 10^3\,\text{yrs} \times 0.1427}{0.693}$$

= **2717.3 years** **Ans.**

$$\because \left[\log \frac{a}{0.72a} = \log 1.3889 = 0.1427\right]$$

Example 55. *The bones of a prehistoric animal were found to have a $^{14}_{6}C$ activity of 1.53 dps (disintegrations per second) g^{-} carbon. How long ago did the animal live ? The current $^{14}_{6}C$ activity is 15.3 dps per gram of carbon. Half-life of $^{14}_{6}C$ is 5730 years.*

Solution. Initial activity, a = 15.3 dps g^{-}; $a - x$ = 1.53 dps g^{-}, $t_{1/2}$ = 5730 years.

(*i*) $$\lambda = \frac{0.693}{t_{1/2}} = \frac{0.693}{5730\,\text{years}}$$

(*ii*) $$t = \frac{2.303}{\lambda} \log \frac{a}{a-x} \quad \text{...(1)}$$

Substituting the values in (1), we get :

$$t = \frac{2.303 \times 5730\,\text{years}}{0.693} \log \frac{15.3\,\text{dps}\,g^{-}}{1.53\,\text{dps}\,g^{-}}$$

$$\because [\log \frac{15.3}{1.53} = \log 10 = 1]$$

$$\therefore \quad t = \frac{2.303 \times 5730\,\text{yrs}}{0.693} \times 1$$

= **1.9042×10^4 years** **Ans.**

Example 56. *One gram of carbon made from green wood gives 15.3 counts per minute whereas one gram of carbon derived from the wood of an Egyptian mummy case gives 9.4 counts per minute under the same conditions. How old is the wood of the mummy case ? ($t_{1/2}$ for ^{14}C = 5770 years).*

Solution. $t_{1/2}$ = 5770 years. We know, $k = 0.693/t_{1/2}$ = 0.693/5770 yr. = 1.2×10^{-4} yr. Also, $\log No/N_t = kt/2.303$. Substituting the values we get, $\log \frac{15.3}{9.4} = \frac{kt}{2.303}$

or $t = \frac{2.303}{k}\left(\log \frac{15.3}{9.4}\right)$. Substituting the values, we get :

$\therefore$ $t = [2.303\,(1.1846 - 0.9731]/1.2 \times 10^{-4}$

Or $t = (2.303 \times 0.2115)/1.2 \times 10^{-4}$

= 4059 yrs. **Ans.**

Example 57. *What should be the age of fossil for meaningful determination of its age ?*

(a) 6 years, (b) 6000 years, (c) 60,000 years, (d) it can be used to calculate any age. **(IIT-JEE, 2006)**

Solution. Radio carbon-dating method ceases to be accurate over periods longer than 30,000 years. So, the correct answer is (*b*).

Example 58. *A sample of a rock contains 0.02 g of Pb-206 for every gram of U-238 present in it. Calculate the age of the rock if half-life of U-238 is 4.5×10^9 years.*

Solution. Wt. of Pb-206 = 0.02 g for every 1g of U-238 present in it.

Let wt. of U-238 present originally = a

$\therefore$ a = [wt. of U-238 present now *i.e.*, at the time of analysis] + wt. of U-238 converted to Pb-206. = Pb-206. 1g + $\left(\frac{238}{206} \times 0.02\text{g}\right)$ = 1g + 0.023g = 1.023g

Also, $a - x$ = wt. of U-238 at the time of analysis = 1g;

$t_{1/2} = 4.5 \times 10^9$ years.

(*i*) $$\lambda = \frac{0.693}{t_{1/2}};\ \lambda = \frac{0.693}{4.5 \times 10^9\,\text{years}}$$

(*ii*) $$t = \frac{2.303}{\lambda} \log \frac{a}{a-x}$$

$$= \frac{2.303 \times 4.5 \times 10^9\,\text{yrs}}{0.693} \log \frac{1.023}{1}$$

$$t = \frac{2.303 \times 4.5 \times 10^9\,\text{yrs}}{0.693} \times 9.876 \times 10^{-3}$$

= **1.477×10^8 yrs** **Ans.**

Example 59. *A sample of uraninite was found on analysis to contain 0.214 g of lead for every gram of uranium. Assuming that all the lead resulted from the radio-active disintegration of* *the uranium since the geological formation of the uraninite and that all isotopes of uranium other than ^{238}U can be neglected, estimate the date when the mineral was formed in the earth's crust. The half life of ^{238}U is 4.5 × 10^9 years.*

Solution. Half-life, $t_{1/2} = 4.5 \times 10^9$ years; disintegration constant, $\lambda = 0.693/t_{1/2} = 0.693/4.5 \times 10^9$ years. Wt. of U-238 present at time of analysis = 1g; Wt. of U-238 present originally = wt. of U-238 present now + wt. of U-238 converted to Pb-206 = 1 + (238/206) × 0.214) = 1 + 0.2472 = 1.2472 g. Let time t is time in which 1.2472 g of U-238 reduced to 1g. Hence $t = (2.303/\lambda)$ [log $a/a - x$] = [2.303 × 4.5 × 10^9/0.693] [log 1.2472/1 = 0.09593].

$\therefore t = (2.303 \times 4.5 \times 10^9 \times 0.09593)/0.693 = 1434589545$ years ≈ 1.4 × 10^9 years **Ans.**

Example 60. *A sample of uranium contains 0.277 g of Pb-208 and 1.667 g of U-238. Calculate the age of sample assuming that all the lead had accumulated due to decay of uranium ($t_{1/2}$ for U-238 = 4.50 × 10^9 years).*

SOLUTION. Half-life, $t_{1/2} = 4.5 \times 10^9$ years; disintegration constant, $\lambda = 0.693/t_{1/2} = 0.693/4.5 \times 10^9$ yrs = 1.54×10^{-10} yr^{-}. Wt. of U-238 = $a - x$ = 1.667 g; wt. of U-238 (initially present) = wt. of U-238 present now + wt. of U-238 converted to Pb-208 = 1.667 + (238 × 0.277/208) = 1.667 + 0.3169 = 1.9839 g. We know that $t = (2.303/\lambda)$ log $a/a - x$. Substituting the values, we get $t = (2.303/1.54 \times 10^{-10}\ \text{yr}^{-})$ [log 1.9839/1.667 = log 1.9839 – log 1.667 = 0.2975 – 0.2219 = 0.0756] **Or** t = (2.303 × 0.0756)/1.54 × 10^{-10} yr^{-} = 1130563636 ≃ 1.13 × 10^9 years **Ans.**

21.12 AVERAGE LIFE

Type. *Average life,*

$$T = \frac{1}{\lambda} \text{ or } \frac{1}{k} = \frac{t_{1/2}}{0.693} = 1.44 \times t_{1/2}$$

Example 61. *The half life time of a radioactive element is 6930 days. Find its average life.*

Solution. Half-life $t_{1/2}$ = 6930 days. Let average life = T. We know, T = 1.44 × $t_{1/2}$ = 1.44 × 6930 = 9979.2 days **Ans.**

Type. When w g of a nucleide loses y% of its radioactivity, then :

$$a = wg;\ a - x = w - \left(w \times \frac{y}{100}\right) g$$

Example 62. *The average life of a radioactive nucleide is 100 hours. How long will it take 10 grams of the nucleide to lose 75% of its radioactivity.*

Solution. Average life, T = 100 hours. Time = t = ?; initial concentration a = 10g; $a - x$ = 10 – (75 × 10/100) = 2.5 g. We know, T = 1.44 × $t_{1/2}$. ∴ $t_{1/2}$ = 1.44/T = 1.44/100 hours = 1.44 × 10^{-2} hrs. But $k = 0.693/t_{1/2}$ = 0.693/1.44 × 10^{-2} = 48.125. But $k = (2.303/t)$ log $a/a - x$. **Or** 48.125 = $(2.303/t)$ (log 10/2.5 or log 4) = $(2.303/t)$ × 0.6020 **Or** t (2.303 × 0.6020)/48.125 = 0.0288 hr. **Ans.**

Type. When initial amount (w) or counts s^{-} (or min^{-}, hr^{-}) of a radioactive substance is given but the mass of substance left behind after given time, t, is to be found out, then :

(i) $a = w$ or count s^{-} or min^{-} or hr^{-} etc. (ii) $a - x$ = ?, (iii) λ *or* $k = \dfrac{2.303}{t} \log \dfrac{a}{a - x}$

Example 63. *The half life of strontium (90) is 28 years. If 2 micro grams of strontium (90) is absorbed by a newly born child, how much of it is left behind in the child (person) after (1) 28 years and (2) 84 years ?* **(IIT 1995 modified)**

Solution. Half-life, $t_{1/2}$ = 28 yrs; initial concentration, a = 2 μg; k = ? $a - x$ = ? Amount left behind after (i) 28 years = ? (ii) 84 years = ?. We know $k = 0.693/t_{1/2}$ = 0.693/28 = 0.02475 yr^{-}. We know, (i) $k = (2.303/t)$ log $a/a - x$. **Or** 0.02475 = (2.303/28) log 2/$a - x$ = (2.303/28) [log 2 – log ($a - x$)] **Or** (0.02457 × 28/2.303) = 0.3010 – log ($a - x$). 0.3009 – 0.3010 = – log ($a - x$) **Or** – 0.0001 = – log ($a - x$) **Or** $a - x$ = antilog of 0.0001 = 1μg = 1 × 10^{-6} g **Ans.** (ii) 0.02475 = (2.303/84) (log 2/$a - x$)] = (2.303/84) [0.3010 – log ($a - x$) or 0.9027 – 0.3010 = – log ($a - x$) **Or** 0.6017 = – log ($a - x$) **Or** log ($a - x$) = – 0.6017. Thus, $a - x$ = antilog – 0.6017 = 0.25 μ g = 0.25 × 10^{-6} g **Ans.**

Example 64. *β-particle emitter element (half-life period = 60.6 min) registers 2408 counts per second. Determine the counting rate after 1.5 hours ?*

Solution. Half-life, $t_{1/2}$ = 60.6 min. = 60.6 × 60 = 3636.0 seconds; time t = 1.5 hours = 1.5 × 60 × 60 = 5400 seconds. Number of counts per second = 2408. We know, k = 0.693/ $t_{1/2}$ = 0.693/3636. But 2.303 log $a/a - x = kt$ **Or** 2.303 log $\dfrac{2408}{a - x}$ = (0.693/3636) × 5400 or log 2408 – log ($a - x$) = 0.693/ (3636 × 2.303) × 5400 = 0.4469 **Or** 3.3816 – log ($a - x$) = 0.4469 – 3.3816 = – 2.9347 **Or** –log ($a - x$) = – 2.9347. Thus $a - x$ = antilog of 2.9347 = 860.3 counts **Ans.**

Example 65. *Starting with 1.0 g of the radioactive sample, 0.25 g of it left after 5 days. Calculate the amount left after one day.* **(CBSE, 1993)**

Solution. Initial concentration, a = 1.0g; $a - x$ = 0.25 g; time = 5 days. Wt. left after one day (time) = ? We know, $k = (2.303/t)$ log $a/a - x$ = (2.303/5) log 1/0.25 = (2.303/5) log 4 = (2.303/5) × 0.6020 = 0.2772. Using relation, $k = (2.303/t)$ log $a/a - x$, we have, 0.2772 = (2.303/1) log 1/$a - x$ **Or** 0.2772/2.303 = log 1 – log ($a - x$) **Or** 0.1203 = 0 – log ($a - x$) or log ($a - x$) = – 0.1203. Hence, $a - x$ = antilog – 0.1203 = 0.758 g **Ans.**

Example 66. *A radioactive substance has a half-life period of 30 days. Calculate (i) the radioactive disintegration constant (ii) the average life period (iii) the time taken by 3/4 of the original number of atoms to disintegrate and (iv) the time taken by 1/8 of the original number of atoms to remain unchanged.*

Solution. Half life $t_{1/2}$ = 30 days; radioactive disintegration constant, λ = ?; average life period, T = ?; time (t_1) taken by 3/4 of the original no. of atoms to disintegrate = ?; time (t_2) taken by 1/8 of the original no. of atoms to remain unchanged = ?. We know (i) $\lambda = 0.693/t_{1/2}$ = 0.693/30 days = 0.0231 day$^-$ **Ans.** (*ii*) T = 1.44 × $t_{1/2}$ = 1.44 × 30 days = 43.20 days. **Ans.** (*iii*) $\lambda = (2.303/t)$ [log 1/1-3/4 = log 4] **Or** 0.0231 = 2.303/t [0.6020]. ∴ t = (2.303 × 0.6020)/0.0231 = 60 days **Ans.** (*iv*) λ = 2.303/t [log 1/1/8 = log 8] **Or** 0.0231 = (2.303/t) [0.9030]. ∴ t = (2.303 × 0.9030)/0.0231 = 90 days **Ans.**

Type. When loss in weight (w_1) of a substance from a given weight (w) of that substance in a given time is given, then :

$$a = w\ ;\ a - x = w - w_1$$

EXAMPLE 67. *One gram of a radioactive substance loses 0.01 g in 50 seconds. Calculate its half-life and average life.*

SOLUTION. Initial amount, a = 1.0 g, $a - x$ = 1.0 – 0.01 = 0.99g; t = 50 sec. We know, $\lambda = (2.303/t)\log a/a - x$ = (2.303/50) [log 1/0.99 **Or** 100/99) = (2.303/50) [log 100 – log 99 = 2.0 – 1.9956 = 0.0044) = (2.303 × 0.0044)/50 = 2.026 × 10^{-4}. But $t_{1/2} = 0.693/\lambda$ = 0.693/2.026 × 10^{-4} = 3420 *s* **Ans.** But average life = 1.44 × $t_{1/2}$ = 1.44 × 3420 ≈ 4925*s* **Ans.**

Type. Activity $-\dfrac{dN}{dt} = \lambda N$; N = no. of atoms.

$\mu = 10^{-6}$; Ci = 3.7 × 10^{10} dps

Activity means no. of particles emitted per second or no. of disintegrations per second.

EXAMPLE 68. *The half-life of $^{100}_{43}Tc$, a β-emitter, is 16 seconds. How many atoms of $^{100}_{43}Tc$ are present in a sample with an activity of 0.200 μ Ci ? Also determine the mass of the sample.*

SOLUTION. Half-life $t_{1/2}$ = 16 sec; no. of atoms, N = ?; activity – dN/dt = 0.2 × 10^{-6} × 3.7 × 10^{10} *dps*. But $-dN/dt = \lambda N$. But $\lambda = 0.693/t_{1/2}$ = 0.693/16 = 0.04331. Substituting the values of $-dN/dt$ and λ, we get : 0.2 × 10^{-6} × 3.7 × 10^{10} = 0.04331 × N. Hence, N = (0.2 × 10^{-6} × 3.7 × 10^{10})/0.04331 = 1.71 × 10^5 atoms **Ans.** Also, 6.02 × 10^{23} atoms weigh = 100 g of $^{100}_{43}$Tc. So, 1.71 × 10^5 atoms would weigh = (100 × 1.71 × 10^5)/6.02 × 10^{23} = 2.8 × 10^{-17}g **Ans.**

EXAMPLE 69. *Na has a half-life period 14.8 hours. How much time will it take to lose 90% of its activity.* **(PSEB, 2000)**

SOLUTION. $t_{1/2}$ = 14.8 hr, a = 100;
$a - x$ = 100 – 90 = 10; t = ?

(*i*) $$\lambda = \frac{0.693}{t_{1/2}} = \frac{0.693}{14.8\text{ hr}}$$

(*ii*) $$t = \frac{2.303}{\lambda}\log\frac{a}{a-x}$$

$$= \frac{2.303 \times 14.8\text{ hr}}{0.693}\log\frac{100}{10}$$

$$= \frac{2.303 \times 14.8\text{ hr}}{0.693} \times 1$$

$$\left[\because \log\frac{100}{10} = \log 10 = 1\right]$$

t = **49.18 hr** **Ans.**

EXAMPLE 70. *The amount of ^{14}C content in a piece of wood is found to be 1/16 of the original amount. Calculate the age of the wood. ($t_{1/2}$ = 5770 years).*

SOLUTION. Half-life $t_{1/2}$ = 5770 yrs; age (t) of wood = ?; initial amount a = 1, $a - x$ = (1/16) × 1 = 1/16. We know, $\lambda = 0.693/t_{1/2}$ = 0.693/5770 yrs. = 1.2 × 10^{-4} yr. But, $t = (2.303/\lambda)$ [log 1/1/16 = log 16] = 1.2041 **Or** t = (2.303/1.2 × 10^{-4}) × 1.2041 = 23108 yrs. **Ans.**

EXAMPLE 71. *What is the age of a vegetation beverage whose tritium content is only 15% of level in living plants ? ($t_{1/2}$ for tritium = 12.3 years).*

SOLUTION. Half-life $t_{1/2}$ = 12.3 yrs; λ = ? age *i.e.*, time, t = ? initial concentration, a = 100; $a - x$ = 15. We know that : $\lambda = 0.693/t_{1/2}$ = 0.693/12.3 yrs. = 0.05634 yr$^-$. Also, $t = (2.303/\lambda)\log a/a - x$ **Or** t = (2.303/0.05634) log 100/15 = (2.303/0.05634) [log 100 – log 15 = 2.0 – 1.1761 = 0.8239) = 33.68 years. **Ans.**

EXAMPLE 72. *A freshly cut sample of a plant gives 20.4 counts per minute per gram. If it is assumed that counts are due to the presence of radioactive carbon (At. wt. 14) only, how many counts would it give after 100 years, if the half life period of ^{14}C is 5760 years ?*

SOLUTION. Half-life, $t_{1/2}$ = 5760 years; decay constant, $\lambda = 0.693/t_{1/2}$ = (0.693/5760 × 365 × 24 × 60 min). = 2.289 × 10^{-10} min$^-$; time, t = 100 years = 100 × 365 × 24 × 60 min; initial concentration, a = ? $a - x$ = 20.4 counts min$^-$g$^-$. We know, $t = (2.303/\lambda)$ [log a/20.4 = log a – log 20.4 = log a – 1.3096]. Substituting the values, we get : 100 × 365 × 24 × 60 min = 2.303/2.289 × 10^{-10} min [log a – 1.3096] **Or** log a – 1.3096 = 100 × 365 × 24 × 60 min. × 2.289 × 10^{-10}min$^-$/2.303. **Or** log a – 1.3096 = 0.00522 **Or** log a = 1.3096 + 0.00522 = 1.3148. Hence a = antilog 1.3148 = 20.6 **Ans.**

EXAMPLE 73. *The ratio of C-14 in an old wooden piece is 13% that of the atmosphere. Calculate the age of the wooden article ($t_{1/2}$ of ^{14}C is 5580 years).*

SOLUTION. Half-life $t_{1/2}$ = 5580 years; decay constant, λ = $0.693/t_{1/2}$ = 0.693/5580 years = 1.2419 × 10^{-4} years$^-$. Age of article, t = ? We know, $t = 2.303/\lambda$ [log 100/13 = log 100 – log 13 = 2.000 – 1.1139 = 0.8861). **Or** t = [2.303/1.2419 × 10^{-4} yr$^-$] × 0.8861 = 16432 yrs **Ans.**

EXAMPLE 74. *Equal amounts of two samples of carbon are burnt and the radioactivities of CO_2 formed were measured. The activities were 2100 and 1400 counts per week respectively. Find the age difference of the samples. In showing radioactivity, how does ^{14}C nucleus change ? [$t_{1/2}$ for ^{14}C = 5600 years].* **(WBJEE, 2004)**

SOLUTION. According to decay rate,

$$-\frac{dN}{dt} = \lambda N$$

$$\therefore \qquad -\frac{dN_1}{dt} = \lambda N_1 = 2100\text{ counts} \qquad ...(i)$$

$$-\frac{dN_2}{dt} = \lambda N_2 = 1400\text{ counts} \qquad ...(ii)$$

Dividing equation (*i*) by equation (*ii*), we have

$$\frac{2100}{1400} = \frac{N_1}{N_2} = \frac{N_0.e^{-\lambda t_1}}{N_0.e^{-\lambda t_2}} = \frac{e^{-\lambda t_1}}{e^{-\lambda t_2}} = e^{-\lambda t_1} + e^{\lambda t_2}$$

or $$\frac{3}{2} = e^{\lambda(t_2 - t_1)} \text{ or } \ln\frac{3}{2} = \lambda(t_2 - t_1)$$

or $$2.303 \log\frac{3}{2} = \frac{0.693}{t_{1/2}}(t_2 - t_1) \qquad \left[\because \lambda = \frac{0.693}{t_{1/2}}\right]$$

or $$2.303 \times 0.1761 = \frac{0.693}{5600\,\text{yrs}}(t_2 - t_1)$$

or $$(t_2 - t_1) = \frac{2.303 \times 0.1761 \times 5600\,\text{yrs}}{0.693}$$

$$= 3277 \text{ years}$$

Thus, the age difference in the two samples is 3277 years.

${}^{14}_{6}C$ is a β-emitter and gets transformed into ${}^{14}_{7}N$ by losing a β-particle.

$${}^{14}_{7}C \rightarrow {}^{14}_{7}N + {}^{0}_{-1}e$$

EXAMPLE 75. *The isotopes ^{238}U and ^{235}U occur in nature in the ratio 140 : 1. Assuming that at the time of earth formation, they were present in the equal ratio, make an estimation of the age of earth. The half-life period of ^{238}U and ^{235}U are 4.5 × 10^9 and 7.13 × 10^8 years respectively.* **(Roorkee, 1983)**

SOLUTION. In nature

$$\frac{N_U{}^{238}}{N_U{}^{235}} = \frac{140}{1} \text{ at } t = t$$

At the time of earth formation,

$$\frac{N_0{}^{238}}{N_0{}^{235}} = \frac{1}{1} \text{ at } t = 0$$

$$\therefore \quad \frac{N_0{}^{238}}{N_0{}^{235}} \times \frac{N_U{}^{235}}{N_U{}^{238}} = \frac{1}{140}$$

For $$U^{238}, \frac{N_0{}^{238}}{N_U{}^{238}} = e^{\lambda^{238}}$$

For $$U^{235}, \frac{N_0{}^{235}}{N_U{}^{235}} = e^{\lambda^{235}}$$

$$\therefore \quad \frac{N_0{}^{238}}{N_0{}^{235}} \times \frac{N_U{}^{235}}{N_U{}^{238}} = e^{(\lambda^{238} - \lambda^{235})t}$$

or $$= \frac{1}{140}\, e^{(\lambda^{238} - \lambda^{235})t}$$

or $$(\lambda^{238} - \lambda^{235})t = \log_e 1 - \log_e 140$$

or $$\left[\frac{0.693}{4.5 \times 10^9} - \frac{0.693}{7.13 \times 10^8}\right] \times t$$

$$= -\,2.303 \log_{10} 140 = -\,4.9425.$$

$$\therefore \quad t = 6.04 \times 10^9 \text{ years.}$$

EXAMPLE 76. *A sample of ^{238}U (half life = 4.5 × 10^9 years) ore is found to contain 23.8 g of ^{238}U and 20.6 g of ^{206}Pb. Calculate the age of the ore.* **(Roorkee, 1996)**

SOLUTION. ^{238}U decays according to the reaction :

$${}^{238}_{92}U \rightarrow {}^{206}_{82}Pb + 8\,{}^{4}_{2}He + 6\,{}^{0}_{-1}e$$

Thus one gram atoms of ^{238}U give one gram atoms of ^{206}Pb.

^{206}Pb present in the ore

$$= \frac{20.6}{206} = 0.1 \text{ gm atoms}$$

$$= {}^{238}U \text{ decayed.}$$

^{238}U present in the ore

$$= \frac{23.8}{238} = 0.1 \text{ g atom}$$

$$N = 0.1 \text{ g atom}$$

$$N_0 = \text{U present + U decayed}$$

$$= 0.1 + 0.1 = 0.2 \text{ g atom}$$

$$\lambda = \frac{0.693}{t_{0.5}} = \frac{0.693}{4.5 \times 10^9 \text{years}}$$

Now, $$t = \frac{2.303}{\lambda}\log\frac{N_0}{N}$$

$$= \frac{2.303 \times 4.5 \times 10^9}{0.693}\log\frac{0.2}{0.1}\text{years}$$

or $t = 4.5 \times 10^9$ years. **Ans.**

21.13 RADIOACTIVE DISINTEGRATION SERIES

The *spontaneous* series of changes, involving transformation of the parent radioactive element into non-radioactive end product is called radioactive disintegration series. For disintegration, series are summarised below :

				Value of n	
Series	*Name of series*	*Initial element*	*Last stable elements*	*Initial element*	*Final element*
4*n*	Thorium series	Thorium 232	Lead 208	58	52
4*n* + 1	Neptunium series	Plutonium 241	Bismuth 209	60	52
4*n* + 2	Uranium series	Uranium 238	Lead 206	59	51
4*n* + 3	Actinium series	Uranium 235	Lead 207	58	51

Location of disintegration series. Divide the mass number by 4 and find out the remainder. 4*n* + remainder gives the name of the series.

Type. To know the name of the disintegration series.

EXAMPLE 77. *Name the series to which (i) ^{226}Ra, (ii) ^{235}U, (iii) ^{209}Bi, (iv) ^{208}Pb belong.*

SOLUTION. (*i*) ^{226}Ra : $\frac{226}{4}$ = 56 + remainder, 2. So, it belongs to 4*n* + 2 series.

(*ii*) ^{235}U : $\frac{235}{4}$ = 58 + remainder, 3. So, it belongs to 4*n* + 3 series.

(*iii*) ^{209}Bi : $\frac{209}{4}$ = 52 + remainder, 1. So, it belongs to 4*n* + 1 series.

(*iv*) ^{208}Pb : $\frac{208}{4}$ = 52 + no remainder. So, it belongs to 4*n* series.

Type. Mass number of an element in a given disintegration series.

= 4 × *n* for element of 4*n* series.

= (4 × *n*) + 1 for element of (4*n* + 1) series.

= (4 × *n*) + 2 for element of (4*n* + 2) series.

= (4 × *n*) + 3 for element of (4*n* + 3) series.

EXAMPLE 78. *Find the mass number of an element in (i) 4n + 2 series having value of n equal to 59. (ii) 4n series having n = 52.*

SOLUTION. (*i*) 4*n* + 2 series, with *n* = 59.

∴ Mass number = 4*n* + 2 = 4 × 59 + 2 = 236 + 2 = 238 a.m.u. **Ans.**

(*ii*) 4*n* series, with

$n = 52$

∴Mass number = 4*n* = 4 × 52 = 208 a.m.u. **Ans.**

EXAMPLE 79. *A 2.4 × 10⁻⁵ g sample of radioactive,* $^{24}_{11}Na$ *disintegrates at the rate of 7.73 × 10¹² atoms per second. Calculate the half-life of* $^{24}_{11}Na$.

SOLUTION. Wt. of ^{24}Na = 2.4×10^{-5}g; at. wt. of ^{24}Na = 24.

∴ Atoms present in 2.4×10^{-5}g ^{24}Na

$$= \frac{2.4 \times 10^{-5}\ \text{g}}{\text{at. wt. of }^{24}\text{Na}} \times 6.02 \times 10^{23}$$

$$= \frac{2.4 \times 10^{-5}}{24} \times 6.02 \times 10^{23} = 6.02 \times 10^{17}$$

Atoms disintegrating per second

$= 7.73 \times 10^{12}$

∴ λ = Fraction of atoms which decay

$$= \frac{\text{Atoms disintegrating per second}}{\text{Atoms present}}$$

$$= \frac{7.73 \times 10^{12}}{6.02 \times 10^{17}}\ \text{s}^{-} = 1.28 \times 10^{-5}\text{s}^{-}$$

But $t_{1/2} = \frac{0.693}{\lambda}$;

$$t_{1/2} = \frac{0.693}{1.28 \times 10^{-5}} \simeq 5.4 \times 10^{4}\ \text{sec}.$$

$$= 5.4 \times 104\ \text{sec} \times \frac{1\,\text{min.}}{60\,\text{sec.}} \times \frac{1\,\text{hr}}{60\,\text{min.}}$$

$$\times \frac{1\,\text{day}}{24\,\text{hr}} \times \frac{1\,\text{yr}}{365\,\text{days}} = \mathbf{1.7 \times 10^{-3}\ year.}$$

EXAMPLE 80. *You have 0.1g atom of a radioactive isotope* $^{A}_{Z}X$ *(half-life = 5 days). How many number of atoms will decay during the eleventh day ?* **(Roorkee, 1988)**

SOLUTION. $t_{1/2}$ = 5 days. Hence,

$$\lambda = \frac{0.693}{t_{1/2}} = \frac{0.693}{5\ \text{days}} = 0.1$$

1g atom of isotope contain atoms

$= 6.023 \times 10^{23}$ atoms

∴ 0.1g atom of isotope contain atoms

$= 6.023 \times 10^{23} \times 0.1 = 6.023 \times 10^{22}$ atoms

Since $t_{1/2}$ = 5 days, so, the no. of atoms after 10 days

$$= \frac{6.023 \times 10^{22}}{2^{n} = 2^{2}} = 1.506 \times 10^{22}\ \text{atoms}$$

$$\left[\because\ n = \frac{10\ \text{days}}{5\ \text{days}} = 2 = \text{no. of half-lives}\right]$$

∴ No. of atoms (N) after 11 days

$= \text{No} \times e^{-\lambda t}$

Or $\frac{\text{No}}{\text{N}} = e^{\lambda t}$. Taking logs of both sides,

We get, $\log\frac{\text{No}}{\text{N}} = \frac{\lambda t}{2.303}$

∴ log No – log N

$$= \frac{\lambda t}{2.303}$$

log 6.023 × 10²² – log N

$$= \frac{0.1386\,\text{day}^{-} \times 11\,\text{days}}{2.303}$$

log 6.023 + log 10²² – log N

= 0.662

0.7798 + 22 – 0.662

= log N; log N = 22.1178

∴ N = antilog 22.1178 = 1.311×10^{22} atoms.

∴ No. of atoms that decay during eleventh day = (1.506×10^{22}) – (1.311×10^{22}) = 10^{22} (1.506 – 1.311) = **0.195×10^{22} atoms** **Ans.**

EXAMPLE 81. *During treatment in a hospital, a patient was injected with one microgram* $^{24}_{11}Na$. *Calculate the time in which* *its radioactivity would become 10% of the original atom ($t_{1/2}$ $^{24}_{11}$Na. = 14.8 hours).*

Solution. $t_{1/2}$ = 14.8 hours.

Hence, $$\lambda = \frac{0.693}{t_{1/2}} = \frac{0.693}{14.8\,\text{hrs}}$$

But $$t_{10\%} = \frac{2.303}{\lambda}\log\frac{\text{No}}{\text{N}}$$

$$t_{10\%} = \frac{2.303}{0.693/14.8\,\text{hr}}\log\frac{\text{M}}{\text{M}/10}$$

$$= \frac{2.303}{0.693/14.8\,\text{hr}}\log 10$$

$$\left[\because \text{M}\times\frac{10}{100} = \frac{\text{M}}{10}\right]$$

Or $$t_{10\%} = \frac{2.303\times 14.8\times 1}{0.693} = \mathbf{49.18\ hours}$$ **Ans.**

Example 82. *Calculate the time in which 75% of $^{95}_{36}Kr$ ($t_{1/2}$ = 10.6 year) would disintegrate.*

Solution. $t_{1/2}$ = 10.6 years.

Hence $$\lambda = \frac{0.693}{t_{1/2}} = \frac{0.693}{10.6\,\text{yrs}} = 0.06538\,\text{yr}^{-}$$

Here, No = 100. So, N = 100 – 75 = 25. We know that :

$$t = \frac{2.303}{\lambda}\log\frac{\text{No}}{\text{N}};$$

$$t = \frac{2.303}{0.06538\,\text{yr}^{-}}\log\frac{100}{25}\ i.e., 4$$

$$\therefore\quad t = \frac{2.303}{0.06538\,\text{yr}^{-}}\times 0.602$$

$$= \mathbf{212\ years}$$ **Ans.**

Example 83. *Calculate the number of curies of $^{239}_{93}Np$ ($t_{1/2}$ = 2.33 days) needed to produce 0.15 mg of $^{239}_{94}Pu$.*

Solution. $t_{1/2}$ = 2.33 days.

Hence $$\lambda = \frac{0.693}{2.33\,\text{days}}$$

$$= \frac{0.693}{2.33\,\text{days}}\times\frac{1\,\text{day}}{24\,\text{hr}}\times\frac{1\,\text{hr}}{60\,\text{min}}\times\frac{1\,\text{min}}{60\text{s}}$$

$$= 3.442\times 10^{-6}\,\text{s}^{-}$$

$$\text{wt. of }^{239}_{94}\text{Pu} = 0.15\text{ mg} = \frac{0.15}{1000}\text{g};$$

$$\text{g at.wt.of }^{239}_{94}\text{Pu} = 239\text{ g}$$

1 g atom of $^{239}_{94}$Pu (= 239 g) contain atoms

$$= 6.023\times 10^{23}.$$

$$\therefore\ \frac{0.15}{1000}\text{g of }^{239}_{94}\text{Pu contains atoms}$$

$$= \frac{6.023\times 10^{23}}{239}\times\frac{0.15}{1000} = 3.78\times 10^{17}\text{ atoms}$$

∴ In order to get 0.15 mg $^{239}_{94}$Pu, $^{239}_{93}$Np must disintegrate.

∴ Rate of disintegration

$$= \text{No. of atoms}\times\text{decay constant}$$

$$= 3.78\times 10^{17}\text{ atoms}\times 3.442\times 10^{-6}s^{-}$$

$$= 1.3\times 10^{12}\text{ atoms }s^{-}$$

One curie = 3.7×10^{10} disintegrations s^{-} (or *dps*)

∴ 3.7×10^{10} dps = 1 curie

$$1.3\times 10^{12}\text{ dps} = \frac{1.3\times 10^{12}}{3.7\times 10^{10}} = \mathbf{35.14\ curie}$$ **Ans.**

Type. To calculate the weight of a radioactive element left behind from a known weight and time when its half-life is given. Use the relation :

Number of half-lives '

$$n' = \frac{\text{Given time after which the sample left behind is required}}{\text{Half-life time}}$$

Wt. of sample left behind

$$= \text{Given weight (in g)}\times\left(\frac{1}{2}\right)^{n}$$

Example 84. *The half-life period of ^{60}Co is 5.2 years. Calculate the wt. of ^{60}Co left behind from a 8.0 g sample of it that will still be radioactive after 20.8 years.*

Solution. $t_{1/2}$ of ^{60}Co = 5.2 years. Wt. of sample = 8.0 g

Time after which ^{60}Co is to remain radioactive = 20.8 years.

∴Number of half-lives,

$$'n' = \frac{20.8}{5.2} = 4.$$

Wt. in gram of sample that will be left behind

$$= 8.0\times\left(\frac{1}{2}\right)^{4}$$

$$= 8\times 0.0625 = 0.5\text{ g}$$

Example 85. *The radioactivity of an element decreases to half its initial value in 5 hours; still how long it will take for the activity to become 1/8th of the initial activity ?* **(BIT, 1995)**

Solution. $t_{1/2}$ = 5 hours. Total time of disintegration =?

Let N = no. of nuclei of radioactive substance after time, *t*.

No = no. of nuclei of radioactive substance initially present

n = no. of half-lives

We know that :

$$N = No\left(\frac{1}{2}\right)^n ;$$

$$N = No \times \frac{1}{8} = \frac{No}{8} \text{ (Given).}$$

Hence, $\frac{No}{8} = No\left(\frac{1}{2}\right)^n ; \frac{1}{8} = \left(\frac{1}{2}\right)^n ; \left(\frac{1}{2}\right)^3 = \left(\frac{1}{2}\right)^n .$

Hence, $n = 3$

∴ Total time of disintegration

$= n \times t_{1/2} = 3 \times 5 \text{ hr} = \mathbf{15\ hr.}$ **Ans.**

EXAMPLE 86. *A radioactive isotope has a half-life of 50 days. What fraction of the material will be left after 100 days?* **(ISC, 1988)**

SOLUTION. $t_{1/2} = 50$ days.

Time after which material is to be left behind = 100 days.

∴No. of half-lives

$$= \frac{100\,\text{days}}{50\,\text{days}} = 2$$

∴ Amount left after 2 half-lives

$$= 1\left(\frac{1}{2}\right)^2 = \frac{1}{4} = \frac{1}{4} \times 100 = \mathbf{25\%}$$ **Ans.**

EXAMPLE 87. *What amount of radioactivity is left behind when one millicurie of radioactive element of half-life 14 days is stored for 42 days ?* **(ISC, 1989)**

SOLUTION. $t_{1/2} = 14$ days.

Time for which the radioactive element was stored = 42 days.

∴ No. of half-lives

$$= \frac{42\,\text{days}}{14\,\text{days}} = 3$$

Hence amount of radioactivity left behind

$$= 1 \times \left(\frac{1}{2}\right)^3 \text{ millicurie} = \frac{1}{8} \textbf{ millicurie}$$

Ans.

EXAMPLE 88. *One gram of* $^{198}_{79}Au$ ($t_{1/2}$ = *65 hours) decays by β-emission to produce stable mercury.*

(i) Write the nuclear reaction for the process.

(ii) How much mercury will be present after 260 hrs ? **(Roorkee, 1984)**

SOLUTION. (*i*) *Reaction* : $^{198}_{79}\text{Au} \rightarrow {}^{198}_{80}\text{Hg} + {}^{0}_{-1}\beta.$

(*ii*) $t_{1/2} = 65$ hrs.

Time after which mercury will be present = 260 hrs.

∴no. of half-lives

$$= \frac{260\,\text{hrs}}{65\,\text{hrs}} = 4.$$

Hence amount of gold that will be left after 260 hrs.

$$= 1 \times \left(\frac{1}{2}\right)^4 = \frac{1}{16}\text{g}$$

∴ Amount of

$$\text{Hg} = 1 - \frac{1}{16} = \frac{15}{16}\text{g}$$ **Ans.**

EXAMPLE 89. *The activity of a radioactive substance reduces to* $\frac{1}{16}$*th of its original value in one and a half hour. Find the value of decay constant of this substance.*

SOLUTION. We know that,

$$\frac{N}{No} = \left(\frac{1}{2}\right)^n$$

∴ $\frac{1}{16} = \left(\frac{1}{2}\right)^4 .\text{Hence}, n = 4$

Also, time $= n \times t_{1/2}$.

So, $t_{1/2} = \frac{\text{time}}{\text{n}} = \frac{1.5\text{ hr}}{4} \times \frac{60\text{ min.}}{1\text{ hr}} = 22.5\text{min.}$

∴ $t_{1/2} = 22.5$ min. But decay constant,

$$\lambda = \frac{0.693}{t_{1/2}}$$

∴ $\lambda = \frac{0.693}{22.5\,\text{min.}} = 0.0308\ \text{min}^{-}$

$= 3.08 \times 10^{-2}\ \text{min}^{-}$ **Ans.**

EXAMPLE 90. *A radioactive isotope has a half-life of 25 days starting with 4g of the isotope. What will be the mass remaining after 75 days ?* **(ISC, 1993)**

SOLUTION. $t_{1/2} = 25$ days.

Time after which the mass left is to be calculated

= 75 days.

∴no. of half-lives

$$= \frac{75\,\text{days}}{25\,\text{days}} = 3$$

∴ Mass remaining after 75 days

$$= 4\text{g} \times \left(\frac{1}{2}\right)^3 = 4 \times \frac{1}{8} = \mathbf{0.5g.}$$

EXAMPLE 91. *A certain radioisotope* $^{A}_{Z}X$ *(half-life 10 days) decays to give* $^{A-4}_{Z-2}Y$. *If 1.0g atom of* $^{A}_{Z}X$ *is kept in a sealed vessel, how much helium would accumulate in 20 days. Express the results in cm³ at STP and in g.* **(Roorkee, 1987)**

SOLUTION. $t_{1/2} = 10$ days.

Time for which helium has to be accumulated

= 20 days.

∴ no. of half-lives

$$= \frac{20\,\text{days}}{10\,\text{days}} = 2$$

∴ Wt. of radioisotope left after 20 days

$$= 1.0\text{g} \times \left(\frac{1}{2}\right)^2 = \frac{1}{4}\text{g}$$

∴ Helium produced

$$= 1-\frac{1}{4}=\frac{3}{4}\text{g atom.}$$

$$= \frac{3}{4}\times 4 = 3g \quad [\because \text{at.wt.of He}=4]$$

1 g. atom of helium occupy volume at STP = 22400 cm^3

∴ $\frac{3}{4}$ g atom of helium occupy volume at STP = 22400 cm^3 × $\frac{3}{4}$

$$= 16800 \text{ cm}^3 = \mathbf{1.68 \times 10^4 cm^3} \qquad \textbf{Ans.}$$

EXAMPLE 92. *A radioactive isotope of polonium,* $^{210}_{84}Po$ *decays by emitting α-particles to ultimately give* $^{206}_{82}Pb$ *(*$t_{1/2}$ *= 138.4 days). If 1.0g of this isotope is placed in a sealed graduated tube, calculate the volume of helium gas that will be collected is 44.4 days. Express the result in cm³ at N.T.P.*

SOLUTION. (*i*) $t_{1/2}$ = 138.4 days. Hence,

$$\lambda = \frac{0.693}{t_{1/2}} = \frac{0.693}{138.4\,\text{days}}$$

or $\lambda = 5.007 \times 10^{-3}$ day$^-$

wt. of Po^{210} = 1.0g

∴ No. of

$$\text{Po}^{210}\text{ atoms} = \frac{\text{wt. in g}}{\text{g at. wt. of Po}} \times 6.023 \times 10^{23}$$

$$= \frac{1.0\text{g} \times 6.023 \times 10^{23}}{210\text{g}}$$

$$= \mathbf{2.87 \times 10^{21}\ atoms\ g^- = No.}$$

No = 2.87 × 10^{21} atoms g$^-$;

N = ? t = 44.4 days

We know that :

$$\lambda = \frac{2.303}{t}\log\frac{\text{No}}{\text{N}};$$

$$5.007\times10^{-3}\,\text{day}^- = \frac{2.303}{44.4\,\text{days}}\log\frac{2.87\times10^{21}}{\text{N}}$$

$$\therefore \log\frac{2.87\times10^{21}}{\text{N}} = \frac{5.007\times10^{-3}\text{day}^-\times 44.4\,\text{days}}{2.303}$$

$$= 0.09653$$

Taking antilogs of both sides, we get :

$$\frac{2.87\times10^{21}}{\text{N}} = \text{antilog } 0.09563 = 1.2489$$

$$\therefore \quad \text{N} = \frac{2.87\times10^{21}}{1.2489} = \mathbf{2.29 \times 10^{21}\ atoms\ g^-}$$

Hence no. of atoms of helium formed = No – N = (2.87 × 10^{21}) – (2.29 × 10^{21}) = 0.58 ×10^{21} atoms g$^-$.

(*ii*) 6.023 × 10^{23} atoms of helium occupy volume = 22400 cm^3 at NTP.

∴ 0.58 × 10^{21} atoms of helium would occupy volume

$$= \frac{22400\,\text{cm}^3}{6.023\times10^{23}} \times 0.58 \times 10^{21}$$

$$= \mathbf{21.57\ cm^3} \qquad \textbf{Ans.}$$

Type. *To calculate value of Avogadro's constant when nuclear particles like α-particles are emitted from a radioactive substance.*

EXAMPLE 93. *A sample of the radioactive element, radium, disintegrated at an average rate of 2.24 × 10^{13} alpha particles per minute. Each alpha particle takes up 2 particles from the air and becomes a neutral He atom. After 420 days, the helium gas collected amounted to 0.5 mL measured at 27°C and 750 mm of mercury pressure. From the above data, calculate the value of Avogadro's constant.* **(ISC, 1991; MLNR, 1991)**

SOLUTION. (*i*) No. of α-particles emitted = 2.24 × 10^{13} min$^-$.

P$_1$ = 750 mm, V$_1$ = 0.5 mL, T$_1$ = 27 + 273 = 300 K. At NTP, P$_2$ = 760 mm, V$_2$ = ?, T$_2$ = 273K. Using gas equation, we have :

$$\frac{P_1V_1}{T_1} = \frac{P_2V_2}{T_2};$$

$$V_2 = \frac{P_1V_1}{T_1}\times\frac{T_2}{P_2}$$

$$= \frac{750\,\text{mm}\times0.5\,\text{mL}\times273\,\text{k}}{300\,\text{K}\times760\,\text{mm}} = 0.449\,\text{mL}$$

(*ii*) 22400 mL He = 1 mol.

$$\therefore\ 0.449\text{ mL He} = \frac{0.449\,\text{mL}}{22400\,\text{mL}}\text{ mol} = 2.0045\times10^{-5}\text{ mol}$$

(*iii*) In 420 days × $\frac{24\,\text{hrs}}{1\,\text{day}}\times\frac{60\,\text{min}}{1\,\text{hr}}$ He gas collected

= 2.0045 × 10^{-5} mol

In 1 minute, He gas collected

$$= \frac{2.0045\times10^{-5}\text{mol}}{420\times24\times60} = 3.3143\times10^{-11}\text{mol.}$$

(*iv*) 3.3143 × 10^{-11} mol

= 2.24 × 10^{13} α-particles

$$\therefore \qquad 1\text{ mol} = \frac{2.24\times10^{13}}{3.3143\times10^{-11}} = \mathbf{6.76\times10^{23}} \qquad \textbf{Ans.}$$

EXAMPLE 94. *Calculate the total radioactivity resulting from radioactive* $^{40}_{19}K$ *decay in a 60kg human body. Half-life of* ^{40}*K = 1.3 × 10^9 years. The human body contains about 0.35% potassium by weight while* ^{40}*K constitutes 0.012% of potassium in nature.*

SOLUTION. (*i*) Wt. of human body

= 60 kg = 60 × 10^{3}g

$$\therefore \qquad \text{Total }^{40}\text{K} = \frac{0.012}{100}\times\frac{0.35}{100}\times60\times10^3\,\text{g} = 0.0252\,\text{g.}$$

(*ii*) No. of ^{40}K atoms,

$$\text{'N'} = \frac{\text{wt. in g}}{\text{g. at. wt. of }^{40}\text{K}} \times 6.02 \times 10^{23}\text{atoms}$$

$$= \frac{0.0252\text{g}}{40\text{g}} \times 6.02 \times 10^{23}\text{atoms}$$

$$= 3.79 \times 10^{20} \text{ atoms}$$

$$(iii)\ \lambda = \frac{0.693}{t_{1/2}} = \frac{0.693}{1.3 \times 10^9\text{yr}} \times \frac{1\text{yr}}{365\text{days}} \times \frac{1\text{day}}{24\text{hr}} \times \frac{1\text{hr}}{60\text{min}} =$$

$$= 1.01 \times 10^{15} \text{ min.}$$

$$(iv) \qquad -\frac{dN}{dt} = N\lambda = 3.79 \times 10^{20} \text{ atoms} \times 1.01 \times 10^{-15} \text{ min}^-$$

$$= 3.82 \times 10^5 \text{ dpm.}$$

Example 95. $^{235}_{92}U$ *yields 4770 disintegrations per minute per mg. Calculate its decay constant (λ) and half-life period ($t_{0.5}$).*

Solution. g at. wt. of ^{235}U = 235 g mol$^-$, Avogadro's number = 6.023×10^{23} mol$^-$.

N [= No. of atoms (nuclei) of $^{235}_{92}$U]

$$= \frac{\text{wt. in g}}{\text{g at. wt. of }^{235}\text{U}} \times 6.023 \times 10^{23}\text{mol}^-$$

$$= \frac{10^{-3}\text{g} \times 6.023 \times 10^{23}\text{mol}^-}{235\,\text{g mol}^-}$$

$$= \frac{6.023 \times 10^{20}}{235}$$

Activity of sample = No. of disintegrations per second

$$= \frac{4770}{60\,\text{sec.}} \qquad [\because 1 \text{ min} = 60 \text{ sec.}]$$

Or $\quad -\frac{dN}{dt} = \frac{4770}{60}\text{s}^-$. But $-\frac{dN}{dt} = N\lambda$.

Hence, $\quad \lambda = -\frac{dN}{dt} \times \frac{1}{N}$

$$\therefore \qquad \lambda = \frac{4770}{60\,\text{s}} \times \frac{1}{N} = \frac{4770}{60\text{s}} \times \frac{60\text{s}}{1\,\text{min}}$$

$$\times \frac{60\,\text{min}}{1\,\text{hr}} \times \frac{24\,\text{hr}}{1\,\text{day}} \times \frac{365\,\text{days}}{1\,\text{year}} \times \frac{235}{6.023 \times 10^{20}}$$

$$= \mathbf{9.78 \times 10^{-10}\ yr^-} \qquad \textbf{Ans.}$$

Also, $\quad t_{1/2} = \frac{0.693}{\lambda};\ t_{1/2} = \frac{0.693}{9.78 \times 10^{-10}\text{yr}^-}$

$$= \mathbf{7.086 \times 10^8\ years} \qquad \textbf{Ans.}$$

Example 96. *Calculate the value of alpha activity in terms of disintegrations per minute of 10^{-4}g sample of ^{232}Th ($t_{1/2} = 1.39 \times 10^{10}$ years; 1 year = 3.15×10^7s).*

Solution. $\quad t_{1/2} = 1.39 \times 10^{10}$ year.

But $\quad \lambda = \frac{0.693}{t_{1/2}};\ \lambda = \frac{0.693}{1.39 \times 10^{10}\text{year}}$

Since 1 year = $3.15 \times 10^7 s$, so 1 year = $3.15 \times 10^7 s \times \frac{1\text{min}}{60 s}$

$$\therefore \qquad \lambda = \frac{0.693}{1.39 \times 10^{10}\text{yr}} \times \frac{1\text{yr}}{3.15 \times 10^7\text{s}} \times \frac{60\,\text{s}}{1\,\text{min}}$$

Also, N (= no. of atoms or nuclei in a given sample).

$$= \frac{\text{wt. in g}}{\text{g. at. wt. of }^{232}\text{Th}} \times 6.023 \times 10^{23}$$

×

$$= \frac{10^{-4}\text{g}}{232\,\text{g mol}^-} \times 6.023 \times 10^{23}\text{mol}^-$$

$$= \frac{6.023 \times 10^{19}}{232}$$

∴ Activity,

$$-\frac{dN}{dt} = \lambda N = \frac{0.693 \times 60\,\text{min}^-}{1.39 \times 10^{10} \times 3.15 \times 10^7} \times \frac{6.023 \times 10^{19}}{232}$$

$$= 24.65 \text{ disintegrations per minute}$$

Ans.

Example 97. *Find the value of mass (in g) and specific activity (Ci g$^-$) of radioactive isotope $^{40}_{19}K$ ($t_{1/2} = 1.3 \times 10^9$ years).*

Solution. $\quad t_{1/2} = 1.3 \times 10^9$ yr. We know that,

$$\lambda = \frac{0.693}{t_{1/2}} = \frac{0.693}{1.3 \times 10^9\text{yr}}$$

Or

$$\lambda = \frac{0.693}{1.3 \times 10^9\text{yr}} \times \frac{1\text{yr}}{365\text{days}} \times \frac{1\text{day}}{24\,\text{hr}}$$

$$\times \frac{1\text{hr}}{60\,\text{min}} \times \frac{1\text{min}}{60\,\text{s}} = 1.69 \times 10^{-17} s^-$$

But $\quad 1 \text{ Ci} = 3.7 \times 10^{10}$ dps

$$= -\frac{dN}{dt} \cdot \text{ We know that,}$$

$$-\frac{dN}{dt} = \lambda N;$$

$$N = -\frac{dN}{dt} \times \frac{1}{\lambda} = 3.7 \times 10^{10} \text{ dps} \times \frac{1}{1.69 \times 10^{-17} s^-}$$

$$= \mathbf{2.19 \times 10^{27}\ disintegrations.}$$

Mass no. of K = 40; Avogadro no. = 6.023×10^{23}.

∴ Mass of Ci *i.e.*, curie of

$$^{40}_{19}\text{K} = \frac{N \times \text{mass no.}}{\text{Avogadro no.}}$$

$$= \frac{2.19 \times 10^{27} \times 40}{6.023 \times 10^{23}} \simeq \mathbf{145,442\ g} \qquad \textbf{Ans.}$$

Hence specific activity

$$= \frac{1}{\text{mass of Ci of } {}^{40}_{19}\text{K}} = \frac{1}{145,442\text{g}}\text{Ci}$$

$$= \mathbf{6.87 \times 10^{-6}\ Ci\ g^{-}}$$ **Ans.**

Example 98. *Find the value of mass (in g) of 1 curie and one rd of ${}^{214}_{82}Pb$ (half-life =26.8 min).*

Solution. (*i*) Let wt. of ${}^{214}_{82}\text{Pb} = xg$; mass no. of Pb = 214.

∴ Total no. of atoms (N) in

$$xg \text{ of } {}^{214}_{82}\text{Pb} = \frac{\text{wt. in g}}{\text{g at. wt.}} \times 6.023 \times 10^{23}\text{atoms}$$

$$= \frac{x \times 6.023 \times 10^{23}}{214}\text{atoms}$$

(*ii*) $t_{1/2}$ = 26.8 min. Hence,

$$\lambda = \frac{0.693}{t_{1/2}} = \frac{0.693}{26.8\,\text{min}} \times \frac{1\,\text{min}}{60\,\text{s}}$$

Or $\lambda = 4.31 \times 10^{-4}s^{-}$. Here time is converted to seconds because according to definition of curie, 1 curie = 3.7×10^{10} disintegrations s^{-} (or dps). We know that,

$$-\frac{dN}{dt} = \lambda N;$$

$$-\frac{dN}{dt} = 4.31 \times 10^{-4}\text{s}^{-} \times \frac{x \times 6.023 \times 10^{23}}{214}$$

Or $$-\frac{dN}{dt} = 1.21 \times 10^{18}x \text{ dps.}$$

∴ 1 curie or 3.7×10^{10} dps

$$= 1.21 \times 10^{18}\ x \text{ dps.}$$

Or $$x = \frac{3.7 \times 10^{10}}{1.21 \times 10^{18}} = 3.06 \times 10^{-8}\text{ g}$$ **Ans.**

(*iii*) But 1 rd *i.e.*, rutherford = 10^6 dsp. Hence, 10^6dps = $1.21 \times 10^{18}x$ dps

∴ $$x = \frac{10^6}{1.21 \times 10^{18}}\text{g} = \mathbf{8.26 \times 10^{-23}\ g}$$ **Ans.**

Type. Concentration of radioactive substance in a solution

$$= \frac{\text{One m mol. in a given solution}}{\text{specific activity in mc (mol)}^{-} \times \text{Volume of solution in mL}}$$

$$= x \text{ m. mol (mL)}^{-} = x\text{M.}$$

Example 99. *A solution of ${}^{14}C$ (uniformally labelled) amino acid contains 1mc of this acid in 3.0 mL of solution. If specific activity of the above acid is 225 mc/m mol, calculate (i) concentration of labelled amino acid in the solution and*

(ii) activity of the solution in terms of CPM/mL at the counting efficiency of 75%.

Solution. (*a*) Given : 1 m. mol = 225 mc

$$\therefore \text{ no. of m. mol that correspond to 1 mc} = \frac{1\text{m.mol}}{225\,\text{mc}}$$

But 1 mc is dissolved in 3.0 mL. Hence :

$$\text{Concentration} = \frac{1\text{m.mol}}{225} \times \frac{1}{3\,\text{mL}}$$

$$= 1.48 \times 10^{-3}\text{m mol (mL)}^{-}$$

$$= 1.48 \times 10^{-3}\text{ M}$$ **Ans.**

(*b*) We know that,

$$1 \text{ mc} = 2.22 \times 10^9 \text{ DPM}$$

∴Total activity in

$$3 \text{ mL} = 2.22 \times 10^9 \text{ DPM} \times \frac{75}{100}$$

∴Total activity in

$$\text{one mL} = 2.22 \times 10^9 \text{ DPM} \times \frac{75}{100} \times \frac{1}{3\,\text{mL}}$$

$$= 5.55 \times 10^8$$

DPM (or CPM)/mL. **Ans.**

Example 100. *Consider an α-particle just in contact with a ${}^{238}_{92}U$ nucleus. Calculate the coulombic repulsion energy (i.e., the height of coulombic repulsion energy between ${}^{238}U$ and α-particle) assuming that the distance between them is equal to the sum of their radii.* **(MLNR, 1996)**

Solution. Radius of Nucleus = $1.3 \times 10^{-13} \times (A)^{1/3}$ where A is mass number

$$\text{Radius of U}^{238} = 1.3 \times 10^{-13}\,(238)^{1/3} = 8.06 \times 10^{-13}\text{ cm}$$

$$\text{Radius of He}^4 = 1.3 \times 10^{-13}\,(4)^{1/3} = 2.06 \times 10^{-13}\text{ cm}$$

∴ Total distance in between ^{238}U and α-nuclei

$$= 8.06 \times 10^{-13} + 2.06 \times 10^{-13}$$

$$= 10.12 \times 10^{-13}\text{ cm}$$

Coulombic repulsion energy

$$= \frac{q_1q_2}{r^2} = \frac{92 \times 4.8 \times 10^{-10} \times 2 \times 4.8 \times 10^{-10}}{(10.12 \times 10^{-13})^2}\text{erg}$$

$$= \frac{4239.36 \times 10^{-20}}{102.41 \times 10^{-26}}\text{erg} = 41.396 \times 10^6\text{erg}$$

$$= 41.396 \times 10^6 \times 6.242 \times 10^{11}\text{ eV}$$

$$= 41.396 \times 6.242 \times 10^{11}\text{ MeV}$$

$$= \mathbf{2.584 \times 10^{13}\ MeV}$$ **Ans.**

Type. To calculate average life T, use the relation,

$$T = \frac{1}{\lambda}\text{or}\frac{1}{k}\text{ where}$$

$$\lambda \text{ or } k = \frac{2.303}{t}\log\frac{a}{a-x} \text{ or } \frac{N}{No}$$

Also, average life,

$$T = 1.44 \times \text{half-life period.}$$

Example 101. *The disintegration concentration of 6.0 mol of radioactive substance was found to be 4.0 mol after 930 hours. Calculate its average life.*

Solution. We know that :

$$\lambda = \frac{2.303}{t}\log\frac{a}{a-x} \qquad \text{... (1).}$$

Where $a = 6.0$ mol; $x = 4.0$ mol; $a - x = 6.0 - 4.0 = 2.0$ mol; $t = 930$ hr. Thus, from relation (1), we have : $\lambda = \frac{2.303}{930\,\text{hr}}\log\frac{6}{2}$ *i.e.*, 3; $\lambda = \frac{2.303}{930\,\text{hr}} \times 0.4771$.

∴ Average life,

$$T = \frac{1}{\lambda} = \frac{1}{2.303 \times 0.4771} \times 930\text{ hr}$$

= 846.4 hr. **Ans.**

Example 102. *The half life of radioactive element is 6930 days. What is the average life of the element ?* **(ISC, 1983)**

Solution. Average life, T = 1.44 × half-life time = 1.44 × 6930 days = **9979.2 days** **Ans.**

Example 103. *The activity of a sample of* $^{35}_{16}S$ *falls to 25% of its initial value after 174.2 days. Calculate the average life as well as half-life of the given isotope of sulphur.*

Solution. (*i*) $a = 100, a - x = 25, t = 174.2$ days. We know that :

$$\lambda = \frac{2.303}{t}\log\frac{a}{a-x}$$

$$= \frac{2.303}{174.2\,\text{days}}\log\frac{100}{25}\ \textit{i.e.},\ 4$$

$$\lambda = \frac{2.303 \times 0.602}{174.2\,\text{days}} = 7.96 \times 10^{-3}\,(\text{days})$$

(*ii*) $$t_{1/2} = \frac{0.693}{\lambda} = \frac{0.693}{7.96 \times 10^{-3}(\text{days})^{-}}$$

$$= 87.06 \text{ dyas}$$

(*iii*) Average life,

$$T = \frac{1}{\lambda} = \frac{1}{7.96 \times 10^{-3}(\text{days})^{-}}$$

= 125.63 days **Ans.**

Example 104. *A radioactive sample on analysis gave the following results :*

(*i*) *In the beginning, its counting state is 23.7 alpha particles per minute.*

(*ii*) *After 5 minutes, its counting state is 13.5 α-particles per minute.*

Calculate the half-life as well as average life of the sample.

Solution. (*i*) $t = 5$ min., No = 23.7, N = 13.5. We know that :

$$\lambda = \frac{2.303}{t}\log\frac{\text{No}}{\text{N}};\ \lambda = \frac{2.303}{5\,\text{min}}\log\frac{23.7}{13.5}$$

$$\lambda = \frac{2.303}{5\,\text{min}}[\log 23.7 - \log 13.5]$$

$$= \frac{2.303}{5\,\text{min}}[1.3747 - 1.1303]$$

$$\lambda = \frac{2.303}{5\,\text{min}} \times 0.2444 = 0.1126\,\text{min}^{-}$$

(*ii*) Half-life, $t_{1/2} = \frac{0.693}{\lambda} = \frac{0.693}{0.1126\,\text{min}^{-}}$

= 6.15 min. **Ans.**

(*iii*) Average life,

$$T = \frac{1}{\lambda};\ T = \frac{1}{0.1126\,\text{min}^{-}}$$

= 8.88 min. **Ans.**

(Or T = 1.44 $t_{1/2}$ = 1.44 × 6.15 min = 8.86 min).

Example 105. *If half-life of 10 g of a radioactive isotope is 30 days, what would be the half-life of 1g of the sample ?* **(UP Board, 1989)**

Solution. We know that half-life period is independent of initial concentration of the radioactive substance for radioactive disintegration (first order reaction). So, the half-life of 1g sample = half-life of 10g sample = **30 days** **Ans.**

Example 106. *Radioactivity is a first order process. Radioactive carbon in wood sample decays with a half-life of 5770 years. What is the rate constant (in* year^{-}*) for the decay ? What fraction would remain after 11540 years ?* **(IIT, 1984)**

Solution. $t_{1/2}$ = 5770 years. We know that :

$$\text{Rate constant, } \lambda = \frac{0.693}{t_{1/2}} = \frac{0.693}{5770\,\text{yr}}$$

$= \mathbf{1.2 \times 10^{-4}\ yr^{-}}$ **Ans.**

No = 1 (say), N = ? t = 11540 yrs.

But, $$\lambda = \frac{2.303}{t}\log\frac{\text{No}}{\text{N}};$$

$$1.2 \times 10^{-4}\,\text{yr}^{-} = \frac{2.303}{11540\,\text{yr}}\log\frac{1}{\text{N}}$$

∴ $$\log\frac{1}{\text{N}} = \frac{1.2 \times 10^{-4}\,\text{yr}^{-} \times 11540\,\text{yr}}{2.303} = 0.6013$$

Taking antilog of both sides, we get : $\frac{1}{\text{N}}$ = antilog 0.6013; $\frac{1}{\text{N}} = 3.993$; $\text{N} = \frac{1}{3.993} = 0.25$

Hence, N = 0.25 × 100 = **25%**. So, the fraction that would remain after 11540 years = **25%** **Ans.**

Example 107. *Calculate the age of dead sea scrolls, the sample of carbon of which is decaying at the rate of 11.5 disintegrations* $\text{min}^{-}\text{g}^{-}$. *(*$t_{1/2}$ *for* ^{14}C *= 5760 yrs). The carbon obtained from living plants disintegrate at the rate of 15.3 disintegrations* $\text{min}^{-}\text{g}^{-}$.

Solution. $t_{1/2}$ = 5760 yrs; No = 15.3 disintegrations $\text{min}^{-}\text{g}^{-}$; N = 11.5 disintegrations $\text{min}^{-}\text{g}^{-}$. We know that :

$$\lambda = \frac{0.693}{t_{1/2}};\ \lambda = \frac{0.693}{5760\,\text{yrs}}$$

Also, $$t = \frac{2.303}{\lambda}\log\frac{\text{No}}{\text{N}};$$

$$t = \frac{2.303 \times 5760\,\text{yrs}}{0.693} \log \frac{15.3}{11.5}$$

$$\therefore \quad t = \frac{2.303 \times 5760\,\text{yrs}}{0.693} [\log 15.3 - \log 11.5]$$

$$= \frac{2.303 \times 5760\text{ yrs}}{0.693} [1.1847 - 1.0607]$$

$$= \frac{2.303 \times 5760\,\text{yrs} \times 0.124}{0.693}$$

$= 2373.58$ years **Ans.**

EXAMPLE 108. *$_{92}U^{238}$ by successive radioactive decay changes to $_{82}Pb^{206}$. A sample of uranium ore was analysed and found to contain 1.0g of U^{238} and 0.1g of Pb^{206}. Assuming that all the Pb^{206} had accumulated due to decay of U^{238}, find out the age of the ore (half-life of U^{238} = 4.5 × 10^9 years).* **(Roorkee, 1990)**

SOLUTION. (*i*) $t_{1/2} = 4.5 \times 10^9$ yrs. Hence

$$\lambda = \frac{0.693}{t_{1/2}} = \frac{0.693}{4.5 \times 10^9 \text{yrs}}$$

Or $\lambda = 1.54 \times 10^{-10} \text{yr}^{-}$

(*ii*) $206\text{g Pb}^{206} \equiv 238\text{g U}^{238}$.

$$0.1\text{g Pb}^{206} \equiv \frac{238}{206} \times 0.1\text{g U}^{238} \equiv 0.1155\text{g U}^{238}$$

Given weight of

$U^{238} = 1.0$ g.

∴ Total weight of

$U^{238} = 1.0 + 0.1155 =$ **1.1155 g**

∴ No = 1.1155g; N = 1 (say). Hence :

$$t = \frac{2.303}{\lambda} \log \frac{\text{No}}{\text{N}};$$

$$t = \frac{2.303}{1.54 \times 10^{-10} \text{yr}^{-}} \log \frac{1.1155}{1}$$

Or
$$t = \frac{2.303}{1.54 \times 10^{-10} \text{yr}^{-}} \times 0.04747$$

≃ 7.099 × 10 years = age of ore. Ans.

EXAMPLE 109. *Calculate the total energy emitted per second in watts by 15 mg of a β-emitter $^{141}_{58}Ce$ ($t_{1/2}$ = 31.11 days). The average energy of β-particles emitted by $^{141}_{58}Ce$ is 0.442 MeV.*

SOLUTION. We know that :

Rate of disintegration s^{-} = no. of β-particles emitted s^{-} = Decay constant (λ) × No. of atoms ...(1).

$$(i)\ \lambda = \frac{0.693}{t_{1/2}} = \frac{0.693}{31.11\text{day}} \times \frac{1\text{day}}{24\,\text{hr}} \times \frac{1\,\text{hr}}{60\,\text{min}} \times \frac{1\,\text{min}}{60\,s}$$

$= 2.58 \times 10^{-7}\, s^{-}$

(*ii*) wt. of sample

$$= 15\text{ mg} = \frac{15}{1000}\text{g} = 0.015\text{g}$$

∴No. of atoms in

$$0.015\text{ g } ^{141}_{58}\text{Ce} = \frac{\text{wt. in g}}{\text{g. at. wt.}} \times 6.023 \times 10^{23}$$

$$= \frac{0.015}{141\text{g}\,(\text{atom})^{-}} \times 6.023 \times 10^{23}$$

$= 6.4 \times 10^{19}$ atoms

Substituting the values of λ and no. of atoms in (1), we get : no. of β-particles = $2.58 \times 10^{-7} s^{-} \times 6.4 \times 10^{19}$ atoms $= 1.65 \times 10^{13}$. Hence total energy = 0.442 MeV × 1.65×10^{13} $= 7.293 \times 10^{12}$ MeV.

$$= 7.293 \times 10^{12}\text{MeV} \times \frac{1.6 \times 10^{-6}\text{erg}\, s^{-}}{1\,\text{MeV}}$$

$$\times \frac{1\,\text{watt}}{10^7\,\text{erg}\, s^{-}} \simeq \textbf{1.167 watt Ans.}$$

[∵ 1 MeV = 1.6×10^{-6} erg s^{-}; 1 Watt = 10^7 erg s^{-}].

EXAMPLE 110. *The half of ^{238}U decomposes to ^{206}Pb in 4.5 × 10^8 years. What will be the age of rock that contain equal masses of both ?* **(BIT, 1986)**

SOLUTION. Let *t* = age of earth; final wt. of U = w g.

(*i*) 206g Pb is obtained from

U = 238g

∴ w g Pb is obtained from

$$\text{U} = \frac{238}{206}\text{w}$$

∴ Initial wt. of U in the rock,

$$a = \text{w} + \frac{238\text{w}}{206} = \text{w}\left(1 + \frac{238}{206}\right) = \frac{444}{206}\text{w}$$

Hence, final wt. of

U, $(a - x) = \text{w}$

$(ii)\ \lambda = \dfrac{0.693}{t_{1/2}}$, $(iii)\ \lambda = \dfrac{2.303}{t} \log \dfrac{a}{a - x}\cdot$ From (*i*), (*ii*) and (*iii*), we have :

$$\frac{0.693}{4.5 \times 10^8 \text{yr}} = \frac{2.303}{t} \log \frac{\frac{444\,\text{w}}{206}}{\text{w}} \quad i.e., \ \frac{444}{206}$$

$$\therefore \quad t = \frac{2.303 \times 4.5 \times 10^8 \text{yr}}{0.693} [\log 444 - \log 206]$$

$$= \frac{2.303 \times 4.5 \times 10^8 \text{yr}}{0.693} [2.6474 - 2.3139]$$

$$= \frac{2.303 \times 4.5 \times 10^8 \times 0.3335\,\text{yr}}{0.693}$$

$= 4.98 \times 10^8$ yrs

∴ Age of rock = **4.98 × 10^8 years** **Ans.**

EXAMPLE 111. *The relative abundance of two isotopes of uranium $^{235}_{92}U$ and $^{238}_{92}U$ is 0.8% and 99.2% respectively. Calculate the age of the earth if their half-lives are respectively 7.1 × 10^8 years and 4.5 × 10^9 years.*

SOLUTION. For ^{235}U, decay constant,

$$\lambda_1 = \frac{0.693}{t_{1/2}} = \frac{0.693}{7.1\times10^{8}\text{yr}}$$

$$= 9.76 \times 10^{-10}\ \text{yr}^{-}$$

For ^{238}U, decay constant,

$$\lambda_2 = \frac{0.693}{4.5\times10^{9}\text{yr}} = 1.54\times10^{-10}\text{yr}^{-}$$

We know that :

$$(i)\quad \frac{N(^{238}U)}{N(^{235}U)} = \frac{99.2\%}{0.8\%}$$

$$(ii)\quad N(^{235}U) = No(^{235}U) \times e^{-\lambda_1 t};$$

$$N(^{238}U) = No(^{238}U) \times e^{-\lambda_2 t};$$

$$\therefore\quad \frac{N(^{238}U)}{N(^{235}U)} = \frac{No(^{238}U)\times e^{-\lambda_2 t}}{No(^{238}U)\times e^{-\lambda_1 t}};\ 124 = \frac{e^{-\lambda_2 t}}{e^{-\lambda_1 t}}$$

Taking logs of both sides, we get :

$$\log_e 124 = -\lambda_2 t - (-\lambda_1 t)\ i.e.,$$

$$\lambda_1 t = \lambda_2 t = t(\lambda_1 - \lambda_2).$$

$$\textbf{Or}\ 2.303 \log 124 = t\,(9.76 \times 10^{-10}) - (1.54 \times 10^{-10})t$$

$$= 10^{-10}t\,(8.22)$$

$$\textbf{Or}\ \frac{2.303\times2.0934}{8.22\times10^{-10}} = t\ ;\ t \simeq 5.86 \times 10^{9}\ \text{years}$$

$\therefore$ Age of earth = 5.86×10^9 years

EXAMPLE 112. *Half life of $^{238}U = 4.5 \times 10^9$ years. If ratio by weight of ^{206}Pb and ^{238}U in a uranium mineral is 0.32 : 1, what will be the age of the mineral ?*

SOLUTION. Given : $^{206}Pb : ^{238}U = 0.32 : 1$.

$$\therefore\ \text{Ratio by mol} = \frac{0.32}{206} : \frac{1}{238}\ \ i.e.,\ 1.55\times10^{-3} : 4.2\times10^{-3}$$

$$= \frac{1.55}{4.2} : \frac{4.2}{4.2}\ i.e.,\ 0.369 : 1$$

$\therefore$ No = g. atoms of ^{238}U originally present = 1 + 0.369 = 1.369; N = 1

$$\lambda = \frac{0.693}{t_{1/2}} = \frac{0.693}{4.5\times10^{9}\text{yr}} = 1.54\times10^{-10}\text{yr}^{-}$$

$$\text{But}\qquad t = \frac{2.303}{\lambda}\log\frac{No}{N};$$

$$t = \frac{2.303}{1.54\times10^{-10}\text{yr}^{-}}\log\frac{1.369}{1}$$

$$\therefore\qquad t = \frac{2.303}{1.54\times10^{-10}\text{yr}^{-}} \times 0.1364$$

$$\simeq 2.04 \times 10^{9}\ \text{yers}$$

EXAMPLE 113. *An old table of wood shows $^{14}_{6}C$ activity which is 80% of the activity found to-day. Find the age of the table. Half-life period of $^{14}_{6}C$ is 5770 years.*

(PSEB, 2007, CBSE, 2008, CBSE (D), 2012)

SOLUTION. $t_{1/2}$ = 5770 yr

$$\therefore\qquad \lambda = \frac{0.693}{t_{1/2}} = \frac{0.693}{5770\ \text{yr}} = 1.2\times10^{-4}\ \text{yr}^{-}$$

Let amount of ^{14}C present in wood to-day = *a*

$$\text{Amount of } ^{14}C \text{ present in old wood} = \frac{a\times80}{100} = 0.8\,a.$$

Let *t* = age of wood piece

$$\text{Then}\qquad t = \frac{2.303}{\lambda}\log\frac{a}{a-x}$$

$$= \frac{2.303}{1.2\times10^{-4}\text{yr}^{-}}\log\frac{a}{0.8\,a};$$

$$t = \frac{2.303}{1.2\times10^{-4}\text{yr}^{-}}\log\frac{10}{8}$$

$$t = \frac{2.303}{1.2\times10^{-4}\text{yr}^{-}}[\log 10 - \log 8];$$

$$t = \frac{2.303}{1.2\times10^{-4}\text{yr}^{-}}(1 - 0.903)$$

$$\text{or}\qquad t = \frac{2.303}{1.2\times10^{-4}\text{yr}^{-}} \times 0.097$$

= **1861.59 years** **Ans.**

EXAMPLE 114. *10 gram atoms of an α-active radio-isotope are disintegrating in a sealed container. In one hour, the helium gas collected at STP is 11.2 cm^3. Calculate the half-life of radio-isotope.* **(Roorkee, 1989)**

SOLUTION. 1 g atom of isotope contain atoms

$$= 6.023 \times 10^{23}$$

10 g atoms of isotope contain atoms

$$= 6.023 \times 10^{23} \times 10 = 6.023 \times 10^{24}$$

$\therefore$ No. of atoms,

$$N = 6.023 \times 10^{24} \qquad ...(1)$$

Also,22400 mL volume contain atoms

$$= 6.023 \times 10^{23}$$

11.2 mL volume contain atoms

$$= \frac{6.023\times10^{23}}{22400}\times11.2$$

$$= 3.01 \times 10^{20}\ \text{hr}^{-}$$

$$\therefore\qquad -\frac{dN}{dt}(= \text{no. of atoms}) = 3.01 \times 10^{20}\ \text{hr}^{-} \qquad ...(2)$$

$$\text{But}\qquad -\frac{dN}{dt} = \lambda N;\ 3.01 \times 10^{20} = \lambda \times 6.023 \times 10^{24}$$

$$\therefore\qquad \lambda = \frac{3.01\times10^{20}\text{hr}^{-}}{6.023\times10^{24}} = 4.998\times10^{-5}\text{hr}^{-}$$

$$\text{But}\qquad t_{1/2} = \frac{0.693}{\lambda} = \frac{0.693}{4.998\times10^{-5}\ \text{hr}^{-}}$$

$$= 13865.55\ \text{hr.}$$

$$\therefore \quad t_{1/2} = 13865.55 \text{ hr} \times \frac{1\text{day}}{24\text{hr}} \times \frac{1\text{hr}}{365\text{days}}$$

$\simeq$ **1.582825 years** **Ans.**

EXAMPLE 115. *Radon is an α-particle emitter. Calculate the amount of heat liberated by a curie of this element in (i) 45 minutes and (ii) its mean life. (Kinetic energy of one α-particle = 6.11 MeV and decay constant for radon = 2 × $10^{-6}s^{-}$).*

SOLUTION. (*i*) 1 curie = 3.7×10^{10} ds^{-}. Reaction : ${}_{86}Rn \rightarrow {}_{84}Po + {}_{2}He$; $\lambda = 2 \times 10^{-6}s^{-}$.

Rate of disintegration = λ No ;

$$\text{No} = \frac{\text{Rate of disintegration}}{\lambda}$$

$$\therefore \quad \text{No} = \frac{3.7 \times 10^{10}\text{ds}^{-}}{2 \times 10^{-6}\text{s}^{-}} = 1.85 \times 10^{16}$$

Let, N = Amount of Rn left after time,

t = 45 min.

$$\therefore \quad t = 45 \text{ min} \times \frac{60\text{s}}{1\text{min}} = 2700\text{ s}$$

But $$t = \frac{2.303}{\lambda}\log\frac{\text{No}}{\text{N}};$$

$$2700\text{s} = \frac{2.303}{2 \times 10^{-6}\text{s}^{-}}\log\frac{1.85 \times 10^{16}}{\text{N}}$$

$$\therefore \log\frac{1.85 \times 10^{16}}{\text{N}} = \frac{2700\text{s} \times 2 \times 10^{-6}\text{s}^{-}}{2.303}$$

$= 2.345 \times 10^{-3} = 0.002345$

log 1.85 + log 10^{16} – log N

= 0.002345; 0.2672 + 16 – log N = 0.002345

∴ log N = 16.2672 – 0.002345 = 16.2648

∴ **N** = antilog 16.2648 = 1.84×10^{16}

Hence number of α-particles formed (= no. of Rn atoms decay)

$= 1.85 \times 10^{16} - 1.84 \times 10^{16} = 0.01 \times 10^{16}$.

K.E. of one α-particle

= 6.11 MeV

∴K.E. of 0.01×10^{16} α-particles

$= 6.11 \text{ MeV} \times 0.01 \times 10^{16}$

$$\times \frac{10^{6}\text{eV}}{1\text{MeV}} \times \frac{1.602 \times 10^{-19}}{1\text{eV}}\text{J}$$

= 97.88 J **Ans.**

(*ii*) Mean life or average life period,

$$t = \frac{1}{\lambda}$$

Let, N = no. of Rn-atoms left after mean time, t.

But, $$t = \frac{2.303}{\lambda}\log\frac{\text{No}}{\text{N}};$$

$$\frac{1}{\lambda} = \frac{2.303}{\lambda}\log\frac{\text{No}}{\text{N}};$$

$$\log\frac{\text{No}}{\text{N}} = \frac{1}{2.303} = 0.4342$$

Or $\log\frac{1.85 \times 10^{16}}{\text{N}}$ = 0.4342; log 1.85 + log 1016 – log N

= 0.4342

0.2672 + 16 – log N

= 0.4342; log N

= 16.2672 – 0.4342 = 15.833

∴ N = antilog 15.833 = 6.81×10^{15}

$= 0.681 \times 10^{16}$

Hence no. of α-particles (= no. of Rn-atoms decay)

$= 1.85 \times 10^{16} - 0.68 \times 10^{16} = 1.169 \times 10^{16}$.

K.E. of one α-particle

= 6.11 MeV

∴K.E. of 1.169×10^{16} α-particles

$= 1.169 \times 10^{16} \times 6.11$ MeV

$$\times \frac{10^{6}\text{eV}}{1\text{MeV}} \times \frac{1.602 \times 10^{-19}\text{J}}{1\text{eV}}$$

= **11442.43 J** **Ans.**

EXAMPLE 116. *An experiment requires minimum beta activity produced at the rate of 346 beta particles per minute. The half-life period of ${}^{99}_{42}Mo$, which is a beta emitter is 66.6 hours. Find the minimum of ${}^{99}_{42}Mo$ required to carry out the experiment in 6.909 hours.* **(IIT, 1989)**

SOLUTION. Minimum Number of β-particles required = 346 min^{-1}.

Number of β-particles required to carry out the experiment in 6.909 hours or 6.909 × 60 min.

= 346 × 6.909 × 60

= 143430.84 = 143431 particles

∴ No. of moles of β-particles required

$$= \frac{143431}{6.023 \times 10^{23}} = 2.3814 \times 10^{-19}\text{mol}$$

$t_{1/2}$ = 66.6 hours

$$\lambda = \frac{0.693}{t_{1/2}} = \frac{0.693}{66.6} = 0.0104054\text{ hr}^{-1}$$

Also, $$\lambda = \frac{2.303}{t}\log\frac{a}{(a-x)}$$

$$\log\frac{a}{(a-x)} = \frac{\lambda t}{2.303} = \frac{0.0104054 \times 6.909}{2.303}$$

or $$\log\frac{a}{(a-x)} = 0.0312162$$

or $$\frac{a}{(a-x)} = 1.07452$$

[∵ antilog 0.0312162 = 1.07452]

Substituting, $x = 2.3814 \times 10^{-19}$

$$\frac{a}{(a - 2.3814 \times 10^{-19})} = 1.07452$$

$$a = 1.07452\,a - 1.07452 \times 2.3814 \times 10^{-19}$$

or $$0.07452\,a = 1.07452 \times 2.3814 \times 10^{-19}$$

$$a = \frac{1.07452 \times 2.3814 \times 10^{-19}}{0.07452}$$

$$= 3.4338 \times 10^{-18} \text{ mol}$$

Example 117. *Calculate the weight of* ^{14}C *(*$t_{1/2} = 5720$ *years) atoms which give* 3.70×10^7 *disintegrations per second.* **(Roorkee, 1986)**

Solution. $t_{1/2} = 5720$ years

$$= 5720 \times 365 \times 24 \times 60 \times 60\text{s}$$

$$\lambda = \frac{0.693}{t_{1/2}} = \frac{0.693}{5720 \times 365 \times 24 \times 60 \times 60\text{s}}$$

$$= 3.84 \times 10^{-12}\text{s}^{-}$$

Now, $$-\frac{dN}{dt} = \lambda N$$

If w is the weight of ^{14}C then

$$N = \frac{w}{14} \times 6.023 \times 10^{23} \text{ atoms}$$

∴ $$-\frac{dN}{dt} = \lambda . \frac{w}{14} \times 6.023 \times 10^{23}$$

or $$3.70 \times 10^7 = \frac{3.84 \times 10^{-12} \times w \times 6.023 \times 10^{23}}{14}$$

or $$w = \frac{3.70 \times 10^7 \times 14}{3.84 \times 6.023 \times 10^{11}} = 2.24 \times 10^{-4}\text{g}$$

Example 118. ^{64}Cu *(half-life = 12.8 h) decays by* β^- *emission (38%),* β^+ *emission (19%) and electron capture (43%). Write the decay products and calculate partial half-lives for each of the decay processes.* **(IIT, 2002)**

Solution. The nuclear reactions are as follows :

β^- emission : ${}^{64}_{29}Cu \rightarrow {}^{64}_{30}Zn + {}^{0}_{-1}\beta$

β^+ emission : ${}^{64}_{29}Cu \rightarrow {}^{64}_{28}Ni + {}^{0}_{1}\beta$

Electron capture : ${}^{64}_{29}Cu + {}^{0}_{-1}e \rightarrow {}^{64}_{28}Ni$

Overall disintegration constant,

$$\lambda = \frac{0.693}{t_{1/2}} = \frac{0.693}{12.8\,\text{h}} = 5.414 \times 10^{-2}\text{hr}^{-1}$$

If r_1, r_2 and r_3 are the respective rates of decay of Cu and r is the overall rate of decay of Cu, then $r = r_1 + r_2 + r_3$.

Or $$\lambda\,[Cu] = \lambda_1\,[Cu] + \lambda_2\,[Cu] + \lambda_3\,[Cu]$$

or $$\lambda = \lambda_1 + \lambda_2 + \lambda_3 \qquad ...(1)$$

Now it is given that

$$\frac{\lambda_1}{\lambda_3} = \frac{38}{43} = 0.884 \text{ and } \frac{\lambda_2}{\lambda_3} = \frac{19}{43} = 0.442$$

or $$\lambda_1 = 0.884\,\lambda_3 \text{ and } \lambda_2 = 0.442\,\lambda_3$$

Substituting these values in eq. (1), we have :

$$\lambda = 0.884\lambda_3 + 0.442\,\lambda_3 + \lambda_3 = 2.326\,\lambda_3$$

Hence, $$\lambda_3 = \frac{\lambda}{2.326} = \frac{5.414 \times 10^{-2}}{2.326}\text{hr}^{-1}$$

$$= 2.328 \times 10^{-2}\text{ hr}^{-1}$$

$$(t_{1/2})_3 = \frac{0.693}{\lambda_3} = \frac{0.693}{2.328 \times 10^{-2}}\text{hr} = 29.77 \text{ hour}$$

$$\lambda_1 = 0.884\,\lambda_3 = 0.884 \times 2.328 \times 10^{-2}\text{ hr}^{-1}$$

$$= 2.058 \times 10^{-2}\text{ hr}^{-1}$$

$$(t_{1/2})_1 = \frac{0.693}{\lambda_1} = \frac{0.693}{2.058 \times 10^{-2}\text{hr}^{-1}}$$

$$= 33.67 \text{ hour}$$

$$\lambda_2 = 0.442\,\lambda_3 = 0.442 \times 2.328 \times 10^{-2}\text{ hr}^{-1}$$

$$= 1.029 \times 10^{-2}\text{ hr}^{-1}$$

$$(t_{1/2})_2 = \frac{0.693}{\lambda_2} = \frac{0.693}{1.029 \times 10^{-2}\text{hr}^{-1}} = 67.35\,\text{hr}$$

Example 119. *An element X has a half-life of 30 days. Calculate the amount of element left after 90 days if you start with an amount of 0.25 g.* **(BCECE, 2000)**

Solution. The number of half-lives elapsed

$$(n) = \frac{T}{t_{1/2}} = \frac{90}{30} = 3$$

Now, $$N_t = N_0\left(\frac{1}{2}\right)^n = 0.25 \times \left(\frac{1}{2}\right)^3 = 0.031\text{g}$$

Hence, 0.031 g of element will be left after 90 days.

Example 120. *The nuclidic ratio* ${}^{3}_{1}H$ *to* ${}^{1}_{1}H$ *in a sample of water is* $8.0 \times 10^{-18} : 1$*. Tritium undergoes decay with a half-life period of 12.3 years. How many tritium atoms would 10.0 g of such a sample contain 40 years after the original sample is collected ?* **(IIT, 1992)**

Solution. Molecular mass of water = 18.

∴ 18 g of water contains 6.023×10^{23} molecules = $2 \times 6.023 \times 10^{23}$ atoms of hydrogen

10 g of water contains hydrogen atoms

$$= \frac{2 \times 6.023 \times 10^{23} \times 10}{18}\text{atoms}$$

$$= 6.692 \times 10^{23} \text{ atoms}$$

$${}^{1}_{1}H : {}^{3}_{1}H = 1 : 8 \times 10^{-18}$$

∴ Number of ${}^{3}_{1}H$ atoms in 10g of water

$$= 6.692 \times 10^{23} \times 8 \times 10^{-18} = 5.3537 \times 10^{6}$$

Half life of ${}^{3}_{1}H$ = 12.3 years

Time of decay = 40 years; $N = N_0\left(\frac{1}{2}\right)^n$

Where n is the number of half-lives elapsed

$$n = \frac{40}{12.3}$$

$$\begin{aligned} N &= (5.3537 \times 10^6)\,(0.5)^{40/12.3} \\ &= (5.3537 \times 10^6)\,(0.5)^{3.252} \\ \log N &= (\log 5.3537 + 6 \log 10 + 3.252 \log 0.5) \\ &= 0.7287 + 6.0 + 3.252\,(\overline{1}.6990) \\ &= 6.7287 - 3.252 \times 0.3010 \\ &\qquad [\because 1 - 0.6990 = 0.3010] \\ &= 6.7287 - 0.9788 = 5.7499 \\ N &= \text{Antilog}\,(5.7499) = \mathbf{5.622 \times 10^5}. \end{aligned}$$

Example 121. *In nature, a decay chain series starts with* $^{232}_{90}Th$ *and finally terminates at* $^{208}_{82}Pb$. *A thorium ore sample was found to contain* 8×10^{-5} *ml of helium at STP and* 5×10^{-7} *g of* ^{232}Th. *Find the age of the ore sample assuming the source of helium to be only due to the decay of* ^{232}Th. *Also assume complete retention of helium with the ore. (Half life of* $^{232}_{90}Th$ $= 1.39 \times 10^{10}$*y).* **(Roorkee, 1992)**

Solution. $\left[{}^{232}_{90}\text{Th} \rightarrow {}^{208}_{82}\text{Pb} + {}^{4}_{2}\text{He}\right]$

$$\begin{aligned} \text{Decrease in mass} &= 232 - 208 = 24 \\ \text{He gas obtained} &= 8 \times 10^{-5}\text{ ml;} \\ 22400 \text{ ml of He at STP} &= 1 \text{ mol} \\ 8 \times 10^{-5}\text{ ml of He at STP} &= \frac{1}{22400} \times 8 \times 10^{-5}\text{ mol} \\ &= 3.57 \times 10^{-9}\text{ mol} \end{aligned}$$

Since 1 mol of thorium gives 6 moles of helium, no. of thorium disintegrated

$$\begin{aligned} &= \frac{1}{22400} \times 10^{-9}\text{ mol} \\ &= 0.59 \times 10^{-9}\text{ mol} \end{aligned}$$

$\therefore$ Number of α-particles emitted by an atom of thorium $= \frac{24}{4} = 6.$

Number of moles of thorium present in the ore

$$\begin{aligned} &= \frac{5 \times 10^{-7}}{232}\text{ mol} \\ &= 2.155 \times 10^{-9}\text{ mol} \end{aligned}$$

Number of moles of thorium present initially = (2.155 + 0.59) × 10^{-9} = 2.745×10^{-9} mol

Half-life period for

$$\begin{aligned} {}^{232}_{90}\text{Th} &= 1.39 \times 10^{10}\text{ year} \\ \therefore \qquad \lambda &= \frac{0.693}{t_{1/2}} = \frac{0.693}{1.39 \times 10^{10}} \\ &= 0.4985 \times 10^{-10}\text{ year}^{-} \\ t &= \frac{2.303}{\lambda} \log \frac{a}{a - x} \\ \therefore \qquad t &= \frac{2.303}{0.4985 \times 10^{-10}\text{year}^{-1}} \log \frac{2.745 \times 10^{-9}}{2.155 \times 10^{-9}} \\ t &= \frac{2.303}{0.4985 \times 10^{-10}\text{year}^{-1}} \times 0.1051 \\ &= \mathbf{4.885 \times 10^9 \text{ year}} \end{aligned}$$

$\therefore$ Age of the ore is 4.885×10^9 years.

21.14 RADIOACTIVE EQUILIBRIUM

If two members *i.e.*, elements A and B are in equilibrium, then :

$$\frac{N_A}{N_B} = \frac{k_B}{k_A} = \frac{t_A}{t_B} \text{ where}$$

N_A and N_B are the number of atoms of elements A and B respectively; k_A and k_B are their respective disintegration constants while t_A and t_B are their respective half-lives.

Example 122. *At radioactive equilibrium, the ratio between the atoms of two radioactive elements A and B is* $1 : 3.1 \times 10^9$. *If the half-life period of element A is 6.45 years, calculate the half-life of B and decay constant of B.*

Solution. No. of atoms of A, $N_A = 1$, that of B = 3.1×10^9. $t_{1/2}$ of t_A is 6.45 yrs. $t_{1/2}$ of B, t_B = ?

(*i*) At radioactive equilibrium,

$$\frac{N_A}{N_B} = \frac{t_A}{t_B} \quad \therefore \quad \frac{1}{3.1 \times 10^9} = \frac{6.45\,\text{yrs}}{t_B}$$

$$\begin{aligned} t_B &= 6.45\text{ yrs} \times 3.1 \times 10^9\text{ yrs} \\ &= \mathbf{2 \times 10^{10}\text{ yrs.}} \end{aligned}$$ **Ans.**

(*ii*) $t = 2 \times 10^{10}$ yrs; λ_B = ?

Since $\lambda_B = \frac{0.693}{t_B}$, we have :

λ_B (= decay constant of B)

$$= \frac{0.693}{2 \times 10^{10}\text{yrs}} = 3.465 \times 10^{-11}\text{yr}^{-}$$ **Ans.**

Example 123. ^{227}Ac *has a half life of 21.8 years with respect to radioactive decay. The decay follows two parallel paths, one leading to* ^{227}Th *and one leading to* ^{223}Fr. *The percentage yield of these two daughter nuclides are 1.2% and 98.8% respectively. What is the rate constant, in year*$^{-1}$*, for each of the separate paths.* **(IIT, 1996)**

Solution. $\lambda_{Ac} = \frac{0.693}{t_{1/2}} = \frac{0.693}{21.8\,\text{year}}$

$$= 3.18 \times 10^{-2}\text{ year}^{-1}$$

Now, the overall rate constant for a set of parallel first order reactions is equal to the sum of the separate rate constants *i.e.*, $\lambda_{Ac} = \lambda_{Th} + \lambda_{Fr}$

Also the fraction yield of either process is equal to the ratio of the rate constant for that process to the overall rate constant *i.e.*,

9 $\qquad \frac{\lambda_{Th}}{\lambda_{Ac}}$ = fractional yield of Th

or $$\lambda_{Th} = 0.012 \times 3.18 \times 10^{-2}\ \text{year}^{-1} \quad \left[\because 1.2\% = \frac{1.2}{100} = 0.012\right]$$

$$= \mathbf{3.8 \times 10^{-4}\ year^{-1}}$$

and $$\frac{\lambda_{Fr}}{\lambda_{Ac}} = \text{fractional yield of Fr}$$

or $$\lambda_{Fr} = 0.988 \times 3.18 \times 10^{-2}\ \text{year}^{-1} \quad \left[\because 98.8\% = \frac{98.8}{100} = 0.988\right]$$

$$= \mathbf{3.14 \times 10^{-2}\ year^{-1}}.$$

21.15 AIEEE PATTERN EXAMPLES

EXAMPLE 124. *An element E has a half-life of 10 years. The time taken to reduce its activity to about 1/8 of its original value will be :*

(a) 80 years *(b) 1.25 years*
(c) 10 years *(d) 30 years.*

SOLUTION. $t_{1/2}$ = 10 years. We know that :

$$\frac{1}{8} = \left(\frac{1}{2}\right)^n;$$

$$\left(\frac{1}{2}\right)^3 = \left(\frac{1}{2}\right)^n$$

So, $n = 3$

∴ No. of half-lives gone through = 3

Hence time taken = 3 × 10 = 30 years. So, the correct answer is (*d*).

EXAMPLE 125. *Which one of the following is not a nuclear isomer or isomeric nuclei.*

(a) ^{80}Br *(*$t_{1/2}$ *= 4.4 hr) and* ^{80}Br *(*$t_{1/2}$ *= 18 min)*
(b) ^{69}Zn *(*$t_{1/2}$ *= 13.8 hr) and* ^{69}Zn *(*$t_{1/2}$ *= 57 min)*
(c) P^{3-} *and* S^{2-}
(d) ^{60}Co *(*$t_{1/2}$ *= x yrs) and* ^{60}Co *(*$t_{1/2}$ *= y yrs).*

SOLUTION. Nuclear isomers are the atoms with the same atomic number and same mass number but with different radioactive properties. Since isomers shown in (*a*), (*b*) and (*d*) have same atomic number among themselves and have different half-life period, so these are nuclear isomers between each other. P^{3-} and S^{2-} do not have the properties of nuclear isomers, so these are not nuclear isomers. Hence correct answer is (*c*).

EXAMPLE 126. *The isotopes of hydrogen are :*

(a) $^{35}_{17}Cl, ^{2}_{1}H$ *(b)* $^{3}_{1}H, ^{19}_{9}F$
(c) $^{2}_{1}H, ^{1}_{1}H$ *(d) none of these*

SOLUTION. ***Isotopes.*** Atoms of the same element having same atomic number but different mass number are called isotopes of that element. Here $^{2}_{1}H$ and $^{1}_{1}H$ have same atomic number (= 1) but different mass numbers, 2 and 1 respectively. So, the correct answer is (*c*).

EXAMPLE 127. *The isobars among the following are :*

(a) $^{35}_{17}Cl, ^{37}_{17}Cl$ *(b)* $^{65}_{30}Zn, ^{69}_{30}Zn$
(c) $^{3}_{1}H, ^{4}_{2}He$ *(d)* $^{40}_{19}K, ^{40}_{20}Ca$

SOLUTION. Atoms of different elements having same mass number but different atomic number are called isobars of each other. So, $^{40}_{19}K$ and $^{40}_{20}Ca$ are isobars because these have same mass number (= 40) but different atomic numbers 19 and 20 respectively. So, the correct answer is (*d*).

EXAMPLE 128. *The isotones among the following are :*

(a) $^{3}_{1}H, ^{7}_{3}Li$ *(b)* $^{30}_{14}Si, ^{32}_{16}S$
(c) $^{35}_{17}Cl, ^{80}_{35}Br$ *(d)* $^{4}_{2}He, ^{1}_{1}H$

SOLUTION. Atoms of different elements with the same number of neutrons but different mass numbers are called isotones.

$^{3}_{1}H$: no. of neutrons = 3 – 1 = 2; $^{7}_{3}Li$: no. of neutrons = 7 – 3 = 4.

$^{30}_{14}Si$: no. of neutrons = 30 – 14 = 16; $^{32}_{16}S$: no. of neutrons = 32 – 16 = 16

$^{35}_{17}Cl$: no. of neutrons = 35 – 17 = 18; $^{80}_{35}Br$: no. of neutrons = 80 – 35 = 45

$^{4}_{2}He$; no. of neutrons = 4 – 2 = 2; $^{1}_{1}H$: no. of neutrons = 1 – 1 = 0.

So, the correct answer is (*b*).

EXAMPLE 129. *Which of the following is not isodiapher ?*

(a) $^{39}_{19}K$ and $^{19}_{9}F$ *(b)* $^{65}_{29}Cu$ and $^{55}_{24}Cr$
(c) $^{235}_{92}U$ and $^{231}_{90}Th$ *(d)* $^{1}_{1}H$ and $^{4}_{2}He$

SOLUTION. Atoms having same isotopic number are called *isodiaphers. Isotopic number* (isotopic excess) = N – Z or A – 2Z where A, N and Z are the mass number, neutrons and atomic number respectively.

$^{39}_{19}K$: N = 39 – 19 = 20; Z = 19. So, N – Z = 20 – 19 = 1

$^{19}_{9}F$: N = 19 – 9 = 10; Z = 9. So, N – Z = 10 – 9 = 1

$^{65}_{29}Cu$: N = 65 – 29 = 36; Z = 29. so, N – Z = 36 – 29 = 7

$^{55}_{24}Cr$: N = 55 – 24 = 31; Z = 24. So, N – Z = 31 – 24 = 7.

$$\left.\begin{array}{l} ^{235}_{92}U: N = 235 - 92 = 143; Z = 92. \text{ So, } N - Z = 143 - 92 = 51 \\ ^{231}_{90}Th: N = 231 - 90 = 114; Z = 90. \text{ So, } N - Z = 141 - 90 = 51 \end{array}\right]$$

Isodiaphers

$$\left.\begin{array}{l} ^{1}_{1}H: N = 1 - 1 = 0; Z = 1. \text{ So, } N - Z = 0 - 1 = -1 \\ ^{4}_{2}He: N = 4 - 2 = 2; Z = 2. \text{ So, } N - Z = 2 - 2 = 0 \end{array}\right]$$

Not Isodiaphers

So, the correct answer is (*d*).

EXAMPLE 130. *Which of the following species is not an isoster?*

(a) N_2 *and CO* *(b)* CO_2 *and* H_2O

Solution. Molecules which have same number of atoms and also same number of electrons are called isosters.

(*a*) N_2 has no. of atoms = 2; CO has one C and one O atoms. So, total no. of atoms = 1 + 1 = 2.

2_7N : no. of electrons

$$= 2\,(Z \text{ of } N) = 2 \times 7 = 14$$

In CO : no. of electrons in

$_6C$ = Z of C = 6; no. of electrons in O_8 = Z of O = 8.

So, total no. of electrons in CO = 6 + 8 = 14. So, N_2 and CO are isosters.

(*b*) CO_2 has no. of atoms

$$= 1 \text{ of } C + 2 \text{ of } O = 3$$

$_6C$: no. of electrons

$$= Z = 6;$$

2_8O : no. of electrons

$$= 2\,(Z \text{ of } O) = 2 \times 8 = 16$$

Hence total no. of electrons in

CO_2 = 6 + 16 = 22.

H_2O : no. of atoms

$$= 2 \text{ of } H + 1 \text{ of } O = 3$$

2_1H : no. of electrons

$$= 2\,(Z \text{ of } H) = 2 \times 1 = 2$$

$_8O$: no. of electrons

$$= Z \text{ of } O = 8$$

∴ Total no. of electrons in H_2O = 2 + 8 = 10

Since CO_2 and H_2O do not obey the conditions of isosters, so, the correct answer is (*b*).

Example 131. *An alpha particle is given out by $_{92}X^{238}$. The new species Y should be :*

(*a*) $^{234}_{90}Y$ (*b*) $^{238}_{90}Y$

(*c*) $^{234}_{92}Y$ (*d*) $^{234}_{94}Y$ **(BET, 2003)**

Solution. $_{92}X^{238} \xrightarrow[-{}^4_2He]{-\alpha \text{ or}} \underset{92-2}{X^{238-4}}$ or $_{90}X^{234}$. So, the correct answer is (*a*).

Example 132. *An element has half-time period of 6.5 hours. Initial number of atoms is 48×10^{19}. Then after 26 hours, the number of atoms will be :*

(*a*) 1.6×10^{19} (*b*) 3×10^{19}

(*c*) 2.4×10^{19} (*d*) 5×10^{19} **(IMS-BHU, 2003)**

Solution. No. of half-time,

$$n = \frac{\text{Total time}}{t_{1/2}}$$

Or $$n = \frac{26\,\text{hr}}{6.5\,\text{hr}} = 4.$$

But $$N = No\left(\frac{1}{2}\right)^n ; No = 48 \times 10^9$$

∴ $$N = 48 \times 10^{19} \times \left(\frac{1}{2}\right)^4$$

$$= 48 \times 10^{19} \times \frac{1}{16} = 3.0 \times 10^{19}.$$

So, the correct answer is (*b*).

Example 133. *A substance has half-life period of 4 sec. After t = 20 sec., how much percentage of substance is destroyed ?*

(*a*) 96.87 (*b*) 3

(*c*) 40 (*d*) 50 **(IMS-BHU, 2003)**

Solution. No. of half-lives

$$= \frac{\text{Total time}}{t_{1/2}} = \frac{20\,\text{sec}}{4\,\text{sec}} = 5$$

Hence, $$\frac{N}{No} = \left(\frac{1}{2}\right)^5 = \frac{1}{32};\ N = \frac{No}{32}$$

Hence, $$\Delta N = No - \frac{No}{32} = No\left[1 - \frac{1}{32}\right]$$

Or $$\Delta N = \frac{31}{32}No.$$

Hence, $$\frac{\Delta N}{No}\% = \left(\frac{\Delta N}{No}\right) \times 100 = \frac{31}{32} \times 100 = 96.87\%$$

So, the correct answer is (*a*).

Example 134. *One gram atom of a radioactive isotope ($t_{1/2}$ = 10 hours) that emits alpha particles was placed in a sealed container. The time taken for 0.875g atom of helium to accumulate in the container is :*

(*a*) 10 hours (*b*) 20 hours

(*c*) 30 hours (*d*) 40 hours

(J and K-CET, 2011)

Solution. $t_{1/2}$ = 10 hours means that 1 g atom of radioactive isotope will change to half by emitting one α-particle. So, the amount of helium emitted in :

10 hours = 0.5 g atom ; 2 × 10 i.e., 20 hours

= 0.5/2 = 0.25 g atom ; 3 × 10

i.e., 30 hours = 0.25/2 = 0.125 g atom. But (0.5 + 0.25 + 0.125) g.

atom = 0.875 g. So total time taken = 30 hours. So,. the correct answer is (*c*).

Example 135. *A radioactive isotope having a half-life of 3 days was received after 12 days. It was found that there were 3g of the isotope in the container. The initial weight of the isotope when packed was :*

(*a*) 48g (*b*) 36g

(*c*) 24g (*d*) 12g

(Karnataka CET, 2000)

Solution. Given N_t = 3g; No = ?; $t_{1/2}$ = 3 days.

$$\text{No. of half-lives} = \frac{\text{Total time}}{t_{1/2}} = \frac{12\,\text{days}}{3\,\text{days}} = 4$$

We know that : $$N_t = No\left(\frac{1}{2}\right)^n ; 3g = No\left(\frac{1}{2}\right)^4 = \frac{No}{16}$$

∴ No = 16 × 3g = 48g. So, the correct answer is (*a*).

EXAMPLE 136. *A sample of radioactive element undergoes 80% decomposition in 325 minutes. Its $t_{1/2}$ in minutes is :*

(a) $\frac{ln 2}{ln 4}$ (b) $\frac{ln 4}{ln 2}$

(c) $\frac{ln 2}{ln 5}$ (d) none of these.

SOLUTION.
$$t_{0.8} = \frac{1}{k}\ln\frac{100}{100-80} = \frac{1}{k}\ln 5$$

$$t_{0.5} \text{ or } t_{1/2} = \frac{1}{k}\ln\frac{100}{100-50} = \frac{1}{k}\ln 2$$

$$\therefore \quad \frac{t_{1/2}}{t_{0.8}} = \frac{1}{k}\ln 2 \times \frac{k}{\ln 5} = \frac{\ln 2}{\ln 5}$$

So, the correct answer is (*c*).

EXAMPLE 137. *If the mass of Co – 59 = 58.9332, the value of its packing fraction will be :*

(a) +11.322 (b) –11.322

(c) +5.661 (d) –5.661

SOLUTION. We know that,

$$\text{Packing fraction} = \frac{\text{Actual mass } - \text{ Mass number}}{\text{Mass number}} \times 10^4$$

$$= \frac{58.9332-59}{59} \times 10^{-4}$$

$$= \frac{-0.0668 \times 10^4}{59} = -11.322$$

So, the correct answer is (*b*).

EXAMPLE 138. *The mass number of a nucleide is 64. What is its nuclear radius in Fermi ?*

(a) 2.8 Fermi (b) 1.4 Fermi

(c) 5.6 Fermi (d) 11.2 Fermi

SOLUTION. Mass number, A = 64; Ro = 1.4×10^{-13} cm.

We know that nuclear radius,

$$R = Ro\,(A)^{1/3}. \text{ Thus :}$$
$$R = 1.4 \times 10^{-13} \text{ cm} \times (64)^{1/3}$$
$$= 1.4 \times 10^{-13} \text{ cm} \times (4 \times 4 \times 4)^{1/3}$$
$$= 1.4 \times 10^{-13} \text{ cm} \times 4$$
$$= 5.6 \times 10^{-13} \text{ cm} = 5.6 \text{ Fermi}$$

[∵ 1 Fermi = 10^{-13}cm]

So, the correct answer is (*c*).

EXAMPLE 139. *The fission of a single $^{235}_{92}U$ nucleus releases energy equal to 200 MeV. The number of fissions that occur per second to produce a power of one kW is :*

(a) $3.125 \times 10^{13}s^{-}$ (b) $3.2 \times 10^{-8}s^{-}$

(c) $3.2 \times 10^{14}s^{-}$ (d) $1.6 \times 10^{14}s^{-}$

SOLUTION. 1 MeV = 10^6 eV; 1 eV = 1.6×10^{-19}J. Thus, 1 MeV = $1.6 \times 10^{-19} \times 10^6$J.

Thus, **200 MeV** = $200 \times 1.6 \times 10^{-19} \times 10^6$ J

$$= \mathbf{3.2 \times 10^{-11}\ J}$$

Required energy

$$= 1 \text{ kW} = 1 \times 10^3 \text{ W} = 1 \times 10^3 \text{ Js}^{-}$$

[∵ 1 Watt = 1 Js^{-}]

Required number of fissions

$$= \frac{\text{Required energy}}{\text{Energy released per fission}}$$

$$= \frac{10^3 \text{Js}^{-}}{3.2 \times 10^{-11}\text{J}}$$

$$= 3.125 \times 10^{13}\text{s}^{-}$$

So, the correct answer is (*a*).

EXAMPLE 140. *Chlorine-35 (34.96885 a.m.u.) is formed when sulphur-35 (34.96903 a.m.u.) emits β-particle but no gamma particle. The maximum energy emitted in the process is:*

(a) 167.67 MeV (b) 16.767 MeV

(c) 1.6767 MeV (d) 0.16767 MeV

SOLUTION. Mass defect,

$$\Delta m = 34.96903 \text{ a.m.u.} - 34.96903 \text{ a.m.u.}$$
$$= 1.8 \times 10^{-4} \text{ a.m.u.}$$

Since energy emitted by

1 a.m.u. = 931.5 MeV, so :

Energy emitted by 1.8×10^{-4}

a.m.u. = $1.8 \times 10^{-4} \times 931.5$

MeV = 0.16767 MeV

So, the correct answer is (*d*).

EXAMPLE 141. *The number of α-particles emitted per second by 2g of thorium ($t_{1/2}$ ^{232}Th = 1.39×10^{10} yrs) will be :*

(a) 8.20×10^3 (b) 4.104×10^3

(c) 2.052×10^4 (d) 2.052×10^{23}

(Avogadro's no. = 6.023×10^{23})

SOLUTION.

Wt. of ^{232}Th = 2g

No. of ^{232}Th atoms,

$$N = \frac{\text{wt. in g}}{\text{g. at. wt. of } ^{232}\text{Th}} \times 6.023 \times 10^{23} \text{atoms}$$

$$= \frac{2}{232} \times 6.023 \times 10^{23} \text{ atoms}$$

$$= 5.19 \times 10^{21} \text{ atoms}$$

$$\lambda = \frac{0.693}{t_{1/2}} = \frac{0.693}{1.39 \times 10^{10}\text{yr}} \times \frac{1\text{yr}}{365\text{d}}$$

$$\times \frac{1\text{d}}{24\text{hr}} \times \frac{1\text{hr}}{60\text{min}} \times \frac{1\text{min}}{60\text{sec}} = 1.58 \times 10^{-18}\text{s}^{-}$$

No. of α-particles emitted per second

$$= -\frac{dN}{dt} = N\lambda$$

$$= 5.19 \times 10^{21} \text{ atoms} \times 1.58 \times 10^{-18}\text{s}^{-}$$

$$= 8.2 \times 10^3 \text{ atoms}$$

So, the correct answer is (*a*).

EXAMPLE 142. *The loss in mass accompanying combustion of one mol of fuel to release 900 kJ heat energy is :*

(a) 2×10^{9} *kg*	*(b)* 2×10^{11} *kg*
(c) 3×10^{11} *kg*	*(d)* 10^{11}*kg*

SOLUTION. Loss in mass = Δm, ΔE = Energy released, C = velocity of light (= $3 \times 10^{8}\ ms^{-}$). We know that : $\Delta E = \Delta m C^2$. Hence :

$$\Delta m = \frac{\Delta E}{C^2} = \frac{900\,kJ}{(3 \times 10^{8} ms^{-})^2} = \frac{900 \times 1000\,J}{(3 \times 10^{8} ms^{-})^2}$$

$$= \frac{900 \times 1000\,kg\,m^2s^{-2}}{9 \times 10^{16} m^2 s^{-2}}$$

$[\because J = kg\ m^2s^{-2}]$

$$= \mathbf{1.0 \times 10^{-11}\ kg.}$$

So, the correct answer is (*d*).

EXAMPLE 143. *A sample of ordinary neon gas was found to contain* ${}^{20}_{10}Ne$, ${}^{21}_{10}Ne$ *and* ${}^{22}_{10}Ne$ *isotopes in the percentage 90.92%, 0.26% and 8.82% respectively. The actual atomic mass of neon is:*

(a) *30.2*	*(b)* *20.18*
(c) *25.17*	*(d)* *10.09*

SOLUTION. Actual atomic mass of neon

$$= \frac{(20 \times 90.92) + (21 \times 0.26) + (22 \times 8.82)}{90.92 + 0.26 + 8.82}$$

$$= \frac{1818.4 + 5.46 + 194.04}{100}$$

$$= \frac{2017.9}{100} \simeq \mathbf{20.18}$$

So, the correct answer is (*b*).

EXAMPLE 144. *The half-life of a radioactive element is 4.8 min. The time taken by a given sample of the element to reduce to 1/4th of its initial activity will be :*

(a) *4.8 min*	*(b)* *9.6 min*
(c) *19.2 min*	*(d)* *1 hour*

SOLUTION. (*i*) $t_{1/2} = 4.8$ min; $\lambda = \frac{0.693}{t_{1/2}}$; $\lambda = \frac{0.693}{4.8\,min}$

(*ii*) $t = ?$ But $t = \frac{2.303}{\lambda}\log\frac{No}{N}$; $t = \frac{2.303 \times 4.8\,min}{0.693}\log\frac{1}{1/4}$

$$\therefore\ t = \frac{2.303 \times 4.8\,min}{0.693}\log 4 = \frac{2.303 \times 4.8\,min \times 0.602}{0.693}$$

or $t = 9.6$ min.

So, the correct answer is (*b*).

EXAMPLE 145. *A radioactive substance decays at such a rate that after 35 minutes, only a quarter of the original substance is left behind. The disintegration constant and half-life of the radioisotope are :*

(a) *0.0396* min^{-}, *17.5 min*	*(b)* *1.2* min^{-}, *10 min*
(c) *2.4* min^{-}, *20 min*	*(d)* *0.003* min^{-}, *1 min*

SOLUTION. (*i*) $t = 35$ min, No = 1, $N = \frac{1}{4}$; λ = disintegration constant. We know that:

$$\lambda = \frac{2.303}{t}\log\frac{No}{N};$$

$$\lambda = \frac{2.303}{35\,min}\log\frac{1}{1/4} = \frac{2.303}{35\,min}\log 4$$

$$\therefore\qquad \lambda = \frac{2.303}{35\,min} \times 0.602 = 0.0396\,min^{-}$$

(*ii*) $$t_{1/2} = \frac{0.693}{\lambda} = \frac{0.693}{0.0396} = 17.5\,min$$

So, the correct answer is (*a*).

EXAMPLE 146. *The half-life of a radioactive isotope is three hours. If the initial mass of the isotope was 256 g, the mass of it remaining undecayed after 18 hours would be :*

(a) *16.0 g*	*(b)* *4.0 g*
(c) *8.0g*	*(d)* *12.0 g* **(AIEEE, 2003)**

SOLUTION. Half-life $t_{1/2}$ = 3 hours; Total hours = 18 hours.

$\therefore$ Number of half-lives,

$$n = \frac{18}{3} = 6$$

But amount of substance left

$$= \frac{\text{Initial mass}}{2^n} = \frac{256}{2^6} = \frac{256}{64} = 4.0\,g$$

So, the correct answer is, (*b*).

EXAMPLE 147. *The radionucleide* ${}^{234}_{90}Th$ *undergoes two successive* β*-decays followed by one* α*-decay. The atomic number and the mass number respectively of the resulting nucleides are:*

(a) *92 and 230*	*(b)* *92 and 234*
(c) *94 and 230*	*(d)* *90 and 230* **(AIEEE, 2003)**

SOLUTION. The decay products can be represented as :

${}^{234}_{90}Th \xrightarrow{-({}^{0}_{-1}\beta)} {}^{234}_{91}X \xrightarrow{-({}^{0}_{-1}\beta)} {}^{234}_{92}Y \xrightarrow{-({}^{4}_{2}\alpha)} {}^{230}_{90}Th$. Since atomic number is 90 and mass number is 230, the correct answer is, (*d*).

EXAMPLE 148. *If No and N are the number of radioactive particles at t = 0 and at time t, then:*

(a) $\lambda = \frac{2.303}{t}\log NoN$	*(b)* $\lambda = \frac{2.303}{t}\log\frac{N}{No}$
(c) $\lambda = \frac{2.303}{t}\log\frac{No}{N}$	*(d)* $\lambda = \frac{1}{t}\log\frac{No}{N}$

SOLUTION. At $t = 0$ and at time t, No and N are related to λ as $\lambda = \frac{2.303}{t}\log\frac{No}{N}\cdot$ So, the correct answer is (*c*).

EXAMPLE 149. *In the first order reaction, the concentration of the reactants is reduced to 25% in one hour. The half-life period of the reaction is :*

(a) *30 seconds*	*(b)* *30 minutes*
(c) *1.5 hr*	*(d)* *.5 hr*

SOLUTION. The concentration has reduced to 25%. It means 75% (100 – 25 = 75) has reacted *i.e.*, $\frac{75}{100} = \frac{3}{4}$. Thus $2 \times t_{1/2}$ (half-life) $= t_{3/4}$ or $t_{1/2} = \frac{1}{2} \times t_{3/4} = \frac{1}{2} \times 1\,\text{hr} = \frac{1}{2}\,\text{hr} = \frac{1}{2} \times 60$ min = 30 min. So, correct answer is, (*b*).

Example 150. *The half-life of a first order reaction is 60 sec. The percentage of reactant left after 3 minutes is :*

(a) 2.5 *(b) 25*

(c) 12.5 *(d) 1.25*

Solution. 3 minutes = 3 × 60 = 180 seconds. Number of half lives, $n = \frac{180\,\text{sec}}{60\,\text{sec}} = 3$.

$\therefore$ Concentration (C) after *n* half-lives

$$= \frac{\text{Co}}{2^n} = \frac{\text{Co}}{2^3} = \frac{\text{Co}}{8}$$

Where Co is original concentration.

$\therefore$ Percentage left

$$= \frac{\text{Co}}{8} \times 100 = \frac{1}{8} \times 100 = \mathbf{12.5}$$

So, the correct answer is (*c*).

Example 151. *Complete the following statements for nuclear reactions.*

(i) $^{239}_{94}Pu\,(\alpha, \beta^-)\,........$

(ii) $........(\alpha, 2n)^{211}_{85}At$

(iii) $^{246}_{96}Cm + {}^{12}_{6}C \longrightarrow .... + 4\,^{1}_{0}n$

(iv) $^{27}_{13}Al(\alpha, n)$

You may use 'X' as symbol if the correct symbol in a reaction is not known.

(CBSE, 2007, HP Board, 2008)

Solution. (*i*) $^{239}_{94}\text{Pu}\,(\alpha, \beta^-)\,........$ is written as

$$^{239}_{94}\text{Pu} + {}^{4}_{2}\text{He} \longrightarrow {}^{0}_{-1}e + {}^{243}_{97}\text{Bk} \quad \left(\because \beta^- = {}^{0}_{-1}e\right)$$

or $^{239}_{94}\text{Pu}\,(\alpha, \beta^-)^{243}_{97}\text{Bk}$ or $^{243}_{97}\text{X}$

(*ii*) $^{209}_{83}\text{Bi} + {}^{4}_{2}\text{He} + 2\,^{1}_{0}\text{n} + {}^{211}_{85}\text{At}$; **Or** $^{209}_{83}\text{Bi}\,(\alpha, 2n)^{211}_{85}\text{At}$

or $^{209}_{83}\text{X}\,(\alpha, 2n)^{211}_{83}\text{At}$

(*iii*) $^{246}_{96}\text{Cm} + {}^{12}_{6}\text{C} \longrightarrow {}^{254}_{102}\text{No} + 4\,^{1}_{0}\text{n}$

or $^{246}_{96}\text{Cm} + {}^{12}_{6}\text{C} \longrightarrow {}^{254}_{102}\text{X} + 4\,^{1}_{0}\text{n}$

(*iv*) $^{27}_{13}\text{Al} + {}^{4}_{2}\text{He} \longrightarrow {}^{1}_{0}\text{n} + {}^{30}_{15}\text{P}$

Note. In all above cases (*i*) sum of mass no. of reactants = sum of mass no. of products. (*ii*) Sum of at. no. of reactants = sum of at. no. of products.

EXAMPLE 152. *The half-life period of polonium is 140 days. If one starts with 1g of polonium, 75% of it would have undergone disintegration in :*

(a) 28 days *(b) 280 days*

(c) 560 days *(d) 1 year*

Solution. $t_{1/2}$ = 140 days. But decay constant, $\lambda = \frac{0.693}{t_{1/2}}; \therefore \lambda = \frac{0.693}{140\,days} = 4.95 \times 10^{-3}$ (days)⁻. We know that :

$$t = \frac{2.303}{\lambda} \log \frac{a}{a - \left(\frac{75}{100}a\right)}$$

$$= \frac{2.303}{4.95 \times 10^{-3}} \log \frac{1}{1 - 0.75}$$

$$= \frac{2.303}{4.95 \times 10^{-3}} \log 4$$

$$\left[\because \frac{1}{1 - 3/4} = \frac{1}{1/4} = 4\right]$$

$$= \frac{2.303}{4.95 \times 10^{-3}} \times 0.6020 = 280\,\text{days}$$

So, the correct answer is, (*b*).

Example 153. *A certain nucleide has half-life period of 30 min. If a sample containing 6 × 10¹⁰ atoms is allowed to decay for 90 min., how many atoms will remain :*

(a) 2.9×10^9 atoms *(b) 7.0×10^9 atoms*

(c) 9.9×10^9 atoms *(d) 7.5×10^9 atoms.*

Solution. $t_{1/2}$ = 30 minutes. Total time = 90 minutes.

$\therefore$ No. of half-lives,

$$n = \frac{90}{30} = 3.$$

Total number of atoms,

$$\text{N} = 6 \times 10^{10}$$

But, $\quad \text{No} = \dfrac{\text{N}}{\left(\frac{1}{2}\right)^n}$

$$\therefore \quad \text{N} = \text{No} \times \left(\frac{1}{2}\right)^n$$

$$= 6.0 \times 10^{10} \times \left(\frac{1}{2}\right)^3 = \frac{6 \times 10^{10}}{8}$$

$$= 0.75 \times 10^{10} = 7.5 \times 10^9$$

So, the correct answer is, (*d*).

Example 154. *The $t_{0.5}$ of radioactive element is related to its average life by the expression :*

(a) $2.1\,t_{0.5}$ *(b) $2.88\,t_{0.5}$*

(c) $1.44\,t_{0.5}$ *(d) $4.32\,t_{0.5}$*

Solution. We know,

$$\text{Average life, T} = \frac{1}{\lambda\,(\text{decay constant})}$$

$$= \frac{1}{0.693 / t_{0.5}} = \frac{t_{0.5}}{0.693} = 1.44\,t_{0.5}$$

So, the correct answer is (*c*).

Example 155. *In a certain old wooden chair, the ratio of* $^{14}_{6}C$ *to* $^{12}_{6}C$ *is 13% that of the atmosphere. If half-life of* $^{14}_{6}C$ *is 5770 years, the age of the wood is :*

(a) 16.991 yrs *(b) 1512 yrs*
(c) 84955 yrs *(d) 16991 yrs*

Solution. (*i*) $t_{1/2}$ = 5770 years.

Hence, $$\lambda = \frac{0.693}{t_{1/2}} = \frac{0.693}{5770\text{ years}}$$

(*ii*) *t* (= age of wood) = ?, No = 100, N = 13. We know:

$$t = \frac{2.303}{\lambda}\log\frac{\text{No}}{\text{N}};$$

$$t = \frac{2.303 \times 5770\text{ years}}{0.693}\log\frac{100}{13}$$

$$= \frac{2.303 \times 5770\text{ yrs}}{0.693}[\log 100 - \log 13]$$

$$= \frac{2.303 \times 5770\text{ yrs}}{0.693}[2.0 - 1.1139]$$

$$t = \frac{2.303 \times 5770\text{ yrs} \times 0.8861}{0.693}$$

$$= 16991\text{ yrs.}$$

So, the correct answer is (*d*).

Example 156. *An experiment on radioactivity revealed that a radioactive element lost its half activity in 2 days and 12 hours. The decay constant as well as average life of the element are :*

(a) 0.01155 hr⁻, 86.58 hr *(b) 0.1155 hr⁻, 8hr*
(c) 1.2 hr⁻, 7hr *(d) 0.0057 hr⁻, 3hr*

Solution. (*i*) $t_{1/2}$ = 2 days + 12 hrs

$$= \left(2\text{days} \times \frac{24\text{ hr}}{1\text{day}}\right) + 12\text{ hrs} = 60\text{ hrs.}$$

∴ Decay constant,

$$\lambda = \frac{0.693}{t_{1/2}} = \frac{0.693}{60\text{ hr}} = 0.01155\text{ hr}^{-}$$

(*ii*) Average life,

$$\text{T} = \frac{1}{\lambda} = \frac{1}{0.01155\text{ hr}^{-}} = 86.58\text{ hr}$$

So, the correct answer is (*a*).

Example 157. *If the amount of radioactive substance is increased three times, the number of atoms disintegrated per unit time would*

(a) be doubled *(b) be tripled*
(c) remain one-third *(d) not change*

(MPPMT, 1994)

Solution. Since the rate of disintegration is directly proportional to the number of radioactive atoms, the number of atoms disintegrated per unit time would be tripled. So, the correct answer is (*b*).

Example 158. *The half-life of a radioactive element is 30 minutes. One sixteenth of the original quantity of the element will remain unchanged after*

(a) One hour *(b) 16 hours*
(c) 4 hours *(d) 2 hours* **(MPPMT, 1994)**

Solution. We know,

$$\frac{\text{N}}{\text{No}} = \left(\frac{1}{2}\right)^n;\ \frac{1}{16} = \frac{1}{16}$$

Hence, $n = 4$

∴ Time = 4 half-lives = 4 × 30 min = 120 min

$$= 120\text{ min} \times \frac{1\text{hr}}{60\text{ min}} = 2\text{hr.}$$

So, the correct answer is (*d*).

Example 159 *After the emission of one α-particle followed by one β-particle from the atom of* $^{238}_{22}X$, *the number of neutrons in the atoms will be*

(a) 142 *(b) 146*
(c) 144 *(d) 143* **(CBSE, 1995)**

Solution. $^{238}_{22}X \xrightarrow{-\alpha\text{ or }^{4}_{-2}\text{He}} {}^{238-4}_{92-2}Y \xrightarrow{-\beta\text{ or }^{0}_{-1}e} {}^{238-4-0}_{92-2+1}Z$ or $^{234}_{91}Z$

∴ No. of neutrons in Z = 234 – 91 = 143. So, the correct answer is (*d*).

Example 160. *Half-life for radioactive* ^{14}C *is 5760 years. In how many years 200 mg of* ^{14}C *sample will be reduced to 25 mg?*

(a) 11520 yrs *(b) 23040 yrs*
(c) 5760 yrs *(d) 17280 yrs* **(CBSE, 1995)**

Solution. We know that :

$$\text{N} = \text{No}\left(\frac{1}{2}\right)^n;\ \frac{\text{N}}{\text{No}} = \left(\frac{1}{2}\right)^n;\ \frac{25}{200}$$

or $$\frac{1}{8} = \left(\frac{1}{2}\right)^3;\ n = 3$$

∴ $t = n \times t_{1/2}$ = 3 × 5760 years = 17280 years. So, the correct answer is (*d*).

Example 161. *The average life period of a radioactive element is the reciprocal of its*

(a) half-life period
(b) disintegration constant
(c) number of atoms present at any time
(d) number of neutrons **(MPPET, 1995)**

Solution. Average life period,

$$\text{T} = \frac{1}{\lambda} = \frac{t_{1/2}}{0.693} = 1.44 \times t_{1/2}\,.$$

So, the correct answer is (*b*).

Example 162. *An isotope* $^{X}_{Y}A$ *undergoes a series of m alpha and n beta disintegrations to form a stable isotope* $^{X-32}_{Y-10}B$. *The values of m and n are, respectively,*

(a) 6 and 8 *(b) 8 and 10*
(c) 5 and 8 *(d) 8 and 6*

(MPPET, 1995)

Solution. Loss in mass = 32. Hence no. of α (*i.e.*, ^{4}He) particles = $\frac{32}{4} = 8$. Decrease in at. no. = 10.

∴ Decrease in at. no. due to the emission of 8 α-particles ($_2$He) = 8 × 2 = 16.

∴ No. of β-particles ($_{-1}^{0}e$) emitted = 16 – 10 = 6. So, the correct answer is (*d*).

Example 163. *In the nuclear reaction:* $^{14}_{7}N + ^{4}_{2}He \rightarrow ^{a}_{b}X + ^{1}_{1}H$, *the nucleus X is :*

(*a*) *Nitrogen of mass 16* (*b*) *Nitrogen of mass 17*
(*c*) *Oxygen of mass 16* (*d*) *Oxygen of mass 17*

(MLNR, 1995)

Solution. To balance a nuclear reaction :

(*i*) Sum of mass no. of reactants = Sum of mass no. of products

$$14 + 4 = a + 1; a = 18 - 1 = 17$$

(*ii*) Sum of at. no. of reactants =Sum of at. no. of products

$$7 + 2 = b + 1; b = 9 - 1 = 8$$

∴ Nucleus, X = $^{17}_{8}$X. Since atomic no. 8 is that of oxygen, so, X is = $^{17}_{8}$O. So, the correct answer is (*d*).

Example 164. *The radioactive decay of* $^{88}_{35}$X *by a beta emission produces an unstable nucleus which spontaneously emits a neutron. The final product is*

(*a*) $^{88}_{37}X$ (*b*) $^{89}_{35}Y$
(*c*) $^{88}_{34}Z$ (*d*) $^{87}_{36}W$ **(MLNR, 1995)**

Solution. $^{88}_{35}\text{X} \xrightarrow[-(^{0}_{-1}e)]{-\beta\text{or}} {}^{88-0}_{35+1}\text{Y} \text{ or } {}^{88}_{36}\text{Y} \longrightarrow {}^{87}_{36}\text{Z} + {}^{1}_{0}n.$

So, the correct answer is (*d*).

Example 165. *A radioactive sample has half-life of 1500 years. A sealed tube containing 1g of the sample will contain after 3000 years :*

(*a*) *1g of the sample* (*b*) *0.5 g of the sample*
(*c*) *0.25 g of the sample* (*d*) *0.00 g of the sample.*

(M.L.N.R., 1994)

Solution. No. of half-lives

$$= \frac{3000\,\text{yrs}}{1500\,\text{yrs}} = 2.$$

So, $n = 2$. But N = No × $\left(\frac{1}{2}\right)^n$;

$$\text{N} = 1\text{g} \times \left(\frac{1}{2}\right)^2 = \frac{1}{4} = 0.25\text{g}.$$

So, the correct answer is (*c*).

Example 166. *Complete the following nuclear reactions* $^{55}_{25}Mn(n, \gamma)$

(*a*) $^{55}_{25}Mn$ (*b*) $^{56}_{25}Mn$
(*c*) $^{56}_{24}Cr$ (*d*) $^{54}_{24}Cr$ **(ISM Dhanbad, 1994)**

Solution. $^{55}_{25}\text{Mn} + ^{1}_{0}n \rightarrow ^{55+1}_{25+0}\text{Mn}$ or $^{56}_{25}\text{Mn} + ^{0}_{0}\gamma$. So, the correct answer is (*b*).

Example 167. $^{232}_{90}Th$ *is the starting material of a decay chain series. This series by successive decays terminates at* $^{208}_{82}Pb$. *The number of α and β-particles emitted in this process are*

(*a*) *6α and 4β* (*b*) *4α and 6β*
(*c*) *10α and 6β* (*d*) *6α and 10β*

(Punjab CET, 1996)

Solution. For $^{232}_{90}\text{Th} \rightarrow ^{208}_{82}\text{Pb}$, (*i*) no. of α-particles = $\frac{232 - 208}{4} = 6$

Decrease in charge = 90 – 82 =8

∴ No. of β-particles = no. of α-particles × 2 – decrease in charge = (6 × 2) – 8 = 4.

So, the correct answer is (*a*).

Example 168. *The half-life of a radionucleide 'X' is 24 hours. The time required for 12.5% of the original X to remain is*

(*a*) *1 day* (*b*) *2 days*
(*c*) *3 days* (*d*) *4 days* **(Pb CET 1996)**

Solution. $\text{N} = \text{No}\left(\frac{1}{2}\right)^n ; 12.5 = 100\left(\frac{1}{2}\right)^n ;$

$$\frac{12.5}{100} = \left(\frac{1}{2}\right)^n ; \frac{1}{8} = \left(\frac{1}{2}\right)^n \text{ or } \left(\frac{1}{2}\right)^3 = \left(\frac{1}{2}\right)^n.$$

Hence $n = 3$.

∴ t = 3 days. So, the correct answer is (*c*).

Example 169. *1.0g of radioactive isotope was found to reduce to 125 mg after 24 hours. The half-life of the isotope is*

(*a*) *8 hrs* (*b*) *24 hrs*
(*c*) *6 hrs* (*d*) *4 hrs*

(MPCET, 1996. J and K CET, 2010)

Solution. $1.\text{g} = 1000\text{ mg}. \frac{\text{N}}{\text{No}} = \left(\frac{1}{2}\right)^n ; \frac{125}{1000} = \left(\frac{1}{2}\right)^n ;$

$$\frac{1}{8} = \left(\frac{1}{2}\right)^n ; \left(\frac{1}{2}\right)^3 = \left(\frac{1}{2}\right)^n.$$

∴ $n = 3$. But $t = t_{1/2} \times n$;

$$t_{1/2} = \frac{t}{n} = \frac{24\,\text{hrs}}{3} = 8\,\text{hrs}.$$

So, the correct answer is (*a*).

Example 170. *The half-life period of a radioactive element is 140 days. In 560 days, a sample of this element would be reduced to ...... of its initial mass :*

(*a*) $\frac{1}{2}$ (*b*) $\frac{1}{4}$
(*c*) $\frac{1}{8}$ (*d*) $\frac{1}{16}$ **(MPCET, 1998)**

Solution. $\frac{\text{Total time}}{t_{1/2}} = \frac{560\,\text{days}}{140\,\text{days}} = 4$

$$\therefore \qquad \frac{\text{N}}{\text{No}} = \left(\frac{1}{2}\right)^4 = \frac{1}{16}.$$

So, the correct answer is (*d*).

EXAMPLE 171. *2 g of a radioactive sample having a half-life of 15 days was synthesised on 1st Jan 2009. The amount of the sample left behind on first March, 2009 (including both days) :*

(*a*) 0.125 g (*b*) 1 g
(*c*) 0.5 g (*d*) 0 g

(AIEEE, 2004, Karnataka CET, 2009)

SOLUTION. No. of days of Jan (31) + Feb (28) + March (31) = 60 days. $t_{1/2}$ = 15 days (given). Thus, no. of half-lives, n = ?

Total time, $T = n \times t_{1/2}$; $n = \frac{60}{15} = 4$

Initial amount, No = 2g. So, sample present after 4 half-lives, $\text{N} = \left(\frac{1}{2}\right)^n \text{No} = \left(\frac{1}{2}\right)^4 \times 2 = \frac{2}{16} = 0.125$ g. So, the correct answer is (*a*)

EXAMPLE 172. *The half-life of a radioactive isotope is three hours. If the initial mass of isotope was 300g, the mass that remained undecayed in 18 hours would be :*

(*a*) 2.34 g (*b*) 1.17 g
(*c*) 9.36g (*d*) 4.68 g **(CBSE, 2000)**

SOLUTION. $$n = \frac{\text{Total time}}{t_{1/2}} = \frac{18\,\text{hrs}}{3\,\text{hrs}} = 6.$$

Also, $$\text{N} = \text{No} \times \left(\frac{1}{2}\right)^n = 300\text{g} \times \left(\frac{1}{2}\right)^6$$

or $$\text{N} = 300\text{ g} \times \frac{1}{64} = 4.68\text{g}.$$

So, the correct answer is (*d*).

EXAMPLE 173. *A human body required 0.01M activity of a radioactive substance after 24 hours. Half-life of the radioactive substance is 6 hours. The injection of maximum activity of the radioactive substance that can be injected is :*

(*a*) 0.08 (*b*) 0.04
(*c*) 0.16 (*d*) 0.32 **(CBSE, 2001)**

SOLUTION. $$n = \frac{\text{Total time}}{t_{1/2}} = \frac{18}{3} = 6.$$

Also, $$\text{N} = \text{No} \times \left(\frac{1}{2}\right)^n ; 0.01\text{M} = \text{No} \times \left(\frac{1}{2}\right)^4 ;$$

$$0.01\text{M} = \text{No} \times \frac{1}{16}$$

Hence, $\text{No} = 16 \times 0.01\text{ M} = 0.16\text{ M}.$

So, the correct answer is (*c*).

EXAMPLE 174. *The radioisotope tritium (^3_1H) has a half-life of 12.3 years. If the initial amount of tritium is 32 mg, how many milligrams of it would remain after 49.2 years ?*

(*a*) 1 mg (*b*) 2 mg
(*c*) 4 mg (*d*) 8 mg **(CBSE, 2003)**

SOLUTION. $$n = \frac{\text{Total time}}{t_{1/2}} = \frac{49.2\,\text{years}}{12.3\,\text{years}} = 4;$$

$$\text{N} = \text{No} \times \left(\frac{1}{2}\right)^n = 32\,\text{mg} \times \left(\frac{1}{2}\right)^4$$

$$\therefore \qquad \text{N} = 32\text{ mg} \times \frac{1}{16} = 2\text{mg}$$

So, the correct answer is (*b*).

EXAMPLE 175. *A radioactive isotope decays at such a rate that after 192 minutes only 1/16 of the original amount remains. The half-life of the radioactive isotope is*

(*a*) 32 min (*b*) 48 min
(*c*) 12 min (*d*) 24 min

(Karnatka CET, 2004)

SOLUTION. $$\frac{\text{N}}{\text{No}} = \frac{1}{16};$$

Hence, $$\frac{\text{N}}{\text{No}} = \left(\frac{1}{2}\right)^4 ; \frac{\text{N}}{\text{No}} = \left(\frac{1}{2}\right)^n$$

So, n = 4. Also,

$$t_{1/2} = \frac{\text{Total time}}{n} = \frac{192\,\text{min}}{4} = 48\,\text{min}.$$

So, the correct answer is (*b*).

EXAMPLE 176. *If radioactive substance after 48 days remains 25% of initial value, then find disintegration constant.*

(*a*) $2.89 \times 10^{-2}\ T^{-1}$ (*b*) $3.89 \times 10^{-3}T^{-1}$
(*c*) $4.89 \times 10^{-2}T^{-1}$ (*d*) *none of these* **(BCECE, 2004)**

SOLUTION. $$\frac{\text{N}}{\text{No}} = \left(\frac{1}{2}\right)^n ; \frac{\text{N}}{\text{No}} = \frac{25}{100} = \frac{1}{4} \text{ or } \left(\frac{1}{2}\right)^2.$$

Hence n = 2.

But $$t_{1/2} = \frac{\text{Total time}}{n} = \frac{48\,\text{days}}{2} = 24\,\text{days}$$

$$\therefore \qquad \lambda = \frac{0.693}{t_{1/2}} = \frac{0.693}{24}\text{T}^{-1} = 2.89 \times 10^{-2}\text{T}^{-}.$$

So, the correct answer is (*a*).

EXAMPLE 177. *What is the half-life of a radioactive substance if 87.5% of any given amount of the substance disintegrates in 40 minutes ?*

(*a*) 0 min (*b*) 20 min
(*c*) 160 min (*d*) 13 min 20 sec.

(Manipal, UGET, 2004)

SOLUTION. Amount of substance left

$$= 100 - 87.5 = 12.5\text{ g}.$$

$$\frac{\text{N}}{\text{No}} = \left(\frac{1}{2}\right)^n . \text{But} \frac{\text{N}}{\text{No}} = \frac{12.5}{100} \textit{ i.e., } \frac{1}{8}.$$

So, $$\frac{1}{8} = \left(\frac{1}{2}\right)^n ; \left(\frac{1}{2}\right)^3 = \left(\frac{1}{2}\right)^n. \text{ Hence } n = 3.$$

But $$t_{1/2} = \frac{\text{Total time}}{n} ; t_{1/2} = \frac{40}{3} = 13\,\text{min}\ 20\,\text{sec}.$$

So, the correct answer is (*d*).

EXAMPLE 178. *A radioactive element has $t_{1/2}$ of 60 minutes. The amount remaining after 3 hrs is*

(a) 17.5% *(b)* 12.5%
(c) 25% *(d)* 50% **(BHU, 1997)**

SOLUTION. $t_{1/2} = 60$ min.

$$\text{Total time} = 3\text{ hrs} \times \frac{60\text{ min}}{1\text{ hr}} = 180\text{ min}.$$

$$\therefore \quad n = \frac{\text{Total time}}{t_{1/2}} = \frac{180\text{ min}}{60\text{ min}} = 3.$$

Hence, $\quad \mathrm{N} = \mathrm{No} \times \left(\frac{1}{2}\right)^3 ; \mathrm{N} = 100 \times \left(\frac{1}{2}\right)^3$

Or $\quad \mathrm{N} = 100 \times \frac{1}{8} = 12.5\%.$

So, the correct answer is (*b*).

EXAMPLE 179. *The half-life of an isotope is 10 hrs. How much will be left after 4 hrs in one gram mole sample ?*

(a) 45.6×10^{23} atoms *(b)* 4.56×10^{23} atoms
(c) 4.56×10^{21} atoms *(d)* 4.56×10^{20} atoms

(BHU 1997)

SOLUTION. $t_{1/2} = 10$ hrs;

$$\lambda = \frac{0.693}{t_{1/2}} = \frac{0.693}{10\text{ hrs}} = 0.0693\text{ hr}^{-}.$$

But : $\quad t = \frac{2.303}{\lambda}\log\frac{a}{a-x}$

So, $\quad 4 = \frac{2.303}{0.0693}\log\frac{1}{1-x};$

$$\log\frac{1}{1-x} = \frac{4 \times 0.0693}{2.303} = 0.1204.$$

Taking antilogs of both sides, we get :

$$\frac{1}{1-x} = \text{antilog } 0.1204 = 1.3195.$$

Hence, $\quad 1 - x = \frac{1}{1.3195} = 0.7579\text{ g mole}$

But $\quad$ 1g mol = 6.02×10^{23} atoms

$\therefore$ 0.7579g mol = $6.02 \times 10^{23} \times 0.7579$ atoms

$= 4.56 \times 10^{23}$ atoms

So, the correct answer is (*b*).

EXAMPLE 180. *A radioactive element X emits 3α, 1β and 1γ -particles and forms $^{225}_{76}Y$. Element X is :*

(a) $^{237}_{81}X$ *(b)* $^{237}_{80}X$

(c) $^{236}_{81}X$ *(d)* $^{236}_{80}X$ **(CMEET, Bihar, 1997)**

SOLUTION. (*i*) Decrease in mass due to emission of 3α *i.e.,* 3 ^{4}He particles = 3 × 4 = 12.

$\therefore$ Mass of X = 225 + 12 = 237

Decrease in at. no. due to emission of 3α *i.e.,* 3 $_2$He particles = 3 × 2 = 6

(*ii*) Increase in at. no. due to emission of β (= $^{0}_{-1}e$) particles = 1

(*iii*) Change in mass no. and at. no. due to $^{0}_{0}\gamma$ -radiations = zero.

$\therefore$ Net decrease in at. no.

= 6 – 1 = 5

$\therefore$ At. no. of X = 76 + 5 = 81. Hence, X is $^{237}_{81}X$. So, the correct answer is (*a*).

EXAMPLE 181. *Which does not take place by α-disintegration?*

(a) $_{92}U^{238} \rightarrow {}_{90}Th^{234}$ *(b)* $_{90}Th^{232} \rightarrow {}_{88}Ra^{228}$
(c) $_{88}Ra^{226} \rightarrow {}_{86}Rn^{222}$ *(d)* $_{83}Bi^{213} \rightarrow {}_{84}Po^{213}$

(MPPMT, 1997)

SOLUTION. (*a*) $_{92}\mathrm{U}^{238} \rightarrow {}_{90}\mathrm{Th}^{234} + {}_{2}\mathrm{He}^{4}$ (possible).

(*b*) $_{90}\mathrm{Th}^{232} \rightarrow {}_{88}\mathrm{Ra}^{228} + {}_{2}\mathrm{He}^{4}$ (possible)

(*c*) $_{88}\mathrm{Ra}^{226} \rightarrow {}_{86}\mathrm{Rn}^{222} + {}_{2}\mathrm{He}^{4}$ (possible)

(*d*) $_{83}\mathrm{Bi}^{213} \rightarrow {}_{84}\mathrm{Po}^{213} + {}_{2}\mathrm{He}^{4}$ (not possible because mass no. of reactants (= 213) is not equal to that of products (= 213 + 4 = 217). So, the correct answer is (*d*). In fact (*d*) should be $_{83}\mathrm{Bi}^{213} \rightarrow {}_{84}\mathrm{Po}^{213} + {}^{0}_{-1}e$ β-particle.

EXAMPLE 182. *Which one of the following notations shows the product incorrectly.*

(a) $^{242}_{96}Cm(\alpha, 2n)\,^{242}_{97}Bk$ *(b)* $^{10}_{5}B(\alpha, n)\,^{13}_{7}N$

(c) $^{14}_{7}N(n, p)\,^{14}_{6}C$ *(d)* $^{28}_{14}Si(d, n)\,^{29}_{15}P$

(MPPET, 1998)

SOLUTION. (*a*) $^{242}_{96}\mathrm{Cm} + {}^{4}_{2}\mathrm{He} \rightarrow {}^{242}_{97}\mathrm{Bk} + 2\,{}^{1}_{0}n$ (not balanced).

(*b*) $^{10}_{5}\mathrm{B} + {}^{4}_{2}\mathrm{He} \rightarrow {}^{13}_{7}\mathrm{N} + {}^{1}_{0}n$ (balanced)

(*c*) $^{14}_{7}\mathrm{N} + {}^{1}_{0}n \rightarrow {}^{14}_{6}\mathrm{C} + {}^{1}_{1}\mathrm{H}$ (balanced)

(*d*) $^{28}_{14}\mathrm{Si} + {}^{2}_{1}\mathrm{D} \rightarrow {}^{29}_{15}\mathrm{P} + {}^{1}_{0}n$ (balanced). So, the correct answer is (*a*).

EXAMPLE 183. *Number of neutrons in a parent nucleus X, which gives $^{14}_{7}N$ after two successive β-emissions would be*

(a) 6 *(b)* 7
(c) 8 *(d)* 9 **(CBSE, 1998)**

SOLUTION.

$$^{14}_{5}\mathrm{X} \xrightarrow[-({}^{0}_{-1}e)]{-\beta\text{ or}} {}^{14}_{5+1}\mathrm{C} \textit{ i.e., } {}^{14}_{6}\mathrm{C} \xrightarrow[-({}^{0}_{-1}e)]{-\beta\text{ or}} {}^{14}_{6+1}\mathrm{N} \text{ or } {}^{14}_{7}\mathrm{N}$$

$\therefore$ No. of neutrons in $^{14}_{5}\mathrm{X} = 14 - 5 = 9$. So, the correct answer is (*d*).

EXAMPLE 184. *The activity of a radioactive nucleide X^{100} is 6.023 curie. If the disintegration constant is 3.7×10^{4} sec^{-}, the mass of X is :*

(a) 110^{-23}g *(b)* 10^{-15}g
(c) 10^{-16}g *(d)* 10^{-14}g **(EAMCET, 1998)**

SOLUTION. 1 curie = 3.7×10^{10} ds^{-}; $-\frac{d\mathrm{N}}{dt} = \mathrm{lN}$; 6.023 × 3.7×10^{10} d s^{-} = 3.7×10^{4} sec^{-} × N

$$\therefore \qquad N = \frac{6.023 \times 3.7 \times 10^{10}}{3.7 \times 10^{4}} = 6.023 \times 10^{6}$$

= no. of radioactive atoms.

$$\therefore \quad \text{Mass of X} = \frac{6.023 \times 10^{6}}{6.023 \times 10^{23}} \times 100 = 10^{-15}\text{g}.$$

So, the correct answer is (*b*).

EXAMPLE 185. *If $_{90}Th^{228}$ disintegrates to $_{83}Bi^{212}$, then the number of α and β-particles emitted is :*

(*a*) 4 and 7	(*b*) 4 and 1
(*c*) 4 only	(*d*) 7 only **(AFMC, 1998)**

SOLUTION. *Reaction* : $_{90}\text{Th}^{228} \rightarrow {}_{83}\text{Bi}^{212}$.

(*i*) no. of α-particles (^4_2He) emitted = $\dfrac{228-212}{4} = \mathbf{4}.$

(*ii*) Decrease in at. no. due to the emission of four α-particles = 2 × 4 = 8.

Actual decrease in at. no. = 90 – 83 = 7. Hence β-particles emitted = 8 – 7 = **1**.

So, the correct answer is (*b*).

EXAMPLE 186. *Loss of a β-particle from neutron is equivalent to*

(*a*) *Increase of one proton only*

(*b*) *Decrease of one neutron only*

(*c*) *Both (a) and (b)*	(*d*) *None of these* **(IIT, 1998)**

SOLUTION. Reaction is : $^1_0n \rightarrow {}^1_1p + {}^{\;\,0}_{-1}e$ *i.e.*, β-particle. So, the correct answer is (*c*).

EXAMPLE 187. *The number of neutrons accompanying the formation of $^{139}_{54}Xe$ and $^{94}_{38}Sr$ by the absorption of slow neutron by $^{235}_{92}U$ followed by nuclear fission is :*

(*a*) 0	(*b*) 2
(*c*) 1	(*d*) 3 **(IIT, 1999)**

SOLUTION. *Reaction is* : $^{235}_{92}\text{U} + {}^1_0n \rightarrow {}^{139}_{54}\text{Xe} + {}^{94}_{38}\text{Sr} + 3\,{}^1_0n$

∴ no. of neutrons = 3. So, the correct answer is (*d*).

EXAMPLE 188. *If it a assumed that $^{235}_{92}U$ decays only by emitting α and β-particles, the possible product of the decay is :*

(*a*) $^{225}_{89}Ac$	(*b*) $^{227}_{89}Ac$
(*c*) $^{230}_{89}Ac$	(*d*) $^{231}_{89}Ac$

(West Bengal, JEE, 2009)

SOLUTION. We know that the number of α and β-particles, emitted should be a whole number. So:

(*a*) $^{235}_{92}\text{U} = {}^{225}_{89}\text{Ac} + x\,{}^4_2\text{He} + y\,{}^{\;\,0}_{-1}e$

∴ 235 = 225 + 4*x* + 0; 4*x* = 10/4 = 2.5.

It is not a whole number.

(*b*) $^{235}_{92}\text{U} = {}^{227}_{89}\text{Ac} + x\,{}^4_2\text{He} + y\,{}^{\;\,0}_{-1}e$

∴ 235 = 227 + 4*x* + 0; 4*x* = 8/4 = 2.

It is a whole number and is possible.

Also, 92 = 89 + 2*x* – *y*; 92 = 89 + (2 × 2) – *y*;

y = 93 – 92 = 1.

It is a whole number and the number of β-particles is possible. So, the correct answer is (*b*).

> **Note.** Number of α-particles (n_α) and β-particles (n_β) can be calculated by using the relations, n_α= (change in mass no.)/4 and n_β = (change in at. no.) - 2n_α

EXAMPLE 189. *Which of the following has maximum N/p ratio ?*

(*a*) ^{16}Ne	(*b*) ^{16}O
(*c*) ^{16}F	(*d*) ^{16}N **(DPMT, 2000)**

SOLUTION. Writing at. no. (or protons) of each species, we have :

$^{16}_{10}\text{Ne}, {}^{16}_{8}\text{O}, {}^{16}_{9}\text{F}$ and $^{16}_{7}\text{N}$. Thus, no. of neutrons in :

(*i*) $^{16}_{10}\text{N} = 16 - 10 = 6$, (*ii*) $^{16}_{8}\text{O} = 16 - 8 = 8$,

(*iii*) $^{16}_{9}\text{F} = 16 - 9 = 7$, (*iv*) $^{16}_{7}\text{N} = 16 - 7 = 9$.

Hence, N/p ratio in (*i*) $^{16}_{10}\text{N} = \dfrac{6}{10} = 0.6$, (*ii*) $^{16}_{8}\text{O} = \dfrac{8}{8} = 1$, (*iii*) $^{16}_{9}\text{F} = \dfrac{7}{9} = 0.77$ and (*iv*) $^{16}_{7}\text{N} = \dfrac{9}{7} = 1.28$. So, the correct answer is (*d*).

EXAMPLE 190. *Decay of $^{235}_{92}U$ is .... order reaction*

(*a*) *zero*	(*b*) *first*
(*c*) *second*	(*d*) *hird* **(OJEE, 2004)**

SOLUTION. All radioactive decay reactions are first order reactions. So, the correct answer is (*b*).

EXAMPLE 191. *An artificial radioactive isotope gave $^{14}_{7}N$ after two successive β-particle emissions. The number of neutrons in the present nucleus must be*

(*a*) 9	(*b*) 14
(*c*) 5	(*d*) 7 **(Karnataka CET, 2004)**

SOLUTION. Increase in at. no. by the emission of 2β ($^{\;\,0}_{-1}e$) particles = 2 × 1 = 2.

Hence, the at. no. of artificial radioactive isotope = 7 – 2 = 5.

So, the nucleide will be $^{14}_{5}\text{B}$. Hence no. of neutrons = 14 – 5 = 9. So, the correct answer is (*a*).

EXAMPLE 192. *A radioactive atom ^x_yM emits two alpha particles successively. The number of neutrons in the nuclous of the product will be :*

(*a*) *x* – 4 – *y*	(*b*) *x* – *y* – 5
(*c*) *x* – *y* – 3	(*d*) *x* – *y* – 6 **(WB-JEE, 2011)**

SOLUTION. Using group displacement law, we have :

$$^{x}_{y}\text{M} \xrightarrow{-\,^4_2\text{He}} {}^{x-4}_{y-2}\,\text{N} \xrightarrow{-\,^4_2\text{He}} {}^{x-4-4}_{y-2-2}\;\text{O} \xrightarrow{^{\;\,0}_{-1}e} {}_{y-2-2+1\,=\,y-3}{}^{x-8}\ \text{P}$$

∴ At. no. of Product = *y* – 3;

mass no. of product = *x* – 8

∴ No. of neutrons = Mass no. – At. no.

= (*x* – 8) – (*y* – 3) = *x* – *y* – 5.

So, the correct answer is (*b*)

EXAMPLE 193. *If the mass defect of ${}^{9}_{4}X$ is 0.09 a.m.u., then binding energy per nucleon is (1 a.m.u. = 931.5 MeV) :*

(a) 9.315 MeV *(b) 931.5 MeV*

(c) 83.0 MeV *(d) 8.38 MeV* **(JKCET, 2004)**

SOLUTION. We know that : Binding energy per nucleon

$$= \frac{\text{Mass defect}}{\text{mass no.}} = \frac{0.09\,\text{a.m.u.}}{9}$$

$$= \frac{0.09 \times 931.5\,\text{MeV}}{9}$$

$$= 9.315\text{ MeV}$$

So, the correct answer is (*a*).

EXAMPLE 194. *Consider the following nuclear reactions :*

$${}^{238}_{92}M \rightarrow {}^{x}_{y}N + 2\,{}^{4}_{2}He\,;\; {}^{x}_{y}N \rightarrow {}^{A}_{B}L + 2\beta^{+}$$

The number of neutrons in the element L is :

(a) 142 *(b) 144*

(c) 140 *(d) 146* **(AIEEE, 2004)**

SOLUTION. ${}^{238}_{92}\text{M} \rightarrow {}^{\text{x}}_{\text{y}}\text{N} + 2\,{}^{4}_{2}\text{He}$.

(*i*) Sum of mass no. of reactants = Sum of mass no. of products

$$238 = X + (2 \times 4)\;;\; X = 230$$

(*ii*) Sum of at. no. of reactants =Sum of at. no. of products

$$92 = y + (2 \times 2);\, y = 92 - 4 = 88.$$

Hence, ${}^{\text{x}}_{\text{y}}\text{N}$ is ${}^{230}_{88}\text{N}$.

Given : ${}^{230}_{88}\text{N} \rightarrow {}^{\text{A}}_{\text{B}}\text{L} + 2\,{}^{0}_{+1}\text{e}$ *i.e.*, β^{+}

$\therefore$ 230 = A + (2 × 0) ; A = 230.

88 = B + (2 × +1); B = 88 – 2 = 86.

So, ${}^{\text{A}}_{\text{B}}\text{L} = {}^{230}_{86}\text{L}$.

It contains neutrons

= 230 – 86 = 144.

So, the correct answer is (*b*).

EXAMPLE 195. *If n_t number of radioatoms are present at time, t, the following expression will be constant.*

(a) n_t/t *(b) $\ln n_t/t$*

(c) $d\ln n_t/dt$ *(b) $t.\, n_t$.* **(West Bengal JEE, 2009)**

SOLUTION. Since $-\dfrac{dn_t}{dt} = \lambda n_t$, so $\lambda = -\dfrac{1}{n_t}\cdot\dfrac{dn_t}{dt}$

or $\dfrac{d}{dt}(\ln n_t) = -\lambda$, a constant. So, the correct answer is (*c*).

EXAMPLE 196. *A first order reaction is 10% complete in 20 minutes. The time taken for 19% completion is :*

(a) 30 min *(b) 40 min*

(c) 50 min *(d) 38 min*

(e) 45 min **(Kerala, PET, 2005)**

SOLUTION. For first order reaction,

$$k = \frac{2.303}{t}\log\frac{a}{a-x}$$

(*i*) ***First case.*** t = 20 min.

$$\therefore \quad k = \frac{2.303}{20}\log\frac{90}{100} \qquad [\because 100 - 10 = 90]$$

(*ii*) ***Second case.*** t = ?

$$\therefore \quad k = \frac{2.303}{t}\log\frac{81}{100} \qquad [\because 100 - 19 = 81]$$

$$\therefore \frac{2.303}{20}\log\frac{90}{100} = \frac{2.303}{t}\log\frac{81}{100}$$

$$\text{or} \quad t = \frac{\dfrac{2.303 \times 20}{2.303}\left(\log\dfrac{81}{100}\right)}{\log\dfrac{90}{100}}$$

$$= \frac{20[\log 81 - \log 100]}{\log 90 - \log 100}$$

$$= \frac{20(1.908 - 2)}{1.954 - 2} = \frac{20(-0.092)}{-0.046} = \mathbf{40\ min.}$$

So, the correct answer is (*b*).

EXAMPLE 197. *The atomic radius and nuclear radii are of the order of 10^{-8} cm and 10^{-13} cm respectively. The fraction of atomic volume occupied by the nucleus, assuming that atom as well as nucleus are spherical in nature is :*

(a) 10^{-12} *(b) 10^{15}*

(c) 10^{-15} *(d) 10^{-13}*

SOLUTION. Let r = radius of sphere. So, volume of sphere $= \dfrac{4}{3}\pi r^3$

(*i*) Volume of atom

$$= \frac{4}{3}\pi r^3 = \frac{4}{3} \times \frac{22}{7} \times (10^{-8}\text{cm})^3$$

$$= 4.19 \times 10^{-24}\text{ cm}^3.$$

(*ii*) Volume of nucleus

$$= \frac{4}{3}\pi\, r^3 = \frac{4}{3} \times \frac{22}{7} \times (10^{-13}\text{cm})^3$$

$$= 4.19 \times 10^{-39}\text{ cm}^3.$$

(*iii*) Fraction of volume occupied by nucleus

$$= \frac{4.19 \times 10^{-39}\text{cm}^3}{4.19 \times 10^{-24}\text{cm}^3} = \mathbf{10^{-15}} \qquad \textbf{Ans.}$$

So the correct answer is (*c*).

EXAMPLE 198. *A photon of hard gamma radiation knocks a proton out of ${}^{24}_{12}Mg$ nucleus to form :*

(a) the isotope of parent nucleus

(b) the isobar of parent nucleus

(c) the nucleide ${}^{23}_{11}Na$ *(d) the isobar of ${}^{23}_{11}Na$*

(AIEEE, 2005)

SOLUTION. *Reaction :* ${}^{24}_{12}\text{Mg} + {}^{0}_{0}\gamma \rightarrow {}^{1}_{1}p + {}^{23}_{11}\text{Na}$. Since ${}^{24}_{12}\text{Mg}$ and ${}^{23}_{11}\text{Na}$ do not have same at. no., these are not isotopes.

These also do not have same mass number. So, these are not isobars. Hence, $^{23}_{11}\text{Na}$ is nucleide. So, the correct answer is (*c*).

EXAMPLE 199. *The half life of a first order reaction having rate constant* $k = 1.7 \times 10^{-5}s^{-}$ *is :*

(*a*) 12.1 h (*b*) 9.7 h
(*c*) 11.3 h (*d*) 1.8 h

(CBSE, 1999, IMS-BHU, 2005)

SOLUTION. Rate constant $k = 1.7 \times 10^{-5}s^{-}$. Half life $t_{1/2}$ is given as :

$$t_{1/2} = \frac{0.693}{k}; t_{1/2} = \frac{0.693}{1.7\times10^{-5}\text{s}^{-}}\times\frac{1\text{hr}}{3600\text{s}} = \mathbf{11.3\,h}$$

So, the correct answer is (*c*).

EXAMPLE 200. *When* $^{27}_{13}Al$ *is bombarded with α-particle, a radioactive isotope of phosphorus* $^{30}_{15}P$ *is formed. Which particle is emitted along with* $^{30}_{15}P$*?*

(*a*) Deutron (*b*) Proton
(*c*) electron (*d*) neutron **(Gujrat, 2006)**

SOLUTION. $^{27}_{13}\text{Al} + \underset{(\alpha\text{-particle})}{^4_2\text{He}} \rightarrow {}^{30}_{15}\text{P} + \underset{\text{Neutron}}{^1_0 n}$

So, the correct answer is (*d*).

EXAMPLE 201. *In a transformation of* $^{238}_{92}U$ *to* $^{234}_{92}U$*, if one emission is an α-particle, what should be the other emission(s)?*

(*a*) two beta (*b*) two β and one β^+
(*c*) one β^- and one γ (*d*) one β^+ and one β^-

(AIEEE, 2006)

SOLUTION. $^{238}_{92}\text{U} \rightarrow {}^{234}_{92}\text{U} + {}^4_2\text{He}$

In the above reaction, though atomic weights are balanced but the sum of atomic numbers are not balance. So, we have

$^{238}_{92}\text{U} \rightarrow {}^{234}_{92}\text{U} + {}^4_2\text{He} + 2\,{}^0_{-1}\beta$. So, the correct answer is (*a*).

EXAMPLE 202. *The net nuclear reaction of a radioactive decay series is written as :*

$$^{238}_{92}U \longrightarrow {}^{206}_{82}Pb + 8\,{}^4_2He + 6\,{}^0_{-1}e$$

Write three points of information that you get from the above equation. **(CBSE, 2007)**

SOLUTION. The three points of information from $^{238}_{92}\text{U} \longrightarrow {}^{206}_{82}\text{Pb} + 8\,{}^4_2\text{He} + 6\,{}^0_{-1}e$ are :

(*i*) It is a uranium decay series.
(*ii*) The stable isotope formed is $^{206}_{82}\text{Pb}$.
(*iii*) In this decay reaction 8 alpha particles and 6 beta particles are liberated.

EXAMPLE 203. *A positron is emitted from* $^{23}_{11}Na$*. The ratio of the atomic mass and atomic number of the resulting nucleide is*

(*a*) $\frac{22}{10}$ (*b*) $\frac{22}{10}$
(*c*) $\frac{23}{10}$ (*d*) $\frac{23}{12}$ **(IIT-JEE, 2007)**

SOLUTION. Reaction: $^{23}_{11}\text{Na} \longrightarrow {}^0_{+1}\beta + {}^{23}_{10}\text{A}$

$$\therefore \quad \frac{\text{Atomic mass of A}}{\text{at. no. of A}} = \frac{23}{10}.$$

So, the correct answer is (*c*).

Type 1. To find number of half-lives (= *n*), use:

$$\left(\frac{1}{2}\right)^n = \frac{\%\text{ age of substance left behind}}{100}$$

or $\left(\frac{1}{2}\right)^n$ = Activity of substance left behind

or $\left(\frac{1}{2}\right)^n$ = Amount of substance left behind after the decay or disintegration

2. Time of disintegration = $t_{1/2}$ × number of half-lives (= *n*)

3. Decay constant, $\lambda = 0.693/t_{1/2}$

EXAMPLE 204. *It is observed that only 6.25% of a given radioactive sample is left undecayed after a period of 16 days. What is the decay constant of this sample in day*$^{-}$*?*

SOLUTION. (*i*) % age of sample left behind = 6.25. We know that:

$$\left(\frac{1}{2}\right)^n = \frac{\%\text{ age of sample left behind}}{100} = \frac{6.25}{100} = \frac{1}{16} = \left(\frac{1}{2}\right)^4$$

∴ number of half-lives (= *n*) = 4

(*ii*) Half-life, $t_{1/2}$

$$= \frac{\text{Time of disintegration}}{\text{number of half-lives}} = \frac{16\text{ days}}{4} = 4\text{ days.}$$ **Ans.**

(*iii*) Decay constant, $\lambda = \frac{0.693}{t_{1/2}} = \frac{0.693}{4\text{ days}} = 0.173\text{ day}$

EXAMPLE 205. *The half-life of a radioactive substance is 20 s. Calculate the time taken for the sample to decay 7/8 of the initial value.*

SOLUTION. $t_{1/2}$ = 20 *s*; since the sample has decayed by 7/8, so:

the amount of sample left behind = 1 – 7/8 = 1/8

$$\therefore \left(\frac{1}{2}\right)^n = \text{Amount of sample left behind} = \frac{1}{8} = \left(\frac{1}{2}\right)^3$$

∴ *n* = 3

Hence, time taken to decay = $t_{1/2}$ × number of half-lives = 20 s × 3 = 60 s. **Ans.**

EXAMPLE 206. *Find the half-life of a radioactive material if its activity drops to 1/16th of its original value in 30 years.*

SOLUTION. $t_{1/2}$ = ? ; Activity left behind = 1/16

Time of disintegration = 30 years. But :

$$\left(\frac{1}{2}\right)^n = \frac{1}{16} = \left(\frac{1}{2}\right)^4 \text{ ; so } n = 4$$

$$t_{1/2} = \frac{\text{Time of disintegration}}{\text{number of half-lives}} = \frac{50\text{ years}}{4} = 12.5\text{ years.}$$

PROBLEMS FOR PRACTICE

1. Fill in the blanks for the following reactions.

(*i*) $^{238}_{92}\mathbf{U} \rightarrow {}^{234}_{90}\mathbf{Th} + ?$, (*ii*) $^{234}_{90}\mathbf{Th} \rightarrow {}^{234}_{91}\mathbf{Pa} + ?$,

(*iii*) $^{27}_{13}\mathbf{Al}(\mathbf{D}, ?)^{25}_{12}\mathbf{Mg}$ **[Ans.** (*i*) $^{4}_{2}\mathbf{He}$, (*ii*) $^{0}_{-1}e$, (*iii*) $^{4}_{2}\mathbf{He}$

2. Fill in the blanks in the following : (*i*) neutron → proton + ?, (*ii*) neutron + ? → proton
(Ans. (*i*) π^-, (*ii*) π^+**)**

3. $^{133}_{56}\text{Ba}$ (group 2) undergoes K-capture. To which group the new element would belong ?
(Ans. Group 1**)**

4. Calculate the packing fraction, mass defect and energy released in the formation of $^{40}_{18}\text{Ar}$. Isotopic mass of proton = 1.007825, neutron = 1.008665 and Ar = 39.962384 amu.

(Ans. Packing fraction = – 9.4025; Mass defect = 0.369096 amu, Energy released = 343.81 MeV**)**

5. The amount of C-14 isotope in a piece of wood is found to be one sixth of its amount present in a fresh piece of wood. Calculate the age of wood. Half-life period of ^{14}C is 5770 years. **(Ans.** 14922 years**)**

6. A piece of wood was found to have C^{14}/C^{12} ratio 0.7 times that in a living plant. How long ago the plant was cut ? (Half-life of ^{14}C = 5770 years).
(Ans. 2970 years**)**

7. A piece of wood shows a ^{14}C activity which is 70% of the activity found in a fresh wood today. Calculate the age of the wood. ($t_{1/2}$ for $^{14}_{6}\text{C}$ is 5770 years).
(PSEB, 2000) (Ans. 2972 yrs**)**

8. Calculate the mass number of an element of 4*n* + 3 series having *n* = 58. **(Ans.** 235 a.m.u.**)**

9. Radioactive decay is a first order process. Radioactive carbon in wood sample decays with a half-life of 5770 years. What is the rate constant (in year^{-1}) for the decay ? What fraction would remain after 11540 years ? **(I.I.T., 1984) (Ans.** 25%**)**

10. It is known that 1g of ^{226}Ra emits 11.6×10^{17} α-particles per year. Given the half-life of ^{226}Ra be 1600 years. Compute the value of Avogadro's number.
(M.L.N.R., 1983) (Ans. 6.052×10^{23}**)**

11. The activity of a radio isotope falls to 12.5% in 90 days. Compute the half-life and the decay constant of the radio-isotope. **(M.L.N.R., 1986)**
(Ans. 30 days**)**

12. Number of β-particles emitted during the transformation of $^{x}_{y}\text{A}$ to $^{m}_{n}\text{B}$

(*a*) $x - m/4$ (*b*) $n + (x - m/2) + y$

(*c*) $n + (x + m/2) - y$ (*d*) $2y - n + x - m$

(AMU, MEd, 2010). Ans (*c*)

13. The number of neutrons emitted when $^{235}_{92}\text{U}$ undergoes controlled nuclear fission to $^{142}_{54}\text{Xe}$ and $^{90}_{38}\text{Sr}$ is : **(Ans. 3) (IIT-JEE, 2010)**

14. Calculate the rate of decay of 1g radium (at. mass = 226) having $t_{1/2}$ = 1600 years in rutherford.
(Ans; 3.7 × 10^4 rutherford).

15. To which radioactive series, $^{227}_{89}\text{Ac}$ appears during disintegration? **(Ans; 4*n* + 3 series).**

16. A positron is emitted from $^{39}_{19}\text{K}$. The ratio of the atomic mass and atomic number of resulting nucleide is :

(*a*) 4 (*b*) 3.1

(*c*) 2.16 (*d*) 1.12 **[Ans. (c)].**

17. What is the half-life of a radioactive substance if 93.75% of any given amount of the substance disintegrates in 30 minutes.

(*a*) 7 min. 30 second (*b*) 6 min

(*c*) 12 min (*d*) 15 min **[Ans. (*a*)].**

18. The radius of nucleus of Ar-40 is :

(*a*) 2×10^{9} m (*b*) 5.1×10^{-15} m

(*c*) 4.4×10^{-9} (*d*) 3.5×10^{-10} **[Ans. (b)].**

19. If the packing mass of S-35 is 34.96903, the value of packing fraction will be :

(*a*) –1.1 (*b*) –2.3

(*c*) –7.234 (*d*) –8.848 **[Ans. (d)].**

20. If half-life of 15g of a radioactive isotope is 25 days, calculate the half-life of 1g sample. **(Ans. 25 days)**

21. Calculate the amount of radioactivity that is left behind when two millicurie of radioactive element of half-life 6 days is stored for 18 days.
(Ans. 1/4 millicurie).

22
CHAPTER

Volumetric Analysis

22.1 VOLUMETRIC ANALYSIS

The analysis which involves the exact measurement of volumes is called volumetric analysis.

Standard Solution. It is a solution of known strength. The concentration of a substance in a given volume of its solution is called its strength.

Standard substances (**Primary standards**). All such substances which are available in pure state and whose standard solution can be prepared by direct weighing are called primary standards. For example, anhydrous sodium carbonate, oxalic acid, potassium dichromate, ferrous ammonium sulphate (Mohr's salt) etc. Such substances are highly pure, stable in air, have high mol. wt. and are readily soluble in water.

Secondary standards. All such substances which do not satisfy the conditions of primary standard and whose standard solutions cannot be prepared by direct weighing are called secondary standards. For example, potassium permanganate, HCl, H_2SO_4, sodium thiosulphate, iodine, sodium hydroxide etc.

Strength of a Solution. It is expressed in gL^-, normality (*i.e.*, gram equivalent per litre) or molarity (*i.e.*, gram mol L^-).

A normal solution (1N) of a substance is that whose 1L solution contains gram equivalent of that substance. A molar solution (1M) of a substance is that whose 1L solution contains gram molecular weight of a substance.

Strength in gL^- = Normality × Eq. wt.

22.2 NORMALITY EQUATION OR LAW OF NORMALITIES

This law is based on the law of equivalents. **According to this law :**

"*Equal volumes of equinormal solutions will completely react with each other*". The substances react in the ratio of their equivalent weights. Thus according to this law, 50 mL of 1N Na_2CO_3 solution will be equivalent to 50 mL of 1N HCl solution. Similarly 50 mL of 1N Na_2CO_3 solution will be equivalent to 100 mL of N/2 HCl solution. It can also be expressed in terms of the following **normality equation** :

$$N_1V_1\text{(one substance)} = N_2V_2\text{ (another substance)}$$

In case of acid-base titration :

$$\mathbf{N_1V_1\text{ (acid)} = N_2V_2\text{ (base)}}$$

This equation is based on the fact that the number of g-equivalents of a given substance contained in a given volume of the given solution is equal to the same number of g. equivalents of the same or different substances contained in the corresponding volume of that solution. Knowing any three of these factors (*i.e.*, N_1, V_1, N_2, V_2) in the normality equation, the fourth factor can be calculated. Here N_1 and V_1 represent the normality and volume of one substance while N_2 and V_2 represent the normality and volume of another substance.

22.3 MOLARITY EQUATION.

A molar solution (1M) of a substance is that which contains one gram molecular weight (or one g. mol) of it per litre of the solution.

For calculations in terms of molarity. Consider the following :

1. **Redox (or oxidation-reduction) reactions.** Consider the following redox reaction between $KMnO_4$ (oxidant) and $H_2C_2O_4$ (reductant)

$$\underset{\text{2 mol}}{2KMnO_4} + 3H_2SO_4 + \underset{\text{5 mol}}{5H_2C_2O_4} \longrightarrow K_2SO_4 + 2MnSO_4 + 10CO_2 + 8H_2O$$

According to balanced chemical equation, 2 mol of $KMnO_4$ react with 5 mol of $H_2C_2O_4$ (oxalic acid)

Hence :

$$\frac{(M_1V_1)/1000}{(M_2V_2)/1000} = \frac{2}{5} \text{ or } \frac{M_1V_1}{2} = \frac{M_2V_2}{5}$$

In general. $$\frac{(M_1V_1)\text{ solution A}}{(M_2V_2)\text{ solution B}} = \frac{\text{no. of mol of A in balanced equation}}{\text{no. of mol of B in balanced equation}}$$

Strength = Molarity of solution × mol. wt. (or molar mass) of solute.

Note: Normality = Molarity × (Valence factor)

2. **Acid - Base reactions.** Consider the following reaction

$$\underset{2\text{ mol}}{2NaOH} + \underset{1\text{ mol}}{H_2SO_4} \longrightarrow Na_2SO_4 + 2H_2O.$$

$$\text{Here, } \frac{M_1V_1(\text{NaOH})}{M_2V_2(H_2SO_4)} = \frac{\text{no. of mol of NaOH in the balanced equation}}{\text{no. of mol of } H_2SO_4 \text{ in the balanced equation}}$$

$$i.e., \quad \frac{M_1V_1(\text{NaOH})}{M_2V_2(H_2SO_4)} = \frac{2}{1}$$

22.4 ACID-BASE TITRATIONS-VISUAL METHOD (SINGLE TITRATION)

Visual method. In this method, different indicators are used to locate the titration end point. The indicators are organic compounds which have different colours at different pH ranges as shown in the following table 22.1.

Table 22.1

Indicator	*pH range and colours*	*Solution of indicator*
Methyl orange	3.0 (Red) – 4.4 (yellow)	0.1% in water
Methyl red	4.4 (red) – 6.2 (yellow)	0.2% in 60% alcohol
Litmus	5.0 (red) – 8.0 (blue)	2.5% in water, filtered on standing and made acidic with 1–2 drops of dil. HNO_3
Phenolphthalein	8.2 (colourless) - 10.0 (red)	0.1% in 50% alcohol

Note. Use methyl orange indicator in Na_2CO_3 or $NaHCO_3$ titrations and phenolphthalein indicator in titrations involving NaOH or KOH alkalies.

Following examples will help to know the use of above indicators in acid-base titrations.

1. **Single titrations.**

EXAMPLE 1. *Prepare exact 100 ml of N/10 HCl solution from the given concentrated acid. Provided N/10 Na_2CO_3 solution.*

SOLUTION. HCl is not a primary standard acid. Thus, following procedure is used to prepare exact N/10 HCl.

(1) *To prepare dilute HCl solution.* Take about 3 ml of concentrated HCl acid in a 250 ml measuring flask with the help of burette. Add distilled water, till exact 250 ml solution is obtained. Shake well.

(2) *To find the normality of above dilute HCl.* Take 20 ml of N/10 Na_2CO_3 solution in a titration flask, add 2-3 drops of methyl orange indicator. Titrate with dilute acid prepared above till yellow to pink colour is obtained. This is the end point. Let normality of dilute acid is N_1.

(3) To prepare, exact 100 ml of N/10 HCl. Using following normality equation we have

Dilute acid prepared *N/10 HCl to be prepared*

$$N_3V_3 = N_4V_4\,;$$

$$N_3 \times V_3 = \frac{1}{10} \times 100\,; \qquad \therefore \quad V_3 = \frac{10}{N_3} \text{ ml} = x \text{ ml (say)}$$

Take x ml of dilute acid prepared in 100 ml measuring flask, add more distilled water and make up the solution to exact 100 ml. It is exact N/10 HCl.

Note. For diluting conc. H_2SO_4, add conc. H_2SO_4 to excess water and not water to conc. H_2SO_4 because of the exothermic nature of the reaction.

EXAMPLE 2. *Prepare exact 100 mL of N/10 NaOH solution. Provided N/10 oxalic acid.*

SOLUTION. NaOH is not a primary standard substance. Thus, following procedure is used to prepare exact N/10 NaOH solution.

(1) **To prepare approximately N/10 NaOH SOLUTION. Eq. wt. of NaOH is 40.** In order to prepare approximately, N/10 NaOH solution, weigh $\frac{40 \times 250}{10 \times 1{,}000}$ *i.e.,* one gram of NaOH, dissolve in distilled water taken in a 250 ml flask, add more water to get 250 ml solution. Take 20 ml of this solution in a titration flask, add 1-2 drops of phenolphthalein as indicator and titrate with $N/10$ oxalic acid till pink to colourless solution is obtained which is the end point. Using normality equation ($N_1V_1 = N_2V_2$), find the normality (N_1) of NaOH.

(2) **To prepare exact 100 ml of N/10 NaOH SOLUTION.** Using normality equation, we have:

N/10 NaOH to be prepared NaOH of N_1 normality

$$N_3V_3 = N_1V_4\,;$$

$$\frac{1}{10} \times 100 = N_1 \times V_4\,;$$

$$\therefore \qquad V_4 = \frac{10}{N_1} \text{ml} = \boldsymbol{x} \textbf{ ml} \text{ (say)}$$

Take x ml of NaOH of N_1 normality in a 100 ml measuring flask, add distilled water and make up the solution to exact 100 ml. It is exact N/10 NaOH solution.

EXAMPLE 3. *Find the percentage purity of sodium carbonate in soda-ash, 2 g of which have been dissolved per 250 mL of the given solution. Provided N/10 H_2SO_4.*

SOLUTION.

250 ml solution contain soda-ash = 2 g

$$1{,}000 \text{ ml solution contain soda-ash} = \frac{2}{250} \times 1{,}000 = \mathbf{8\ g}$$

$$\therefore \qquad \text{Strength of } Na_2CO_3 = 8\ (gL^{-})$$

(2) Strength of pure Na_2CO_3 = Normality × Eq. wt. of $Na_2CO_3 = N_1 \times 53\ (gL^{-})$

(3) % age purity of Na_2CO_3

$$= \frac{53\ N_1}{8} \times 100 = x \text{ (say)}$$

EXAMPLE 4. *Determine the number of molecules (x) of crystallisation in $Na_2CO_3 . xH_2O$, 8 gram of which have been dissolved per litre of the given solution. Provided $N/10\ H_2SO_4$.*

SOLUTION. (1) Calculate normality (N_1) of Na_2CO_3 solution with the help of normality equation ($N_1V_1 = N_2V_2$)

(2) Eq. wt. of $Na_2CO_3xH_2O = 8/N_1 = a$ (say)

(3) Mol. wt. of $Na_2CO_3xH_2O$ = Eq. wt. × acidity of $Na_2CO_3xH_2O = a \times 2 = 2a$

(4) Mol. wt. of anhydrous $Na_2CO_3 = (2 \times 23) + 12 + (3 \times 16) = 106$

(5) Number of water molecules

$$(x) = \frac{\begin{array}{c}\text{Mol. wt. of}\\ Na_2CO_3 . xH_2O\end{array} (-) \begin{array}{c}\text{Mol. wt. of}\\ Na_2CO_3\end{array}}{18}$$

$$= \frac{2a - 106}{18} = \boldsymbol{b}\ \textbf{(say)}$$

EXAMPLE 5. *You are provided with a solution of sodium carbonate and potassium carbonate, 6.0 g of which have been dissolved per litre of the given solution. Calculate their percentage composition. Provided N/10 HCl.*

SOLUTION. (1) Using normality equation, ($N_1V_1 = N_2V_2$), let total normality of mixture is N_1.

(2) To find weight of Na_2CO_3 and K_2CO_3. Let Strength of $Na_2CO_3 = x$ (gL^-).

∴ Strength of $K_2CO_3 = 6 - x$ (gL^-)

Eq. wt. of $Na_2CO_3 = 53$; Eq. wt. of $K_2CO_3 = 69$

$$\therefore \text{Normality of } Na_2CO_3 = \frac{\text{Strength}}{\text{Eq. Wt.}} = \frac{x}{53}; \text{Normality of } K_2CO_3 = \frac{6-x}{69}$$

$$\therefore \quad \frac{x}{53} + \frac{6-x}{69} = N_1 \text{ (already calculated). From}$$

this equation, find x.

(3) Percentage composition of

$$Na_2CO_3 = \frac{x \times 100}{6} = a \text{ (say) ; Percentage}$$

composition of $K_2CO_3 = 100 - a = b$ (say).

EXAMPLE 6. *5.3 g of carbonate of a monovalent metal are dissolved per litre of a given solution. Determine volumetrically the atomic weight of the metal. Given $N/10\ H_2SO_4$.*

SOLUTION. *Reaction :*

$$M_2CO_3 + H_2SO_4 \longrightarrow M_2SO_4 + CO_2 + H_2O$$

Using normality equation ($N_1V_1 = N_2V_2$), find the normality (N_1) of the carbonate solution.

Eq. wt. of metal carbonate
= Strength/Normality ;
= $5.3/N_1 = x$ (say)

∴ Mol. wt. of M_2CO_3
= Eq. wt. × acidity of
M_2CO_3 ; $= x \times 2 = 2x$

If a = at. wt. of M, then

$a + 12 + (3 \times 16) = 2x$;

$$\therefore \quad a = \frac{2x - 60}{2}$$

22.5 DOUBLE TITRATIONS IN ACID-BASE REACTIONS

Such titrations are based on the selective use of indicators. The indicator phenolphthalein is affected by CO_2 while methyl orange is not. So, in order to determine the percentage composition of a mixture of NaOH and Na_2CO_3 or mixture of Na_2CO_3 and $NaHCO_3$, *firstly methyl orange is used as indicator.* This leads to the complete neutralisation of NaOH + Na_2CO_3 or Na_2CO_3 + $NaHCO_3$ respectively with standard acids.

$$NaOH + HCl \rightarrow NaCl + H_2O \ ; \ Na_2CO_3 + 2HCl \rightarrow 2NaCl + CO_2 + H_2O$$

In the second titration, phenolphthalein indicator is used which leads to the complete neutralisation of NaOH and half neutralisation of Na_2CO_3 with standard acid.

$$NaOH + HCl \longrightarrow NaCl + H_2O \ ; \ Na_2CO_3 + HCl \longrightarrow NaHCO_3 + HCl.$$

A similar method is used to analyse a mixture of (*i*) NaOH + K_2CO_3 (*ii*) KOH + Na_2CO_3 (*iii*) KOH + K_2CO_3 (*iv*) $KHCO_3$ + Na_2CO_3. (*v*) $KHCO_3$ + K_2CO_3 (*iv*) K_2CO_3 + $NaHCO_3$

EXAMPLE 7. *Determine the percentage composition of a mixture of sodium hydroxide and sodium carbonate in a solution. Provided 0.1 N HCl. Also 20 mL of given solution require 18.10 mL of acid (methyl orange indicator) and 11.80 mL of acid (phenolphthalein indicator used) for neutralisation.*

SOLUTION. First titration (methyl orange indicator). 20 mL of mixture solution ≡ 18.10 mL of 0.1 N HCl used to neutralise total NaOH and Na_2CO_3.

Second titration (phenolphthalein indicator). 20 mL of mixture solution ≡ 11.80 mL of 0.1 N HCl used to neutralise total NaOH and half of Na_2CO_3.

∴ Vol. of 0.1 N HCl used to neutralise Na_2CO_3 only = 2 (18.10 – 11.80) = 12.60 mL

Vol. of 0.1 N HCl used to neutralise NaOH = 18.10 – 12.60 = 5.5 mL

(*a*) To find strength of Na_2CO_3 (eq. wt. 53)

(*b*) To find strength of NaOH (eq. wt. 40)

Na_2CO_3 HCl	NaOH HCl
$N_1V_1 = N_2V_2$	$N_3V_3 = N_4V_4$
$N_1 \times 20.0 = 0.1 \times 12.6$,	$N_3 \times 20 = 0.1 \times 5.5$;
$\therefore N_1 = (0.1 \times 12.6)/20 = \frac{126}{2000}$	$\therefore N_3 = 55/2000$
Strength of $Na_2CO_3 = N_1 \times$ Eq. wt. = $(126 \times 53)/2000 = 3.339\ gL^-$	Strength of NaOH = $N_3 \times$ Eq. wt. = $(55 \times 40)/2000 = 1.1\ gL^-$
Total amount of Na_2CO_3 and NaOH = 3.339 + 1.1 = 4.439 g.	

∴ % age of Na_2CO_3 = (3.339 × 100)/4.439 = **75.22%**; % age of NaOH = 100 – 75.22 = **24.78%**

EXAMPLE 8. *Determine the percentage composition of sodium carbonate and sodium bicarbonate in a solution. Provided 0.095 N HCl. Also, 20 mL of the given solution require 21.30 mL of acid (methyl orange indicator) and 7.5 mL of acid (phenolphthalein indicator)* for *neutralisation.*

SOLUTION. *First titration (methyl orange indicator).* 20 mL of mixture solution ≡ 21.30 mL of 0.095 N HCl used to neutralise total Na_2CO_3 and $NaHCO_3$.

Second titration (phenolphthalein indicator). 20 mL of mixture solution ≡ 7.5 mL of 0.095 N HCl to neutralise half of Na_2CO_3

∴ Volume of 0.095 N HCl used for complete neutralisation of $Na_2CO_3 = 2 \times 7.5 = 15.0$ mL

Volume of 0.095 N HCl used to neutralise $NaHCO_3$ = 21.30 – 15.0 = 6.30 mL

(*a*) To find strength of Na_2CO_3 (eq. wt. 53)

Na_2CO_3 HCl

$N_1 V_1 = N_2 V_2$

$N_1 \times 20 = 0.095 \times 15$;

$\therefore N_1 = (15 \times 0.095)/20$

Strength of Na_2CO_3 $= N_1 \times$ Eq. wt. (= 53)

= (15 × 0.095) × 53/20

= 3.78 *g*

(*b*) To find strength of $NaHCO_3$ (eq. wt. 84)

$NaHCO_3$ HCl

$N_3 V_3 = N_4 V_4$; $N_3 \times 20 = 0.095 \times 6.3$

$N_3 = (0.095 \times 6.3)/20 = 0.0299$

Strength of $NaHCO_3$ $= N_3 \times$ Eq. wt. = 0.0299 × 84 = 2.51 gL^-

Total strength of Na_2CO_3 and $NaHCO_3$ = 3.78 + 2.51 = 6.29 gL^-

% age of Na_2CO_3 = (3.78 × 100)/6.29 = 60.1% ; % age of $NaHCO_3$ = 100 – 60.1 = 39.9%

EXAMPLE 9. *5g of a mixture of NaOH and KOH is dissolved in water and the solution made up to one litre. 20 mL of this solution required 22.0 mL of 0.095 N NHCl for complete neutralisation. Calculate the percentage composition of the mixture.*

SOLUTION. $NaOH + HCl \longrightarrow NaCl + H_2O$;

$KOH + HCl \longrightarrow KCl + H_2O$.

Let wt. of NaOH = *x* g ;

wt. of KOH = (5 – *x*) g.;

Eq. wt. of NaOH = 40 ;

∴ normality of NaOH = *x*/40; Eq. wt. of KOH = 56;

∴ Normality of KOH = (5 – *x*)/56

∴ Total normality = *x*/40 + (5 – *x*)/56

To find total normality of NaOH + KOH solution mixture.

Mixture alkali HCl

$N_1 V_1 = N_2 V_2$; $N_1 \times 20 = 0.095 \times 22$;

$N_1 = (0.095 \times 22)/20 = 0.1045$ (*ii*)

From (*i*) and (*ii*) we get, *x*/40 + (5 – *x*)/56 = 0.1045 or 56*x* + 200 – 40*x* = 234.08

or *x* = 2.13 g = wt. of NaOH ; wt. of KOH = 5 – 2.13 = 2.87 g

∴ % age of NaOH = (2.13 × 100)/5 = **42.6%** ; % age of KOH = 100 – 42.6 = 57.4%

EXAMPLE 10. *2.76g of a mixture of $CaCO_3$ and $MgCO_3$ was treated with 75 mL of 0.97 N HCl solution. The excess of acid required 12.75 mL of 1N NaOH for neutralisation. Calculate the percentage composition of the mixture.*

SOLUTION. Let wt. of $CaCO_3$ = *x* g ; wt. of $MgCO_3$ = 2.76 – *x* g.

Total acid taken = 75 mL of 0.97 N HCl = 75 × 0.97 = 72.75 mL of 1N HCl.

Acid left unreacted = 12.75 mL of 1N NaOH = 12.75 mL of 1N HCl.

∴ Vol. of 1N acid used = 72.75 – 12.75 = 60.0 mL.

(*a*) $\underset{100\text{ g}}{CaCO_3} + \underset{\substack{2\times1000\text{ mL}\\ \text{of 1 N acid}}}{2HCl} \longrightarrow CaCl_2 + CO_2 + H_2O$;

$\underset{84\text{ g}}{MgCO_3} + \underset{\substack{2\times1000\text{ mL}\\ \text{of 1 N acid}}}{2HCl} \longrightarrow MgCl_2 + CO_2 + H_2O$

100 g $CaCO_3$ require 1 N HCl = 2000 mL

x g $CaCO_3$ require 1 N HCl = (2000 *x*)/100 mL = 20 *x*

84 g $MgCO_3$ require 1N HCl = 2000 mL

(2.76 – *x*) g $MgCO_3$ require 1 N HCl = 2000 × (20.76 – x)/84

∴ Total 1N HCl acid used = [20 *x* + 2000 (2.76 – *x*)]/84 ;

∴ [20 *x* + 2000 (2.76 – *x*)/84] = 60

∴ *x* = 1.5 g = wt. of $CaCO_3$; wt. of $MgCO_3$ = 2.76 – 1.5 = 1.26 g.

% age of $CaCO_3$ = (1.5 × 100)/2.76 = **54.36%** ; % age of $MgCO_3$ = 100 – 54.36 = **45.64%**

EXAMPLE 11. *What volume of 12N H_2SO_4 be mixed with 3N H_2SO_4 to give one litre of 6N H_2SO_4 ?*

SOLUTION. Let *x* mL of 12N H_2SO_4 is mixed with *y* mL of 3N H_2SO_4. So, *x* × 12 + *y* × 3 = (*x* + *y*) × 6 or 12*x* + 3*y* = 6*x* + 6*y* or 2*x* = *y*.

But *x* + *y* = 1000 mL ; (∵ 2*x* = *y*)

∴ *x* + 2*x* = 100 ml; *x* = 1000 mL/3

or *x* = 333.33 mL and

y = 1000 – 333.33 = 666.67 mL.

Hence volume of 12N H_2SO_4 = 333.33 mL and that of 3N H_2SO_4 (= 666.67 mL) should be mixed to get 1L of 6N H_2SO_4.

EXAMPLE 12. *Calculate the strength of the resulting solution obtained by mixing 20 mL of N/2 HCl with 19.6 mL of 2N HNO_3 and 12.4 mL of N/10 H_2SO_4.*

SOLUTION. 20 mL of *N*/2 HCl = 10 mL of 1N HCl;

19.6 mL of 2N HNO_3 = 39.2 mL of 1N HNO_3 ;

12.4 mL of $N/10$ H_2SO_4 = 1.24 mL of 1N H_2SO_4.

Thus, total volume of given resulting solution

= 20 + 19.6 + 12.4

= 52.0 mL

Let N_1 = strength of resulting solution.

52 mL of resulting solution of

N_1 strength = 10 + 39.2 + 1.24

= 50.44 mL of 1 N acid

∴ $N_1 = (50.44 \times 1)/52 =$ **0.97.**

Example 13. *0.5 g of carbonate of a metal was dissolved in 12.5 mL of 1N HCl. The resulting solution required 25 mL of N/10 NaOH for complete neutralisation. Calculate the equivalent weight of the metal carbonate and the metal.*

Solution. 25 mL of $N/10$ NaOH = 25 × 1/10 = 2.5 mL of 1N NaOH

Volume of unreacted 1N HCl = 2.5 mL of 1N NaOH = 2.5 mL of 1N HCl

∴ Vol. of 1N HCl that reacted with 0.5 g metal carbonate = 12.5 – 2.5 = 10 mL

10 mL of 1N HCl reacted with metal carbonate = 0.5 g

1000 mL of 1N HCl that will react with 0.5 g metal carbonate = (0.5 × 1000)/10 = **50 g**

∴ Eq. wt. of metal carbonate = **50**

Eq. wt. of metal = Eq. wt. of metal carbonate – Eq. wt. of CO_3^{2-} = 50 – 30 = **20**

Example 14. *12.5 mL of a solution of N/10 H_2SO_4 exactly neutralised 10 mL of a base containing 2.4 g per 500 mL of the solution. Calculate the equivalent weight of the base.*

Solution. Since 12.5 mL of N/10 HCl ≡ 10 mL of N_1 base. So the normality (N_1) of the base = 12.5/ (10 × 10) = 0.125. Hence

$$\text{Eq. wt. of base} = gL^{-}/N_1 = \frac{(1000/500 \times 2.4)}{0.125} = \mathbf{38.4}$$

Example 15. *1.5 g of an acid having mol. wt. 90 required 33.2 mL of 1N NaOH for complete neutralisation. Calculate the basicity of the acid.*

Solution. 33.2 mL of 1N NaOH ≡ 1.5 g of acid

1000 mL of 1N NaOH ≡ (1.5 × 1000)/33.2 = 45 g of acid = g. Eq. wt. of acid

∴ Basicity of acid = Mol. wt/Eq. wt. = 90/45 = **2.**

Example 16. *1.03 g of a given sample of chalk ($CaCO_3$) was dissolved in 50 mL of 1N HCl and solution was made up to 250 mL. 20 mL of given 0.11N NaOH neutralised 18.5 mL of diluted residual acid. Calculate the percentage purity of chalk (at. wt. of Ca = 40, C = 12, O = 16).*

Solution. Wt. of chalk ($CaCO_3$) = 1.03 g ; Eq. wt. of $CaCO_3$ = [40 + 12 + (3 × 16)]/2 = 50

(*a*) *To find normality of diluted acid.*	(*b*) *To find volume of acid left unused.*
Diluted acid NaOH	Original HCl Diluted HCl
$N_1 V_1 = N_2 V_2$;	$N_3 V_3 = N_4 V_4$
$N_1 \times 18.5 = 0.11 \times 20$;	$1 \times V_3 = 0.1189 \times 250$;
∴ $N_1 = (0.11 \times 20)/18.5 =$ 0.1189	∴ $V_3 = 29.72$ mL
	∴ Vol of 1N HCl used to decompose $CaCO_3$ = 50 – 29.72 = 20.28 mL

(*c*) Wt. of pure $CaCO_3$ in 1.03 g chalk = (20.28 × 50)/1000 = 1.014 g.

(*d*) Percentage purity of chalk = (1.014 × 100)/1.03 = **98.45%**

Example 17. *5 mL of 8N nitric acid, 4.8 mL of 5N HCl and a certain volume of 17 M H_2SO_4 are mixed together and made up to 2 litre. 30 mL of this mixture exactly neutralised 42.9 mL of sodium carbonate solution containing 1g of Na_2CO_3. $10H_2O$ in 100 mL of water. Calculate the amount in grams of the sulphate ions in the solution.*

Solution. Molarity of H_2SO_4 = 17 M;

∴ Normality of H_2SO_4 = 2 × 17 = 34 N

Let volume of 34 N H_2SO_4 = V mL ; Na_2CO_3 per litre

= (1 × 1000)/100 = 10 g

∴ Total number of *m* gm equivalent of acid mixture

= (8 × 5) + (5 × 4.8) + 34

V = 64 + 34V

Normality of mixture solution = (64 + 34 V)/2000

[∵ 2L = 2 × 1000 = 2000 mL]

Number of *m*gm equivalent in 30 mL mixture solution

= (64 + 34 V) × 30/2000

Also, normality of $Na_2CO_3.10H_2O$ solution

= gL^{-}/Eq. wt. of $Na_2CO_3.10H_2O$

= 10/143 ...(*i*)

∴ Number of *m*gm equivalent of $Na_2CO_3.10H_2O$

= (10 × 42.9)/143 ...(*ii*)

Form (*i*) and (*ii*), we get, (64 + 34 V)/2000

= (10 × 42.9)/143

Thus 64 + 34 V = 200 or 34V = 136 or V = 4 mL

∴ mgm. equivalent of 34N H_2SO_4 = 34 × 4 = 136

Number of equivalents of H_2SO_4 = 136/1000 = 0.136

Number of equivalents of SO_4^{2-} = 0.136

Hence wt. of SO_4^{2-} in solution = 0.136 × Eq. wt. of SO_4^{2-} = 0.136 × 48 = **6.53g**

Example 18. *1.1g of impure sodium carbonate is dissolved in water and the solution is made up to 250 mL. To 50 mL of this made up solution, 50 mL of 0.1 NHCl is added and the mixture after shaking well required 10 mL of 0.16N NaOH solution for complete neutralisation. Calculate the percentage purity of the sample of sodium carbonate.*

Solution. No. of *m*gm equivalents of HCl added to 50 mL Na_2CO_3 solution = 50 × 0.1 = 5

mgm. equivalents of HCl left after reaction with 50 mL of Na_2CO_3 solution = *m*gm. equivalent of NaOH used = 10 × 0.16 = 1.6

$\therefore$ No. of *m*gm eq. of HCl used for 50 mL Na_2CO_3 solution = 5 – 1.6 = 3.4

$\therefore$ No of the *m*gm. eq. of Na_2CO_3 in 250 mL solution = (3.4 × 250)/50 = 17

$\therefore$ Amount of Na_2CO_3 in 17 *m*gm. eq. = (17 × 53)/1000 = 0.901g

[$\because$ Eq. wt. of Na_2CO_3 = 53]

Hence % age purity of Na_2CO_3 = (0.901 × 100)/1.1 = **81.9%**

Example 19. *A solution contains $NaHCO_3$ and Na_2CO_3. 20 mL of this solution required 4 mL of 1N HCl for titration with phenolphthalein as indicator. The titration was repeated with the same volume of the solution but with methyl orange as indicator. 10.5 mL of 1N HCl was required this time. Calculate the amount of $NaHCO_3$ and Na_2CO_3 in the solution.*

Solution. *Experiment 1*, when phenolphthalein is the indicator.

$$Na_2CO_3 + HCl \longrightarrow NaHCO_3 + NaCl$$

[Here eq. wt. of Na_2CO_3 = 106]

Experiment 2, when methyl orange is indicator

$$Na_2CO_3 + HCl \longrightarrow NaHCO_3 + HCl\,;$$

$$NaHCO_3 + HCl \longrightarrow NaCl + CO_2 + H_2O.$$

$$NaHCO_3 + HCl \longrightarrow NaCl + CO_2 + H_2O$$

(originally present).

(*i*) With phenolphthalein, no. of *m*gm. eq. of

Na_2CO_3 = 4 mL of 1N HCl = 1.0 × 4 = 4

$\therefore$ g. eq. of Na_2CO_3 = 4/1000 = 0.004;

$\therefore$ wt. of Na_2CO_3 = 0.004 × 106 = 0.424 g.

(*ii*) With methyl orange, no. of mgm. equivalent of Na_2CO_3 + mgm. eq. of $NaHCO_3$ (produced) + mgm. eq. of $NaHCO_3$ (originally present) = mgm eq. of 10.5 mL of 1.0N HCl

Or 4 + 4 + mgm. eq. of

$NaHCO_3$ = 1 N × 10.5 = 10.5;

8 + mgm. eq. of $NaHCO_3$ = 10.5

$\therefore$ mgm. eq. of $NaHCO_3$ = 10.5 – 8 = 2.5 ;

$\therefore$ wt. of $NaHCO_3$ = (2.5 × 84)/1000

= **0.21 g.**

22.6 TITRATIONS INVOLVING CALCULATIONS IN TERMS OF MOLARITY

In such titrations in which molarity of a reaction is involved, molarity of unknown solution can be calculated by the use of following general relation.

$$\frac{(\text{Molarity, }M_1 \times \text{Volume, }V_1)\text{ of acid}}{(\text{Molarity, }M_2 \times \text{Volume, }V_2)\text{ of alkali or base}}$$

$$= \frac{\text{no. of moles of acid used in acid – base reaction}}{\text{no. of moles of base used in acid – base reaction}}$$

For example, in sodium hydroxide and oxalic acid ($H_2C_2O_4$) titration, the balanced equation is :

$$\underset{\text{2 mole}}{2NaOH} + \underset{\text{1 mole}}{H_2C_2O_4} \longrightarrow Na_2C_2O_4 + 2H_2O$$

In this reaction, 2 mole of NaOH react completely with 1 mole of oxalic acid to form the products. So, if 20 mL of *M*/20 NaOH is neutralised by 20.1 mL of $H_2C_2O_4$ having unknown molarity, M_1 then M_1 can be calculated by using the relation :

$$\frac{(\text{Molarity, }M_1 \times \text{Volume, 20.1 mL})\text{ of }H_2C_2O_4}{(\text{Molarity, }1/20 \times \text{Volume, 20 mL})\text{ of NaOH}}$$

$$= \frac{\text{no. of moles of }H_2C_2O_4(=1)}{\text{no. of moles of NaOH}(=2)}$$

$$\therefore \quad \frac{M_1 \times 20.1}{1/20 \times 20} = \frac{1}{2}\,;$$

$$M_1 = \frac{1}{2} \times \frac{1}{20} \times \frac{20}{20.1} = \frac{1}{40.2}$$

Method to find strength in gL⁻. The strength of an acid or base can be determined by using the relation :

Strength = (Molarity × Molecular weight) of acid or base in gram per litre.

Following example is given for better understanding.

Example 20. *Calculate the atomic weight of the metal in the given solution of metal carbonate (M_2CO_3), 5.3 g of which are dissolved in one litre solution. 20 mL of carbonate solution is completely neutralised by 20.1 mL of the given M/10 HCl.*

Solution. $\underset{\text{1 mole}}{M_2CO_3} + \underset{\text{2 mole}}{2HCl} \longrightarrow 2MCl + CO_2 + H_2O$

(*i*) *To find molarity of M_2CO_3.* Applying molarity equation, we have

$$\frac{(\text{Molarity, }M_1 \times \text{Volume, }V_1)\text{ of HCl}}{(\text{Molarity, }M_2 \times \text{Volume, }V_2)\text{ of }M_2CO_3} = \frac{2}{1}$$

Substituting the values, we get

$$\frac{1/10 \times 20.1}{M_2 \times 20} = \frac{2}{1} \text{ or } M_2 = \frac{1}{10} \times \frac{20.1}{2 \times 20} = \frac{201}{4000}$$

(*ii*) *To find atomic weight of metal, M*

Wt. of M_2CO_3 = 5.3 gL⁻. Volume of M_2CO_3 taken for each titration, V_1 = 20 mL; Molarity of HCl,

M_2 = 1/10 Volume of HCl used

= 20.1 mL Molarity of M_2CO_3.

M_1 = ? Let atomic weight of metal,

M = *a*; Mol. wt. of M_2CO_3

= 2*a* + 12 + 48 = 2*a* + 60

Strength of M_2CO_3 = Molarity × mol. wt.

$$5.3 = \frac{201}{4000} \times (2a + 60)$$

$$\therefore \quad a = \frac{1}{2}\left[\frac{5.3 \times 4000}{201} - 60\right]$$

or *a* = 22.73 i.e., atomic weight of metal, M.

22.7 REDOX OR OXIDATION-REDUCTION TITRATIONS-$KMnO_4$, $K_2Cr_2O_7$, I_2 etc.

Equivalent weights of oxidising and reducing agents.

(*i*) In a redox reaction, **the equivalent weight of an oxidising agent** (oxidant) *is the weight that accepts one mole of electrons.*

(*ii*) In a redox reaction, **the equivalent weight of a reducing agent** (reductant) *is the weight that loses one mole of electrons.*

Thus equivalent weight of an oxidant or reductant is equal to its molecular weight divided by the number of electrons gained or lost in its ion-electron equation respectively.

Table 22.2

Substance	*Ion-electron equation*	*Eq. wt = mol wt. / No. of electrons lost or gained*
1. Potassium Permanganate ($KMnO_4$)	$MnO_4^- + 8H^+ + 5e^- \longrightarrow Mn^{2+} + 4H_2O$	$\frac{158}{5} = 31.6$
2. Hydrated ferrous sulphate ($FeSO_4.7H_2O$)	$Fe^{2+} \longrightarrow Fe^{3+} + e^-$	$\frac{278}{1} = 278$
3. Anhydrous ferrous sulphate ($FeSO_4$)	$Fe^{2+} \longrightarrow Fe^{3+} + e^-$	$\frac{152}{1} = 152$
4. Hydrated oxalic acid ($H_2C_2O_4.2H_2O$)	$C_2O_4^{2-} \longrightarrow 2CO_2 + 2e^-$	$\frac{126}{2} = 63$
5. Anhydrous oxalic acid ($H_2C_2O_4$)	$Fe^{2+} \longrightarrow Fe^{3+} + e^-$	$\frac{90}{2} = 45$
6. Mohr's salt (Ferrous ammonium sulphate, $FeSO_4(NH_4)_2SO_4.6H_2O$)	$Fe^{2+} \longrightarrow Fe^{3+} + e^-$	$\frac{392}{1} = 392$
7. Ferrous oxalate $FeC_2O_4.2H_2O$	$Fe^{+2} \longrightarrow Fe^{3+} + e^-$ $C_2O_4^{2-} \longrightarrow 2CO_2 + 2e^-$ $Fe^{2+} + C_2O_4^{2-} \longrightarrow Fe^{3+} + 2CO_2 + 3e^-$	$\frac{180}{3} = 60$
8. Sodium oxalate, $Na_2C_2O_4$	$C_2O_4^{2-} \longrightarrow 2CO_2 + 2e^-$	$\frac{134}{2} = 67$
9. Ammonium oxalate $(NH_4)_2C_2O_4$,	$C_2O_4^{2-} \longrightarrow 2CO_2 + 2e^-$	$\frac{142}{2} = 71$
10. Sulphur dioxide (SO_2)	$SO_2 + 2H_2O \longrightarrow HOSO_3^- + 3H^+ + 2e^-$	$\frac{64}{2} = 32$
11. Potassium dichromate ($K_2Cr_2O_7$)	$Cr_2O_7^{2-} + 14H^+ + 6e^- \longrightarrow 2Cr^{3+} + 7H_2O$	$\frac{294}{6} = 49$
12. Iodine (I_2)	$2I + 2e^- \longrightarrow 2I^-$	$\frac{254}{2} = 127$
13. Copper sulphate (hydrated) ($CuSO_4.5H_2O$)	$Cu^{2+} + e^- \longrightarrow Cu^+$	$\frac{249.5}{1} = 249.5$
14. Anhydrous copper sulphate, $CuSO_4$	$Cu^{2+} + e^- \longrightarrow Cu^+$	$\frac{159.5}{1} = 159.5$
15. Sodium thiosulphate ($Na_2S_2O_3.5H_2O$)	$S_2O_3^{2-} \longrightarrow \frac{1}{2}S_4O_6^{2-} + e^-$	$\frac{248}{1} = 248$
16. Sodium thiosulphate (anhydrous)	$S_2O_3^{2-} \longrightarrow \frac{1}{2}S_4O_6^{2-} + e^-$	$\frac{158}{1} = 158$
17. Stannous chloride ($SnCl_2.2H_2O$)	$Sn^{2+} \longrightarrow Sn^{4+} + 2e^-$	$\frac{225.6}{2} = 112.8$
18. Arsenous oxide (As_2O_3)	$2As^{3+} \longrightarrow 2As^{5+} + 4e^-$	$\frac{198}{4} = 49.5$
19. Arsenic (As)	$As^{3+} \longrightarrow As^{5+} + 2e^-$	$\frac{75}{2} = 37.5$
20. Sodium arsenite (Na_3AsO_3)	$AsO_3^{3-} + H_2O \longrightarrow AsO_4^{3-} + 2H^+ + 2e^-$	$\frac{192}{2} = 96$
21. Tartaremtic CH(OH)COOK | $CHOHCOO(OSb)\frac{1}{2}H_2O$	$Sb^{3+} \longrightarrow Sb^{5+} + 2e^-$	$\frac{334}{2} = 167$
22. Antimonous oxide (Sb_2O_3)	$2Sb^{3+} \longrightarrow 2Sb^{5+} + 4e^-$	$\frac{292}{4} = 73$
23. Antimony (Sb)	$Sb^{3+} \longrightarrow Sb^{5+} + 2e^-$	$\frac{122}{2} = 61$

Another definition of equivalent weight. *The equivalent weight of a substance is that weight of it which gives rise to or react with 127 parts by weight of iodine and 8 parts by weight of oxygen.* The equivalent weight of some oxidants and reductants are found as follows by using this definition.

(*i*) **To find equivalent weight of $KMnO_4$** from the equation

$$\underset{\substack{3(39+55+64)\\=316\text{ g}}}{2KMnO_4} + 3H_2SO_4 \longrightarrow K_2SO_4 + 2MnSO_4 + 3H_2O + \underset{\substack{5\times16\\=80\text{g}}}{5O}$$

we have, 80 g oxygen ≡ 316 g $KMnO_4$;

$$\therefore \quad 8 \text{ g oxygen} \equiv \frac{316}{80} \times 8 = 31.6 \text{ g } KMnO_4$$

$\therefore$ Eq. wt. of $KMnO_4$ = **31.6.**

(*ii*) **To find equivalent weight of $FeSO_4$** from the reaction.

$$\underset{\substack{2(56+32+64)\\=304\text{ g}}}{2FeSO_4} + H_2SO_4 + \underset{\substack{1\times16\\=16\text{ g}}}{O} \longrightarrow Fe_2(SO_4)_3 + H_2O$$

we have,

$$16 \text{ g oxygen} = 304 \text{ g } FeSO_4;$$

$$\therefore \quad 8 \text{ g Oxygen} = \frac{304}{16} \times 8 = 152 \text{ g } FeSO_4.$$

$$\therefore \quad \text{Eq. wt. of } FeSO_4 = 152.$$

22.8 POTASSIUM PERMANGANATE TITRATIONS

$KMnO_4$ (potassium permanganate) is a powerful oxidising agent. It acts as an oxidant in acidic, basic as well as neutral medium. But in basic and neutral medium, it does not change exclusively into Mn^{2+} ions. So, **$KMnO_4$ titrations** to estimate reducing agents like *ferrous sulphate, ferrous ammonium sulphate* (*Mohr's salt*), *oxalic acid, oxalates* and *hydrogen peroxide* are done in **acidic medium.** The titrations in acidic medium involve the following key equation.

$$2KMnO_4 + 3H_2SO_4 \longrightarrow K_2SO_4 + 2MnSO_4 + 3H_2O + 5O;$$

Or $MnO_4^- + 8H^+ + 5e^- \longrightarrow Mn^{2+} + 4H_2O$ (Ionic equation)

The electrons required in the above reaction are provided by reducing agents such as :

$$Fe^{2+} \longrightarrow Fe^{3+} + e^- \,;\, C_2O_4^{2-} \longrightarrow 2CO_2 + 2e^-$$

Use of H_2SO_4 in titration. Out of the mineral acids (H_2SO_4, HCl, HNO_3) available, only H_2SO_4 is used in the redox titrations because it has no action on reductants in $KMnO_4$ solution. HNO_3 is not suitable because it is itself an oxidant and may oxidise some reducing agents like Fe^{2+} ions. HCl cannot be used because it reacts with $KMnO_4$ particularly in presence of Fe^{2+} ions to produce *chlorine* (an oxidant).

Visual method. $KMnO_4$ solution has dark purple colour. During redox titration (say $KMnO_4$ *vs.* Fe^{2+} in acidic medium), $KMnO_4$ (oxidant) solution is taken in the burette and Fe^{2+} (*i.e.* $FeSO_4$) solution is taken in the titration flask. When a drop of $KMnO_4$ is added to Fe^{2+} ion solution, the pink colour disappears because of the formation of Mn^{2+} ions (colourless). As soon as, the reducing agent (say Fe^{2+}) is used up, a single drop of $KMnO_4$ imparts faint pink colour, which is the end point. So, $KMnO_4$ acts as a **self-indicator.**

Following examples will help to know the method of titration and applications of $KMnO_4$ as **self-indicator.**

EXAMPLE 21. *How can you prepare one litre of 0.02 M solution of $KMnO_4$? (at. wt. K = 39, Mn = 55).*

SOLUTION. $KMnO_4$ is not a primary standard. So, its standard solution (0.02M) can be prepared by titrating it with a primary standard reducing agent such as Mohr's salt *i.e.* $FeSO_4.(NH_4)_2SO_4.6H_2O$, sodium oxalate etc.

Procedure. g. mol. wt. of $KMnO_4 = 39 + 55 + (4 \times 16) = 158$ g

$\therefore$ 1M $KMnO_4 \equiv 158$ gL⁻ $KMnO_4$; 0.02 M $KMnO_4 \equiv 158 \times 0.02$ or 3.16 g L⁻ $KMnO_4$. Take a pyrex beaker of 1500 mL capacity, add about 3.2g $KMnO_4$ in it, add 1L water, cover the beaker with a clock glass, boil gently for 15 to 30 minutes, filter the solution through a funnel containing a plug of purified glass wool, store this $KMnO_4$ solution in a clean glass stoppered dark brown glass bottle. This solution is approximately 0.02 M.

Prepare a standard solution of 0.1 M Mohr's salt (primary standard) and titrate it with $KMnO_4$ solution prepared above. Let 19.8 mL of $KMnO_4$ is needed to oxidise 20 mL of Mohr's salt solution in dil H_2SO_4 medium (end point = appearance of pink colour). Now use the following equation to find the molarity of $KMnO_4$.

$$\underset{2\text{ mole}}{2KMnO_4} + 8H_2SO_4 + \underset{10\text{ mole}}{10FeSO_4} \longrightarrow K_2SO_4 + 2MnSO_4 + 5Fe_2(SO_4)_3 + 8H_2O$$

(*i*) *To find molarity, M_1 of $KMnO_4$ prepared.*

$$\frac{(\text{Molarity, } M_1 \times \text{Volume, } V_1) \text{ of } KMnO_4}{(\text{Molarity, } M_2 \times \text{Volume, } V_2) \text{ of Mohr's salt}} = \frac{2}{10};$$

$$\frac{M_1 \times 19.8}{0.1 \times 20} = \frac{2}{10}$$

$$\therefore \quad M_1 = \frac{2 \times 0.1 \times 20}{10 \times 19.8} = \frac{0.4}{19.8}$$

(*ii*) *To prepare exact 0.02 M $KMnO_4$.* Applying molarity equation, we have :

$KMnO_4$ solution to be prepared *$KMnO_4$ solution already prepared*

$$M_3 V_3 = M_4 V_4$$

$$0.02 \times 1000 = \frac{0.4}{19.8} \times V_4$$

$$\therefore \quad V_4 = [(0.02 \times 1000) \times 19.8]/0.4 = 990 \text{ mL}$$

Thus take 990 mL $KMnO_4$ solution prepared above in a 1L flask, add water and make the solution exact one litre. This solution is exact 0.02 M.

EXAMPLE 22. *How one litre of 0.1 N $KMnO_4$ solution is prepared ? (At. wt. of K = 39, Mn = 55, O = 16)*

SOLUTION. Eq. wt. of

$KMnO_4$ = 31.6 (See table 22.2)

Procedure. Prepare $KMnO_4$ solution as shown in example 21 by weighing 3.2 g $KMnO_4$; this solution is approximately 0.1 N.

Now prepare a standard solution of 0.1N Mohr's salt (primary standard) and titrate it with $KMnO_4$ solution prepared above. Let 19.0 mL of $KMnO_4$ is needed to oxidise 20 mL of Mohr's salt solution in dil. H_2SO_4 medium (end point = appearance of pink colour). Now use the following equation to find the normality (N_1) of $KMnO_4$ solution prepared.

(*i*) $KMnO_4$ solution Mohr's salt solution prepared

$$N_1 V_1 = N_2 V_2$$

$$N_1 \times 19.0 = 0.1 \times 20$$

$$\therefore \quad N_1 = (0.1 \times 20)/19 = 2/19$$

(*ii*) To prepare exact 0.1N $KMnO_4$

Required $KMnO_4$ Solution (say, 1000 mL) Prepared $KMnO_4$ solution

$$N_3 V_3 = N_4 V_4$$

$$0.1 \times 1000 = 2/19 \times V_2$$

$$\therefore \quad V_2 = (0.1 \times 1000 \times 19)/2 = 950 \text{ mL}$$

(*iii*) Thus take 950 mL of the $KMnO_4$ solution in one litre flask, add distilled water and make up the solution to exact one litre. This solution will be exact 0.1N.

EXAMPLE 23. *How will you prepare 250 mL of N/20 oxalic acid solution ?*

SOLUTION. Eq. wt. oxalic acid ($H_2C_2O_4.2H_2O$) = 63 (from table 22.2)

$$\begin{aligned} \therefore \quad \text{1 N oxalic acid} &\equiv \text{1 g equivalent of} \\ \text{oxalic acid/1,000 ml} &= \text{63 g/1,000 ml.} \\ \text{N/20 oxalic acid} &= \frac{63}{20}\ \text{g/1,000 ml or} \\ \text{3.15 g/litre} &= \frac{63 \times 250}{20 \times 1,000}\ \text{g/250 ml} \\ &= \text{0.7875 g/250 ml.} \end{aligned}$$

Weigh exactly 0.7875 g oxalic acid on a watch glass, transfer to 250 ml measuring flask, shake to dissolve, add more distilled water and make up the solution to exact 250 ml. It is N/20 oxalic acid.

EXAMPLE 24. *Determine the percentage purity of a given sample of $KMnO_4$, 0.8 g of which have been dissolved per 250 ml of the given solution. Provided N/10 $FeSO_4$ solution.*

SOLUTION. (*1*) *To find strength of $KMnO_4$.* Take 20 mL of $FeSO_4$ solution, add 20 ml dil H_2SO_4 and titrate with $KMnO_4$ solution till light pink colour (end point). From the volume of $KMnO_4$ used and using normality equation ($N_1V_1 = N_2V_2$), find the normality (N_1) of $KMnO_4$.

$$\begin{aligned} \text{Strength of } KMnO_4 &= \text{Normality} \times \text{Eq. wt. of } KMnO_4 \\ &= N_1 \times 31.6\ (gL^-) = a\ \text{(say)} \end{aligned}$$

(2) *% age purity of $KMnO_4$:*

$$\begin{aligned} \text{250 ml solution contains } KMnO_4 &= 0.8\ \text{g} \\ \text{1,000 ml solution contains } KMnO_4 &= \frac{0.8 \times 1,000}{250} \\ &= 3.2\ \text{g} \\ \therefore \quad \text{\% age purity of } KMnO_4 &= \frac{a}{3.2} \times 100 \end{aligned}$$

EXAMPLE 25. *Determine the number of molecules of water of crystallisation in oxalic acid, $H_2C_2O_4.xH_2O$, 6.3 g of which have been dissolved per litre of the given solution. Provided N/10 $KMnO_4$.*

SOLUTION. (1) *To find normality of oxalic acid.* Take 20 ml of oxalic acid, 20 mL dil. H_2SO_4, heat to 60° and titrate with N/10 $KMnO_4$ till just pink colour (end point). Let volume of $KMnO_4$ used is V_1. Using normality equation ($N_1V_1 = N_2V_2$), calculate the normality (N_2) of oxalic acid.

(2) Eq. wt. of oxalic acid = Strength/normality

$$= 6.3/N_2 = a\ \text{(say)}$$

Mol. wt. of (hydrated) oxalic acid = Eq. wt. × basicity of acid = a × 2 or **2*a*.**

(3) *To find the value of x.*

Mol. wt. of anhydrous oxalic acid,

$$H_2C_2O_4 = (2 \times 1) + (2 \times 12) + (4 \times 16) = 90$$

Mol. wt. of hydrated oxalic acid ($H_2C_2O_4.xH_2O$) (–)

Mol. wt. of anhydrous oxalic acid,

$$H_2C_2O_4 = 18x\ ;\ 2a - 90 = 18x$$

$$x = \mathbf{2a - 90/18.}$$

EXAMPLE 26. *You are provided with a solution of mixture of potassium permanganate and potassium sulphate, 4 g of which have been dissolved per litre of the given solution. Find the percentage composition of $KMnO_4$ and K_2SO_4. Provided N/10 $FeSO_4$ solution.*

SOLUTION. K_2SO_4 does not react with $KMnO_4$ but $FeSO_4$ reacts (see reaction page 581)

(1) *To find normality of $KMnO_4$ solution.* Take 20 ml of $FeSO_4$ solution in a titration flask, add 20 ml dil. H_2SO_4 and titrate with N/10 $KMnO_4$ till just pink colour (end point). Let the volume of $KMnO_4$ used is V_1 ml. Using normality equation ($N_1V_1 = N_2V_2$), the normality (N_1) of $KMnO_4$ is found out.

$$\begin{aligned} \text{(2) Strength of } KMnO_4 &= \text{Normality} \times \text{Eq. wt. of } KMnO_4 \\ &= N_1 \times 31.6 = a\ (gL^-)\ \text{(say)} \\ \text{(3) \% age of } KMnO_4 &= a \times 100/4 = \mathbf{25a}\ ; \\ \text{\% age of } K_2SO_4 &= \mathbf{100 - 25\,a.} \end{aligned}$$

EXAMPLE 27. *You are provided with a solution of a mixture of $FeSO_4$ and Mohr's salt, 35 g of which have been dissolved per litre of the given solution. Find the percentage composition of the mixture. Provided N/10 $KMnO_4$ solution.*

SOLUTION. (1) *To find total normality of mixture.* Take 20 ml of mixture solution, add 20 ml dil. H_2SO_4 and titrate with *N*/10 $KMnO_4$ solution till just pink colour (end point) is obtained. Let volume of *N*/10 $KMnO_4$ used is V_2. Using normality equation ($N_1V_1 = N_2V_2$), the normality (N_2) of mixture is found.

$$\begin{aligned} \text{(2) Let weight of } FeSO_4 &= x\ \text{g and thus wt. of} \\ \text{Mohr's salt} &= (35 - x)\ \text{g} \\ \text{Eq. wt. of } FeSO_4 &= 278\ ;\ \text{Eq. wt. of Mohr's salt} = 392 \end{aligned}$$

$$\therefore \text{ Normality of } FeSO_4 = \text{Strength/Eq. wt.} = \frac{35}{278}$$

$$\text{Normality of Mohr's salt} = \frac{\text{Strength}}{\text{Eq. wt.}} = \frac{35 - x}{392}$$

$$\therefore\ N_2\ \text{(found experimentally)} = \frac{35}{278} + \frac{35 - x}{392}$$

From this equation, value of 'x' is calculated.

$$\begin{aligned} \text{(3) \quad \% age of } FeSO_4 &= x \times 100/35 = a\ \text{(say)} \\ \text{\% age of Mohr's salt} &= \mathbf{100 - a.} \end{aligned}$$

22.9 BACK TITRATIONS

EXAMPLE 28. *Calculate the percentage purity of a given sample of lead acetate $Pb(CH_3COO)_2 3H_2O$, 1.1g of which was boiled with 50 mL of N/3 oxalic acid and about 5 mL of acetic acid, filtered and filtrate was made to exact 250 mL. 20 mL of* *diluted residual oxalic acid was completely oxidised by 18.50 mL of N/20 KMnO$_4$ (at. wt. of Pb = 207, C = 12, O = 16)*

Solution. The given 100 mL solution of lead acetate is boiled with 50 mL of N/3 oxalic acid, filtered and filtrate made up to exact 250 mL solution.

$$Pb(CH_3COO)_2 + H_2C_2O_4 \longrightarrow PbC_2O_4\downarrow + 2CH_3COOH$$

(*i*) *To find normality of diluted residual oxalic acid*

Residual diluted KMnO$_4$ Oxalic acid

$N_1 V_1 = N_2 V_2$

Or $N_1 \times 20 = 1/20 \times 18.5$;

$\therefore$ $N_1 = 185/4000 = 0.04625$

(*ii*) *To find volume of N/3 oxalic acid used.*

Diluted oxalic acid Original oxalic acid.

$N_3 V_3 = N_4 V_4$

$0.04625 \times 250 = 1/3 \times V_4$

$\therefore$ $V_4 = 0.04625 \times 250 \times 3$

$= 34.89$ mL

(*iii*) *Eq. wt. of hydrated lead acetate is as :*

$Pb(CH_3COO)_2.3H_2O \equiv H_2C_2O_4 \equiv O$

379 g 16 g

379/2 **8 g**

$\therefore$ Eq. wt. of hydrated lead acetate

$= 379/2 =$ **189.5**

(*iv*) Wt. of lead acetate = 1.10 g

(*v*) % age purity of sample

$= (0.967 \times 100)/1.1$

$= 87.9\%$ **Ans.**

$\therefore$ Volume of N/3 oxalic acid used

$= 50 - 34.69 = 15.31$ mL

Thus 15.31 mL of N/3 oxalic acid

$\equiv$ 0.967 g lead acetate

$\therefore$ Wt. of pure lead acetate

= (Eq. wt. × Vol. ×

normality)/1000 = $(189.5 \times 15.31)/3 \times 1000$

$= 0.967$ g

Example 29. *Calculate the percentage of MnO$_2$ and available oxygen in pyrolusite, 1.1 g of which was boiled with 50 mL of 1N oxalic acid and 50 mL dil. H$_2$SO$_4$, filtered and filtrate was made to exact 250 mL. 20 mL of this residual oxalic acid required 23.5 mL of 0.1N KMnO$_4$ for complete oxidation. Also calculate the available oxygen in the pyrolusite. (at. wt. of Mn = 55, O = 16).*

Solution. Wt. of pyrolusite = 1.1 g ;

volume of residual oxalic acid = 250 mL

(*i*) *To find volume of 1N oxalic acid consumed.*

(*a*) Residual oxalic acid KMnO$_4$

$N_1V_1 = N_2 V_2$

$N_1 \times 20 = 0.1 \times 23.5$;

$\therefore N_1 = (0.1 \times 23.5)/20 = 0.1175$

(*b*) Residual oxalic acid Original oxalic acid

$N_3V_3 = N_4V_4$

$0.1175 \times 250 = 1 \times V_4$;

$\therefore$ $V_4 = 29.375$ mL

(*c*) Vol. of 1N oxalic acid used

$= 50 - 29.375 = 20.625$ mL

(*d*) Eq. wt. MnO$_2$ = Mol. wt./2 = 87/2 = 43.5

$[\therefore\ MnO_2 + H_2SO_4 \longrightarrow MnSO_4 + H_2O + \underset{\text{Available oxygen}}{O}]$

$H_2C_2O_4 + O \longrightarrow 2CO_2 + H_2O$

$\therefore$ $MnO_2 \equiv O$; 16g 16g O ≡ 87 g MnO$_2$

55 + (2 × 16)g ; = 87g 8g O ≡ (87 × 8)/16 = 43.5]

$\therefore$ Wt. of pure MnO$_2$ in 1.1g pyrolusite

$= (20.625 \times 43.5)/1000 = 0.897$ g

(*e*) $\therefore$ % age of MnO$_2$ = $(0.897 \times 100)/1.1 = 81.54\%$

(*f*) *To find available oxygen.* (eq. wt. of O = 8)

Wt. of available 'O' in 1.1g pyrolusite

$= (20.625 \times 8)/1000 = 0.165$ g

$\therefore$ % age of available oxygen = $(0.165 \times 100)/1.1 = 15\%$

22.10 DOUBLE TITRATIONS

Example 30. *Calculate volumetrically the amount of each of oxalic acid (H$_2$C$_2$O$_4$) and sulphuric acid (H$_2$SO$_4$) per litre of the given solution if 18.7 mL of acid solution neutralises 20 mL of 0.1N NaOH and 20 mL of the mixture is oxidised completely by 21.2 mL of 0.05 N KMnO$_4$.*

Solution. *First titration*

Mixed acid solution NaOH solution

$N_1V_1 = N_2V_2$

$N_1 \times 18.7 = 1/10 \times 20$;

$\therefore$ $N_1 = 20/18.7 = 0.017$

Or Total normality of H$_2$SO$_4$, and oxalic acid = 0.107

$\therefore$ Normality of H$_2$SO$_4$ = 0.107– 0.053 = 0.054

Second titration. Only oxalic acid will react with KMnO$_4$

Oxalic acid solution KMnO$_4$ solution

$N_3V_3 = N_4V_4\ N_3 \times 20$

$= 0.05 \times 21.2$;

$\therefore$ $N_3 = (0.05 \times 21.2)/20 = 0.053$

= normality of oxalic acid

$\therefore$ Strength of H$_2$SO$_4$ = 0.054 × 49 = 2.64 gL$^-$

($\because$ Eq. wt. of H$_2$SO$_4$ = 49)

Also, strength of oxalic acid = 0.053 × 45 = 2.835 gL$^-$

($\because$ Eq. wt. of oxalic acid = 45)

Example 31. *Calculate volumetrically the amount of each of KOH and sodium oxalate Na$_2$C$_2$O$_4$ per litre of the given solution if 17.5 mL of the 0.1 N HCl neutralises 20 mL of the given solution and 20 mL of the given solution oxidises completely 22.6 mL of 0.1N KMnO$_4$.*

Solution. (*a*) *Titration I.* Mixture Vs HCl

$$N_1V_1 = N_2V_2\ ;\ N_1 \times 20 = 0.1 \times 17.5$$

$$\therefore \quad V_1 = (0.1 \times 17.5)/20 = 0.0875\ ;$$

Eq. wt. KOH = 56

∴ Wt. of KOH = 0.0875 × 56 = 4.9 gL^-

(*b*) *Titration II.* Mixture Vs $KMnO_4$

$$N_3V_3 = N_4V_4$$

$$N_3 \times 20 = 0.1 \times 22.6\ ;$$

$$N_3 = (0.1 \times 22.6)/20 = 0.113\ ;$$

Eq. wt. of $Na_2C_2O_4$ = Mol. wt./2 = 134/2 = 67

∴ Wt. of $Na_2C_2O_4$ = 0.113 × 67 = 7.571 g L^-

(*c*) Total wt. of KOH and $Na_2C_2O_4$

= 4.9 + 7.571 = 12.471 g

% age of KOH = (4.9 × 100)/12.471

= **39.29%**

% age of $Na_2C_2O_4$ = 100 – 39.29 = **60.71%**

22.11 $KMnO_4$ TITRATIONS IN TERMS OF MOLARITY OF A GIVEN SOLUTION

Following relation is used for this purpose.

$$\frac{(\text{Molarity, } M_1 \times \text{Volume, } V_1) \text{ of } KMnO_4 \text{ (oxidant)}}{(\text{Molarity, } M_2 \times \text{Volume, } V_2) \text{ of reductant (e.g., } FeSO_4)}$$

$$= \frac{\text{no. of moles of } KMnO_4 \text{ used in redox reaction}}{\text{no. of moles of reductant (e.g., } FeSO_4) \text{ used in redox reaction.}}$$

Method to find strength in gL^-. The strength of an oxidant ($KMnO_4$) or reductant (*e.g.*, $FeSO_4$) can be determined by using the relation :

Strength = (Molarity × Molecular weight) of oxidant, $KMnO_4$ or reductant (*e.g.* $FeSO_4$) respectively.

Following example is given for clarity.

Example 32. *Determine the molarity and strength in* gL^- *of a given solution of* $KMnO_4$ *if 20 mL of M/50 oxalic acid need 20.5 mL of* $KMnO_4$ *for its complete oxidation.*

Solution.

$$\underset{2\text{ mole}}{2KMnO_4} + 3H_2SO_4 + \underset{5\text{ mole}}{5H_2C_2O_4} \rightarrow K_2SO_4 + 2MnSO_4 + 8H_2O + 10CO_2$$

From above relation, we find that 2 moles of $KMnO_4$ oxidise 5 moles of oxalic acid. Volume of $KMnO_4$ used, V_1 = 20.5 mL

$$\therefore \frac{(\text{Molarity} \times \text{Volume}) \text{ of } KMnO_4}{(\text{Molarity} \times \text{Volume}) \text{ of oxalic acid}} = \frac{2}{5} \qquad ...(i)$$

Molarity of $KMnO_4$, M_1 = ?

Substituting the values in equation (*i*),

Volume of oxalic acid, V_2 = 20 mL
Molarity of oxalic acid, M_2 = 1/50

$$\text{we get :} \quad \frac{M_1 \times 20.5}{1/50 \times 20} = \frac{2}{5}\ ;$$

$$M_1 = \frac{2}{5} \times \frac{1}{50} \times \frac{20}{20.5}$$

$$= \mathbf{7.8 \times 10^{-3}} \qquad \textbf{Ans.}$$

Example 33. *Determine the number of molecules of water of crystallisation in a given sample of Mohr's salt,* $FeSO_4.(NH_4)_2SO_4.xH_2O$, *9.8 g of which have been dissolved per 250 mL of the given solution. Experiment indicates that 19.8 mL of M/50* $KMnO_4$ *completely oxidised 20 mL of Mohr's salt solution.*

Solution. The required reaction is :

$$\underset{(2\text{ mole})}{2KMnO_4} + 8H_2SO_4 + \underset{(10\text{ mole})}{10FeSO_4.(NH_4)_2SO_4.xH_2O} \rightarrow K_2SO_4 + 2MnSO_4 + 5Fe_2(SO_4)_3 + 10(NH_4)_2SO_4 + (10x + 8)H_2O$$

From above relation, we find that 2 moles of $KMnO_4$ oxidise 10 moles of Mohr's salt.

(*i*) *To find molarity of Mohr's salt.*

$$\frac{(\text{Molarity} \times \text{Volume}) \text{ of } KMnO_4}{(\text{Molarity} \times \text{Volume}) \text{ of Mohr's salt}} = \frac{2}{10} \qquad ...(1)$$

Substituting the values in equation (1), we get :

$$\frac{1/50 \times 19.8}{M_2 \times 20} = \frac{2}{10}\ ;\ M_2 = 0.099\ ;$$

Molarity of Mohr's salt = 0.099.

(*ii*) *To find the value of x.*

Volume of $KMnO_4$ used, V_1 = 19.8 mL
Volume of oxalic acid, V_2 = 20 mL
Molarity of $KMnO_4$, M_1 = 1/50
Molarity of Mohr's salt, M_2 = ?
Mol. wt. of Mohr's salt = 248 + 18*x*
Wt. of Mohr's salt = (9.8 × 1000)/250
= 39.2 g

Strength of Mohr's salt = Molarity × Mol. wt. of Mohr's salt

$$39.2 = 0.099 \times (284 + 18x)$$

$$\therefore \quad x = \frac{1}{18}\left[\left(\frac{39.2}{0.099}\right) - 284\right]$$

$$= \mathbf{6.2 \simeq 6} \qquad \textbf{Ans.}$$

22.12 POTASSIUM DICHROMATE ($K_2Cr_2O_7$) TITRATIONS

For such titrations, one must know the equivalent weights and molecular weights of oxidants and reductants taking part in their redox titrations. *e.g.*,

(*i*) To find equivalent weight of $K_2Cr_2O_7$ from the ionic reactions in acidic medium.

$$Cr_2O_7^{2-} + 14H^+ + 6e^- \longrightarrow 2Cr^{3+} + 6H_2O \text{ (reduction)}$$

$$\therefore \text{Eq. wt. of } K_2Cr_2O_7 = \frac{\text{Mol. wt. of } K_2Cr_2O_7}{\text{no. of electrons gained}}$$

$$= \frac{(2 \times 39) + (2 \times 52) + (7 \times 16)}{6} = 49$$

(*ii*) To find equivalent weight of reductants like $FeSO_4.7H_2O$, Mohr's salt, oxalic acid, sodium oxalate, SO_2 etc, see table 22.2.

Example 34. *You are provided with a solution of Mohr's salt,* $FeSO_4.(NH_4)_2SO_4.xH_2O$, *20 g of which have been dissolved* *per litre. Determine volumetrically, the value of x. Given N/20 $K_2Cr_2O_7$ solution.*

Solution. (1) *To find the normality of Mohr's salt.* Take 20 ml of the Mohr's salt solution, add 100 ml of 2 N H_2SO_4, about 8 drops of N-phenylanthranilic acid as indicator and titrate with N/20 $K_2Cr_2O_7$ solution till green to violet red colour (end point). From the volume (V_2) of $K_2Cr_2O_7$ used, calculate the *normality* (N_1) of Mohr's salt solution using normality equation ($N_1V_1 = N_2V_2$).

(2) *To find the value of 'x'*

Eq. wt. of hydrated Mohr's salt = Strength/normality = $20/N_1 = a$ (say) = Mol. wt. of hydrated salt

Eq. wt. of anhydrous Mohr's salt, $FeSO_4.(NH_4)_2SO_4$ = 284.

Mol. wt. of hydrated salt (–) Mol. wt. of anhydrous salt = $18x$; $a - 284 = 18x$

$$\boldsymbol{x = a - 284/18.}$$

Example 35. *The given solution has been prepared by dissolving ferric alum, $Fe_2(SO_4)_3.(NH_4)_2SO_4.\ 24H_2O$ in very dilute sulphuric acid. Determine volumetrically, the following:*

(*i*)*Fe^{3+} ions in gram molecules* (*ii*) *Ferric alum in gram equivalents. Provided N/10 Mohr's salt solution.*

Solution. A known volume of ferric alum is reduced with stannous chloride method and titrated with $K_2Cr_2O_7$ to get different strengths of ions etc.

Reactions

(*i*) $Fe_2(SO_4)_3.(NH_4)_2SO_4.24H_2O \longrightarrow Fe_2(SO_4)_3 + (NH_4)_2SO_4 + 24H_2O$

(*ii*) $Fe_2(SO_4)_3 + 6HCl \longrightarrow 2FeCl_3 + 3H_2SO_4$;

$2FeCl_3 + SnCl_2 \longrightarrow 2FeCl_2 + SnCl_4$

(*iii*) $\underset{\text{(excess)}}{SnCl_2} + 2HgCl_2 \longrightarrow SnCl_4 + Hg_2Cl_2\downarrow$;

$$2FeCl_2 + 2HCl + \underbrace{[O]}_{\text{From } K_2Cr_2O_7/H_2SO_4} \longrightarrow 2FeCl_3 + H_2O$$

Eq. wt. of ferric alum. From above equations, we have

$$\underset{\text{964 parts}}{Fe_2(SO_4)_3.(NH_4)_2SO_4.24H_2O} \equiv Fe_2(SO_4)_3 \equiv 2FeCl_3 \equiv 2FeCl_2 \equiv \underset{\text{16 parts}}{O}$$

16 parts by weight of oxygen ≡ 964 parts by weight of ferric alum

8 parts by weight of oxygen ≡ $\frac{964}{16} \times 8$ parts by weight of ferric alum ≡ 482

(*i*) *To find ferric alum in g.equivalents.* Let normality of $K_2Cr_2O_7$ is N_1 and V_1 mL of it is used for oxidation of Fe^{2+} ions.

$N_1V_1(K_2Cr_2O_7) = N_2$ (Fe^{2+} obtained after reducing ferric alum) × V_2; $N_2 = \frac{N_1V_1}{V_2}$

(*ii*) *To find Fe^{3+} ions in g. molecules L^- or molarity.* N_2 × Eq. wt. = Molarity × mol. wt.

∴ Molarity = (N_2 × 482)/964 (found above) = $N_2/2$ **Ans.**

Example 36. *A solution 'B' contains 17 g of partially dehydrated sample of Mohr's salt dissolved per litre. Determine volumetrically, the percentage of dehydration of the given sample. Provided N/20 $K_2Cr_2O_7$ solution.*

Solution. (1) *To find normality of Mohr's solution.* Take 20 ml of Mohr's solution, add 100 ml of 2 N H_2SO_4, about 8 drops of N-phenylanthranilic acid indicator and titrate with N/20 $K_2Cr_2O_7$ solution till green to violet red colour (end point). Let volume of $K_2Cr_2O_7$ solution used is V_2 ml. From this find the **normality (N_1) of** Mohr's solution using normality equation ($N_1V_1 = N_2V_2$).

(2)*To find percentage dehydration of the given sample.*

Eq. wt. of hydrated Mohr's salt [$FeSO_4.(NH_4)_2SO_4.6H_2O$] = 392

Strength of hydrated Mohr's salt = Normality × Eq. wt. = $N_1 \times 392 = a$ (gL^-) say.

But strength of partially hydrated sample = 17 gL^-

∴ Loss in weight due to dehydration of Mohr's salt = $a - 17 = b$ g (say)

Thus, % age dehydration of the sample = $\boldsymbol{b \times 100/a}$.

(*b*) **$K_2Cr_2O_7$ titrations in terms of molarity of a solution.** For calculations see section 22.3.

Example 37. *You are provided with a solution af alkali metal dichromate ($M_2Cr_2O_7$), 2.2 g of which have been dissolved per 250 mL of the given solution. Find volumetrically, the atomic weight of the metal if 19.8 mL of 0.1 M oxalic acid reduces completely 20 mL of the given dichromate solution.*

Solution. The required equation is :

$$\underset{\text{(1 mole)}}{K_2Cr_2O_7} + 4H_2SO_4 + \underset{\text{3 mole}}{3H_2C_2O_4} \longrightarrow K_2SO_4 + Cr_2(SO_4)_3 + 7H_2O + 6CO_2$$

From above equation we see that

$$\frac{(\text{Molarity } M_1 \times \text{Volume, } V_1) \text{ of } M_2Cr_2O_7}{(\text{Molarity, } M_2 \times \text{Volume, } V_2) \text{ of } H_2C_2O_4} = \frac{1}{3}$$

$$\frac{M_1 \times 20}{0.1 \times 19.8} = \frac{1}{3} \ \therefore\ M_1 = \frac{0.1 \times 19.8}{20 \times 3} = 0.033$$

But strength of $M_2Cr_2O_7$

= Molarity × mol. wt. of $M_2Cr_2O_7$

8.8 = 0.033 × ($2a$ + 216)

∴ a = (266.7)– 216)/2 = **25.35.**

∴ Atomic weight of metal,

M = **25.35 a.m.u.**

250 mL solution contain

$M_2Cr_2O_7$ = 2.2g; 1000 mL solution contain

$M_2Cr_2O_7 = \frac{2.2 \times 1000}{250} = 8.8\ gL^-$; Volume of

$M_2Cr_2O_7$ used = 20 mL; Volume of

$H_2C_2O_4$ used = 19.8 mL

Mol. wt. of $M_2Cr_2O_7$ = 2 × at. wt. of M + 2 × 52 + 7 × 16

= $2a$ + 216 **where at. wt. of metal,**

M = a

22.13 IODINE TITRATIONS-IODIMETRY

Iodine is insoluble in water. Its solution is prepared in KI solution because of the formation of soluble KI_3. This **iodine solution acts as an oxidant.** Strong reducing agents like sodium thiosulphate and stannous chloride can react completely with iodine even in the acidic medium. However, weak reducing agents like arsenous oxide, sodium arsenite, trivalent antimony (*e.g.* tartaremetic, Sb_2O_3 etc.) react completely with iodine in **neutral medium.** The reactions of iodine with some reducing agents are :

(*i*) $I_2 + 2Na_2S_2O_3 \longrightarrow 2NaI + Na_2S_4O_6$.
(*ii*) $I_2 + SnCl_2 + 2HCl \longrightarrow SnCl_4 + 2HI$.
(*iii*) $I_2 + Na_3AsO_3 + H_2O \longrightarrow Na_3AsO_4 + 2HI$.
(*iv*) $2I_2 + Sb_2O_3 + 2H_2O \longrightarrow Sb_2O_5 + 4HI$.

From the above reactions, the equivalent weight of reducing agents ($Na_2S_2O_3$, $SnCl_2$, As_2O_3, Na_3AsO_3, Sb_2O_3 and tartaremetic) can be calculated by the use of following relations. The equivalent weight of the reducing agent will be equal to the number of parts of the substance that combine with 127 parts of iodine, I. (at. wt. of I = 127, Na = 23, S = 32, O = 16, Sn = 118.6, As = 75, Sb = 122)

$$I_2 \equiv 2Na_2S_2O_3.5H_2O \equiv$$
$$\frac{1}{2}As_2O_3 \equiv Na_3AsO_3 \equiv \frac{1}{2}Sb_2O_3 \equiv \text{Tartaremtic}$$

or
$$I \equiv Na_2S_2O_3.5H_2O \equiv \frac{1}{4}As_2O_3 \equiv$$
$$\frac{1}{2}Na_3AsO_3 \equiv \frac{1}{4}Sb_2O_3 \equiv \frac{1}{2}\text{ Tartaremtic} \quad ...(1)$$

No. of parts for equation (1) i.e., for I, $Na_2S_2O_3.5H_2O$...
(= eq. wt.) 127 248 1/4 × 198 1/2 × 192 1/4 × 292 1/2 × 334
= 49.5 = 96 = 73 = 167

For equivalent weights also see table 22.2.

EXAMPLE 38. *How will you prepare 1 litre of 0.1N and 0.1M sodium thiosulphate solution?*

SOLUTION. Sodium thiosulphate is a secondary standard substance. It reacts with iodine quantitatively as follows.

$$\underset{\text{2 mole}}{2Na_2S_2O_3} + \underset{\text{1 mole}}{I_2} \longrightarrow 2NaI + Na_2S_4O_6$$

Dissolve 24.8 g $Na_2S_2O_3$ in boiled out distilled water and make up the solution to one litre. Add 0.1 g Na_2CO_3 or a few drops of chloroform to make it stable for a few days.

(*I*) *To find exact molarity of $Na_2S_2O_3$ solution.* Let 19.6 mL of $Na_2S_2O_3$ solution reduce 20 mL of already standardised I_2 solution (0.05 M) completely. Thus we have,

1 mole $Na_2S_2O_3.5H_2O$
= [46 + 64 + 48 + 5(48)] = 248 g
1 mole I_2 = 2 × 127 = 254 g
∴ 1M $Na_2S_2O_3$ ≡ 248 g
0.1 M $Na_2S_2O_3$ ≡ 24.8 gL^-
Also 1M I_2 ≡ 254 gL^-
0.1 M I_2 ≡ 25.4 gL^-
Eq. wt. of
$Na_2S_2O_3.5H_2O$ = 248
Eq. wt. of I_2 = 127.

$$\frac{(\text{Molarity, } M_1 \times \text{Volume, } V_1) \text{ of } I_2}{(\text{Molarity, } M_2 \times \text{Volume, } V_2) \text{ of } Na_2S_2O_3} = \frac{1}{2}; \textbf{ Or } \frac{0.05 \times 20}{M_2 \times 19.6} = \frac{1}{2}$$

$$\therefore \quad M_2 = \frac{2 \times 0.05 \times 20}{19.6} = \frac{2}{19.6}$$

(*ii*) *To prepare exact 1000 mL of 0.1 M $Na_2S_2O_3$ solution.*

$Na_2S_2O_3$ solution to be prepared vs Orignal $Na_2S_2O_3$ solution.

$$M_3V_3 = M_4V_4;$$

Or 0.1 × 1000 mL = 2/19.6 × V_4 ; V_4 = 980 mL. Take 980 mL of $Na_2S_2O_3$ solution in a 1L flask and add water to get exact 1L solution. It will be exact 0.1 M $Na_2S_2O_3$. Or Take 1/2 × 980 *i.e.* 440 mL of $Na_2S_2O_3$ solution in a 500 mL measuring flask, add water to get exact 500 mL solution. It will be exact **0.1 M $Na_2S_2O_3$ SOLUTION.**

(*II*) (*i*) *To find exact normality of $Na_2S_2O_3$ solution.* Let 19.6 mL of $Na_2S_2O_3$ solution reduce 20 mL of already standardised I_2 solution (0.1N) completely. Thus, we have :

$Na_2S_2O_3$ solution vs I_2 solution

$$N_1V_1 = N_2V_2; N_1 \times 19.6 = 0.1 \times 20;$$
$$\therefore N_1 = \frac{2}{19.6}$$

(*ii*) *To prepare exact 1000 mL of 0.1N $Na_2S_2O_3$ solution.*

Required $Na_2S_2O_3$ Original $Na_2S_2O_3$ solution

$$N_3V_3 = N_4V_4;$$
$$0.1 \times 1000 \text{ mL} = 2/19.6 \times V_4; \therefore V_4 = 980 \text{ mL}$$

Take 980 mL of $Na_2S_2O_3$ solution in a 1L flask, add water to get exact 1 litre. This solution will be exact 0.1N $Na_2S_2O_3$ solution.

EXAMPLE 39. *How will you prepare 1L of 0.05 N iodine solution?*

SOLUTION. Iodine is a secondary standard substance. In order to prepare its standard solution, its approximate 0.05 N solution is prepared and its exact normality is found experimentally by the primary standard reductant (0.05 N As_2O_3 solution). From the redox reaction.

$$As_2O_3 + 2I_2 + 2H_2O \longrightarrow As_2O_5 + 4HI$$

Equivalent weight of As_2O_3 = 49.5

∴ 1N As_2O_3 ≡ 49.5 gL^- As_2O_3
0.05 N As_2O_3 ≡ 49.5 × 0.05
= 2.475 gL^- As_2O_3
Similarly, 1N I_2 ≡ 127 g L^- I_2
0.05 N I_2 ≡ 127 × 0.05 = 6.35 gL^-

$$\begin{aligned} 2I_2 \text{ or } 4I &\equiv As_2O_3 \\ 4 \times 127 \text{ gI} &\equiv (2 \times 75) + (23 \times 16) \equiv 198 \text{ g} \\ \therefore \quad 127 \text{ gI} &\equiv 198/4 = 49.5 \text{ g} \\ \therefore \text{Eq wt. of } As_2O_3 &= 49.5; \text{Eq. wt. of } I_2 = 127 \end{aligned}$$

Weigh about 6.35 g I_2, add in 1L measuring flask, dissolve it in concentrated KI solution, add more water and make up the solution to exact one litre with distilled water. Stopper the measuring flask and keep in a cool, dark place.

(*i*) *To find exact normality of I_2 solution.* Suppose 19.70 mL of I_2 solution completely oxidise 20 mL of 0.05 N As_2O_3 (reductant) solution. Using normality equation, we have :

$$\begin{array}{lcl} I_2 \text{ solution} & \text{vs} & As_2O_3 \text{ solution} \\ N_1V_1 & = & N_2V_2\,; \\ N_1 \times 19.7 & = & 0.05 \times 20;\ \therefore N_1 = 20 \times 0.05/19.7 \end{array}$$

(*ii*) *To prepare exact 1000 mL of 0.05 N I_2 solution.*

I_2 solution to be prepared vs Original I_2 solution

$$\begin{aligned} N_1V_1 &= N_2V_2\,; 0.05 \times 1000 \text{ mL} \\ &= (20 \times 0.05)/19.7 \times V_2 \\ \therefore \quad V_2 &= \frac{0.05 \times 1000 \times 19.7}{20 \times 0.05} \\ &= 985 \text{ mL} \end{aligned}$$

Take 985 mL of original I_2 solution in a 1L measuring flask, add distilled water and make up the solution to exact one litre. This solution will be exact 0.05N I_2 solution.

Example 40. *How will you prepare 1 litre of 0.05 M iodine solution?*

Solution. Iodine is a secondary standard substance. In order to prepare its standard solution, its approximate 0.05 M solution is prepared and then its exact molarity is found experimentally by a primary standard reductant (*e.g.*, 0.025M arsenic (III) oxide solution). Mol. wt. of I_2 is 254 (*i.e.* 2 × 127 = 254). So, 1M $I_2 \equiv 254 \text{ gL}^- I_2$; 0.05 M $I_2 \equiv 0.05 \times 254 = 12.7 \text{ gL}^- I_2$.

Weigh about 12.7 g I_2 and prepare its solution as shown in example 39

(*i*) *To find exact molarity of iodine solution.* Suppose 19.8 mL of I_2 solution completely oxidise 20 mL of 0.025 M As_2O_3 (reductant) solution according to following equation

$$As_2O_3 + 2I_2 + 2H_2O \rightleftarrows As_2O_5 + 4HI$$

1 mole 2 mole

$$\text{We know that: } \frac{(\text{Molarity, } M_1 \times \text{Volume, } V_1) \text{ of } I_2}{(\text{Molarity, } M_2 \times \text{Volume, } V_2) \text{ of } As_2O_3}$$

$$= \frac{2}{1}\,; \frac{M_1 \times 19.8}{0.025 \times 20} = \frac{2}{1}$$

$$M_1 = \frac{0.025 \times 20 \times 2}{19.8} = 0.0505$$

(*ii*) *To prepare exact 1 litre of 0.05 M I_2 solution.*

I_2 solution to be prepared Original I_2 solution.

$$\begin{aligned} M_1V_1 &= M_2V_2 \\ 0.05 \times 1000 \text{ mL} &= 0.505 \times V_2 \\ V_2 &= (0.05 \times 1000)/0.0505 \\ &= 990.1 \text{ mL} \end{aligned}$$

Take 990.1 mL of original iodine solution in 1L measuring flask, add distilled water and make exact 1000 mL. This solution will be 0.05 M I_2 solution.

Example 41. *12.4 g of $Na_2S_2O_3.xH_2O$ are dissolved per litre. Find the value of x. Given N/20 iodine solution. Use 20 mL of $Na_2S_2O_3.xH_2O$ solution for titration.*

Solution. 20 ml of $Na_2S_2O_3xH_2O$ solution is mixed with 2-3 drops of freshly prepared starch solution **(indicator)** and titrated with N/20 iodine solution till end point (colourless to blue) is reached.

Let V_2 ml of iodine solution is used to get end point. The normality (N_1) of $Na_2S_2O_3xH_2O$ is calculated as follows:

$$\begin{array}{ll} Na_2S_2O_3xH_2O & I_2 \text{ solution} \end{array}$$

$$N_1V_1 = N_2V_2$$

$$N_1 \times 20 = \frac{1}{20} \times V_2\,; \quad \therefore \quad N_1 = \frac{V_2}{400}$$

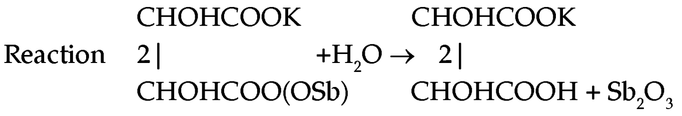
To calculate value of '*x*'

$$\begin{aligned} \text{Eq. wt. of } Na_2S_2O_3xH_2O &= \frac{\text{Strength}}{\text{Normality}} \\ &= \frac{12.4}{N_1 \textit{ i.e.}, V_2/400} = a \text{ (say)} \\ &= \text{Mol. wt. of } Na_2S_2O_3 \cdot xH_2O \\ \text{Mol. wt. of } Na_2S_2O_3 &= 2 \times 23 + 2 \times 32 + 3 \times 16 \\ &= 158 \end{aligned}$$

$$\begin{aligned} \text{Mol. wt. of } Na_2S_2O_3xH_2O \ (-) \text{ Mol. wt. of} & \\ Na_2S_2O_3 &= 18x\,; a - 158 = 18x \\ \boldsymbol{x} &= \boldsymbol{a - 158/18} \end{aligned}$$

Example 42. *Calculate the percentage of antimony in potassium antimony tartrate (tartaremtic), 2 g of which are dissolved per 250 mL of the given solution. Provided N/20 I_2* solution.

Solution.



$$\text{Reaction} \quad 2\begin{array}{l} CHOHCOOK \\ | \\ CHOHCOO(OSb) \end{array} + H_2O \rightarrow 2\begin{array}{l} CHOHCOOK \\ | \\ CHOHCOOH \end{array} + Sb_2O_3$$

$$Sb_2O_3 + 2I_2 + 2H_2O \rightleftarrows Sb_2O_5 + 4HI$$

Let V_1 ml of tartaremtic solution is used to get end point.

(*i*) The normality (N_1) of tartaremtic is calculated as follows :

$$\begin{array}{lcl} \text{Tartaremtic} & & I_2 \text{ solution} \\ N_1V_1 & = & N_2V_2 \end{array}$$

$$N_1 \times V_1 = \frac{1}{20} \times 20\,; \; N_1 = \frac{1}{V_1}$$

(*ii*) **To calculate strength of tartaremtic and antimony.**

250 ml solution contains tartaremtic = 2 g

1,000 ml solution contains tartaremtic

$$= \frac{2}{250} \times 1{,}000 = \mathbf{8\ gL^-}$$

Eq. wt. of antimony = 61

Strength of antimony = Normality × Eq. wt.

$$= N_1 \times 61 = x\ \text{gL}^-$$

To calculate percentage of antimony (Sb). Strength of tartaremtic $= 8\ \text{gL}^-$

$$\%\ \text{age of Sb} = \frac{x\ \text{gL}^-}{8\ \text{gL}^-} \times 100 = \frac{\mathbf{25}x}{\mathbf{2}}.$$

Example 43. *0.3 g of a sample of arsenous oxide (As_2O_3) was dissolved in NaOH solution, neutralised by HCl and volume made up to 100 ml. Determine volumetrically, the percentage purity of the sample. Given $\frac{N}{20}$ iodine solution.*

Solution. *Reaction* :

$$As_2O_3 + 6NaOH \longrightarrow 2Na_3AsO_3 + 3H_2O\ ;$$

$$Na_3AsO_3 + I_2 + H_2O \rightleftharpoons Na_3AsO_4 + 2HI$$

The above reaction is reversible. To check the backward reaction due to HI formed, sodium bicarbonate is added which neutralises HI and the reaction becomes irreversible.

$$NaHCO_3 + HI \longrightarrow NaI + CO_2 + H_2O$$

20 ml of N/20 iodine solution is mixed with 2-3 drops of freshly prepared starch solution (*indicator*) and titrated with sodium arsenite solution till end point (blue to colourless) is obtained.

Let V_1 ml of arsenite solution is used to get end point.

(*i*)The normality (N_1) of arsenite solution is calculated as follows :

Arsenite solution I$_2$-solution

$$N_1V_1 = N_2V_2$$

$$N_1 \times V_1 = \frac{1}{20} \times 20\ ;\ N_1 = \frac{1}{V_1}$$

(*ii*) **To calculate strength of arsenous oxide.**

100 ml solution contains As_2O_3 = 0.3 g

$$1{,}000 \text{ ml solution contains } As_2O_3 = \frac{0.3}{100} \times 1{,}000 = 3.0\ \text{g}$$

$$\text{Eq. wt. of } As_2O_3 = \frac{198}{4} = 49.5$$

Strength of As_2O_3 = Normality × Eq. wt.

$$= N_1 \times 49.5\ \text{gL}^- = x \text{ (say)}$$

(*iii*) **To calculate the percentage purity of arsenous oxide.**

Wt. of impure sample = 3.0 gL$^-$; Wt. of pure sample $= x\ \text{gL}^-$

$$\therefore \text{Percentage purity} = \frac{\mathbf{x}}{\mathbf{3}} \times \mathbf{100}.$$

22.14 IODOMETRIC TITRATIONS

In such titrations, the oxidants like $K_2Cr_2O_7$, $KMnO_4$, $CuSO_4.5H_2O$ etc. are treated with KI solution in acidic medium. The iodine so produced is titrated with standard sodium-thiosuphate solution, using freshly prepared starch solution as indicator. Disappearance of blue colour is the end point.

The equivalent weight of oxidants and reductants in such titration are given in table 22.2.

Example 44. *You are provided with a mixture of ferrous sulphate ($FeSO_4.7H_2O$) and sodium sulphate (Na_2SO_4), 20 g of which have been dissolved per litre of the given solution. Determine volumetrically, the percentage composition of the mixture. Provided 0.05 N hypo (sodium thiosuphate) solution and approximately 0.05N $K_2Cr_2O_7$ solution.*

Solution. (1) Let the normality of $K_2Cr_2O_7$ solution is N_1.

(2) Let the normality of $FeSO_4$ (because Na_2SO_4 does not react with $K_2Cr_2O_7$) solution is N_2.

(3) *Strength of $FeSO_4.7H_2O$* = Normality × Eq. wt. of $FeSO_4.7H_2O = N_2 \times 278 = x$ (gL$^-$)

(4) *Percentage of $FeSO_4.7H_2O$* $= \frac{x \times 100}{20} = 5x$

Example 45. *Determine the percentage purity and available oxygen in the given commercial sample of potassium permanganate, 2 g of which have been dissolved per litre of the given solution. Provided N/20 hypo solution.*

Solution. (1) *Let the normality of $KMnO_4$ is N_1.*

(2) Strength of $KMnO_4$ = Normality × Eq. wt. of $KMnO_4 = N_1 \times 31.6 = x$ (gL$^-$)

(3) Percentage purity of $KMnO_4 = \frac{x \times 100}{2} = 50x$

(4) Eq. wt. of oxygen = 8

Strength of available oxygen = Normality × Eq. wt. $= N_1 \times 8 = y$ (gL$^-$)

$$\therefore \text{Percentage of available oxygen} = \frac{y \times 100}{2} = 50y$$

Example 46. *Write the procedure for finding the nomality of a given solution of $CuSO_4$ iodometrically if 20 mL of the given solution require 19.9 mL of 0.1N $Na_2S_2O_3$ solution.*

(1) *To find normality of $CuSO_4$ solution.* Take 20 ml of given $CuSO_4$ solution, add a pinch of Na_2CO_3 to get turbidity, and 1 : 1 acetic acid till turbidity dissolves, add 10 ml of 10% KI solution, wait for one minute to liberate I_2, dilute with water and titrate with hypo solution. Add freshly prepared starch solution near the end point when solution is pale yellow. Blue to white precipitate of cuprous iodide (Cu_2I_2) is the end point. (*i*) *To find normality of $CuSO_4$ solution.*

$CuSO_4$ solution. vs $Na_2S_2O_3$ solution

$$N_1V_1 = N_2V_2\ ;\ N_1 \times 20 = 0.1 \times 19.9\ ;$$

$$\therefore \quad N_1 = 199/2000 = \mathbf{0.0995}$$

22.15 IODINE (I_2) TITRATIONS IN TERMS OF MOLARITY
(For Calculations see section 22.3)

Example 47. *Calculate the atomic weight (m) of a metal, M in $M_2S_2O_3.5H_2O$, 2.48 g of which have been dissolved per 100 mL of the given solution. 19.9 mL of the given solution reduced 20 mL of 0.05 M I_2.*

Solution. The required reaction is :

$$\underset{2 \text{ mole}}{2Na_2S_2O_3} + \underset{1 \text{ mole}}{I_2} \longrightarrow 2NaI + Na_2S_4O_6$$

We know

$$\frac{(\text{Molarity, } M_1 \times \text{Volume, } V_1) \text{ of } I_2}{(\text{Molarity, } M_2 \times \text{Volume, } V_2) \text{ of } M_2S_2O_3.5H_2O} = \frac{1}{2}$$

$$\frac{0.05 \times 20}{M_2 \times 19.9} = \frac{1}{2}; \therefore M_2 = \frac{2 \times 0.05 \times 20}{19.9} = 0.1005$$

$\therefore$ Strength of $M_2S_2O_3.5H_2O$

$= \text{Molarity} \times \text{Mol. wt. of } M_2S_2O_3.5H_2O$

$24.8 = 0.1005 \times (2m + 202)$

$$\therefore \quad m = \frac{1}{2}\left[\frac{24.8}{0.1005} - 202\right] = \mathbf{22.4}$$

$\therefore$ At. wt. of metal, M = **22.4 a.m.u.**

100 mL solution contain

$M_2S_2O_3.5H_2O = 1.24$ g

1000 mL solution contain

$M_2S_2O_3.5H_2O = (2.48 \times 1000)/100$

$= 24.8\ gL^{-}$

Molarity of I_2 = 0.05M

Volume of I_2 = 20 mL Molarity of

$M_2S_2O_3.5H_2O = M_2$ = ? Volume of

$M_2S_2O_3.5H_2O$ = 19.9 mL

Let at. wt. of M = m

Mol. wt. of $M_2S_2O_3.5H_2O$

$= 2m + (2 \times 32) + (3 \times 16) + 5(18)$

$= 2m + 202$

Notes: (*i*) *For $K_2Cr_2O_7$ titrations in presence of KI and dil. H_2SO_4.*

$$K_2Cr_2O_7 + 4H_2SO_4 \longrightarrow K_2SO_4 + Cr_2(SO_4)_3 + 4H_2O + 3O$$

$$2KI + H_2SO_4 + O \longrightarrow K_2SO_4 + H_2O + I_2;$$

$$I_2 + \text{Starch} \rightarrow I_2\text{-starch [complex (blue)]}$$

(*ii*) *For $KMnO_4$ titrations in presence of KI and dil. H_2SO_4.*

$$2KMnO_4 + 3H_2SO_4 \longrightarrow K_2SO_4 + 2MnSO_4 + 3H_2O + 5O$$

$$2KI + H_2SO_4 + O \longrightarrow K_2SO_4 + H_2O + I_2;$$

$$I_2 + \text{Starch} \longrightarrow I_2 - \text{starch complex (blue)}$$

(*iii*) *For $CuSO_4.5H_2O$ titrations in presence of KI, Na_2CO_3 and acetic acid.*

$$2CuSO_4 + 4KI \longrightarrow Cu_2I_2 + I_2 + 2K_2SO_4;$$

$$I_2 + \text{Starch} \longrightarrow I_2 - \text{starch complex (blue).}$$

In all the above three cases, I_2 produced is titrated with sodium thiosulphate solution (hypo). The quantitative reaction that takes place is given below.

$$\underset{\text{Sodium thiosulphate}}{2Na_2S_2O_3} + I_2 \longrightarrow \underset{\text{Sodium tetrathionate}}{Na_2S_4O_6} + 2NaI$$

Example 48. *$Na_2S_2O_3.5H_2O$ was partially dehydrated and 20.2 g of the latter were dissolved per litre of the given solution. 20 mL of 0.1 N $K_2Cr_2O_7$ solution was treated with dil. H_2SO_4 and excess of KI. I_2 liberated required 18.5 mL of given thiosulphate solution. Calculate the precentage loss of weight due to dehydration of salt.*

Soluton. *To find normality of $Na_2S_2O_3$ solution.*

$Na_2S_2O_3$ vs $K_2Cr_2O_7$

$N_1V_1 = N_2V_2$; $N_1 \times 18.5 = 0.1 \times 20$;

$$N_1 = \frac{20}{185}$$

(*i*) Eq. wt. of $Na_2S_2O_3.5H_2O$ = 248

(*ii*) Wt. of partially dehydrated thiosulphate = 20.2 g.

$\therefore$ Wt. of $Na_2S_2O_3.5H_2O$ = (20/185) × 248 = 26.81 g

Loss of weight due to dehydration = 26.81 – 20.2 = 6.61 g

% loss of weight due to partial dehydration = (6.61 × 100)/26.81 = 24.65%

Example 49. *Calculate the value of x in $CuSO_4xH_2O$, 6.575 g of which have been dissolved per 250 mL of the given solution. 20 mL of this solution on treatment with dil. H_2SO_4 and KI liberated I_2 which was reduced by 21.1 mL of 0.1N $Na_2S_2O_3$ solution (At. wt. of Cu = 63.5, S = 16, O = 16, H = 1).*

Solution. (*i*) To find normality (N_1) of $CuSO_4$ solution.

$CuSO_4$ $K_2Cr_2O_7$

$N_1V_1 = N_2V_2$

$N_1 \times 20 = 0.1 \times 21.1$;

$\therefore N_1 = 211/2000 = 0.1055$

$\therefore$ Eq. wt. of $CuSO_4.xH_2O$ = Strength/N_1 = 26.3/0.1055 = 249.23

Now 159.5 + 18x = 249.23 ; x = (249.23 – 159.5)/18

$x = 4.985 \simeq 5$

(*i*) 250 mL $CuSO_4$ solution ≡ 6.575 g $CuSO_4xH_2O$
1000 mL $CuSO_4$ solution ≡ (6.575 × 1000)/250 = 26.3 gL^{-}

(*ii*) Eq. wt. of $CuSO_4$ = 63.5 + 32 + (4 × 16) = 159.5

Example 50. *Calculate volumetrically, the atomic weight (m) of an alkali metal, 6.0 g of the arsenite of which has been dissolved per 250 mL of the given solution. 20 mL of the arsenite solution require 19.9 mL of 0.1N I_2 solution.*

Solution. Let alkali metal arsenite = M_3AsO_3

(*i*) *To find normality of M_3AsO_3 solution.*

M_3AsO_3 solution $\qquad$ I_2 solution

$$N_1V_1 = N_2V_2$$

$$\therefore \quad N_1 \times 20 = 0.1 \times 19.9\,;$$

$$N_1 = 199/2000 = 0.0995$$

Let at. wt. of M $= m$;

250 mL solution contain $M_3AsO_3 = 6.0$ g

1000 mL solution contain

$$M_3AsO_3 = (1 \times 1000)/250 = 24 \text{ g}$$

∴ Eq. wt. or Mol. wt. of

$$M_3\,AsO_3 = 24.0/0.0995 = 241.2 \text{ g}$$

∴ Eq. wt. or mol. wt. of

$$M_3AsO_3 = 3\,m + 75 + (3 \times 16) = 3m + 123$$

$$\therefore \quad 3m + 123 = 241.2\,;\ m = (241.2 - 123)/3 = \mathbf{39}$$

EXAMPLE 51. *You are provided with a solution of 7.5 g of arsenous oxide (As_2O_3) and sodium arsenite (Na_3AsO_3) per litre. If 20 mL of this solution consumed 20.30 mL of 0.1 NI_2 solution for reducing I_2, calculate the percentage composition of the mixture (at. wt. of As = 75, O = 16, Na = 23).*

SOLUTION. Let wt. of

$$As_2O_3 = x \text{ g};$$

$$\text{wt. of } Na_3AsO_3 = 7.5 - x \text{ g}.$$

$$\text{Eq. wt. of } As_2O_3 = 49.5\,;$$

Eq. wt. of Na_3AsO_3= 96 (from table 22.2)

(*i*) To find total normality of solution

Mixed solution vs I_2 solution

$$N_1V_1 = N_2V_2$$

$$N_1 \times 20 = 0.1 \times 20.3\,;$$

$$\therefore \quad N_1 = \frac{203}{2000} = \mathbf{0.1015}$$

(*ii*) $$\text{Normality of } As_2O_3 = \frac{x}{49.5}\,;$$

$$\text{normality of } Na_3AsO_3 = (7.5 - x)/96$$

(*iii*) From (*i*) and (*ii*) $$\frac{x}{49.5} + \frac{7.5 - x}{96} = 0.1015$$

$$96x + 371.25 - 49.5x = 482.33$$

$$\therefore \quad 46.5x = 111.08\,;\ x = 2.39 \text{ g}$$

$$\therefore \quad \%\text{ age of } As_2O_3 = (2.39 \times 100)/7.5 = \mathbf{31.87\%}$$

$$\%\text{ age of } Na_3AsO_3 = 100 - 31.87 = \mathbf{68.13\%}$$

EXAMPLE 52. *8.82 g of potassium antimony tartrate. $C_4H_4O_6K(SbO)\frac{1}{2}H_2O$ salt were dissolved in water and the solution made up to one litre. Calculate the atomic weight of antimony if 20 mL of this solution reduced 21.55 mL of 0.049 N I_2 solution completely (at. wt. of K = 39, C = 12, H = 1, O = 16)*

SOLUTION. (*i*) *To find mol. wt. of potassium antimony tartrate* (*ii*) *Let at. wt. of Sb = x*

Given solution $\qquad$ I_2 solution

$$N_1V_1 = N_2V_2\,;\ 20 \times N_1 = 0.049 \times 21.55$$

$$\therefore \quad N_1 = (0.049 \times 21.55)/20 = 0.0428$$

$$\text{Wt. of given salt} = 8.82 \text{ gL}^{-}\,;\ \text{eq. wt.}$$

$$\text{of salt} = 8.82/0.0528 = 167.$$

(*iii*) Mol. wt. of $C_4H_4O_6.K(SbO).\ \frac{1}{2}H_2O$

$$= (4 \times 12) + (4 \times 1) + (6 \times 16) + 39 + x + 16 + 9 = \mathbf{212 + x.}$$

Equating mol. wts we have,

$$212 + x = 334\,; \qquad \therefore\ x = 334 - 212 = \mathbf{122}$$

Or $\qquad$ Mol. wt. $= 2 \times 167 = 334$

($\because$ Eq. wt. of salt = 167 (see table 22.2)

22.16 NORMALITY = MOLARITY × CHANGE IN OXIDATION STATE

EXAMPLE 53. *In a volumetric experiment, it was found that a solution of $KMnO_4$ is reduced to $MnSO_4$. If the normality of a solution is 1.0 N, then molarity of the solution will be:*

(*a*) 0.5 M $\qquad$ (*b*) 0.2 M

(*c*) 1.0 M $\qquad$ (*d*) 0.4 M

J and K-CET, 2011

SOLUTION. Normality = Molarity × change in oxidation state. ...(1)

Given $K\overset{7+}{Mn}O_4 \longrightarrow \overset{2+}{Mn}SO_4$. So, change in oxidation state = 7 – 2 = 5. Substituting in equation (1), we have: 1 = Molarity × 5. So, molarity = 1/5 = 0.2. So, the correct answer is (*b*)

22.17 MISCELLANEOUS EXAMPLES

EXAMPLE 53. *Calculate the normality of NaOH solution whose 25 mL are exactly neutralised by 20 mL of N/20 H_2SO_4.*

SOLUTION. Normality of NaOH = N_1, Volume = 25 mL; Normality of $H_2SO_4 = \frac{1}{20}$, Volume = 20 mL. Using normality equation, we have :

$$N_1V_1\,(NaOH) = N_2V_2\,(H_2SO_4)$$

$$N_1 \times 25 = \frac{1}{20} \times 20\,;$$

$$N_1 = \frac{20 \times 1}{20 \times 25} = \frac{1}{25} = \mathbf{0.04\ N} \qquad \textbf{Ans.}$$

EXAMPLE 54. *Calculate the molarity of NaOH solution whose 25 mL are exactly neutralised by 20 mL of M/20 H_2SO_4.*

SOLUTION. *Reaction* :

$$\underset{2\text{ mol}}{2NaOH} + \underset{1\text{ mol}}{H_2SO_4} \longrightarrow Na_2SO_4 + 2H_2O$$

$$\frac{M_1V_1(NaOH)}{M_2V_2(H_2SO_4)} = \frac{\text{no. of mol of NaOH in balanced equation}}{\text{no. of mol of } H_2SO_4 \text{ in balanced equation}}$$

$$\frac{M_1 \times 25}{\frac{1}{20} \times 20} = \frac{2}{1} \quad M_1, = 2 \times \frac{1}{20} \times \frac{20}{25}$$

$$= \mathbf{0.08\ M} \qquad \textbf{Ans.}$$

EXAMPLE 55. *Calculate the molarity of $KMnO_4$ solution whose 25 mL exactly oxidise 20 mL of M/20 oxalic acid solution.*

SOLUTION. Reaction.

$$\underset{2\text{ mol}}{2KMnO_4} + \underset{5\text{ mol}}{5H_2C_2O_4} + 3H_2SO_4 \longrightarrow K_2SO_4 + 2MnSO_4 + 10CO_2 + 8H_2O$$

$$\frac{M_1V_1\,(\text{K MnO}_4)}{M_2V_2\,(\text{H}_2\text{C}_2\text{O}_4)} = \frac{\begin{array}{l}\text{no. of mol of KMnO}_4\\ \text{in a balanced equation}\end{array}}{\begin{array}{l}\text{no. of mol of H}_2\text{C}_2\text{O}_4\\ \text{in a balanced equation}\end{array}}$$

$$\frac{\text{M}_1\times 25}{\frac{1}{20}\times 20} = \frac{2}{5}\,;\; M_1 = \frac{2}{5}\times\frac{1}{20}\times\frac{20}{25}$$

$$= \mathbf{0.016\ M} \qquad \textbf{Ans.}$$

EXAMPLE 56. *Determine the number of molecules of water of crystallisation in Mohr's salt [$FeSO_4.(NH_4)_2SO_4.xH_2O$] whose 9.8 g have been dissolved per 250 mL of the solution. 20 mL of this solution required 20 mL of M/50 $KMnO_4$ for complete oxidation. (at. wt., Fe = 56, S = 32, O = 16, N = 14, H = 1)*

SOLUTION. Mol. wt. of $\text{FeSO}_4.(\text{NH}_4)_2\text{SO}_4.x\text{H}_2\text{O}$ = 56 + 32 + (4 × 16) + 2[14 + (4 × 1)] + 32 + (4 × 16) + x[(2 × 1) + 16] = 248 + 18x

Reaction. $\text{MnO}_4^- + 5\text{Fe}^{2+} + 8\text{H}^+ \longrightarrow \text{Mn}^{2+} + 5\text{Fe}^{3+} + 4\text{H}_2\text{O}$

1 mol 5 mol

$$\frac{M_1V_1\,(\text{K MnO}_4)}{M_2V_2\,(\text{Mohr's salt})} = \frac{\begin{array}{l}\text{no. of mol of K MnO}_4\\ \text{in the balanced equation}\end{array}}{\begin{array}{l}\text{no. of mol of Fe}^{2+}\\ \text{in the balanced equation}\end{array}}$$

$$\frac{\frac{1}{50}\times 20}{M_2\times 20} = \frac{1}{5}\,;\; M_2 = \frac{1}{50}\times\frac{20}{20}\times 5 = \frac{1}{10}\,M$$

(*i*) ∴ Strength of Mohr's salt = Molariy × mol. wt.

$$= \frac{1}{10}\times(284+18x)$$

(*ii*) 250 mL solution contain Mohr's salt = 9.8 g

1000 mL solution contain Mohr's salt

$$= \frac{9.8}{250}\times 1000 = 39.2\ \text{g}$$

From (*i*) and (*ii*), we have

$$\frac{284+18\,x}{10} = 39.2\,;\; 18x = (39.2\times 10) - 284$$

$$= 108\,;\; x = \frac{108}{18} = 6$$

∴ no. of molecules of water of crystallisation = **6** **Ans.**

> **Note.** For more numericals, see chapter 17 "Solution-Concentration"

DIFFERENT METHODS TO EXPRESS CONCENTRATION OF SOLUTION.

Methods to express concentration of solutions include **normality** (N), **molarity** (M), **molality** (*m*), **Strength of solution** (S) in **terms of percentage, mole fraction** (*x*)., **Formality** (F) and **ionic strength** (μ)

1. **Normality (N).** The number of equivalents of a solute present in one litre of solution gives the normality of solution.

(*a*) **Equivalent (Eq.) of solute** = Normality (N) × Volume in litre (L) = $\dfrac{\text{wt. of solute}}{\text{Eq. wt. of solute}}$

Or $\quad$ **Eq.** $= \boldsymbol{N\times V}$ **in L** $= \dfrac{\mathbf{W}}{\mathbf{E}}$

Where : **Normality (*N*)**

$$= \frac{\text{Equivalent of solute}}{\text{Volume of solution in litre (L)}}\,;$$

$$= \frac{\text{wt. of solute (= w)}}{\text{Eq. wt. of solute (E)}\times\text{Volume of solution in litre (L)}}$$

Or $\quad N = \dfrac{W}{E\times V\text{ in }L}\ \text{g. eq L}^{-}.$

Since 1L = 1000 mL = 1000 cm^3

$$\therefore\quad N = \frac{W}{E}\times\frac{1000}{V\text{ in mL (or cm}^3)}$$

Also,no. of equivalent of an acid

$$= \frac{\text{wt.}}{\text{Formula wt.}}\times\text{basicity}$$

no. of equivalents of a base

$$= \frac{\text{wt.}}{\text{Formula wt.}}\times\text{Acidity}$$

(*b*) **Milliequivalent** (M.eq) of solute = Normality (*N*) × Volume in mL (or cm^3)

$$= \frac{\text{wt. of solute}}{\text{Eq. wt. of solute}}\times 1000$$

Or $\quad \text{M.eq} = \dfrac{W}{E}\times 1000$

> **Note1.** Normality of a solution depends upon temperature because it involves volumes which changes with temperature. It changes with dilution.
> **2.** Equivalent and milliequivalent of reactants react in equal number to give same number of equivalent or milliequivalent of products. Also, eq. and M.eq do not change with dilution.
> **3.** While solving numericals based on equivalent or milliequivalent, there is no need to balance the chemical reaction. In such cases :
> **4.** No. of M.eq = Normality × Volume in mL
> **5.** Normality = m.eq (mL)$^-$ *i.e.*, no. of milliequivalent per millilitre of solution.

EXAMPLE 57. *Calculate the number of milliequivalent in 25 mL of 0.1 N $CaCl_2$ solution.*

SOLUTION. $\text{CaCl}_2 \rightleftharpoons \text{Ca}^{2+} + 2\text{Cl}^-$

∴ No. of M.eq = Normality × Volume in mL

= 0.1 × 25 = **2.5** **Ans.**

EXAMPLE 58. *1.98 L of ammonia at 303 K and 0.2 atm pressure neutralised completely 130 mL of sulphuric acid. Find the normality of sulphuric acid.*

SOLUTION. P = 0.2 atm, V = 1.98 L, n = no. of mol of NH_3, R = 0.0821 L atm K$^-$ mol$^-$, T = 303 K. We know that :

$$PV = nRT\,;$$

$$n = \frac{PV}{RT} = \frac{0.2\ \text{atm}\times 1.98\ \text{L}}{0.0821\ \text{L atm K}^{-}\text{mol}^{-}\times 303\ \text{K}}$$

Or $n = 0.01592$

But no. of mol of

NH_3 = no. of equivalent of NH_3

no. of equivalent of

$H_2SO_4 = 0.01592$ ∴ M.eq of NH_3

= No. of equivalent of $NH_3 \times 1000$

$= 0.01592 \times 1000 = 15.92$

But no. of M.eq of

H_2SO_4 = no. of M.eq of NH_3

Or Normality × Volume in mL of

$H_2SO_4 = 15.92$

$N \times 130 = 15.92$;

$$N = \frac{15.92}{130} = \mathbf{0.1225} \qquad \textbf{Ans.}$$

EXAMPLE 59. *The formula weight of an acid is 82.0. 100 cm³ of a solution of this solution containing 39.0 g of the acid per litre were completely neutralised by 95.0 cm³ of aqueous NaOH containing 40.0 g of NaOH per litre. What is the basicity of the acid?* **(UPSEAT, 2000)**

SOLUTION. (*i*) wt. of acid = 39.0 g ;

Formula weight of acid = 82.0g. Basicity of acid $= n$;

$$\text{Eq. wt. of acid} = \frac{\text{Formula wt.}}{\text{Basicity}} = \frac{82}{n}$$

$$\therefore \quad \text{Normality of acid} = \frac{\text{wt.}}{\text{eq. wt.} \times \text{volume in litre}}$$

$$= \frac{39}{\frac{82}{n} \times 1} = \frac{39\,n}{82}$$

(*ii*) wt. of alkali = 40 g ; eq. wt. of

$$\text{NaOH} = \frac{23+16+1}{1} = 40,$$

Volume = 1L

$$\therefore \text{ Normality of NaOH} = \frac{\text{wt.}}{\text{eq. wt.} \times \text{volume in litre}}$$

$$= \frac{40}{40 \times 1} = 1.$$

Using normality equation, we have :

N_1V_1 (acid) $= N_2V_2$ (alkali)

$$\frac{39n}{82} \times 100 = 1 \times 95 ;$$

$$n = \frac{95 \times 82}{39 \times 100} = 1.99 \simeq 2$$

∴ Basicity of acid = **2** **Ans.**

EXAMPLE 60. *Find the normality of the resulting solution obtained by mixing 4 drops (0.2 mL) of 0.1N H_2SO_4 in one litre of distilled water.*

SOLUTION. Note that the milliequivalents of a solute do not change on dilution

∴ M.eq. of dil H_2SO_4 = M.eq. of conc. H_2SO_4

$N_1V_1 = N_2V_2$

[∵ M.eq = Normality × Volume in mL}

$N_1 \times 1000 = 0.1 \times 0.2$;

$$N_1 = \frac{0.1 \times 0.2}{1000} = \mathbf{2 \times 10^{-5}N} \quad \textbf{Ans.}$$

Type. No. of equivalents $= \dfrac{\text{wt.}}{\text{Eq. wt.}}$;

$$\text{Normality} = \frac{\text{no. of equivalents}}{\text{Volume in litre}}$$

EXAMPLE 61. *2 g of calcium was burnt in excess of oxygen to get CaO. CaO so formed was dissolved in water and the solution was made up to 500 mL. Calculate the normality of the alkaline solution. (at. wt. Ca = 40, O = 16)*

SOLUTION. $\underset{\substack{40\text{ g}\\20\text{ g}}}{Ca} + \underset{\substack{16\text{ g}\\8\text{ g}}}{1/2\,O_2} \longrightarrow \underset{\substack{40+16=56\text{ g}\\28\text{ g}}}{CaO}$ ...(*i*)

wt. of Ca = 2 g ; Eq. wt. of

$$\text{Ca} = \frac{\text{At. wt.}}{\text{Valency}} = \frac{40}{2} = 20.$$

$$\text{Eq. wt. of CaO} = \frac{\text{Mol. wt. of CaO}}{\text{Total} + \text{ve charge}} = \frac{40+16}{2} = 28$$

From equation (*i*) : 20 g Ca form

CaO = 28 g; 2 g Ca form

$$\text{CaO} = \frac{28}{20} \times 2 = 2.8\text{ g}$$

(*ii*) Normality of

$$\text{CaO} = \frac{\text{wt. of CaO}}{\text{Eq. wt. of CaO}} \times \frac{1000}{\text{Volume in mL}}$$

$$= \frac{2.8}{28} \times \frac{1000}{500} = 0.2 \qquad \textbf{Ans.}$$

Type. *To find specific gravity of acid or base*

EXAMPLE 62. *25 cm³ of a H_3PO_4 solution, whose 1 cm³ was diluted to 250 cm³, needed 35.15 cm³ of 0.101 N NaOH solution for neutralisation when phenolphthalein was used as an indicator. Calculate the specific gravity of H_3PO_4 (at. wt ; H = 1 P = 31, O = 16)*

SOLUTION. Mol. wt. of

H_3PO_4 ($H_3PO_4 \rightleftharpoons 3H^+ + PO_4^{3-}$)

$= (3 \times 1) + 31 + (4 \times 16) = 98.$

$$\text{So,Eq. wt of } H_3PO_4 = \frac{\text{Mol. wt.}}{\text{Total charge on cation or anion}}$$

$$= \frac{98}{3} = 32.67$$

(*i*) *To find normality of original H_3PO_4.*

H_3PO_4 NaOH

$N_1V_1 = N_2V_2$

$N_1 \times 1 = 0.101 \times 35.15$

∴ $N_1 = 0.101 \times 35.15 = 3.55$

(*ii*) *To find normality of diluted H_3PO_4.*

Original H_3PO_4 Diluted H_3PO_4

$N_3V_3 = N_4V_4$; $(0.101 \times 35.15) \times 250$

$= N_4 \times 25$

$$\therefore \quad N_4 = \frac{0.101 \times 35.15 \times 250}{25} = 35.5$$

$$\text{But} \quad \text{Normality} = \frac{\text{wt. of } H_3PO_4}{\text{Eq. wt. of } H_3PO_4} \times \frac{1000}{\text{Volume in cm}^3}$$

$$\therefore \quad \text{wt. of } H_3PO_4$$

$$= \frac{\text{normality} \times \text{Eq. wt. of } H_3PO_4 \times \text{Volume in cm}^3}{1000}$$

$$= \frac{35.5 \times 32.67 \times 1}{1000} = 1.597 \simeq 1.16 \text{ g}$$

$\therefore$ Specific gravity of H_3PO_4 = **1.16 gL$^-$ Ans.**

Double titration

In such titrations, different indicators are used. For example, consider the titration of a solution containing NaOH, Na_2CO_3 and inert impurities, with HCl. In this titration, two indicators are used. One is phenolphthalien while the other is methyl orange.

(*a*) **Use of phenolphthalein indicator.** When phenolphthalein indicator is used, NaOH is completely neutralised while Na_2CO_3 gets neutralised to half of its amount present. The reactions are :

(*i*) $NaOH + HCl \longrightarrow NaCl + H_2O$
$(n = 1)$

(*ii*) $Na_2CO_3 + HCl \longrightarrow NaHCO_3 + NaCl$
$(n = 2)$

$$\text{Here, eq. of } \underset{(n=1)}{NaOH} = \frac{1}{2} \text{ eq. of } \underset{(n=2)}{Na_2CO_3} = \text{eq. of HCl} \quad ...(1)$$

For $NaOH \rightleftharpoons Na^+ + OH^-$
1 mol
oxidation state = + 1
$\therefore n = 1 \times 1 = 1$
For $Na_2CO_3 \rightleftharpoons 2Na^+ + CO_3^{2-}$
2 mol
oxidation state = +1
$\therefore n = 2 \times 1 = 2$

Phenolphthalein indicates end point when Na_2CO_3 is converted to $NaHCO_3$.

(*b*) Use of methyl orange indicator. When methyl orange indicator is used, NaOH as well as Na_2CO_3 get completely neutralised by HCl. The reactions are :

(*i*) $NaOH + HCl \longrightarrow NaCl + H_2O$

(*ii*) $Na_2CO_3 + 2HCl \longrightarrow 2NaCl + CO_2 + H_2O$

Here, eq. of NaOH = eq. of Na_2CO_3 = eq. of HCl.
$n = 2$

Note. Titration of a mixture of solutions of NaOH, Na_2CO_3 and inert impurities can be done by two methods :

(*i*) Firstly use phenolphthalein indicator and titrate with acid (say, HCl) till pink to colourless end point is obtained. Now, use methyl orange indicator in the same solution till light yellow to pink end point is obtained.

(*ii*) Firstly use phenolphthalein indicator and titrate solution with acid (say, HCl) till pink to colourless end point is obtained. Volume of HCl used gives the neutralisation of total NaOH and half of Na_2CO_3. Now again take known volume of mixture, add methyl orange indicator and titrate with acid (HCl) till light yellow to pink end point is obtained. Volume of HCl used gives the neutralisation of total NaOH and total Na_2CO_3. Using law of equivalents ($N_1V_1 = N_2V_2$), the percentage composition of mixture can be calculated.

EXAMPLE 63. *1.98 g sample of a mixture of potassium sulphate, sodium carbonate and sodium bicarbonate was heated till CO_2 gas stopped coming out. The volume of CO_2 gas liberated at 298 K and 740 mm pressure was 125 mL. A 1.48 g of the sample required 145 mL of 0.1 M HCl for complete neutralisation. Calculate the % age composition of the given mixture.*

SOLUTION. Out of K_2SO_4, Na_2CO_3 and $NaHCO_3$, K_2SO_4 and Na_2CO_3 do not liberate CO_2 gas on heating. $NaHCO_3$ decomposes as :

$$\underset{(2\text{ mol})}{2NaHCO_3} \longrightarrow Na_2CO_3 + \underset{(1\text{ mol})}{CO_2} + H_2O \quad ...(1)$$

$$P = \frac{740}{760} \text{ atm} ; V = \frac{125}{1000} \text{L} ;$$

R = 0.082 L atm K$^-$ mol$^-$;

T = 298 K ; number of moles of

CO_2, n = ? We know :

$$PV = nRT \quad \textbf{Or} \quad n = \frac{PV}{RT}$$

$$\textbf{Or} \quad n = \frac{740}{760} \text{ atm} \times \frac{125}{1000} \text{ L} \times \frac{1}{0.82 \text{ L atm K}^- \text{mol}^-} \times \frac{1}{298 \text{ K}}$$

$= 4.98 \times 10^{-3}$ mol

$\therefore$ Number of moles of $NaHCO_3$ from reaction (1)

$$= 4.98 \times 10^{-3} \times 2 \left[\begin{matrix} 2NaHCO_3 & \equiv CO_2 \\ 2 \text{ mol} & 1 \text{ mol} \end{matrix} \right.$$

$= 9.96 \times 10^{-3}$

Equivalents of HCl used

$$= \text{vol in L} \times \text{normality} = \frac{145}{1000} \times 0.1$$

$= 0.0145$

$$\underset{1\text{ mol}}{NaHCO_3} + \underset{1\text{ mol}}{HCl} \longrightarrow NaCl + CO_2 + H_2O \quad ...(2)$$

Equivalents of $NaHCO_3$ in 1.98 g sample = 9.96×10^{-3}

Equivalents of $NaHCO_3$ in 1.48 g sample

$$= \frac{9.96 \times 10^{-3}}{1.98} \times 1.48 = 7.4 \times 10^{-3}$$

$\therefore$ Equivalents of $Na_2CO_3 = 0.0145 - (7.4 \times 10^{-3}) = 0.0145 - 0.0074 = 7.1 \times 10^{-3}$

$$\underset{1\text{ mol}}{Na_2CO_3} + \underset{2\text{ mol}}{2HCl} \longrightarrow 2NaCl + CO_2 + H_2O \qquad ...(3)$$

Since no atom in reaction (3) undergoes oxidation number change, so 'n' factor of $Na_2CO_3 = 2$

$$\left[\therefore\ Na_2CO_3 \rightleftharpoons \underset{2\times +1 = 2}{2Na^+} + CO_3^{2-}\right]$$

$$\therefore \text{Moles of } Na_2CO_3 = \frac{7.1\times 10^{-3}}{n(=2)} = 3.55\times 10^{-3}$$

(*a*) Mass of $NaHCO_3$ in 1.48 g = Equivalents of $NaHCO_3$ × Eq. wt. of $NaHCO_3 = 7.4 \times 10^{-3} \times 84 = 0.6216$ g.

$$\left[\because \text{Eq.wt. of } NaHCO_3 = \frac{\text{Mol. wt.}}{2} = \frac{23+1+12+3\times 16}{1} = 84\right]$$

$$\therefore \text{ \% age of } NaHCO_3 = \frac{\text{wt. of } NaHCO_3}{\text{Total wt.}} \times 100$$

$$= \frac{0.6216}{1.48} \times 100 = \mathbf{42} \quad \textbf{Ans.}$$

(*b*) Mass of Na_2CO_3 in 1.48 g sample = Equivalents of Na_2CO_3 × Eq. wt. of $Na_2CO_3 = 7.1 \times 10^{-3} \times 53 = 0.3763$

$$\left[\begin{aligned}&\because \text{Eq. wt. of } Na_2CO_3 = \frac{\text{Mol. wt.}}{2}\\ &= \frac{(2\times 23)+12+(3\times 16)}{2} = 53\end{aligned}\right]$$

$$\text{\% age of } Na_2CO_3 = \frac{\text{wt. of } Na_2CO_3}{\text{Total wt.}} \times 100$$

$$= \frac{0.3763}{1.48} \times 100 = \mathbf{25.43} \qquad \textbf{Ans.}$$

(*c*) Mass of K_2SO_4 = Total mass – (mass of $NaHCO_3$ + mass of Na_2CO_3) = 1.48 – (0.6216 + 0.3763) = 1.48 – 0.9979 = 0.4821

$$\text{\% age of } K_2SO_4 = \frac{\text{wt. of } K_2SO_4}{\text{Total wt.}} \times 100$$

$$= \frac{0.4821\times 100}{1.48} = \mathbf{32.57} \qquad \textbf{Ans.}$$

EXAMPLE 64. *20 mL of a solution containing NaOH and Na_2CO_3 was titrated with 0.96 N HCl using phenolphthalein indicator. As a result, 16 mL of acid was used up to the end point. With methyl orange indicator, 20 mL of the mixture solution required 22 mL of the same acid up to the end point. Calculate the amount of each substance in the mixture in grams per litre.*

SOLUTION. (*a*) *Use of phenolphthalein indicator.*

$$\begin{aligned}\text{M.eq. of HCl acid} &= \text{Volume in mL}\\ \times \text{ normality} &= 20 \times 0.96 = 19.20\end{aligned}$$

$$\text{But M.eq. of acid} = \text{M.eq. of NaOH} + \frac{1}{2} \text{ M.eq. of } Na_2CO_3 \qquad ...(1)$$

$$19.20 = \text{M.eq. of NaOH} + \frac{1}{2} \text{ M.eq. of } Na_2CO_3 \qquad ...(2)$$

(*b*) *Use of methyl orange indicator.*

$$\begin{aligned}\text{M.eq. of HCl acid} &= \text{Volume in mL}\\ \times \text{ Normality} &= 22 \times 0.96 = 21.12\end{aligned}$$

$$\text{But M.eq. of acid} = \text{M.eq. of NaOH} + \text{M.eq. of } Na_2CO_3$$

$$21.12 = \text{M.eq. of NaOH} + \text{M.eq. of } Na_2CO_3 \qquad ...(3)$$

Subtracting equation (1) from (2), we get :

$$\begin{aligned}21.12 &= \text{M.eq. of NaOH} + \text{M.eq. of } Na_2CO_3\\ 19.20 &= \text{M.eq. of NaOH} + \frac{1}{2}\text{ M.eq. of } Na_2CO_3\\ - \quad & \quad - \qquad\qquad\qquad -\\ \hline 1.92 &= \frac{1}{2}\text{ M.eq. of } Na_2CO_3.\end{aligned}$$

$\therefore$ M.eq. of $Na_2CO_3 = 2 \times 1.92 = 3.84$ ...(4)

Substituting the value of M.eq. of Na_2CO_3 from equation (4) in equation (3), we get :

$$21.12 = \text{M.eq. of NaOH} + 3.84$$

$$\therefore \text{ M.eq. of NaOH} = 21.12 - 3.84 = 17.28 \qquad ...(5)$$

(*c*) M.eq. of

$$Na_2CO_3 = \frac{\text{wt. of } Na_2CO_3}{\text{Eq. wt. of } Na_2CO_3} \times 1000$$

$$3.84 = \frac{\text{wt. of } Na_2CO_3}{53} \times 1000$$

$$\left[\begin{aligned}&\because \text{Eq. wt. of } Na_2CO_3 = \frac{\text{Mol. wt.}}{2}\\ &= \frac{(2\times 23)+12+(3\times 16)}{2} = 53\end{aligned}\right]$$

$$\therefore \quad \text{wt. of } Na_2CO_3 = \frac{53\times 3.84}{1000}$$

Wt. of Na_2CO_3 in one litre

$$= \frac{53\times 3.84}{1000} \times \text{Eq. wt. of } Na_2CO_3$$

$$= \frac{53\times 3.84\times 53}{1000} = \mathbf{10.79\ g} \qquad \textbf{Ans.}$$

$$(d)\ \text{M.eq. of NaOH} = \frac{\text{wt. of NaOH}}{\text{Eq. wt. of NaOH}} \times 1000$$

$$17.28 = \frac{\text{wt. of NaOH}}{40} \times 1000$$

$$\left[\because \text{ Eq. wt. of NaOH} = \frac{\text{Mol. wt.}}{1} = \frac{23+16+1}{1} = \frac{40}{1} = 40\right]$$

$$\therefore \quad \text{Wt. of NaOH} = \frac{17.28\times 40}{1000}$$

$$\text{Wt. of NaOH in one litre} = \frac{17.28\times 40}{1000} \times \text{Eq, wt. of NaOH}$$

$$= \frac{17.28\times 40\times 40}{1000} = \mathbf{27.65\ g} \qquad \textbf{Ans.}$$

EXAMPLE 65. *50 mL of a solution containing one gram of each of NaOH, $NaHCO_3$ and Na_2CO_3 was titrated with 1N HCl. What will be the titre reading if :*

(*a*) *Only methyl orange is used as indicator from the very beginning.*

(*b*) *Only phenolphthalein is used as an indicator.*

(*c*) *Methyl orange is added after the first end point with phenolphthalein.*

(*at. wt. Na = 23, O = 16, H = 1, C = 12*)

Solution. Mixture solution contains NaOH, $NaHCO_3$ and Na_2CO_3.

$$\text{Eq. wt. of NaOH} = \frac{\text{Mol. wt.}}{1} = \frac{23+16+1}{1} = 40.$$

$$\text{Eq. wt. of } Na_2CO_3 = \frac{\text{Mol. wt.}}{2}$$

$$= \frac{(2\times 23)+12+(3\times 16)}{2} = \frac{106}{2} = 53$$

$$\text{Eq. wt. of } NaHCO_3 = \frac{\text{Mol. wt.}}{1}$$

$$= \frac{23+12+12+(3\times 16)}{1} = 84.$$

Wt. of NaOH = 1 g ; Na_2CO_3 = 1 g ; $NaHCO_3$ = 1 g.

$$\text{M.eq. of NaOH} = \frac{\text{wt.}}{\text{Eq. wt.}}\times 1000 = \frac{1}{40}\times 1000 = 25$$

$$\text{M.eq. of } Na_2CO_3 = \frac{\text{wt.}}{\text{Eq. wt.}}\times 1000 = \frac{1}{53}\times 1000 = \frac{1000}{53}$$

$$\text{M.eq. of } NaHCO_3 = \frac{\text{wt.}}{\text{Eq. wt.}}\times 1000 = \frac{1}{84}\times 1000 = \frac{1000}{84}$$

(*a*) When methyl orange is used as an indicator, whole of NaOH, Na_2CO_3 and $NaHCO_3$ get neutralised by HCl

$$NaOH + HCl \longrightarrow NaCl + H_2O\ ;$$

$$Na_2CO_3 + 2HCl \longrightarrow 2NaCl + CO_2 + H_2O$$

$$NaHCO_3 + HCl \longrightarrow NaCl + CO_2 + H_2O.$$

Let Volume of 1N HCl used = V_1 mL

M.eq. of NaOH + M.eq. of $NaHCO_3$ + M.eq. of

$$Na_2CO_3 = \text{Volume}\times\text{normality}$$

$$= V_1\times 1 = V_1$$

$$25+\frac{1000}{84}+\frac{1000}{53} = V_1$$

Or $$\frac{25\times 84\times 53+1000\times 53+1000\times 84}{84\times 53} = V_1$$

Or $$V_1 = \frac{111300+53000+84000}{4452}$$

$$= \mathbf{55.8\ mL}$$ **Ans.**

(*b*) When only phenolphthalein is used as an indicator, whole of NaOH and 1/2 of Na_2CO_3 reacts with HCl to form $NaHCO_3$.

$$Na_2CO_3 + HCl \longrightarrow NaHCO_3 + NaCl$$

Let volume of 1N HCl used = V_2 mL

M.eq. of NaOH + $\frac{1}{2}$ M.eq. of

$$Na_2CO_3 = \text{Volume}\times\text{normality}$$

$$= V_2\times 1 = V_2$$

$$25+\frac{1}{2}\times\frac{1000}{53} = V_2$$

Or $$V_2 = \frac{25}{1}+\frac{500}{53} = \frac{25\times 53+500}{53}$$

$$= \frac{1325+500}{53},$$

Or $$V_2 = \frac{1825}{53} = \mathbf{34.4\ mL}$$ **Ans.**

(*c*) When methyl orange is added after the first end point with phenolphthalein, let the volume of HCl used is V_3 mL

V_3 = Volume of HCl used when methyl orange in used as indicator – Volume of HCl used when phenolphthallein is used as indicator

$$V_3 = 55.8 - 34.4 = \mathbf{21.4\ mL}$$ **Ans.**

Example 66. *A mixture of Na_2CO_3 and $NaHCO_3$ has a mass of 22.0 g. Treatment with excess HCl solution liberates 6.00 litre CO_2 at 25°C and 0.947 atm. Determine the percentage of Na_2CO_3 in the mixture.* **(IIT 1993)**

Solution. Let there be *x* g of Na_2CO_3 in the mixture

Weight of $NaHCO_3$ in the mixture = (22.0 – *x*) g

Let the volume of CO_2 collected at NTP be V litre

∴ According to gas equation, $(P_1V_1/T_1) = P_2V_2/T_2$

$$\frac{1\times V}{273} = \frac{0.947\times 6}{273+25}$$

or $$V = \frac{0.947\times 6\times 273}{298} = 5.2 \text{ litre}$$

Reactions involved are :

$$\underset{\substack{2\,\times\,23\,+\,12\,+\,3\,\times\,16\\=\,106\text{ g}}}{Na_2CO_3} + 2HCl \longrightarrow 2NaCl + H_2O + \underset{22.4\text{ L at NTP}}{CO_2}$$

$$\underset{\substack{23\,+\,1\,+\,12\,+\,3\,\times\,16\\=\,84\text{ g}}}{NaHCO_3} + HCl \longrightarrow NaCl + H_2O + \underset{22.4\text{ L at NTP}}{CO_2}$$

According to the balanced chemical equation,

106 g of Na_2CO_3 liberates CO_2 = 22.4 L at NTP

$$x \text{ g of } Na_2CO_3 \text{ liberates } CO_2 = \left(\frac{22.4}{106}\times x\right)\text{L at NTP}$$

$$= 0.2113x \text{ L at NTP}$$

Again 84 g of $NaHCO_3$ liberates

CO_2 = 22.4 L at NTP

∴ (22 – *x*) g of $NaHCO_3$ liberates

$$CO_2 = \frac{22.4}{84}\times(22-x)$$

L et NTP =0.267(22 – *x*) L at NTP

Thus, $0.2113x + 0.267\,(22-x) = 5.2$

or $5.874 + 0.2113x - 0.267x = 5.2$

or $5.874 - 5.2 = 0.267x - 0.2113x$

or $0.674 = 0.0557x$

∴ $$x = \frac{0.674}{0.0557} = \mathbf{12.1.}$$

Hence weight of Na_2CO_3 in the mixture = 12.1 g

Weight of $NaHCO_3$ in the mixture = 22 – 12.1 = 9.9 g
Hence percentage of Na_2CO_3 in the mixture

$$= \frac{12.1}{22} \times 100 = \mathbf{55\%}$$

Percentage of $NaHCO_3$ in the mixture

$$= \frac{9.9}{22} \times 100 = \mathbf{45\%}$$

Example 67. *A mixture of potassium carbonate and lithium carbonate weighing 0.5 g needed 25 mL of 0.3 N HCl for complete neutralisation. Calculate the percentage of lithium carbonate in the mixture. (at. wt ; Li = 7, K = 39, C = 12, O = 16,)*

(Roorkee, 1989)

Solution. Let wt. of $K_2CO_3 = x$ g ; wt. of $Li_2CO_3 = (0.5 - x)$g

Reactions. (A)

$$\underset{\substack{(2\times 39)+12+(3\times 16)\\ = 138\text{ g}}}{K_2CO_3} + \underset{\substack{2(1+35.5)\\ = 73\text{ g}}}{2HCl} \longrightarrow 2KCl + CO_2 + H_2O$$

138 g K_2CO_3 require HCl = 73 g

$$x \text{ g } K_2CO_3 \text{ require HCl} = \frac{73\,x}{138} \text{ g} \qquad ...(i)$$

$$\text{(B) } \underset{\substack{(2\times 7)+12+(3\times 16)\\ = 74\text{ g}}}{Li_2CO_3} + \underset{\substack{2(1+35.5)\\ = 73\text{ g}}}{2HCl} \longrightarrow 2LiCl + CO_2 + H_2O$$

74 g Li_2CO_3 need HCl = 73 g

$$(0.5 - x) \text{ g } Li_2CO_3 \text{ need HCl} = \frac{73}{74} \times (0.5 - x) \text{ g} \qquad ...(ii)$$

From (*i*) and (*ii*), total wt. of HCl used

$$= \left[\frac{73\,x}{138} + \frac{73}{74}(0.5 - x)\right] \text{g} \qquad ...(iii)$$

(*c*) Eq. wt. of HCl = 1 + 35.5 = 36.5. Also :

$$\text{Normality of HCl} = \frac{\text{wt. of HCl}}{\text{Eq. wt. of HCl}} \times \frac{1000}{\text{Volume of HCl used in mL.}}$$

$\therefore$ wt. of HCl

$$= \frac{\text{Normality} \times \text{Eq. wt. of HCl} \times \text{Volume of HCl used}}{1000}$$

$$= \frac{0.3 \times 36.5 \times 25}{1000} = 0.2737 \text{ g} \qquad ...(iv)$$

Equating equations (*iii*) and (*iv*), we have :

$$\frac{73\,x}{138} + \frac{73}{74}(0.5 - x) = 0.2737\ (73x \times 74) + (138 \times 73)$$

$$(0.5 - x) = 138 \times 74 \times 0.2737\ 5402x + 5037$$

$$-\ 10{,}074x = 2795.02\ ;\ 4672x = 2241.98$$

$$\therefore \quad x = 0.4798 \text{ g} = \text{wt. of } K_2CO_3$$

$$\therefore \quad \text{wt. of } Li_2CO_3 = 0.5 - 0.4798 = 0.0202 \text{ g}$$

$$\%\text{ age of } Li_2CO_3 = \frac{0.0202}{0.5} \times 100 = \mathbf{4.04\%} \qquad \textbf{Ans.}$$

Example 68. *12 mL of 1.25 M H_2SO_4, 20 mL of 5M HCl and 20 mL of HNO_3 of unknown normality were mixed and made up to one litre. 25mL of this solution required 30 mL of $Ba(OH)_2$ solution prepared by dissolving 4.8 g of $Ba(OH)_2.8H_2O$ in water and making up the solution to 250 mL. Calculate the normality of HNO_3 solution. (at. wt., Ba = 137, O = 16, H = 1).*

Solution. (*i*) Eq. wt. of $Ba(OH)_2.\ 8H_2O$

$$[Ba(OH)_2 \rightleftharpoons Ba^{2+} + 2OH^-]$$

$$= \frac{137 + 2(16+1) + 8[(2\times 1) + 16]}{(\text{Total + ve or} - \text{ve charge}) = 2}$$

$$= \frac{315}{2} = 157.5.$$

$$(ii) \qquad \text{Normality} = \frac{\text{wt.}}{\text{Eq. wt.}} \times \frac{1000}{\text{Volume of solution in mL}}$$

$$= \frac{4.8 \times 1000}{157.5 \times 250} = 0.122 \qquad ...(A)$$

(*iii*) Normality of acid mixture

$$= \frac{N_1V_1 + N_2V_2 + N_3V_3}{1000}$$

$$= \frac{(12 \times 1.25 \times 2) + (20 \times 5) + (20 \times x)}{1000}$$

where x = normality of HNO_3 ;
mol. wt. of H_2SO_4 = (2 × 1) + 32 + (4 × 16) = 98 ;
Eq. wt. of H_2SO_4 ($H_2SO_4 \rightleftharpoons 2H^+ + H_2SO_4$)

$$= \frac{\text{Mol. wt.}}{2} = \frac{98}{2}$$

= 49 and for H_2SO_4 :

Normality × Eq. wt. = Molarity × Mol wt

Normality × 49 = 1.25 × 98

$$\therefore \qquad \text{Normality} = \frac{1.25 \times 98}{49} = 1.25 \times 2 \text{ N.}$$

$\therefore$ Normality of acid mixture

$$= \frac{30 + 100 + 20\,x}{1000} = \frac{130 + 20\,x}{1000} \qquad ...(B)$$

(*iv*) To find normality of HNO_3 in mixture solution.

Acid mixture $\quad Ba(OH)_2.8H_2O$

$$N_1V_1 = N_2V_2$$

$$\frac{130 + 20x}{1000} \times 25 = 0.122 \times 30$$

$$\frac{0.122 \times 30 \times 1000}{25} = 130 + 20x\ ;\ 146.4 - 130 = 20x\ ;$$

$$x = \mathbf{0.82\ N} \qquad \textbf{Ans.}$$

Example 69. *Excess of carbon dioxide is passed through 50 mL of 0.5 M calcium hydroxide solution: After the completion of reaction, the solution was evaporated to dryness. The solid calcium carbonate was completely neutralised by 0.1 N hydrochloric acid. The volume of hydrochloric acid required is (at. mass of calcium = 40)*

(*a*) 200 cm^3 (*b*) 500 cm^3
(*c*) 400 cm^3 (*d*) 300 cm^3

(Karnataka CET, 2009)

SOLUTION. Reaction:

$$\underset{\substack{74\\(=1\text{ mol})}}{Ca(OH)_2} + \underset{\substack{44\\(=1\text{ mol})}}{CO_2} \longrightarrow \underset{\substack{100\\(=1\text{ mol})}}{CaCO_3} + \underset{\substack{18\\(=1\text{ mol})}}{H_2O}$$

Mol. wt.

Eq. wt. of $CaCO_3$ = Mol. wt./2 = 100/2 = 50; normality of $CaCO_3$ = ? We know: N_{CaCO_3} × Eq. wt. of $CaCO_3$ = Molarity of $CaCO_3$ × Mol. wt. of $CaCO_3$

$$N_{CaCO_3} \times 50 = 0.5 \times 100; N_{CaCO_3} = \frac{0.5 \times 100}{50} = 1N$$

Volume of C_{CaCO_3} = 50 mL (given). But

$$N_{HCl} \times V_{HCl} = N_{CaCO_3} \times V_{CaCO_3}$$
$$0.1 \times V_{HCl} = 1 \times 50;$$
$$V_{HCl} = \frac{1 \times 50}{0.1} = \frac{50 \times 10}{1} = 500 \text{ mL.}$$

So, the correct answer is (*b*)

Type. Eq. wt. of an acid

$$= \frac{\text{Mol. wt. of acid}}{\text{no. of replacable H}^+ \text{ ions}}$$

EXAMPLE 70. *Calculate the equivalent weight of* H_3PO_4 *in the following reaction.*

$$H_3PO_4 + Ca(OH)_2 \longrightarrow CaHPO_4 + 2H_2O.$$

$CaHPO_4$ formation shows that number of replaceable H^+ ions in H_3PO_4 = 2.

$$\therefore \text{Eq. wt. of } H_3PO_4 = \frac{\text{Mol. wt.}}{2}$$
$$= \frac{(3 \times 1) + 31 + (4 \times 16)}{2} = \frac{98}{2} = \mathbf{49}$$

Ans.

Type. Eq. wt. of a base

$$= \frac{\text{Mol. wt. of base}}{\text{no. of replaceable OH}^- \text{ ions}}$$

EXAMPLE 71. *Calculate the equivalent weight of* $Ca(OH)_2$ *in the following reaction.*

$$Ca(OH)_2 + HCl \longrightarrow Ca(OH)Cl + H_2O.$$

The Ca(OH)Cl formation shows that number of replaceable OH^- ions in $Ca(OH)_2$ = 1

$$\therefore \text{Eq. wt. of } Ca(OH)_2 = \frac{\text{Mol. wt. of } Ca(OH)_2}{\text{no. of replaceable OH}^- \text{ ions}}$$
$$= \frac{40 + 2(16+1)}{1} = \mathbf{74} \qquad \textbf{Ans.}$$

EXAMPLE 72. *A partially hydrated sodium carbonate* $Na_2CO_3.H_2O$ *weighing 0.31 g is added to 100 mL of 0.05 N* H_2SO_4 *solution. Will the resulting solution be neutral, acidic or basic?*

SOLUTION. Eq. wt. of

$$H_2SO_4 = \frac{(2 \times 1) + 32 + (4 \times 16)}{2} = \frac{98}{2} = 49.$$

$$\text{Normality of } H_2SO_4 = \frac{\text{wt.}}{\text{Eq. wt.}} \times \frac{1000}{\text{Volume of solution in mL}}$$

$$\therefore \quad \text{Wt. of } H_2SO_4 = \frac{\text{Normality} \times \text{Eq. wt.} \times \text{Volume in mL}}{1000}$$
$$= \frac{0.05 \times 49 \times 100}{1000} = 0.245 \text{ g}$$

Reaction.

$$Na_2CO_3.H_2O + H_2SO_4 \longrightarrow Na_2SO_4 + CO_2 + 2H_2O$$

(2 × 23) + 12 + (3 × 16) + [(2 × 1) + 16] = 124 g (2 × 1) + 32 + (4 × 16) = 98 g

98 g H_2SO_4 need $Na_2CO_3.H_2O$ = 124 g

$$0.245 \text{ g } H_2SO_4 \text{ need } Na_2CO_3.H_2O = \frac{124}{98} \times 0.245$$
$$= \mathbf{0.31\ g.}$$

Since the wt. of given $Na_2CO_3.H_2O$ (= 0.31 g) is the same as the wt. of $Na_2CO_3.H_2O$ neutralised, no quantity of $Na_2CO_3.H_2O$ is left behind. So, the resulting solution is neutral.

EXAMPLE 73. *Two acids X and Y were separately titrated each time with 20 mL of 1N NaOH solution and needed 8.0 mL and 32 mL respectively for complete neutralisation. What volume of acids X and Y would be needed to mix to produce 1L of 1N acid?*

SOLUTION. (*i*) Acid, *X*.

$$N_1V_1 \text{ (acid)} = N_2V_2 \text{ (NaOH)}$$
$$N_1 \times 8 = 1 \times 20 ; N_1 = \frac{20 \times 1}{8} = 2.5$$

(*ii*)Acid, *Y*. N_3V_3 (acid) = N_4V_4 (NaOH)

$$N_3 \times 32 = 1 \times 20 ; N_3 = \frac{20}{32} = 0.625$$

According to the law of normalities, the acids should be mixed in the inverse ratio of their normalities to form equinormal solutions. At the same time, their normalities will be one each. So, the ratio of volumes of *X* and *Y* is : 0.625 : 2.5 *i.e.,* $\frac{0.625}{0.625} : \frac{2.5}{0.625}$ *i.e.,* 1 : 4. Hence to get 1L *i.e.,* 1000 mL solution of 1N : Volume of $X = \frac{1 \times 1000}{1+4} = 200$ mL ; volume of $Y = \frac{4 \times 1000}{1+4} = 800$ mL.

EXAMPLE 74. *4.8 mL of 6N HCl, 5.0 mL of 5N* HNO_3 *and a certain volume of 17 M* H_2SO_4 *were mixed togather and the volume was made up to 1.5 litre. 25 mL of this acid mixture exactly neutralised 35 mL of sodium carbonate solution containing 1.0 g of* $Na_2CO_3.10H_2O$ *in 100 mL of water. Find the amount in gram of* SO_4^{2-} *ions in the solutions.*

SOLUTION. Volume of solution = 1.5 L = 1.5 × 1000 mL = 1500 mL.

(*i*) *Resultant normality of HCl* $= \frac{4.8\times 6}{1000} = \frac{28.8}{1000} = 0.0288$

(*ii*) *Resultant normality of* $HNO_3 = \frac{5\times 5}{1000} = \frac{25}{1000} = 0.025$

Let normality of H_2SO_4 in the acid mixture = N.

$$\text{Eq. wt. of } Na_2CO_3.10H_2O = \frac{\text{Mol. wt.}}{2}$$

$$= \frac{(2\times 23)+12+(3\times 16)+10[(2\times 1)+16]}{2} = \frac{286}{2} = 143$$

(*iii*) *To find normality of* Na_2CO_3*. 10* H_2O *solution.*

$$\text{Normality} = \frac{\text{wt.}}{\text{Eq. wt}}\times\frac{1000}{\text{Volume of solution in mL}}$$

$$= \frac{1}{143}\times\frac{1000}{100} = \frac{10}{143}$$

(*iv*) *To find normality of acid mixture.*

Acid mixture $Na_2CO_3 10H_2O$ solution

$$N_1V_1 = N_2V_2$$

$$N_1 \times 25 = \frac{10}{143}\times 35 \;;\; N_1 = \frac{10\times 35}{143\times 25} = 0.0979$$

(*v*) *To find normality of* H_2SO_4*.*

0.0288 HCl + 0.025 HNO_3 + $NH_2SO_4 = 0.0979$

∴ $NH_2SO_4 = 0.0979 - 0.0288 - 0.025 = 0.0441$

Ionic weight of SO_4^{2-} ion = 32 + (4 × 16) = 96

$$\therefore \text{ionic eq. wt. of } SO_4^{2-} \text{ ion} = \frac{\text{Ionic wt.}}{\text{Total valency of ion } (= 2)}$$

$$= \frac{96}{2} = 48$$

$$\text{But normality} = \frac{\text{wt.}}{\text{Eq. wt.}}\times\frac{1000}{\text{Volume of solution in mL}}$$

$$\therefore \text{wt. of } SO_4^{2-} \text{ ions} = \frac{\text{normality}\times\text{Eq. wt.}\times\text{Volume in mL}}{1000}$$

$$= \frac{0.0441\times 48\times 1500}{1000} = 3.1752 \text{ g}$$

EXAMPLE 75. *1.0 g of a fuming sulphuric acid (or oleum) was diluted with water. The resulting solution needed 26.5 mL of 0.8 N NaOH for complete neutralisation. Calculate the percentage of* SO_3 *is the fuming sulphuric acid.*

SOLUTION. (*i*) *To find weight of NaOH for complete neutralisation.*

$$\text{Normality} = \frac{\text{wt.}}{\text{Eq. wt.}}\times\frac{1000}{\text{Vol of solution in mL}}$$

$$\therefore \quad \text{wt. of NaOH} = \frac{\text{Normality}\times\text{Eq. wt.}\times\text{Volume in mL}}{1000}$$

$$= \frac{0.8\times 40\times 26.5}{1000} = 0.848 \text{ g.} \quad \ldots(A)$$

Fuming sulphuric acid = $H_2SO_4 + SO_3$.

Reactions

$$(i) \quad \underset{\substack{2(23+16+1)\\ = 80\text{ g}}}{2NaOH} + \underset{\substack{(2\times 1)+32\\ +(4\times 16) = 98\text{ g}}}{H_2SO_4} \longrightarrow Na_2SO_4 + 2H_2O$$

Let wt. of H_2SO_4 = x g ; wt. of SO_3 = $(1 - x)$g.

(*i*) 98 g H_2SO_4 need NaOH = 80 g

x g H_2SO_4 need NaOH = $\frac{80}{98}\times x$ g .

$$(ii) \quad \underset{\substack{2(23+16+1)\\ = 80\text{ g}}}{2NaOH} + \underset{\substack{32+(3\times 16)\\ = 80\text{ g}}}{SO_3} \longrightarrow Na_2SO_4 + H_2O$$

80 g SO_3 need NaOH = 80 g

$(1 - x)$ g SO_3 need NaOH = $\frac{80}{80}\times 1 - x = (1 - x)$ g

$$\text{Total NaOH needed} = \left(\frac{80x}{98} + 1 - x\right)\text{g} \quad \ldots(B)$$

Equating equations (*A*) and (*B*), we get :

$$0.848 = \frac{80x}{98} + 1 - x$$

$$98 \times 0.848 = 80x + 98 - 98x \;;\; 83.1 - 98 = -18x$$

$$\therefore \quad x = \frac{14.9}{18} = 0.828 \text{ g} = \text{wt. of } H_2SO_4$$

$$\therefore \quad \text{wt. of } SO_3 = 1 - 0.828 = 0.172 \text{ g}$$

$$\%\text{ age of } SO_3 = \frac{0.172}{1}\times 100 = \mathbf{17.2\%} \quad \textbf{Ans.}$$

EXAMPLE 76. *A mixture of oxalic acid,* $(COOH)_2$ *and formic acid HCOOH was heated with conc.* H_2SO_4*. The resulting gas was passed through KOH solution. The volume of gas reduced by 1/6 th. Find the molar ratio of two acids in original mixture of acids.*

SOLUTION. Let amount of HCOOH = x mol ; amount of $(COOH)_2$ = y mol.

Reactons.

$$(i) \quad \underset{x\text{ mol}}{HCOOH} \xrightarrow{H_2SO_4} H_2O + \underset{x\text{ mol}}{CO\uparrow}$$

$$(ii) \quad \underset{y\text{ mol}}{(COOH)_2} \xrightarrow{H_2SO_4} \underset{y\text{ mol}}{CO\uparrow} + \underset{y\text{ mol}}{CO_2\uparrow} + H_2O$$

It may be noted that only CO_2 is absorbed by KOH.

$$2KOH + CO_2 \longrightarrow K_2CO_3 + H_2O.$$

Total mol of CO and CO_2 = $x + 2y$

$$\therefore \quad \text{Mole fraction of } CO_2 = \frac{y}{x+2y}$$

$$\text{Hence} \quad \frac{y}{x+2y} = \frac{1}{6} \;;\; 6y = x + 2y \;;$$

$$6y - 2y = x \;;\; 4y = x$$

or $x : y$ = 4 : 1. Thus ; the ratio of

HCOOH : $(COOH)_2$ = **4 : 1** **Ans.**

EXAMPLE 77. *An alkaline solution contains 4.0 g caustic soda and 2.65 g* Na_2CO_3 *per 500 mL. 20 mL of this mixture was titrated with decinormal HCl. Calculate the reading if* (*i*) *phenolphthalein is used as indicator in the beginning and if* (*ii*) *methyl orange in used as indicator in the beginning.*

SOLUTION. (*i*) 500 mL NaOH solution contain

NaOH = 4.0 g

∴ 1000 mL (= 1L) NaOH solution contain

$$\text{NaOH} = \frac{4}{500}\times 1000 = 8\text{ g}$$

$$\therefore\ \text{Normality of NaOH} = \frac{\text{wt. L}^-}{\text{Eq. wt.}} = \frac{8}{40} = 0.2$$

(*ii*)
$$\text{Eq. wt. of Na}_2\text{CO}_3 = \frac{\text{Mol. wt.}}{\text{Total + ive charge on Na}^+}$$
$$= \frac{(2\times 23)+12+(3\times 16)}{2}$$
$$= \frac{106}{2} = 53$$

500 mL Na_2CO_3 solution contain Na_2CO_3 = 2.65 g CO_3
1000 mL (= 1L) Na_2 solution contain Na_2CO_3
$$= \frac{2.65}{500}\times 1000 = 5.3\text{ g}$$

$$\text{Normality of Na}_2\text{CO}_3 = \frac{\text{wt. L}^-}{\text{Eq. wt.}} = \frac{5.3}{53} = 0.1$$

(*iii*) When methyl orange is used as an indicator, whole of the NaOH as well as Na_2CO_3 get titrated.

(*iv*) When phenolphthalein is used as an indicator, whole of NaOH and half the amount of Na_2CO_3 get titrated.

(*v*) *To find volume of HCl used by NaOH*

NaOH HCl
$$N_1V_1 = N_2V_2$$
$$0.2 \times 20 = 0.1 \times V_2\ ;\ V_2 = \frac{0.2\times 20}{0.1} = 40\text{ mL}$$

(*vi*) *To find volume of HCl used by Na_2CO_3*

Na_2CO_3 HCl
$$N_3V_3 = N_4V_4$$
$$0.1 \times 20 = 0.1 \times V_4\ ;\ V_4 = \frac{0.1\times 20}{0.1} = 20\text{ mL}$$

∴ Volume of HCl used when methyl orange is used as indicator = 40 mL + 20 mL = 60 mL

[See (*iii*) above]

Volume of HCl used when phenolphthalein is used as indicator
$$= 40+\left(\frac{1}{2}\times 20\right) = 40 + 10$$
= 50 mL **Ans** [see (*iv*) above]

EXAMPLE 78. *20 mL of a mixture of sodium bicarbonate and sodium carbonate needed 8.0 mL of 0.05 N H_2SO_4 when titrated in presence of phenolphthalein indicator. Also, 20 mL of the same mixture when titrated separately in presence of methyl orange indicator needed 20 mL of 0.05 N H_2SO_4. Find the respective amounts of both compounds in gL^-.*

SOLUTION. (*i*) When methyl orange is used as an indicator, total Na_2CO_3 and total $NaHCO_3$ solution get titrated.

(*ii*) When phenolphthalein is used as an indicator, half the amount of Na_2CO_3 only gets titrated.

∴ For $\frac{1}{2}$ amount of Na_2CO_3 titration, 0.5

N H_2SO_4 used = 8.0 mL

For full amount of Na_2CO_3 titration, 0.5N

H_2SO_4 used = 8 × 2 = 16 mL

(*iii*) When methyl orange is used as an indicator, full amount of Na_2CO_3 and full amount of $NaHCO_3$ is titrated.

Volume of 0.5 N H_2SO_4 used to titrate total Na_2CO_3 and total $NaHCO_3$ = 20 mL (given)

∴ Volume of 0.5 N H_2SO_4 used to titrate total

$NaHCO_3$ = 20 – 16 = 4 mL

(*iv*) Eq. wt. of
$$\text{Na}_2\text{CO}_3 = \frac{\text{Mol. wt.}}{\text{Total + ve charge on Na}^+}$$
$$= \frac{(2\times 23)+12+(3\times 16)}{2} = \frac{106}{2} = 53$$
$$\text{Eq. wt. of NaHCO}_3 = \frac{\text{Mol. wt.}}{\text{Total + ve charge on Na}^+}$$
$$= \frac{23+1+12+(3\times 16)}{1} = 84$$

(*v*) *To find normality of Na_2CO_3.*

Na_2CO_3 H_2SO_4
$$N_1V_1 = N_2V_2$$
$$N_1 \times 20 = 0.05 \times 16\ ;\ N_1 = \frac{0.05\times 16}{20}$$
$$\therefore\ \text{Strength of Na}_2\text{CO}_3 = N_1 \times \text{Eq. wt}$$
$$= \frac{0.05\times 16}{20}\times 53 = \mathbf{2.12\ gL^-}$$ **Ans.**

(*vi*) *To find normality of $NaHCO_3$.*

$NaHCO_3$ H_2SO_4
$$N_3V_3 = N_4V_4$$
$$N_3 \times 20 = 0.05 \times 4\ ;\ N_3 = \frac{0.05\times 4}{20}$$
$$\therefore\ \text{Strength of NaHCO}_3 = N_3 \times \text{Eq. wt.}$$
$$= \frac{0.05\times 4}{20}\times 84 = \mathbf{0.84\ gL^-}$$ **Ans.**

EXAMPLE 79. *One gram of a sample containing chalk ($CaCO_3$) and $CaSO_4$ was dissolved in 200 mL of decinormal HCl. 35 mL of N/9.6 NaOH is needed to neutralise the excess acid. Calculate the percentage of chalk and $CaSO_4$ in the mixture.*

SOLUTION. Let wt. of chalk ($CaCO_3$) = x g ; $CaSO_4$ does not react with HCl, wt of $CaSO_4$ = 1 – x.

(*i*) *To find volume of unused HCl.*
$$N_1V_1\ (\text{HCl}) = N_2V_2\ (\text{NaOH})$$
$$\frac{1}{10}\times V_1 = \frac{1}{9.6}\times 35\ ;$$
$$V_1 = \frac{1}{9.6}\times 35\times 10 = 36.45\text{ mL}$$

∴ Volume of used HCl = 200 – 36.45 = 163.55

(*ii*) Eq. wt. of HCl = 1 + 35.5 = 36.5
$$\text{Normality of HCl} = \frac{\text{wt.}}{\text{Eq. wt.}} \times \frac{1000}{\text{Volume of HCl used in mL}}$$
$$\therefore\ \text{wt. of HCl} = \frac{\text{Normality}\times\text{Eq. wt.}\times\text{Volume of HCl in mL}}{1000}$$

$$= \frac{1}{10} \times \frac{36.5 \times 163.55}{1000} = 0.5969 \text{ g} \quad ...(A)$$

Reaction. $CaCO_3 + 2HCl \longrightarrow CaCl_2 + CO_2 + H_2O$

$40 + 12 + (3 \times 16) = 100 \text{ g}$ $\quad 2(1 + 35.5) = 73 \text{ g}$

100 g $CaCO_3$ react with HCl = 73 g

$$x \text{ g } CaCO_3 \text{ react with HCl} = \frac{73\,x}{100} \quad ...(B)$$

Equating equations (*A*) and (*B*), we have :

$$0.5969 = \frac{73\,x}{100}\,; x = \frac{100 \times 0.5969}{73}$$

$$= 0.8177 \text{ g} = \text{wt of } CaCO_3$$

$$\therefore \quad \%\text{ age of } CaCO_3 = \frac{0.8177}{1} \times 100$$

$$= \mathbf{81.77\%} \quad \textbf{Ans.}$$

$$\%\text{ age of } CaSO_4 = 100 - 81.77$$

$$= \mathbf{18.23\%} \quad \textbf{Ans.}$$

EXAMPLE 80. *2L of NH_3 neutralised 125 mL of H_2SO_4 at 27°C and 0.95 atmospheric pressure. Calculate the normality of H_2SO_4.*

SOLUTION. (*i*) *To find wt.* (*W*) *of NH_3.* Mol. wt. of NH_3 = 14 + (3 × 1) = 17 g mol^-; P = 0.95 atm; V = 2L ; wt. = ? ; R = 0.0821 L atm K^- mol^- ; T = 27 + 273 = 300 K

$$\text{But} \quad PV = \frac{W}{M} \times RT\ ; W = \frac{MPV}{RT}$$

$$= \frac{17 \text{ g mol}^- \times 0.95 \text{ atm} \times 2\text{L}}{0.0821 \text{ L atm K}^-\text{mol}^- \times 300 \text{ K}}$$

$$= 1.31 \text{ g}$$

(*ii*) *Reaction.* $2NH_3 + H_2SO_4 \longrightarrow (NH_4)_2SO_4$

$2[14 + (3 \times 1)] = 34 \text{ g}$ $\quad (2 \times 1) + 32 + (4 \times 16) = 98 \text{ g}$

34 g NH_3 need H_2SO_4 = 98 g

$$1.31 \text{ g } NH_3 \text{ need } H_2SO_4 = \frac{98}{34} \times 1.31 = 3.7759 \text{ g}$$

(*iii*) *To find normality of H_2SO_4.*

$$\text{Normality} = \frac{\text{wt.}}{\text{Eq. wt.}} \times \frac{1000}{\text{Volume of acid in mL}}$$

$$= \frac{3.7759 \times 1000}{49 \times 125} = \mathbf{0.616} \quad \textbf{Ans.}$$

EXAMPLE 81. *0.6238 g of oxalic acid $H_2C_2O_4.xH_2O$ are dissolved in water and volume made up to 100 mL. 20 mL of this acid required 19.8 mL of N/10 NaOH for complete neutralisation. Calculate the value of x.*

SOLUTION. (*i*) $N_1V_1 \text{ (acid)} = N_2V_2 \text{ (NaOH)}$

$$N_1 \times 20 = \frac{1}{10} \times 19.8\,;$$

$$N_1 = \frac{19.8}{10 \times 20} = \frac{198}{2000}$$

(*iii*) To find eq. wt. of acid.

$$\text{Normality} = \frac{\text{wt.}}{\text{Eq. wt.}} \times \frac{1000}{\text{Volume of acid in mL}}$$

$$\therefore \quad \text{Eq. wt.} = \frac{\text{wt.} \times 1000}{\text{Normality} \times \text{Volume of acid in mL}}$$

$$= \frac{0.6238 \times 1000 \times 2000}{198 \times 100} = 63$$

Since the acid is dibasic ; Eq. wt. of

$$H_2C_2O_4.xH_2O = \frac{\text{Mol. wt. of } H_2C_2O_4.xH_2O}{2}$$

$$63 = \frac{(2 \times 1) + (2 \times 12) + (4 \times 16) + x[(2 \times 1) + 16]}{2}$$

$$= \frac{90 + 18\,x}{2}\ \frac{(2 \times 63) - 90}{18}$$

$$= x\,;\ x = \frac{36}{18} = \mathbf{2} \quad \textbf{Ans.}$$

Type. Estimation of mixture of acids.

EXAMPLE 82. *20 mL of $\frac{N}{10}$ NaOH was needed to neutralise 12 mL of a solution containing HCl and H_2SO_4. When excess of $BaCl_2$ solution was added to 20 mL of acid solution, 0.296 g of $BaSO_4$ was obtained. Calculate the amount of HCl per litre of the solution. (at. wt., Ba = 137, S = 32, O = 16, H = 1)*

SOLUTION. (*i*) Only H_2SO_4 reacts with $BaCl_2$ solution.

$$\therefore \quad BaCl_2 + H_2SO_4 \longrightarrow BaSO_4\downarrow + 2HCl$$

$(2 \times 1) + 32 + (4 \times 16) = 98 \text{ g}$ $\quad 137 + 32 + (4 \times 16) = 233 \text{ g}$

233 g $BaSO_4$ is obtained from

H_2SO_4 = 98 g

0.296 g $BaSO_4$ is obtained from H_2SO_4

$$= \frac{98}{233} \times 0.296 = 0.1245 \text{ g}$$

(*ii*) 20 mL solution contain

H_2SO_4 = 0.1245 g

1000 mL solution contain

$$H_2SO_4 = \frac{0.1245}{20} \times 1000 = 6.225 \text{ gL}^-$$

$= \text{Strength of } H_2SO_4$

$$\text{Eq. wt. of } H_2SO_4 = \frac{\text{Mol. wt.}}{2} = \frac{(2 \times 1) + 32 + (4 \times 16)}{2}$$

$= 49 \qquad \therefore$ Normality of

$$H_2SO_4 = \frac{\text{Strength}}{\text{Eq. wt.}} = \frac{6.225}{49} = 0.127$$

(*iii*) N_1V_1 (acid mixture)

$= N_2V_2$ (NaOH)

$$N_1 \times 12 = \frac{1}{10} \times 20\,; N_1 = \frac{20}{10 \times 12} = 0.167$$

$\therefore$ Normality of HCl = 0.167 – 0.127 = 0.04

$$(iv) \text{ Eq. wt. of HCl} = \frac{1 + 35.5}{1} = 36.5$$

$\therefore$ Strength of HCl = Normality × Eq. wt

$= 0.04 \times 36.5 = \mathbf{1.46\ gL^-}$ **Ans.**

Type. Solutions whose sp. gravity or density is given.

EXAMPLE 83. *A 20 mL solution of Na_2CO_3 (sp. gravity, 1.35) needed 26.3 mL of HCl solution containing 87.5 g of acid per litre for complete neutralisation. Find the volume of 0.75N H_2SO_4 that would be required to completely neutralise 106 g of Na_2CO_3 solution.*

SOLUTION. (*i*) Eq. wt. of

$$\text{HCl} = 1 + 35.5 = 36.5$$

$$\therefore \text{ Normality of HCl} = \frac{\text{Strength}}{\text{Eq. wt.}} = \frac{87.5 \text{ g L}^{-}}{36.5} = 2.4$$

(*ii*) $N_1V_1\,(Na_2CO_3) = N_2V_2\,(HCl)$

$$N_1 \times 20 = 2.4 \times 26.3\,;\, N_1 = \frac{2.4 \times 26.3}{20} = 3.156$$

(*iii*) Volume of 106 g Na_2CO_3 solution

$$= \frac{\text{wt.}}{\text{sp. gr.}} = \frac{106}{1.35} = 78.5 \text{ mL}$$

(*iv*) $N_1V_1\,(Na_2CO_3) = N_2V_2\,(H_2SO_4)$

$$3.156 \times 78.5 = 0.75 \times V_2\,;$$

$$V_2 = \frac{3.156 \times 78.5}{0.75} = 330.3 \text{ mL}$$

$\therefore$ 330.3 mL H_2SO_4 will be used to neutralise 106 g Na_2CO_3.

EXAMPLE 84. *A mixture of anhydrous Na_2CO_3 and K_2CO_3 weighing 1.0 g was dissolved in 250 mL measuring flask. 17.4 mL of this solution was neutralised by 18 mL of HCl. The resulting solution required 15.0 mL of N/10 $AgNO_3$ solution for precipitation. Calculate the strength of HCl and percentage composition of the sample.*

SOLUTION. (*i*) N_1V_1 (HCl)

$$= N_2V_2\,(AgNO_3)$$

$$N_1 \times 18 = \frac{1}{10} \times 15\,;\, N_1 = \frac{15}{180}$$

(*ii*) wt. of HCl used by mixture (250 mL) is calculated as follows.

$$\text{Normality} = \frac{\text{wt.}}{\text{Eq. wt.}} \times \frac{1000}{\text{Volume of acid in mL}}$$

$$\text{Eq. wt. of HCl} = 1 + 35.5 = 36.5$$

$$\therefore \quad \text{wt.} = \frac{\text{Normality} \times \text{Eq. wt.} \times \text{Volume in mL}}{1000}$$

$$= \frac{15}{180} \times \frac{36.5 \times 18}{1000}$$

17.4 mL solution contain $Na_2CO_3 + K_2CO_3$

$$= \frac{15 \times 36.5 \times 18}{180 \times 1000} \text{ g}$$

$\therefore$ 250 mL solution contain $Na_2CO_3 + K_2CO_3$

$$= \frac{15 \times 36.5 \times 18}{180 \times 1000} \times \frac{250}{17.4} = 0.7866 \text{ g}$$

(*iii*) Let wt. of Na_2CO_3 = x g ; wt. of K_2CO_3 = $(1 - x)$ g

$$\underset{\substack{(2 \times 23) + 12 + (3 \times 16) \\ = 106 \text{ g}}}{Na_2CO_3} + \underset{\substack{2[1 + 35.5] \\ = 73 \text{ g}}}{2HCl} \longrightarrow 2NaCl + CO_2 + H_2O$$

106 g Na_2CO_3 need

$$\text{HCl} = 73 \text{ g}$$

$$x \text{ g } Na_2CO_3 \text{ need HCl} = \frac{73\,x}{106} \text{ g}$$

$$\underset{\substack{(2 \times 39) + 12 \\ + (3 \times 16) = 138 \text{ g}}}{K_2CO_3} + \underset{\substack{2[1 + 35.5] \\ = 73 \text{ g}}}{2HCl} \longrightarrow 2KCl + CO_2 + H_2O$$

138 g K_2CO_3 need

$$\text{HCl} = 73 \text{ g}$$

$$(1 - x) \text{ g } K_2CO_3 \text{ need HCl} = \frac{73}{138}(1 - x)\text{g}$$

$$\therefore \quad \frac{73\,x}{106} + \frac{73(1-x)}{138} = 0.7866$$

$$73 \times 138x + 106 \times 73 - 106 \times 73x = 0.7866 \times 106 \times 138\ 10{,}074 + 7738$$

$$- 7738x = 11506.4\,;\, 7738x = 6305.6$$

$$\therefore \quad x = \frac{6305.6}{7738} = 0.8149 \text{ g.}$$

$\therefore$ wt. of Na_2CO_3 = 0.8149 g

$$\% \text{ age of } Na_2CO_3 = \frac{0.8149}{1} \times 100 = \mathbf{81.49\%} \qquad \textbf{Ans.}$$

$$\% \text{ age of } K_2CO_3 = 100 - 81.49 = \mathbf{18.51\%} \qquad \textbf{Ans.}$$

EXAMPLE 85. *25 mL of a solution of HCl neutralises 27.0 mL of 4% solution of Na_2CO_3. How much water should be added to get 250 mL of N/10 HCl.*

SOLUTION. wt. of Na_2CO_3 = 4.0 g ; Volume = 100 mL because of 4% Na_2CO_3 solution. Eq. wt. of Na_2CO_3 = Mol. wt/2 = [(2 × 23) + 12 + (3 × 16)]/2 = 53 ; wt. of Na_2CO_3 per 1000 mL (= 1L) = $\frac{4 \times 1000}{100}$ = 40 g L^{-}.

$\therefore$ Normality of

$$Na_2CO_3 = \frac{\text{Strength in g L}^{-}}{\text{Eq. wt.}} = \frac{40}{53} = 0.7547$$

(*ii*) $N_1V_1\,(Na_2CO_3) = N_2V_2\,(HCl)$

$$0.7547 \times 27 = N_2 \times 25\,;\, N_2 = \frac{0.7547 \times 27}{25} = 0.815$$

(*iii*) To find volume of water to be added to get 250 mL of $\frac{N}{10}$ HCl.

$$N_1V_1 \text{ (given HCl)} = N_2V_2 \text{ (acid to be prepared)}$$

$$0.815 \times V_1 = \frac{1}{10} \times 250\,;$$

$$V_1 = \frac{250}{10} \times \frac{1}{0.815} = 30.7 \text{ mL}$$

$\therefore$ In order to prepare 250 mL of N/10 HCl, take exact 30.7 mL of given acid in 250 mL measuring flask, add water to get exact 250 mL.

$\therefore$ Volume of water to be added to 30.7 mL given acid

$$= 250 - 30.7 = \mathbf{219.3 \text{ mL}} \qquad \textbf{Ans.}$$

EXAMPLE 86. *48 cm^3 of a solution containing a mixture of $NaHCO_3$ and Na_2CO_3 were titrated with N HCl. First of* *all phenolphthalein was used as indicator and the end point was obtained with 28 cm^3 of N HCl. After this, methyl orange indicator was added to this resulting solution and end point was obtained with further addition of 48 cm^3 of N HCl. Calculate the strength of both $NaHCO_3$ and Na_2CO_3 in gL$^-$.*

(IIT 1979, Orissa JEE, 2009)

Solution. (*i*) *Phenolphthalein indicator.* Only half Na_2CO_3 is neutralised.

$\therefore$ 1N HCl used to titrate $\frac{1}{2}$ Na_2CO_3 = 28 cm^3

(*ii*) *Methyl orange indicator.* Here $\frac{1}{2}Na_2CO_3$ and full $NaHCO_3$ is neutralised.

$\therefore$ 1N HCl used to titrate $\frac{1}{2}Na_2CO_3$ + full

$NaHCO_3$ = 48 cm^3.

$\therefore$ 1N HCl used to titrate full

$NaHCO_3$ = 48 – 28 = 20 cm^3.

Also, 1N HCl used to neutralise full

Na_2CO_3 = 2 × 28 = 56 cm^3.

(*iii*) Eq. wt. of

$$Na_2CO_3 = \frac{\text{Mol. wt.}}{2} = \frac{(2\times23)+12+(3\times16)}{2} = \frac{106}{2} = 53$$

$$N_1V_1\,(Na_2CO_3) = N_2V_2\,(HCl)$$

$$N_1 \times 48 = 1 \times 56\,;\; N_1 = \frac{56}{48}$$

$$\text{Normality} = \frac{\text{wt. of } Na_2CO_3}{\text{Eq. wt. of } Na_2CO_3} \times \frac{1000}{\text{Volume of solution in mL}}$$

$$\therefore \quad \text{wt. of } Na_2CO_3 = \frac{\text{Normality}\times\text{Eq. wt.}\times\text{Volume}}{1000}$$

$$= \frac{56}{48}\times53\times\frac{1000}{1000} = \mathbf{61.83\ gL^-}\ \textbf{Ans.}$$

(*iv*) $N_1V_1\,(NaHCO_3) = N_2V_2\,(HCl)$

$$N_1 \times 48 = 1 \times 20\,;\; N_1 = \frac{20}{48}$$

$$\text{Eq. wt. of } NaHCO_3 = 23 + 1 + 12 + (3 \times 16) = 84$$

$$\text{Normality of } NaHCO_3 = \frac{\text{wt.}}{\text{Eq. wt.}} \times \frac{1000}{\text{Volume of solution in mL}}$$

$$\therefore \quad \text{wt.} = \frac{\text{Normality}\times\text{Eq. wt.}\times\text{Volume of solution in mL}}{1000}$$

$$= \frac{20}{48}\times\frac{84\times1000}{1000} = \mathbf{35\ gL^-}\quad \textbf{Ans.}$$

Example 87. *48 mL of a solution containing NaOH and Na_2CO_3 were neutralised by 40 mL of 1N H_2SO_4, using methyl orange indicator from the very beginning. Na_2CO_3 was precipitated by adding $CaCl_2$ solution and solution filtered. The resulting solution containing NaOH required 19.0 mL of 1N H_2SO_4 for complete neutralisation using phenolphthalein as indicator. Calculate the weight of Na_2CO_3 and NaOH in gL$^-$ in the mixture.*

Solution. (*i*) *Phenolphthalein indicator.*

$$N_1V_1\,(NaOH) = N_2V_2\,(H_2SO_4)$$

$$N_1 \times 48 = 1 \times 19\,;\; N_1 = \frac{19}{48}$$

$$\text{But wt. of NaOH} = \frac{\text{Normality}\times\text{Eq. wt.}\times\text{Volume of solution in mL}}{1000}$$

$$= \frac{19}{48}\times\frac{40\times1000}{1000} = \mathbf{15.83\ gL^-}\ \textbf{Ans.}$$

(*ii*) **Methyl orange indicator**. Here, full NaOH and full Na_2CO_3 will be neutralised by H_2SO_4.

$\therefore$ Volume of 1N H_2SO_4 used = 40 – 19 = 21 mL

$$N_1V_1\,(Na_2CO_3) = N_2V_2\,(H_2SO_4)$$

$$N_1 \times 48 = 1 \times 21\,;\; N_1 = \frac{21}{48}$$

$$\therefore \quad \text{wt. of } Na_2CO_3 = \frac{\text{Normality}\times\text{Eq. wt.}\times\text{Volume of solution in mL}}{1000}$$

$$= \frac{21}{48}\times\frac{53\times1000}{1000} \simeq \mathbf{23.19\ gL^-}\ \textbf{Ans.}$$

Example 88. *0.68 g sample containing washing soda, caustic soda and inert substance was dissolved in water and titrated with 0.48 N H_2SO_4 using phenolphthalein indicator. 19.8 mL of this acid was used to get end point. 4.8 mL of more acid was added to get end point of red colour using methyl orange as indicator. Calculate the percentage composition of the given sample.*

(Orissa JEE, 2009)

Solution. (*i*) Phenolphthalein indicator. Total NaOH and $\frac{1}{2}$ Na_2CO_3 gets neutralised with the given acid.

$\therefore$ Volume of 0.48 N H_2SO_4 used to neutralise total NaOH + $\frac{1}{2}$ Na_2CO_3 = 19.8 mL

(*ii*) Methyl orange indicator. $\frac{1}{2}$ Na_2CO_3 is neutralised by 0.48 N H_2SO_4

$\therefore$ Volume of 0.48 N H_2SO_4 used to neutralise total

Na_2CO_3 = 2 × 4.8 = 9.6 mL

$\therefore$ Volume of 0.5 N H_2SO_4 used to neutralise

NaOH = 19.8 – 4.8 = 15 mL

(*iii*) 9.6 mL of 0.48 N H_2SO_4

$\equiv$ 9.6 mL 0.48 N Na_2CO_3

$\therefore$ 1000 mL of 1N

Na_2CO_3 = g. eq. wt. of Na_2CO_3 = 53 g

$$9.6\text{ mL of }0.48\text{ N } Na_2CO_3 = \frac{53}{1000}\times9.6\times0.48 = 0.244\text{ g}$$

$\therefore$ % age of $Na_2CO_3 = \dfrac{0.244}{0.68} \times 100$ = **35.88%** **Ans.**

(*iv*) 15mL of 0.48 N

$H_2SO_4 \equiv$ 15 mL of 0.48 N NaOH

$\therefore$ 1000 mL of 1N NaOH

$\equiv$ g. eq. wt. of NaOH = 40 g

$\therefore$ 15 mL of 0.48 N NaOH

$= \dfrac{40}{1000} \times 15 \times 0.48 = 0.288$ g

$\therefore$ % age of NaOH $= \dfrac{0.288}{0.68} \times 100$ = **42.35%** **Ans.**

(*v*) % age of inert substance

= 100 − 35.88 − 42.35 = **21.77%** **Ans.**

Example 89. *2.1 g of a sample containing NaOH and Na_2CO_3 was dissolved in water and solution was made up to exact 250 mL. A 20 mL of this solution required 40 mL of N/10 H_2SO_4 for complete neutralisation. Calculate the percentage by weight of NaOH and Na_2CO_3.*

Solution. Let wt. of

$Na_2CO_3 = x$ g ; wt. of NaOH = (2.1 − x) g

(*i*) $Na_2CO_3 + H_2SO_4 \longrightarrow Na_2SO_4 + CO_2 + H_2O$

$(2 \times 23) + 12 + (3 \times 16) = 106$ g $\quad (2 \times 1) + 32 + (4 \times 16) = 98$ g

106 g Na_2CO_3 react with H_2SO_4 = 98 g

x g Na_2CO_3 react with $H_2SO_4 = \dfrac{98\,x}{106}$ g

(*ii*) $2NaOH + H_2SO_4 \longrightarrow Na_2SO_4 + 2H_2O$

2[23 + 16 + 1] = 80 g $\quad (2 \times 1) + 32 + (4 \times 16) = 98$ g

80 g NaOH react with H_2SO_4 = 98 g

(2.1 − x) g NaOH react with $H_2SO_4 = \dfrac{98}{80} \times (2.1 - x)$g

$\therefore$ Total H_2SO_4 required $= \dfrac{98x}{106} + \dfrac{98(2.1-x)}{80}$ ...(*A*)

(*iii*) 20 mL solution require N/10

H_2SO_4 = 40 mL; 250 mL solution require

N/10 $H_2SO_4 = \dfrac{40}{20} \times 250$ = 500 mL.

$\therefore$ Wt. of $H_2SO_4 = \dfrac{\text{Normality} \times \text{Eq. wt.} \times \text{Volume in mL}}{1000}$

$= \dfrac{1}{10} \times 49 \times \dfrac{500}{1000} = 2.45$ g ...(*B*)

Equating equations (*A*) and (*B*), we get :

$$\frac{98\,x}{106} + \frac{98(2.1-x)}{80} = 2.45$$

98 × 80x + (98 × 106 × 2.1) − (106 × 98x)

= 2.45 × 106 × 80

7840x + 21814.8 − 10388x

= 20776 ; 2548x = 1038.8 ;

x = 0.4077 g = wt. of Na_2CO_3

% age of $Na_2CO_3 = \dfrac{0.4077}{2.1} \times 100$ = **19.4%** **Ans.**

% age of NaOH = 100 − 19.4 = **80.6%** **Ans.**

Example 90. *Firstly 24 cm^3 of formaldehyde were added to 48 cm^3 of 1N NaOH and then oxidised with hydrogen peroxide. The resulting solution needed 25 mL of 0.85 N HCl for complete neutralisation. Calculate the concentration of the formaldehyde solution.*

Solution. Reaction.

(*i*) $HCHO + H_2O_2 \longrightarrow HCOOH + H_2O$.

Formaldehyde $\quad$ Formic acid

$HCOOH + NaOH \longrightarrow HCOONa + H_2O$.

(*ii*) N_1V_1 (NaOH) = N_2V_2 (HCl); 1 × V_1 = 0.85 × 25 ;

V_1 = 0.85 × 25 = 21.25 cm^3.

It is the volume of unused NaOH

$\therefore$ Volume of used NaOH = 48 − 21.25 = 26.75 cm^3.

(*iii*) Eq. wt. of

HCHO = 1 + 12 + 1 + 16 = 30 26.75 cm^3 of

1N NaOH ≡ 26.75 cm^3 of 1N HCHO.

Also, 1000 cm^3 of 1N HCHO contain

HCHO = g. eq. wt. of

HCHO = 30 g

26.75 cm^3 of 1N HCHO contain HCHO $= \dfrac{30}{1000} \times 26.75 \times 1$

= 0.8025 g

(*iv*) 24 cm^3 solution contain

HCHO = 0.8025 g

1000 cm^3 solution contain HCHO

$= \dfrac{0.8025}{24} \times 1000$ = **33.44 gL^{-}** **Ans.**

Example 91. *1.1 g of a mixture of Na_2CO_3 and K_2CO_3 was dissolved in water and solution was made up to 100 mL. 19.5 mL of this solution required 39.5 mL of decinormal HCl for complete neutralisation. Find the amount of Na_2CO_3 in the mixture if another solution of 19.5 mL of solution is treated with excess of $BaCl_2$. Find the weight of precipitate formed. (at. wt. of Ba = 137).* **(IIT 1976)**

Solution. Let wt. of

$Na_2CO_3 = x$ g ; wt. of K_2CO_3 = (1.1 − x) g

(*i*) $Na_2CO_3 + 2HCl \longrightarrow 2NaCl + CO_2 + H_2O$

$(2 \times 23) + 12 + (3 \times 16) = 106$ g $\quad 2[1 + 35.5] = 73$ g

106 g Na_2CO_3 react with

HCl = 73 g

x g Na_2CO_3 react with HCl $= \dfrac{73}{106} \times x = \dfrac{73\,x}{106}$ g

(*ii*) $K_2CO_3 + 2HCl \longrightarrow 2KCl + CO_2 + H_2O$

$(2 \times 39) + 12 + (3 \times 16) = 138$ g $\quad 2(1 + 35.5) = 73$ g

138 g K_2CO_3 react with

$$\text{HCl} = 73 \text{ g}$$

$$(1.1 - x) \text{ g } K_2CO_3 \text{ react with HCl} = \frac{73}{138} \times (1.1 - x)$$

$$\therefore \text{ Total HCl used} = \frac{73\,x}{106} + \frac{73\,(1.1 - x)}{138} \quad ...(A)$$

(*iii*) 19.5 mL solution = 39.5 mL of 0.1N HCl 100 mL

$$\text{solution} = \frac{39.5}{19.5} \times 100 \text{ mL of 0.1N HCl}$$

$$= 202.55 \text{ mL of 0.1N HCl.}$$

$$\text{Eq. wt. of HCl} = 1 + 35.5 = 36.5$$

$$\text{Normality of HCl} = \frac{\text{wt.}}{\text{Eq. wt.}} \times \frac{1000}{\text{Volume of solution in mL}}$$

$$\therefore \quad \text{wt. of HCl} = \frac{\text{Normality} \times \text{Eq. wt.} \times \text{Volume in mL}}{1000}$$

$$= \frac{1}{10} \times \frac{36.5 \times 202.55}{1000} = 0.7393 \text{ g} \; ...(B)$$

Equating equations (*A*) and (*B*), we get.

$$\frac{73\,x}{106} + \frac{73\,(1.1 - x)}{138} = 0.7393$$

$$(73 \times 138x) + (106 \times 73 \times 1.1) - (106 \times 73x) = 0.7393 \times 106 \times 138 \;\; 10074x + 8511.8$$

$$- 7738x = 10814.48 \; ; \; 2336x = 2302.68$$

$$\therefore \quad x = \frac{2302.68}{2336} = \mathbf{0.9857 \text{ g}}$$

$$= \textbf{wt. of } \mathbf{Na_2CO_3}$$

$$\textbf{wt. of } \mathbf{K_2CO_3} = 1.1 - 0.9857 = \mathbf{0.1143 \text{ g}}$$

(*iv*) $\underset{\substack{(2 \times 23) + 12 + (3 \times 16) \\ = 106 \text{ g}}}{Na_2CO_3} + BaCl_2 \longrightarrow \underset{\substack{137 + 12 + (3 \times 16) \\ = 197 \text{ g}}}{BaCO_3} + 2NaCl$

$\underset{\substack{(2 \times 39) + 12 + (3 \times 16) \\ = 138 \text{ g}}}{K_2CO_3} + BaCl_2 \longrightarrow \underset{\substack{137 + 12 + (3 \times 16) \\ = 197 \text{ g}}}{BaCO_3\downarrow} + 2KCl$

To find the weight of $BaCO_3$ ppt. in 20 mL of given mixture.

wt. of Na_2CO_3 in 20 mL mixture solution = 0.9857 g

wt. of K_2CO_3 in 20 mL mixture solution = 0.1143 g

(*a*) 106 g Na_2CO_3 form $BaCO_3$ ppt. = 197 g

0.9857 g Na_2CO_3 form $BaCO_3$ ppt.

$$= \frac{197}{106} \times 0.9857 = 1.8319 \text{ g}$$

(*b*) 138 g K_2CO_3 form $BaCO_3$ ppt.

$$= 197 \text{ g}$$

$$0.1143 \text{ g } K_2CO_3 \text{ form } BaCO_3 \text{ ppt.} = \frac{197}{138} \times 0.1143$$

$$= 0.1632 \text{ g}$$

∴ Total wt. of $BaCO_3$ ppt.

$$= 1.8319 + 0.1632 = \mathbf{1.9951 \text{ g}} \quad \textbf{Ans.}$$

EXAMPLE 92. *A commercial sample (3.0 g) containing $CaCO_3$ and SiO_2 was treated with 98 mL of 1N HCl. After filtration, the solution was made up to 200 mL. 20 mL of this solution required 24.5 mL of 0.2 N NaOH for neutralisation. Find the weight of $CaCO_3$ in the given sample.*

SOLUTION. Let. wt. of $CaCO_3$ = *x* g ; wt. of SiO_2 = (3.0 – *x*) g. Only $CaCO_3$ will react with HCl.

(*i*) $\underset{\substack{40 + 12 + (3 \times 16) \\ = 100 \text{ g}}}{CaCO_3} + \underset{\substack{2(1 + 35.5) \\ = 73 \text{ g}}}{2HCl} \longrightarrow CaCl_2 + CO_2 + H_2O$

100 g $CaCO_3$ react with

$$\text{HCl} = 73 \text{ g}$$

$$x \text{ g } CaCO_3 \text{ react with HCl} = \frac{73\,x}{100} \text{ g}. \quad ...(A)$$

(*ii*) To find volume of unused HCl :

$$N_1V_1 \text{ (HCl)} = N_2V_2 \text{ (NaOH)}$$

$$1 \times V_1 = 0.2 \times 24.5 \; ;$$

$$V_1 = 0.2 \times 24.5 = 4.9 \text{ mL}$$

$$= \text{Volume of unused HCl}$$

∴ Volume of used

$$\text{HCl} = 98 - 4.9 = 93.1 \text{ mL}$$

(*iii*) Eq. wt. of HCl = 1 + 35.5 = 36.5

$$\text{Normality of HCl} = \frac{\text{wt.}}{\text{Eq. wt.}} \times \frac{1000}{\text{Volume of acid in mL}}$$

$$\therefore \quad \text{wt. of HCl} = \frac{\text{Normality} \times \text{Eq. wt.} \times \text{Volume of acid in mL}}{1000}$$

$$= \frac{1}{10} \times \frac{36.5 \times 93.1}{1000} = 0.3398 \text{ g} \quad ...(B)$$

From equations (*A*) and (*B*), we have :

$$\frac{73\,x}{100} = 0.3398 \; ; \; x = \frac{0.3398 \times 100}{73}$$

$$= \mathbf{0.4655 \text{ g}} = \text{wt. of } CaCO_3 \quad \textbf{Ans.}$$

EXAMPLE 93. *In a volumetric method, a few gram of $CaCO_3$ completely neutralised 550 mL of N/10 HCl and no acid was left behind. The $CaCl_2$ so formed was completely converted to plaster of Paris. Find the weight of Plaster of Paris so formed.*

(Dhanbad 1991)

SOLUTION.

(*i*) To find weight of HCl.

$$\text{wt. of HCl} = \frac{\text{Normality} \times \text{Eq.wt.} \times \text{Volume in mL}}{1000}$$

$$= \frac{1}{10} \times \frac{36.5 \times 550}{1000} = 2.0 \text{ g}$$

(*ii*) $\underset{\substack{40 + 12 + (3 \times 16) \\ = 100 \text{ g}}}{CaCO_3} + \underset{\substack{2(1 + 35.5) \\ = 73 \text{ g}}}{2HCl} \longrightarrow CaCl_2 + CO_2 + H_2O$

73 g HCl react with

$$CaCO_3 = 100 \text{ g}$$

$$2 \text{ g HCl react with } CaCO_3 = \frac{100}{73} \times 2 = \mathbf{2.7397 \text{ g}}$$

1 mol $CaCO_3$ ≡ 1 mol plaster of Paris *i.e.*, $CaSO_4 \cdot \frac{1}{2} H_2O$.

$$40 + 12 + (3 \times 16) \qquad 40 + 32 + (4 \times 16) + \frac{1}{2}[(2 \times 1) + 16]$$

$$= 100 \text{ g} \qquad\qquad = 145 \text{ g}$$

100 g $CaCO_3$ form plaster of Paris

$$= 145 \text{ g}$$

$$2.7397 \text{ g } CaCO_3 \text{ form plaster of Paris} = \frac{145}{100} \times 2.7397$$

$$= \mathbf{3.9726 \text{ g}} \qquad \textbf{Ans.}$$

Type. To fnd number of molecules of water of crystallisation.

Example 94. *1.5 g of hydrated sodium carbonate were dissolved in 100 cm^3 of water. 20 cm^3 of the solution required 10.4 cm^3 of N/5 H_2SO_4 for complete neutralisation. Calculate the number of molecules of water of crystalisation of hydrated sodium carbonate.*

Solution. Let hydrated sodium carbonate

$$= Na_2CO_3.xH_2O$$

Eq. wt. of $Na_2CO_3\ xH_2O$

$$= \frac{\text{Mol. wt.}}{2}$$

$$= \frac{(2 \times 23) + 12 + (3 \times 16) + x[(2 \times 1) + 16]}{2} = 53 + 9x.$$

(*i*) $N_1V_1\ (Na_2CO_3) = N_2V_2\ (H_2SO_4)$

$$N_1 \times 20 = \frac{1}{5} \times 10.4\ ; N_1 = \frac{1}{5} \times \frac{10.4}{20} = 0.104$$

Strength of $Na_2CO_3.xH_2O$ = Normality × eq. wt.

$$= 0.104 \times (53 + 9x) \text{ gL}^- \qquad ...(A)$$

(*ii*) 100 cm^3 solution contain $Na_2CO_3.xH_2O$ = 1.5 g
1000 cm^3 (= 1L) solution contain

$$Na_2CO_3.xH_2O = \frac{1.5}{100} \times 1000 = 15 \text{ g} \qquad ...(B)$$

Equating equations (*A*) and (*B*) we get :

$$0.104(53 + 9x) = 15\ ; (0.104 \times 53) + (0.104 \times 9x)$$

$$= 15\ 5.512 + 0.936x = 15\ ; 0.936x$$

$$= 15 - 5.512 = 9.488$$

$$\therefore \qquad x = \frac{9.488}{0.936} \simeq 10.$$

So, number of molecules of water of crystallisation of

$$Na_2CO_3.xH_2O = \mathbf{10} \qquad \textbf{Ans.}$$

Example 95. *20 cm^3 of a solution containing 6.1 gL$^-$ of compound $K_xH_y(C_2O_4)_z.nH_2O$ required for titration, 28.8 cm^3 of N/20 NaOH and 38.55 cm^3 of N/20 $K_2Cr_2O_7$ for complete oxidation. Calculate the value of x, y, z and n. (At. wt., K = 39, H = 1, C = 12, O = 16)*

Solution. The compound oxalate $K_xH_y(C_2O_4)_z.nH_2O$ can act both as an acid and reductant.

(*i*) **As acid.**N_1V_1 (acid)

$$= N_2V_2 \text{ (NaOH)}$$

$$N_1 \times 20 = \frac{1}{20} \times 28.8\ ; N_1 = \frac{28.8}{20 \times 20} = 0.072$$

$$\text{Eq. wt. of acid} = \frac{\text{Strength}}{\text{normality}} = \frac{6.1}{0.072} = 84.72$$

$$\text{Also,eq. wt. of acid} = \frac{\text{Mol. wt.}}{\text{Basicity (= no. of replaceable } H^+ \text{ ions)}}$$

$$84.72 = \frac{\text{Mol. wt.}}{y} \qquad ...(i)$$

(*ii*) *As reductant.*N_1V_1 (reductant)

$$= N_2V_2\ (K_2Cr_2O_7)$$

$$N_1 \times 20 = \frac{1}{20} \times 38.55\ ; N_1 = \frac{38.55}{20 \times 20} = 0.096.$$

$$\therefore \text{ Eq. wt. of reductant} = \frac{\text{Strength}}{\text{normality}} = \frac{6.1}{0.096} = 63.54$$

Also,Eq. wt. of reductant

$$= \frac{\text{Mol. wt.}}{2z} \left[\because C_2O_4^{2-} \rightarrow 2CO_2 + 2e^-\right]$$

$$63.54 = \frac{\text{Mol. wt.}}{2z} \qquad ...(ii)$$

Dividing equations (*i*) by (*ii*), we get

$$\frac{84.72}{63.54} = \frac{2z}{y}\ ; y = \frac{2 \times 63.54}{84.72} z\ ;$$

$$y = 1.5z \qquad ...(iii)$$

(*iii*) In $K_xH_y(C_2O_4)_z.nH_2O$, total positive charge = total negative charge.

$$\therefore x \times (+1) + y \times (+1) = 2 \times z\ ; x + y = 2z$$

$$\text{or} \qquad x + 1.5z = 2z\ ; \mathbf{x = 0.5z}$$

$$\therefore \qquad x : y : z = 0.5z : 1.5z : z\ ;\ x : y : \underline{z}$$

$$= \frac{36}{18}\ i.e\ ; 1 : 3 : 2$$

$$\therefore \qquad \mathbf{x = 1, y = 3, z = 2} \qquad \textbf{Ans.}$$

(*iv*) Mol. wt. = 84.72 y [from equation, (*i*)]

$$= 84.72 \times 3$$

$$= 254.16 \text{ g mol}^- \simeq 254 \text{ g mol}^-$$

∴ Mol. wt. of

$$K_xH_y(C_2O_4)_z.nH_2O = 254\ (x \times 39) + (y \times 1) + z[(2 \times 12) + (4 \times 16)] + n[(2 \times 1) + 16]$$

$$= 254\ 39x + y + 88z + 18n$$

$$= 254\ (39 \times 1) + 3 + (88 \times 2)$$

$$+ 18n = 254\ ; 39 + 3 + 176 + 18n = 254$$

$$\therefore \qquad n = \frac{36}{18} = 2$$

$$\therefore \qquad \mathbf{x = 1, y = 3\ z = 2, n = 2} \qquad \textbf{Ans.}$$

Example 96. *A 10 cm^3 solution of ammonium sulphate was boiled with excess NaOH solution. The evolved ammonia gas was absorbed in 40 cm^3 of 0.1N HCl. 25 cm^3 of 0.1N NaOH was required to neutralise the unreacted HCl. Calculate the strength of ammonium sulphate in the solution.*

Solution. Reactions

(*i*) $(NH_4)_2SO_4 + 2NaOH \longrightarrow Na_2SO_4 + 2NH_3 + 2H_2O$

(*ii*) $NH_3 + HCl \longrightarrow NH_4Cl$

(*iii*) $NaOH + HCl \longrightarrow NaCl + H_2O$

$$\text{Eq. wt. of HCl} = 1 + 35.5 = 36.5$$

(*iv*) N_1V_1 (excess HCl) = N_2V_2 (NaOH)

$$0.1 \times V_1 = 0.1 \times 25 \; ; \; V_1 = 25 \text{ cm}^3$$

∴ Volume of HCl used by NH_3

$$= 40 - 25 = 15 \text{ cm}^3$$

$$\therefore \quad \text{wt. of HCl} = \frac{\text{Normality} \times \text{eq. wt.} \times \text{Volume in mL}}{1000}$$

$$= \frac{0.1 \times 36.5 \times 15}{1000} = 0.05475 \text{ g}$$

(*v*)

$$\underset{\substack{14 + (3 \times 1) \\ = 17 \text{ g}}}{NH_3} + \underset{\substack{1 + 35.5 \\ = 36.5 \text{ g}}}{HCl} \longrightarrow NH_4Cl$$

36.5 g HCl react with

$$NH_3 = 17 \text{ g}$$

0.05475 g HCl react with

$$NH_3 = \frac{17}{36.5} \times 0.05475 = 0.0255 \text{ g}$$

(*vi*)

$$\underset{\substack{2[14 + (4 \times 1)] + 32 \\ + (4 \times 16) = 132 \text{ g}}}{(NH_4)_2SO_4} + 2NaOH \longrightarrow Na_2SO_4 + \underset{\substack{2[14 + (3 \times 1)] \\ = 34 \text{ g}}}{2NH_3} + 2H_2O$$

34 g NH_3 is produced from

$$(NH_4)_2SO_4 = 132 \text{ g}$$

0.0255 g NH_3 is produced from

$$(NH_4)_2SO_4 = \frac{132}{34} \times 0.0255 = 0.099 \text{ g}$$

(*vii*) 10 cm³ solution contain $(NH_4)_2SO_4$ = 0.099 g

∴ 1000 cm³ (= 1L) solution contain

$$(NH_4)_2SO_4 = \frac{0.099}{10} \times 1000 = \mathbf{9.9 \ gL^{-}} \qquad \textbf{Ans.}$$

EXAMPLE 97. *A sample of carbon weighing 10.9 g reacts completely with 21.1 L oxygen at 291 K and 750 mm pressure. The liberated gases were cooled and passed through 1.9 L of 2.4 N NaOH solution. Calculate the amount of NaOH remaining in solution which is not converted to sodium carbonate. Also calculate the mole fraction of CO in the gases also. Note that under the above conditions, CO does not react with NaOH solution. (At. wt., C = 12)*

SOLUTION. (*i*) At. wt. (or mol. wt.) of

carbon = 12 g mol⁻. Wt. of carbon = 10.9 g

$$\therefore \text{Moles of carbon} = \frac{\text{wt.}}{\text{Mol. wt.}} = \frac{10.9}{12} = 0.9083$$

(*ii*)

$$P = 750 \text{ mm} \times \frac{1 \text{ atm}}{760 \text{ mm}} = \frac{75}{76} \text{ atm} \; ;$$

$$V = 21.1\text{L}, n = ? \; ;$$

$$R = 0.0821 \text{ L atm K}^{-} \text{mol}^{-} \; ;$$

$$T = 291 \text{ K. We know; } PV = nRT \; ;$$

$$n = \frac{PV}{RT} = \frac{75}{76} \text{ atm} \times \frac{21.1 \text{ L}}{0.0821 \text{ L atm K}^{-}\text{mol}^{-} \times 219 \text{ K}}$$

or n = 0.8716 mol = no. of mol of O_2

(*iii*) Let mol of CO_2 formed = x ; mol of CO formed = y

$$\underset{x \text{ mol}}{C} + \underset{x \text{ mol}}{O_2} \longrightarrow \underset{x \text{ mol}}{CO_2} \quad ; \quad \underset{y \text{ mol}}{C} + \underset{\frac{1}{2} y \text{ mol}}{\frac{1}{2} O_2} \longrightarrow \underset{y \text{ mol}}{CO}$$

$$\therefore \text{ No. of mol of carbon} = x + y$$

$$0.9083 = x + y \qquad \ldots(A)$$

$$\text{No. of mol of } O_2 = x + \frac{1}{2}y$$

$$0.8716 = x + \frac{1}{2}y \qquad \ldots(B)$$

Subtracting equation (*B*) from equation (*A*), we get

$$x + y - x - \frac{1}{2}y = 0.9083 - 0.8716 \; ;$$

$$\frac{1}{2}y = 0.0367$$

$$\therefore \quad y = 2 \times 0.0367 = \mathbf{0.0734 \ mol}$$

$$= \text{mol of CO}$$

Using equation (*A*), we have ; 0.9083 = x + 0.0734

$$\therefore \quad x = 0.9083 - 0.0734$$

$$= \mathbf{0.8349 \ mol} = \text{mol of } CO_2$$

(*iv*) Mole fraction of CO =

$$\frac{y}{x + y} = \frac{0.0734}{0.0734 + 0.8349} = \frac{0.0734}{0.9083} = \mathbf{0.08081}$$

(*v*) Eq. wt. of NaOH = 23 + 16 + 1 = 40;

Volume = 1.9 × 1000 = 1900 mL

$$\text{Normality of NaOH} = \frac{\text{wt.}}{\text{Eq. wt.}} \times \frac{1000}{\text{Volume of NaOH in mL}}$$

$$\therefore \quad \text{wt. of NaOH} = \frac{\text{Normality} \times \text{Eq. wt.} \times \text{Volume of NaOH in mL}}{1000}$$

$$= \frac{2.4 \times 40 \times 1900}{1000} = 182.4 \text{ g}$$

$$\therefore \text{ no. of mol of NaOH} = \frac{\text{wt.}}{\text{Mol. wt.}} = \frac{182.4}{40} = 4.56$$

Strength of remaining NaOH

$$= \frac{\text{no. of mol}}{\text{Volume in litre}} = \frac{4.56}{1.9}$$

$$= \mathbf{2.4} \qquad \textbf{Ans.}$$

EXAMPLE 98. *What volume at NTP of ammonia gas will be required to be passed into 30 mL 1N H_2SO_4 to bring down the acid normality to 0.2 N.* **(UPSEAT, 1991)**

SOLUTION. No. of milliequivalent (Meq) = Normality × Volume in mL

(*i*) No. of Meq of H_2SO_4 given = 1 × 30 = 30

(*ii*) No. of Meq of H_2SO_4 required = 0.2 × 30 = 6

∴ No. of Meq. of H_2SO_4 consumed = 30 – 6 = 24

∴ Meq of NH_3 passed

= Meq. of H_2SO_4 consumed = 24

∴ Meq. of NH_3 passed

$$= \frac{\text{wt. of } NH_3}{\text{Eq. wt. of } NH_3} \times 1000\,;$$

$$24 = \frac{\text{wt. of } NH_3}{17} \times 1000$$

$$\therefore \quad \text{wt. of } NH_3 = \frac{17 \times 24}{1000} = 0.408 \text{ g.}$$

(*iii*) 22400 mL NH_3 weighs

$$= \text{g. eq. wt. of } NH_3 = 17 \text{ g}$$

Or 17 g NH_3 occupy volume

$$= 22400 \text{ mL}$$

0.408 g NH_3 occupy volume

$$= \frac{22400}{17} \times 0.408 = \mathbf{537.6\ mL} \qquad \textbf{Ans.}$$

EXAMPLE 99. *What volume of a solution of hydrochloric acid containing 73 g of acid per litre would suffice for the exact neutralisation of sodium hydroxide obtained by allowing 0.46 g of metallic sodium to act upon water?* **(UPSEAT, 1997)**

SOLUTION. Reactions

$$Na + H_2O \longrightarrow NaOH + \frac{1}{2} H_2 \qquad \ldots(A)$$

$$NaOH + HCl \longrightarrow NaCl + H_2O \qquad \ldots(B)$$

(*i*) wt. of HCl = 73 g ; eq. wt. of HCl

$$= \frac{\text{Mol. wt.}}{\text{Total + ve charge}} = \frac{1 + 35.5}{1}$$

= 36.5 ; Volume of HCl = ?

$$\text{Normality of HCl} = \frac{\text{wt.}}{\text{Eq. wt.}} \times \frac{1000}{\text{Volume in mL} (= 1000 \text{ mL})}$$

$$= \frac{73}{36.5} \times 1 = 2$$

(*ii*) From reactions (*A*) and (*B*), we see that :

Meq of Na = Meq. of NaOH = Meq of HCl

$$\therefore \quad \text{Meq. of Na} = \frac{\text{wt. of Na}}{\text{Eq. wt. of Na}} \times 1000$$

$$= \frac{0.46}{23} \times 1000$$

Meq. of HCl = Normality × Volume in mL

$$= 2 \times V = 2V$$

$$\text{Thus,} \quad 2V = \frac{0.46}{23} \times 1000\,;$$

$$V = \frac{0.46}{23} \times \frac{1000}{2} = \mathbf{10\ mL} \qquad \textbf{Ans.}$$

EXAMPLE 100. *Calculate the weight of $BaSO_4$ precipitate formed when 25 mL of 0.1 M $Ba(NO_3)_2$ solution is mixed with 20 mL of 0.25 M of $Al_2(SO_4)_3$ solution.* (*At. wt., Ba = 137, S = 32, O = 16*)

SOLUTON.

$$3Ba(NO_3)_2 + Al_2(SO_4)_3 \longrightarrow 3BaSO_4\downarrow + 2Al(NO_3)_3$$

(Balanced)

Or $Ba(NO_3)_2 + Al_2(SO_4)_3 \longrightarrow BaSO_4\downarrow + Al(NO_3)_3$ (unbalanced).

Total charge on Ba^{2+} = 2 ; total + ve charge on

$$2Al^{3+} = 2 \times 3 = 6$$

[∵ $Ba(NO_3)_2 \rightleftharpoons Ba^{2+} + 2NO_3^-$; $Al_2(SO_4)_3 \rightleftharpoons 2Al^{3+} + 3SO_4^{2-}$]

First method. Use of unbalanced equation.

∴ In	$Ba(NO_3)_2$ +	$Al_2(SO_4)_3$ ⟶	$BaSO_4\downarrow$ +	$Al(NO_3)_3$
Meq before reaction = *m* × *V* in mL × valency factor	0.1 × 25 × 2 = 5	0.25 × 20 × 6 = 30	0	0
Meq after reacton	5 – 5 = 0	30 – 5 = 25	5	5

[∵ Out of 5 and 30 Meq of reactants, 5 is less than 30, so 5 Meq of $Ba(NO_3)_2$ will react with 5 Meq of $Al_2(SO_4)_3$ to form 5 Meq of $BaSO_4$ and 5 Meq of $Al(NO_3)_3$. *i.e.*, Meq $Ba(NO_3)_2$ = Meq $Al_2(SO_4)_3$ = Meq $BaSO_4$ = Meq $Al(NO_3)_3$].

$$\text{Hence Meq of } BaSO_4 = 5; \ \frac{\text{wt. of } BaSO_4}{\text{Eq. wt. of } BaSO_4} \times 1000 = 5$$

$$\left[\text{Eq. wt. of } BaSO_4 = \frac{\text{Mol. wt.}}{\text{Total + ve charge}} \right.$$

$$\left. \frac{137 + 32 + (4 \times 16)}{2} = \frac{233}{2} = 116.5 \right]$$

$$\frac{\text{wt. of } BaSO_4}{116.5} \times 1000 = 5$$

$$\therefore \quad \text{wt. of } BaSO_4 = \frac{5 \times 116.5}{1000} = \mathbf{0.5825\ g} \qquad \textbf{Ans.}$$

Second method. Use of balanced equation.

	$3Ba(NO_3)_2$ +	$Al_2(SO_4)_3$ →	$3BaSO_4\downarrow$ +	$2Al(NO_3)_3$
	3 mol	1 mol	3 mol	2 mol
	1 mol	$\frac{1}{3}$ mol	$\frac{3}{3}$ or 1 mol	$\frac{2}{3}$ mol
m. mol before reaction = $M \times V$ in L	0.1×25 $= 2.5$	0.25×20 $= 5$	0	0
m mol after reaction	$2.5 - 2.5$ $= 0$	$5 - \left(2.5 \times \frac{1}{3}\right)$	2.5×1 $= 2.5$	$2.5 \times \frac{2}{3}$

$$\therefore \ m \text{ Mol of } BaSO_4 = 2.5; \ \frac{\text{wt.}}{\text{mol. wt.}} \times 1000 = 2.5$$

$$\therefore \quad \text{wt. of } BaSO_4 = \frac{2.5 \times \text{mol. wt. of } BaSO_4}{1000}$$

$$= \frac{2.5 \times 233}{1000}\,;$$

$$\text{wt. of } BaSO_4 = \mathbf{0.5825\ g} \qquad \textbf{Ans.}$$

Type. Mixing of same type of solutions.

EXAMPLE 101. *How will you prepare exactly 4.0 L of 0.5 M HCl by mixing portions of stock solutions of 2.5 M HCl and 0.4 M HCl?*

Solution. Required : $4.0\,L \times \frac{0.5 \text{ mol.}}{L} = 2.0$ mol;

Let x = number of L of 2.5 M HCl

∴ no. of mol = $2.5 \times x = 2.5x$;

$4 - x$ = number of L of 0.4 M HCl

∴ no. of mol = $0.4(4 - x)$

∴ $2.5x + 0.4(4 - x) = 2$; $2.5x + 1.6 - 0.4$

$x = 2$; $2.1\,x = 0.4$

∴ $x = \frac{0.4}{2.1} = 0.19$ L ;

$4 - x = 4 - 0.19 = 3.81$ L

Hence by mixing 0.19 L of 2.5 M HCl and 3.81 L of 0.4 M HCl, we get 4.0 L of 0.5 M HCl.

Example 102. *How will you prepare exactly 2.5 L of 2.0 M NaCl by mixing portions of stock solutions of 4.5 M NaCl and 0.2 M NaCl?*

Solution. Needed : $2.5\,L \times \frac{2.0 \text{ mol.}}{L} = 5.0$ mol;

Let x = no. of L of 4.5 M NaCl ;

∴ no. of mol = $4.5 \times x = 4.5x$; Total volume required = 2.5 L ;

∴ $2.5 - x$ = no. of L of 0.2 M NaCl

Hence, no. of mol of

HCl = $(2.5 - x)\,0.2 = 0.5 - 0.2\,x$

∴ $4.5x + 0.5 - 0.2x = 5.0$ mol ; $4.3x = 4.5$

Or $x = \frac{4.5}{4.3} = 1.05$;

$2.5 - x = 2.5 - 1.05 = 1.45$

∴ 2.5 L of 2 M NaCl solution can be prepared by mixing 1.05 L of 4.5 M NaCl and 1.45 L of 0.2 M NaCl.

Example 103. *How will you prepare 3.0 L of 1.0 M NaOH by mixing portions of stock solutions of 2.0 M NaOH and 0.35 M NaOH ?*

Solution. Required number of mol of

NaOH = Molarity × Volume in L

$= \frac{1.0 \text{ mol}}{L} \times 3.0\,L = 3.0$ mol

Let x = no. of L of 2.0 M NaOH ;

∴ no. of mol = $2.0 \times x = 2x$;

Total volume = 3.0 L

$3 - x$ = no. of L of 0.35 M NaOH ;

∴ no. of mol = $0.35(3 - x)$

$(x \times 2) + (3 - x) \times 0.35 = 3.0$ mol ; $2x + 1.05 - 0.35x = 3$

$1.65x = 1.95$; $x = \frac{1.95}{1.65} = 1.18$ L ;

$2 - x = 2 - 1.18 = 0.82$ L

∴ By mixing 1.18 L of 2.0 M NaOH with 0.82 L of 0.35 M NaOH, 3.0 L of 1.0 M NaOH solution is prepared.

TYPE. Mixing of different salt solutions.

Example 104. *Calculate the concentration of each type of ion which remains in solution when 75 mL of 0.5 M NaCl is mixed with 40 mL of 0.25 M KCl.*

Solution. (*a*) $NaCl \rightleftharpoons Na^+ + Cl^-$

1 mol 1 mol 1 mol

No. of m. mol of $Na^+ = 75 \times 0.5 = 37.5$

No. of m. mol of $Cl^- = 75 \times 0.5 = 37.5$

(*b*) $KCl \rightleftharpoons K^+ + Cl^-$

1 mol 1 mol 1 mol

No. of m. mol of $K^+ = 40 \times 0.25 = 10$

No. of m. mol of $Cl^- = 40 \times 0.25 = 10$

Total volume of NaCl solution and KCl solution = 75 + 40 = 115 mL

∴ $[Na^+] = \frac{37.5 \text{ m. mol of } Na^+}{\text{Total volume} = 115 \text{ mL}}$

= **0.33 M** **Ans.**

$[K^+] = \frac{10 \text{ m. mol of } K^+}{\text{Total volume} = 115 \text{ mL}}$

= **0.087 M** **Ans.**

Total m. mol of Cl^- = 37.5 + 10 = 47.5.

∴ $[Cl^-] = \frac{47.5 \text{ m. mol of } Cl^-}{\text{Total volume} = 115 \text{ mL}}$

= **0.41 M** **Ans.**

Example 105. *Calculate the concentration of each type of ion which remains in solution when 50 mL of 0.4 M KCl is mixed with 75 mL of 2.0 m. mol of KCl and 125 mL of water.*

Solution. $KCl \rightleftharpoons K^+ + Cl^-$

1 mol 1 mol 1 mol

No. of m. mol of K^+ = $(0.4 \times 50) + 2.0 = 22$

Total volume of solution = 50 + 75 + 125 = 250 mL

∴ $[K^+] = \frac{22 \text{ m. mol}}{250 \text{ mL}} = 0.088 = [Cl^-]$ **Ans.**

Example 106. *Calculate the concentration of each type of ion which remains in solution when 100 mL of 0.5 M KCl is mixed with 50 mL of 0.25 M $AgNO_3$.*

Solution.

$AgNO_3 \rightleftharpoons Ag^+ + NO_3^-$; $KCl \rightleftharpoons K^+ + Cl^-$

1 mol 1 mol 1 mol 1 mol 1 mol 1 mol

$Ag^+ + Cl^- \longrightarrow AgCl\downarrow$

(*a*) No. of m. mol of $K^+ = 0.5 \times 100 = 50$

No. of m. mol of $Cl^- = 0.5 \times 100 = 50$

(*b*) No. of m. mol of $Ag^+ = 50 \times 0.25 = 12.5$

= no. of m. mol of NO_3^-

Since 12.5 m. mol of Ag^+ react with 12.5 m. mol of Cl^- to form AgCl ppt, the no. of m. mol of Cl^- left behind = 50 − 12.5 = 37.5.

Total volume = 100 + 50 = 150 mL

∴ $[Cl^-] = \frac{37.5}{150}$ = **0.25 M** **Ans.**

$[K^+] = \frac{50}{150}$ = **0.33 M** **Ans.**

$$[NO_3^-] = \frac{12.5}{150} = \mathbf{0.083\ M} \qquad \textbf{Ans.}$$

EXAMPLE 107. *Calculate the volume of 96% H_2SO_4 density, 1.84 g/mL that is needed to prepare 1.5 L of 2.5 M H_2SO_4 solution. (At. wt., H = 1, S = 32, O = 16).*

SOLUTON. (*a*) No. of mol of

$$H_2SO_4 = \text{Molarity} \times \text{Volume in L}$$

$$= \frac{2.5\ \text{mol}}{\text{L}} \times 1.5\ \text{L} = .3.75\ 96\%$$

H_2SO_4 means that 96 g of H_2SO_4 is present in 100 g solution.

$$\text{g. mol. wt. of } H_2SO_4 = (2 \times 1) + 32 + (4 \times 16)$$

$$= \mathbf{98\ g = 1\ mol}\ H_2SO_4$$

$$1 \text{ mol } H_2SO_4 \text{ weighs} = 98 \text{ g}$$

$\therefore$ 3.75 mol H_2SO_4 weighs

$$= 98 \times 3.75 = 367.5 \text{ g}$$

(*b*) 96 g H_2SO_4 is present in solution = 100 g

$$367.5 \text{ g } H_2SO_4 \text{ is present in solution } = \frac{100}{96} \times 367.5 \text{ g}$$

(*c*) $\text{Density} = \frac{\text{mass}}{\text{Volume}}$; $\text{Volume} = \frac{\text{mass}}{\text{density}}$

$$= \frac{100 \times 367.5}{96 \times 1.84} = \mathbf{208\ mL} \qquad \textbf{Ans.}$$

EXAMPLE 108. *How many mL of 2.0 M of HCl should be added to react completely with 16.8 g $NaHCO_3$? (At. wt., Na = 23, H = 1, C = 12, O = 16)*

SOLUTION. Reaction :

$$\underset{\substack{1\ \text{mol} \\ 23+1+12+ \\ (3\times 16) = 84\ \text{g}}}{NaHCO_3} + \underset{1\ \text{mol}}{HCl} \longrightarrow NaCl + CO_2 + H_2O$$

$$\text{Molarity of } NaHCO_3 = \frac{\text{wt.}}{\text{g. mol. wt.}} = \frac{16.8}{84} = 0.2\ \text{molL}^-$$

Using molarity equation, we have :

$$\frac{M_1V_1(\text{HCl})}{M_2V_2(\text{NaHCO}_3)} = \frac{1 \text{ mol HCl}}{1 \text{ mol NaHCO}_3}$$

$$\frac{2 \times V_1}{0.2 \times 1 L} = \frac{1}{1}; V_1 = \frac{0.2}{2} = 0.1 \text{ L}$$

$$= 0.1 \times 1000 \text{ mL} = \mathbf{100\ mL} \qquad \textbf{Ans.}$$

EXAMPLE 109. *Calculate the volume in mL of 0.45 M $KMnO_4$ solution that will react completely with 18.0 g of $K_2C_2O_4.H_2O$ as follows :*

$$2MnO_4^- + 5C_2O_4^{2-} + 16\,H^+ \longrightarrow 2Mn^{2+} + 10CO_2 + 8H_2O$$

(At. wt. K = 39, C = 12, O = 16, H = 1)

SOLUTION. Reaction :

$$\underset{2\ \text{mol}}{2MnO_4^-} + \underset{5\ \text{mol}}{5C_2O_4^{2-}} + 16H^+ \longrightarrow 2Mn^{2+} + 10CO_2 + 8H_2O$$

Molarity (M_1) of $KMnO_4$ = 0.45 M ; Volume, V_1 = ?

wt. of $K_2C_2O_4.H_2O$ = 18.0 g ; g. mol. wt. of $K_2C_2O_4.H_2O$ = (2 × 39) + (2 × 12) + (4 × 16) + (2 × 1) + 16 = 184 g.

$\therefore$ Molarity (M_2) of

$$K_2C_2O_4.H_2O = \frac{18}{184} \text{ mol} = 0.098 \text{ M}$$

Volume of $K_2C_2O_4.H_2O$ = 1L = 1000 mL

$$\text{We know}: \frac{M_1V_1(\text{KMnO}_4)}{M_2V_2(\text{K}_2\text{C}_2\text{O}_4\text{H}_2\text{O})}$$

$$= \frac{\text{no. of mol of KMnO}_4}{\text{no. of mol of K}_2\text{C}_2\text{O}_4.\text{H}_2\text{O}}$$

$$\frac{0.45 \times V_1}{0.098 \times 1000} = \frac{2}{5};$$

$$V_1 = \frac{2 \times 0.098 \times 1000}{5 \times 0.45} = \mathbf{87\ mL.} \qquad \textbf{Ans.}$$

Type. To calculate mass of a substance when molarity and volume of substance from which it is formed, is given.

EXAMPLE 110. *Calculate the mass of calcium chlorate formed from 0.2 L of 1.5 M chloric acid solution plus excess of calcium hydroxide. (At. wt., Ca = 40, Cl = 35.5, O = 16)*

SOLUTION. Reaction :

$$Ca(OH)_2 + \underset{2\ \text{mol}}{2HClO_3} \longrightarrow \underset{\substack{1\ \text{mol} \\ 40 + 2[35.5 + (3 \times 16)] \\ = 207\ \text{g}}}{Ca(ClO_3)_2} + 2H_2O$$

(*a*) number of mol of $HClO_3$

$$= \text{Molarity} \times \text{Volume in litre}$$

$$= \frac{1.5 \text{ mol}}{\text{L}} \times 0.2 \text{ L} = 0.3 \text{ mol}$$

(*b*) 2 mol $HClO_3$ form $Ca(ClO_3)_2$ = 207 g

$$\therefore 0.3 \text{ mol } HClO_3 \text{ form } Ca(ClO_3)_2 = \frac{207}{2} \times 0.3$$

$$= \mathbf{31.05\ g} \qquad \textbf{Ans.}$$

EXAMPLE 111. *How many gram of $(NH_4)_2SO_4$ are required to prepare 250 mL of 0.1 M $(NH_4)_2SO_4$ solution? (At. wt., N = 14, H = 1, S = 32, O = 16)*

SOLUTION. g. mol. wt. of $(NH_4)_2SO_4$ = 2[14 + (4 × 1)] + 32 + (4 × 16) = 132 g

(*a*) Number of mol of $(NH_4)_2SO_4$

$$= \text{Molarity} \times \text{Volume in litre}$$

$$= \frac{0.1 \text{ mol}}{\text{L}} \times \frac{250}{1000} \text{ L} = 0.025 \text{ mol.}$$

1 mol of $(NH_4)_2SO_4$ weigh

$$= 132 \text{ g}$$

$\therefore$ 0.025 mol of $(NH_4)_2SO_4$ weigh

$$= 132 \times 0.025 = \mathbf{3.3\ g} \qquad \textbf{Ans.}$$

Type. To find weight of a substance from weight of atoms.

EXAMPLE 112. *Calculate the molarity of each ion in solution after mixing 2L of 1.5 M $MnCl_2$ with 1.5 L of 4.0 M $AgNO_3$ solution.*

SOLUTION. Reactions :

$$MnCl_2 + 2AgNO_3 \longrightarrow 2AgCl\downarrow + Mn(NO_3)_2$$

(*i*) No. of mol of $MnCl_2 = 2\text{ L}\times\frac{1.5\text{ mol}}{\text{L}} = 3.0\text{ mol}$

(*ii*) No. of mol of $AgNO_3 = 1.5\text{ L}\times\frac{4.0\text{ mol}}{\text{L}} = 6.0\text{ mol}$

(*a*) 3.0 mol $MnCl_2$ is 3.0 mol Mn^{2+} + 2 × 3.0 *i.e.*, ; 6.0 mol Cl^-

(*b*) 6.0 mol $AgNO_3$ is 6.0 mol NO_3^- + 6 mol Ag^+

Adding :

$$\frac{3.0\text{ mol Mn}^{2+}}{\text{Total Volume} = 2+1.5 = 3.5\text{ L}} = 0.86\text{ M Mn}^{2+}$$ **Ans.**

$$\frac{6.0\text{ mol NO}_3^-}{3.5\text{ L}};\ 6.0\text{ mol AgCl(s)} = 1.71\text{ M NO}_3^-$$ **Ans.**

Type. Number of m. mol = Molarity × Volume in mL.

EXAMPLE 113. *Calculate the concentration of each ion in solution after mixing 25 mL of 0.3 M HNO_3 with 50 mL of 0.5 M NH_3.*

SOLUTION. Reaction : $NH_3 + HNO_3 \longrightarrow NH_4^+ + NO_3^-$

(*a*) No. of m. mol of HNO_3

$= 0.3\text{ M} \times 25.0\text{ mL} = 7.5$ m. mol

(*b*) No. of m. mol of NH_3

$= 0.5\text{ M} \times 50\text{ mL} = 25$ m. mol

7.5 m. mol HNO_3 is 7.5 m. mol. H^+ + 7.5 m. mol NO_3^-

$$\underset{7.5\text{ m. mol}}{NH_3} + \underset{7.5\text{ m. mol}}{H^+} \longrightarrow \underset{7.5\text{ m. mol}}{NH_4^+}$$

The reaction yields 7.5 m. mol of NH_4^+. So, m. mol of NH_3 left unreacted = 25.0 – 7.5 = 17.5 m. mol. Total volume = 25 mL + 50 mL = 75 mL

∴ Concentration of different ions left unreacted are :

(*i*) $NH_3 = \frac{17.5\text{ m. mol}}{\text{Total Volume} = 75\text{ mL}}$

$= \mathbf{0.23\ M}$ **Ans.**

(*ii*) $NO_3^- = \frac{7.5\text{ m. mol}}{75\text{ mL}} = \mathbf{0.1M}$ **Ans.**

(*iii*) $NH_4^+ = \frac{7.5\text{ m. mol}}{75\text{ mL}} = \mathbf{0.1\ M}$ **Ans.**

EXAMPLE 114. *Calculate the volume of 4.2 M H_2SO_4 required to react exactly with 10.8 g aluminium. (At. wt., Al = 27, H = 1, S = 32, O = 16)*

SOLUTION. Reaction $\underset{\substack{2\times 27\\ = 54\text{ g}}}{2Al} + \underset{3\text{ mol}}{3H_2SO_4} \longrightarrow Al_2(SO_4)_3 + 3H_2$

54 g Al require

$H_2SO_4 = 3$ mol

10.8 g Al require

$H_2SO_4 = \frac{3}{54\text{ g}}\times 10.8 = 0.6$ mol.

We know :number of mol of

H_2SO_4 = Molarity of H_2SO_4 × Volume in litre

∴ 0.6 = 4.2 × Volume in litre ; Volume of

H_2SO_4 in litre $= \frac{0.6}{4.2} = .0143$ L

Or Volume of H_2SO_4 required

= 0.0143 × 1000 mL = **143 mL Ans.**

EXAMPLE 115. *What will be the molarity of each type of ion that remains in solution after mixing 40 mL of 2.5 M $Ba(OH)_2$, 20.0 mL of 6.5 M HNO_3 and 50.0 mL water?*

SOLUTION. (*i*) No. of m. mol of $Ba(OH)_2$

$= 40\text{ mL}\times\frac{2.5\text{ m. mol}}{\text{mL}} = 100$ m. mol

(*ii*) No. of m. mol of

$HNO_3 = 20.0\text{ mL}\times\frac{6.5\text{ m. mol}}{\text{mL}}$

= 130.0 m. mol

∴ 100 m. mol of $Ba(OH)_2$ yield, 100 m. mol of Ba^{2+} + 2 × 100 *i.e.*, 200 m. mol of OH^-

130 m. mol of HNO_3 yield, 130 m. mol of H^+ + 130 m. mol of NO_3^-

But $\underset{1\text{ m. mol}}{H^+} + \underset{1\text{ m. mol}}{OH^-} \longrightarrow H_2O$

∴ no. of m. mol of OH^- left behind = 200 – 130 = 70 m. mol. So, ions left behind are :

∴ $Ba^{2+} = \frac{100\text{ m. mol}}{\text{Total Volume}(= 40+20+50 = 110\text{ mL})}$

$= 0.91\text{ M Ba}^{2+}$;

$OH^- = \frac{70\text{ m. mol}}{110\text{ mL}} = 0.64\text{ M OH}^-$;

$NO_3^- = \frac{130\text{ m. mol}}{110\text{ mL}} = \mathbf{1.18\ M\ NO_3^-}$ **Ans.**

EXAMPLE 116. *When 100 mL of 2.5 M NaOH solution was added to 90.0 mL of H_2SO_4, it required 37.0 mL of 0.48 M HCl to neutralise the excess NaOH. Calculate the original concentration of H_2SO_4 used.*

SOLUTION. (*i*) No. of m. mol of NaOH

= Molarity × Volume in mL

$= \frac{2.5\text{ m. mol}}{\text{mL}}\times 100\text{ mL}$

= 250 m. mol

(*ii*) No. of m. mol of HCl $= \frac{0.48\text{ m. mol}}{\text{mL}}\times 37.0\text{ mL}$

= 17.8 m. mol

∴ m. mol of NaOH that reacted with

H_2SO_4 = 250 – 17.8 = 232.2

Reaction. $\underset{2\text{ m. mol}}{2NaOH} + \underset{1\text{ m. mol}}{H_2SO_4} \longrightarrow Na_2SO_4 + 2H_2O$

Thus :2 m. mol NaOH reacted with

H_2SO_4 = 1 m. mol

232.2 m. mol NaOH reacted with

$H_2SO_4 = \frac{1}{2}\times 232.2 = 116.1$ m. mol

∴ Original concentration of

H_2SO_4 used $= \frac{116.1\text{ m. mol}}{90.0\text{ mL}}$

$= \mathbf{1.29\ M\ H_2SO_4}$ **Ans.**

EXAMPLE 117. *While standardising silver nitrate solution, 45.7 mL of this solution precipitated all the Cl^- ions present in 35.0 mL of 0.5 M KCl solution. Find the weight in g of Ag that could be obtained from 90.0 mL of the silver nitrate solution. (At. wt., Ag = 108).*

SOLUTION. *Reaction.* $\underset{1\text{ mol}}{AgNO_3} + \underset{1\text{ mol}}{KCl} \longrightarrow AgCl\downarrow + KNO_3$

(*i*) Number of mol of KCl

$$= \text{Molarity} \times \text{Volume in litre}$$

$$= \frac{0.5\text{ mol}}{\text{L}} \times \frac{35.0}{1000}\text{ L} = 0.0175\text{ mol.}$$

$\therefore$ no. of mol of KCl = no. of mol of $AgNO_3$ = 0.0175 mol.

$$\underset{1\text{ mol}}{AgNO_3} \rightleftharpoons \underset{\substack{1\text{ mol}\\108\text{ g}}}{Ag^+} + NO_3^-$$

45.7 mL solution contain

$$AgNO_3 = 0.0175\text{ mol}$$

$\therefore$ 90.0 mL solution contain

$$AgNO_3 = \frac{0.0175}{47.5} \times 90 = 0.033\text{ mol}$$

(*ii*) 1 mol of $AgNO_3$ contain

$$Ag = 108\text{ g}$$

0.033 mol of $AgNO_3$ contain

$$Ag = 108 \times 0.033 \simeq \mathbf{3.6\ g}$$ **Ans.**

EXAMPLE 118. *During the titration of 50.0 mL HCl solution with 0.1 M NaOH, two drops of phenolphthalein indicator were added. When 40.0 mL of NaOH solution was added, pink colour appeared which disappeared on shaking. The addition of NaOH solution was continued till pink colour persisted with one drop of added NaOH solution. At this end point, 41.8 mL of NaOH solution was consumed. Calculate the concentration of HCl solution used.*

SOLUTION. *Reaction :* $\underset{1\text{ m. mol}}{NaOH} + \underset{1\text{ m. mol}}{HCl} \longrightarrow NaCl + H_2O$

$$\frac{M_1V_1\,(\text{NaOH})}{M_2V_2\,(\text{HCl})} = \frac{1\text{ m. mol of NaOH}}{1\text{ m. mol of HCl}}$$

[no. of m. mol = Molarity × Volume in mL]

$$\frac{\frac{0.1\text{ m. mol}}{\text{mL}} \times 41.8\text{ mL}}{M_2 \times 50\text{ mL}} = \frac{1}{1};$$

$$M_2 = \frac{0.1\text{ m. mol} \times 41.8}{50\text{ mL}} = 0.0836\text{ M}$$

$\therefore$ Concentration of HCl = **0.0836 M** **Ans.**

EXAMPLE 119. *How would you prepare 40.0 g of 8.0% $BaCl_2$ solution, starting with $BaCl_2.2H_2O$ and deionised water? (At. wt., Ba = 137, Cl = 35.5, H = 1, O = 16)*

SOLUTION. g. mol. wt. of $BaCl_2.2H_2O$

$$= 137 + (2 \times 35.5) + 2[(2 \times 1) + 16]$$

$$= 244\text{ g}$$

g. mol. wt. of $BaCl_2$ = 137 + (2 × 35.5) = 208 g

(*a*) 8% $BaCl_2$ solution means that 8 g of $BaCl_2$ is present in 100 g solution. So :

100 g solution contain

$$BaCl_2 = 8\text{ g}$$

$\therefore$ 40 g solution contain

$$BaCl_2 = \frac{8}{100} \times 40 = 3.2\text{ g}$$

$$\underset{\substack{1\text{ mol}\\244\text{ g}}}{BaCl_2.2H_2O} \longrightarrow \underset{\substack{1\text{ mol}\\208\text{ g}}}{BaCl_2} + 2H_2O$$

$\therefore$ 208 g $BaCl_2$ is present in $BaCl_2.2H_2O$

$$= 244\text{ g}$$

3.2 g $BaCl_2$ is present in

$$BaCl_2.2H_2O = \frac{244}{208} \times 3.2 = \mathbf{3.75\ g}$$ **Ans.**

EXAMPLE 120. *Calculate the molar concentration of each ion when 300 mL of 1.5 M KCl is diluted to 0.75 L.*

SOLUTION. Number of m. mol of

$$KCl = \text{Molarity} \times \text{Volume in mL}$$

$$= \frac{1.5\text{ m. mol}}{\text{mL}} \times 300\text{ mL}$$

$$= 450\text{ m. mol}$$

Total volume = 0.75 L = 0.75 × 1000 = 750 mL

$$\underset{\substack{1\text{ m. mol}\\450\text{ m. mol}}}{KCl} \rightleftharpoons \underset{\substack{1\text{ m. mol}\\450\text{ m. mol}}}{K^+} + \underset{\substack{1\text{ m. mol}\\450\text{ m. mol}}}{Cl^-}$$

$$\therefore \quad K^+ = \frac{450\text{ m. mol}}{750\text{ mL}} = 0.6\text{ M }K^+;$$

$$Cl^- = \frac{450\text{ m. mol}}{750\text{ mL}} = 0.6\text{ M }Cl^-$$ **Ans.**

EXAMPLE 121. *Calculate the molar concentration of each ion when 300 mL of 2.0 M $Al_2(SO_4)_3$ is added to 200 mL of 1.5 M $Al_2(SO_4)_3$ solution.*

SOLUTION. (*i*) No. of m. mol of

$$Al_2(SO_4)_3 = \text{Molarity} \times \text{Volume in mL}$$

$$= \frac{2\text{ m. mol}}{\text{mL}} \times 300\text{ mL} = 600\text{ m. mol}$$

(*ii*) No. of m. mol of

$$Al_2(SO_4)_3 = \frac{1.5\text{ m. mol}}{\text{mL}} \times 200\text{ mL}$$

$$= 300\text{ m. mol}$$

$\therefore$ Total m. mol of

$$Al_2(SO_4)_3 = 600 + 300 = 900\text{ m. mol}$$

$$\underset{\substack{1\text{ m. mol}\\900\text{ m. mol}}}{Al_2(SO_4)_3} \rightleftharpoons \underset{\substack{2\text{ m. mol}\\2 \times 900\\= 1800\text{ m. mol}}}{2Al^{3+}} + \underset{\substack{3\text{ m. mol}\\3 \times 900\\2700\text{ m. mol}}}{3SO_4^{2-}}$$

Total Volume = 300 mL + 200 mL = 500 mL

$$\therefore \quad Al^{3+} = \frac{1800\text{ m. mol}}{500\text{ mL}} = 3.6\text{ M }Al^{3+};$$

$$SO_4^{2-} = \frac{2700\text{ m. mol}}{500\text{ mL}} = \mathbf{5.4\ M\ SO_4^{2-}}$$ **Ans.**

EXAMPLE 122. *Calculate the molar concentration of each ion when 200 mL of 1.5 M KOH and 100 mL of 2.0 M HCl are mixed with 50 mL water and 150 mL of 4.0 M NaCl.*

SOLUTION. (*i*) no. of m. mol of

$$\text{KOH} = \frac{1.5 \text{ m. mol}}{\text{mL}} \times 200 \text{ mL}$$

$$= 300 \text{ m. mol}$$

$\therefore$ 300 m. mol KOH yield 300 m. mol K^+ and 300 m. mol OH^- $[\because KOH \rightleftharpoons K^+ + OH^-]$

(*ii*) no. of m. mol of

$$\text{HCl} = \frac{2.0 \text{ m. mol}}{\text{mL}} \times 100 \text{ mL}$$

$$= 200 \text{ m. mol}$$

$HCl \rightleftharpoons H^+ + Cl^-$. So, m. mol of H^+ = m. mol of Cl^- = 200 m. mol.

(*iii*) no. of m. mol of

$$\text{NaCl} = \frac{4.0 \text{ m. mol}}{\text{mL}} \times 150 \text{ mL}$$

$$= 600 \text{ m. mol.}$$

$NaCl \rightleftharpoons Na^+ + Cl^-$. So, m. mol. of

Na^+ = m. mol = Cl^- = 600 m. mol

But $H^+ + OH^- \longrightarrow H_2O$

$\therefore$ m. mol of OH^- left behind

= 300 – 200 = 100 m. mol

Total Volume = 200 + 100 + 50 + 150 = 500 mL

Total m. mol of Cl^- ions = 200 + 600 = 800

$$\therefore \quad OH^- = \frac{100 \text{ m. mol}}{\text{Total Volume} = 500 \text{ mL}}$$

$$= 0.2 \text{ M } OH^- ;$$

$$K^+ = \frac{300 \text{ m. mol}}{500 \text{ mL}} = 0.6 \text{ M } K^+ ;$$

$$Na^+ = \frac{600 \text{ m. mol}}{500 \text{ mL}} = 1.2 \text{ M } Na^+$$

$$Cl^- = \frac{800 \text{ m. mol}}{500 \text{ mL}} = 1.6 \text{ M } Cl^- \quad \textbf{Ans.}$$

EXAMPLE 123. *Calculate the concentration of each ion present in solution obtained by mixing 2.0 L of 3.5 M NH_4Cl and 3.5 L of 3.0 M $MnCl_2$ and diluted to 8 litre.*

SOLUTION. (*i*)no. of mol of

NH_4Cl = Molarity × Volume in litre

$$= \frac{3.5 \text{ mol}}{\text{L}} \times 2.0 \text{ L} = 7 \text{ mol}$$

$$\begin{array}{ccccc} NH_4Cl & \rightleftharpoons & NH_4^+ & + & Cl^- \\ 7 \text{ mol} & & 7 \text{ mol} & & 7 \text{ mol} \end{array}$$

(*ii*) no. of mol of

$MnCl_2$ = Molarity × Volume in litre

$$= \frac{3.0 \text{ mol}}{\text{L}} \times 3.5 \text{ L} = 10.5 \text{ mol}$$

$$\begin{array}{ccccc} MnCl_2 & \rightleftharpoons & Mn^{2+} & + & 2Cl^- \\ 1 \text{ mol} & & 1 \text{ mol} & & 2 \text{ mol} \\ 10.5 \text{ mol} & & 10.5 \text{ mol} & & 2 \times 10.5 = 21 \text{ mol} \end{array}$$

$\therefore$Concentrations of : (*i*)

$$Mn^{2+} = \frac{10.5 \text{ mol}}{\text{Total Volume} = 8 \text{ L}} = 1.31 \text{ M}$$

(*ii*)Total mol of Cl^- = 7 + 21 = 28 mol

$$\therefore \quad \text{Conc. of } Cl^- = \frac{28 \text{ mol}}{8 \text{ L}} = 3.5 \text{ M} ;$$

$$NH_4^+ = \frac{7 \text{ mol}}{8 \text{ L}} = \mathbf{0.875 \text{ M}} \quad \textbf{Ans.}$$

EXAMPLE 124. *200 mL of 4.5 M antifreeze were mixed with 400 mL of 4.0 M antifreeze and the solution was diluted to 4.0 litre with water. Calculate the final concentration of the solute.*

SOLUTION. (*i*) no. of mol of antifreeze

= Molarity × Volume in litre

$$= \frac{4.5 \text{ mol}}{\text{L}} \times \frac{200 \text{ L}}{1000} = 0.9 \text{ mol}$$

(*ii*) no. of mol of antifreeze

=Molarity × Volume in litre.

$$= \frac{4.0 \text{ mol}}{\text{L}} \times \frac{400}{1000} \text{ L} = 1.6 \text{ mol}$$

Total mol of antifreeze

= 0.9 + 1.6 = 2.5 mol

Total Volume = 4 L

$\therefore$ Molar concentration of antifreeze

$$= \frac{2.5 \text{ mol}}{4.0 \text{ L}} = \mathbf{0.625 \text{ M}} \quad \textbf{Ans.}$$

EXAMPLE 125. *One litre of a mixture of O_2 and O_3 at NTP was allowed to react with an excess of acidified solution of KI. The iodine liberated required 40 ml of M/10 sodium thiosulphate solution for titration. What is the weight per cent of ozone in the mixture? Assuming that one photon can decompose one ozone molecule, how many photons would have been required for the complete decomposition of ozone in the original mixture?*

(IIT, May 1997)

SOLUTION. The reactions involved are :

$$O_3 + 2I^- + 2H^+ \longrightarrow I_2 + O_2 + H_2O$$

$$2S_2O_3^{2-} + I_2 \longrightarrow S_4O_6^{2-} + 2I^-$$

$$\therefore \quad 2 \text{ mol } S_2O_3^{2-} \equiv 1 \text{ mol } I_2 \equiv 1 \text{ mol } O_3$$

Amount of $S_2O_3^{2-}$ consumed

$$= (40 \times 10^{-3} \text{ L})\left(\frac{1}{10} \text{mol L}^{-1}\right)$$

$$= 40 \times 10^{-4} \text{ mol} = 4 \times 10^{-3} \text{ mol}$$

$$\equiv 2 \times 10^{-3} \text{ mol } I_2 \equiv 2 \times 10^{-3}$$

$$= 0.2 \times 10^{-2} \text{ mol } O_3$$

Amount of O_3 present in 1L mixture

$$= 2 \times 10^{-3} \times 48 \text{ g} = \mathbf{9.6 \times 10^{-2} \text{ g}}$$

$[\because$ Mol. wt. of $O_3 = 3 \times 16 = 48$ g mol$^{-1}]$

Total amount of O_2 and O_3 present in one L mixture of O_2 and O_3 at STP is given by

$$n_{\text{total}} = \frac{PV}{RT}$$

$$= \frac{1 \text{ atm.} \times 1 \text{ L}}{(0.0821 \text{ L atm. K}^{-1}\text{mol}^{-1}) \times 273 \text{ K}}$$

$$= 4.462 \times 10^{-2} \text{ mol}$$

Amount of O_2 present in 1L of mixture

$$= (4.462 \times 10^{-2} - 0.2 \times 10^{-2}) \text{ mol}$$

$$= 4.262 \times 10^{-2} \text{ mol}$$

Mass of O_2 pesent in 1L of mixture

$$= 4.262 \times 10^{-2} \times 32 \text{ g}$$

$$[\because \text{Mol. wt. of } O_2 = 2 \times 16 = 32 \text{ g mol}^{-}]$$

$$= 1.364 \text{ g}$$

Mass percent of O_3 in the mixture

$$= \frac{9.6 \times 10^{-2}}{9.6 \times 10^{-2} + 1.364} \times 100 = 6.575$$

Amount of photons required to decompose O_3

$$= \text{Amount of } O_3 = 2 \times 10^{-3} \text{ mol}$$

Number of photons required

$$= 2 \times 10^{-3} \times 6.02 \times 10^{23} = \mathbf{1.204 \times 10^{21}}$$

Example 126. *0.5 g mixture of $K_2Cr_2O_7$ and $KMnO_4$ was treated with excess of KI in acidic medium. Iodine liberated required 100 cm³ of 0.15 N sodium thiosulphate solution for titration. Find the percent amount of each in the mixture.*

(Roorkee 1995)

Solution. The redox changes involved are :

$$\underset{(\text{in } MnO_4^-)}{Mn^{7+} + 5e^- \longrightarrow Mn^{2+}} \qquad \underset{(\text{in } Cr_2O_7^{2-})}{Cr_2^{6+} + 6e^- \longrightarrow 2Cr^{3+}}$$

$$2I^- \longrightarrow I_2 + 2e^-$$

$$2S_2O_3^{2-} \longrightarrow S_4O_6^{2-} + 2e^-$$

Let the amounts of $K_2Cr_2O_7$ and $KMnO_4$ be a and b g respectively.

$$\therefore \qquad a + b = 0.5; \quad b = 0.5 - a$$

Further Meq. of $K_2Cr_2O_7$ + Meq. of $KMnO_4$

= Meq. of KI = Meq. of I_2 liberated

= Meq. of $Na_2S_2O_3$ used

$$\text{Eq. wt. of } K_2Cr_2O_7 = \frac{\text{Mol. wt.}}{6} = \frac{294}{6}$$

$$\text{Eq. wt. of } KMnO_4 = \frac{\text{Mol. wt.}}{5} = \frac{158}{5}$$

$$\text{Meq. of } Na_2S_2O_3 = 0.15 \times 100 = 15$$

$$\therefore \frac{a}{\frac{294}{6}} \times 1000 + \frac{b}{\frac{158}{5}} \times 1000 = 15$$

$$\text{or } \frac{a}{49} \times 1000 + \frac{(0.5 - a)}{31.6} \times 100 = 15;$$

$$20.408a + (0.5 - a)31.64 = 15$$

$$(20.408 - 31.64)a + 15.82 = 15$$

$$\text{or} \qquad 11.23a = 0.82; \; a = \frac{0.82}{11.23} = 0.073 \text{ g}$$

$$b = 0.5 - 0.073 = 0.427 \text{ g}$$

$$\therefore \% \text{ age of } K_2Cr_2O_7 = \frac{0.073}{0.5} \times 100 = \mathbf{14.6\%}$$

$$\% \text{ of } KMnO_4 = \frac{0.427}{0.5} \times 100 = \mathbf{85.4\%}$$

Example 127. *The Mn_3O_4 formed on strong heating of a sample of $MnSO_4.4H_2O$ was dissolved in 100 cm³ of 0.1 N $FeSO_4$ containing H_2SO_4. The resulting solution reacted completely, with 50 cm³ of $KMnO_4$ solution, 25 cm³ of this $KMnO_4$ solution requires 30 cm³ of 0.1 N $FeSO_4$ solution for complete reaction. Calculate the amount of $MnSO_4.4H_2O$ in the sample.*

(Roorkee 2001)

Solution. From the given problem, we see that 25 cm³ of $KMnO_4$ solution = 30 cm³ of 0.1 N $FeSO_4$ solution

$$\therefore \text{ 50 cm}^3 \text{ of } KMnO_4 \text{ solution} \equiv \frac{30}{25} \times 50 = 60 \text{ cm}^3 \text{ of 0.1}$$

N $FeSO_4$ solution

It means that 0.1 N $FeSO_4$ left unreacted = 60 cm³

$\therefore$ 0.1 N $FeSO_4$ consumed = 100 – 60 = 40 cm³

Thus, Mn_3O_4 reacted ≡40 cm³ of 0.1N $FeSO_4$ ≡ 40 × 0.1 i.e., 4 milli eq.

$MnSO_4$. $4H_2O$ in sample = 4 milli eq.

$$MnSO_4.4H_2O \longrightarrow MnSO_4 + 4H_2O$$

$$3MnSO_4 \cdot 4H_2O + \frac{1}{2}O_2 \longrightarrow Mn_3O_4 + 3SO_3$$

$\therefore$ Equivalent weight of $MnSO_4.4H_2O$

$$= \frac{3 \times 223}{2} = 334.5$$

Hence 4 milli equivalents of $MnSO_4.4H_2O$

$$\frac{4}{1000} \times 334.5 = \mathbf{1.338 \text{ g}}$$

$$\left\{ \begin{array}{lcl} 3MnSO_4 \cdot 4H_2O & \equiv & \frac{1}{2}O_2 \\ 3(55 + 32 + 4 \times 16) & & \frac{1}{2} \times 2 \times 16 \\ + 4(2 \times 1 + 16) & = & 16 \text{ parts} \\ = 3 \times 223 \text{ parts} & & \frac{16}{2} = 8 \text{ parts} \end{array} \right.$$

$$= \frac{3 \times 223}{2} \text{ parts}$$

Example 128. *A 3.0 g sample containing Fe_3O_4, Fe_2O_3 and an inert impure substance is treated with excess of KI solution in presence of dilute H_2SO_4. The entire iron is converted into Fe^{2+} along with liberation of iodine. The resulting solution is diluted to 100 ml. A 20 mL of the diluted solution requires 11.0 ml of 0.5 M $Na_2S_2O_3$ solution to reduce the iodine present. A 50 mL of the diluted solution after complete extraction of iodine requires 12.8 mL of 0.25 M $KMnO_4$ solution in dilute H_2SO_4 medium for the oxidation of Fe^{2+}. Calculate the percentages of Fe_2O_3 and Fe_3O_4 in the original shape.* **(IIT 1996)**

Solution. We know that Fe_3O_4 is an equimolar mixture of FeO and Fe_2O_3. The reactions involved in the given problem are :

$$(i) \quad FeO + H_2SO_4 \longrightarrow FeSO_4 + H_2O$$

$$\text{Also} \quad Fe_2O_3 + 2H_2SO_4 \longrightarrow 2FeSO_4 + 2H_2O + O$$

$$2KI + H_2SO_4 \longrightarrow K_2SO_4 + 2HI$$

$$\underline{2HI + O \longrightarrow H_2O + I_2}$$

$$(ii) \quad Fe_2O_3 + 3H_2SO_4 + 2KI \longrightarrow 2FeSO_4 + K_2SO_4 + 3H_2O + I_2$$

$$(iii) \quad 2Na_2SO_3 + I_2 \longrightarrow Na_2S_4O_6 + 2NaI$$

$$2KMnO_4 + 3H_2SO_4 \longrightarrow K_2SO_4 + 2MnSO_4 + 3H_2O + 5O$$

$$2FeSO_4 + H_2SO_4 + O \longrightarrow Fe_2(SO_4)_3 + H_2O] \times 5$$

Add: $2KMnO_4 + 8H_2SO_4 + 10FeSO_4 \longrightarrow K_2SO_4 + 2MnSO_4 + Fe_2(SO_4)_3 + 8H_2O$

1 mol   10/2 = 5 mol

In the problem, it is given that the resulting solution containing I_2 and Fe^{2+} after dilution = 100 mL

20 mL of diluted solution

$= 11$ mL of 0.5 M $Na_2S_2O_3$

$\therefore$ 100 ml of diluted solution $\dfrac{11}{20} \times 100$

$= 55$ ml of 0.5 M $Na_2S_2O_3$

$= \dfrac{55 \times 0.5}{1000}$

$= 0.0275$ moles of $Na_2S_2O_3$

Thus, $\dfrac{0.0275}{2} = 0.01375$ moles of

$I_2 = 0.01375$ moles of Fe_2O_3

(See chemical reactions above)

50 ml of diluted solution

$= 12.8$ mL of 0.25 M $KMnO_4$

$\therefore$ 100 ml of diluted solution $= \dfrac{12.8}{50} \times 100$

$= 25.6$ ml of 0.25 M $KMnO_4$

$= \dfrac{25.6 \times 0.25}{1000}$

$= 0.0064$ moles of $KMnO_4$

$= 5 \times 0.0064 = 0.032$ mole of $FeSO_4$

Clearly 0.032 moles of $FeSO_4$ is obtained from 0.01375 mole of Fe_2O_3 and the remaining from FeO

Since, 1 mole Fe_2O_3 = 2 mole $FeSO_4$

0.01375 mole $Fe_2O_3 = 2 \times 0.01375$ mole

$FeSO_4 = 0.0275$ mole of $FeSO_4$

$\therefore$ $FeSO_4$ formed from FeO

$= 0.032 - 0.0275 = 0.0045$ mole

But 1 mole $FeSO_4$ = 1 mole FeO

$\therefore$ 0.0045 mole $FeSO_4$ = 0.0045 mole FeO.

Also Fe_3O_4 contains equal moles of FeO and Fe_2O_3

$\therefore$ Fe_2O_3 present in Fe_3O_4

$= 0.0045$ mol

Thus, free Fe_2O_3 present in the mixture

$= 0.01375 - 0.0045 = 0.00925$ mole

Hence the amount of Fe_3O_4 in the mixture

$= 0.0045$ mole $= 0.0045 \times 232$

$= 1.044$ g

[$\because$ Mol. wt. of $Fe_3O_4 = (3 \times 56) + (4 \times 16) = 232\ \text{g mol}^{-}$]

Amount of Fe_2O_3 = 0.00925 mole

$= 0.00925 \times 160 = 1.48$ g

[$\because$ Mol. wt. of $Fe_2O_3 = (2 \times 56) + (3 \times 16) = 160\ \text{g mol}^{-}$]

$\therefore$ Precentage of Fe_3O_4 in the mixture

$= \dfrac{1.044}{3} \times 100 = \mathbf{34.8}$

Percentage of Fe_2O_3 in the mixture

$= \dfrac{1.48}{3} \times 100 = \mathbf{49.33}$

EXAMPLE 129. *An aqueous solution containing 0.1 g* KIO_3 *(formula weight = 214.0) was treated with an excess of KI solution. The solution was acidified with HCl. The liberated* I_2 *consumed 45.0 mL of thiosulphate solution to decolourise the blue starch-iodine complex. Calculate the molarity of the sodium thiosulphate solution.* **(IIT 1998)**

SOLUTION. The reactions involved are :

$KIO_3 + 5KI + 6HCl \longrightarrow 6KCl + 3H_2O + 3I_2$

$2S_2O_3^{2-} + I_2 \longrightarrow S_4O_6^{2-} + 2I^-$

From the above equations, we can write

1 mole $KIO_3 \equiv 3$ mol I_2

1 mole $I_2 = 2$ mol $S_2O_3^{2-}$

Amount of $KIO_3 = \dfrac{0.1\ \text{g}}{214\ \text{g mol}^{-1}} = 4.6729 \times 10^{-4}$ mol

Amount of I_2 liberated

$= 3 \times 4.6729 \times 10^{-4}$ mol

Amount of $S_2O_3^{2-}$ consumed

$= 2 \times (3 \times 4.6729 \times 10^{-4})$ mol

Let *M* be the molarity of thiosulphate solution

$\therefore$ Amount of $S_2O_3^{2-}$ consumed

$= M \times V = M \times (45 \times 10^{-3}\ \text{L})$

or $M\,(45 \times 10^{-3}\ \text{L}) = 2(3 \times 4.6729 \times 10^{-4}\ \text{mol})$

$$M = \frac{2 \times 3 \times 4.6729 \times 10^{-4}\ \text{mol}}{45 \times 10^{-3}\ \text{L}}$$

$= \mathbf{0.0623\ molL^{-1}}$

EXAMPLE 130. *You are given 2.198 g sample containing a mixture of XO and* X_2O_3*. It requires 0.015 mol of* $K_2Cr_2O_7$ *to oxidise. The sample reacts to form* XO_4^- *and* Cr^{3+}*. If 0.0187 mol of* XO_4^- *is formed, what is the atomic mass of X?* **(Roorkee 2001)**

SOLUTION. For the given reaction, the chemical equation can be written as

(*i*) $XO + 3H_2O \longrightarrow XO_4^- + 6H^+ + 5e] \times 6$

$Cr_2O_7^{2-} + 14H^+ + 6e \longrightarrow 2Cr^{3+} + 7H_2O] \times 5$

$6XO + 5Cr_2O_7^{2-} + 34H^+ \longrightarrow 6XO_4^- + 17H_2O + 10Cr^{3+}$

(*ii*) Also$X_2O_3 + 5H_2O \longrightarrow 2XO_4^- + 10H^+ + 8e^-] \times 3$

$Cr_2O_7^{2-} + 14H^+ + 6e \longrightarrow 2Cr^{3+} + 7H_2O] \times 4$

$3X_2O_3 + 26H^+ + 4Cr_2O_7^{2-} \longrightarrow 6XO_4^- + 8Cr^{3+} + 13H_2O$

In a mixture, let the amount of

$XO = wg = \dfrac{\text{w mol}}{\text{M + 16}}$

(*M* is the at. wt. of *X*)

Amount of X_2O_3 in the mixture

$= (2.198 - w)\ \text{g} = \dfrac{(2.198 - w)\ \text{mol}}{2M + 48}$

1 mol $XO \equiv 1$ mol of XO_4^-

Also, 1 mol $X_2O_3 \equiv 2$ mol of XO_4^-

Thus, $\dfrac{w}{M+16} + \dfrac{2(2.198 - w)}{2M + 48}$

$= 0.0187$ ...(*iii*)

From the equation (*i*) 6 mol

$$XO \equiv 5 \text{ mol } Cr_2O_7^{2-}$$

From equation (*ii*) 3 mol of $X_2O_3 \equiv 4$ mol $Cr_2O_7^{2-}$

Thus, $$\frac{5w}{6(M+16)} + \frac{4}{3} \times \frac{(2.198 - w)}{2M + 48} = 0.015 \qquad \text{...}(iv)$$

Multiplying equation (*iii*) by $\frac{2}{3}$; we get

$$\frac{2w}{3(M+16)} + \frac{4}{3} \times \frac{(2.198 - w)}{2M + 48} = 0.0125 \qquad \text{...}(v)$$

Subtracting equation (*v*) from (*iv*), we get

$$\frac{1}{6} \cdot \frac{w}{M+16} = 0.0025 \quad \text{or}$$

$$w = 0.0150\text{M} + 0.24 \qquad \text{...}(vi)$$

Also multiplying equation (*iii*) by 5/6

$$\frac{5}{6} \times \frac{w}{(M+16)} + \frac{5}{3} \times \frac{(2.198 - w)}{(2M + 48)} = 0.0156 \qquad \text{...}(vii)$$

Subtracting (*iv*) from (*vii*) $\frac{1}{3}$.

$$\frac{(2.198 - w)}{2M + 48} = 0.0006\ 2.198 - w$$

$$= 0.0036\,M + 0.0864$$

or $$w = 2.1116 - 0.0036\,M \qquad \text{...}(viii)$$

From equations (*vi*) and (*viii*)

$$0.0150\,M + 0.24 = 2.1116 - 0.0036\,M$$

On solving,0.0186 M = 1.8716 or M = 100.6

Hence, the atomic weight of

$$M = 100.6$$

Example 131. *Calculate the molality of one litre solution of 93%* H_2SO_4 *by volume. The density of solution is 1.84 g mL⁻.*

(IIT, 2003)

Solution. Volume = 1L ; Volume of H_2SO_4 = 100 mL ; wt. of H_2SO_4 = 93 g ; density = 1.84 g (mL)⁻ ; mol. wt. of $H_2SO_4 = (2 \times 1) + 32 + (4 \times 16) = 98$ g mol⁻

$\therefore$ wt. of solution = Volume × density

$$= 100 \text{ mL} \times 1.84 \text{ g (mL)}^{-} = 184 \text{ g}$$

wt. of H_2O (solvent) = 184 – 93 = 91 g

$$= 91 \text{ g} \times \frac{1 \text{ kg}}{1000 \text{ g}} = \frac{91}{1000} \text{ kg}$$

$$\therefore \quad \text{Molality} = \frac{\text{wt.}}{\text{Mol. wt.} \times \text{wt. of solvent in kg}}$$

$$= \frac{93 \times 1000}{98 \times 91} = \mathbf{10.43} \qquad \textbf{Ans.}$$

Example 132. *A 100 mL solution of* Na_2CO_3 *is prepared by dissolving 8.653 g of the salt in water. The density of the solution is 1.0816 gram per milli litre. What are the molality and molarity of the solution? (At. wt., Na = 23, C = 12, O = 16).*

(MDU 1980)

Solution. (*i*) wt. of Na_2CO_3 = 8.653 g ; mol. wt. of $Na_2CO_3 = (2 \times 23) + 12 + (3 \times 16) = 106$ g mol⁻, Volume = 100 mL.

$$\text{Molarity of } Na_2CO_3 = \frac{\text{wt.}}{\text{Mol. wt.}} \times \frac{1000}{\text{Volume in mL}}$$

$$= \frac{8.653 \text{ g}}{106 \text{ g mol}^{-}} \times \frac{1000}{100}$$

$$= \mathbf{0.816\ M} \qquad \textbf{Ans.}$$

(*ii*) wt. of solution = Volume × density = 100 mL × 1.0816 g (mL)⁻ = 108.16 g

wt. of solute = 8.653 g. Hence wt. of solvent = 108.16 – 8.653 = 99.507 g

$\therefore$ Molality of Na_2CO_3

$$= \frac{\text{wt.}}{\text{Mol. wt.}} \times \frac{1000}{\text{wt. of solvent}}$$

$$= \frac{8.653}{106} \times \frac{1000}{99.507}$$

$$= \mathbf{0.82\ m} \qquad \textbf{Ans.}$$

> **Note.** For more numericals, see chapter 17 of solution – concentration.

2. **Ionic strength (μ) of a Solution.** It is given by the relation :

$$\mu = \frac{1}{2} \sum C Z^2$$

where Z = valence of ion ;

C = concentration in mol L⁻.

Example 133. *Calculate the ionic strength of a solution that is 0.2 M in* $(NH_4)_3PO_4$, *0.5 M in* $AlCl_3$ *and 0.4 M in* $ZnSO_4$.

Solution. (*i*) $(NH_4)_3PO_4 \rightleftharpoons 3NH_4^+ + PO_4^{3-}$

For $3NH_4^{+1}$, $Z = 1$, $C = 3 \times 0.2 = 0.6$ mol L⁻.

For PO_4^{3-}, $Z = 3$, $C = 0.2$ mol L⁻

(*ii*) $AlCl_3 \rightleftharpoons Al^{3+} + 3Cl^-$

For Al^{3+}, $Z = 3$, $C = 0.5 \times 1 = 0.5$ mol L⁻.

For $3Cl^{-1}$, $Z = 1$, $C = 3 \times 0.5 = 1.5$ mol L⁻

(*iii*) $ZnSO_4 \rightleftharpoons Zn^{2+} + SO_4^{2-}$

For Zn^{2+}, $Z = 2$, $C = 0.4$ mol L⁻. For SO_4^{2-}, $Z = 2$, $C = 0.4$ mol L⁻

We know that : $$\mu \text{ (Ionic strength)} = \frac{1}{2} \sum C Z^2 \qquad \text{...}(A)$$

C = concentration of ion in mol L⁻, Z = Valency of ion.

Substituting the values of Z and C in equation (A) for ions of $(NH_4)_3PO_4$, $AlCl_3$ and $ZnSO_4$, we have :

$$\mu = \frac{1}{2} [(0.6 \times 1^2 + 0.2 \times 3^2) + (0.5 \times 3^2 + 1.5 \times 1^2) + (0.4 \times 2^2 + 0.4 \times 2^2)] \text{ mol L}^{-}$$

$$= \frac{1}{2} [0.6 + 1.8 + 4.5 + 1.5 + 1.6 + 1.6] = \frac{1}{2} \times 11.6 = \mathbf{5.8} \qquad \textbf{Ans.}$$

Example 134. *How much amount of NaOH is needed to neutralise 20 meq. of HCl?*

Solution. *Reaction :*

$$\underset{20 \text{ meq.}}{NaOH} + \underset{20 \text{ meq.}}{HCl} \longrightarrow NaCl + H_2O.$$

From above reaction, we find that 20 meq.

NaOH = 20 meq. HCl.

But No. of meq. of a solute

$$= \frac{\text{wt. of solute (g)}}{\text{g. eq. wt. of solute}} \times 1000$$

$$\therefore \quad 20 = \frac{\text{wt. of solute (g)}}{40} \times 1000$$

Or wt. of solute $= \frac{20 \times 40}{1000} = \mathbf{0.8\ g}$ **ns.**

EXAMPLE 135. *Calculate the volume of 2.5 M H_2SO_4 required to neutralise a solution containing 2.0 g of sodium hydroxide.*

SOLUTION. NaOH = 2.0 g ; g. eq. wt. of NaOH = 23 + 16 + 1 = 40 g.

$$\text{Meq. of NaOH} = \frac{\text{wt. of NaOH}}{\text{g. eq. wt. of NaOH}} \times 1000$$

$$= \frac{2}{40} \times 1000 = 50$$

Now Meq. of H_2SO_4 = Meq. of NaOH.

H_2SO_4 ionises as : $\underset{2.5\text{ M}}{H_2SO_4} \rightleftharpoons \underset{2 \times 2.5\text{ M}}{2H^+} + SO_4^{2-}$

Let Volume of H_2SO_4 = V mL

$\therefore$ Meq. of H_2SO_4 = $V \times 2 \times 2.5 = 5V$

$\therefore$ $5V = 50$ or $V = 50/5 = \mathbf{10\ mL}$ **Ans.**

EXAMPLE 136. *Calculate the volume of 0.1 M NaOH needed for the neutralisation of 20 mL of 0.05 M oxalic acid.*

SOLUTION. Let volume of NaOH = V mL.

$$\underset{0.1\text{ M}}{NaOH} \rightleftharpoons Na^+ + \underset{0.1\text{ M}}{OH^-}$$

$\therefore$ Meq. of NaOH = $V \times 0.1$ ...(1)

Oxalic acid, $H_2C_2O_4$ ionises as :

$$\underset{0.05\text{ M}}{H_2C_2O_4} \rightleftharpoons \underset{2 \times 0.05\text{ M}}{2H^+} + C_2O_4^{2-}$$

$\therefore$ Meq. of $H_2C_2O_4$ = $20 \times 2 \times 0.05$ ...(2)

Since Meq. of NaOH = Meq. of $H_2C_2O_4$

$\therefore$ $V \times 0.1 = 20 \times 2 \times 0.05$

$\therefore$ $V = \frac{20 \times 2 \times 0.05}{0.1} = \mathbf{20\ mL}$ **Ans.**

EXAMPLE 137. *One kilogram of a sea water sample contains 6 mg of dissolved oxygen. The concentration of O_2 in the sample in ppm is :*

(*a*) 0.6
(*b*) 6.0
(*c*) 60.0
(*d*) 16.0
(*e*) 32.0

(Kerala PMT, 2010)

SOLUTION. ppm is parts per million. It is the quantity of the solute in grams persent in 10^6 grams of solution. 6 mg = 6×10^{-3} g. Thus : ppm = [Mass of solute/mass of solution] $\times 10^6$ = $(6 \times 10^{-3}\text{ g}/1000\text{g}) \times 10^6 = 6$ [$\because$ 1 kg = 1000g].

So, correct answer is (*b*).

EXAMPLE 138. *7.2 g of bleaching powder was suspended in 500 mL water. 20 mL of this solution when treated with KI solution in presence of HCl, liberated I_2. This I_2 required 18.9 mL of 0.1 N $Na_2S_2O_3$ for complete oxidation. Calculate the percentage of available chlorine from the bleaching powder.*

SOLUTION. Meq. of $Na_2S_2O_3$ = Meq. of I_2 = Meq. of Cl_2.

Meq. of $Na_2S_2O_3$ = Volume of $Na_2S_2O_3$ × normality of $Na_2S_2O_3$ = $18.9 \times 0.1 = \mathbf{1.89}$

Meq. of Cl_2 in 20 mL = 1.89

$$\text{Meq. of } Cl_2 \text{ in 500 mL} = \frac{1.89}{20} \times 500 = 47.25$$

But Meq. of Cl_2 = Meq. of bleaching powder = Meq. of available Cl_2 in bleaching powder

$$\text{Meq. of } Cl_2 = \frac{\text{wt. of } Cl_2}{\text{Eq. wt. of } Cl_2} \times 1000$$

$$\left[\text{Eq. wt. of } Cl_2 = \frac{\text{Mol. wt.}}{2} = \frac{2 \times 35.5}{2} = 35.5\right]$$

$$47.25 = \frac{\text{wt. of } Cl_2}{35.5} \times 1000$$

$$\text{or} \quad \text{wt. of } Cl_2 = \frac{47.25 \times 35.5}{1000} = 1.68$$

$$\therefore \quad \%\text{ age of } Cl_2 = \frac{\text{wt. of } Cl_2}{\text{wt. of bleaching powder}} \times 100$$

$$= \frac{1.68 \times 100}{7.2}$$

or % age of Cl_2 = **23.3** **Ans.**

EXAMPLE 139. *An excess of acidified KI solution was treated with 1000 cm^3 of a mixture of oxygen and ozone. I_2 so liberated required 41.3 cm^3 of 0.1 M $Na_2S_2O_3$ solution for quantitative titration. If U.V. radiations of wavelength 300 nm can decompose ozone and one photon can decompose one ozone molecule, calculate the number of photons required to decompose ozone completely in the original mixture. Also, calculate the mass percent of ozone in the mixture.*

SOLUTION. 1000 cm^3 = 1L

$\therefore$ Moles of O_2 and O_3 in the mixture

$$= \frac{1\text{ L}}{22.4\text{ L}} = 0.0446$$

Equivalents of

$$Na_2S_2O_3 = \text{vol.} \times \text{molarity} \times n$$

$$= \frac{41.3}{1000} \times \frac{1}{10} \times 1 = 4.13 \times 10^{-3}$$

Equivalent of I_2 = Equivalent of KI = Equivalent of O_3 = 4.13×10^{-3}

For the reaction :

$$S_2O_3^{2-} \rightarrow \frac{1}{2}\, S_4O_6^{2-} + 1e^-;\ n = 1$$

$$\underset{1\text{ mol}}{O_3} \rightarrow O_2 + O$$

$$KI + H_2O + \underset{1\text{ mol}}{O} \rightarrow 2KOH + I_2$$

$$2Na_2S_2O_3 + \underset{1\text{ mol}}{I_2} \rightarrow Na_2S_4O_6 + 2NaI$$

When O_3 reacts with KI, it converts to O^{2-} and O_2^0. So '*n*' factor = oxidation number change = 0 – (– 2) = 2.

$$\therefore \quad \text{Moles of } O_3 = \frac{4.13\times10^{-3}}{n} = \frac{4.13\times10^{-3}}{2}$$

$$= 2.065\times10^{-3} = 0.002065$$

$$\text{Moles of } O_2 = 0.0446 - 0.002065 = 0.042535$$

$$\text{Mass of } O_3 = \text{no. of moles} \times \text{mol. wt.}$$

$$= 0.002065 \times (3 \times 16) = 0.09912 \text{ g}$$

$$\text{Mass of } O_2 = \text{no. of moles} \times \text{mol. wt}$$

$$= 0.042535 \times (2 \times 16) = 1.36112$$

$$\%\text{ age of } O_3 = \frac{\text{wt. of } O_3}{\text{wt. of } O_3 + \text{wt. of } O_2} \times 100$$

$$= \frac{0.09912}{0.09912 + 1.36112} \times 100$$

$$= \frac{0.09912}{1.46024} \times 100 = \mathbf{6.79}$$ **Ans.**

Number of O_3 molecules

$$= \text{no. of moles} \times 6.023 \times 10^{23}$$

$$= 0.002065 \times 6.023 \times 10^{23}$$

$$= \mathbf{1.24 \times 10^{21}}$$ **Ans.**

Hence number of photons required

$$= \mathbf{1.24 \times 10^{21}}$$ **Ans.**

EXAMPLE 140. *During a titration of a solution of 0.2 g of a compound containing Cu^{2+} and $C_2O_4^{2-}$ ions, 22.6 mL of 0.02 M $KMnO_4$ oxidant was consumed. The resulting solution was neutralised with sodium carbonate solution and then acidified with dil. CH_3COOH and treated with excess KI. The liberated iodine required 11.3 mL of N/20 hypo solution for complete reduction. Calculate the mole ratio of Cu^{2+} to $C_2O_4^{2-}$ in the compound. Also write the redox reactions involved.*

SOLUTION. $KMnO_4$ and Cu^{2+} are oxidants while $C_2O_4^{2-}$ and I^- (of KI) are reductants. $KMnO_4$ is a stronger oxidant and would react with $C_2O_4^{2-}$ ions as follows.

$$2MnO_4^- + 5C_2O_4^{2-} + 16H^+ \longrightarrow 2Mn^{2+} + 10CO_2 + 8H_2O$$

Now I^- ions react with Cu^{2+} ions as follows :

$$2Cu^{2+} + 4I^- \longrightarrow Cu_2I_2 + I_2$$

Now I_2 reacts with hypo ($Na_2S_2O_3$) as follows :

$$I_2 + 2S_2O_3^{2-} \longrightarrow 2I^- + S_4O_6^{2-}$$

Equivalents of $KMnO_4$ solution

$$= \frac{\text{Vol in mL} \times \text{molarity} \times n}{1000}$$

$$[MnO_4^- + 8H^+ + 5e^- \rightarrow Mn^{2+} + 4H_2O;\ n = 5]$$

$$= \frac{22.6 \times 0.02 \times 5}{1000} = 0.00226$$

$$\therefore \quad \text{Moles of } C_2O_4^{2-} = \frac{0.00226}{n} = \frac{0.00226}{2} = 0.00113$$

$$\left[\because\ C_2O_4^{2-} \rightarrow 2CO_2 + 2e^-;\ n = 2\right]$$

Equivalents of $Na_2S_2O_3$ solution

$$= \frac{\text{Vol in mL} \times \text{normality}}{1000}$$

$$= \frac{11.3 \times 1}{20 \times 1000} = 5.65 \times 10^{-4}$$

$$\therefore \quad \frac{\text{Moles of } Cu^{2+} \text{ ions}}{n} = \text{Equivalents of } Na_2S_2O_3$$

Or $$\frac{\text{Moles of } Cu^{2+} \text{ ions}}{1} = 5.65 \times 10^{-4}$$

$$[\because\ Cu^{2+} + 1e^- \longrightarrow Cu^+]$$

But moles of $C_2O_4^{2-}$ = 0.00113 (found above)

∴ Ratio of moles of Cu^{2+} to $C_2O_4^{2-}$

$$= \frac{5.65 \times 10^{-4}}{0.00113} = \mathbf{0.5}$$ **Ans.**

EXAMPLE 141. *Calculate the mass of $KMnO_4$ that is required to produce from excess oxalic acid ($H_2C_2O_4$), 4.5 L of CO_2 at 71°C and 1.02 atmospheric pressure (At. wt. Mn = 55, K = 39, O = 16)*

SOLUTION. P = 1.02 atm. ; V = 4.5 L ; R = 0.0821 L atm K^- mol$^-$; T = 71 + 273 = 244 K. n = no. of moles of CO_2 required. We know :

$$PV = nRT \text{ Thus, } n = \frac{PV}{RT}$$

$$= \frac{1.02 \text{ atm} \times 4.5 \text{ L}}{0.0821 \text{ L atm K}^- \text{mol}^- \times 244 \text{ K}}$$

or $$n = 0.229 \text{ mol}$$

Reactions. $MnO_4^- + 8H^+ + 5e^- \longrightarrow Mn^{2+} + 4H_2O] \times 2$

$$C_2O_4^{2-} \longrightarrow 2CO_2 + 2e^-] \times 5$$

$$2MnO_4^- + 16H^+ + 5C_2O_4^{2-} \longrightarrow 2Mn^{2+} + 8H_2O + 10CO_2$$

2 mol 10 mol

1 mol 5 mol

5 mol of CO_2 is due to $KMnO_4$ = 1 mol

0.229 mol of CO_2 is due to $KMnO_4$

$$= \frac{1 \times 0.229}{5} = 0.0458 \text{ mol}$$

g. molar mass of

$$KMnO_4 = 39 + 55 + (4 \times 16)$$

$$= 39 + 55 + 64 = 158 \text{ g}$$

$$\therefore \text{ Mass of } KMnO_4 = \text{no. of moles} \times \text{Mol. wt}$$

$$= 0.0458 \times 158 = \mathbf{7.2364 \text{ g}}$$ **Ans.**

EXAMPLE 142. *3.32×10^{-3} mol of A^{n+} ions in a solution require 2.0×10^{-3} mol of MnO_4^- for the complete oxidation of A^{n+} into AO_3^- in acidic solution. Calculate the value of n.*

(IIT 1984)

SOLUTION. Reaction

$$MnO_4^- + 8H^+ + 5e^- \longrightarrow Mn^{2+} + 4H_2O \quad \text{...(1)}$$

$$n = 5$$

'*n*' factor in reaction (1) is 5.

∴ Equivalents of MnO_4^-

$$= \text{Moles of } KMnO_4 \times \text{'}n\text{' factor}$$
$$= 2.0 \times 10^{-3} \times 5 = 10.0 \times 10^{-3}$$

Equivalents of $A^{n+} = 10.0 \times 10^{-3}$

$\therefore$ n factor of $AO_3^- = 5 - n$

Thus $(5 - n) \times 3.32 \times 10^{-3} = 10.0 \times 10^{-3}$

Or $$5 - n = \frac{10.0 \times 10^{-3}}{3.32 \times 10^{-3}} = 3$$

Or $n = 5 - 3 = 2$ $\therefore$ $n = \mathbf{2}$ **Ans.**

EXAMPLE 143. *How much volume of HCl (sp. gr. 1.2 g mL^- and 5% nature by weight) and amount of MnO_2 are needed to liberate 1.5 L of Cl_2 gas at N.T.P. by the reaction.*

$$MnO_2 + 4HCl \longrightarrow MnCl_2 + Cl_2 + H_2O.$$

(At. wt. Mn = 55, O = 16)

SOLUTION. (*a*) Given reaction is :

$$\begin{array}{cccc} MnO_2 & + \; 4HCl & \longrightarrow MnCl_2 + Cl_2 + H_2O & \quad ...(1) \\ 1 \text{ mol} & 4 \text{ mol} & 22.4 \text{ L} & \\ = 55 + (2 \times 16) & = 4 \times 36.5 & = 1 \text{ mol} & \\ = 87 & = 146 & & \end{array}$$

$$\text{Moles of } Cl_2 = \frac{\text{Vol of } Cl_2 \text{ in L}}{22.4 \text{ L}}$$
$$= \frac{1.5 \text{ L}}{22.4 \text{ L}} = 0.067 \text{ mol}$$

But from reaction (1), Moles of

MnO_2 = Moles of Cl_2

$\therefore$ Moles of $MnO_2 = 0.067$

$\therefore$ Wt. of MnO_2 = no. of moles × g. mol. wt. of MnO_2

$= 0.067 \times 87$ g

Wt. of MnO_2 = **5.829 g** **Ans.**

[$\because$ Mol. wt. of $MnO_2 = 55 + (2 \times 16) = 87$]

(*b*) 87 g MnO_2 react with HCl

= 146 g [from reaction (1)]

$\therefore$ 5.829 g MnO_2 react with

$$HCl = \frac{146}{87} \times 5.829 = 9.782 \text{ g.}$$

$\therefore$ Mass of HCl = 9.782 g

$$\text{Volume} \times \text{density} = \text{Mass} \quad \textbf{Or} \quad \text{Volume} \times 1.2 \times \frac{5}{100} = \text{Mass.}$$

$$\text{Volume} \times 1.2 \times \frac{5}{100} = 9.782$$

Or $$\text{Volume} = \frac{9.782 \times 100}{1.2 \times 5} = \mathbf{163 \text{ ml}}$$ **Ans.**

EXAMPLE 144. *A mixture containing $NaHC_2O_4$ and $H_2C_2O_4$ was dissolved in water and the solution was made up to one litre. 10 cm^3 of this mixture solution required 3.0 cm^3 of N/10 NaOH solution for complete neutralisation. In second experiment, 10 cm^3 of the same mixture required 4 cm^3 of N/10 $KMnO_4$ in dil. H_2SO_4 medium for complete oxidation. Calculate the amounts of $NaHC_2O_4$ and $H_2C_2O_4$ in the mixture.*

SOLUTION. Let wt. of $H_2C_2O_4$ in the mixture = x gL^-

Wt. of $NaHC_2O_4$ in the mixture = y gL^-

$\therefore$ Wt. of $H_2C_2O_4$ in 10 cm^3

$$= \frac{x}{1000} \times 10 = \frac{x}{100} \text{ g}$$

($\because$ 1L = 1000 cm^3)

Wt. of $NaHC_2O_4$ is 10 cm^3

$$= \frac{y}{1000} \times 10 = \frac{y}{100} \text{ g}$$

(*a*) Equivalents of NaOH

$$= \frac{\text{Vol. in cm}^3 \times \text{normality}}{1000 \text{ cm}^3}$$
$$= \frac{3 \times 1}{10 \times 1000} = 0.0003$$

Both $H_2C_2O_4$ and $NaHC_2O_4$ are acids. So, these will react with NaOH

$$(H_2C_2O_4 \rightleftharpoons 2H^+ + C_2O_4^{2-};$$
$$\mathbf{n = 2}$$
$$NaHC_2O_4 \rightleftharpoons Na^+ + H^+ + C_2O_4^{2-})$$
$$\mathbf{n = 1}$$

Mol. wt. of $H_2C_2O_4 = (2 \times 1) + (2 \times 12) + (4 \times 16)$

$= 2 + 24 + 64 = 90$

Mol. wt. of $NaHC_2O_4 = 23 + 1 + (2 \times 12) + (4 \times 16)$

$= 23 + 1 + 24 + 64 = \mathbf{112}$

Equivalents of $H_2C_2O_4$ = no. of moles × n

$$= \frac{\text{wt.}}{\text{mol. wt.}} \times n = \frac{x}{100 \times 90} \times 2 = \frac{x}{4500}$$

Equivalents of $NaHC_2O_4$ = no. of moles × n

$$= \frac{\text{wt.}}{\text{mol. wt.}} \times n = \frac{y}{100 \times 112} \times 1$$
$$= \frac{y}{11200}$$

But, Equivalents of $H_2C_2O_4$ + Equivalents of $NaHC_2O_4$ = Equivalents of NaOH

Or $$\frac{x}{4500} + \frac{y}{11200} = 0.0003 \quad ...(1)$$

(*b*) Equivalents of $KMnO_4$

$$= \frac{\text{Vol. in mL} \times \text{normality}}{1000}$$
$$= \frac{4 \times 1}{10 \times 1000} = 0.0004$$

$KMnO_4$ oxidises $H_2C_2O_4$ (oxidation state of C = + 3) to CO_2 (oxidation state of C = +4), the oxidation no. change = + 4 – (+ 3) = + 1

For two C-atoms in both $H_2C_2O_4$ and NaH C_2O_4, the 'n' factor = + 1 × 2 = 2.

Hence, from equation (1), we have.

$$\frac{x \times 2}{90 \times 100} + \frac{y \times 2}{100 \times 112} = 0.0004$$

Or $$\frac{x}{4500} + \frac{y}{5600} = 0.0004 \quad ...(2)$$

Subtracting equation (1) from (2), we get.

$$\frac{y}{5600}-\frac{y}{11200} = 0.0004 - 0.0003$$

Or $$\frac{2y-y}{11200} = 0.0001$$

$y = 0.0001 \times 11200 = 1.12$ g

= wt. of $NaHC_2O_4$ **Ans.**

Substituting the value of

$y = 1.12$ in equation (2), we get :

$$\frac{x}{4500}+\frac{1.12}{5600} = 0.0004$$

Or $\frac{x}{4500}+0.0002 = 0.0004;\ \frac{x}{4500}$

$= 0.0004 - 0.0002 = 0.0002$

or $x = 0.0002 \times 4500 = 0.9$ g

∴ Wt. of $H_2C_2O_4$ = **0.9 g** **Ans.**

Back Titration.

EXAMPLE 145. *1.8 g of pyrolusite ore was warmed with 50 mL of 1N oxalic acid and some dil. H_2SO_4. The undecomposed oxalic acid solution was diluted to exact 250 mL. 25 mL of this solution on titration with 0.1 N $KMnO_4$ required 32 mL of the solution. Calculate the percentage of MnO_2 and available oxygen in pyrolusite. (At. wt. Mn = 55, O = 16).* **(Roorkee, 1996)**

SOLUTION. (*a*) wt. of pyrolusite, MnO_2 = 1.8 g.

Let normality of diluted oxalic acid

$= N_1$; Volume, V_1 = 250 mL

Meq. of excess dil. oxalic acid is 25 mL

= Meq. of $KMnO_4$

= Vol. of $KMnO_4$ × normality of

$KMnO_4 = 32 \times 0.1$

∴ Meq. of excess dil. oxalic acid in 250 mL

$$= \frac{32 \times 0.1}{25} \times 250 = 32$$

Meq. of oxalic acid added

= Vol of oxalic acid × normality

= 50 × 1 = 50

But Meq. of MnO_2 = Meq. of oxalic acid added – Meq. of excess oxalic acid. = 50 – 32 = **18**

Let weight of MnO_2 = w g.

But $$\text{Meq.} = \frac{\text{wt. of } MnO_2}{\text{Eq. wt. of } MnO_2} \times 1000$$

$$18 = \frac{\text{wt. of } MnO_2}{\frac{87}{2}} \times 1000$$

∴ $$\text{wt. of } MnO_2 = \frac{18 \times 87}{2} \times \frac{1}{1000} = 0.783 \text{ g.}$$

$$\text{\% age of } MnO_2 = \frac{\text{wt. of } MnO_2}{\text{wt. of pyrolusite}} \times 100$$

$$= \frac{0.783}{1.8} \times 100 = \mathbf{43.5}$$ **Ans.**

$MnO_2 + 4H^+ + 2e^- \rightarrow Mn^{2+} + 2H_2O$

∴ n = 2 because of two e⁻s.

$$\therefore \text{Eq. wt. of } MnO_2 = \frac{\text{Mol. wt. of } MnO_2}{n}$$

$$= \frac{55+(2\times16)}{2} = \frac{87}{2}$$

(*b*) 1g. eq. of MnO_2 produces oxygen = 1 g eq ;

$$\text{Meq} = \frac{\text{wt. of } O_2}{\text{Eq. wt. of } O_2} \times 1000\ ;$$

$$18 = \frac{\text{wt. of } O_2}{8} \times 1000$$

∴ $$\text{wt. of } O_2 = \frac{18 \times 8}{1000} = 0.144 \text{ g}$$

∴ % age of available oxygen

$$= \frac{0.144}{1.8} \times 100 = \mathbf{6.33\%}$$ **Ans.**

EXAMPLE 146. *10 g of a sample of gas liquor (NH_4^+ salt) is boiled with NaOH and the resulting NH_3 is passed into 60 mL of 0.9 N H_2SO_4. Excess H_2SO_4 required 10 cm³ of 0.4 N NaOH. What is the percentage of NH_3 in gas liquor ?*

SOLUTION. Meq. of H_2SO_4 taken

= Vol of H_2SO_4 × Normality of

H_2SO_4 = 60 × 0.9 = **54**

Volume of NaOH = 10 cm³ or 10 mL

Meq. of excess H_2SO_4 left behind

= Meq. of NaOH

Meq. of NaOH = Vol of NaOH × normality of

NaOH = 10 × 0.4 = 4 = Meq of NH_3

∴ Meq. of excess H_2SO_4 = 4

∴ Meq. of H_2SO_4 used to form

NH_3 = 54 – 4 = 50.

Let wt. of NH_3 = wg ; Eq. wt. of

NH_3 = 14 + (3 × 1) = 17

But $$\text{Meq. of } NH_3 = \frac{\text{wt. of } NH_3}{\text{Eq. wt. of } NH_3} \times 1000$$

$$50 = \frac{\text{wt. of } NH_3}{17} \times 1000$$

∴ $$\text{Wt. of } NH_3 = \frac{17 \times 50}{1000} = 0.85 \text{ g}$$

$$\text{\% age of } NH_3 = \frac{\text{wt. of } NH_3}{\text{wt. of } NH_4^+ \text{ salt}} \times 100$$

$$= \frac{0.85 \times 100}{10} = \mathbf{8.5}$$ **Ans.**

EXAMPLE 147. *The formula weight of an acid is 82.0. In a titration, 100 cm³ of a solution of this acid containing 39.0 g of the acid per litre were completely neutralised by 95.0 cm³ of aqueous solution containing 40.0 g of NaOH per litre. What is the basicity of the acid.* **(Roorkee 2000)**

SOLUTION. Given that 40 g of NaOH is present in 1 litre solution.

It means that the normality of NaOH is 1N

[∵ Eq. wt. of NaOH = 23 + 16 + 1 = 40]

Let the normality of the acid

$$= N_1$$

Volume of the acid used = 100 cm^3

Applying normality equation

$$N_1V_1 = N_2V_2$$

$$N_1 \times 100 = 1\times 95 \therefore \text{Normality of the solution}$$

$$(N_1) = \frac{95}{100}$$

Given the strength of acid solution = 39 g litre^{-1}

∴ Equivalent weight of acid

$$= \frac{\text{Strength}}{\text{normality}} = \frac{39}{95/100}$$

$$= \frac{39\times 100}{95} = 41.105$$

Molecular mass of acid = 82.0 (given)

$$\therefore \text{ Basicity of acid } = \frac{\text{Mol. mass}}{\text{Eq. wt.}} = \frac{82}{41.05} = 2$$

Hence, the basicity of the acid = 2.

EXAMPLE 148. *Calculate the molarity and mass of sodium bromate of the solution required to prepare 86.5 mL of 0.55 N solution when the half cell reaction is* $2BrO_3^- + 12H^+ + 10e^- \rightarrow Br_2 + 6H_2O$? (*At. wt. Na = 23, Br = 80, O = 16*)

SOLUTION. *Given reaction.*

$$2BrO_3^- + 12H^+ + 10e^- \longrightarrow Br_2 + 6H_2O.$$

For 1 mole of BrO_3^-, the reaction will be :

$$BrO_3^- + 6H^+ + 5e^- \longrightarrow \frac{1}{2} Br_2 + 3H_2O$$

$$n = 5$$

(*a*) Mol. wt. of $NaBrO_3$ (sodium bromate)

$$= 23 + 80 + (3 \times 16) = 151$$

$$\text{Eq. wt. of } NaBrO_3 = \frac{\text{Mol. wt.}}{n} = \frac{151}{5}$$

But Molarity × Mol. wt. = Normality × Eq. wt.

$$\therefore \quad \text{Molarity} = \frac{\text{Normality}\times\text{Eq. wt.}}{\text{Mol. wt.}}$$

$$= \frac{0.55}{151}\times\frac{151}{5} = \mathbf{0.11} \qquad \textbf{Ans.}$$

(*b*)To find mass of $NaBrO_3$. We know :

$$\text{Molarity} = \frac{\text{wt. of solute}}{\text{g. mol. wt. of solute}} \times \frac{1000}{\text{Volume of solution in mL}}$$

Substituting the values, we get :

$$0.11 = \frac{\text{wt. of solute}}{151}\times\frac{1000}{86.5}$$

Or $\text{wt. of solute} = \frac{0.11\times 151\times 86.5}{1000}$ ∴ wt. of solute

$$(NaBrO_3) = \mathbf{1.4368\ g}$$

EXAMPLE 149. *A 1.2 g sample of* Fe_2O_3 *solid of 46% purity was dissolved in an acid. The resulting solution was reduced by heating with zinc dust. This solution was then cooled and diluted to exact 100 cm³. 25 cm³ of this solution required 18.9 mL of 0.015 M solution of an oxidant for titration. Calculate the number of electrons taken up by the oxidant in the reaction of above titration.* (*At. wt. Fe = 56, O = 16*).

SOLUTION. Wt. of impure Fe_2O_3 = 1.2 g ;

% age purity = 46%

$$\therefore \text{ Wt. of pure } Fe_2O_3 = \frac{1.2\times 46}{100} = 0.552 \text{ g.}$$

$$\text{Mol. wt. of } Fe_2O_3 = (2 \times 56) + (3 \times 16)$$

$$= 112 + 48 = 160.$$

$$\therefore \text{ Moles of } Fe_2O_3 = \text{wt/Mol. wt}$$

$$= 0.552/160 = 3.45 \times 10^{-3}$$

Equivalent of oxidant

$$= \frac{n\times\text{Vol. of oxidant}\times\text{molarity of oxidant}}{1000}$$

[n = no. of electrons involved in oxidant reaction]

$$= \frac{n\times 18.9\times 0.015}{1000} = 2.84 \times 10^{-4}\, n$$

Zinc dust has reduced total Fe^{3+} ions of Fe_2O_3 to Fe^{2+} ions.

$$(\underset{1\text{ mol}}{Fe_2O_3} \longrightarrow \underset{2\text{ mol}}{2Fe^{2+}}\ ;\ n = 2)$$

∴ Moles of Fe^{2+} in 100 cm^3

$$= 2 \times 3.45 \times 10^{-3}$$

Moles of Fe^{2+} in 25 cm^3

$$= \frac{2\times 3.45\times 10^{-3}}{100}\times 25 = 1.725 \times 10^{-3}$$

According to law of equivalents :

Equivalents of oxidant = Equivalent of Fe^{2+}

$$2.84 \times 10^{-4}\, n = 1.725 \times 10^{-3}$$

$$\therefore \qquad n = \frac{1.725\times 10^{-3}}{2.84\times 10^{-4}} = 6.07 \simeq 6 \qquad \textbf{Ans.}$$

EXAMPLE 150. *A sample weighing 7.5 g contained* Fe_2O_3, Fe_3O_4 *and inert material. When treated with an excess of aqueous KI solution in acidic medium, reduced* Fe^{3+} *ions to* Fe^{2+} *ions. The resulting solution was diluted to 50 mL. Out of it, 10 mL was taken. The liberated* I_2 *in this solution required 7.4 mL of 1M* $Na_2S_2O_3$ *for reduction to iodide. Iodine from another 25 mL sample was extracted, after which the* Fe^{2+} *ions was titrated with 1M* $KMnO_4$ *in acidic medium. The volume of* $KMnO_4$ *solution used was found to be 4.15 mL. Calculate the mass percentages of* Fe_2O_3 *and* Fe_3O_4 *in the original mixture.*

SOLUTION. Wt. of Fe_2O_3 + wt. of

Fe_3O_4 = 7.5 g ; $Fe_3O_4 = Fe_2O_3 + FeO$.

Let moles of Fe_3O_4 = x g ; moles of Fe_2O_3 = y g

(*a*) *First titration.* Equivalents of

$$Na_2S_2O_3 = \frac{\text{Vol}\times\text{molarity}\times n}{1000}$$

$$\left[S_2O_3^{2-} \rightarrow \frac{1}{2}S_4O_6^{2-} + 1e^- ; n = 1\right]$$

$$= \frac{7.4\times 1\times 1}{1000} = 7.4 \times 10^{-3}$$

Since equivalent of $Na_2S_2O_3$ = equivalent of I_2

$= \text{Equivalent of } Fe_2O_3 + Fe_2O_3$ (from Fe_3O_4)

$\therefore$ Equivalent of 10 mL

$I_2 = 7.4 \times 10^{-3}$

Equivalent of 50 mL

$$I_2 = \frac{7.4\times10^{-3}}{10}\times 50 = 3.7 \times 10^{-2}$$

$\therefore$ Total equivalent of

$Fe_2O_3 = 3.7 \times 10^{-2}$

Fe_3O_4 consists of Fe_2O_3 + FeO. For Fe_2O_3 and Fe_2O_3 (from Fe_2O_3 + FeO), n factor is 2 because Fe_2O_3 on reduction gives Fe^{2+} *i.e.*, $Fe_2O_3 \rightarrow 2Fe^{2+}$). Thus :

$$2x + 2y = 3.7 \times 10^{-2} \qquad ...(1)$$

(*b*) **Second titration**. In acidic $KMnO_4$, we have :

$$MnO_4^- + 8H^+ + 5e^- \longrightarrow Mn^{2+} + 4H_2O$$

$n = 5$

$\therefore$ Equivalent of $KMnO_4$

$$= \frac{\text{Vol.}\times\text{molarity}\times n}{1000} = \frac{4.15\times1\times5}{1000} = 2.08 \times 10^{-2}$$

But Equivalent of $KMnO_4$ = Equivalent of Fe^{2+}

Equivalent of Fe^{2+} in 25 mL = 2.08×10^{-2}

$\therefore$ Equivalent of Fe^{2+} in 50 mL

$$= \frac{2.08\times10^{-2}\times50}{25} = 4.16 \times 10^{-2}$$

$\therefore$ Moles of $Fe^{2+} = 4.16 \times 10^{-2}$

For Fe_3O_4, n = 3 because $Fe_3O_4 \rightarrow 3Fe^{2+}$ and for Fe_2O_3, n = 2 because $Fe_2O_3 \rightarrow 2Fe^{2+}$.

Thus, $3x + 2y = 4.16 \times 10^{-2}$ ...(2)

Subtracting equation (1) from (2), we get :

$$3x + 2y - 2x - 2y = 4.16 \times 10^{-2} - 3.7 \times 10^{-2}$$
$$= 10^{-2}(4.16 - 3.7) = 0.46 \times 10^{-2}$$

Or $x = 4.6 \times 10^{-3}$.

Or moles of $Fe_3O_4 = 4.6 \times 10^{-3}$

(*c*) $\therefore$ Wt. of $Fe_3O_4 = 4.6 \times 10^{-3} \times 232 = 1.0672$ g

[$\because$ Mol. wt. of $Fe_3O_4 = (3 \times 56) + (4 \times 16) = 232$]

$\therefore$ % age of $Fe_3O_4 = \frac{1.0672}{7.5}\times 100 =$ **14.23%** **Ans.**

(*d*) *To find weight of* Fe_2O_3.

Substituting the value of $x = 4.6 \times 10^{-3}$ in equation (1), we get :

$2 \times 4.6 \times 10^{-3} + 2y = 3.7 \times 10^{-2}$

Or $9.2 \times 10^{-3} + 2y = 3.7 \times 10^{-2}$

Or $0.92 \times 10^{-2} + 2y = 3.7 \times 10^{-2}$

Or $2y = 3.7 \times 10^{-2} - 0.92 \times 10^{-2}$

$2y = 10^{-2}(3.7 - 0.92) = 10^{-2} \times 2.78$

or $y = (2.78 \times 10^{-2})/2 = 1.39 \times 10^{-2}$

$\therefore$ Moles of $Fe_2O_3 = 1.39 \times 10^{-2}$

Wt. of $Fe_2O_3 = 1.39 \times 10^{-2} \times 160 = 2.224$ g

[$\because$ Mol. wt. of $Fe_2O_3 = (2 \times 56) + (3 \times 16) = 160$]

$$\%\text{ age of } Fe_2O_3 = \frac{\text{wt. of } Fe_2O_3}{\text{Total wt.}}\times 100 = \frac{2.224}{7.5}\times 100$$

= **29.65%** **Ans.**

EXAMPLE 151. *18 g of a sample of* $Ba(OH)_2$ *is dissolved in 50 mL of 0.1 N HCl solution. The excess of HCl was titrated with 0.1 N NaOH solution. The volume of NaOH used was 18.9 mL. Calculate the percentage of* $Ba(OH)_2$ *in the sample (at. wt. Ba = 137, O = 16, H = 1)*

SOLUTION. $Ba(OH)_2 \longrightarrow Ba^{2+} + 2OH^-$

$n = 2$

$$\text{Eq. wt. of } Ba(OH)_2 = \frac{171}{2}$$

$$\left[\because \text{Eq. wt.} = \frac{\text{Mol. wt.}}{n} = \frac{137+2(16+1)}{2} = \frac{171}{2}\right]$$

Initial milliequivalent of HCl

= Vol × normality = 50 × 0.1 = **5**

Milliequivalent of HCl in excess

= Vol × normality = 18.9 × 0.1 = **1.89**

$\therefore$ M.eq. of NaOH consumed = 1.89

Meq. of HCl consumed

= Meq. of $Ba(OH)_2$ = 5 – 1.89 = 3.11

Equivalents of $Ba(OH)_2$

$$= \frac{\text{Meq. of } Ba(OH)_2}{1000} = \frac{3.11}{1000}$$

$$\text{Wt. of } Ba(OH)_2 = \frac{3.11}{1000}\times\frac{171}{2} = 0.266 \text{ g}$$

$$\%\text{ age of } Ba(OH)_2 = \frac{\text{wt. of } Ba(OH)_2}{\text{Total wt.}}\times 100$$

$$= \frac{0.266 \text{ g}}{18}\times 100 = \mathbf{1.48}$$ **Ans.**

EXAMPLE 152. *Calculate the volume of 0.1 M* $KMnO_4$ *used to completely oxidise 20 mL of 0.05 M* $FeSO_4$ *under acidic conditions.*

SOLUTION. In acidic medium, $KMnO_4$ or MnO_4^- undergoes reduction as follows :

$MnO_4^- + 8H^+ + 5e^- \longrightarrow Mn^{2+} + 4H_2O$. Thus, $n = 5$

$\therefore$ Meq. of $KMnO_4$ = Vol. of solution in mL × molarity × n Let Volume of

$KMnO_4 = V$ mL

$\therefore$ Meq. of $KMnO_4 = V \times 0.1 \times 5$ ...(1)

$FeSO_4$ undergoes oxidation as :

$Fe^{2+} \longrightarrow Fe^{3+} + 1e^-$; Thus $n = 1$

$\therefore$ Meq. of $FeSO_4$ = Vol. of solution in mL × molarity × n

Meq. of $FeSO_4 = 20 \times 0.05 \times 1$ ...(2)

But Meq. of $KMnO_4$ = Meq. of $FeSO_4$. Hence from (1) and (2) we have:

$$V \times 0.1 \times 5 = 20 \times 0.05 \times 1$$

$$\therefore \quad V = \frac{20\times0.05}{0.1\times5} = \mathbf{2.0 \text{ mL}}$$ **Ans.**

EXAMPLE 153. *For the following half cell reaction*

$$BrO_3^- + 6H^+ + 6e^- \longrightarrow Br^- + 3H_2O$$

calculate the weight of sodium bromate as well as molarity of solution to prepare 250 mL of 0.3N solution. (At. wt. Na = 23, Br = 80, O = 16)

SOLUTION. g. mol. wt. of sodium bromate, $NaBrO_3 = 23 + 80 + (3 \times 16) = 151$ g. Since the given reaction

$$BrO_3^- + 6H^+ + 6e^- \longrightarrow Br^- + 3H_2O$$

involves six electron change, so :

$$\text{Eq. wt. of } NaBrO_3 = \frac{\text{Mol. wt.}}{6} = \frac{151}{6}$$

$$\text{Meq. of } NaBrO_3 = \text{Vol in mL} \times \text{normality}$$
$$= 250 \times 0.3 = 75$$

$$\text{But} \qquad \text{Meq} = \frac{\text{wt. of solute}}{\text{Eq. wt. of solute}} \times 1000$$

$$\therefore \qquad 75 = \frac{\text{wt. of solute}}{151/6} \times 1000$$

$$\text{Or} \quad \text{wt. of solute} = \frac{75 \times 151}{1000 \times 6} = 1.8875 \text{ g}$$

$$\text{Molarity} = \frac{\text{wt. of solute}}{\text{Mol. wt. of solute}} \times \frac{1000}{\text{Vol. of solution in mL}}$$

$$= \frac{1.8875}{151} \times \frac{1000}{250} = \mathbf{0.05\ M} \qquad \textbf{Ans.}$$

EXAMPLE 154. *0.2986 g of a sample of iron piece was dissolved in dil. H_2SO_4 and solution was made up to 150 mL. 30.0 mL of this solution required 25 mL of N/25 $K_2Cr_2O_7$ solution for oxidation. Calculate the percentage of pure iron in the given piece. (at. wt. Fe = 56).*

SOLUTION. $Fe + H_2SO_4 \longrightarrow FeSO_4 + H_2 \uparrow$

$$FeSO_4 \rightleftharpoons Fe^{2+} + SO_4^{2-};$$
$$Fe^{2+} \longrightarrow Fe^{3+} + 1e^-$$

$$\therefore \quad \text{Eq. wt. of } Fe^{2+} = \frac{\text{at. wt. of Fe}}{1} = \frac{56}{1} = 56.$$

To find normality of Fe^{2+} solution.

$FeSO_4$ solution $\quad K_2Cr_2O_7$ solution

$$N_1V_1 = N_2V_2$$
$$N_1 \times 30 = 25 \times \frac{1}{25}; N_1 = \frac{1}{30}$$

We Know that :

1000 mL of 1N $FeSO_4$ solution contain

Fe = Eq. wt. of Fe = 56 g

150 mL of $\frac{N}{30}$ $FeSO_4$ solution contain

$$Fe = \frac{56}{1000} \times 150 \times \frac{1}{30} = 0.28 \text{ g}$$

$$\therefore \quad \%\text{ age of Fe} = \frac{\text{wt. of pure Fe}}{\text{wt. of Fe sample}} \times 100$$

$$= \frac{0.28}{0.2986} \times 100 = \mathbf{93.8\%} \qquad \textbf{Ans.}$$

EXAMPLE 155. *(a) $CuSO_4$ reacts quantitatively with KI in an acidic medium to liberate I_2. Write the balanced equation for this reaction.*

(b) Mercuric iodate $[Hg_5(IO_6)_2]$ reacts with a mixture of KI and HCl according to the following equation.

$$Hg_5(IO_6)_2 + 34KI + 24HCl \longrightarrow 5K_2HgI_4 + 8I_2 + 24KCl + 12H_2O$$

The liberated iodine is treated with $Na_2S_2O_3$ solution, one mL of which is equivalent to 0.0499 g of $CuSO_4.5H_2O$. What volume (in mL) of the $Na_2S_2O_3$ solution will be required to react with iodine liberated from 0.7245 g of $Hg_5(IO_6)_2$? (Hg = 200.5, Cu = 63.5, I = 127). **(IIT, 1970)**

SOLUTION. (*a*) *Reaction.*

$$2CuSO_4.5H_2O + 4KI \longrightarrow Cu_2I_2 \downarrow + I_2 + 2K_2SO_4 + 10H_2O$$

(*b*) $Hg_5(IO_6)_2 + 34KI + 24HCl \longrightarrow 5K_2HgI_4 + 8\,I_2 + 24KCl + 12H_2O$

$$I_2 + 2Na_2S_2O_3 \longrightarrow 2NaI + Na_2S_4O_6$$

From reaction

(*a*) $\qquad I_2 \equiv 2CuSO_4 . 5H_2O$

$8I_2 \equiv 2 \times 8\ CuSO_4.5H_2O$

or $\ 16CuSO_4.5H_2O$

From reaction

(*b*) $\qquad Hg_5(IO_6)_2 \equiv 8I_2$

$\therefore \qquad Hg_5(IO_6)_2 \equiv 8I_2 \equiv 16CuSO_4.5H_2O$

$(5 \times 200.5) + 2[127 + (6 \times 16)] = 1002.5 + 446 = 1448.5$

$16[63.5 + 32 + (4 \times 16) + 5(2 \times 1 + 16)] = 16[63.5 + 32 + 64 + 90] = 3992$

(*i*) 1448.5 g $Hg_5(IO_6)_2$

$\equiv 3992$ g $CuSO_4.5H_2O$

$$0.7245 \text{ g } Hg_5(IO_6)_2 \equiv \frac{3992}{1448.5} \times 0.7245 \text{ g } CuSO_4 . 5H_2O$$

(*ii*) 0.0499 g $CuSO_4.5H_2O$

$\equiv 1$ mL of $Na_2S_2O_3$ solution

$$\frac{3992}{1448.5} \times 0.7245 \text{ g } CuSO_4 . 5H_2O$$

$$\equiv \frac{3992 \times 0.7245}{1448.5 \times 0.0499} = \mathbf{40\ mL} \qquad \textbf{Ans.}$$

EXAMPLE 156. *The reaction, $Zn + CuSO_4 \rightarrow Cu + ZnSO_4$ goes completely to right. In one experiment, 10.0 g of metallic zinc was added to 200 mL of copper sulphate solution. After, all the copper was precipitated, it was found that not all the zinc had dissolved. After filtration, the total solid at the end of reaction was 9.81 g. Calculate (i) the weight of copper deposited and (ii) molarity of copper sulphate in the original solution (Cu = 63.5, Zn = 65.4).* **(IIT 1971)**

SOLUTION. Volume of $CuSO_4$ solution = 200 mL. Let *m* = molarity of $CuSO_4$ solution.

But M (= Molarity of Cu^{2+})

$$= \frac{\text{wt. of Cu}}{\text{mol. wt. of Cu}} \times \frac{1000}{\text{Volume of solution in mL(= 200 mL)}}$$

= at wt. of Cu = (63.5)

$$\therefore \qquad \text{wt. of Cu} = \frac{M \times 63.5 \times 200}{1000} = 12.7 \text{ m g.}$$

In $Zn + CuSO_4 \longrightarrow ZnSO_4 + Cu$, Zn and Cu react in equivalent proportion, so :

$$\text{wt. of Zn reacted} = 65.4\ \text{M} \times \frac{200}{1000}\ \text{g} = 13.08\ \text{mg}$$

[∵ at. wt. of Zn = 65.4]

wt. of unreacted zinc

$$= 10 - 13.08\ \text{M}$$

$$\therefore 12.7\ \text{M} + 10 - 13.08\ \text{M}$$

$$= 9.81\ \text{(given)}\ ; 0.38\ \text{M} = 0.19$$

$$\therefore \quad \text{M} = \frac{0.19}{0.38} = \mathbf{0.5\ M} \qquad \textbf{Ans.}$$

wt. of Cu deposited = 12.7 m = 12.7 × 0.5 = **6.35 g** **Ans.**

Example 157. *Find out the volume in mL of 0.1N hydrochloric acid required to react completely with 1g of a mixture of sodium carbonate and sodium bicarbonate containing equimolar amounts of the two compounds.* **(IIT 1971)**

Solution. wt. of a substance = no. of mol × mol. wt.

(*i*) Mol. wt. of

$$Na_2CO_3 = (2 \times 23) + 12 + (3 \times 16)$$

$$= 106\ \text{g mol}^{-}.$$

$$\text{Mol. wt. of } NaHCO_3 = 23 + 1 + 12 + (3 \times 16) = 84\ \text{g mol}^{-}$$

no. of mol of Na_2CO_3 = no. of mol of

$NaHCO_3$ = x suppose.

$$\therefore \quad \text{wt. of } Na_2CO_3 = \text{no. of mol} \times \text{Mol. wt.}$$

$$= x \times 106 = 106x\ \text{g}$$

$$\text{wt. of } NaHCO_3 = \text{no. of mol} \times \text{mol. wt.}$$

$$= x \times 84 = 84x\ \text{g}$$

$$\therefore \quad 106x + 84x = 1\ \text{g (given)}\ ; x = \frac{1}{190}$$

(*ii*)

$$\underset{\substack{1\ \text{mol} \\ 1/190\ \text{mol}}}{Na_2CO_3} + \underset{\substack{2\ \text{mol} \\ 2/190\ \text{mol}}}{2HCl} \longrightarrow NaCl + CO_2 + H_2O$$

(*iii*)

$$\underset{\substack{1\ \text{mol} \\ \frac{1}{190}\ \text{mol}}}{NaHCO_3} + \underset{\substack{1\ \text{mol} \\ \frac{1}{190}\ \text{mol}}}{HCl} \longrightarrow NaCl + CO_2 + H_2O$$

∴ Total amount of HCl required

$$= \frac{2}{190} + \frac{1}{190} = \frac{3}{190}\ \text{mol}$$

(*iv*)

$$1\ \text{mol of HCl} = 1\text{L of 1N HCl}$$

$$= 10\text{L of 0.1N HCl}$$

(∵ given HCl = 0.1N)

$$\frac{3}{190}\ \text{mol of HCl} = 10 \times \frac{3}{190}\ \text{L of 0.1N HCl} = \frac{3}{19}\ \text{L}$$

$$= \frac{3}{19}\text{L} \times \frac{1000\ \text{mL}}{1\ \text{L}} = \mathbf{157.9\ mL} \textbf{Ans.}$$

Example 158. *A piece of aluminium weighing 2.7 g is heated with 75.0 mL of sulphuric acid (sp. gr. 1.18 containing 24.7 percent H_2SO_4 by weight). After the metal is carefully dissolved, the solution is diluted to 400 mL. Calculate the molarity of free H_2SO_4 in the resulting solution. (at. wt., Al = 27, S = 32, O = 16, H = 1)* **(IIT 1972)**

Solution. (*i*) **Reaction.**

$$\underset{\substack{2 \times 27 \\ = 54\ \text{g}}}{2Al} + \underset{\substack{3[(2 \times 1) + 32 + \\ (4 \times 16)] = 294\ \text{g}}}{3H_2SO_4} \longrightarrow Al_2(SO_4)_3 + 3H_2$$

54 g Al react with H_2SO_4 = 294 g

2.7 g Al react with

$$H_2SO_4 = \frac{294}{54} \times 2.7 = 14.7\ \text{g}$$

(*ii*) wt. of H_2SO_4 in 75 mL

$$H_2SO_4 = \frac{\text{Volume} \times \text{sp. gr.} \times \text{percent}}{100}$$

$$= \frac{75 \times 1.18 \times 24.7}{100} = 21.86\ \text{g}$$

∴ wt. of unreacted H_2SO_4 diluted to 400 mL

$$= 21.86 - 14.7 = 7.16\ \text{g}$$

$$\therefore \text{Molarity of } H_2SO_4 = \frac{\text{wt.}}{\text{mol. wt.}} \times \frac{1000}{\text{Volume in mL}}$$

$$= \frac{7.16 \times 1000}{98 \times 400} = \mathbf{0.183} \qquad \textbf{Ans.}$$

Example 159. *Upon heating a litre of a N/2 HCl solution, 2.675 g of hydrogen chloride is lost and the volume of the solution shrinks to 750 mL. Calculate (i) the normality of the resulting solution and (ii) number of milliequivalents of HCl in 100 mL of the original solution.* **(IIT 1975)**

Solution. (*i*) 1000 mL of 1N HCl weighs = g. eq. wt. of

$$HCl = 1 + 35.5 = 36.5\ \text{g}$$

$$\text{One litre (= 1000 mL) of } \frac{N}{2}\ \text{HCl weighs}$$

$$= \frac{36.5}{1000} \times 1000 \times \frac{1}{2} = 18.25\ \text{g}$$

wt of HCl evaporated = 2.675 g

∴ wt. of HCl left behind

$$= 18.25 - 2.675 = 15.575\ \text{g}$$

$$\text{Normality} = \frac{\text{wt.}}{\text{Mol. wt.}} \times \frac{1000}{\text{Volume in mL}}$$

$$= \frac{15.575}{36.5} \times \frac{1000}{750} = \mathbf{0.569} \qquad \textbf{Ans.}$$

(*ii*) No. of milliequivalent of original solution

$$= \begin{array}{c}\text{Normality of} \\ \text{original HCl}\end{array} \times \text{Volume in mL}$$

$$= \frac{1}{2} \times 100 = 50\ \text{milliequivalent} \quad \textbf{Ans.}$$

Example 160. *How many milli litre of conc. H_2SO_4 (sp. gr. 1.84 containing 98% H_2SO_4 by weight) are required to prepare 200 mL of 0.5 N solution?* **(IIT 1976)**

Solution. Volume of conc.

$$H_2SO_4 = ?\ \text{sp. gr.} = 1.84,\ \%\ \text{age} = 98$$

$$\text{Eq. wt. of } H_2SO_4 = \frac{(2 \times 1) + 32 + (4 \times 16)}{\text{Basicity of } H_2SO_4} = \frac{98}{2} = 49$$

(*i*) 1000 mL of 1N H_2SO_4 contain

$$H_2SO_4 = \text{g. eq. wt. of } H_2SO_4 = 49\ \text{g}$$

200 mL of 0.5N H_2SO_4 contain

$$H_2SO_4 = \frac{49}{1000}\times 200\times 0.5 = 4.9\text{ g}$$

(*ii*) $$\text{wt. of } H_2SO_4 = \frac{\text{Volume}\times\text{sp. gr.}\times\text{percent}}{100}$$

$$4.9\text{ g} = \frac{\text{Volume}\times 1.84\times 98}{100};$$

$$\text{Volume} = \frac{4.9\times 100}{1.84\times 98} = 2.72\text{ mL.}$$

∴ Volume of conc.

H_2SO_4 = **2.72 mL.** **Ans.**

EXAMPLE 161. *0.108 g of finely divided copper was treated with an excess of ferric sulphate solution until copper was completely dissolved. The solution after addition of excess dilute sulphuric acid required 33.7 mL of 0.1N $KMnO_4$ for complete oxidation. Find the equation which represents the reaction between metallic copper and ferric sulphate solution. (Cu = 63.5, Fe = 56)* **(IIT, 1971)**

SOLUTION. Cu powder reduces $Fe_2(SO_4)_3$ to $FeSO_4$ *i.e.,* Fe^{2+} ions

33.7 mL of 0.1N $KMnO_4$ ≡ 33.7 mL of 0.1N $FeSO_4$

But 1000 mL of 1N $FeSO_4$ or Fe^{2+}

≡ g. at. wt of Fe^{2+} = 56 g

33.7 mL of 0.1N $FeSO_4$ of

$$Fe^{2+} \equiv \frac{56}{1000}\times 33.7\times 0.1\text{ g}$$

(*i*) ∴ No. of g atoms of Fe^{2+} reacted

$$= \frac{56\times 33.7\times 0.1}{1000}\times\frac{1}{56}$$

[∵ g. at. wt. of Fe = 56]

= 0.00337

(*ii*) no. of g. atoms of

$$Cu = \frac{\text{wt.}}{\text{at. wt.}} = \frac{0.108}{63.5} = 0.0017$$

0.0017 g. atom of Cu produce

Fe^{2+} = 0.00337 g atom

1 g. atom of Cu produce

$$Fe^{2+} = \frac{0.00337}{0.0017} \simeq 2\text{ g atom or 2g. mol of}$$

$FeSO_4$

∴ *Reaction* $Cu + Fe_2(SO_4)_3 \longrightarrow CuSO_4 + 2FeSO_4$.

1 g atom 2 g atom.

EXAMPLE 162. *1.0 g of a moist sample of a mixture of potassium chloride and potassium chlorate was dissolved in water and made up to 250 mL. 25 mL of this solution was treated with SO_2 to reduce the chlorate to chloride and excess SO_2 was removed by boiling. The total chloride was precipitated as silver chloride. The weight of the precipitate was 0.1435 g. In another experiment, 25 mL of the original solution was heated with 30 mL of 0.2N solution of ferrous sulphate and unreacted ferrous sulphate required 37.5 mL of 0.08N solution of an oxidising agent for complete oxidation. Calculate the molar ratio of the chlorate to the chloride in the given mixture. Fe^{2+} reacts with ClO_3^- according to the following reaction.*

$$ClO_3^- + 6Fe^{+2} + 6H^+ \longrightarrow Cl^- + 6Fe^{+3} + 3H_2O$$ **(IIT, 1972)**

SOLUTION. (*i*) N_1V_1 (oxidant) = N_2V_2 ($FeSO_4$)

$0.08 \times 37.5 = 0.2 \times V_2$;

$$V_2 = \frac{0.08\times 37.5}{0.2} = 15\text{ mL}$$

∴ Volume of 0.2N $FeSO_4$ used

= 30 mL (given) – 15 mL

= 15 mL. by $KClO_3$

(*ii*) 1000 mL of 1N

$FeSO_4$ = 1 g. eq. wt. of

$FeSO_4$ = 1 g mol of $FeSO_4$. 15 mL of 0.2N

$$FeSO_4 = \frac{1}{1000}\times 15\times 0.2$$

$= 3 \times 10^{-3}$ mol of $FeSO_4$.

From the reaction :

$$ClO_3^- + 6Fe^{2+} + 6H^+ \longrightarrow Cl^- + 6Fe^{+3} + 3H_2O$$

1 mol 6 mol

it is clear that 6 mol Fe^{2+} used

$KClO_3$ = 1 mol

3×10^{-3} mol Fe^{2+} uses

$$KClO_3 = \frac{1}{6}\times 3\times 10^{-3} = 0.5\times 10^{-3}\text{ mol } KClO_3$$

(*iii*) wt. of AgCl ppt. obtained from 25 mL solution

= 0.1435 g

Mol. wt. of AgCl = 108 + 35.5 = 143.5 g mol^-

∴ no. of mol of AgCl = no. of mol of

$$Cl^- = \frac{\text{wt.}}{\text{Mol. wt.}} = \frac{0.1435}{143.5} = \mathbf{1.0\times 10^{-3}}$$

But 1.0×10^{-3} mol Cl^- are obtained from Cl^- and ClO_3^-.

So: no. of mol of Cl^- + no. of mol of

$ClO_3^- = 1.0 \times 10^{-3}$

no. of mol of $ClO_3^- = 0.5 \times 10^{-3}$

∴ no. of mol of Cl^- = $(1.0 \times 10^{-3}) - (0.5 \times 10^{-3})$

= $\mathbf{0.5 \times 10^{-3}}$ **Ans.**

EXAMPLE 163. *A 0.5 g sample of an iron containing mineral mainly in the form of $CuFeS_2$ was reduced suitable to convert all the ferric iron into the ferrous form and was obtained as a solution. In the absence of any interferring matter, the solution required 42.0 mL of 0.01 M $K_2Cr_2O_7$ solution for titration. Calculate the percentage of $CuFeS_2$ in the mineral. (Cu = 63.5, Fe = 55.8, S = 32, O = 16).* **(I.I.T., 1976)**

SOLUTION. (*i*) *Reaction.*

$$Cr_2O_7^{2-} + 14H^+ + 6e^- \longrightarrow 2Cr^{3+} + 7H_2O$$

$$\therefore \text{ Eq. wt. of } K_2Cr_2O_7 = \frac{\text{Mol. wt.}}{\text{no. of electrons gained}}$$

$$= \frac{(2\times 39)+(2\times 52)+(7\times 16)}{6}$$

$$= \frac{294}{6} = 49$$

Normality of 0.01M

$K_2Cr_2O_7$ = molarity × valency factor

= 0.01 × 6 = 0.06 N 1000 mL of 1N

$$K_2Cr_2O_7 = \text{g. eq. wt. of } K_2Cr_2O_7 = 49 \text{ g}$$

$$42 \text{ mL of } 0.06 \text{ N } K_2Cr_2O_7 = \frac{49 \text{ g}}{1000} \times 42 \times 0.06 = 0.1235 \text{ g}$$

(*ii*)
$$\begin{aligned}
K_2Cr_2O_7 + 4H_2SO_4 &\longrightarrow K_2SO_4 + Cr_2(SO_4)_3 + 4H_2O + 3O \\
CuFeS_2 &\longrightarrow CuS + FeS] \times 6 \\
FeS + H_2SO_4 &\longrightarrow FeSO_4 + H_2S] \times 6 \\
2FeSO_4 + H_2SO_4 + O &\longrightarrow Fe_2(SO_4)_3 + H_2O\} \times 3 \\
\hline
K_2Cr_2O_7 + 13H_2SO_4 + 6CuFeS_2 &\longrightarrow K_2SO_4 + Cr_2(SO_4)_3 + 7H_2O + 6CuS + 6H_2S + 3Fe_2(SO_4)_3
\end{aligned}$$

$$\therefore \quad K_2Cr_2O_7 \equiv 6CuFeS_2$$

$(2 \times 39) + (2 \times 52) + (7 \times 16) = 294$ g $\qquad 6[63.5 + 56 + (2 \times 32)] = 6 \times 183.5$ g

$$294 \text{ g } K_2Cr_2O_7 \equiv 6 \times 183.5 \text{ g } CuFeS_2$$

$$0.1235 \text{ g } K_2Cr_2O_7 \equiv \frac{6 \times 183.5 \text{ g}}{294 \text{ g}} \times 0.1235 \text{ g} \equiv 0.462 \text{ g}$$

$$\therefore \ \% \text{ age of } CuFeS_2 = \frac{\text{wt. of } CuFeS_2}{\text{Total wt.}} \times 100$$

$$= \frac{0.462}{0.5} \times 100 = \mathbf{92.4\%}$$ **Ans.**

EXAMPLE 164. *1.0 g of a mixture, consisting of equal number of mol of carbonates of two alkali metals, required 44.4 mL of 0.5 N HCl for complete reaction. If atomic weight of one of the metals is 7.0, find the at. wt. of the other metal. What will be the amount of sulphate formed on quantitative conversion of 1.0 g of mixture into sulphates? (at. wt., Ca = 40, S = 32, O = 16)*

(IIT 1972)

SOLUTION. (*i*)1000 mL of

1N HCl ≡ 1 g. equivalent of HCl

$$44.4 \text{ mL of } 0.5\text{N HCl} = \frac{1}{1000} \times 44.4 \times 0.5$$

$$= 0.0222 \text{ g. eq. of HCl}$$

Reaction. $M_2CO_3 + 2HCl \longrightarrow 2MCl + CO_2 + H_2O$

1 g. eq $\qquad$ 2 g. eq

$\frac{0.0222}{2}$ $\qquad$ 0.0222 g. eq.

= 0.111 g mol

(*ii*) *One of the alkali metal.*

at. wt. = 7

∴ Mol. wt. of $M_2CO_3 = (2 \times 7) + 12 + (3 \times 16) = 74$ g mol$^-$

Second alkali metal. Let at. wt. of this metal = *a*

∴ Mol. wt. of $M_2CO_3 = 2a + 12 + (3 \times 16) = 2a + 60$

Since the mixture contains equal no. of moles of each carbonate, so :

wt. of one of the carbonates

$$= \frac{74 \times 0.0111}{2} = 0.4107$$

wt. of second carbonate

$$= \frac{(2x + 60) \times 0.0111}{2}$$

$$= (x + 30) \times 0.0111$$

Hence $0.4107 + (x + 30) \times 0.0111$

= 1.0 (given) ; $0.4107 + 0.0111x + 0.333$

$= 1 \ 0.0111x = 0.2563$. Hence, x

$= 0.2563/0.0111 = 23.1$

∴ at. wt. of second metal = 23.1 a.m.u.

(*iii*) *To find amount of sulphate formed*

Reaction $M_2CO_3 + H_2SO_4 \longrightarrow M_2SO_4 + H_2O + CO_2$

Mol. wt. of first carbonate = (2 × 7) + 12 + (3 × 16) = 74 g mol$^-$; Mol. wt. of M_2SO_4 = (2 × 7) + 32 + (4 × 16) = 142.2 g mol$^-$

Mol. wt. of second carbonate = (2 × 23.1) + 12 + (3 × 16) = 106.2 g mol$^-$; mol. wt. of M_2SO_4 = (2 × 23.1) + 32 + (4 × 16) = 110 g mol$^-$

∴wt. of M_2SO_4 formed from $\frac{0.0111}{2}$ mol of each carbonate will be :

no. of mol × mol. wt. of M_2SO_4 + no. of mol × mol. wt. of second M_2SO_4

$$= \frac{0.0111}{2} \times 110 + \frac{0.0111}{2} \times 142.2$$

$$= 0.6105 + 0.7892 \simeq \mathbf{1.4 \text{ g}}$$ **Ans.**

EXAMPLE 165. (*i*) *A solution of a mixture of potassium chloride and potassium hydroxide was neutralised with 120 mL of 0.12 N hydrochloric acid. Calculate the amount of potassium hydroxide in the mixture.*

(*ii*) *After titration, the resultant solution was made acidic with nitric acid. Then excess of silver nitrate solution was added to precipitate the silver chloride which weighed 3.7 g after drying. Calculate the percentage of potassium hydroxide in the original mixture.*

(IIT, 1973)

SOLUTION. (*i*) Only KOH will react with HCl.

So ; 1000 mL of 1N KOH weigh

= g. eq. wt. of KOH = 39 + 16 + 1

= 56 g

120 mL of 0.12 N

$$\text{KOH weigh} = \frac{56}{1000} \times 120 \times 0.12 = 0.8064 \text{ g}$$

Also,no. of g. equivalents of

$$\text{KOH} = \frac{\text{Volume in mL} \times \text{normality}}{1000}$$

$$= \frac{120 \times 0.12}{1000} = 0.0144.$$

(*ii*) In this process, AgCl is formed from KCl as well as from KOH from the following reaction

$$KOH + HCl \longrightarrow KCl + H_2O$$

∴ no. of g. equivalents of AgCl formed from KOH and

$$\text{KCl} = \frac{\text{wt. of AgCl}}{\text{eq. wt. of AgCl}}$$

$$= \frac{3.7}{108 + 35.5 = 143.5} = 0.0258$$

$\therefore$ no. of equivalents of KCl initially present

$$= 0.0258 - 0.0144 = 0.0114$$

$\therefore$ wt of KCl initially present

$$= \text{no. of g. eq} \times \text{mol. wt. of KCl}$$
$$= 0.0114 \times (39 + 35.5 = 74.5)$$
$$= 0.8493 \text{ g}$$

$$(iii)\ \%\text{ age of KOH} = \frac{0.8064}{0.8064 + 0.8493} \times 100$$
$$= \frac{0.8064}{1.6557} \times 100 = \mathbf{48.7\%} \qquad \textbf{Ans.}$$

EXAMPLE 166. (*i*) *In a quantitative determination of iron in an ore, an analyst converted 0.42 g of the ore into its ferrous form. This required 42.0 mL of 0.1N solution of* $KMnO_4$ *for titration.*

(*ii*) *How many milliequivalents of iron were present in the sample of the ore taken for analysis.*

(*iii*) *How many grams of iron were present in the sample ?*

(*iv*) *What is the percentage of iron in the ore?*

(*v*) *What is the molarity of* $KMnO_4$ *solution used?*

(*vi*) *How many moles of* $KMnO_4$ *were used for titration?*

(Fe = 56) **(IIT 1974)**

SOLUTION. (*i*) No. of milliequivalents of

$$KMnO_4 = \text{Normality} \times \text{Volume in mL}$$
$$= 0.1 \times 42$$
$$= \mathbf{4.2\ milliequivalent} \qquad \textbf{Ans.}$$

(*ii*) No. of milliequivalents of iron

$$= \text{no. of milliequivalents of } KMnO_4$$
$$= 4.2 \text{ milliequivalents}$$

[see (*i*) above]

$\therefore$ No. of equivalents of iron

$$= \frac{4.2}{1000} = \mathbf{0.0042\ equivalent.} \quad \textbf{Ans.}$$

(*iii*) Eq. wt. of Fe in $Fe^{2+} \rightarrow Fe^{+3} + 1e^-$

$$= \frac{\text{at. wt. of Fe}}{1} = \frac{56}{1} = 56$$

$$\therefore \quad \text{wt. of iron} = 0.0042 \times 56 = \mathbf{0.2352\ g} \qquad \textbf{Ans.}$$

$$(iv)\quad \%\text{ age of iron} = \frac{\text{wt. of iron}}{\text{Total wt.}} \times 100$$
$$= \frac{0.2352 \text{ g}}{0.42 \text{ g}} \times 100 = \mathbf{56\%} \qquad \textbf{Ans.}$$

(*v*) *Reaction* $MnO_4^- + 8H^+ + 5e^- \longrightarrow Mn^{+2} + 4H_2O$

$\therefore$ Valency factor = 5 due to 5 electrons.

$$\text{Molarity} = \frac{\text{Normality}}{\text{Valency factor}} = \frac{0.1}{5}$$
$$= \mathbf{0.02\ M} \qquad \textbf{Ans.}$$

(*vi*) No. of mol of

$$KMnO_4 = \text{Molarity} \times \text{Volume in litre}$$
$$= 0.02 \times \frac{42}{1000} = \mathbf{8.4 \times 10^{-4}\ mol} \quad \textbf{Ans.}$$

EXAMPLE 167. *A commercial sample (2.013 g)* o*f NaOH containing* Na_2CO_3 *as an impurity was dissolved to give 250 mL of solution. A 10 mL portion of this solution required 20 mL of 0.1N* H_2SO_4 *for complete neutralisation. Calculate the percentage by weight of* Na_2CO_3 *in the sample.* **(IIT, 1977)**

SOLUTION. (*i*) N_1V_1 (NaOH)

$$= N_2V_2\ (H_2SO_4)$$
$$N_1 \times 10 = 0.1 \times 20\ ;\ N_1 = \frac{0.1 \times 20}{10} = \mathbf{0.2\ N.}$$

(*ii*) Letwt. of NaOH = x g ; wt. of

$$Na_2CO_3 = (2.013 - x) \text{ g.}$$
$$\text{Eq. wt. of NaOH} = \frac{23 + 16 + 1}{1} = 40\ ;$$
$$\text{eq. wt. of } Na_2CO_3 = \frac{(2 \times 23) + 12 + (3 \times 16)}{2} = 53$$

250 mL solution contain

$$\text{NaOH} = x \text{ g}$$

1000 mL solution contain

$$\text{NaOH} = \frac{x}{250} \times 1000 = 4x \text{ g}$$

$$\therefore \textbf{ normality of NaOH} = \frac{\text{Strength}}{\text{eq. wt.}} = \frac{4x}{40}$$

250 mL solution contain

$$Na_2CO_3 = (2.013 - x) \text{ g}$$

1000 ml solution contain

$$Na_2CO_3 = \frac{2.013 - x}{250} \times 1000 = 8.052 - 4x$$

$$\therefore \text{Normality of } Na_2CO_3 = \frac{\text{Strength}}{\text{eq. wt.}} = \frac{8.052 - 4x}{53}$$

$$(iii)\quad \frac{4x}{40} + \frac{8.052 - 4x}{53} = 0.2\ ;\ 4x \times 53 + (40 \times 8.052) - 40(4x)$$
$$= 0.2 \times 40 \times 53$$
$$212x + 322.08 - 160x = 424\ ;\ 52x = 101.92\ ;$$
$$x = 1.96 \text{ g} = \text{wt. of NaOH}$$
$$\therefore \quad \text{wt. of } Na_2CO_3 = 2.013 - 1.96 = 0.053 \text{ g}$$
$$\%\text{ age of } Na_2CO_3 = \frac{0.053}{2.013} \times 100 = \mathbf{2.63\%} \qquad \textbf{Ans.}$$

EXAMPLE 168. A *sample of magnesium metal containing some magnesium oxide as impurity was dissolved in 125 mL of 0.1N* H_2SO_4*. The volume of hydrogen evolved at 27.3°C and 1 atm was 120.1 mL. The resulting solution was found to be 0.02 N with respect to sulphuric acid. Calculate (i) the weight of sample dissolved and (ii) the percentage by weight of magnesium in the sample. Neglect any change in the volume of the solution.* (*Mg = 24.3*). **(IIT 1977)**

SOLUTION. Given condition. P_1 = 1 atm; V_1 = 120.1 mL, T_1 = 27.3 + 273 = 300.3 K ; at NTP, P_2 = 1 atm, V_2 = ?, T_2 = 273 K.

$$\frac{P_1V_1}{T_1} = \frac{P_2V_2}{T_2}$$
$$V_2 = \frac{P_1V_1}{T_1} \times \frac{T_2}{P_2}$$
$$= \frac{1 \text{ atm} \times 120.1 \text{ mL} \times 273 \text{ K}}{300.3 \text{ K} \times 1 \text{ atm}}$$
$$= 109.2 \text{ mL}$$

$$\underset{24.3\text{ g}}{Mg} + H_2SO_4 \longrightarrow MgSO_4 + \underset{22400\text{ mL}}{H_2}$$

(*i*) 22400 mL H_2 is formed from

$$Mg = 24.3 \text{ g}$$

109.2 mL H_2 is formed from

$$Mg = \frac{24.3}{22400} \times 109.2 = 0.1185 \text{ g}$$

$\therefore$ wt. of Mg = 0.1185 g.

(*ii*) 1000 mL of 1N H_2SO_4 weigh

$$= \text{g. eq. wt. of } H_2SO_4$$

$$= \frac{(2\times1)+32+(4\times16)}{2} = 49 \text{ g}$$

125 mL of 0.1 N H_2SO_4 weigh

$$= \frac{49 \text{ g}}{1000 \text{ mL}} \times 125 \text{ mL} \times 0.1$$

$$= 0.6125 \text{ g} \qquad \therefore \text{ wt. of original}$$

$$H_2SO_4 = 0.6125 \text{ g } 1000 \text{ mL of } 1 \text{ N}$$

$$H_2SO_4 \text{ weigh} = \text{g eq. wt. of } H_2SO_4 = 49 \text{ g}$$

125 mL of 0.02 N H_2SO_4 weigh

$$= \frac{49 \text{ g}}{1000 \text{ mL}} \times 125 \text{ mL} \times 0.02$$

$$= 0.1225 \text{ g}$$

$\therefore$ wt. of unused H_2SO_4 = 0.1225 g

$\therefore$ wt. of used H_2SO_4 by Mg and

$$MgO = 0.6125 - 0.1225 = 0.49 \text{ g}$$

(*iii*)
$$\underset{24.3\text{ g}}{Mg} + \underset{(2\times1)+32+(4\times16)=98\text{ g}}{H_2SO_4} \longrightarrow MgSO_4 + H_2$$

24.3 g Mg uses H_2SO_4 = 98 g

$$0.1185 \text{ g Mg uses } H_2SO_4 = \frac{98}{24.3} \times 0.1185 = 0.4779 \text{ g}$$

$\therefore$ wt. of H_2SO_4 used by

$$MgO = 0.49 - 0.4779 = 0.0121 \text{ g}$$

(*iv*)
$$\underset{\substack{24.3+16\\=40.3\text{ g}}}{MgO} + \underset{\substack{(2\times1)+32\\+(4\times16)=98\text{ g}}}{H_2SO_4} \longrightarrow MgSO_4 + H_2O$$

98 g H_2SO_4 is used by

$$MgO = 40.3 \text{ g}$$

0.0121 g H_2SO_4 is used by

$$MgO = \frac{40.3}{98} \times 0.0121 = 0.00498 \text{ g}$$

$\therefore$ wt. of MgO = 0.00498 g Total wt. of

$$Mg + MgO = 0.1185 \text{ g} + 0.00498 \text{ g} = 0.1235 \text{ g}$$

$$\%\text{ age of Mg} = \frac{\text{wt. of Mg}}{\text{Total wt.}} \times 100 = \frac{0.1185 \text{ g}}{0.1235 \text{ g}} \times 100$$

$$= \mathbf{95.95\%}$$ **Ans.**

EXAMPLE 169. (*a*) *A zinc rod weighing 25 g was kept in 100 mL of 1 M $CuSO_4$ solution. After a certain time, the molarity of Cu^{++} in the solution was 0.8. What was the molarity of SO_4^{2-}? What was the weight of zinc rod after cleaning?* (*b*) *If the above experiment is done with copper rod of weight 25g and 50 mL of 2M $ZnSO_4$ solution, what would be the molarity of Zn^{++} at the end of the same interval?* (*Zn = 65.4, Cu = 63.5*).

SOLUTION. Wt. of Zn rod = 25 g

Reaction. $Zn + CuSO_4 \longrightarrow ZnSO_4 + Cu$

Or $\underset{65.4\text{ g}}{Zn} + \underset{63.5\text{ g}}{Cu^{2+}} \longrightarrow Zn^{2+} + Cu$

$$ZnSO_4 \rightleftharpoons Zn^{2+} + SO_4^{2-}$$

Initial molarity of Cu SO_4 or

$$Cu^{2+} = 1M$$

Molarity of Cu^{2+} after sometime = 0.8 M

Decrease in molarity = 1.0 – 0.8 = 0.2 M

$\therefore$ wt. of Cu reacted = 0.2 × 63.5

$$= 12.70 \text{ g}$$

63.5 g Cu react with Zn = 65.4 g

$$12.7 \text{ g Cu react with Zn} = \frac{65.4}{63.5} \times 12.7 = \mathbf{13.08 \text{ g}}$$

$\therefore$ wt. of Zn rod after cleaning

$$= 25.0 \text{ g} - 13.08 \text{ g} = \mathbf{11.92 \text{ g}}$$ **Ans.**

There is no change in the concentration of SO_4^{2-} ions as it does not take part in the reaction. So, the concentration of SO_4^{2-} ion is the same as that of 1 M $CuSO_4$ *i.e.,* 1M.

(*b*) Oxidation potential of Zn (= + 0.76 V) is greater than that of Cu (= – 0.34 V), so Cu will not react with 2 M $ZnSO_4$ solution. Hence the molarity of Zn^{2+} will be the same as that of 2M $ZnSO_4$ *i.e.,* **2 M.**

EXAMPLE 170. *What is the molarity and molality of a 13% solution* (*by weight*) *of sulphuric acid? Its density is 1.090 g/mL. To what volume should 100 mL of this acid be diluted in order to prepare 1.5 N solution?*

(*b*) *Two litres of ammonia at 30°C and 0.2 atm pressure neutralised 134 mL of a solution of sulphuric acid. Calculate the normality of the acid.* **(IIT, 1978)**

SOLUTION. (*a*) wt. of H_2SO_4 = 13 g ; wt. of solution = 100 g

wt. of solvent = 100 – 13 = 87 g ; mol. wt. of

$$H_2SO_4 = (2\times1) + 32 + (4\times16) = 98 \text{ g mol}^{-}$$

$$\therefore \quad \text{Molality} = \frac{\text{wt.}}{\text{Mol. wt.}} \times \frac{1000}{\text{wt. of solvent}}$$

$$= \frac{13}{98} \times \frac{1000}{87} = \mathbf{1.52 \text{ m}}$$ **Ans.**

$$\text{Volume of solution} = \frac{\text{wt. of solution}}{\text{density}} = \frac{100 \text{ g}}{1.09 \text{ g (mL)}^{-}}$$

$$\therefore \quad \text{Molarity} = \frac{\text{wt.}}{\text{Mol. wt.}} \times \frac{1000}{\text{Volume in mL}}$$

$$= \frac{13}{98} \times 1000 \times \frac{1.09}{100}$$

$$= \mathbf{1.44 \text{ M}}$$ **Ans.**

$$H_2SO_4 \rightleftharpoons 2H^+ + SO_4^{2-}$$

2 = valency factor

$$\therefore \quad \text{Normality} = \text{Molarity} \times \text{Valency factor}$$

$$= 1.44 \times 2 = \mathbf{2.88 \text{ N}}$$ **Ans.**

$$N_1V_1 \text{ (original acid)} = N_2V_2 \text{ (dilute acid)}$$

$$2.88 \times 100 = 1.5 \times V_2$$

$$V_2 = \frac{2.88\times100}{1.5} = \mathbf{192\ mL} \qquad \textbf{Ans.}$$

(*b*) Given conditions. $P_1 = 0.2$ atm, $V_1 = 2\text{L} = 2 \times 1000 = 2000$ mL ; $T_1 = 30 + 273 = 303$ K; **At NTP.** $P_2 = 1$ atm, $V_2 = ?$, $T_2 = 273$ K.

$$\frac{P_1V_1}{T_1} = \frac{P_2V_2}{T_2}\ ;\ V_2 = \frac{P_1V_1}{T_1}\times\frac{T_2}{P_2} \quad \text{(Gas law)}$$

$$\therefore \quad V_2 = \frac{0.2\ \text{atm}\times2000\ \text{mL}\times273\ \text{K}}{303\ \text{K}\times1\ \text{atm}}$$

$$= 360.4\ \text{mL.}$$

Reaction $2NH_3 + H_2SO_4 \longrightarrow (NH_4)_2SO_4$

2×22400 ml $\quad (2 \times 1) + 32 +$

$= 2[14 + (3 \times 1)] = 34$ g $\quad (4 \times 16) = 98$ g

(*i*) 2×22400 mL NH_3 weigh

$$= 34\ \text{g}$$

$$360.4\ \text{mL } NH_3 \text{ weigh} = \frac{34\ \text{g}}{2\times22400\ \text{mL}}\times360.4$$

(*ii*) 34 g NH_3 neutralise

$$H_2SO_4 = 98\ \text{g}$$

$$\frac{34\times360.4}{2\times22400}\ \text{g } NH_3 \text{ neutralise}$$

$$H_2SO_4 = \frac{98}{34}\times\frac{34\times360.4}{2\times22400} = 0.788\ \text{g}$$

∴ Normality of

$$H_2SO_4 = \frac{\text{wt.}}{\text{Eq. wt.}}\times\frac{1000}{\text{Volume in mL}}$$

$$= \frac{0.788}{49}\times\frac{1000}{134}$$

$$= \mathbf{0.12\ N} \qquad \textbf{Ans.}$$

EXAMPLE 171. *A polyvalent metal weighing 0.1 g and having atomic weight 51.0, reacted with dil. H_2SO_4 to give 43.9 mL of H_2 at NTP. This solution containing the metal in the lower oxidation state was found to require 58.8 mL of 0.1 N permanganate for complete oxidation. What are the valencies of the metal?* **(IIT, 1977)**

SOLUTION. Wt. of metal

= 0.1 g ; at. wt. of metal = 51.0

Volume of H_2 = 43.9 mL. But wt. of 1mL

H_2 = 0.00009 g

∴ Wt. of 43.9 mL $H_2 = 43.9 \times 0.00009\ \text{g} = 3.951 \times 10^{-3}$ g

$$\text{But} \quad \frac{\text{wt. of metal}}{\text{wt. of } H_2} = \frac{\text{Eq. wt. of metal}}{\text{Eq. wt. of } H_2}\ ;$$

$$\frac{0.1}{3.951\times10^{-3}} = \frac{E}{1.008}$$

$$\therefore \text{Eq. wt. of metal} = \frac{0.1\times1.008}{3.951\times10^{-3}} = 25.5$$

At. wt. of metal = 51.0 (given)

$$\therefore \text{Valency of metal} = \frac{\text{At. wt.}}{\text{Eq. wt.}} = \frac{51}{25.5} = 2 \qquad \textbf{Ans.}$$

(*b*) 58.8 mL of 0.1 N $KMnO_4$ is reduced by metal in its lower oxidation state = 0.1 g

∴ 1000 mL of 1N $KMnO_4$ is reduced by metal in its lower oxidation state

$$= \frac{0.1}{58.8\times0.1}\times1000\times1$$

= 17 g = eq. wt. of metal

At. wt. of metal = 51 ; eq. wt. of metal = 17

∴ Valency of metal in the lower oxidation state

$$= \frac{\text{at. wt.}}{\text{Eq. wt.}} = \frac{51}{17} = 3$$

∴ Valencies of the metal are 2 and 2 + 3 (= 5). **Ans.**

EXAMPLE 172. (*a*) (*i*) *A sample of $MnSO_4.4H_2O$ is strongly heated in air. The residue is Mn_3O_4. (ii) The residue is dissolved in 100 mL of 0.1N $FeSO_4$ solution containing dil. H_2SO_4. (iii) The solution reacts completely with 60 mL of $KMnO_4$ solution, (iv) 25 mL of the $KMnO_4$ solution used in step (ii) require 30 mL of 0.1 N $FeSO_4$ solution for complete reaction. Find the amount of $MnSO_4.4H_2O$ present in the sample.*

(*b*) *0.5 g of fuming H_2SO_4 (oleum) is diluted with water. The solution is completely neutralised by 26.7 mL of 0.4 N NaOH. Find the percentage of free SO_3 in the sample of oleum.* **(IIT, 1980)**

SOLUTION. Reaction.

$$\begin{array}{rcl} Mn_3O_4 + 3H_2SO_4 & \longrightarrow & 3MnSO_4 + 3H_2O + O \\ 2FeSO_4 + H_2SO_4 + O & \longrightarrow & Fe_2(SO_4)_3 + H_2O \\ \hline Mn_3O_4 + 4H_2SO_4 + 2FeSO_4 & \longrightarrow & 3MnSO_4 + 4H_2O \\ & & + Fe_2(SO_4)_3 \end{array}$$

∴ $2FeSO_4 \equiv 3MnSO_4$ **Or** $2FeSO_4.7H_2O \equiv 3MnSO_4.4H_2O$

$2[56 + 32 + (4 \times 16)$ $\quad 3[55 + 32 + (4 \times 16)]$

$+ 7(2 \times 1) + 16] = 2 \times 278$ g $\quad = 3 \times 223$ g

(*i*) 60 mL of given $KMnO_4$ = 60 mL of 0.1 N $FeSO_4$

∴ Volume of $FeSO_4$ solution used by

Mn_3O_4 = 100 – 60 = 40

(*ii*) 1000 mL of 1N $FeSO_4$

= g eq. wt. of $FeSO_4.7H_2O$ = 278 g

$$40\ \text{mL of 0.1N } FeSO_4 = \frac{278\times40\times0.1}{1000}\ \text{g} = 1.112\ \text{g}$$

But 2×278 g $FeSO_4.7H_2O$

$\equiv 3 \times 223$ g $MnSO_4.4H_2O$

$$\therefore\ 1.112\ \text{g } FeSO_4.7H_2O \equiv \frac{3\times223}{2\times278}\times1.112 = \mathbf{1.338\ g} \qquad \textbf{Ans.}$$

(*b*) Oleum = $H_2SO_4 + SO_3$. Let wt. of $SO_3 = x$; wt. of $H_2SO_4 = (0.5 - x)$ g

Reactions. $SO_3 + 2NaOH \longrightarrow Na_2SO_4 + H_2O$ ...(*A*)

$32 + (3 \times 16)$ $\quad 2(23 + 16 + 1)$

$= 80$ g $\quad = 80$ g

$H_2SO_4 + 2NaOH \longrightarrow Na_2SO_4 + 2H_2O$ ...(*B*)

$(2 \times 1) + 32$ $\quad 2[23 + 16 + 1]$

$+ (4 \times 16) = 98$ g $\quad = 80$ g

(*i*) 1000 mL of 1N NaOH = g. eq. wt. of

$$\text{NaOH} = 23 + 16 + 1 = 40 \text{ g}$$

$$26.7 \text{ mL of } 0.4 \text{ N NaOH} = \frac{40 \text{ g}}{1000} \times 26.7 \times 0.4 = 0.4272 \text{ g}$$

(*ii*) Let wt. of $SO_3 = x$ g : wt. of $H_2SO_4 = (0.5 - x)$ g

From reaction (*A*) :

80 g SO_3 react with NaOH = 80 g

∴ x g SO_3 react with

$$\text{NaOH} = \frac{80}{80} \times x = x \text{ g}$$

(*iii*) From equation (*B*) :

98 g H_2SO_4 react with

NaOH = 80 g

$(0.5 - x)$ g H_2SO_4 react with

$$\text{NaOH} = \frac{80}{98} \times (0.5 - x)\text{g} = \frac{40 - 80\,x}{98}$$

$$\therefore x \text{ g} + \frac{40 - 80\,x}{98} = 0.4272 \text{ g} ; 98x + 40 - 80x$$

$$= 98 \times 0.4272 \text{ g}$$

$$\therefore \quad 18x = 41.8656 \text{ g} - 40 = 1.8656 \text{ g} ;$$

$$x = 0.1036 \text{ g} = \text{wt. of } SO_3$$

$$\therefore \quad \% \text{ age of } SO_3 = \frac{\text{wt. of } SO_3}{\text{Total wt.}} \times 100 = \frac{0.1036}{0.5} \times 100$$

$$= \mathbf{20.72\%}$$ **Ans.**

EXAMPLE 173. *A given solution of sulphuric acid contains 45 g of the acid per litre [sp. gr = 1.049 g (mL)*$^{-}$*]. Find the strength of the solution in terms of normality, molality and milliequivalents.*

SOLUTION. Wt. of H_2SO_4 = 45 g ;

Volume = 1L = 1000 mL ;

$$\text{Eq. wt. of } H_2SO_4 = \frac{\text{Mol. wt.}}{\text{basicity}} = \frac{(2 \times 1) + 32 + (4 \times 16)}{2}$$

= 49 ; wt. of solution

= Volume × sp. gr.

= 1000 mL × 1.049 g $(\text{mL})^{-}$

= 1049 g

∴ wt. of solvent, H_2O = 1049 – 45 = 1004 g

(*i*) $$\text{Normality} = \frac{\text{wt.}}{\text{Eq. wt.}} \times \frac{1000}{\text{Volume in mL}}$$

$$= \frac{45}{49} \times \frac{1000}{1000} = \frac{45}{49} N$$ **Ans.**

(*ii*) $$\text{Molality} = \frac{\text{wt.}}{\text{mol. wt.}} \times \frac{1000}{\text{wt. of solvent}}$$

$$= \frac{45}{98} \times \frac{1000}{1004} = \mathbf{0.457 \ m}$$ **Ans.**

(*iii*) no. of milli equivalents per litre

$$= \left(\frac{\text{Wt.}}{\text{Eq. wt.}} \times 1000\right) = \frac{45}{49} \times 1000$$

Or no. of milliequivalents per mL

$$= \frac{45}{49} \times \frac{1000}{1000} = \mathbf{0.918}$$ **Ans.**

22.18 AIEEE PATTERN EXAMPLES

EXAMPLE 174. *Equal volumes of molar hydrochloric acid and sulphuric acid are neutralised by dilute NaOH solution and x k cal and y k cal of heat are liberated respectively. Which of the following is true?*

(*a*) $x = y$ (*b*) $x = y/2$

(*c*) $x = 2y$ (*d*) *none of the above*

(West Bengal JEE, 2009)

SOLUTION. $HCl \rightleftharpoons H^+ + Cl^-$;

$H_2SO_4 \rightleftharpoons 2H^+ + SO_4^{2-}$

∴ By equal volumes of molar HCl and H_2SO_4, the ratio of H^+ ions furnished = 1 : 2

∴ Ratio of heat liberated

$$= \frac{x}{y} = \frac{1}{2} ; x = y/2.$$

So, the correct answer is (*b*)

EXAMPLE 175. *An aqueous solution containing 6.5 g of NaCl of 90% purity was subjected to electrolysis. After the complete electrolysis, the solution was evaporated to get solid NaOH. The volume of 1M acetic acid required to neutralise NaOH obtained above is:*

(*a*) *2000 cm*^{3} (*b*) *100 cm*^{3}

(*c*) *200 cm*^{3} (*d*) *1000 cm*^{3}

(Karnataka CET, 2009)

SOLUTION. Wt. of pure NaCl

$$= 6.5 \text{ g} \times \frac{90}{100} = 5.85 \text{ g}$$

No. of equivalents of

$$\text{NaCl} = \frac{\text{wt. of NaCl}}{\text{Molar mass of NaCl}}$$

$$= \frac{5.85}{58.5} = 0.1$$

∴ $N_{NaOH} \times V_{NaOH} = N_{CH_3COOH} \times V_{CH_3COOH}$; 0.1 × 1000 = 1 × V_{CH_3COOH}; V_{CH_3COOH} = 100 cm^3.

So, the correct answer is(*b*)

EXAMPLE 176. *The strength of N/50 potassium bicarbonate in gram per litre is :*

(*a*) 2.0 (*b*) 3.0

(*c*) 4.0 (*d*) 1.5

(*At. wt., K = 39, H = 1, C = 12, O = 16*)

SOLUTION. Strength in gL$^-$ = Normality × eq. wt.

$$KHCO_3 \rightleftharpoons K^+ + HCO_3^-$$

$$\text{Eq. wt. of } KHCO_3 = \frac{\text{Mol. wt.}}{\text{Total + ve charge}}$$

$$= \frac{39 + 1 + 12 + (3 \times 16)}{1} = 100$$

$$\therefore \quad \text{Strength} = \text{Normality} \times \text{eq. wt.}$$

$$= \frac{1}{50} \times 100 = 2.0 \text{ gL}^-$$

So, the correct answer is (*a*).

EXAMPLE 177. *The strength of 1.5 N HNO_3 in gram equivalents per litre is :*

(*a*) *0.152* (*b*) *1.68*
(*c*) *6.1* (*d*) *1.5*

(*at. wt., H = 1 N = 14, O = 16*)

SOLUTION. Normality of HNO_3 = 1.5 N.

But : no. of gram equivalent per litre = Normality.

So : no. of gram equivalent of HNO_3 per litre = 1.5. So, the correct answer is (*d*).

EXAMPLE 178. *The number of gram mol of 2.0 L of 3 M H_2SO_4 are :*

(*a*) *2.0* (*b*) *3.0*
(*c*) *6.0* (*d*) *none of these*

SOLUTION. 3M H_2SO_4 means 3 g mol of H_2SO_4 per litre.

$\therefore$ 1L H_2SO_4 contain g. mol = 3

2.0 L H_2SO_4 contain g. mol = 3 × 2 = 6 g mol.

So, the correct answer is (*c*).

EXAMPLE 179. *The number of grams of $Ca(OH)_2$ in 1.5 litre of 0.25 M $Ca(OH)_2$ are :*

(*a*) 25.0 g (*b*) 27.75 g
(*c*) 1.5 g (*d*) 15 g

(*at. wt., Ca = 40, O = 16, H = 1*)

SOLUTION. No. of gram of substance

$$= \text{Molarity} \times \text{Volume in L} \times \text{mol. wt}$$
$$= 0.25 \times 1.5 \times 74 = 27.75 \text{ g}$$

So, the correct answer is (*b*).

EXAMPLE 180. *The molarity of sulphuric acid [sp. gr. 1.249 g $(mL)^{-}$] containing 98% by weight of sulphuric acid is :*

(*a*) *1.4 M* (*b*) *2.8 M*
(*c*) *6.245 M* (*d*) *12.49 M*

SOLUTION. wt. of H_2SO_4 = 98 g ; wt. of H_2SO_4 solution = 100 g (because of 98% H_2SO_4 by weight)

$\therefore$ Volume of H_2SO_4 solution

$$= \frac{\text{wt.}}{\text{sp. gr.}} = \frac{100 \text{ g}}{1.249 \text{ g (mL)}^{-}}$$
$$= 80.06 \text{ mL ;}$$

$$\text{mol. wt. of } H_2SO_4 = (2 \times 1) + 32 + (4 \times 16) = 98 \text{ g mol}^{-}$$

$$\therefore \quad \text{Molarity} = \frac{\text{wt.}}{\text{mol. wt.}} \times \frac{1000}{\text{Volume in mL}}$$
$$= \frac{98 \text{ g}}{98 \text{ g mol}^{-}} \times \frac{1000}{80.06}$$
$$= 12.49 \text{ M}$$

So, the correct answer is (*d*).

EXAMPLE 181. *The number of millimoles of $Cd(NO_3)_2 . 4H_2O$ present in 250 mL of 2.5 M $Cd(NO_3)_2$ solution are :*

(*a*) *2.5* (*b*) *250*
(*c*) *1.25* (*d*) *625*

SOLUTION. Molarity = 2.5 M, Volume = 250 mL.

$$\text{But : no. of millimol} = \text{Molarity} \times \text{Volume in mL}$$
$$= 2.5 \times 250 = 625 \text{ millimoles.}$$

So, the correct answer is (*d*).

Second method. 2.5 M solution contain 2.5 mol L^{-} of $Cd(NO_3)_2$. Thus :

1000 mL (= 1L) solution contain millimol

= 2.5 × 1000 millimoles

250 mL solution contain millimoles

$$= \frac{2.5 \times 1000 \text{ millimoles}}{1000 \text{ mL}} \times 250 \text{ mL}$$
$$= 625 \text{ millimoles.}$$

So, the correct answer is (*d*).

EXAMPLE 182. *A certain volume of H_2SO_4 (eq. wt. 49) containing 9.8 gL^{-} was diluted with equal amount of water. The volume of diluted acid required to make one litre of N/25 solution will be:*

(*a*) *1000 mL* (*b*) *100 mL*
(*c*) *400 mL* (*d*) *1 L*

SOLUTION. 1L of original solution contain H_2SO_4 = 9.8 g

But the solution is diluted with equal amount of water *i.e.*, 1L.

So : 2L diluted solution contain

$$H_2SO_4 = 9.8 \text{ g}$$

1L diluted solution contain

$$H_2SO_4 = \frac{9.8 \text{ g}}{2} = 4.9 \text{ g}$$

$\therefore$ Strength of diluted

$$H_2SO_4 = 4.9 \text{ gL}^{-}$$

(*i*)
$$\text{Normality} = \frac{\text{wt.}}{\text{Eq. wt.}} \times \frac{1000}{\text{Volume in mL}}$$
$$= \frac{4.9}{49} \times \frac{1000}{1000 \text{ mL}} = 0.1 \text{ N}$$

(*ii*) N_1V_1 (dilute solution) = N_2V_2 (required solution)

$$0.1 \times V_1 = \frac{1}{25} \times 1000 \text{ mL ;}$$
$$V_1 = \frac{1000}{25 \times 0.1} = 400 \text{ mL}$$

So, the correct answer is (*c*).

EXAMPLE 183. *The normality of a solution prepared by diluting 100 cm^3 of 0.25 N H_2SO_4 with 1000 cm^3 of water would be :*

(*a*) *0.0227 N* (*b*) *1.12 N*
(*c*) *0.09 N* (*d*) *none of these.*

SOLUTION. Original volume = 100 cm^3. Water added = 1000 cm.

$\therefore$ New volume = 100 + 1000 = 1100 cm^3

N_1V_1(original solution) = N_2V_2 (new solution)

$$0.25 \times 100 = N_2 \times 1100 \text{ ;}$$
$$N_2 = \frac{0.25 \times 100}{1100} = 0.0227$$

So, the correct answer is (*a*).

EXAMPLE 184. *10 mL of 1M NaOH solution will neutralise.*

(*a*) *2.5 mL* (*b*) *5 mL*
(*c*) *10 mL* (*d*) *20 ml. of 1 M H_2SO_4*

(IIT, 1975)

Solution. (*i*) $NaOH \rightleftharpoons Na^+ + OH^-$

one OH^- ; valency factor = 1

$$\text{Normality of NaOH} = \text{Molarity} \times \text{Valency factor} = 1 \times 1 = 1$$

$$\text{Volume} = 10 \text{ mL}$$

(*ii*) $H_2SO_4 \rightleftharpoons 2H^+ + SO_4^{2-}$

Two H^+ ; valency factor = 2

$$\therefore \text{Normality of } H_2SO_4 = \text{Molarity} \times \text{Valency factor} = 1 \times 2 = 2$$

$$N_1V_1 \text{ (NaOH)} = N_2V_2 \text{ } (H_2SO_4)$$

$$1 \times 10 = 2 \times V_2 \text{ ; } V_2 = \frac{10}{2} = 5 \text{ mL.}$$

So, the correct answer is (*b*).

Example 185. *The equivalent weight of a metal carbonate, 0.84 g of which react exactly with 40 mL of N/2 sulphuric acid is :*

(*a*) *21* (*b*) *42*

(*c*) *84* (*d*) *8.4.* **(M.D.U. 1980)**

Solution. Given 40 mL of N/2 H_2SO_4 ; wt. of metal carbonate = 0.84 g

1000 mL of 1N H_2SO_4 weigh = g. eq. wt. of H_2SO_4

$$= \frac{(2\times1)+32+(4\times16)}{2} = \frac{98}{2} = 49 \text{ g}$$

40 mL of N/2 H_2SO_4 weigh

$$= \frac{49 \text{ g}}{1000} \times 40 \times \frac{1}{2} = 0.98 \text{ g}$$

$$\text{But } \frac{\text{wt. of metal carbonate}}{\text{wt. of } H_2SO_4} = \frac{\text{Eq. wt. of metal carbonate}}{\text{Eq. wt. of } H_2SO_4}$$

$$\therefore \quad \frac{0.84 \text{ g}}{0.98 \text{ g}} = \frac{\text{Eq. wt. of metal carbonate}}{49}$$

$\therefore$ Eq. wt. of metal carbonate

$$= \frac{0.84 \times 49}{0.98} = 42.$$

So, the correct answer is (*b*).

Example 186. *5.5 g of a mixture of $FeSO_4.7H_2O$ and $Fe_2(SO_4)_3.9H_2O$ require 5.4 mL of 0.1N $KMnO_4$ solution for complete oxidation. The number of g. moles of hydrated ferric sulphate in the mixture are :*

(*a*) *774 mol* (*b*) *0.774 mol*

(*c*) *0.00774* (*d*) *none of these.*

(IIT, 1979 modified)

Solution. wt. of $FeSO_4.7H_2O + Fe_2(SO_4)_3.9H_2O = 5.5$ g

Out of $FeSO_4.7H_2O$ and $Fe_2(SO_4)_3.9H_2O$, only Fe^{2+} of $FeSO_4.7H_2O$ would be oxidised by 5.4 mL of 0.1 N $KMnO_4$.

(*i*) no. of milliequivalents of

$$KMnO_4 = \text{Normality} \times \text{Volume in mL} = 0.1 \times 5.4 = 0.54.$$

Since $FeSO_4.7H_2O$ solution is completely oxidised.

no. of m eq. of $KMnO_4$ = no. of m eq. of $FeSO_4.7H_2O$ = 0.54

But meq. of $FeSO_4.7H_2O$

$$= \frac{\text{wt.}}{\text{Eq. wt.}} \times 1000 \text{ ;}$$

$$0.54 = \frac{\text{wt.}}{278} \times 1000$$

$$\therefore \text{ wt. of } FeSO_4.7H_2O = \frac{0.54 \times 278}{1000} = 0.15 \text{ g}$$

$\because$ $Fe^{2+} \longrightarrow Fe^{3+} + 1e^-$

$$\therefore \text{Eq. wt. of } FeSO_4.7H_2O = \frac{\text{Mol. wt.}}{1} = \frac{56+35+(4\times16)+7[(2\times1)+16]}{1} = \frac{278}{1} = 278$$

wt. of $Fe_2(SO_4)_3.9H_2O$

$$= 5.5 - 0.15 = 4.35 \text{ g}$$

Mol. wt. of

$$Fe_2(SO_4)_3.9H_2O = (2 \times 56) + 3[32 + (4 \times 16) + 9[(2 \times 1) + 16] = 112 + 288 + 162 = 562 \text{ g mol}^-$$

$\therefore$ no. of mol of $Fe_2(SO_4)_3.9H_2O$

$$= \frac{\text{wt.}}{\text{mol. wt.}} = \frac{4.35 \text{ g}}{562 \text{ g mol}^-} = 7.74 \times 10^{-3} \text{ mol} = 0.00774 \text{ mol.}$$

So, the correct answer is (*c*).

Example 187. *A 1.0 g sample of H_2O_2 solution containing x per cent H_2O_2 by weight requires x mL of a $KMnO_4$ solution for complete oxidation under acidic conditions. The normality of $KMnO_4$ solution is :*

(*a*) *0.588 N* (*b*) *1.16 N*

(*c*) *0.244 N* (*d*) *0.1 N*

(IIT, 1981 modified)

Solution. Reactions

$$MnO_4^- + 8H^+ + 5e^- \longrightarrow Mn^{2+} + 4H_2O] \times 2$$

$$H_2O_2 \longrightarrow O_2 + 2H^+ + 2e^-] \times 5$$

$$2MnO_4^- + 6H^+ + 5H_2O_2 \longrightarrow 2Mn^{2+} + 8H_2O + 5O_2$$

or $2KMnO_4 \equiv 5H_2O_2$

$2[39 + 55 + (4 \times 16)]$ $5[(2 \times 1) + (2 \times 16)]$

$= 2 \times 158$ g $= 5 \times 34$ g

$$\text{wt. of } H_2O_2 = 1 \times \frac{x}{100} = \frac{x}{100} \text{ g ;}$$

Volume of $KMnO_4 = x$ mL

5×34 g H_2O_2 is oxidised by $KMnO_4$ = 2×158 g

$\frac{x}{100}$ g H_2O_2 is oxidised by $KMnO_4$

$$= \frac{2 \times 158 \times x}{5 \times 34 \times 100} \times \frac{1000}{31.6 \times x} \text{ } KMnO_4$$

We know that : Normality of

$$KMnO_4 = \frac{\text{wt.}}{\text{Eq. wt.}} \times \frac{1000}{\text{Volume in mL}}$$

$$= \frac{2 \times 158 \times x}{5 \times 34 \times 100} \times \frac{1000}{31.6 \times x} = 0.588 \text{ N.}$$

$$\left[\because \text{Eq. wt. of } KMnO_4 = \frac{\text{Mol. wt.}}{\text{no. of electrons gained}} = \frac{39+55+(4\times16)}{5} = 31.6\right.$$

So, the correct answer is (*a*).

EXAMPLE 188. *The volume of 0.5M H_2SO_4 required to produce 34.0 g H_2S by the reaction*

$$8NaI + 5H_2SO_4 \longrightarrow 4Na_2SO_4 + 4H_2O + 4I_2 + H_2S$$

will be :

(*a*) *2.5 L* (*b*) *5 L*

(*c*) *8 L* (*d*) *10 L*

SOLUTION. Reaction.

$$\underset{5\text{ mol}}{8NaI + 5H_2SO_4} \longrightarrow 4Na_2SO_4 + 4H_2O + 4I_2 + \underset{1\text{mol}}{H_2S}$$

wt. of H_2S = 34.0 g ; mol. wt. of

H_2S = (2 × 1) + 32 = 34g mol^{-}

$$\therefore \text{ no. of mol of } H_2S = \frac{\text{wt. of } H_2S}{\text{mol. wt. of } H_2S}$$

$$= \frac{34 \text{ g}}{34 \text{ g mol}^{-}} = 1 \text{ mol}$$

∴ 1 mol H_2S ≡ 5 mol H_2SO_4. It means :

$0.5 \times V(H_2SO_4) = 5$

∴ Volume of 0.5 M H_2SO_4 required

$$= \frac{5}{0.5} = 10 \text{ L}$$

So, the correct answer is (*d*).

EXAMPLE 189. *The amount of NaOH required to neutralise 25 Meq of the following*

(*i*) *CO_2* (*ii*) *HCl*

(*iii*) *$NaHSO_4$ is :*

(*a*) *0.5 g* (*b*) *1.0 g*

(*c*) *1.5 g* (*d*) *2.0 g*

SOLUTION. Since 25 Meq of each (*i*), (*ii*) and (*iii*) separately react with NaOH, so each time 25 Meq of NaOH are required. *i.e.*,

Meq of NaOH needed = 25

$$\text{But Meq of NaOH} = \frac{\text{wt. of NaOH}}{\text{Eq. wt. of NaOH}} \times 1000$$

$$25 = \frac{\text{wt. of NaOH}}{40} \times 1000$$

$$\left[\because \text{Eq. wt. of NaOH} = \frac{23+16+1}{1} = 40\right]$$

$$\therefore \quad \text{wt. of NaOH} = \frac{25 \times 40}{1000} = 1 \text{ g.}$$

So, the correct answer is (*b*).

EXAMPLE 190. *If density of water is 1000 kg m^{-3}, the molarity of water will be :*

(*a*) *18* (*b*) *5.6*

(*c*) *55.6* (*d*) *none of these*

SOLUTION. Let volume of water

= 1 L = 1000 mL = 10^{-3} m^3

∴ 1 m^3 H_2O weighs = 10^3 kg

$$10^{-3} \text{ m}^3 \text{ } H_2O \text{ weighs} = \frac{10^3 \text{ kg}}{1 \text{ m}^3} \times 10^{-3} \text{m}^3 = 1 \text{ kg} = 1000 \text{ g}$$

Mol. wt. of water (H_2O)

= (2 × 1) + 16 = 18 g mol^{-}

$$\text{Molarity} = \frac{\text{wt. of } H_2O}{\text{mol. wt. of } H_2O} \times \frac{1000}{\text{Volume in mL}} = \frac{1000 \text{ g}}{18 \text{ g mol}^{-}} \times \frac{1000}{1000} = 55.6.$$

So, the correct answer is (*c*).

EXAMPLE 191. *An aqueous solution of KOH (6.9 M) contains 30% KOH by weight. The density of solution will be :*

(*a*) *0.6 g $(mL)^{-}$* (*b*) *2.4 g mL^{-}*

(*c*) *0.23 g $(mL)^{-}$* (*d*) *1.288 g $(mL)^{-}$*

SOLUTION. (*i*) 30% KOH by weight means :

Wt. of KOH = 30 g ; Wt. of solution = 100g.

Mol. wt. of KOH = 39 + 16 + 1 = 56 g mol^{-}

$$\therefore \text{ Volume of solution} = \frac{\text{Mass of solution}}{\text{density of solution}} = \frac{100 \text{ g}}{d}$$

(*ii*)
$$\text{Molarity} = \frac{\text{wt.}}{\text{Mol. wt.}} \times \frac{1000}{\text{Volume in mL}}$$

$$= \frac{30}{56} \times \frac{1000 \times d}{100}$$

$$6.9 = \frac{30}{56} \times \frac{1000\, d}{100} \text{ ;}$$

$$d = \frac{6.9 \times 56 \times 100}{30 \times 1000}$$

= 1.288 g (mL^{-}) **Ans.**

So, the correct answer is (*d*).

EXAMPLE 192. *A metal foil [d = 2.7 g (mL^{-}), thickness 10^{-4}m] was treated with one drop of 12 M HCl on its surface. The maximum area of the hole produced on the Al foil surface if one drop of acid occupies 0.04 mL volume will be*

(*a*) *0.1 cm^2* (*b*) *0.15 cm^2*

(*c*) *0.2 cm^2* (*d*) *0.16 cm^2*

SOLUTION. We know that : Meq of Al = Meq of HCl

But Meq of HCl = Molarity of HCl × Volume in mL × total + ve charge on H^+

= 12 × 0.04 × 1 = 0.48 = Meq of Al

$$\therefore \quad \text{Meq of Al} = \frac{\text{wt. of Al}}{\text{Eq. wt. of Al}} \times 1000$$

$$\left[\begin{array}{l}\because \text{ Valency of Al} = 3\text{, so :} \\ \text{eq. wt. of Al} = \dfrac{\text{at. wt. of Al}}{\text{Valency}} = \dfrac{27}{3} = 9\end{array}\right]$$

$$\therefore \quad \text{Wt. of Al} = \frac{\text{Meq of Al} \times \text{eq. wt. of Al}}{1000}$$

$$= \frac{0.48 \times 9}{1000}$$

$$\text{Volume of Al – foil} = \frac{\text{Mass}}{\text{density}} = \frac{0.48\text{ g} \times 9}{1000} \times \frac{\text{cm}^3}{2.7\text{ g}}$$

$$= 1.6 \times 10^{-3}\text{ cm}^3$$

$$\therefore \quad \text{Area} = \frac{\text{Volume}}{\text{thickness}} = \frac{1.6 \times 10^{-3}\text{cm}^3}{0.01\text{ cm}}$$

$$= 0.16\text{ cm}^2$$

$$\left[\because \text{ Thickness} = 10^{-4}\text{m} \times \frac{100\text{ cm}}{\text{m}} = 0.01\text{ cm}\right]$$

So, the correct answer is (*d*).

EXAMPLE 193. *Gastric juice contains 3.0 g of HCl per litre. If a person produces 2.5 litre of gastric juice per day, the number of anti-acid tablets each containing 400 mg of Al(OH)$_3$ needed to neutralise the acid produced in one day will be :*

(*a*) *14* (*b*) *12*

(*c*) *10* (*d*) *2*

(Dhanwad 1991, modified)

SOLUTION. Wt. of HCl = 3.0 g ; eq. wt. of HCl = 1 + 35.5 = 36.5 g

$$\therefore \quad \text{Volume} = 2.5\text{ L} = 2.5\text{ L} \times \frac{1000\text{ mL}}{1\text{ L}}$$

$$= 2500\text{ mL.}$$

$$\text{Normality of HCl} = \frac{\text{wt.}}{\text{Eq. wt.}} = \frac{3}{36.5}$$

(*i*) Milliequivalent *i.e*, Meq of

$$\text{HCl} = \text{Normality} \times \text{Volume}$$

$$= \frac{3}{36.5} \times 2500 = 205.48$$

(*ii*) wt. of $Al(OH)_3 = w$; $Al(OH)_3 \rightleftharpoons Al^{3+} + 3OH^-$

$$\therefore \text{ Eq. wt. of } Al(OH)_3 = \frac{\text{Mol. wt.}}{3} = \frac{27 + 3(16+1)}{3}$$

$$= \frac{27+51}{3} = \frac{78}{3} = 26$$

$$\text{Meq. of } Al(OH)_3 = \frac{\text{wt.}}{\text{Eq. wt.}} \times 1000 = \frac{w}{26} \times 1000$$

But Meq of Al(OH)$_3$ required = Meq. of HCl

$$\therefore \quad \frac{w}{26} \times 1000 = 205.48\text{ ;}$$

$$w = \frac{205.48 \times 26}{1000} = 5.342\text{ g}$$

$$\text{or} \quad \frac{5.342\text{ g} \times 1000\text{ mg}}{1\text{ g}} = 5342\text{ mg.}$$

∴ No. of anti acid tablets

$$= \frac{5342\text{ mg}}{400\text{ mg}} \simeq 14.$$

So, the correct answer is (*a*).

EXAMPLE 194. *The volume of a solution of HCl containing 73 g of acid per litre that would suffice for the exact neutralisation of sodium hydroxide obtained by allowing 0.46 g of metallic sodium to act upon water is :*

(*a*) *2 mL* (*b*) *5 ml*

(*c*) *10.0 mL* (*d*) *15.0 mL*

(MLNR, 1997 modified)

SOLUTION. Reactions : $Na + H_2O \longrightarrow NaOH + \frac{1}{2} H_2$

$$NaOH + HCl \longrightarrow NaCl + H_2O$$

(*i*) wt. of Na = 0.46 g ; eq. wt. of Na = 23

$$\therefore \quad \text{Meq. of Na} = \frac{\text{wt.}}{\text{Eq. wt.}} \times 1000 = \frac{0.46}{23} \times 1000$$

(*ii*) wt. of HCl = 73 g,

eq. wt. of HCl = 1 + 35.5 = 36.5

$$\text{meq. of HCl} = \frac{\text{wt.}}{\text{Eq. wt.}} \times \text{Volume} = \frac{73}{36.5} \times V$$

But Meq of Na = Meq of HCl

$$\frac{0.46}{23} \times 1000 = \frac{73\,V}{36.5}\text{ ;}$$

$$V = \frac{0.46}{23} \times \frac{1000 \times 36.5}{73} = 10\text{ mL.}$$

So, the correct answer is (*c*).

EXAMPLE 195. *25 mL of a solution of Na$_2$CO$_3$ having a specific gravity of 1.25 g (mL)$^-$ required 32.9 mL of a solution of HCl containing 109.5 gram of the acid per litre for complete neutralisation. The volume of 0.84 N H$_2$SO$_4$ that will be completely neutralised by 125 gram of the Na$_2$CO$_3$ solution is:*

(*a*) *117.5 mL* (*b*) *470 mL*

(*c* *3.25 cm^3* (*d*) *325 mL*

(MLNR, 1991, modified)

SOLUTION. (*i*) wt. of HCl = 109.5 g, eq. wt. of HCl = 1 + 35.5 = 36.5, Volume of HCl = 32.9 mL

$$\therefore \quad \text{Meq of HCl} = \frac{\text{wt.}}{\text{Eq. wt.}} \times \text{Volume} = \frac{109.5}{36.5} \times 32.9$$

$$= 98.7 = N_2V_2\text{ (HCl)}$$

$$\text{Also : } N_1V_1\ (Na_2CO_3) = N_2V_2\text{ (HCl)}$$

$$N_1 \times 25 = 98.7\text{ ;}$$

$$N_1 = \frac{98.7}{25} = \text{Normality of } Na_2CO_3$$

(*ii*) Volume of Na$_2$CO$_3$

$$= \frac{\text{wt. of } Na_2CO_3}{\text{Density or sp. gr. of } Na_2CO_3}$$

$$= \frac{125\text{ g}}{1.25\text{ g (mL)}^-} = 100\text{ mL}$$

$$\text{Also : } N_1V_1\ (H_2SO_4) = N_2V_2\ (Na_2CO_3)$$

$$0.84 \times V_1 = \frac{98.7}{25} \times 100\text{ ;}$$

$$V_1 = \frac{98.7 \times 100}{0.84 \times 25} = 470\text{ mL}$$

So, the correct answer is (*b*).

EXAMPLE 196. *4.0 g of a mixture of NaCl and Na_2CO_3 were dissolved in water and volume made up to 250 mL. 25 mL of this solution required 50 mL of N/10 HCl for complete neutralisation. The percentage of Na_2CO_3 will be :*

(*a*) *33.75%* (*b*) *66.25%*
(*c*) *16.8%* (*d*) *8.16%*

(Roorkee 1982, modified)

SOLUTION. Out of NaCl and Na_2CO_3, only Na_2CO_3 reacts with HCl. Eq. wt. of

$$Na_2CO_3 = \frac{\text{Mol. wt. of } Na_2CO_3}{2} = \frac{(2\times23)+12+(3\times16)}{2} = 53$$

$$Na_2CO_3 + 2HCl \longrightarrow 2NaCl + CO_2 + H_2O$$

$$N_1V_1\,(Na_2CO_3) = N_2V_2\,(HCl)$$

$$N_1 \times 25 = \frac{1}{10}\times 50\,;\ N_1 = \frac{1}{10}\times\frac{50}{25} = 0.2$$

∴ Strength of Na_2CO_3

$$= \text{Normality} \times \text{Eq. wt.}$$

$$= 0.2 \times 53 = 10.6\ g\ L^{-}$$

1000 mL Na_2CO_3 solution contain Na_2CO_3 = 10.6 g

250 mL Na_2CO_3 solution contain

$$Na_2CO_3 = \frac{10.6\ g}{1000\ mL}\times 250\ mL = 2.65\ g$$

$$\therefore \%\text{ age of } Na_2CO_3 = \frac{\text{wt. of } Na_2CO_3}{\text{Total wt. of } Na_2CO_3}\times 100 = \frac{2.65\ g}{4.0\ g}\times 100 = 66.25\%$$

So, the correct answer is (*b*).

EXAMPLE 197. *The equivalent weight of each of the following compounds (i) $Na_2SO_4.12H_2O$ (ii) $Na_3PO_4.12H_2O$ and (iii) $Ca_3(PO_4)_2$, assuming the formula weight of these compounds as X, Y and Z is :*

(*a*) *X/3, Y/2, Z/6* (*b*) *X/2, Y/3/, Z/6*
(*c*) *X/6, Y/3, Z/2* (*d*) *X/2, Y/6, Z/3*

(at. wt. Na = 23, P = 31, O = 16, H = 1, Ca = 40)

(MLNR, 1991, modified)

SOLUTION. Eq. wt. of a salt = $\dfrac{\text{Mol. wt. of salt.}}{\text{Total + ve or – ve charge}}$

(*i*) $Na_2SO_4 \rightleftharpoons 2Na^+ + SO_4^{2-}$. Total + ve charge = 2

$$\therefore \quad \text{Eq. wt. of } Na_2SO_4 = \frac{X}{2}$$

(*ii*) $Na_3PO_4 \rightleftharpoons 3Na^+ + 2PO_4^{3-}$. Total + ve charge = 3

$$\therefore \text{ Eq. wt. of } Na_3PO_4.12H_2O = \frac{Y}{3}$$

(*iii*) $Ca_3(PO_4)_2 \rightleftharpoons 3Ca^{2+} + 2PO_4^{3-}$. Total + ve charge = 3 × 2 = 6

$$\therefore \quad \text{Eq. wt. of } Ca_3(PO_4)_2 = \frac{Z}{6}$$

So, the correct answer is (*b*).

EXAMPLE 198. *Equivalent weight of KIO_3 in the reaction*

$$IO_3^- \longrightarrow ICl \quad \text{is :}$$

(*a*) *214* (*b*) *107*
(*c*) *10.7* (*d*) *53.5*

(*at. wt. I = 127, O = 16, Cl = 35.5, K = 39*)

SOLUTION. (*i*) In IO_3^-, O.N. of I + 3 × O. N. of O = –1; O. N. of I + 3(–2) = – 1 ; O. N. of I = –1 + 6 = +5

(*ii*) In ICl, O. N. of I + O.N. of Cl = 0

O. N. of I+ (–1) = 0 ; O. N. of I = 0 + 1 = 1

$$I^{+5}O_3^- \longrightarrow I^+Cl$$

Change in O. N = +5 – (+1) = + 4

$$\therefore \text{ Eq. wt. of } KIO_3 = \frac{39+127+(3\times16)}{4} = \frac{214}{4} = 53.5. \qquad \textbf{Ans.}$$

So, the correct answer is (*d*).

EXAMPLE 199. A *sample of $Na_2CO_3.H_2O$ weighing 0.62 g is added to 100 mL of 0.1 N H_2SO_4. The resulting solution will be :*

(*a*) *Acidic* (*b*) *Basic*
(*c*) *neutral*

(IIT 1976 modified)

SOLUTION. Eq. wt. of

$$Na_2CO_3.H_2O = \frac{(2\times23)+12+(3\times16)+[(2\times1)+16]}{2} = \frac{124}{2} = 62$$

wt. of Na_2CO_3 = 0.62 g

$$\therefore \text{Meq. of } Na_2CO_3 = \frac{\text{wt.}}{\text{Eq. wt.}}\times 1000 = \frac{0.62\ g}{62}\times 1000 = 10$$

Meq. of H_2SO_4 = Normality × Volume in mL
= 0.1 × 100 = 10

Since Meq. of Na_2CO_3 (= 10) = Meq. of H_2SO_4 (= 10), so the solution is neutral.

So, the correct answer is (*c*).

EXAMPLE 200. *The formula weight of an acid is 82.0. In a titration, 100 cm^3 of a solution of this acid containing 39.0 g of the acid per litre were completely neutralised by 95 cm^3 of aqueous NaOH containing 40 g of NaOH per litre. The basicity of the acid is :*

(*a*) *1* (*b*) *2*
(*c*) *3* (*d*) *4*

(Roorkee, 2000 modified)

SOLUTION. (*i*) wt. of acid = 39 g ; Formula wt. of acid = 82. Basicity of acid = *x*.

But no. of equivalent of acid

$$= \frac{\text{wt.}}{\text{Formula wt.}}\times \text{basicity} = \frac{39\,x}{82} = \text{Normality}$$

(*ii*) wt. of NaOH = 40 g ; Formula wt. of NaOH = 23 + 16 + 1 = 40, acidity of NaOH = 1.

No. of equivalent of

$$\text{NaOH} = \frac{\text{wt.}}{\text{Formula wt.}} \times \text{acidity}$$

$$= \frac{40}{40} \times 1 = 1 = \text{Normality}$$

But N_1V_1 (acid) = N_2V_2 (acid)

$$\frac{39\,x}{82} \times 100 = 1 \times 95$$

$$\therefore \quad x = \frac{95 \times 82}{100 \times 39} \simeq 2.$$

So, the correct answer is (*b*).

Example 201. A *1.0 g sample of Fe_2O_3 solid of 55.2 percent purity is dissolved is acid and reduced by heating the solution with zinc dust. The resultant solution is cooled and made up to 100.0 mL. An aliquot of 25.0 mL requires 17.0 mL of 0.0167 M solution of an oxidant for titration. The number of electrons taken up by the oxidant in the reaction of the above titration is :*

(*a*) *1*	(*b*) *2*
(*c*) *4*	(*d*) *6*

(IIT 1991 modified)

Solution. wt. of pure $Fe_2O_3 = \frac{55.2}{100} \times 1.0 \text{ g} = 0.552 \text{ g}$

Mol. wt. of Fe_2O_3 = (2 × 56) + (3 × 16) = 112 + 48 = 160 g mol^-

$Fe_2O_3 \equiv 2Fe^{3+}$

$$\therefore \text{ no. of mol of } Fe_2O_3 = \frac{\text{wt.}}{\text{Mol. wt.}} = \frac{0.552 \text{ g}}{160 \text{ g mol}^-}$$

$= 3.45 \times 10^{-3}$ mol

no. of mol of $Fe^{3+} = 2 \times 3.45 \times 10^{-3} \text{ mol} = 6.9 \times 10^{-3}$ mol

$Fe^{3+} + 1e^- \longrightarrow Fe^{2+}$ (Reduction by $1e^-$)

(*i*) ∴ Amount of Fe^{2+} in 100 ml solution

$$= 6.9 \times 10^{-3} \text{mol} \times \frac{1 \text{ m. mol}}{10^{-3}\text{mol}}$$

= 6.9 m mol of reductant, Fe^{2+}.

= 6.9 m eq because Fe^{3+} to Fe^{2+} is one electron change. So, the mol. wt. = equivalent weight.

(*ii*) To find m mol of oxidant and number of electrons taken up by the oxidant.

25 mL reductant require oxidant = 17 mL

100 mL reductant require oxidant

$$= \frac{17 \text{ mL}}{25 \text{ mL}} \times 100 \text{ mL} = 68 \text{ mL}$$

∴ Amount of oxidant used for 100 mL

Fe^{2+} solution = 68 × 0.0167 m mol

$$\frac{\text{m mol (oxidant)}}{\text{m mol (reductant)}} = \frac{\text{no. of electrons lost by reductant}}{\text{no. of electrons gained by oxidant}}$$

$$\frac{68 \times 0.0167}{6.9} = \frac{1}{n} \; ; n = \frac{6.9}{68 \times 0.0167} = 6.$$

So, the correct answer is (*d*).

Example 202. *0.804 g sample of an iron ore was dissolved in acid. Iron was reduced to +2 state and it required 47.2 mL of 0.112 N $KMnO_4$ solution for titration. The percentage of Fe and Fe_3O_4 in the ore is :*

(*a*) *36.82, 60*	(*b*) *50.87, 36.82*
(*c*) *36.82, 50.87*	(*d*) *18.41, 25.44*

(*at. wt. Fe = 56, K = 39, Mn = 55, O = 16*)

(Roorkee 1988, modified)

Solution. (*i*) wt. of

Fe^{2+} = *w* g, $Fe^{2+} \longrightarrow Fe^{3+} + 1e^-$. So :

$$\text{Eq. wt. of } Fe^{2+} = \frac{\text{at. wt.}}{1} = \frac{56}{1} = 56$$

$$\therefore \quad \text{Meq. of } Fe^{2+} = \frac{\text{wt.}}{\text{Eq. wt.}} \times 1000 = \frac{w}{56} \times 1000 .$$

(*ii*) $Mn^{7+}O_4^- + 5e^- \longrightarrow Mn^{2+}$

Meq. of $KMnO_4$

= Normality × Volume is mL

= 0.112 × 47.2

But Meq. of Fe^{2+} = Meq of $KMnO_4$

$$\frac{w \times 1000}{56} = 0.112 \times 47.2 \; ;$$

$$w = \frac{0.112 \times 47.2 \times 56}{1000} = 0.296$$

$$\therefore \quad \%\text{ age of Fe} = \frac{\text{wt. of Fe}}{\text{wt. of ore}} \times 100$$

$$= \frac{0.296 \times 100}{0.804} = 36.82\%$$

(*iii*)

$$\begin{array}{ccc} Fe_3O_4 & \rightleftharpoons & 3Fe \\ (3 \times 56) + (4 \times 16) & & 3 \times 56 \\ = 168 + 64 = 232 & & = 168 \end{array}$$

168 g Fe is obtained from

Fe_3O_4 = 232 g

0.296 g Fe is obtained from

$$Fe_3O_4 = \frac{232 \text{ g}}{168 \text{ g}} \times 0.296 \text{ g} = 0.409 \text{ g}$$

$$\therefore \quad \%\text{ age of } Fe_3O_4 = \frac{\text{wt.}}{\text{wt. of ore}} \times 100$$

$$= \frac{0.409}{0.804} \times 100 = 50.87\%$$

So, the correct answer is (*c*).

Example 203. *0.1 M $KMnO_4$ is used for the following titration. The volume of solution in mL required to react with 0.158 g of $Na_2S_2O_3$ will be :*

(*a*) *26.67 mL*	(*b*) *2.4 mL*
(*c*) *24 mL*	(*d*) *2.7 mL*

$$S_2O_3^{2-} + MnO_4^- + H_2O \longrightarrow MnO_2\,(s) + SO_4^{2-} + OH^-$$

(MLNR, 1992, modified)

Solution. (*i*) **Reaction**

$$S_2O_3^{2-} \longrightarrow SO_4^{2-}$$

or $S_2^{+2}O_3^{2-} \longrightarrow 2S^{+6}O_4^{-2} + 8e^-$ [$\because$ $(2\times+6)-(2\times+2)=8$]

$$\therefore \text{ Eq. wt. of } Na_2S_2O_3 = \frac{\text{Mol. wt.}}{8}$$

$$= \frac{(2\times 23)+(2\times 32)+(3\times 16)}{8} = 19.75$$

$$\therefore \text{ Meq of } Na_2S_2O_3 = \frac{\text{wt.}}{\text{Eq. wt.}}\times 1000$$

$$= \frac{0.158\text{ g}}{19.75}\times 1000 = \mathbf{8}$$

(*ii*) $Mn^{+7}O_4^- + 3e^- \longrightarrow Mn^{+4}O_2$ [$\because$ $+7-4=+3$]

Normality of $KMnO_4$ = Molarity of $KMnO_4$ × $\begin{bmatrix}\text{no. of electrons gained by}\\ \text{one molecule of } KMnO_4\end{bmatrix}$

$= 0.1 \times 3 = 0.3$

But Meq of $KMnO_4$ = Meq of $Na_2S_2O_3$

So : Normality of $KMnO_4$ × volume in mL

= Meq of $Na_2S_2O_3$

$$0.3 \times V = 8\ ;\ V = \frac{8}{0.3} = \mathbf{26.67\ mL}$$

So, the correct answer is (*a*).

Example 204. *A 0.5 g sample containing MnO_2 is treated with HCl, liberating Cl_2. The chlorine is passed through a solution of KI and 30 cm³ of 0.1 M $Na_2S_2O_3$ are required to titrate the liberated iodine. The percentage of MnO_2 in the sample is :*

(*a*) *13.05%*	(*b*) *26.1%*
(*c*) *52.2%*	(*d*) *3%*

(*at. wt., Mn = 55, O = 16*) **(Roorkee 1994 modified)**

Solution. (*i*) **Reactions.**

$$MnO_2 + HCl \longrightarrow Cl_2 \xrightarrow{KI} I_2 \xrightarrow{Na_2S_2O_3} Na_2S_4O_6$$

$$MnO_2 + 2HCl \longrightarrow MnCl_2 + Cl_2 + H_2O$$

or $Mn^{4+}O_2 \longrightarrow Mn^{2+}Cl_2$. O. N. change = 4 – 2 = 2

$$\therefore \text{Eq. wt. of } MnO_2 = \frac{\text{Mol. wt.}}{2} = \frac{55+(2\times 16)}{2}$$

$$= \frac{87}{2} = 43.5$$

$$\therefore \quad \text{Meq of } MnO_2 = \frac{\text{wt. of } MnO_2}{\text{Eq. wt.}}\times 1000$$

$$= \frac{\text{wt. of } MnO_2 \times 1000}{43.5}$$

(*ii*)

$$\begin{array}{ccc} 2S_2O_3^{2-} & \longrightarrow & S_4O_6^{2-} + 2e^- \\ 2\text{ mol} & & 2\ e^- \\ 1\text{ mol} & & 1e^- \end{array}$$

$$\therefore \text{ Eq. wt. of } Na_2S_2O_3 = \frac{\text{Mol. wt. of } Na_2S_2O_3}{1}\ \textit{i.e.}, 0.1\text{ M}$$

$= 0.1$ N

M.eq. of $Na_2S_2O_3$ = Normality × Volume in mL
= 30 × 0.1 = 3

$$\therefore \frac{\text{wt. of } MnO_2 \times 1000}{43.5} = 3\ ;\text{wt. of } MnO_2 = \frac{3\times 43.5}{1000} = 0.1305$$

$$\%\text{ age of } MnO_2 = \frac{0.1305}{0.5}\times 100 = 26.1\%.$$

So, the correct answer is (*b*).

Example 205. *In x mL 0.3 N HCl, firstly addition of 200 mL distilled water and then addition of 100 mL 0.1 N NaOH, gives same final acid strength. Determine, x*

(WB-JEE, 2011)

Solution. First case. $x(0.3) = (x+200)\,y;\ y = 0.3x/200 + x$. Second case. No. of equivalents of HCl after adding NaOH solution $= \frac{0.3x}{1000} - 0.01$

[$\because$ 0.1N NaOH $= \frac{0.1}{1000} \times 100 = 0.01$]

$$\therefore \text{ Concentration} = \frac{\frac{0.3x}{1000} - 0.01}{100+x} \times 1000$$

[$\because$ Total conc. in 1L = 100 + x]

Since both concentrations are equal,

$$\frac{\left[\frac{0.3x}{1000} - 0.01\right]\times 1000}{100+x} = \frac{0.3x}{200+x};\ \frac{0.3x-10}{100+x} = \frac{0.3x}{200+x}$$

or $(200+x)(0.3x-10) = 0.3\,(100+x)$; $60x + 0.3x^2 - 2000 - 10x = 30x + 0.3x^2$ or $20x = 2000$; $x = 100$ mL. **Ans.**

Example 206. *50 cm³ of 0.2 N HCl is titrated against 0.1 N NaOH solution. The titration was discontinued after adding 50 cm³ of NaOH. The remaining titration is completed by adding 0.5 N KOH. The volume of KOH required for completing the titration is:* **(Karnataka, JEE, 2011)**

(*a*) *10 cm³*	(*b*) *12 cm³*
(*c*) *16.2 cm³*	(*d*) *21.0 cm³*

Solution. No. of milliequivalents = $N \times V$ (in mL)

Milliequivalents of NaOH = 0.1 × 50 = 5

Milliequivalents of HCl = 0.2 × 50 = 10

$\therefore$ Milliequivalents of HCl left behind = 10 – 5 = 5

Total volume of solution = 50 + 50 = 100 mL

$$\therefore \text{ Normality of HCl left} = \frac{5}{100} = 0.05\ N$$

Using normality equation N_1V_1 (acid) = N_2V_2 (KOH)

$$0.05 \times 100 = 0.5 \times V_2$$

$\therefore$ $V_2 = (0.05 \times 100)/0.5 = 10\text{cm}^3$.

So, the correct answer is (*a*).

Example 207. *100 mL of 0.1 M acetic acid is completely neutralised using a standard solution of NaOH. The volume of ethane obtained at STP after the complete electrolysis of the resulting solution is:*

(*a*) *112 mL*	(*b*) *56 mL*
(*c*) *224 mL*	(*d*) *560 mL*

(Karnataka, CET, 2012)

Solution. $CH_3COOH + NaOH \longrightarrow CH_3COONa + H_2O$

$$\underset{\text{2 mol}}{2CH_3COONa} \xrightarrow{\text{Electrolysis}} \underset{\text{1 mol = 22400 mL}}{C_2H_6} + 2CO_2 + 2Na$$

$$\text{no. of mol of} CH_3COOH \text{ given} = \frac{100}{1000} L \times 0.1 = \frac{1}{100}$$

2 mol CH_3COOH form C_2H_6 = 22400 mL

$$\frac{1}{100} \text{ mol } CH_3COOH \text{ form } C_2H_6 = \frac{1}{2} \times \frac{22400}{100} = 112 \text{ mL}$$

So, the correct answer is (*a*).

Example 208. *A given solution containing 20 mg NaCl per mL should be diluted to get a solution containing 8 mg NaCl per mL*

(*a*) *12.0 mL* (*b*) *2.5 mL*
(*c*) *3.0 mL* (*d*) *4.0 mL*

Solution. 20 mg = (20/1000)g ; 8 mg = (8/1000) g. But:

Millequivalent of conc. NaCl ≡ Milliequivalent of Dilute NaCl (Eq. wt. of NaCl = 23 + 35.5 = 58.5). So:

$$\frac{20}{1000} \times \frac{1000}{58.5} \times 1 = \frac{8}{1000} \times \frac{1000}{58.5} \times V; V = 2.5 \text{ mL}.$$

So, the correct answer is (*b*).

Note: Milliequivalents of one solution = Milliequivalent of solid solute

$$\text{Normality} \times \text{volume in mL} = \frac{\text{wt.}}{\text{Eq. wt.}} \times 1000$$

$$\frac{\text{Mol wt.} \times \text{Molarity}}{\text{Eq. wt.}} \times \text{Volume in mL} = \frac{\text{wt.}}{\text{Eq. wt.}} \times 1000$$

Example 209. *Calculate the volume in millilitre of 0.25 M H_2SO_4 those are needed to dissolve 0.20 g of calcium carbonate.*

(*a*) *7.0 mL* (*b*) *7.5 mL*
(*c*) *8.9 mL* (*d*) *8.0 mL*

(H.P. Board, 2012)

Solution. Mol. wt. of $CaCO_3$ = 40 + 12 + (3 × 16) = 100 g mol$^-$

$$\therefore \text{ Eq. wt. of } CaCO_3 = \frac{100}{\text{Charge on } Ca^{2+}} = \frac{100}{2} = 50.$$

Mol. wt. of H_2SO_4 = (2 × 1) + 32 + (4 × 16) = 98 g mol$^-$

∴ Eq. wt. of H_2SO_4

$$= \frac{\text{Mol. wt. of } H_2SO_4}{\text{Charge on cation, } 2H^+ (= 2)} = \frac{98}{2} = 49$$

But Milliequivalent of H_2SO_4 = Milliequivalent of $CaCO_3$

$$\text{Normality} \times \text{Vol in mL} = \frac{\text{wt.}}{\text{Eq. wt.}} \times 1000$$

$$\frac{\text{Molarity} \times \text{Mol. wt.}}{\text{Eq. wt.}} \times V = \frac{0.2}{50} \times 1000$$

$$\frac{0.25 \times 98}{49} \times V = \frac{0.2}{50} \times 1000;$$

$$\text{So, } V = \frac{0.2 \times 1000 \times 49}{50 \times 0.25 \times 98} = 8.0 \text{ mL}$$

So, the correct answer is (*d*).

Example 210. *Calculate the volume of 0.1 M NaOH to completely neutralise 15.0 mL of 0.2 M H_3PO_3.*

(*a*) *40 mL* (*b*) *50 mL*
(*c*) *60 mL* (*d*) *70 mL*

(Haryana School Board, 2012)

Solution. $H_3PO_3 \rightleftharpoons HPO_3^{2-} + 2H^+$ (Dibasic acid)

$$\underset{\text{2 mol}}{2KOH} + \underset{\text{1 mol}}{H_3PO_3} \longrightarrow K_2HPO_3 + 2H_2O$$

$$\frac{M_1V_1 \text{ of KOH}}{M_2V_2 \text{ of } H_3PO_3} = \frac{\text{no. of moles of KOH}}{\text{no. of moles of } H_3PO_3}$$

$$\frac{0.1 \times V}{0.2 \times 15} = \frac{2}{1}; \; 0.1 \times V = 2 \times 0.2 \times 15;$$

$$V = \frac{2 \times 0.2 \times 15}{0.1} = 60 \text{ mL}$$

So, the correct answer is (*c*).

Example 211. *25 mL of 0.2 M H_3BO_3 solution needs .... mL of 0.1 M NaOH for complete neutralisation*

(*a*) *20 mL* (*b*) *25 mL*
(*c*) *50 mL* (*d*) *60 mL*

(PSEB, 2012)

Solution. $H_3BO_3 + NaOH \longrightarrow NaH_2BO_3 + H_2O$

Monobasic

1 mol 1 mol

$$\frac{\text{Molarity} \times \text{Volume of } H_3BO_3}{\text{Molarity} \times \text{Volume of NaOH}} = \frac{\text{no. of mol of } H_3BO_3}{\text{no. of mol of NaOH}}$$

$$\frac{0.2 \times 25}{0.1 \times V} = \frac{1}{1}; V = \frac{0.2 \times 2.5}{0.1} = 50 \text{ mL}$$

So, the correct answer is (*c*).

Example 212. *What is the volume of CO_2 liberated (in litres) at 1 atmosphere and 0°C when 10 g of 100% pure calcium carbonate is treated with excess dilute sulphuric acid?*

(atomic mass, Ca = 40, C = 12, O = 16).

(*a*) *0.224* (*b*) *2.24*
(*c*) *22.4* (*d*) *224*
(*e*) *11.2*

(Keral PMT, 2012)

Solution. Mol. wt. (or wt. of 1 mol) of $CaCO_3$ = 40 + 12 + (3 × 16) = 100 g mol$^-$

Reaction: $CaCO_3 + H_2SO_4 \longrightarrow CaSO_4 + CO_2(g) + H_2O$

1 mol 1 mol

100 g 12 + (2 × 16) = 44 g mol$^-$

= 22.4 L at NTP

100 g $CaCO_3$ produce $CO_2(g)$ = 22.4 L

$$10 \text{ g } CaCO_3 \text{ produce } CO_2(g) = \frac{22.4}{100} \times 10 = 2.24 \text{ L}.$$

So, the correct answer is (*b*).

Type. Conversion of molarity of a solution into normality and vice-versa. Use the relation:

$$\boxed{\textbf{Normality} \times \textbf{Eq. wt.} = \textbf{Molarity} \times \textbf{mol. wt.}}$$

EXAMPLE 213. *The volume of 0.1 M $Ca(OH)_2$ required to neutralise 10 mL of 0.1 N HCl is:*

(*a*) 10 mL (*b*) 20 mL (*c*) 5 mL (*d*) 15 mL

(J&K, CET, 2012)

SOLUTION. $\underset{\text{1 mol}}{Ca(OH)_2} \rightleftharpoons Ca^{2+} + \underset{\text{2mol}}{2OH^-}$

$40 + 2(16 + 1)$
$= 74$ g

$$\therefore \text{ Eq. wt. of Ca (OH)}_2 = \frac{\text{Mol. wt.}}{\text{no. of OH}^- \text{ ions}} = \frac{74}{2} = 37$$

$N_1 V_1$ of $Ca(OH)_2 = N_2 V_2$ of HCl.

$$\frac{0.1 \times 74}{37} \times V_1 = 0.1 \times 10; V_1 = 10/2 = 5 \text{ mL}.$$

So, the correct answer is (*c*).

EXAMPLE 214. *25 mL of house hold bleach solution was mixed with 30 mL of 0.50 MKI and 10 mL of 4 N acetic acid. In the titration of liberated iodine, 48 mL of 0.25 N $Na_2S_2O_3$ was used to reach the end point. The molarity of household bleach solution is:*

(*a*) 0.48 M (*b*) 0.96 M (*c*) 0.24 M (*d*) 0.024 M

(IIT-JEE 2012)

SOLUTION. $\underset{\text{Bleaching powder}}{CaOCl_2} + 2CH_3COOH \longrightarrow Ca(CH_3COO)_2 + H_2 + Cl_2$

$Cl_2 + 2KI \longrightarrow 2KCl + I_2$

$I_2 + 2Na_2S_2O_3 \longrightarrow Na_2S_4O_6 + 2NaI$

From above equations, we infer that:

1 millimole of $CaOCl_2$ = 1 millimole of $I_2 = \frac{1}{2}$ millimole of $Na_2S_2O_3$

$\therefore$ Millimoles of $CaOCl_2 = \frac{1}{2} \times 0.25 \times 48 = 6$. Also:

Molarity × volume = 6 millimoles

$\therefore$ Molarity × 25 = 6. So, molarity = 6/25 = 0.24 M

So, the correct answer is (*c*).

PROBLEMS FOR PRACTICE

1. One litre solution contains 4 g of hydroxide of a monovalent metal. Determine volumetrically the atomic weight of the metal. Given N/10 HCl.

   Ans. $(40\ V_1/V_2) - 17$

2. Determine volumetrically the number of molecules of water of crystallisation in oxalic acid, $H_2C_2O_4 \cdot xH_2O$, 6.3 g of which have been dissolved per litre of the given solution. Provided N/10 NaOH solution.

   Ans. 2.

3. You are provided with a solution of a mixture of NaOH and KOH, 9 g of which have been dissolved per litre. Find the % age composition of each. (Given M/10 HNO_3. M_1, is molarity of total solution and x is wt. of NaOH).

   Hints: NaOH = $\frac{100x}{9}$ %;

   KOH = $100 - \left(\frac{100x}{9}\right)$ % **Ans.**

4. You are provided with a solution prepared by dissolving 5.0 g of a copper coin in acid solution making the solution to one litre. Determine the percentage of Cu in the coin. 20 mL of the solution on treatment with Na_2CO_3, CH_3COOH and KI liberated iodine which reacted completely with 16.0 mL of 0.058 N $Na_2S_2O_3$ solution. (at. wt. of Cu = 63.5). **Ans.** 58.93%.

   Hint. Eq. wt. of Cu = 63.5.

5. How will you prepare exactly 3.0 L of 1.0 M HCl by mixing portions of stock solutions of 2.5 M HCl and 0.4 M HCl?

   [**Ans.** 0.857 L of 2.5 M and 2.14 L of 0.4 M HCl should be mixed to get exact 3L of 1.0 M HCl]

6. Calculate the concentration of $Ba(OH)_2$ solution if it takes 40 mL of 3.5 M HNO_3 to neutralise 30.0 mL of this base.

   Hint. $\underset{\text{1 m. mol}}{Ba(OH)_2} + \underset{\text{2 m. mol}}{2HNO_3} \longrightarrow Ba(NO_3)_2 + 2H_2O$

   $$\frac{(30.0 \text{ mL} \times M_1) \text{ of } Ba(OH)_2}{(40 \text{ mL} \times 3.5\ M) \text{ of } HNO_3} = \frac{1 \text{ m. mol}}{2 \text{ m. mol}}; M_1 = \mathbf{2.67\ M}$$

   Ans.

7. Find the ionic strength of the solution containing. 0.1 M $CuSO_4$, 0.2 M $Al_2(SO_4)_3$ and 0.3 M NaCl.

   Ans. 3.7 mol L^-

8. Calculate the equivalent weight of $Mg(OH)_2$ in the following reaction.

   $Mg(OH)_2 + HCl \longrightarrow Mg(OH)Cl + H_2O.$

   Ans. 58

9. Calculate the molar concentration of Na^+ ions when 200 mL of 2.0 M NaCl is diluted to 1/2 litre.

   Ans. 0.8 M

10. 20 mL of 1M KOH solution neutralise

    (*a*) 5 mL (*b*) 10 mL
    (*c*) 15 mL (*d*) 20 mL of 2M H_2SO_4.

    Ans. (*a*)

11. Calculate the molarity of 1.5 N H_2SO_4.

    Ans. (0.75 M)

12. An aqueous solution of NaOH (5.1 M) contains 40% NaOH by weight. The density of solution will be:

    (*a*) 1.6 g mL^- (*b*) 0.1 g $(mL)^-$
    (*c*) 0.51 g $(mL)^-$ (*d*) 10 g $(mL)^-$

    Ans. (*c*)

13. Calculate the molarity of water if its density is 1 kg m^{-3}.

    (*a*) 55.6 (*b*) 16 (*c*) 18 (*d*) 20

    Ans. (*a*)

23

CHAPTER

Physical and Chemical Equilibrium

23.1 EQUILIBRIUM

It represents the state of a process in which the properties like temperature, pressure, concentration of the system do not show any change with passage of time.

Physical equilibrium. If the opposing processes in a reversible reaction involve only physical changes, the equilibrium is called physical equilibrium. e.g.,

$$\text{Solid} \rightleftharpoons \text{liquid; liquid} \rightleftharpoons \text{gas ; solid} \rightleftharpoons \text{gas}$$

Chemical equilibrium. If the opposing processes involve chemical changes (*i.e.*, chemical reactions), the equilibrium is called chemical equilibrium.

23.2 SOME IMPORTANT POINTS REGARDING CHEMICAL EQUILIBRIUM

1. Most of the processes including chemical reactions which take place in a closed vessel, do not go to completion. The reaction **appears to stop** after sometime but the reactants may still be present. The state so reached is called equilibrium state. These are reversible reactions.
2. At equilibrium, the reaction continues both in the forward as well as backward direction *i.e.*, the rate of forward reaction is equal to rate of backward reaction.
3. **Law of mass action** (Proposed by Guldberg and Waage). It states that the rate at which a substance reacts is proportional to its active mass and the rate of a chemical reaction is proportional to the product of active masses of reactants each raised to the power equal to corresponding stoichiometric coefficients in the balanced reaction. For dilute solutions, active masses are equal to concentration. For example, for a reaction :

(*i*)
$$aA + bB \rightleftharpoons cC + dD \text{(reversible)}$$

Rate of forward reaction, $r_f = k_f[A]^a[B]^b$

Rate of backward reaction, $r_b = k_b[C]^c[D]^d$

where k_f and k_b are the rate constant or velocity constants for the forward and backward reactions respectively.

(*ii*) For irreversible reaction, $aA + bB \longrightarrow$ Products.
Rate of forward reaction, $r_f = k_f [A]^a [B]^b$ where k_f is rate constant for the forward reaction.

4. **Equilibrium constant, k_C and k_P. (*i*)** For a reversible reaction, involving solid, solution and gases :

$$a A (s) + b B (g) \rightleftharpoons c C (g) + d D \text{ (solution)}$$

$$\frac{k_f}{k_b} = \frac{[C]^c [D]^d}{[A]^a [B]^b}$$

where $\frac{k_f}{k_b}$ = equilibrium constant, K.

$$\therefore \qquad K = \frac{[C]^c [D]^d}{[A]^a [B]^b} \qquad \text{... (1)}$$

Since A is a solid, concentration of A (s) = a constant (d/M). So, above relation (1) can be written as :

$$K \times [A\ (s)] = \frac{[C]^c [D]^d}{[B]^b}$$

$$= \text{constant, called } K_C$$

The distinction between K and K_C is that, the word K is used when all the substances in the reaction are involved. The word K_C is used when only solutions and gases are involved. The expression of K_C is devoid of pure liquids and solids.

Note. By convention, concentration of solid = 1; Concentration of liquid = 1; concentration of aqueous, [aq] = 1 **Thus** [solid] = 1 ; (liquid] = 1 ; [aq] = 1.

(*ii*) For a reversible reaction, involving **gases only :**

$$a A(g) + b B(g) \rightleftharpoons c C (g) + d D (g) \qquad \text{... (2)}$$

$$K_p = \frac{p_C^c \times p_D^d}{p_A^a \times p_B^b}$$

where p_A, p_B, p_C and p_D are the partial pressures (each raised to the power of their respective co-efficients) of gases A, B, C and D respectively. If any one of the reactant or product species is a solid or solution, K_p will be replaced by K_c. The constant K_p is only used for gaseous reactants and products.

> **Note.** K_c is constant at a given temperature irrespective of the initial concentration of *e.g.*, $H_2(g)$, $I_2(g)$ and HI (g) in $H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$ reaction.

5. **Reaction quotient, Q.** At each point in a reaction, a ratio of concentration terms can be formulated. This formulation is similar to that for equilibrium constant expression shown for K_c and K_p above. This ratio, called reaction quotient (Q) helps to predict the direction of a reaction described below.

(*i*) If $Q < K_c$, the reaction proceeds from left to right direction *i.e.*, in forward direction.

(*ii*) If $Q > K_c$, the reaction proceeds from right to left direction *i.e.*, in backward direction.

(*iii*) If $Q = 0$, the reaction is at equilibrium.

Thus, for a reaction, $a\,A + b\,B \rightleftharpoons c\,C + d\,D$

$$Q = \frac{[C]^c\,[D]^d}{[A]^a\,[B]^b}$$

For chemical equilibrium to exist in a reaction mixture, the reaction quotient Q must be equal to the equilibrium constant, K_c.

23.3 CALCULATION OF DEGREE OF DISSOCIATION (OR IONISATION), α

In order to calculate, α of a reactant that undergoes dissociation, use the following concept and use the following relation

Degree of dissociation,

$$\alpha = \frac{\text{no. of mol dissociated}}{\text{Total no. of mol present before dissociation}}$$

Let, x = no. of mol dissociated

(*i*)

$$\begin{array}{llll} & nA & \rightleftharpoons B & + \ C \\ \text{no. of mol at } t=0 & a & 0 & 0 \\ \text{or initial no. of mol} & & & \\ \text{no. of mol at equilibrium} & a-ax & \dfrac{ax}{n} & \dfrac{ax}{n} \end{array}$$

$$\therefore \quad \alpha = \frac{ax}{a} = x$$

For example.

$$\begin{array}{llll} & 2\,HI & \rightleftharpoons H_2 & + \ I_2 \\ \text{no. of mol at } t=0 & a & 0 & 0 \\ \text{no. of mol at equilibrium} & a-ax & \dfrac{ax}{2} & \dfrac{ax}{2} \\ \text{or} & = a(1-x) & & \end{array}$$

$$\therefore \quad \alpha = \frac{ax}{a} = x$$

(*ii*)

$$\begin{array}{llll} & n\,A & \rightleftharpoons B & + \ C \\ \text{no. of mol at } t=0 & a & 0 & 0 \\ \text{no. of mol at equilibrium} & a-x & \dfrac{x}{n} & \dfrac{x}{n} \end{array}$$

$$\therefore \quad \alpha = \frac{x}{a}$$

For example

$$\begin{array}{llll} & 2\,HI & \rightleftharpoons H_2 & + \ I_2 \\ \text{no. of mol at } t=0 & a & 0 & 0 \\ \text{no. of mol at equilibrium} & a-x & \dfrac{x}{2} & \dfrac{x}{2} \end{array}$$

$$\therefore \quad \alpha = \frac{x}{a}$$

(*iii*)

$$\begin{array}{llll} & n\,A & \rightleftharpoons B & + \ C \\ \text{no. of mol at } t=0 & a & 0 & 0 \\ \text{no. of mol at equilibrium} & a-2x & \dfrac{2x}{n} & \dfrac{2x}{n} \end{array}$$

$$\therefore \quad \alpha = \frac{2x}{a}$$

For example.

$$\begin{array}{llll} & 2\,HI & \rightleftharpoons H_2 & + \ I_2 \\ \text{no. of mol at } t=0 & a & 0 & 0 \\ \text{no. of mol at equilibrium} & a-2x & \dfrac{2x}{2} = x & \dfrac{2x}{2} = x \end{array}$$

$$\therefore \quad \alpha = \frac{2x}{a}$$

(*iv*)

$$\begin{array}{llll} & n\,A & \rightleftharpoons B & + \ C \\ \text{no. of mol at } t=0 & 1 & 0 & 0 \\ \text{no. of mol at equilibrium} & 1-x & \dfrac{x}{n} & \dfrac{x}{n} \end{array}$$

$$\therefore \quad \alpha = \frac{x}{1} = x$$

For example.

$$\begin{array}{llll} & 2\,HI & \rightleftharpoons H_2 & + \ I_2 \\ \text{no. of mol at } t=0 & 1 & 0 & 0 \\ \text{no. of mol at equilibrium} & 1-x & \dfrac{x}{2} & \dfrac{x}{2} \end{array}$$

$$\therefore \quad \alpha = \frac{x}{1} = x$$

(*v*)

$$\begin{array}{llll} & nA & \rightleftharpoons B & + \ C \\ \text{no. of mol at } t=0 & 1 & 0 & 0 \\ \text{no. of mol at equilibrium} & 1-2x & \dfrac{2x}{n} & \dfrac{2x}{n} \end{array}$$

$$\therefore \quad \alpha = \frac{2x}{1} = 2x$$

For example.

$$\begin{array}{llll} & 2\,HI & \rightleftharpoons H_2 & + \ I_2 \\ \text{no. of mol at } t=0 & 1 & 0 & 0 \\ \text{no. of mol at equilibrium} & 1-2x & \dfrac{2x}{2} = x & \dfrac{2x}{2} = x \end{array}$$

$$\therefore \qquad \alpha = \frac{2x}{1} = 2x$$

Significance of magnitude of equilibrium constant.

(*i*) If the magnitude of K_c or K_p is very high, the forward reaction goes to completion or nearly so.

(*ii*) If the magnitude of K_c or K_p is very low, the forward reaction does not occur to any significant extent.

(*iii*) If the magnitude of K_c or K_p is neither very high nor very low, the reaction is expected to reach a state of equilibrium.

23.4 HOMOGENEOUS AND HETEROGENEOUS EQUILIBRIA

Type. (*i*) Reactions in homogeneous equilibria are those in which reactants and products are in the same physical state *i.e.*, solid, liquid or gas. e.g., $N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$

(*ii*) Reactions in heterogeneous equilibria are those in which reactants and products are in different physical states. e.g., $CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g)$

Example 1. *Classify the following reversible reactions as systems involving homogeneous equilibria or heterogenous equilibria.*

(*i*) $Ca(OH)_2(s) \rightleftharpoons Ca^{2+}(aq) + 2OH^-(aq)$

(*ii*) $Fe^{3+}(aq) + 3\,OH^-(aq) \rightleftharpoons Fe(OH)_3(s)$

(*iii*) $2\,NOCl(g) \rightleftharpoons 2\,NO(g) + Cl_2(g)$

(*iv*) $Fe^{3+}(aq) + SCN^-(aq) \rightleftharpoons [Fe(SCN)]^{2+}(aq)$

Solution. Reactions (*iii*) and (*iv*) involve homogeneous equilibria because of same physical states (gas) and aqueous (aq) respectively.

Reactions (*i*) and (*ii*) involve heterogeneous equilibria because of different physical states *i.e.*, in (*i*), solid and aqueous ; in (*ii*) aqueous (aq) and solid (s).

23.5 WRITING EQUILIBRIUM CONSTANT OF REVERSIBLE REACTIONS

Type. (*i*) For a reversible reaction, involving solid, solution and gases e.g.,

$a\,A(s) + b\,B(g) \rightleftharpoons c\,C(g) + d\,D$ (solution), the equilibrium constant K is written as :

$$K = \frac{[C]^c\,[D]^d}{[A]^a\,[B]^b}$$

Since A is a solid,

So $\qquad [A] = a$ constant.

$$\text{So,} \qquad [A]^a \times K = K_c \qquad \therefore K_c = \frac{[C]^c\,[D]^d}{[B]^b}$$

(*ii*) For a reversible reaction involving gases only e.g., $a\,A(g) + b\,B(g) \rightleftharpoons c\,C(g) + d\,D(g)$, the equilibrium constant, K_p is written as :

$$K_p = \frac{P_C^c \times P_D^d}{P_A^a \times P_B^b}$$

where p_A, p_B, p_C and p_D are the **partial pressures** (each raised to the power of their **respective co-efficients**) of gases A, B, C and D respectively.

Example 2. *Write the equilibrium constant expressions for the following reactions.*

(*i*) $Na_2CO_3(s) + SO_2(g) + ½\,O_2(g) \rightleftharpoons Na_2SO_4(s) + CO_2(g)$

(*ii*) $2H_2(g) + O_2(g) \rightleftharpoons 2H_2O(g)$

Solution. For $Na_2CO_3(s) + SO_2(g) + \frac{1}{2}O_2(g) \rightleftharpoons Na_2SO_4(s) + CO_2(g)$, equilibrium constant, K_c is given as:

$$K_c = \frac{[Na_2SO_4(s)]\,[CO_2(g)]}{[Na_2CO_3(s)]\,[SO_2(g)]\,[O_2(g)]^{1/2}}$$

Since by convention, concentration of solid is taken as 1, we have

$$K_c = \frac{[CO_2(g)]}{[SO_2(g)]\,[O_2(g)]^{1/2}}$$

(*ii*) For $2H_2(g) + O_2(g) \rightleftharpoons 2H_2O(g)$, equilibrium constant K_p (for gaseous reactants and products) is given as :

$$K_p = \frac{(p_{H_2O})^2}{(p_{H_2})^2 \times p_{O_2}}$$

It can also be expressed in terms of K_c where

$$K_c = \frac{[H_2O(g)]^2}{[H_2(g)]^2\,[O_2(g)]}$$

Type. Greater the value of K_c, greater will be the tendency of a reaction to proceed farthest towards completion *i.e.*, greater will be the speed of the reaction in the forward direction.

Example 3. *Which of the following reactions will tend to proceed farthest towards completion.*

(*i*) $2\,HBr(g) \rightleftharpoons H_2(g) + Br_2(g)$; $K_c = 7.0 \times 10^{-20}$

(*ii*) $2\,NO(g) + O_2(g) \rightleftharpoons 2\,NO_2(g)$; $K_c = 3.4 \times 10^{13}$

(*iii*) $4\,NH_3(g) + 5\,O_2(g) \rightleftharpoons 4\,NO(g) + 6\,H_2O$; $K_c = 5 \times 10^{198}$

Solution. Greater the value of K_c, greater is the speed of reaction. K_c values of given reactions (*i*), (*ii*) and (*iii*) are 7.0×10^{-20}, 3.4×10^{13} and 5×10^{198}. Thus value of K_c of (*iii*) > (*ii*) > (*i*). So, reaction (*iii*) will move farthest towards completion.

Type. When the direction of an equation is reversed, the new equilibrium constant is the reciprocal of the original value *i.e.*,

$$K_C' = 1/K_C$$

Similarly, $\qquad K_p' = 1/K_p$

Example 4. *The value of K_p for the reaction, $N_2(g) + 3\,H_2(g) \rightleftharpoons 2\,NH_3(g)$ is 41at 400 K. Calculate the value of K_p for the* *reaction,* $2\,NH_3\,(g) \rightleftharpoons N_2\,(g) + 3\,H_2\,(g)$

SOLUTION. For $N_2\,(g) + 3H_2\,(g) \rightleftharpoons 2NH_3\,(g)\,;\, K_p = 41$ ... (1)

The other equation is : $2\,NH_3\,(g) \rightleftharpoons N_2\,(g) + 3\,H_2(g);$

$K'_p = ?$ ... (2)

Since this equation (2) is reverse of the given equation (1) :

$$K'_p = \frac{1}{K_p} = \frac{1}{41} = 2.44 \times 10^{-2}$$

Type. When each of the co-efficients in a balanced equation is divided by factor '*n*', the equilibrium constant value is *n*th root of the previous value.

Thus, $K'_c = (K_c)^{1/n}\,;\; K'_p = (K_p)^{1/n}$

So, when an equation is divided by 2, the new equilibrium constant is the square root of the original value.

Thus, $K'_c = (K_c)^{1/2}$ or $\sqrt{K_c}$;

$K'_p = (K_p)^{1/2}$ or $\sqrt{K_p}$.

EXAMPLE 5. *The value of K_p for the reaction, $N_2(g) + 3\,H_2(g) \rightleftharpoons 2\,NH_3\,(g)$ at 400 K is 41. Find the value of K_p for the reaction, $\frac{1}{2}N_2\,(g) + \frac{3}{2}H_2\,(g) \rightleftharpoons NH_3\,(g)$ at the same temperature.*

SOLUTION. Given

$N_2\,(g) + 3\,H_2\,(g) \rightleftharpoons 2\,NH_3\,(g)\,;\, K_p = 41$ ... (1)

Required equation:

$\frac{1}{2}N_2\,(g) + \frac{3}{2}H_2\,(g) \rightleftharpoons NH_3\,(g)\;;\; K'_p = ?$ ...(2)

Since equation (2) is obtained by dividing equation (1) by 2, the value of K'_p will be equal to square root of K_p value .

$\therefore$ $K'_p = (K_p)^{1/2} = (41)^{1/2} = 6.4$ **Ans.**

Type. When each of the co-efficients in a balanced equation is multiplied by a factor '*n*', the equilibrium constant value is raised to the same factor.

Thus, $K'_c = (K_c)^n\,;\; K'_p = (K_p)^n$

For example, when an equation is multiplied by 2, the new equilibrium constant is the square of the original value *i.e.,*

$$K'_c = (K_c)^2\,;\quad K'_p = (K_p)^2.$$

EXAMPLE 6. *The value of K_p for the reaction, $N_2\,(g) + 3H_2\,(g) \rightleftharpoons 2NH_3\,(g)$ at 400 K is 41. Find the value of K_p for the reaction,*

$2N_2\,(g) + 6H_2\,(g) \rightleftharpoons 4NH_3\,(g)$

SOLUTION. Given.

$N_2\,(g) + 3H_2\,(g) \rightleftharpoons 2NH_3\,(g)\,;\, K_p = 41$ ...(1)

Required equation :

$2N_2\,(g) + 6H_2\,(g) \rightleftharpoons 4NH_3\,(g)\,;\, K'_c = ?$ ... (2)

The equation (2) is obtained by multiplying equation (1) by 2.

So, $K'_p = (K_p)^2$

So, $K'_p = (41)^2 = \mathbf{1681}.$ **Ans.**

Type. When there are two or more partial equations for a net reaction, the individual equations are combined and their equilibrium constant values are multiplied for the net reaction. Suppose K_1, K_2 and K_3 are the stepwise equilibrium constant values for $A \rightleftharpoons B$, $B \rightleftharpoons C$ and $C \rightleftharpoons D$ respectively, then net equilibrium constant, $K = K_1 \times K_2 \times K_3$.

EXAMPLE 7. *Calculate the magnitude of equilibrium constant for the reaction $X \rightleftharpoons Y$ if :*

(*i*) $X \rightleftharpoons A\,;\, K_1 = 2$ (*ii*) $A \rightleftharpoons B\,;\, K_2 = 6$

(*iii*) $B \rightleftharpoons Y\,;\, K_3 = 4.$

SOLUTION.

(*i*) $X \rightleftharpoons A\,;\, K_1 = 2$ (*ii*) $A \rightleftharpoons B\,;\, K_2 = 6$

(*iii*) $B \rightleftharpoons Y\,;\, K_3 = 4$

Net reaction $X \rightleftharpoons Y\,;\, K = 2 \times 6 \times 4 = 48$ **Ans.**

EXAMPLE 8. *Calculate the magnitude of equilibrium constant for the reaction $2N_2 + 4O_2 \rightleftharpoons 4\,NO_2$ if :*

(*i*) $2N_2 + O_2 \rightleftharpoons 2N_2O;\, K_c = K_{c_1}$

(*ii*) $2N_2O + 3O_2 \rightleftharpoons 4NO_2\,;\, K_c = K_{c_2}$

Give Proof also.

SOLUTION. Given :

(*i*) $2N_2 + O_2 \rightleftharpoons 2N_2O\,;\, K_c = K_{c1}$

(*ii*) $2N_2O + 3O_2 \rightleftharpoons 4NO_2\,;\, K_c = K_{c2}$

Adding (*i*) and (*ii*), we get

Net reaction $2N_2 + 4O_2 \rightleftharpoons 4NO_2\,;\, K'_c = ?$ (*iii*)

Since net reaction is obtained by adding the given partial equations, the net equilibrium constant K is given as : $K'_C = K_{C_1} \times K_{C_2}$ **Ans.**

Proof : For reaction (*i*)

$$K_{C_1} = \frac{[N_2O]^2}{[N_2]^2\,[O_2]}$$

(*ii*) $$K_{C_2} = \frac{[NO_2]^4}{[N_2O]^2\,[O_2]^3}$$

(*iii*) $$K'_C = \frac{[NO_2]^4}{[N_2]^2\,[O_2]^4}$$

$\therefore$ $$K_{C_1} \times K_{C_2} = \frac{[N_2O]^2}{[N_2]^2\,[O_2]} \times \frac{[NO_2]^4}{[N_2O]^2\,[O_2]^3}$$

$$= \frac{[NO_2]^4}{[N_2]^2\,[O_2]^1\,[O_2]^3}$$

$$= \frac{[NO_2]^4}{[N_2]\,[O_2]^4}$$

From above we see that

$$K_{C_1} \times K_{C_2} = K'_C$$

EXAMPLE 9. *For $2NO\,(g) \rightleftharpoons N_2(g) + O_2\,(g)$,*

$K_C = 2.4 \times 10^{30}$ at 298 K

For $NO\,(g) + \frac{1}{2}\,Br_2\,(g) \rightleftharpoons NOBr\,(g),$

$$K_C = 1.4 \text{ at } 298\text{ K}.$$

Using above data, calculate the value of K_C for the reaction

$$\frac{1}{2}\,N_2\,(g) + \frac{1}{2}\,O_2\,(g) + \frac{1}{2}\,Br_2\,(g) \rightleftharpoons NOBr\,(g)$$

SOLUTION.

$$NO\,(g) + \frac{1}{2}\,Br_2\,(g) \rightleftharpoons NOBr\,(g) \quad \text{... (1)}$$

$$2\,NO\,(g) \rightleftharpoons N_2\,(g) + O_2(g)]] \times \frac{1}{2} \quad \text{... (2)}$$

Subtract. – – –

$$\frac{1}{2}\,N_2\,(g) + \frac{1}{2}\,O_2\,(g) + \frac{1}{2}\,Br_2\,(g) \rightleftharpoons NOBr\,(g) \quad \text{... (3)}$$

∴ For $N_2(g) + O_2\,(g) \rightleftharpoons 2NO\,(g)$ ... (4)

$$K'_C = \frac{1}{K_C}$$

[∵ it is reverse of equation, 2]

Or (*i*) $\frac{1}{2}\,N_2\,(g) + \frac{1}{2}\,O_2\,(g) \rightleftharpoons NO\,(g)$ ... (5)

$$K''_C = (K'_C)^{1/2}$$

[∵ equation 5 is obtained by dividing equation (4) by 2]

$$\therefore \quad K''_C = \left(\frac{1}{2.4 \times 10^{30}}\right)^{1/2}$$

$$= 0.6455 \times 10^{-15}$$ **Ans.**

(*ii*) $NO\,(g) + \frac{1}{2}\,Br_2\,(g) \rightleftharpoons NOBr\,(g)\,;\, K'''_C = 1.4$

Since net reaction (3) is obtained by the addition of reactions (*i*) and (*ii*), *K* will be equal to $K''_C \times K'''_C$. Thus we have :

$$K = \frac{[NO\,(g)]}{[N_2\,(g)]^{1/2}\,[O_2\,(g)]^{1/2}} \times \frac{[NOBr\,(g)]}{[NO\,(g)]\,[Br_2\,(g)]^{1/2}}$$

$$= \frac{[NOBr\,(g)]}{[N_2\,(g)]^{1/2}\,[O_2\,(g)]^{1/2}}$$

Or

$$K = K''_C \times K'''_C$$
$$= (0.6455 \times 10^{-15}) \times 1.4$$
$$= 9.037 \times 10^{-16}$$ **Ans.**

23.6 LE-CHATELIER'S PRINCIPLE

It states that when a system in equilibrium is subjected to change in temperature, pressure, concentration etc, the equilibrium shifts in a direction to undo the effect of the change. In order to understand it, consider the following general reaction at equilibrium.

$$c\,A(g) \rightleftharpoons a\,B(g) + b\,C(g)$$

where *c*, *a* and *b* are the moles of *A*, *B* and *C* gases respectively. Let total pressure is P_T. Thus :

$$K_p = \frac{\left[\frac{a}{a+b+c} \times P_T\right]\left[\frac{b}{a+b+c} \times P_T\right]}{\left[\frac{c}{a+b+c} \times P_T\right]}$$

$$= \frac{a\,b\,P_T}{c\,(a+b+c)} \quad \text{...(1)}$$

But $P_T = \frac{n\,RT}{V}$ and $n = a + b + c.$ ... (2)

Hence $P_T = \frac{(a+b+c)\,RT}{V}$

Substituting the value of P_T in (1) from (2), we get :

$$K_p = \frac{a\,b\,RT}{c\,V} \quad \text{... (3)}$$

Or $Q = \frac{a\,b\,RT}{c\,V}$ ...(4)

The equations (3) and (4) are helpful to know the effect of various changes done on equilibrium of a reaction. For example :

(*i*) If volume of the system is increased, *Q* becomes $\frac{a\,b\,RT}{c\,V'}$ where $V' > V$. So, *Q* becomes less than k_p.

Hence reaction would move in the forward direction to attain equilibrium.

(*ii*) If volume of the system is increased by adding noble gas at constant pressure, the reaction would proceed in the forward direction.

(*iii*) If a noble gas is added to the system at constant volume, Q remains as $Q = \frac{a\,b\,RT}{c\,V}$. So, reaction will remain at equilibrium and nothing will happen.

(*iv*) If *d* moles of *C* (*g*) are added, *Q* becomes,

$$Q = \frac{a\,(b+d)\,RT}{c\,V}.$$

Thus Q becomes more than K_p [equation, (3)]. So, the system will move in the backward direction.

EXAMPLE 10. *Write the conditions under which the following reactions proceed in the forward direction.*

(*i*) $C(s) + H_2O\,(g) \rightleftharpoons CO_2\,(g) + H_2(g) + x\,k\,cal$

(*ii*) $N_2O_4(g) \rightleftharpoons 2NO_2(g) - 14\,k\,cal$

SOLUTION.

(*i*) $C\,(s) + H_2O\,(g) \rightleftharpoons CO_2\,(g) + H_2\,(g) + x\,k\,\text{cal}$

1 mol 1 mol 1 mol

$$K_C = \frac{[CO_2\,(g)]\,[H_2\,(g)]}{[C\,(s)]\,[H_2O\,(g)]}$$

Since reaction is exothermic and accompanied by decrease in volume, low temperature and high pressure will favour the forward reaction. To keep K_C constant, excess of C and H_2O will favour forward reaction.

(*ii*) $N_2O_4\,(g) + 14\,k\text{ cal} \rightleftharpoons 2\,NO_2\,(g)$

1 mol (1 Vol) 2 mol (2 Vol)

$$K_C = \frac{[NO_2\,(g)]^2}{[N_2O_4\,(g)]}$$

Since reaction is endothermic and accompanied by increase in volume, high temperature and low pressure will favour forward reaction. To keep K_C constant, excess of N_2O_4 (g) will favour forward reaction.

23.7 CALCULATION OF ACTIVE MASSES

Type. Calculation of active mass of substances when their densities are given. For this purpose, use :

(*i*) 1 L substance weighs

$= 1000$ mL substance × density in $\text{g(mL)}^{-} = x\text{ g}$

(*ii*) no. of mol of substance

$$= \frac{x\text{ g}}{g.\text{ mol. wt. of substance}}$$

= Active mass of substance in mol L^{-}.

Example 11. *Calculate the active masses of carbon tetrachloride [density = 1.58 g (mL)⁻].*

Solution. g. mol. wt. of CCl_4

$= 12 + (4 \times 35.5) = 12 + 142.0 = 154$

1L CCl_4 weighs $= 1000\text{ mL} \times$ density in g $(\text{mL})^{-}$

$= 1000\text{ mL} \times 1.58\text{ g (mL)}^{-} = 1580$ g.

∴ no. of mol of CCl_4

$$= \frac{1580}{154} = 10.26\text{ mol L}^{-}$$

or Active mass of CCl_4

$= \mathbf{10.26\text{ mol L}^{-}}$ **Ans.**

23.8 PHYSICAL EQUILIBRIUM

Example 12. *A solid A having molar mass 100 has solubility 0.002 mol L⁻. How much A will remain undissolved ?*

(*i*) *If 0.4 g of it were shaken with 200 cm³ of water till equilibrium is reached ?*

(*ii*) *How much A will be left undissolved if another 200 cm³ of water is added to the above mixture.*

Solution. (*a*) Molar mass of A = 100

Solubility of A $= 0.002\text{ mol L}^{-}$

$= 0.002 \times 100 = 0.2\text{ g L}^{-}$

Wt. of A = 0.4 g

1000 mL H_2O contain A = 0.2 g

200 mL H_2O contain A $= \frac{0.2}{1000} \times 200 = 0.04$ g

∴ Wt. of soluble A = 0.04 g

and Wt. of insoluble A = 0.4 – 0.04 = **0.36 g Ans.**

(*b*) Total volume = 200 mL + 200 mL

= 400 mL

1000 mL water contain A = 0.2 g

∴ 400 mL water contain A $= \frac{0.2}{1000} \times 400 = 0.08$ g

∴ Wt. of undissolved A = 0.4 – 0.08 = **0.32 g Ans.**

Example 13. *If 0.1 g of I_2 [I_2 (aq) at equilibrium = 0.0011 mol L⁻ at 298 K] is stirred in 100 cm³ of water till equilibrium is reached, what will be the mass of iodine found in solution and the mass that is left undissolved ? After equilibrium is reached with 0.1 g of I_2 and 100 cm³ of water, we add 150 cm³ of water to the system. How much iodine will be dissolved and how much will be left undissolved and what will be the concentration of iodine in solution ?*

Solution. Wt. of I_2 = 0.1 g ;

g. molar mass of $I_2 = 2 \times 127 = 254$ g ;

solubility of $I_2 = 1.1 \times 10^{-3}\text{ mol L}^{-}$

$= 1.1 \times 10^{-3} \times 254 = 0.279\text{ g L}^{-}$

$= 0.279$ g per 1000 cm³

∴ Wt. of I_2 dissolved in 100 cm³

$$= \frac{0.279}{1000} \times 100 = 0.0279\text{ g}$$

∴ Wt. of undissolved I_2 in 100 cm³

= 0.1 – 0.0279 = 0.07 g

Total volume after equilibrium when 150 cm³ water is added

= 100 + 150 = 250 cm³

∴ Wt. of I_2 dissolved in 250 cm³ water

$$= \frac{0.279 \times 250}{1000} = 0.0698\text{ g}$$

∴ Wt. of undissolved I_2 = 0.1 – 0.0698 = **0.03 g Ans.**

Example 14. *At 299 K, the data of solubility of O_2 in water is given in the following table.*

Experiment	$[O_2\,(g)]_{eq}$ mol L^{-}	O_2 *pressure* (*k Pa*)	$[O_2\,(aq)]_{eq}$ mol L^{-}	$\frac{[O_2\,(aq)]_{eq}}{[O_2\,(g)]_{eq}}$
1	A	466.1	0.053	B
2	0.08	C	D	0.029
3	0.13	333.3	E	0.029

Calculate the value of A, B, C, D and E.

Solution. Experiment 1. (*a*) We know that

$$PV = n\,RT$$

or $P = \frac{n}{V}RT$ *i.e.*, $P = cRT$ or $c = \frac{P}{RT}$

$$\therefore \quad c = \frac{466.1\text{ k Pa}}{(8.314\text{ k Pa L K}^{-}\text{ mol}^{-}) \times 299\text{ K}}$$

$= 0.1875\text{ mol L}^{-}$

$\therefore \quad A = 0.1875 \text{ mol L}^-$

(*b*) $B = \dfrac{[O_2(aq)]_{eq}}{[O_2(g)]_{eq}} = \dfrac{0.053 \text{ mol L}^-}{0.1875 \text{ mol L}^-}$

$= \mathbf{0.28}$ **Ans.**

Experiment 2.

(*a*) $\dfrac{[O_2\,(aq)]_{eq}}{[O_2\,(g)]_{eq}} = 0.029\,;$

$\therefore \quad \dfrac{D}{0.08 \text{ mol L}^-} = 0.029$

$\therefore \quad D = 0.08 \times 0.029 = 0.002 \text{ mol L}^-$

(*b*) We know $P = C\,RT$ (see experiment 1)

$\therefore \quad P = 0.08 \text{ mol L}^- \times 8.314 \text{ k Pa L K}^- \text{mol}^- \times 299 \text{ K} = 198.9 \text{ k Pa}$

$\therefore \quad C = 198.9 \text{ k Pa}$

Experiment 3.

$\dfrac{[O_2(aq)]_{eq}}{[O_2(g)]_{eq}} = \dfrac{E}{0.13 \text{ mol L}^-} = 0.029\,;$

$\therefore \quad E = 0.13 \text{ mol L}^- \times 0.029$

$= \mathbf{0.0038 \text{ mol L}^-}$ **Ans.**

23.9 HENRY'S LAW

According to this law, the 'mass of a gas dissolved per unit volume of a solvent is directly proportional to the pressure of the gas in equilibrium with the solution at a given temperature. *i.e.*,

$$C = k\,P$$

where C = concentration of dissolved solute, k = constant characteristic of a particular solution and is called Henry's law constant, P = partial pressure of the gaseous solute above the solution.

Also, see section 17.11.

Example 15. *A soda-water bottle contains CO_2 gas at a pressure of 5 atm over the liquid at 298 K. If partial pressure of CO_2 in the atmosphere is 4×10^{-4} atm, what will be the equilibrium concentrations of CO_2 in soda-water both before and after the bottle is opened. The Henry's law constant for CO_2 in aqueous solution is 0.031 mol L^- atm^- at 298 K.*

Solution. (*a*) For sealed bottle, $P = 5$ atm ;

$k = 0.031 \text{ mol L}^- \text{atm}^-$

According to Henry's law,

$C = k\,P$

$\therefore \quad C = 0.031 \text{ mol L}^- \text{atm}^- \times 5 \text{ atm}$

$= 0.155 \text{ mol L}^-$

(*b*) For opened bottle, CO_2 (g) in the bottle comes in equilibrium with the atmospheric CO_2 gas. Thus

$P_{CO_2(g)} = 4 \times 10^{-4}$ atm.

According to Henry's law :

$C = k\,P\,;$

$C = 0.031 \text{ mol L}^- \text{atm}^- \times 4 \times 10^{-4} \text{atm}$

$= \mathbf{1.24 \times 10^{-5} \text{ mol L}^-}$ **Ans.**

Example 16. *At N.T.P., the solubility of a gas is 0.039 g L^-. At what pressure, its solubility will be 2.5 g L^-?*

Solution. $C_1 = 0.039 \text{ g L}^-$

$P_1 = 1$ atm

($\because$ at N.T. P., $P = 1$ atm, $T = 273$ K)

$C_2 = 2.5 \text{ g L}^-;\ P_2 = ?$

According to Henry's law :

$C_1 = k\,P_1;\ C_2 = k\,P_2$

or $\dfrac{C_1}{C_2} = \dfrac{P_1}{P_2}$

Hence : $\dfrac{0.039 \text{ g L}^-}{2.5 \text{ g L}^-} = \dfrac{1 \text{ atm}}{P_2}\,;$

$P_2 = \dfrac{2.5 \text{ g L}^- \times 1 \text{ atm}}{0.039 \text{ g L}^-}$

$= \mathbf{64.1 \text{ atm}}$ **Ans.**

Example 17. *A mixture of gases contains 40% A and 60% B at 25° C and 740 mm pressure. The solubilities of these gases A and B were found to be 0.0475 g L^- and 0.3 g L^- respectively at 0°C and one atmospheric pressure. Find the weight of each gas which dissolves when passed through 500 mL water at 25°C.*

Solution. (*i*) Partial pressure of gas A

$= \dfrac{40}{100} \times 740 = 296 \text{ mm}$

Partial pressure of gas B

$= \dfrac{60 \times 740}{100} = 444 \text{ mm}$

(*ii*) **To find solubility of gas, A.**

1000 mL (= 1L) of water at 760 mm contain,

A = 0.0475 g

Or 1000 mL of water will dissolve A at 296 mm pressure

$= \dfrac{0.0475 \text{ g L}^-}{760 \text{ mm}} \times 296 \text{ mm}$

$= 0.0185 \text{ g L}^-$

Or 500 mL of water will dissolve A

$= \dfrac{0.0185 \text{ g L}^-}{1000 \text{ mL}} \times 500 \text{ mL}$

$= 0.00925 \text{ gL}^-$

(*iii*) **To find solubility of gas, B**

1000 mL (= 1 L) of water at 760 mm contain,

$B = 0.3 \text{ g L}^-$

Or 1000 mL of water will dissolve B at 444 mm pressure

$= \dfrac{0.3 \text{ g L}^-}{760 \text{ mm}} \times 444 \text{ mm}$

$= 0.175 \text{ g L}^-$

Or 500 mL of water will dissolve B

$$= \frac{0.175 \text{ g L}^{-} \times 500 \text{ mL}}{1000 \text{ mL}}$$

$$= \mathbf{0.0875 \text{ g L}^{-}}$$

23.10 FINDING THE VALUE OF K_C AND K_P

Type. Calculation of K_c and K_p for homogeneous gaseous equilibrium reactions involving formation (or synthesis) of product with **change in volume** or having different number of mol of reactants and products.

In order to understand it, consider the synthesis of ammonia.

(*a*) **Determination of K_c**

	N_2	$+\ 3H_2 \rightleftharpoons$	$2NH_3$
Initial conc.	1 mol	3 mol	0
Conc. at equilibrium	$\frac{1-x}{V}$ mol	$\frac{3(1-x)}{V}$ mol	$\frac{2x}{V}$ mol

Let us start with one mol of N_2 and 3 mol of H_2 in a closed vessel of volume of 'V' litre.

V = Volume of the closed vessel in which reaction takes place; x = number of mol of N_2 and $3x$ are the number of mol of H_2 that are used up at equilibrium.

Molar concentrations at equilibrium are :

$$[N_2] = \frac{1-x}{V}; \ [H_2] = \frac{3(1-x)}{V};$$

$$[NH_3] = \frac{2x}{V}$$

Applying law of mass action, we get :

$$K_C = \frac{[NH_3]^2}{[N_2][H_2]^3} = \frac{\left(\frac{2x}{V}\right)^2}{\left(\frac{1-x}{V}\right)\left(\frac{3(1-x)}{V}\right)^3}$$

$$= \frac{4x^2}{V^2} \times \frac{V}{1-x} \times \frac{V^3}{27(1-x)^3}$$

$$\therefore \quad K_C = \frac{4x^2 V^2}{27(1-x)^4}$$

(*b*) **Determination of K_p.**

Total number of mol

$$= 1 - x + 3(1-x) + 2x$$

$$= 1 - x + 3 - 3x + 2x = \mathbf{4 - 2x}$$

Let P = Total pressure of the system

Molar concentrations at equilibrium are :

$$p_{N_2} = \frac{(1-x)P}{4-2x}; p_{H_2} = \frac{(3-3x)P}{4-2x};$$

$$p_{NH_3} = \frac{2xP}{4-2x}$$

$$\therefore \quad K_p = \frac{(p_{NH_3})^2}{(p_{N_2})(p_{H_2})^3}$$

$$= \frac{\left(\frac{2xP}{4-2x}\right)^2}{\left(\frac{(1-x)P}{4-2x}\right)\left(\frac{3-3x}{4-2x}\cdot P\right)^3}$$

$$= \frac{4x^2P^2}{(4-2x)^2} \times \frac{4-2x}{(1-x)P} \times \frac{(4-2x)^3}{(3-3x)^3 \cdot P^3}$$

$$= \frac{4x^2P^2}{4(2-x)^2} \times \frac{2(2-x)}{(1-x)P} \times \frac{8(2-x)^3}{27(1-x)^3 p^3}$$

$$= \frac{16x^2(2-x)^2}{27P^2(1-x)^4}$$

23.11 FORMATION OF NH_3

Example 18. *A closed vessel contains a mixture of N_2 (g) and H_2 (g) initially in the ratio 1 : 3 at 573 K and 30 atmosphere. If % age of NH_3 (g) by volume at equilibrium is 17.8, find the value of K_p of $N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$ reaction.*

Solution. Given :

	$N_2(g) +$	$3H_2(g) \rightleftharpoons$	$2NH_3(g)$
Initial Conc.	1 mol	3 mol	0
Conc. at equilibrium	$1-x$	$3-3x$	$2x$

($\because$ x = degree of dissociation)

Total number of moles

$$= 1 - x + 3 - 3x + 2x = 4 - 2x.$$

Since percentage by volume of NH_3 (g) is same as percentage by mole,

$$\frac{2x}{4-2x} = \frac{17.8}{100} \text{ i.e., } 0.178;$$

Or $100 \times 2x = 17.8(4-2x)$ **Or** $200x = 71.2 - 35.6x$

$\therefore$ $200x + 35.6x = 71.2$

Or $x = \frac{71.2}{235.6} = \mathbf{0.302}$

Mole fraction of N_2 (x_{N_2}) at equilibrium

$$= \frac{1-x}{4-2x} = \frac{1-0.302}{4-(2\times 0.302)}$$

$$= \frac{0.698}{3.396} = \mathbf{0.2055}$$

Mole fraction of H_2 i.e., $[x_{H_2}]$ at equilibrium

$$= \frac{3-3x}{4-2x} = \frac{3-(3\times 0.302)}{4-(2\times 0.302)}$$

$$= \frac{2.094}{3.396} = \mathbf{0.6166}$$

Hence, $K_p = \frac{(x_{NH_3} \times P_T)^2}{(x_{N_2} \times P_T) \times (x_{H_2} \times P_T)^3}$

$$= \frac{(0.178 \times 30)^2}{(0.2055 \times 30) \times (0.6166 \times 30)^3}$$

$$= \frac{28.5156}{6.165 \times 6329.57}$$

$\therefore$ K_p = **7.307 × 10^{-4}** **Ans.**

> **Note.** We have taken initial moles of N_2 and H_2 as 1 and 3 respectively. This assumption is valid because K_p will not depend upon the exact number of moles of N_2 and H_2. We can even start with x and $3x$ moles of N_2 and H_2 respectively.

EXAMPLE 19. *One mol of N_2 is mixed with 3 mol of H_2 in a 4 litre container. If 0.0025 mol of N_2 is converted to ammonia by the following reaction*

$$N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$$

calculate the value of K_c in concentration units. What will be the value of K_c for the following equilibrium.

$$\frac{1}{2}N_2(g) + \frac{3}{2}H_2(g) \rightleftharpoons NH_3(g)$$

(IIT 1981, ISC 1989)

SOLUTION. Mol of N_2 converted to NH_3

= 0.0025 ;

Volume of container = 4 L ;

mol of N_2 = 1; mol of H_2 = 3

Given reaction is :	$N_2(g)$ +	$3H_2(g)$ $\rightleftharpoons$	$2NH_3(g)$
Initial conc.	1 mol	3 mol	0
Conc. at equilibrium	$\frac{1-\alpha}{4}$	$\frac{3-\alpha}{4}$	$\frac{2 \times 0.0025}{4}$

[$\because V = 4L$]

(*i*)
$$K_c = \frac{[NH_3]^2}{[N_2][H_2]^3} = \frac{\left(\frac{2 \times 0.0025}{4}\right)^2}{\left(\frac{1-\alpha}{4}\right) \times \left(\frac{3-\alpha}{4}\right)^3}$$

Since α is very small, it is neglected in the denominator. Thus :

$$K_c = \frac{\left(\frac{2 \times 0.0025}{4}\right)^2}{\frac{1}{4} \times \frac{3}{4} \times \frac{3}{4} \times \frac{3}{4}}$$

$$= \frac{\frac{2 \times 0.0025}{4} \times \frac{2 \times 0.0025}{4} \times \frac{4 \times 4 \times 4 \times 4}{1}}{3 \times 3 \times 3}$$

= **1.48 × 10^{-5} atm^2 mol^{2-}**

(*ii*) For the reaction $\frac{1}{2}N_2(g) + \frac{3}{2}H_2(g) \rightleftharpoons NH_3(g)$, we have :

$$K_c = \frac{[NH_3]}{[N_2]^{1/2}[H_2]^{3/2}} = \frac{\frac{0.0025 \times 2}{4}}{\left(\frac{1}{4}\right)^{1/2}\left(\frac{3}{4}\right)^{3/2}}$$

$$= \frac{\frac{0.0025}{2}}{\frac{1}{2} \times \left(\frac{3}{4} \times \frac{3}{4} \times \frac{3}{4}\right)^{1/2}}$$

$$= \frac{0.0025}{2} \times \frac{2}{1} \times \left(\frac{4 \times 4 \times 4}{3 \times 3 \times 3}\right)^{1/2}$$

$$= \frac{0.0025}{2} \times \frac{2}{1} \times \frac{8}{5.196}$$

= 3.85 ×10^{-3} L mol^{-}

EXAMPLE 20. *Calculate the equilibrium concentration of NH_3 after 2 mol of N_2 and 3 mol of H_2 are placed in a 1 L vessel and are allowed to achieve equilibrium. K = 0.444 for the formation of NH_3.*

SOLUTION.	N_2 +	$3H_2$ $\rightleftharpoons$	$2NH_3$
(*i*) *n* mol at start	2	3	0
(*ii*) *n* mol produced	–	–	$2x$
(*iii*) *n* mol used up	$-x$	$-3x$	–
(*iv*) *n* mol at equilibrium	$2-x$	$3-3x$	$2x$

$$K_p = \frac{[NH_3]^2}{[N_2][H_2]^3}; \; 0.444 = \frac{(2x)^2}{(2-x)(3-3x)^3}$$

On solving and ignoring x^2 and x^3 from the denominator, we get:

$$0.444 = \frac{4x^2}{27(2-x)(1-3x)}; \; 4x^2 + 84 - 24 = 0$$

$$\therefore \quad x = \frac{-84 \pm \left[(84)^2 - (4 \times 4 \times -24)\right]^{1/2}}{2 \times 4}$$

= **0.275;**

$2x$ = 2 × 0.275 = **0.55.**

EXAMPLE 21. (*a*) *If helium gas is added to a system containing N_2, H_2 and NH_3 gases, what effect helium gas will have on the partial pressure of each gas ?*

(*b*) *What effect, will the added helium gas have on the position of equilibrium ?*

SOLUTION. Helium gas is an inert gas. So, it will have no effect on the partial pressures of each gas present and (*b*) it does not effect the position of following equilibrium.

$$K_p = \frac{p(NH_3)^2}{p(N_2) \times p(H_2)^3}$$

$$\left[\because N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)\right]$$

EXAMPLE 22. *For the reaction $\frac{1}{2}N_2 + \frac{3}{2}H_2 \rightleftharpoons NH_3$ the value of equilibrium constant at 500°C is 3.9 × 10^{-3} (atm)$^{-}$. If sufficient ammonia is added into an evacuated container at 500°C to give a pressure of 1 atm before any decomposition occurred, calculate the partial pressures of N_2, H_2 and NH_3 at equilibrium?*

SOLUTION.	$\frac{1}{2}N_2$ +	$\frac{3}{2}H_2$ $\rightleftharpoons$	NH_3
(*i*) *n* mol at start	0	0	1

(*ii*) n mol used	–	–	$1-x$
(*iii*) n mol produced	$\frac{1-x}{2}$	$\frac{(3-3x)}{2}$	
– (*iv*) n mol at equilibrium	$0.5-\frac{x}{2}$ $\simeq 0.5$	$1.5-\frac{3x}{2}$ $\simeq 1.5$	x

$$K_p = \frac{p\,(NH_3)}{p\,(N_2)^{1/2}\;p\,(H_2)^{3/2}}\;;$$

$$3.9\times10^{-3} = \frac{x}{(0.5)^{1/2}\,(1.5)^{3/2}}$$

$$3.9\times10^{-3} = \frac{x}{(0.5)^{1/2}\,\sqrt{(1.5)^3}} = \frac{x}{0.707\times\sqrt{3.375}}$$

$$= \frac{x}{0.707\times1.837} = \frac{x}{1.3}$$

$$\therefore \quad x = 3.9\times10^{-3}\times1.3 = 5.07\times10^{-3}\text{ atm}$$

$$= 0.00507\text{ atm}$$

$$\therefore \quad p_{(NH_3)} = x = 5.07\times10^{-3}\text{ atm}\;;$$

$$p_{N_2} = 0.5-\frac{0.00507}{2} = 0.5-0.0025$$

$$= 0.498\text{ atm};$$

$$p_{H_2} = 1.5\text{ atm}$$

EXAMPLE 23. *Assuming that for the reaction*

$$3H_2(g) + N_2(g) \rightleftharpoons 2NH_3(g)$$

Δ S is independent of temperature and heat capacities of $H_2(g)$, $N_2(g)$ and $NH_3(g)$ do not vary with temperature, calculate the minimum temperature at which this reaction will occur spontaneously with all reactants at unit activity. [ΔH_f° *(NH_3) = –11.04 k cal ; S° (NH_3) = 192.5 J, S° (H_2) = 130.57 J and S° (N_2) = 191 J.*]

SOLUTION. For

$$3H_2(g) + N_2(g) \rightleftharpoons 2NH_3(g)$$

$$\Delta H = 2\,\Delta H_f^\circ\,(NH_3) - 3\,\Delta H_f^\circ\,(H_2) - \Delta H^\circ_f(N_2)$$

$$= (2\times-11.04\text{ k cal}) - (3\times0) - 0$$

$$= -22.08\text{ k cal}$$

$$= -22.08\times4.148\text{ k J} = -92.38\text{ k J}$$

[∵ 1 k cal = 4.184 k J]

$$\Delta S = 2\,S^\circ\,(NH_3) - 3\,S^\circ\,(H_2) - S^\circ\,(N_2)$$

$$= (2\times192.5\text{ J}) - 3\,(130.57\text{ J}) - 191\text{ J}$$

$$= 385.0 - 391.71 - 191$$

$$= -197.7\text{ J K}^-$$

To find minimum temperature, at which the reaction occurs spontaneously:

$$\Delta G = \Delta H - T\,\Delta S = 0 \textbf{ Or } \Delta H - T\,\Delta S = 0$$

$$\therefore \quad \Delta H = T\,\Delta S \text{ or } T = \frac{\Delta H}{\Delta S} = \frac{-92.38k\,J}{-197.7\,J}$$

$$= \frac{-92.38\times1000\,J}{-197.7\,J}$$

$$\therefore \quad T = \mathbf{467.3\ K} \qquad \textbf{Ans.}$$

EXAMPLE 24. *When a mixture of nitrogen and hydrogen in the volume ratio of 1 : 3 is allowed to attain equilibrium at 400°C and 1000 atm., 0.2491 mole fraction of ammonia is formed. Calculate the equilibrium constant for the above reaction at the experimental temperature and pressure.* **(Kerala, 1968)**

SOLUTION.	N_2 +	$3H_2$ $\rightleftharpoons$	$2NH_3$
(*i*) n mol at start	1	3	0
(*ii*) change by reaction	$-x$	$-3x$	$2x$
(*iii*) n mol at equilibrium	$1-x$	$3-3x$	$2x$

Total number of mol at equilibrium

$$= 1-x+3-3x+2x = 4-2x$$

$$K_p = \frac{p_{(NH_3)^2}}{p_{N_2}\times p_{(H_2)^3}}$$

$$= \frac{\left(\frac{2x}{4-2x}\times P\right)^2}{\left(\frac{1-x}{4-2x}\times P\right)\left(\frac{3-3x}{4-2x}\times P\right)^3}$$

$$= \frac{\frac{4x^2P^2}{(4-2x)^2}}{\frac{(1-x)P}{4-2x}\times\left[\frac{3\,(1-x)}{4-2x}\right]^3}$$

$$= \frac{4x^2\,P^2}{(4-2x)^2}\times\frac{4-2x}{(1-x)P}\times\frac{(4-2x)^3}{27(1-x)^3P^3}$$

$$K_p = \frac{4x^2\,(4-2x)^2}{27(1-x)^4\times P^2} \qquad \text{...(1)}$$

$$\left[\begin{array}{l}\because \text{ for } ax^2+bx+c=0\\ x = \dfrac{-b\pm(b^2-4ac)^{1/2}}{2a}\end{array}\right.$$

But P = 1000 atm and

mole fraction of NH_3

$$= \frac{2x}{4-2x} = 0.2491$$

$$\therefore \quad \frac{2x}{4-2x} = 0.2491\;;$$

$$2x = 0.2491\,(4-2x) = 0.9964 - 0.4982x$$

Or $2x + 0.4982x = 0.9964$; $2.4982x = 0.9963$; $x = 0.4$

Substituting the values of x and P in equation (1), we get :

$$K_p = \frac{4\times(0.4)^2\,[4-(2\times0.4)]^2}{27\,(1-0.4)^4\times(1000)^2}$$

$$= \frac{4\times0.16\times(4-0.8)^2}{27\,(0.6)^4\,(1000)^2}$$

$$= \frac{4\times0.16\times(3.2)^2}{27\,(0.6)^4\,(1000)^2}$$

$$= \frac{6.5536}{27 \times 0.1296 \times 1000000}$$

$$= \mathbf{1.9 \times 10^{-6}}$$ **Ans.**

EXAMPLE 25. *Calculate the value of equilibrium constant, K_c for the reaction*

$$N_2 + 3H_2 \rightleftharpoons 2NH_3$$

from the following data.

Nitrogen and hydrogen are added to a 5 litre flask under pressure. The flask was sealed and heated. The equilibrium mixture contained 18.5 g NH_3, 0.15 g H_2 and 3.3 g N_2

SOLUTION. (*a*) Wt. of N_2 = 3.3 g ;

g. mol. wt. of N_2 = 2 × 14 = 28 g

∴ number of mol of N_2

$$= \frac{3.3}{28} = 0.118\ ; \quad [N_2] = \frac{0.118 \text{ mol}}{5\text{L}}$$

(*b*) Wt. of H_2 = 0.15 g ;

g. mol. wt. of H_2

$$= 2 \times 1 = 2\text{g}$$

∴ number of mol of H_2

$$= \frac{0.15}{2} = 0.075\ ; \quad [H_2] = \frac{0.075 \text{ mol}}{5\text{L}}$$

(*c*) Wt. of NH_3 = 18.5 g ;

g. mol. wt. of NH_3

$$= 14 + (3 \times 1) = 17 \text{ g}$$

∴ number of mol of NH_3

$$= \frac{18.5}{17} = 1.09\ ; \quad [NH_3] = \frac{1.09 \text{ mol}}{5\text{L}}$$

∴ For the reaction, $N_2 + 3H_2 \rightleftharpoons 2NH_3$

$$K_c = \frac{(NH_3)^2}{[N_2][H_2]^3}$$

$$= \frac{\left(\dfrac{1.09 \text{ mol L}^{-}}{5}\right)^2}{\left(\dfrac{0.118 \text{ mol L}^{-}}{5}\right)\left(\dfrac{0.075 \text{ mol L}^{-}}{5}\right)^3}$$

$$= \frac{1.09 \text{ mol}^2 \text{ L}^{-2}}{25} \times \frac{5}{0.118 \text{ mol L}^{-}} \times \frac{125}{0.000422 \text{ mol}^3 \text{ L}^{-3}}$$

$$= 5.97 \times 10^5$$

∴ $$K_c = \mathbf{5.97 \times 10^5 \text{ mol}^{-2} \text{ L}^2}$$ **Ans.**

EXAMPLE 26. *A mixture of 1 mol of N_2 and 3 mol of H_2 react under a constant pressure of 100 atm to form 0.5 mol NH_3 at equilibrium. Calculate K_p for the reaction*

$$\frac{1}{2}N_2 + \frac{3}{2}H_2 \rightleftharpoons NH_3$$

at the same temperature.

SOLUTION.

	$\frac{1}{2}N_2$ +	$\frac{3}{2}H_2 \rightleftharpoons$	NH_3
(*i*) *n* mol at start	1	3	0
(*ii*) change by reaction	$0.5 \times \frac{1}{2}$ = 0.25	$0.5 \times \frac{3}{2}$ = 0.75	–
(*iii*) *n* mol at equilibrium	1 – 0.25 = 0.75	3 – 0.75 = 2.25	0.5

Total number of mol at equilibrium

$$= 0.75 + 2.25 + 0.5 = 3.5$$

Partial pressure of N_2 (p_{N_2})

$$= \text{mole fraction of } N_2 \times 100$$

$$= \frac{0.75}{3.5} \times 100 = 21.4 \text{ atm.}$$

Partial pressure of H_2 (p_{H_2})

$$= \text{mole fraction} \times 100$$

$$= \frac{2.25}{3.5} \times 100 = 64.3$$

Partial pressure of NH_3 (P_{NH_3})

$$= \text{mole fraction} \times 100$$

$$= \frac{0.5}{3.5} \times 100 = 14.3$$

∴ $$K_p = \frac{p_{NH_3}}{(p_{N_2})^{1/2}\,(p_{H_2})^{3/2}}$$

$$= \frac{14.3}{(21.4)^{1/2} \times \sqrt{(64.3)^3}}$$

$$= \frac{14.3}{4.63 \times \sqrt{265{,}848}}$$

$$K_p = \frac{14.3}{4.63 \times 515.6} = \mathbf{0.00599}$$ **Ans.**

EXAMPLE 27. *For the gas reaction $N_2 + 3H_2 \rightleftharpoons 2NH_3$ the partial pressures of H_2 and N_2 are 0.4 and 0.8 atm respectively. The total pressure of the entire system is 2.8 atm. What will be the value of K_p if all the concentrations are given in atmospheres.* **(MLNR, 1989)**

SOLUTION.

	N_2 +	$3H_2 \rightleftharpoons$	$2NH_3$
(*i*) Pressure (atm) at start	0.8	0.4	0
(*ii*) Change by reaction	–	–	2.8 – (0.4 + 0.8) = 2.8 – 1.2 = 1.6
(*iii*) Pressure (atm) at equilibrium	0.8	0.4	1.6

$$K_p = \frac{P_{(NH_3)^2}}{P_{N_2} \times P(H_2)^3} = \frac{(1.6)^2}{0.8 \times (0.4)^3}$$

$$= \frac{2.56}{0.0512}$$

$$= \mathbf{50}$$ **Ans**

EXAMPLE 28. *At 773 K, the value of equilibrium constant for $N_2 + 3H_2 \rightleftharpoons 2NH_3$ reaction is 6.4×10^{-2}. If the reaction is started with 1 mol of H_2 and 1 mol of N_2 in a 2L flask at 473K, calculate the concentration of each component in the given reaction.*

SOLUTION. $\qquad N_2 \quad + \quad 3H_2 \rightleftharpoons 2NH_3$

(*i*) n mol L^{-} at start $\quad \frac{1}{2} = 0.5 \quad \frac{1}{2} = 0.5 \quad -$

[∵ Volume = 2L]

(*ii*) change by reaction $\quad -0.5x \quad -0.5x \times 3 = -1.5x \quad 2 \times 0.5x = x$

(*iii*) n mol L^{-} at equilibrium $\quad 0.5 - 0.5x \quad 0.5 - 1.5x \quad x$

$$\therefore \quad K_P = \frac{[NH_3]^2}{[N_2][H_2]^3};$$

$$6.4 \times 10^{-2} = \frac{x^2}{(0.5 - 0.5x)(0.5 - 1.5x)^3}$$

On solving, we get

$$x = 4.9 \times 10^{-2} \text{ mol L}^{-}$$

$$\therefore \quad [N_2] = 0.5 - 0.5x = 0.5 - 0.5 \times 4.9 \times 10^{-2}$$

$$= 0.5 - 0.024 = 0.476 \text{ mol L}^{-}$$

$$[H_2] = 0.5 - 1.5x = 0.5 - 1.5 \times 4.9 \times 10^{-2}$$

$$= 0.5 - 0.073$$

$$= 0.427 \text{ mol L}^{-}$$

$$[NH_3] = x = \mathbf{4.9 \times 10^{-2} \text{ mol L}^{-}}$$

EXAMPLE 29. *One mol of N_2 was treated with 3 mol of H_2 to get ammonia. At 500°C and 10 atm pressure, the mole fraction of NH_3 was 0.012. Find K_p. Also, calculate the pressure at which the mol % of NH_3 will be 10.4 at the same temperature.*

SOLUTION. $\qquad N_2 \quad + \quad 3H_2 \rightleftharpoons 2NH_3$

	N_2	$3H_2$	$2NH_3$
(*i*) n mol at start	1	3	0
(*ii*) Change by reaction	$-x$	$-3x$	$2x$
(*iii*) n mol at equilibrium	$1 - x$	$3 - 3x$	$2x$

Total number of mol at equilibrium

$$= 1 - x + 3 - 3x + 2x = 4 - 2x$$

∴ Mol fraction of NH_3

$$= \frac{2x}{4-2x}; \; 0.012 = \frac{2x}{4-2x};$$

$$0.012(4 - 2x) = 2x$$

$$0.048 - 0.024x = 2x \textbf{ Or } 2x + 0.024x = 0.048;$$

$$2.024x = 0.048; \therefore x = \frac{0.048}{2.024}$$

Or $\qquad x = 0.237; p = 10$ atm.

$$(a) \therefore \quad K_p = \frac{p_{(NH_3)^2}}{p_{N_2} \times p_{(H_2)^3}}$$

$$= \frac{\left(\frac{2x}{4-2x} \times P\right)^2}{\left(\frac{1-x}{4-2x} \times P\right)\left(\frac{3-3x}{4-2x} \times P\right)^3}$$

$$= \frac{4x^2(4-2x)^2}{P^2(1-x)(3-3x)^3}$$

$$\therefore \quad K_p = \frac{4 \times (0.0237)^2 [4 - (2 \times 0.0237)]^2}{(10)^2 (1 - 0.0237)[3 - 3(0.0237)]^3}$$

$$= \frac{4 \times 5.617 \times 10^{-4} \times (4 - 0.0474)^2}{100 \times 0.976 \times (3 - 0.0711)^3}$$

$$= \frac{4 \times 5.617 \times 10^{-4} \times (3.953 \times 3.953)}{100 \times 0.976 \times (2.93)^3}$$

$$= \frac{0.0351}{2455}$$

$$= \mathbf{1.43 \times 10^{-5} \text{ atm}}$$

(*b*) $\qquad N_2 \quad + \quad 3H_2 \rightleftharpoons 2NH_3$

	N_2	$3H_2$	$2NH_3$
(*i*) n mol at start	1	3	0
(*ii*) Change by reaction	$-x$	$-3x$	$2x$
(*iii*) n mol at equilibrium	$1 - x$	$3 - 3x$	$2x$

Total number of mol at equilibrium

$$= 1 - x + 3 - 3x + 2x = 4 - 2x$$

$$\therefore \text{ Mole fraction of } NH_3 = \frac{2x}{4-2x};$$

$$\therefore \quad \frac{2x}{4-2x} = 10.4\,\% = \frac{10.4}{100} = 0.104$$

Or $\qquad 2x = 0.104(4 - 2x);$

$$2x = 0.416 - 0.208x;$$

$$2x + 0.208x = 0.416; \; 2.208x = 0.416;$$

$$\therefore \quad x = \frac{0.416}{2.208} = 0.188$$

But $\qquad K_p = \dfrac{p_{(NH_3)^2}}{p_{N_2} \times p_{(H_2)^3}};$

$$1.43 \times 10^{-5} = \frac{4x^2(4-2x)^2}{P^2(1-x)(3-3x)^3}$$

$$1.43 \times 10^{-5} = \frac{4 \times (0.188)^2 (4 - (2 \times 0.188)^2)}{P^2 (1 - 0.188)[3 - (3 \times 0.188)]^3}$$

$$= \frac{4 \times 0.0353 \times 3.624 \times 3.624}{P^2 \times 0.812 \times 2.436 \times 2.436 \times 2.436}$$

$$= \frac{1.854}{P^2 \times 11.738};$$

Or $\qquad P^2 = \dfrac{1.854}{11.738 \times 1.43 \times 10^{-5}} = 11045.35$

$$\therefore \quad P = \sqrt{11045.35} = \mathbf{105.1 \text{ atm.}} \qquad \textbf{Ans.}$$

EXAMPLE 30. *In an experiment, the concentrations of different species at 1000 K are $[N_2] = 1.1$ mol dm^{-3}, $[H_2] = 1.5$ mol dm^{-3}, $[NH_3] = 0.105$ mol dm^{-3}. Calculate (i) K_c and K_p for $N_2 + 3H_2 \rightleftharpoons 2NH_3$ (ii) K_c for $2NH_3 \rightleftharpoons N_2 + 3H_2$ reaction.*

Solution. (*a*) $N_2 + 3H_2 \rightleftharpoons 2NH_3$ ...(*i*)

n mol dm^{-3} at equilibrium 1.1 1.5 0.105

$$\therefore \quad K_c = \frac{[NH_3]^2}{[N_2][H_2]^3}$$

$$= \frac{(0.105)^2 \text{ mol}^2 \text{ dm}^{-6}}{1.1 \text{ mol dm}^{-3} \times (1.5)^3 \text{ mol}^3 \text{ dm}^{-9}}$$

$$K_c = \frac{0.011}{1.1 \times 3.375} \text{mol}^{-2} \text{ dm}^6$$

$$= 2.96 \times 10^{-3} \text{ mol}^{-2} \text{ dm}^6$$

But $K_p = K_c (RT)^{\Delta n}$

In reaction (1),

$$\Delta n = 2 - (1 + 3) = -2 ;$$

$$R = 0.0821 \text{ atm dm}^3 \text{ K}^- \text{mol}^-, T = 1000 \text{ K}$$

$$\therefore \quad K_p = 2.96 \times 10^{-3} \text{ mol}^{-2} \text{ dm}^6 (0.0821 \text{ atm dm}^3 \text{ K}^- \text{ mol}^- \times 1000 \text{ K})^{-2}$$

$$= \frac{2.96 \times 10^{-3} \text{ mol}^{-2} \text{ dm}^6}{(0.0821 \text{ atm dm}^3 \text{ K}^- \text{ mol}^- \times 1000 \text{ K})^2}$$

$$= \frac{2.96 \times 10^{-3} \text{ mol}^{-2} \text{ dm}^6}{6740.41 \text{ atm}^2 \text{ dm}^6 \text{ K}^{-2} \text{ mol}^{-2} \text{ K}^2}$$

$$= \mathbf{4.39 \times 10^{-7} \text{ atm}^{-2}}$$ **Ans.**

(*b*) For reverse,

$$2NH_3 \rightleftharpoons N_2 + 3H_2,$$

$$K_c' = \frac{1}{K_c} = \frac{1}{2.96 \times 10^{-3} \text{ mol}^{-2} \text{ dm}^6}$$

$$= \mathbf{337.8 \text{ mol}^2 \text{ dm}^{-6}}$$ **Ans.**

23.12 EFFECT OF TEMPERATURE ON THE VALUE OF EQUILIBRIUM CONSTANT

Temperature effect. The magnitude of equilibrium constant changes with change in temperature. Let K_1 and K_2 are the equilibrium constant values for a reversible reaction at temperatures T_1 and T_2 respectively. Then, according to Arrhenius equation :

$$\log \frac{K_2}{K_1} = \frac{\Delta H°}{2.303 \text{ R}} \left[\frac{1}{T_1} - \frac{1}{T_2} \right] \quad ... (1)$$

It is the integrated form of van't Hoff isochore for two temperatures.

Or $K = Ae^{-\Delta H°/RT}$ (for one temperature only)

Where K is equilibrium constant, T is absolute temperature, $\Delta H°$ is heat of reaction, A is frequency factor while R is molar gas constant.

From the above relation (1), it is clear that :

1. If $T_2 > T_1$, ΔH = +ve. Hence, $\log_{10} \frac{K_2}{K_1}$ = +ve i.e., $\log_{10} K_2 > \log_{10} K_1$ or $K_2 > K_1$. Hence for endothermic reactions, equilibrium constant increases with increase in temperature.

2. If $T_2 < T_1$, ΔH = –ve. Hence, log10 $\frac{K_2}{K_1}$ = –ve i.e., $\log_{10} K_2 < \log_{10} K_1$ or $K_2 < K_1$. Hence for exothermic reactions, the equilibrium constant decreases with increase in temperature.

Type. Use the relation,

$$\log K_{P_2} - \log K_{P_1} = \frac{\Delta H}{2.303 R} \left[\frac{T_2 - T_2}{T_1 T_2} \right]$$

Example 31. *At 673 K, the equilibrium constant value for the reaction :*

$$N_2 + 3H_2 \rightleftharpoons 2NH_3$$

is 1.64 × 10^{-4} atm. Calculate K_p at 500°C if the heat of reaction for this temperature range is – 105.2 k J.

Solution. $T_1 = 673 \text{ K} ; T_2 = 500 + 273 = 773 \text{ K} ;$

$$\Delta H = -105.2 \times 1000 \text{ J} = -105200 \text{ J} ;$$

$$K_{p_1} = 1.64 \times 10^{-4} \text{ atm} ;$$

$$K_{p_2} = ? ; R = 8.314 \text{ J K}^-$$

we know :

$$\log K_{p_2} - \log K_{p_1} = \frac{\Delta \text{H}}{2.303 \text{ R}} \left[\frac{T_2 - T_1}{T_1 T_2} \right];$$

$$\log K_{p_2} = \log K_{p_1} + \frac{\Delta \text{H}}{2.303 R} \left[\frac{T_2 - T_1}{T_1 T_2} \right]$$

$$\therefore \quad \log K_{p_2} = \log (1.64 \times 10^{-4}) + \frac{-105200}{2.303 \times 8.314} \left[\frac{773 - 673}{773 \times 673} \right]$$

$$= \log 1.64 + (-4) \log 10 - \left(\frac{105200}{19.147} \times \frac{100}{520.229} \right)$$

$$\log K_{p_2} = 0.2148 - 4 - 1.056$$

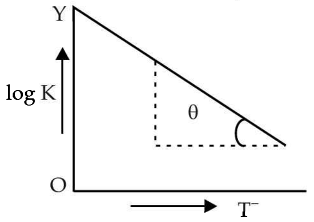
$$= -4.8412 = -4 - 1 + 1 - 0.8412 = \bar{5}.1588$$

$$\therefore \quad K_{p_2} = \text{antilog } \bar{5}.1588 = \mathbf{1.44 \times 10^{-5} \text{ atm}}$$ **Ans.**

Example 32. *According to van't Hoff equation,*

$$\log K = \log A - \frac{\Delta H°}{2.303 \, RT}$$

when a graph is drawn between log K and T$^-$, a straight line was obtained (See Fig below). If tan θ is 0.5 and OY is 10, then find the value of equilibrium constant, K at 298 K and value of K at 700 K if ΔH° is assumed to be independent of temperature.



Solution. (*i*) Since graph is a straight line,

$$\text{slope}, -\tan \theta = \frac{-\Delta H°}{2.303 R} \text{ Or } -0.5 = \frac{-\Delta H°}{2.303 \times 8.314}$$

Hence : $\Delta H° = 0.5 \times 2.303 \times 8.314 \text{ J mol}^-$

$$= 9.574 \text{ J mol}^-.$$

Also, intercept = log A = OY = 10 (given). Thus :

$$\log K = \log A - \frac{\Delta H°}{2.303\,RT};$$

$$\log K = 10 - \frac{9.574}{2.303 \times 8.314 \times 298}$$

$$= 10\,(1.68 \times 10^{-3})$$

$$\log K = 9.998;$$

$$K = \text{antilog } 9.998 = \mathbf{9.95 \times 10^{9}} \qquad \textbf{Ans.}$$

(*ii*) To find *K* at 700 *K*. we have :

$$\log \frac{K_2}{K_1} = \frac{\Delta H°}{2.303\,R}\left[\frac{T_2 - T_1}{T_1\,T_2}\right];$$

$$\log \frac{K_2}{9.95 \times 10^{9}} = \frac{9.574}{2.303 \times 8.314}\left[\frac{700 - 298}{298 \times 700}\right]$$

$$\log K_2 - \log 9.95 \times 10^{9}$$

$$= 9.6 \times 10^{-4}$$

$$\log K_2 = \log 9.95 + \log 10^{9} + 9.6 \times 10^{-4}$$

$$= 0.9978 + 9 + 9.6 \times 10^{-4}$$

$$= 9.9987$$

$$\therefore \quad K_2 = \text{antilog } 9.9987 = \mathbf{9.97 \times 10^{9}} \qquad \textbf{Ans.}$$

Type. To find K_c or K_p, use the relation

$$K_p = K_c\,(RT)^{\Delta n}$$

where Δn = (no. of mol of products) – (no. of mol of reactants)

$$R = 8.31\ \text{J mol}^{-}\,\text{K}^{-} = 8.31\ \text{k Pa L mol}^{-}\,\text{K}^{-}$$

$$= 0.0831\text{L bar mol}^{-}\,\text{K}^{-}$$

$$\simeq 0.0831\ \text{L atm mol}^{-}\,\text{K}^{-}$$

$$\simeq 0.082\ \text{L atm mol}^{-}\,\text{K}^{-}$$

EXAMPLE 33. *For the following gaseous reaction*

$$2Cl_2(g) + 2H_2O(g) \rightleftharpoons O_2(g) + 4HCl\,(g)$$

the value of K_p *at 673 K is 0.035 atmosphere. Find the value of* K_c *for* $\frac{1}{2}O_2\,(g) + 2HCl\,(g) \rightleftharpoons Cl_2(g) + H_2O(g)$ *(R = 0.082 L atm mol⁻K⁻)*

SOLUTION. For

$$\begin{array}{lcccc} 2Cl_2(g) & + 2H_2O\,(g) & \rightleftharpoons O_2(g) & + 4HCl\,(g) & \quad ...(1) \\ 2\text{ mol} & 2\text{ mol} & 1\text{ mol} & 4\text{ mol} & \end{array}$$

$$\Delta n = (1 + 4) - (2 + 2) = 1\text{ mol};\ T = 673\text{ K}.$$

$$K_p = K_c\,(RT)^{\Delta n}$$

Or $\quad 0.035\text{ atm} = K_c\,(0.082\text{ L atm} \times 673\text{ K})^{1}$

$$\therefore \quad K_c = \frac{0.035\text{ atm}}{0.082\text{ L atm mol}^{-}\,\text{K}^{-} \times 673\text{ K}}$$

$$= 6.342 \times 10^{-4}\text{ mol L}^{-}$$

The other given reaction is reverse of reaction (1)

(*i*) So, $\quad K'_c = \dfrac{1}{K_c} = \dfrac{1}{6.342 \times 10^{-4}\text{ mol L}^{-}}$

$$= 1576.8\text{ L mol}^{-}$$

Also, the other reaction, $\frac{1}{2}O_2\,(g) + 2\,HCl\,(g) \rightleftharpoons Cl_2\,(g) + H_2O\,(g)$ is obtained by dividing the coefficients of reaction (1) by 2, the new equilibrium constant K'_c will be the square root of the value of K_c. Hence :

$$K'_c = (1576.8\text{ L mol}^{-})^{1/2}$$

$$= \mathbf{39.7\ (L\ mol^{-})^{1/2}} \qquad \textbf{Ans.}$$

EXAMPLE 34. *The concentration equilibrium constant* K_c*, for the reaction,* $N_2 + 3H_2 \rightleftharpoons 2NH_3$ *at 673 K is 0.5. Find* K_p*. (R = 0.082 L atm K⁻ mol⁻)* **(MLNR 1996)**

SOLUTION. For

$$\begin{array}{ccccc} N_2 & + & 3\,H_2 & \rightleftharpoons & 2\,NH_3 \\ 1\text{ mol} & & 3\text{ mol} & & 2\text{ mol} \end{array}$$

$$\Delta n = 2 - (1 + 3) = -2$$

$$R = 0.082\text{ L atm K}^{-}\,\text{mol}^{-};\ T = 673\text{ K};$$

$$K_c = 0.5$$

We know $\quad K_p = K_c(RT)^{\Delta n} = 0.5\,(0.082\text{ L atm K}^{-}\,\text{mol}^{-} \times 673\text{ K})^{-2}$

$$\therefore \quad K_p = 0.5 \times (55.186)^{-2}$$

or $\quad K_p = \dfrac{0.5}{55.186 \times 55.186} = \dfrac{0.5}{3045.5}$

$$= \mathbf{1.64 \times 10^{-4}\ atm^{-2}} \qquad \textbf{Ans.}$$

EXAMPLE 35. *The magnitude of* K_p *for the reaction,* $N_2O_4\,(g) \rightleftharpoons 2\,NO_2\,(g)$*, is 0.14 bar at 298 K. Calculate the value of* K_c*.*

SOLUTION. $\quad K_p = 0.14\text{ bar};\ K_c = ?;$

$$R = 0.0831\text{ L bar mol}^{-}\,\text{K}^{-};$$

$$T = 298\text{ K}.$$

For the reaction

$$\begin{array}{ccc} N_2O_4(g) & \rightleftharpoons & 2NO_2\,(g) \\ 1\text{ mol} & & 2\text{ mol} \end{array}$$

$$\Delta n = n_p - n_R = 2 - 1 = 1.$$

We know : $\quad K_p = K_c\,(RT)^{\Delta n} = K_c.\,RT$

Or $\quad K_c = \dfrac{K_p}{RT}$

$$\therefore \quad K_c = \frac{0.14}{0.0831 \times 298} = \mathbf{5.65 \times 10^{-3}} \qquad \textbf{Ans.}$$

23.13 DISSOCIATION OF NH_3

Type. Calculation of K_c for homogeneous gaseous dissociation reversible reaction involving change in volume or having different number of mol of reactants and products.

SOLUTION. Dissociation of NH_3.

	$2\,NH_3$	$\rightleftharpoons N_2$	$+\ 3H_2$
(*i*) *n* mol at start	*a*	0	0
(*ii*) Change by reaction	$-x$	$\frac{x}{2}$	$\frac{3x}{2}$
(*iii*) *n* mol at equilibrium	$\frac{a-x}{V}$	$\frac{x}{2V}$	$\frac{3x}{2V}$

x = Amount of NH_3 dissociated;

V = Volume of the reaction vessel.

$$\therefore \quad K_c = \frac{[N_2]\,[H_2]^3}{[NH_3]^2} = \frac{\left(\dfrac{x}{2V}\right)\left(\dfrac{3x}{2V}\right)^3}{\left(\dfrac{a-x}{V}\right)^2}$$

$$= \frac{27x^4}{16\,V^2\,(a-x)^2}$$

$$\therefore \qquad K_c = \frac{27x^4}{16\,V^2\,(a-x)^2}$$

EXAMPLE 36. *4 mol of NH_3 are introduced in one litre container in which it dissociates at high temperature as follows :*

$$2\,NH_3 \rightleftharpoons N_2 + 3\,H_2$$

If 2 mol of NH_3 remains undecomposed at equilibrium, find the value of K_c. **(ISC, 2013)**

SOLUTION.	$2\,NH_3 \rightleftharpoons$	$1\,N_2$	$+\,3H_2$
(*i*) *n* mol at start	4	0	0
(*ii*) Change by reaction	$-\,2$	$\frac{1\times 2}{2} = 1$	$\frac{3\times 2}{2} = 3$
(*iii*) *n* mol L⁻ at equilibrium	$\frac{4-2}{V\,(=1\,L)}$	$\frac{1}{V\,(=1L)}$	$\frac{3}{V\,(=1\,L)} = 2$

$$\therefore \qquad K_c = \frac{[H_2]^3\,[N_2]}{[NH_3]^2} = \frac{(3)^3 \times 1}{2\times 2}$$

$$= \mathbf{\frac{27}{4}\,mol^2\,L^{-2}} \qquad \textbf{Ans}$$

EXAMPLE 37. *Pure ammonia (one mol) was injected into a one litre container at a certain temperature. On analysing the equilibrium mixture, $2NH_3 \rightleftharpoons N_2 + 3H_2$, 0.3 mol of H_2 was found. Calculate :*

(*a*) *the concentration of N_2 and*

(*b*) *concentration of NH_3 at equilibrium.*

SOLUTION. Given reaction

$$\begin{array}{l} 2NH_3 \rightleftharpoons N_2 + 3H_2 \\ 2\text{ mol} \end{array}$$

For 1 mol NH_3, the reaction will be

$$NH_3 \rightleftharpoons \frac{1}{2}N_2 + \frac{3}{2}H_2 \qquad \ldots(1)$$

$$1\text{ mol} \qquad \frac{1}{2}\text{mol} \quad \frac{3}{2}\text{mol}$$

At equilibrium,

$[H_2] =$ 0.3 mol. From reaction (1), we have:

(*a*) $\frac{3}{2}\text{mol } H_2 \equiv \frac{1}{2}\text{mol } N_2$

$\therefore \quad 0.3\text{ mol } H_2 \equiv \frac{1}{2}\times\frac{2}{3}\times 0.3 = 0.1\text{ mol.}$

(*b*) $\frac{3}{2}\text{mol } H_2 \equiv 1\text{ mol } NH_3$

$\therefore \quad 0.3\text{ mol } H_2 \equiv \frac{2}{3}\times 0.3 = 0.2\text{ mol}$

∴ Amount of undissociated NH_3 at equilibrium or concentration of NH_3 at equilibrium $= 1.0 - 0.2 =$ **0.8 mol.** **Ans**

EXAMPLE 38. *Ammonia under a pressure of 15 atmosphere at 27°C is heated to 374°C in a closed vessel in the presence of a catalyst. Under the conditions, NH_3 is partially decomposed according to the equation :*

$$2NH_3 \rightleftharpoons N_2 + 3H_2$$

The vessel is such that the volume remains effectively constant whereas pressure increases to 50 atmosphere. Calculate the percentage of NH_3 actually decomposed. **(MLNR, 1991)**

SOLUTION. $P_1 = 15\text{ atm}, P_2 = ?, T_1 = 27 + 273$
$= 300\text{ K}; T_2 = 347 + 273 = 620\text{ K}.$

Since volume is kept constant,

$$\frac{P_1}{T_1} = \frac{P_2}{T_2}\;;\quad \frac{15}{300} = \frac{P_2}{620}\;;$$

$$P_2 = \frac{15\times 620}{300} = 31\text{ atm.}$$

Considering 1 mol NH_3 in the start, we have.

	$NH_3 \rightleftharpoons$	$\frac{1}{2}N_2 +$	$\frac{3}{2}H_2$
(*i*) no. of mol at start	1	0	0
(*ii*) Change by reaction	$-\,x$	$\frac{x}{2}$	$\frac{3x}{2}$
(*iii*) *n* mol at equilibrium	$1-x$	$\frac{x}{2}$	$\frac{3x}{2}$

Total number of mol at equilibrium

$$= 1 - x + \frac{x}{2} + \frac{3\,x}{2} = 1 + x$$

Thus, 1 + *x* mol concentration corresponds to 50 atm at the same temperature and volume. Thus

$$\frac{\text{No. of mol of } NH_3 \text{ without decomposition}}{\text{No. of mol of } NH_3 \text{ after dissociation}}$$

$$= \frac{1}{1+x}$$

$$\text{Or} \qquad \frac{31\text{ atm}}{50\text{ atm}} = \frac{1}{1+x}\;;\quad 31\,(1+x) = 50\;;$$

$$31 + 31x = 50\;;$$

$$\therefore \qquad 31\,x = 50 - 31 = 19\;;$$

$$\therefore \qquad x = \frac{19}{31} = 0.613$$

∴ percentage decomposition of NH_3

$$= 0.613 \times 100$$

$$= \mathbf{61.3\ \%} \qquad \textbf{Ans.}$$

23.14 DISSOCIATION OF N_2O_4

(*a*) **Determination of K_c**	$N_2O_4 \rightleftharpoons$	$2NO_2$
Original conc.	1mol	0
Conc. at equilibrium	$\frac{1-x}{V}$ mol	$\frac{2x}{V}$ mol

Let us start with one mol of N_2O_4 enclosed in a vessel of volume '*V*' litre

V = Volume of the closed vessel in which reaction takes place

x = number of mol of N_2O_4 that decompose at equilibrium to yield 2*x* mol of NO_2

Molar concentrations at equilibrium are :

$$[N_2O_4] = \frac{1-x}{V} \;;\; [NO_2] = \frac{2x}{V}$$

Applying law of mass action, we get :

$$K_c = \frac{[NO_2]^2}{[N_2O_4]} = \frac{\left(\frac{2x}{V}\right)^2}{\frac{1-x}{V}} = \frac{4x^2}{V^2} \times \frac{V}{1-x}$$

$$\therefore \quad K_c = \frac{4\,x^2}{V\,(1-x)}$$

(*b*) **Determination of K_p**

Total number of mol

$$= 1 - x + 2x = 1 + x$$

Let P = Total pressure of the system

$$\therefore \quad p_{N_2O_4} = \frac{(1-x)\,P}{1+x} \;;\; p_{NO_2} = \frac{2x\,P}{1+x}$$

$$\therefore \quad K_p = \frac{(p_{NO_2})^2}{p_{N_2O_4}} = \frac{\left(\frac{2x\,P}{1+x}\right)^2}{\frac{(1-x)\,P}{1+x}}$$

$$= \frac{4x^2\,P^2}{(1+x)\,(1+x)} \times \frac{1+x}{(1-x)\,P}$$

$$\therefore \quad K_p = \frac{4x^2\,P}{1-x^2}$$

Example 39. *At 1 atm and 350 K, N_2O_4 dissociates to 66% as :*

$$N_2O_4\,(g) \rightleftharpoons 2NO_2\,(g)$$

Calculate the volume that would 15.0g of N_2O_4 occupy under these conditions.

Solution. α = degree of dissociation

= 66 % = 66/100 = 0.66.

	N_2O_4	$\rightleftharpoons$	$2NO_2$
(*i*) *n* mol at start	1		0
(*ii*) Change by reaction	– 0.66		2 × 0.66 = 1.32
(*iii*) *n* mol at equilibrium	1 – 0.66 = 0.34		1.32

Total number of mol at equilibrium

= 0.34 + 1.32 = 1.66

Wt. of N_2O_4 = 15.0 g ;

g. mol. wt. of N_2O_4

= (2 × 14) + (4 × 16) = 92 g

$\therefore$ Number of mol of $N_2O_4 = \frac{15}{92}$

Or number of mol of N_2O_4 at equilibrium

$$= 1.66 \times \frac{15}{92} = 0.27 = n$$

But $PV = nRT$ (gas equation)

Or $V = \frac{n\,RT}{P}$

$$= \frac{0.27 \text{ mol} \times 0.082 \text{ L atm K}^{-} \text{ mol}^{-} \times 350 \text{ K}}{1 \text{ atm}}$$

V = **7.749 L** **Ans.**

Example 40. *$N_2O_4\,(g)$ dissociates as, $N_2O_4\,(g) \rightleftharpoons 2NO_2\,(g)$. Calculate the equilibrium constant of this reaction if the density of the equilibrium mixture of $NO_2\,(g)$ and $N_2O_4\,(g)$ at 75°C and 1 atmospheric pressure is 1.84 g dm^{-3}.*

Solution.	N_2O_4 (g) $\rightleftharpoons$	2 NO_2 (g)
Initial conc.	C mol	0
Conc. at equilibrium	C – C α	2 C α

($\because$ α = degree of dissociation)

Total moles at equilibrium

= C – C α + 2 C α = C + C α

= C (1 + α)

Initial vapour density, V.D. of N_2O_4

$$= \frac{\text{Mol. wt. of } N_2O_4}{2}$$

$$= \frac{(2 \times 14) + (4 \times 16)}{2} = \frac{92}{2} = \mathbf{46.}$$

We know that :

$$\frac{\text{Total moles at equilibrium}}{\text{Total initial moles}} = \frac{\text{Initial V.D.}}{\text{V.D. at equilibrium } (= d)}$$

$$\therefore \quad \frac{C\,(1+\alpha)}{C} = \frac{46}{d}$$

or $$1 + \alpha = \frac{46}{d} \qquad \text{...(1)}$$

Also, V.D. (d) and actual density (d_1) are related as :

$$d = \frac{d_1\,RT}{2\,P}$$

$$\therefore \quad d = \frac{1.84 \times 0.0821 \times (75 + 273 = 348)}{2 \times 1}$$

$$d = 26.28 \qquad \text{...(2)}$$

From equations (1) and (2), we get

$$1 + \alpha = \frac{46}{26.28} \text{ or } \alpha = \frac{46}{26.28} - 1$$

= 1.75 – 1 = **0.75** **Ans.**

Also $$K_p = \frac{(p_{NO_2})^2}{p_{N_2O_4}} = \frac{\left[\frac{2\,C\,\alpha}{C\,(1+\alpha)} \times P_T\right]^2}{\frac{C\,(1-\alpha)}{C\,(1+\alpha)} \times P_T}$$

$$= \frac{\left[\frac{2\,\alpha}{1+\alpha} \times P_T\right]^2}{\frac{1-\alpha}{1+\alpha} \times P_T} = \frac{\left(\frac{2 \times 0.75}{1+0.75} \times 1\right)^2}{\frac{1-0.75}{1+0.75} \times 1}$$

$$= \frac{(0.857)^2}{\frac{0.25}{1.75}} = \frac{0.7344}{0.1428} = \mathbf{5.14 \text{ atm.}} \quad \textbf{Ans.}$$

Example 41. *The K_p for the reaction $N_2O_4\,(g) \rightleftharpoons 2NO_2(g)$ is 640 mm at 775 K. Calculate the percentage dissociation of N_2O_4 at equilibrium pressure of 160 mm. At what pressure, the dissociation will be 50% if its K_p is taken as $4x^2p/_{1-x^2}$*

(Roorkee 1997)

SOLUTION. $N_2O_4(g) \rightleftharpoons 2NO_2$

When $x = 50\%$ or $\frac{50}{100} = 0.5$, $P = ?$

$$\therefore \quad K_p = \frac{(p_{NO_2})^2}{p_{N_2O_4}};$$

$$\text{or} \quad 640 = \frac{4x^2\,P}{1-x^2} = \frac{4\times(0.5)^2\,P}{1-(0.5)^2} = \frac{4\times 0.25\,P}{1-0.25};$$

$$640 = \frac{P}{0.75}$$

or $P = 640 \times 0.75 = \mathbf{480\ mm}$ **Ans.**

EXAMPLE 42. *N_2O_4 is 25% dissociated at 37°C and one atmospheric pressure. Calculate (i) K_p and (ii) the percentage dissociation at 1.1 atmosphere and 37°C.* **(IIT 1988)**

SOLUTION. (*a*) $x = 25\% = 25/100 = 0.25$

	$N_2O_4(g)$	$\rightleftharpoons 2NO_2(g)$
(*i*) *n* mol at start	1	0
(*ii*) Change by reaction	-0.25	$2\times 0.25 = 0.5$
(*iii*) *n* mol at equilibrium	$1 - 0.25 = 0.75$	0.5

Total number of mol

$= 0.75 + 0.50 = 1.25$; $P = 1$ atm.

$$K_p = \frac{(p_{NO_2})^2}{p_{N_2O_4}} = \frac{\left(\frac{0.5}{1.25}\times P\right)^2}{\left(\frac{0.75}{1.25}\times P\right)}$$

$$= \frac{\left(\frac{0.5}{1.25}\times 1\right)^2}{\left(\frac{0.75}{1.25}\times 1\right)}$$

$$K_p = \frac{50}{125}\times\frac{50}{125}\times\frac{125}{75} = 0.267\ \text{atm.}$$

(*b*) α = Degree of dissociation.

	$N_2O_4(g)$	$\rightleftharpoons 2NO_2(g)$
(*i*) *n* mol at start	1	0
(*ii*) Change by reaction	$-\alpha$	2α
(*iii*) *n* mol at equilibrium	$1-\alpha$	2α

Total number of mol

$= 1 - \alpha + 2\alpha = 1 + \alpha$; $P = 1.1$ atm.

$$K_p = \frac{(p_{NO_2})^2}{p_{N_2O_4}} = \frac{\left(\frac{2\alpha}{1+\alpha}\times P\right)^2}{\frac{1-\alpha}{1+\alpha}\times P}$$

$$= \frac{2\alpha}{1+\alpha}\times 1.1\times\frac{2\alpha\times 1.1}{1+\alpha}\times\frac{1+\alpha}{(1-\alpha)\times 1.1}$$

$$0.267 = \frac{4\alpha^2\times 1.1}{1-\alpha^2};\ \frac{0.267}{1.1} = \frac{4\alpha^2}{1-\alpha^2};$$

$$0.243 = \frac{4\alpha^2}{1-\alpha^2}$$

$0.243\,(1-\alpha^2) = 4\alpha^2$; $0.243 - 0.243\,\alpha^2 = 4\,\alpha^2$;

$4\,\alpha^2 + 0.243\,\alpha^2 = 0.243$

Or $4.243\,\alpha^2 = 0.243$; $\alpha^2 = \frac{0.243}{4.243} = 0.0573$

Or $\alpha = (0.0573)^{1/2} = 0.239$

$\therefore$ % age dissociation

$= 0.239 \times 100 = \mathbf{23.9\ \%}$ **Ans.**

EXAMPLE 43. *At 25°C and one atmospheric pressure, the partial pressures in an equilibrium mixture of N_2O_4 and NO_2 are 0.7 and 0.3 atmosphere respectively. Calculate the partial pressure of these gases when they are in equilibrium at 25°C and at a total pressure of 10 atmosphere.* **(Dhanbad, 1992, MLNR 1990)**

SOLUTION. (*a*) $N_2O_4(g) \rightleftharpoons 2NO_2(g)$

	$N_2O_4(g)$	$2NO_2(g)$
n mol at equilibrium	0.7	0.3

Total number of mol

$= 0.7 + 0.3 = 1.0$; $P = 1$ atm.

$$K_p = \frac{(p_{NO_2})^2}{p_{N_2O_4}} = \frac{\left(\frac{0.3}{1}\times 1\right)^2}{\frac{0.7}{1}\times 1} = \frac{0.3\times 0.3}{0.7}$$

$= 0.128$ atm.

(*b*) x = degree of dissociation, $P = 10$ atm.

	$N_2O_4(g)$	$\rightleftharpoons 2NO_2(g)$
(*i*) *n* mol at start	1	0
(*ii*) Change by reaction	$-x$	$2x$
(*iii*) *n* mol at equilibrium	$1-x$	$2x$

Total number of mol at equilibrium

$= 1 - x + 2x = 1 + x$

$$K_p = \frac{(p_{NO_2})^2}{p_{N_2O_4}} = \frac{\left(\frac{2x}{1+x}\times P\right)^2}{\frac{1-x}{1+x}\times P}$$

$$= \frac{4x^2\,P}{1-x^2} = \frac{4x^2\times 10}{1-x^2} = \frac{40x^2}{1-x^2}$$

Or $0.128 = \frac{40x^2}{1-x^2}$;

$0.128\,(1-x^2) = 40x^2$; $0.128 - 0.128\,x^2 = 40\,x^2$

$\therefore\ 40\,x^2 + 0.128\,x^2 = 0.128$; $40.128\,x^2 = 0.128$;

$$x^2 = \frac{0.128}{40.128} = 3.19\times 10^{-3};$$

$$\therefore \quad x = \left(\frac{3.19}{1000}\right)^{1/2} = (0.00319)^{1/2} = 0.056$$

$$\therefore \quad p_{NO_2} = \frac{2x}{1+x}\times 10 = \frac{2\times 0.056\times 10}{1+0.056} = \frac{1.12}{1.056}$$

$= \mathbf{1.06\ atm}$ **Ans.**

$$p_{N_2O_4} = \frac{1-x}{1+x}\times 10 = \frac{(1-0.056)\times 10}{1+0.056} = \frac{9.44}{1.056}$$

$= \mathbf{8.94\ atm}$ **Ans.**

EXAMPLE 44. *The vapour density (hydrogen = 1) of a mixture containing NO_2 and N_2O_4 is 38.3 at 27°C. Calculate the number of mol of NO_2 in 100 g of the mixture.* **(MLNR 1993)**

SOLUTION. (*a*) Mol. wt. of $N_2O_4 = (2 \times 14) + (4 \times 16) = 28 + 64 = 92$

$\therefore$ Vapour density (D) of N_2O_4 before dissociation

$$= \frac{\text{Mol. wt.}}{2} = \frac{92}{2} = 46$$

V.D (d) after dissociation = 38.3.

For $\quad N_2O_4 \rightleftharpoons 2NO_2$

2 mol ; $n = 2$

Let degree of dissociation = α.

But $\quad \alpha = \dfrac{D-d}{d(n-1)}$;

$$\therefore \quad \alpha = \frac{46-38.3}{38.3(2-1)} = \frac{7.7}{38.3} = 0.201$$

(*b*)	N_2O_4	$\rightleftharpoons$ $2NO_2$
(*i*) *n* mol at start	1	0
(*ii*) Change by reaction	$-\alpha\,(=-0.201)$	$2\alpha\,(= 2 \times 0.201) = 0.402$
(*iii*) *n* mol at equilibrium	$1 - 0.201 = 0.799$	0.402

(*c*) $\therefore$ Number of mol of $N_2O_4 = 0.799$;

g. mol. wt. of N_2O_4

$$= (2 \times 14) + (4 \times 16) = 92 \text{ g}$$

$\therefore$ Mass of $N_2O_4 = 0.799 \times 92 = 73.508$ g.

Number of mol of $NO_2 = 0.402$;

g mol. wt. of $NO_2 = 14 + (2 \times 16) = 46$ g

$\therefore$ Mass of $NO_2 = 0.402 \times 46 = 18.492$ g

Total mass of mixture

$$= 73.508 + 18.492 = 92 \text{ g}$$

92 g mixture contain $NO_2 = 18.492$ g

$\therefore$ 100 g mixture contain NO_2

$$= \frac{18.492}{92} \times 100 \text{ g} = 20.1 \text{ g}$$

$\therefore$ Number of mol of NO_2

$$= \frac{\text{Wt. of } NO_2}{\text{g. mol. wt. of } NO_2} = \frac{20.1}{46} = \mathbf{0.437}$$

EXAMPLE 45. *For the $N_2O_4 \rightleftharpoons 2NO_2$, the equilibrium constant, Kp at 25°C is 0.113 atm. Determine the partial pressure of $NO_2(g)$ in a system under a total pressure of 1.0 atmosphere when 0.04 mol of N_2O_4 (g) are sealed in a container and allowed to come to equilibrium at 25°C.*

SOLUTION. $K_p = 0.113$ atm; total pressure, $P = 1.0$ atm.

	N_2O_4	$\rightleftharpoons$ $2NO_2$
(*i*) *n* mol at start	0.04	0
(*ii*) Change by reaction	$-x$	$2x$
(*iii*) *n* mol at equilibrium	$0.04 - x$	$2x$

Total number of mol at equilibrium

$$= 0.04 - x + 2x = 0.04 + x.$$

$$K_p = \frac{(p_{NO_2})^2}{p_{N_2O_4}} = \frac{\left(\dfrac{2x}{0.04+x} \times P\right)^2}{\dfrac{0.04-x}{0.04+x} \times P}$$

$$= \frac{\left(\dfrac{2x}{0.04+x} \times 1\right)^2}{\dfrac{0.04-x}{0.04+x} \times 1} = \frac{4x^2}{(0.04+x)(0.04-x)}$$

Or $\quad 0.113 = \dfrac{4x^2}{(0.04)^2 - x^2} = \dfrac{4x^2}{0.0016 - x^2}$;

$0.113\,(0.0016 - x^2) = 4x^2$

Or $0.00018 - 0.113\,x^2 = 4\,x^2$;

$$4\,x^2 + 0.113\,x^2 = 0.00018$$

Or $\quad 4.113\,x^2 = 0.00018$;

$$x^2 = \frac{0.00018}{4.113} = 0.000044\,;$$

$$x = (0.000044)^{1/2} \;\therefore\; x = 6.63 \times 10^{-3}$$

$$\therefore \quad p_{NO_2} = \frac{2x}{0.04+x} \times P = \frac{2 \times 6.63 \times 10^{-3} \times 1}{0.04 + 6.63 \times 10^{-3}}$$

$$= \frac{13.26 \times 10^{-3}}{0.04 + 0.00663} = \frac{0.01326}{0.04663}$$

$= \mathbf{0.284\ atm}$ **Ans.**

EXAMPLE 46. *An equilibrium mixture at 300 K contains N_2O_4 and NO_2 at 0.28 and 1.1 atm pressure respectively. If the volume of the container is doubled, calculate the new equilibrium pressure of the two gases.* **(Roorkee, 1991)**

SOLUTION. $p_{NO_2} = 1.1$ atm ; $p_{N_2O_4} = 0.28$ atm.

Thus, total pressure = 1.1 + 0.28 = 1.38 atm.

For $\quad N_2O_4 \rightleftharpoons 2NO_2$

$$K_p = \frac{(p_{NO_2})^2}{p_{N_2O_4}} = \frac{(1.1)^2}{0.28} = \frac{1.21}{0.28} = \frac{121}{28}$$

At constant temperature, since, $V \propto \dfrac{1}{p}$, when volume is doubled, pressure becomes one half.

$\therefore$New pressure $= \dfrac{1.38}{2} = 0.69$ atm.

Let new pressure of $N_2O_4 = P$.

So, $\quad p_{NO_2} = 0.69 - P$

$$\therefore \quad K_p = \frac{(p_{NO_2})^2}{p_{N_2O_4}} = \frac{(0.69-P)^2}{P}\,;$$

Or $\quad \dfrac{121}{28} = \dfrac{(0.69-P)^2}{P}$

Or $121\,P = 28\,(0.69 - P)^2\,;$

$$121\,P = 28\,(0.4761 + P^2 - 1.38\,P)$$

$$121\,P = 13.33 + 28\,P^2 - 38.64\,P\,;$$

$$28\,P^2 - 38.64\,P - 121\,P + 13.33 = 0\,;$$

$$28\,P^2 - 159.64\,P + 13.33 = 0$$

$$\therefore \quad P = \frac{-(-159.64) \pm \sqrt{(-159.64)^2 - 4\,(28 \times 13.33)}}{2 \times 28}$$

$$= \frac{159.64 \pm \sqrt{25485 - 1493}}{56}$$

$$= \frac{159.64 \pm \sqrt{23992}}{56}$$

$$= \frac{159.64 \pm 154.89}{56}$$

$$\left[\because \text{for } ax^2 + bx + c = 0,\quad x = \frac{-b \pm \sqrt{b^2 - 4\,ac}}{2\,a}\right]$$

$$P = \frac{314.53}{56} = 5.6 \text{ (on addition) or } \frac{4.75}{56}$$

(on subtraction) = 0.085

∴ Partial pressure of N_2O_4

= P = 0.085 atm.

Partial pressure of NO_2

= $0.69 - P = 0.69 - 0.085$

= **0.605 atm.** **Ans.**

Example 47. *The value of Kp at 46°C for $N_2O_4\,(g) \rightleftharpoons 2NO_2\,(g)$ is 0.66 atm. Compute the percent dissociation of N_2O_4 at 46°C and a total pressure of 380 torr. What are the partial pressures of N_2O_4 and NO_2 at equilibrium ?* **(Kanpur IIT 1996)**

Solution. (*a*) Total pressure of NO_2 and N_2O_4

$$= 380 \text{ torr} = \frac{380}{760} = 0.5 \text{ atm.}$$

Let partial pressure of $NO_2 = P$

Partial pressure of $N_2O_4 = 0.5 - P$

For $N_2O_4 \rightleftharpoons 2NO_2$

$$K_p = \frac{(p_{NO_2})^2}{p_{N_2O_4}}\,;\quad 0.66 = \frac{P^2}{0.5 - P}\,;$$

$$\left[\because \text{for } ax^2 + bx + c = 0,\quad x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}\right]$$

$$0.66\,(0.5 - P) = P^2$$

or $P^2 = 0.33 - 0.66\,P;\ P^2 + 0.66\,P - 0.33 = 0$

$$\therefore \quad P = \frac{-(+0.66) \pm \sqrt{(+0.66)^2 - 4(1 \times -0.33)}}{2 \times 1}$$

$$= \frac{-0.66 \pm \sqrt{0.4356 + 1.32}}{2}$$

$$= \frac{-0.66 \pm \sqrt{1.7556}}{2}$$

$$= \frac{-0.66 \pm 1.32}{2} = \frac{-0.66 + 1.32}{2} = \frac{-0.66 + 1.32}{2} = \frac{0.66}{2} = +0.33;$$

Or $= \dfrac{-0.66 - 1.32}{2} = \dfrac{-1.98}{2} = -0.99$

Since, value cannot be negative, so

$$P = 0.33 \text{ atm.}\ \therefore\ p_{NO_2} = 0.33 \text{ atm}\,;$$

$$p_{N_2O_4} = 0.5 - 0.33 = \mathbf{0.17\ atm.}$$

(*b*) Let degree of dissociation = x

		$N_2O_4 \rightleftharpoons$	$2NO_2$
(*i*)	n mol of start	1	0
(*ii*)	Change by reaction	$-x$	$2x$
(*iii*)	n mol at equilibrium	$1 - x$	$2x$

Total number of mol at equilibrium

= $1 - x + 2x = 1 + x$; P = 0.5 atm.

$$K_p = \frac{(p_{NO_2})^2}{p_{N_2O_4}} = \frac{\left(\dfrac{2\,x}{1+x} \times P\right)^2}{\dfrac{1-x}{1+x} \times P} = \frac{4\,P\,x^2}{1-x^2}\,;$$

$$0.66 = \frac{4 \times 0.5\,x^2}{1 - x^2} = \frac{2\,x^2}{1 - x^2}$$

Or $0.66\,(1 - x^2) = 2\,x^2\,;$

$$0.66 - 0.66\,x^2 = 2\,x^2\,;$$

$$2\,x^2 + 0.66\,x^2 = 0.66\,;\ 2.66\,x^2 = 0.66$$

$$x^2 = \frac{0.66}{2.66} = 0.248\,;$$

$$\therefore \quad x = \sqrt{0.248} = 0.498\,;$$

∴ % age dissociation

= 0.498 × 100 = **49.8 %** **Ans.**

Example 48. *The V.D. of N_2O_4 at a certain temperature is 30. Calculate the percentage dissociation of N_2O_4 at this temperature.* **(MDU, Pre-med, Pre-engg 1980, UP 1990)**

Solution. g. mol. wt. of N_2O_4

= (2 × 14) + (4 × 16) = 92

∴ *V.D.* (*D*) of undissociated N_2O_4

$$= \frac{\text{Mol. wt.}}{2} = \frac{92}{2} = 46$$

For $N_2O_4 \rightleftharpoons 2NO_2$ (*i.e.*, 2 mol ; $n = 2$)

Degree of dissociation = α (say)

V.D. (*d*) of N_2O_4 at the given temperature = 30

But $$\alpha = \frac{D - d}{d\,(n - 1)} = \frac{46 - 30}{30\,(2 - 1)} = \frac{16}{30} = 0.533$$

∴ % age dissociation

= 0.533 × 100 = **53.3** **Ans.**

Example 49. *The equilibrium constant for $N_2O_4 \rightleftharpoons 2NO_2$ at 27°C and 1 atm is 0.17. What is the extent of dissociation in* *a 69 g sample of N_2O_4 confined in a 20 L vessel at 27°C.*

Solution. g. mol. wt. of N_2O_4

$$= (2 \times 14) + (4 \times 16) = 92\text{ g};$$

$$\text{Wt. of } N_2O_4 = 69\text{ g}$$

$\therefore$ number of mol of N_2O_4

$$= \frac{96}{92} = 0.75\text{ mol}$$

Let α = degree or extent of dissociation.

Thus for :	$N_2O_4 \rightleftharpoons$	$2NO_2$
(*i*) *n* mol at start	0.75	–
(*ii*) Change by reaction	$-0.75\,\alpha$	$+ 2\,(0.75\,\alpha) = 1.50\,\alpha$
(*iii*) *n* mol at equilibrium	$0.75\,(1-\alpha)$ $= 0.75 - 0.75\,\alpha$	$1.50\,\alpha$

Let pressure = P ; $R = 0.082\text{ L atm K}^{-}\text{ mol}^{-}$;

$$T = 27 + 273 = 300\text{ K};\ V = 20\text{ L}$$

But $\quad PV = n\,RT$;

$$\therefore \quad P_{(N_2O_4)} = \frac{n\,(N_2O_4)\,RT}{V}$$

$$= \frac{[0.75\,(1-\alpha)\text{ mol}] \times 0.082\text{ L atm K}^{-}\text{ mol}^{-}) \times 300\text{ K}}{20\text{ L}}$$

or $\quad P_{N_2O_4} = 0.92\,(1-\alpha)$ atm

$$\text{Similarly, } P_{(NO_2)} = \frac{n\,(NO_2)\,RT}{V}$$

$$= \frac{150\,\alpha \times 0.082\text{ L atm mol}^{-}\text{K}^{-} \times 300\text{ K}}{20\text{ L}}$$

$$= 1.84\,\alpha\text{ atm}$$

$$\text{But} \quad K_p = \frac{P_{(NO_2)^2}}{P_{(N_2O_4)}} = \frac{(1.84\,\alpha)^2}{0.92\,(1-\alpha)};$$

$$0.17 = \frac{3.38\,\alpha^2}{0.92 - 0.92\,\alpha};$$

$0.17\,(0.92 - 0.92\,\alpha) = 3.38\,\alpha^2$; $0.16 - 0.16\,\alpha = 3.38\,\alpha^2$;

$3.38\,\alpha^2 + 0.16\,\alpha - 0.16 = 0$

$$\therefore \quad \alpha = \frac{-0.16 \pm \sqrt{(0.16)^2 - 4\,(3.38 \times -0.16)}}{2 \times 3.38}$$

$$= \frac{-0.16 \pm \sqrt{0.026 + 2.16}}{6.76}$$

$$= \frac{-0.16 \pm \sqrt{2.186}}{6.76}$$

$$= \frac{-0.16 \pm 1.48}{6.76}; \quad \left[\because \text{ for } ax^2 + bx + c = 0,\ x = \frac{-b \pm \sqrt{b^2 - 4\,ac}}{2\,a}\right]$$

$$\alpha = \frac{-1.64}{6.76} \text{ (after subtraction)}$$

or $\dfrac{1.32}{6.7}$ (after addition) = –0.24 or 0.197 respectively.

The negative value has to be rejected, So, $\alpha = 0.197$

$\therefore$ % age dissociation

$= 0.197 \times 100 =$ **19.7 %** **Ans.**

Example 50. *20% of N_2O_4 molecules are dissociated in a sample of gas at 27°C and 760 torr. Calculate the density of equilibrium mixture.* **(Roorkee, 1996)**

Solution. Degree of dissociation,

$$\alpha = 20\,\% = \frac{20}{100} = 0.2$$

	$N_2O_4 \rightleftharpoons$	$2NO_2$
(*i*)*n* mol at start	1	0
(*ii*) Change by reaction	– 0.2	$2 \times 0.2 = 0.4$
(*iii*) *n* mol at equilibrium	$1 - 0.2 = 0.8$	0.4

Total number of mol at equilibrium

$$= 0.8 + 0.4 = 1.2 = n$$

But $\quad P\,V = n\,RT$ (gas equation)

$$\therefore \quad V = \frac{n\,RT}{P}$$

$$= \frac{1.2\text{ mol} \times 0.082\text{ L atm K}^{-}\text{ mol}^{-} \times (27 + 273)\text{ K}}{760\text{ torr } (= 1\text{ atm})}$$

$$\textbf{Or } V = \frac{1.2\text{ mol} \times 0.082\text{ L atm K}^{-}\text{ mol}^{-} \times 300\text{ K}}{1\text{ atm}} = 29.52\text{ L}$$

g. mol. wt. of N_2O_4

$$= (2 \times 14) + (4 \times 16) = 92\text{ g.}$$

$$\text{But} \quad \text{Density} = \frac{\text{Mass}}{\text{Volume}} = \frac{92\text{ g}}{29.52\text{ L}} = \mathbf{3.12\ g\ L^{-}}\ \textbf{Ans.}$$

Example 51. *'a' litre of N_2O_4 decomposes as : $N_2O_4 \rightleftharpoons 2NO_2$ at 273 K and one atmospheric pressure. If original volume is 20% less than that of the existing volume, calculate the extent to which the decomposition has taken place.*

Solution. At constant temperature and pressure, the volume can be taken as mol.

	$N_2O_4 \rightleftharpoons$	$2NO_2$
(*i*) *n* mol at start	*a*	0
(*ii*) Change by reaction	$-x$	$2\,x$
(*iii*) *n* mol at equilibrium	$a - x$	$2\,x$

Total number of mol at equilibrium

$$= a - x + 2x = a + x$$

$$\therefore \text{ Original mol} = \frac{(100 - 20)}{100} \text{ of mol at equilibrium}$$

$$a = \frac{80}{100} \times (a + x)$$

$$\textbf{Or} \quad a = 0.80\,(a + x);\ \frac{a}{0.8} = a + x;$$

$$x = \frac{a}{0.8} - a = a\left(\frac{1}{0.8} - 1\right)$$

$$\textbf{Or} \quad x = a\left(\frac{1 - 0.8}{0.8}\right) = \frac{0.2}{0.8}\,a = 0.25\,a$$

∴ % decomposition

$$= \frac{x}{a} \times 100 = \frac{0.25\,a}{a} \times 100 = \mathbf{25\%}\ \textbf{Ans.}$$

EXAMPLE 52. *0.1 mol of N_2O_4 (g) was sealed in a tube under atmospheric conditions at 25°C. Calculate the number of mol of NO_2 (g) present if the equilibrium*

$$N_2O_4\,(g) \rightleftharpoons 2NO_2\,(g)\ \ (Kp = 0.14)$$

is reached after some time **(MLNR, 1997)**

SOLUTION.

		$N_2O_4 \rightleftharpoons$	$2NO_2$
(*i*)	*n* mol at start	1	0
(*ii*)	Change by reaction	$-\alpha$	2α
(*iii*)	*n* mol at equilibrium	$1-\alpha$	2α

∴ Total number of mol at equilibrium

$$= 1 - \alpha + 2\alpha = 1 + \alpha$$

Pressure = P

$$\therefore \quad p_{N_2O_4} = \frac{1-\alpha}{1+\alpha} \times P \quad ; \quad p_{NO_2} = \frac{2\alpha}{1+\alpha} \times P$$

$$\text{But} \quad K_p = \frac{p_{(NO_2)^2}}{p_{N_2O_4}} \quad ; \quad 0.14 = \frac{\left(\dfrac{2\alpha P}{1+\alpha}\right)^2}{\dfrac{1-\alpha}{1+\alpha} \times P}$$

$$= \frac{4\alpha^2 P^2}{(1+\alpha)^2} \times \frac{1+\alpha}{P(1-\alpha)}$$

$$0.14 = \frac{4\alpha^2 P}{1-\alpha^2} \quad ; \quad 0.14 = \frac{4\alpha^2 \times 1}{1-\alpha^2}$$

$$\therefore \quad 0.14\,(1-\alpha^2) = 4\alpha^2 ;\ 0.14 - 0.14\,\alpha^2 = 4\alpha^2 ;$$

$$4\alpha^2 + 0.14\,\alpha^2 = 0.14 ;$$

$$4.14\,\alpha^2 = 0.14 ;$$

$$\therefore \quad \alpha = \left(\frac{0.14}{4.14}\right)^{1/2} = 0.18$$

Since 0.1 mol of N_2O_4 is taken, so :

Number of mol of NO_2

$$= 0.1 \times 2\alpha = 0.18 \times 0.1 \times 2 = \mathbf{0.036}\ \textbf{Ans.}$$

EXAMPLE 53. *For the following equilibrium at 450°C and one atmospheric pressure, $N_2O_4\,(g) \rightleftharpoons 2NO_2$, calculate the partial pressure of NO_2 (g). Provided $\Delta G_f^\circ\,(NO_2) = 51.84$ k J, $\Delta G_f^\circ\,(N_2O_4) = 98.29$ k J. Assume that ΔG° does not change. The number of mol of N_2O_4 taken initially is 2.*

SOLUTION. (*a*) Calculation of K_p for

$$N_2O_4(g) \rightleftharpoons 2NO_2\,(g)$$

$$\Delta G^\circ = 2\,\Delta G_f^\circ\,(NO_2) - \Delta G^\circ_f\,(N_2O_4)$$

$$= (2 \times 51.84) - (98.29) = 5.39 \text{ k J}$$

$$= 5.39 \times 1000 = 5390 \text{ J}$$

$$\text{But} \quad \Delta G^\circ = -\,2.303\ RT \log K_p ;$$

$$\log K_p = \frac{-\,\Delta G^\circ}{2.303\,RT}$$

$$\textbf{Or} \quad \log K_p = -\frac{5390}{2.303 \times 8.314 \text{ J K}^{-} \text{ mol}^{-} \times (450 + 273) \text{ K}}$$

$$= (-\,0.3894)$$

$$\therefore \quad K_p = \text{antilog}\,(-\,0.3894)$$

$$= \text{antilog}\,(-\,1 + 1 - 0.3894)$$

$$= \text{antilog}\ \bar{1}.6106 = 0.408$$

(*b*) **To find amount of NO_2 and N_2O_4.**

		$N_2O_4 \rightleftharpoons$	$2NO_2$
(*i*)	*n* mol at start	2	0
(*ii*)	Change by reaction	$-\,2\alpha$	$2\,(2\alpha)$
(*iii*)	*n* mol at equilibrium	$2 - 2\alpha$	4α

Total number of mol at equilibrium

$$2 - 2\alpha + 4\alpha = 2 + 2\alpha ;\ \text{Pressure} = P$$

$$p_{NO_2} = \frac{4\alpha}{2+2\alpha} \times P = \frac{2\alpha P}{1+\alpha} ;$$

$$p_{N_2O_4} = \frac{2-2\alpha}{2+2\alpha} \times P = \frac{2\,(1-\alpha)}{2\,(1+\alpha)} \times P = \frac{(1-\alpha)\,P}{1+\alpha}$$

$$\therefore \quad K_p = \frac{p_{\,(NO_2)^2}}{p_{\,(N_2O_4)}} = \frac{4\alpha^2 P^2}{(1+\alpha)^2} \times \frac{1+\alpha}{(1-\alpha)\,P}$$

$$= \frac{4\alpha^2 P}{(1+\alpha)\,(1-\alpha)} = \frac{4\alpha^2 \times 1}{1-\alpha^2} = \frac{4\alpha^2}{1-\alpha^2}$$

$$\therefore \quad 0.408 = \frac{4\alpha^2}{1-\alpha^2} ;\ 0.408\,(1-\alpha^2) = 4\alpha^2 ;$$

$$0.408 - 0.408\,\alpha^2 = 4\alpha^2$$

$$\textbf{Or} \quad 4\alpha^2 + 0.408\,\alpha^2 = 0.408 ;\ 4.408\,\alpha^2 = 0.408 ;$$

$$\therefore \quad \alpha = \left(\frac{0.408}{4.408}\right)^{1/2} \quad \textbf{Or}\ \alpha = (0.092)^{1/2} = 0.303$$

$$(a) \quad p_{NO_2} = \frac{4\alpha}{2+2\alpha} \times P = \frac{2\,(2\alpha)}{2\,(1+\alpha)} \times P = \frac{2\alpha P}{1+\alpha}$$

$$= \frac{2 \times 0.303 \times 1}{1 + 0.303} = \frac{0.606}{1.303} = \mathbf{0.465\ atm}$$

(*b*) Amount of NO_2 at equilibrium = $4\alpha = 4 \times 0.303 =$ **1.212 mol. Ans.**

(*c*) Amount of N_2O_4 at equilibrium = $2 - 2\alpha$

$$= 2 - (2 \times 0.303) = 2 - 0.606$$

$$= \mathbf{1.394\ mol.} \qquad \textbf{Ans.}$$

EXAMPLE 54. *The K_p value of $N_2O_4 \rightleftharpoons 2NO_2$ reaction at equilibrium is 0.6. The value of degree of dissociation of N_2O_4 at 318 K and a total pressure of 10 bar will be :*

(*a*) 0.02 (*b*) 0.03

(*c*) 0.121 (*d*) 0.242

SOLUTION. Let degree of dissociation of $N_2O_4 = x$. Let the vessel contains one mol of N_2O_4, $K_p = 0.6$, Total pressure, $P = 10$ bar. Thus, for the following reaction, we have :

	$N_2O_4 \rightleftharpoons$	$2NO_2$
Initial conc.	1	0
Conc. at equilibrium	$1 - x$	$2x$

Total no. of mol at equilibrium

$$= 1 - x + 2x = 1 + x$$

$$\therefore \quad p_{N_2O_4} = \frac{10(1-x)}{1+x};\ p_{NO_2} = \frac{10 \times 2x}{1+x}$$

[$\because$ P = 10 bar]

Using law of chemical equilibrium for the above reaction, we have :

$$K_p = \frac{[NO_2]^2}{[N_2O_4]} = \frac{\left(\frac{20x}{1+x}\right)^2}{\frac{10(1-x)}{1+x}}$$

$$= \frac{400x^2}{(1+x)(1+x)} \times \frac{(1+x)}{10(1-x)} = \frac{40x^2}{(1+x)(1-x)}$$

$$0.6 = \frac{40x^2}{1-x^2};\ 0.6 - 0.6x^2 = 40x^2$$

Or $40x^2 + 0.6x^2 = 0.6$

$$\therefore \quad 40.6x^2 = 0.6 \text{ Or } x^2 = \frac{0.6}{40.6} = 0.0148$$

$$\therefore \quad x = (0.148)^{1/2} = \mathbf{0.121}$$

So, the correct answer is, (*c*)

Example 55. *Find the value of K_c in moles per litre for the reaction, $N_2O_4(g) \rightleftharpoons 2NO_2(g)$, $K_p = 0.15$ atm at 298 K.*

(HP Board, 2007)

Solution. $N_2O_4(g) \rightleftharpoons 2NO_2(g)$

no. of mol 1 2

Δn = no. of mol of products – no. of mol of reactants

$= 2 - 1 = 1;\ R = 0.0821$ L atm K^{-} mol^{-};

T = 298 K

But $K_p = K_c(RT)^{\Delta n}$

0.15 atm $= K_c(0.0821 \text{ L atm K}^{-} \text{mol}^{-} \times 298 \text{ K})^1$

$$\therefore \quad K_c = \frac{0.15 \text{ atm}}{0.0821 \text{ L atm K}^{-}\text{mol}^{-} \times 298 \text{ K}}$$

$= 6.13 \times 10^{-3}$ mol L^{-} **Ans.**

23.15 SYNTHESIS OF N_2O_4

Example 56. *One mol of NO_2 and 1 mol of N_2O_4 are placed in a one litre flask. At equilibrium, 0.75 mol of N_2O_4 is present in the flask. Calculate the value of K for the reaction :*

$$2\,NO_2 \rightleftharpoons N_2O_4$$

Solution.	$2\,NO_2 \rightleftharpoons$	N_2O_4
(*i*) *n* mol at start	1	1
(*ii*) *n* mol used	–	1 – 0.75 = 0.25
(*iii*) *n* mol produced	2 × 0.25 = 0.5	–
(*iv*) *n* mol at equilibrium	1 + 0.5 = 1.5	0.75

$$K_p = \frac{[N_2O_4]}{[NO_2]^2} = \frac{0.75}{(1.5)^2} = \frac{0.75}{1.5 \times 1.5}$$

$= \mathbf{0.33}$ **Ans.**

Example 57. (*i*) *Calculate $\Delta G°$ and K_p for*

$$2NO_2 \rightleftharpoons N_2O_4 \text{ at } 25°C.$$

(*ii*) *Calculate $\Delta G°$ and K_p for the reverse reaction,*

$$N_2O_4 \rightleftharpoons 2NO_2 \text{ at } 25°C$$

(*iii*) *Calculate $\Delta G°$ and K_p for the forward reaction written with different co-efficients.*

$$NO_2 \rightleftharpoons \frac{1}{2}N_2O_4$$

$$\Delta G_f^\circ (N_2O_4) = 97.82 \text{ kJ mol}^{-};$$

$$\Delta G_f^\circ (NO_2) = 51.30 \text{ kJ mol}^{-};\ R = 8.314 \text{ J K}^{-}.$$

Solution. (*i*) For

$$2NO_2 \rightleftharpoons N_2O_4,\ T = 25 + 273 = 298 \text{ K}$$

$$\Delta G° = \Delta G_f^\circ (N_2O_4) - 2\Delta G_f^\circ (NO_2)$$

$$= 97.82 - 2(51.3) = 97.82 - 102.6$$

$$= -4.78 \text{ kJ}$$

$$= -4.78 \times 1000 = -4780 \text{ J.}$$

But $\Delta G° = -2.303 \text{ RT} \log K_p$

$$\therefore \quad \log K_p = \frac{\Delta G°}{-2.303 \text{ RT}}$$

$$= \frac{-4780 \text{ J}}{-2.303 \times 8.314 \text{ J K}^{-} \times 298 \text{ K}} = 0.837$$

$\therefore$ K_p = antilog 0.837 = **6.87** **Ans.**

(*ii*) We know that (*a*) the value of ΔG is the negative of ΔG for the forward reaction, so,

$$\Delta G = -(-4.78 \text{ kJ})$$

$= +4.78$ kJ for the reverse reaction.

(*b*) the value of K_p for the reverse reaction is reciprocal of the value for forward reaction,

so, $K'_p = \dfrac{1}{K_p} = \dfrac{1}{6.87} = \mathbf{0.146}$ **Ans.**

(*c*) For $NO_2 \rightleftharpoons \frac{1}{2}N_2O_4$

$$\Delta G° = \frac{1}{2}\Delta G_f^o (N_2O_4) - \Delta G_f^o (NO_2)$$

$$= \frac{1}{2}(97.82) - 51.3$$

$$= 48.91 - 51.3 = -2.39 \text{ kJ}$$

$$= -2.39 \times 1000 = -2390 \text{ J}$$

But $\Delta G° = -2.303 \text{ RT} \log Kp$

$$\therefore \quad \log K_p = \frac{\Delta G°}{-2.303 \text{ RT}}$$

$$= \frac{-2390 \text{ J}}{-2.303 \times 8.314 \text{ J K}^{-} \times 298 \text{ K}} = 0.418$$

$\therefore$ K_p = antilog 0.418 = **0.262** **Ans.**

Example 58. *The free energy of formation of NO is 78 kJ mol^{-} at the temperature of an automobile engine (1000 K). What is the equilibrium constant for this reaction at 1000 K ?*

(*a*) 8.4×10^{-5} (*b*) 7.7×10^{-9}

(*c*) 4.2×10^{-10} (*d*) 1.7×10^{-19} **(Dumet, 2010)**

SOLUTION. ΔG° = 78 kJ mol^{-}, = 78 × 1000 = 78,000 J mol^{-}. But : K_{equi} = antilog $(-\Delta G^\circ/2.303RT)$ = antilog $(-78000/2.303 \times 1000 \times 8.314)$ = antilog (–4.0737) = 8.4×10^{-5}. So, the correct answer is (*a*)

EXAMPLE 59. *The ΔH° value for the reaction*

$$2NO_2\,(g) \rightleftharpoons N_2O_4\,(g)$$

is – 13.9 k cal. at 298 K. Calculate the value of equilibrium constant at 273 K, if equilibrium constant value at 298 K is 8.8.

SOLUTION. $T_1 = 298\text{ K},\ T_2 = 273\text{ K},$

$\Delta H^\circ = -13.9$ k cal,

K_1 at 298 K = 8.8 ; K_2 at 273 K = ?.

We know that :

$$\log K_2 - \log K_1 = \frac{-\Delta H^\circ}{2.303\,R}\left[\frac{1}{T_2} - \frac{1}{T_1}\right]$$

$$\log K_2 - \log 8.8 = \frac{-(-13.9 \times 1000\text{ cal})}{2.303 \times 2\text{ cal}}\left[\frac{1}{273} - \frac{1}{298}\right]$$

$$\log K_2 - 0.9444 = \frac{13900}{2.303 \times 2} \times \left[\frac{298-273}{273 \times 298}\right]$$

$$= \frac{13900 \times 25}{2.303 \times 2 \times 273 \times 298}$$

$$\log K_2 - 0.9444 = +0.9274\ ;$$

$$\log K_2 = +0.9274 + 0.9444 = 1.8718$$

$\therefore$ K_2 = antilog 1.8718 = **74.4** **Ans.**

EXAMPLE 60. *On mixing NO_2 (g) with NO (g), following equilibria was obtained.*

(*i*) $NO + NO_2 \rightleftharpoons N_2O_3$

(*ii*) $2NO_2 \rightleftharpoons N_2O_4$ $[K_p = 6.8\ (atm)^{-}]$

On mixing NO and NO_2 in the ratio 1 : 2, the total pressure was 5.05 atm and the partial pressure of N_2O_4 was 1.7 atm. Calculate

(*a*) *Partial pressure of NO (g) at equilibrium*

(*b*) *Calculate K_p for the reaction (i).*

SOLUTION. For reaction (*ii*)

$$2\,NO_2 \rightleftharpoons N_2O_4\ ;\ K_p = 6.8\text{ atm}^{-}$$

$$\therefore \quad K_p = \frac{p_{N_2O_4}}{p_{(NO_2)^2}}\ ;\ 6.8\text{ atm}^{-} = \frac{1.7\text{ atm}}{p_{(NO_2)^2}}$$

$$\therefore \quad p_{(NO_2)^2} = \frac{1.7\text{ atm}}{6.8\text{ atm}^{-}} = 0.25\text{ atm}^2\ ;$$

$$p_{NO_2} = (0.25\text{ atm}^2)^{1/2} = \mathbf{0.5\ atm.}$$

For reaction (*i*)

	NO (g) +	NO_2 (g) $\rightleftharpoons$	N_2O_3 (g)
(*i*) Pressure at start	P	2 p	0
(*ii*) Change by reaction	– *x*	– *x* – (2 × 1.7) = – *x* – 3.4	*x*
(*iii*) Pressure at equilibrium	P – *x*	2 P – *x* – 3.4 (= 0.5)	*x*

Since 3.4 atm of NO_2 are used for equilibrium, 2P – *x* – 3.4 will be equal to 0.5 atm. Thus:

Total pressure at equilibrium

$$= p_{NO} + p_{NO_2} + p_{N_2O_3} + p_{N_2O_4}$$

Or $5.05 = P - x + 0.5 + x + 1.7;$

$5.05 = P + 2.2\ ;\ P = 5.05 - 2.2 = 2.85$ atm.

But $2\,P - x - 3.4 = 0.5$.

So, $(2 \times 2.85) - x - 3.4 = 0.5\ ;$

$5.70 - x - 3.4 = 0.5$

Or $x = 5.7 - 3.4 - 0.5 = \mathbf{1.8} = \boldsymbol{p_{N_2O_3}}$

Hence $p_{NO} = P - x = 2.85 - 1.8 =$ **1.05 atm**

For reaction (*i*) :

$$K_p = \frac{p_{N_2O_3}}{p_{NO} \times p_{NO_2}} = \frac{1.8}{1.05 \times 0.5} = \mathbf{3.43\ atm^{-}}$$

23.16 COMPARISON OF THERMAL DECOMPOSITION AND THERMAL DISSOCIATION

Thermal decomposition. Substances like PCl_5, N_2O_4, NH_4Cl, HI when heated in a closed vessel, form two or more simple molecules. When such a reaction is cooled, the original substance is formed. Such a process is called **thermal dissociation.** For example :

$$PCl_5 \underset{\text{Cool}}{\overset{\text{Heat}}{\rightleftharpoons}} PCl_3 + Cl_2\ ;\ N_2O_4 \rightleftharpoons 2NO_2$$

$$NH_4Cl \rightleftharpoons NH_3 + HCl\ ;\ 2HI \rightleftharpoons H_2 + I_2$$

Thermal decomposition can be reversible (shown above) or irreversible. For example :

$$2\,KClO_3 \longrightarrow 2\,KCl + 3O_2 \text{ (irreversible).}$$

When the products formed on heating in a closed vessel do not form the original substance on cooling, the process is called **thermal decomposition.**

Degree of dissociation. It is the ratio of number of mol dissociated and total number of mol originally present. Mathematically :

Degree of dissociation,

$$\alpha = \frac{\text{Number of mol or molecules dissociated}}{\text{Total number of mol or molecules taken}}$$

$$= \frac{D-d}{d\,(n-1)}$$

Where D = Vapour density of a substance when there is no dissociation.

$= \frac{1}{2} \times$ Mol. mass of substance.

d = Vapour density of the substance at any temperature at which degree of dissociation is α.

Number of mol of products after dissociation = n

EXAMPLE 61. *The vapour density of nitrogen peroxide at 373 K and under 760 mm pressure is 25.67. Calculate the percentage of NO_2 molecules in the gas at this temperature. (At. mass, N = 14, O = 16).*

SOLUTION. Molar mass of nitrogen peroxide, N_2O_4= (2 × 14) + (4 × 16) = 28 + 64 = 92

$\therefore$ Vapour density (D) of N_2O_4

$$= \frac{1}{2} \times \text{mol. mass} = \frac{1}{2} \times 92 = 46.$$

For $\quad N_2O_4 \rightleftharpoons 2NO_2$

$\qquad\qquad$ 2 mol, $\quad n = 2$

Vapour density (d) of N_2O_4 at 373 K = 25.67

But $\qquad \alpha = \dfrac{D-d}{d\,(n-1)} = \dfrac{46-25.67}{25.67\,(2-1)}$

$$= \frac{20.33}{25.67} = 0.792$$

Let us consider the dissociation of N_2O_4.

	N_2O_4	$\rightleftharpoons 2NO_2$
Initial conc.	1	0
Conc. at equilibrium	$1-\alpha$	2α

Here volume is constant. Since in the reaction, number of mol of reactants and products differ, total number of mol of reaction are taken.

Total number of mol

$$= 1 - \alpha + 2\alpha = 1 + \alpha$$

$\therefore \qquad [NO_2] = \dfrac{2\alpha}{1+\alpha}$ and % of NO_2 in the mixture

$$= \frac{2\alpha}{1+\alpha} \times 100.$$

Since $\qquad \alpha = 0.792,$

$$\% \text{ of } NO_2 = \frac{2 \times 0.792}{1+0.792} \times 100 = \frac{1.584}{1.792} \times 100$$

$$= 88.4\ \%$$ **Ans.**

23.17 ORGANIC ACID + ALCOHOL $\rightleftharpoons$ ESTER + WATER

Type. Calculation of equilibrium constant for reactions involving homogenous liquid systems. In order to understand it, consider the following reaction.

$$CH_3COOH + C_2H_5OH \rightleftharpoons CH_3COOC_2H_5 + H_2O \ldots(i)$$

Initial conc.	a	b	0	0
Conc. at equilibrium	$a-x$	$b-x$	x	x

Let $\qquad$ V = Total volume of system in litre.

Then :

$$[CH_3COOH] = \frac{a-x}{V} \text{ mol L}^- ; [C_2H_5OH] = \frac{b-x}{V} \text{ mol L}^-$$

$$[CH_3COOC_2H_5] = \frac{x}{V} \text{ mol L}^- ; [H_2O] = \frac{x}{V} \text{ mol L}^-$$

Applying law of chemical equilibrium to reaction (i), we have :

$$K_C = \frac{[CH_3COOC_2H_5]\,[H_2O]}{[CH_3COOH]\,[C_2H_5OH]}$$

$$= \frac{\frac{x}{V} \text{ mol L}^- \times \frac{x}{V} \text{ mol L}^-}{\frac{a-x}{V} \text{ mol L}^- \times \frac{b-x}{V} \text{ mol L}^-}$$

$$K_c = \frac{x^2}{(a-x)\,(b-x)}$$

Note I. In order to solve such type of problems, an entry is made on following three lines (given in table) under each substance in the balanced equation. 'n' in the table represents amount of the substance.

Acid, e.g., + Alcohol, e.g. $\quad$ Ester, e.g., $\quad$ + Water

$$CH_3COOH + C_2H_5OH \rightleftharpoons CH_3COOC_2H_5 + H_2O$$

(i) n mol at start

(ii) Change by reaction

(iii) n mol at equilibrium.

II. Volume (V) of the vessel is not considered because $\Delta n = 0$ in the balanced equation; Δn = number of mol of products (–) number of mol of reactants.

Type. To find the value of equilibrium constant, K for the reaction acid + alcohol $\rightleftharpoons$ ester + water, use the relation :

$$K = \frac{[\text{ester}]\,[\text{water}]}{[\text{acid}]\,[\text{alcohol}]}$$

EXAMPLE 62. *When one mol of acetic acid is mixed with one mol of ethyl alcohol at room temperature, the equilibrium mixture contains 2/3 mol each of ester and water. Calculate the value of equilibrium constant.*

SOLUTION.

CH_3COOH = 1 mol ; C_2H_5OH = 1 mol.

Reaction :

CH_3COOH +	C_2H_5OH $\rightleftharpoons$	$CH_3COOC_2H_5$ +	H_2O
(i) n mol at start			
1	1	0	0
(ii) Change for reaction			
$-\frac{2}{3}$	$-\frac{2}{3}$	$+\frac{2}{3}$	$+\frac{2}{3}$
(iii) n mol at equilibrium			
$1-\frac{2}{3}=\frac{1}{3}$	$1-\frac{2}{3}=\frac{1}{3}$	$\frac{2}{3}$	$\frac{2}{3}$

Applying law of chemical equilibrium to the given reaction, we have :

$$K = \frac{[CH_3COOC_2H_5]\,[H_2O]}{[CH_3COOH]\,[C_2H_5OH]}$$

$$= \frac{\frac{2}{3} \times \frac{2}{3}}{\frac{1}{3} \times \frac{1}{3}} = 4$$

Note. Volume is not considered here because $\Delta n = 0$.

EXAMPLE 63. *When ethanol is mixed with ethanoic acid in equivalent proportion, following equilibrium takes place*

$$C_2H_5OH + CH_3COOH \rightleftharpoons CH_3COOC_2H_5 + H_2O$$

and two third of the ethanol and ethanoic acid get consumed. Calculate the amount of ester formed in equilibrium mixture if we start with 115g ethanol and 150 g ethanoic acid.

(MLNR, 1981)

SOLUTION. (*a*)

$$C_2H_5OH + CH_3COOH \rightleftharpoons CH_3COOC_2H_5 + H_2O$$

(*i*) n mol at start

$1 \qquad 1 \qquad 0 \qquad 0$

(*ii*) Change by reaction

$-\frac{2}{3} \qquad -\frac{2}{3} \qquad \frac{2}{3} \qquad \frac{2}{3}$

(*iii*) n mol at equilibrium

$1-\frac{2}{3}=\frac{1}{3} \qquad 1-\frac{2}{3}=\frac{1}{3} \qquad \frac{2}{3} \qquad \frac{2}{3}$

Since $\Delta n = 0$, volume is not considered.

$$K_c = \frac{[CH_3COOC_2H_5][H_2O]}{[C_2H_5OH][CH_3COOH]} =$$

$$= \frac{\frac{2}{3} \times \frac{2}{3}}{\frac{1}{3} \times \frac{1}{3}} = 4$$

(*b*) Wt. of ethanol

$= 115$ g ;

g. mol. wt. of C_2H_5OH

$= (2 \times 12) + (5 \times 1) + 16 + 1 = 46$ g

$\therefore$ no. of mol of ethanol $= \frac{115}{46} = 2.5$

Wt. of ethanoic acid = 150 g ;

g. mol. wt. of CH_3COOH

$= 12 + (3 \times 1) + 12 + (2 \times 16) + 1$

$= 60$ g

$\therefore$ no. of mol of ethanoic acid $= \frac{150}{60} = 2.5$ mol

$$C_2H_5OH + CH_3COOH \rightleftharpoons CH_3COOC_2H_5 + H_2O$$

(*i*) n mol at start

$2.5 \qquad 2.5 \qquad 0 \qquad 0$

(*ii*) Change by reaction

$-x \qquad -x \qquad x \qquad x$

(*iii*) n mol at equilibrium

$2.5-x \qquad 2.5-x \qquad x \qquad x$

Since $\Delta n = 0$, Volume is not considered.

$$K_c = \frac{[CH_3COOC_2H_5][H_2O]}{[C_2H_5OH][CH_3COOH]}$$

$$= \frac{x \times x}{(2.5-x)(2.5-x)} = \frac{x^2}{(2.5-x)^2}$$

Or $\quad 4 = \frac{x^2}{(2.5-x)^2}$

Taking square root of both sides, we get :

$$2 = \frac{x}{2.5-x} \,;\, 2(2.5-x) = x \,;\, 5 - 2x = x$$

Or $\quad x + 2x = 5; 3x = 5$;

$\therefore \quad x = \frac{5}{3} = 1.67$

g. mol. wt. of ester, $CH_3COOC_2H_5 = 12 + (3 \times 1) + 12 + (2 \times 16) + (2 \times 12) + (5 \times 1) = 88$ g

$\therefore$ Amount of ester, ethyl acetate

$= 88 \times 1.67 =$ **146.96 g** **Ans.**

EXAMPLE 64. *The equilibrium constant for the reaction* $CH_3COOH + C_2H_5OH \rightleftharpoons CH_3COOC_2H_5 + H_2O$ *is 4. What will be the composition of the equilibrium mixture if one mol of acid is taken along with 8 mol of alcohol ? Equilibrium constant, K = 4*

SOLUTION. Consider the following reaction :

$$CH_3COOH + C_2H_5OH \rightleftharpoons CH_3COOC_2H_5 + H_2O$$

(*i*) n at start

1mol $\qquad$ 8 mol $\qquad 0 \qquad 0$

(*ii*) Change for reaction

$-x \qquad -x \qquad x \qquad x$

(*iii*) n at equilibrium

$1-x \qquad 8-x \qquad x \qquad x$

Applying law of chemical equilibrium, we have :

$$K = \frac{[CH_3COOC_2H_5][H_2O]}{[CH_3COOH][C_2H_5OH]}$$

$$4 = \frac{x \times x}{(1-x)(8-x)} = \frac{x^2}{8 - x - 8x + x^2}$$

$$= \frac{x^2}{x^2 - 9x + 8}$$

$$4x^2 - 36x + 32 = x^2 \quad \text{or} \quad 3x^2 - 36x + 32 = 0$$

$$\therefore \quad x = \frac{-(-36) \pm \sqrt{(-36)^2 - 4(3 \times 32)}}{2 \times 3}$$

$$= \frac{+36 \pm \sqrt{1296 - 384}}{6}$$

$$= \frac{+36 \pm \sqrt{912}}{6} = \frac{+36 \pm 30.2}{6}$$

$$= \frac{66.2}{6} \text{ (when added)}$$

or $\frac{5.8}{6}$ (when subtracted) = 11.03 or 0.967;

$x = 0.967$ respectively.

$$\left[\because x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a} \text{ for } ax^2 + bx + c = 0\right]$$

x is not equal to 11.03 because minimum number of mol in the reaction is 1 (of CH_3COOH) and x cannot be more than 1.

$\therefore$ $[CH_3COOH] = 1 - x = 1 - 0.967 = \mathbf{0.033}$ **g mol Ans.**

$[C_2H_5OH] = 8 - x = 8 - 0.967 = \mathbf{7.033}$ **g mol Ans.**

$[CH_3COOC_2H_5] = [H_2O] = x = \mathbf{0.967}$ **g mol** **Ans.**

Type. When number of mol of products are also given, add these to x to get 'n' at equilibrium

EXAMPLE 65. *For the following reaction, the value of equilibrium constant is 4.0.*

$$CH_3COOH + C_2H_5OH \rightleftharpoons CH_3COOC_2H_5 + H_2O$$

Determine the amount of ester present at equilibrium when 1 mol of alcohol reacts with 1 mol of acid in presence of 1 mol of water.

SOLUTION. Consider the reaction.

$$CH_3COOH + C_2H_5OH \rightleftharpoons CH_3COOC_2H_5 + H_2O$$

(i) n at start

$$\begin{array}{llll} 1 \text{ mol} & 1 \text{ mol} & 0 & 1 \end{array}$$

(ii) Change for reaction

$$\begin{array}{llll} -x & -x & x & x \end{array}$$

(iii) n at equilibrium

$$\begin{array}{llll} 1-x & 1-x & x & 1+x \end{array}$$

$$\therefore \quad K = \frac{[CH_3COOC_2H_5][H_2O]}{[CH_3COOH][C_2H_5OH]}$$

$$= \frac{x(1+x)}{(1-x)(1-x)}$$

$$4 = \frac{x + x^2}{1 + x^2 - 2x};$$

$$4 + 4x^2 - 8x = x + x^2;$$

$$4x^2 - x^2 - 8x - x + 4 = 0$$

or $3x^2 - 9x + 4 = 0$

$$\therefore \quad x = \frac{-(-9) \pm \sqrt{(-9)^2 - 4(3 \times 4)}}{2 \times 3}$$

$$= \frac{9 \pm \sqrt{81 - 48}}{6} = \frac{9 \pm \sqrt{33}}{6}$$

$$x = \frac{9 + 5.74}{6} = 2.45$$

$$\text{or } x = \frac{9 - 5.74}{6} = 0.54.$$

$$\left[\because x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a} \text{ for } ax^2 + bx + c = 0\right]$$

So, $x = 0.54$ as the second value 2.45 is not admissible.

EXAMPLE 66. *In an experiment, starting with 1 mol of ethyl alcohol, 1 mol of acetic acid and 1 mol of water at 100°C, the equilibrium mixture on analysis shows that 54.3 % of the acid esterified. Calculate the equilibrium constant for this reaction.*

(Roorkee, 1982)

SOLUTION. Reaction

$$CH_3COOH + C_2H_5OH \rightleftharpoons CH_3COOC_2H_5 + H_2O$$

(i) n at start

$$\begin{array}{llll} 1 \text{ mol} & 1\text{mol} & 0 & 1 \end{array}$$

(ii) Change for reaction

$$\begin{array}{llll} \frac{-54.3}{100} & \frac{-54.3}{100} & \frac{+54.3}{100} & 1+\frac{+54.3}{100} \\ = -0.543 & = -0.543 & = +0.543 & = +1.543 \end{array}$$

(iii) n at equilibrium

$$\begin{array}{llll} 1-0.543 & 1-0.543 & 0.543 & 1.543 \\ = 0.457 & = 0.457 & & \end{array}$$

$$\therefore \quad K = \frac{[CH_3COOC_2H_5][H_2O]}{[CH_3COOH][C_2H_5OH]}$$

$$= \frac{0.543 \times 1.543}{0.457 \times 0.457}$$

$K = \mathbf{4.01}$ **Ans.**

EXAMPLE 67. *The equilibrium constant for the reaction*

$$CH_3COOH + C_2H_5OH \rightleftharpoons CH_3COOC_2H_5 + H_2O$$

is 4.0. How much ester will be present in the equilibrium mixture if we start with 240 g of acetic acid and 138 g of ethyl alcohol.

SOLUTION. (i) g. mol. wt. of $CH_3COOH = 12 + (3 \times 1) + 12 + 2(16) + 1 = 60$ g

wt. of $CH_3COOH = 240$ g ;

no. of mol of $CH_3COOH = \frac{240}{60} = 4$ mol

(ii) g. mol. wt. of

$C_2H_5OH = (2 \times 12) + (5 \times 1) + 16 + 1 = 46$ g

wt. of $C_2H_5OH = 138$ g ;

no. of mol of $C_2H_5OH = \frac{138}{46} = 3$ mol

Consider the reaction :

$$CH_3COOH + C_2H_5OH \rightleftharpoons CH_3COOC_2H_5 + H_2O$$

(i) n at start

$$\begin{array}{llll} 4 \text{ mol} & 3 \text{ mol} & 0 & 0 \end{array}$$

(ii) Change for reaction

$$\begin{array}{llll} -x & -x & x & x \end{array}$$

(iii) n at equilibrium

$$\begin{array}{llll} 4-x & 3-x & x & x \end{array}$$

$$\therefore \quad K = \frac{[CH_3COOC_2H_5][H_2O]}{[CH_3COOH][C_2H_5OH]}$$

$$4 = \frac{x \times x}{(4-x)(3-x)} \quad ; \quad 4 = \frac{x^2}{12 - 7x + x^2};$$

$$48 - 28x + 4x^2 = x^2$$

Or $3x^2 - 28x + 48 = 0$

$$x = \frac{-(-28) \pm \sqrt{(-28)^2 - 4\,(3 \times 48)}}{2 \times 3} s$$

$$\left[\because x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a} \text{ for } ax^2 + bx + c = 0\right]$$

$$= \frac{28 \pm \sqrt{784 - 576}}{6}$$

$$= \frac{28 \pm \sqrt{208}}{6}$$

$$= \frac{28 \pm 14.4}{6} = \frac{42.6}{6} \text{ (when added) or}$$

$\frac{13.6}{6}$ (when subtracted) = 7.06 or 2.26 respectively.

So, $x = 2.26$ mol because second value is not permissible.

g. mol. wt. of ester,

$$CH_3COOC_2H_5 = 12 + (3 \times 1) + 12 + 2\,(16) + (2 \times 12) + (5 \times 1)$$

$$= 12 + 3 + 12 + 32 + 24 + 5 = 88 \text{ g}$$

$\therefore$ Wt. of ester = 2.26 × 88 = **198.88 g** **Ans.**

EXAMPLE 68. *When acetic acid is mixed with ethyl alcohol in equal proportions, 67 % are converted into ethyl acetate ester. Calculate the amount of ester formed when 2 mol of acetic acid is heated with 1 mol of ethyl alcohol.*

SOLUTION. Consider the following reaction :

$$CH_3COOH + C_2H_5OH \rightleftharpoons CH_3COOC_2H_5 + H_2O$$

	CH_3COOH	C_2H_5OH	$CH_3COOC_2H_5$	H_2O
(*i*) *n* at start	100	100	0	0
(*ii*) Change for reaction	– 67	– 67	67	67
(*iii*) *n* at equilibrium	100 – 67 = 33	100 – 67 = 33	67	67

$$\therefore \quad K = \frac{[CH_3COOC_2H_5]\,[H_2O]}{[CH_3COOH]\,[C_2H_5OH]}$$

$$= \frac{67 \times 67}{33 \times 33} \text{Ă } 4$$

Again consider the reaction :

$$CH_3COOH + C_2H_5OH \rightleftharpoons CH_3COOC_2H_5 + H_2O$$

	CH_3COOH	C_2H_5OH	$CH_3COOC_2H_5$	H_2O
(*i*) *n* at start	2 mol	1 mol	0	0
(*ii*) Change for reaction	$-x$	$-x$	x	x
(*iii*) *n* at equilibrium	$2-x$	$1-x$	x	x

$$\therefore \quad K = \frac{[CH_3COOC_2H_5]\,[H_2O]}{[CH_3COOH]\,[C_2H_5OH]}$$

$$4 = \frac{x \times x}{(2-x)(1-x)} \quad ; \quad 4 = \frac{x^2}{2 - 3x + x^2}$$

$$8 - 12x + 4x^2 = x^2 \quad ; \quad 3x^2 - 12x + 8 = 0$$

$$\therefore \quad x = \frac{-(-12) \pm \sqrt{(-12)^2 - 4\,(3 \times 8)}}{2 \times 3}$$

$$\left[\because x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a} \text{ for } ax^2 + bx + c = 0\right]$$

$$= \frac{12 \pm \sqrt{144 - 98}}{6} = \frac{12 \pm \sqrt{46}}{6}$$

$$= \frac{12 \pm 6.78}{6}$$

$$= \frac{18.78}{6} \text{ (on addition) or } \frac{5.22}{6} \text{ (on subtraction)}$$

$$= 3.13 \text{ or } 0.87 \text{ respectively.}$$

So, $x = 0.87$ mol because second value is not permissible.

$\therefore$ Amount of ester formed = 0.87 mol.

Type: For problems involving ΔG, RT and equilibrium constant *K*, Use (*i*) $\Delta G^0_f = \Delta G^0_f \text{ (products)} - \Delta G^0_f \text{(reactants)}$ (*ii*) $\Delta G^0 = -2.303\ RT \log K$.

EXAMPLE 69. *Calculate the amount of ester formed when 0.4 mol of n – butyric acid is mixed with 2 mol of ethyl alcohol and allowed to come to equilibrium at 298 K. Given : standard free energies of formation of n-butyric acid, ethyl alcohol, ethyl n-butyrate and water are – 91.5 k. cal, – 41.63 k. cal, –76.0 k. cal and – 56.69 k. cal respectively.*

SOLUTION. Given reaction :

$$CH_3CH_2CH_2COOH + C_2H_5OH \rightleftharpoons CH_3CH_2CH_2COOC_2H_5 + H_2O$$

	$CH_3CH_2CH_2COOH$	C_2H_5OH	$CH_3CH_2CH_2COOC_2H_5$	H_2O
(*i*) *n* at start	0.4 mol	2 mol	0	0
(*ii*) Change for reaction	$-x$	$-x$	$+x$	$+x$
(*iii*) *n* at equilibrium	$0.4-x$	$2-x$	x	x
(*iv*) $\Delta G_f°$ (k. cal)	– 91.5	– 41.63	– 76.0	– 56.69

(*a*) $\Delta G_f° = \Delta G_f° \text{ (Products)} - \Delta G_f° \text{ (reactants)}$

$$= (-76.0 - 56.69) - (-91.5 - 41.63)$$

$$= -132.69 + 133.13$$

$$= 0.44 \text{ k. cal}$$

(*b*) $\Delta G_f° = -2.303\ RT \log K$

$$0.44 = -2.303 \times \frac{1.987}{1000} \times 298 \times \log K$$

$$\left[\because R = \frac{1.987}{1000}\text{ k cal}\right.$$

$$\log K = -\frac{0.44 \times 1000}{2.303 \times 1.987 \times 2.98} = -0.323$$

$$\therefore \quad K = \text{Antilog}\,(-0.323)$$

$$= \text{antilog} -1 + 1 - 0.323 = \bar{1}.677 = 0.48$$

Also, $$K = \frac{[CH_3CH_2CH_2COOC_2H_5]\,[H_2O]}{[CH_3CH_2CH_2COOH]\,[C_2H_5OH]}$$

Or $$0.48 = \frac{x \times x}{(0.4 - x)\,(2 - x)};$$

$$0.48 = \frac{x^2}{0.8 - 2.4\,x + x^2};$$

$$0.384 - 1.152x + 0.48x^2 = x^2$$

$$\therefore x^2 - 0.48\,x^2 + 1.152\,x - 0.384 = 0\,;$$

$$0.52\,x^2 + 1.152\,x - 0.384 = 0$$

$$\therefore \quad x = \frac{-1.152 \pm \sqrt{(1.152)^2 - 4\,(0.52 \times -0.384)}}{2 \times 0.52}$$

$$= \frac{-1.152 \pm \sqrt{1.33 + 0.799}}{1.04}$$

$$= \frac{-1.152 \pm \sqrt{2.129}}{1.04}$$

$$\left[\because \text{ for } ax^2 + bx + c = 0,\quad x = \frac{-b \pm \sqrt{b^2 - 4\,ac}}{2\,a}\right]$$

$$= \frac{-1.152 \pm 1.459}{1.04} = 0.295 \text{ mol}$$

Amount of ester ($CH_3CH_2CH_2COOC_2H_5$) formed = **0.295 mol.** **Ans.**

Type. To calculate active masses, calculate the number of mol (n) of substances concerned by using the relation : n = wt. of substance/mol. wt. of the substance.

Active mass = *n*/volume in litre

Example 70. *4.0 g H_2 and 128 g HI were taken in a 2 litre container at 400°C. Calculate their active masses.* **(UP 1980, 1984)**

Solution. (*a*)

Wt. of H_2 = 4.0 g ; g. mol. wt. of H_2 = 2 × 1 = 2g

∴ no. of mol of H_2 = 4/2 = 2

(*b*) Wt. of HI = 128 g ; g. mol. wt. of HI = 1 + 127 = 128 g

∴ no. of mol of HI = 128/128 = 1; Volume of container = 2 L

(*c*) Active mass of

$$H_2 = \frac{\text{no. of mol of } H_2}{\text{Volume in litre}} = \frac{2}{2}$$

= **1 g mol L^{-}** **Ans.**

Active mass of

$$HI = \frac{\text{no. of mol of HI}}{\text{Volume in litre}} = \frac{1}{2}$$

= **0.5 g mol L^{-}** **Ans.**

Type. To know whether equilibrium has reached or not, use the concept :

(*a*) If the value of Q (concentration quotient) is **less** than K (equilibrium constant), the equilibrium has not been reached, and the reaction will proceed in the forward direction.

(*b*) If the value of Q is nearly equal or equal to K, the equilibrium has reached.

(*c*) If Q >> K, the equilibrium has not been reached and the reaction will proceed in the backward direction.

Example 71. *Following two experiments were performed. Predict, whether in these experiments, the equilibrium has reached or not.*

(*a*) *When 1 mol of acetic acid is treated with 0.5 mol of ethyl alcohol, 0.214 mol of ethyl acetate is formed at constant temperature, 298 K. (K = 4).*

(*b*) *When 1 mol of acetic acid is treated with 0.180 mol of ethyl alcohol, 0.170 mol of ethyl acetate is formed after sometime. (K = 4)*

Solution. Given reaction :

$$CH_3COOH + C_2H_5OH \rightleftharpoons CH_3COOC_2H_5 + H_2O$$

(1) First-Case

(*i*) n mol at start

1.0 mol 0.5 mol 0 0

(*ii*) Change by reaction

− 0.214 mol − 0.214 mol + 0.214 mol + 0.214 mol

(*iii*) n mol at equilibrium

1 − 0.214 = 0.786 mol 0.5 − 0.214 = 0.286 mol 0.214 mol 0.214 mol

∴ Concentration quotient,

$$Q = \frac{[CH_3COOC_2H_5]\,[H_2O]}{[CH_3COOH]\,[C_2H_5OH]}$$

Or $$Q = \frac{0.214 \times 0.214}{0.786 \times 0.286} = 0.2\,;\; K = 4 \text{ (given)}$$

Since the value of Q is less than K, the equilibrium has not reached.

(2) **Second Case.**

$$CH_3COOH + C_2H_5OH \rightleftharpoons CH_3COOC_2H_5 + H_2O$$

(*i*) n mol at start

1.0 0.18 0 0

(*ii*) Change by reaction

− 0.17 − 0.17 + 0.17 +0.17

(*iii*) n mol at equilibrium

1 − 0.17 = 0.83 0.18 − 0.17 = 0.01 + 0.17 +0.17

$\therefore$ Concentration Quotient,

$$Q = \frac{[CH_3COOC_2H_5]\,[H_2O]}{[CH_3COOH]\,[C_2H_5OH]}$$

$$= \frac{0.17 \times 0.17}{0.83 \times 0.01} \simeq 3.5$$

But $K = 4$ (given).

Since the value of Q is very near to the value of K, the equilibrium has reached.

23.18 METHOD TO FIND DEGREE OF DISSOCIATION (α) FROM VAPOUR DENSITY (V.D.) MEASUREMENT OF A GAS

This method is applicable for those reactions only which have no solution but have atleast one gas.

EXAMPLE 72. *The vapour density of PCl_5 was found to be 65 at a certain temperature. Calculate the degree of dissociation at this temperature.*

SOLUTION. Mol. mass of PCl_5

$$= 31 + 5\,(35.5) = 31 + 177.5 = 208.5$$

$\therefore$ Vapour density (D) of PCl_5

$$= \frac{1}{2} \times 208.5 = 104.25$$

For PCl_5, $PCl_5 \rightleftharpoons PCl_3 + Cl_2$

1 mol 1 mol] ; $n = 1 + 1 = 2$

Vapour density (d) at a given temperature = $d = 65$

But $\alpha = \dfrac{D-d}{d\,(n-1)}$ **Or** $\alpha = \dfrac{104.25 - 65}{65\,(2-1)}$

$$\alpha = \frac{39.25}{65} = 0.603$$

$= 0.603 \times 100 =$ **60.3 %** **Ans.**

EXAMPLE 73. *3.6 g of PCl_5 volatilises completely at 200 °C and the volume occupied by the vapour is 1 litre under a pressure of 1 atmosphere. A partial dissociation of PCl_5 also takes place giving PCl_3 and Cl_2. Calculate the degree of dissociation of PCl_5 at this temperature. (At. wt. P = 31 ; Cl = 35.5)*

SOLUTION. $P_1 = 1$ atm ; $V_1 = 1$ L ;

$T_1 = 200 + 273 = 473$ K

At N.T. P. ; $P_2 = 1$ atm ; $V_2 = ?$ $T_2 = 273$ K

Applying gas equation,

$$\frac{P_1 V_1}{T_1} = \frac{P_2 V_2}{T_2} \quad \text{or} \quad V_2 = \frac{P_1 V_1 T_2}{P_2 T_1}$$

$$\therefore \quad V_2 = \frac{1\,\text{atm} \times 1\,\text{L} \times 273\,\text{K}}{1\,\text{atm} \times 473\,\text{K}} = 0.577\ \text{L}$$

0.577 L of gaseous mixture weighs = 3.6 g

11.2 L of gaseous mixture weigh

$$= \frac{3.6}{0.577} \times 11.2 = 69.9\ \text{g}$$

$\therefore$ Density (d) of mixture = 69.9

Mol. mass of $PCl_5 = 31 + 5(35.5) = 31 + 177.5 = 208.5$

$$\left[\begin{array}{c} \because \text{g. mol. mass of a gas} \\ \text{occupies volume} = 22.4\ \text{L;} \\ V.D = \frac{1}{2} \times \text{mol. mass ;} \\ \text{Volume occupied} \\ = \frac{1}{2} \times 22.4 = 11.2\ \text{L} \end{array}\right]$$

$\therefore$ Vapour density (D) of $PCl_5 = \dfrac{1}{2} \times 208.5 = 104.25.$

For $PCl_5 \rightleftharpoons PCl_3 + Cl_2$

1 mol 1 mol] $\therefore n = 1 + 1 = 2$

But $\alpha = \dfrac{D-d}{d\,(n-1)}$

$$\therefore \quad \alpha = \frac{104.25 - 69.9}{69.9\,(2-1)} = \frac{34.35}{69.9}$$

$= 0.49 = 0.49 \times 100 =$ **49 %.** **Ans.**

EXAMPLE 74. *At one atmospheric pressure and 127°C, the degree of dissociation of PCl_5 ($PCl_5 \rightleftharpoons PCl_3 + Cl_2$) is 0.4. Assuming ideal behaviour of all the gases, calculate the equilibrium constant at the same temperature and pressure.* **(I.I.T. 1998)**

SOLUTION.	PCl_5	$\rightleftharpoons$	PCl_3	$+ Cl_2$
(*i*) *n* mol at start	1		0	0
(*ii*) Change by reaction	$-\alpha$		α	α
(*iii*) *n* mol at equilibrium	$1-\alpha$		α	α

$\therefore$ Total number of mol $= 1 - \alpha + \alpha + \alpha = 1 + \alpha$

g. mol. wt. of $PCl_5 = 31 + (5 \times 35.5) = 31 + 177.5$

$= 208.5$

$\therefore$ Before dissociation of PCl_5, V.D. of PCl_5

$=$ Mol. Wt./2 = 208.5/2 = 104.25.

Let $d =$ density at equilibrium.

But $\alpha = \dfrac{D-d}{d\,(n-1)}.$

But $\alpha = 0.4$ and $n = 1$ mol PCl_3 + 1 mol Cl_2

$= 2$ mol

$$\therefore \quad 0.4 = \frac{104.25 - d}{d \times 1}\ ;$$

$$0.4\,d = 104.25 - d;$$

$$d + 0.4\,d = 104.25 \ \text{Or}\ 1.4\,d = 104.25\ ;$$

$$\therefore \quad \boldsymbol{d} = \frac{104.25}{1.4} = \mathbf{74.46}\ ;$$

$$T = 127 + 273 = 400\ \text{K}$$

$\therefore$ Mol. wt. of PCl_5 at 127°C = $2 \times d = 2 \times 74.46$

$= 148.92$ g mol^{-}

But $PV = nRT$ or

$$PV = \frac{W}{\text{mol. wt}} \times RT \quad \text{[Ideal gas equation]}$$

Or $\dfrac{W}{V} = \dfrac{P \times \text{mol. wt}}{RT}$

or $$\text{Density} = \frac{1 \text{ atm} \times 148.92 \text{ g mol}^{-}}{0.082 \text{ L atm K}^{-} \text{ mol}^{-} \times 400 \text{ K}}$$

∴ Density = **4.54 g L^{-}** **Ans.**

Example 75. *At 523 K, PCl_5 gets dissociated to 80%. Calculate the vapour density of PCl_5 at 523 K.*

Solution.

	$PCl_5 \rightleftharpoons$	PCl_3 +	Cl_2
(*i*) *n* mol at start	100	0	0
(*ii*) Change by reaction	– 80	80	80
(*iii*) *n* mol at equilibrium	100 – 80 = 20	80	80

Total number of mol = 20 + 80 + 80 = 180

Mol. wt. of PCl_5 = 31 + (5 × 35.5) = 31 + 177.5 = 208.5

Density (**D**) of undissociated PCl_5 = Mol. wt/2 = 208.5/2 = **104.25**

We know that :

Densities are inversely proportional to molar volume while molar volume is directly proportional to molar concentration.

$$\therefore \quad D \propto \frac{1}{100} \qquad ...(1)$$

Density (d) at equilibrium of all

$$\text{mol} \propto \frac{1}{180} \qquad ... (2)$$

Dividing (1) and (2), we get :

$$\frac{D}{d} = \frac{180}{100}$$

Or $$d = \frac{D \times 100}{180} = \frac{104.25 \times 100}{180} = \mathbf{57.9}$$ **Ans.**

23.19 DECOMPOSITION OF PCl_5

Example 76. *The equilibrium constant for the reaction :*

$$PCl_5\,(g) \rightleftharpoons PCl_3\,(g) + Cl_2\,(g)$$

is 0.041 at 250° C. Calculate the number of mol of Cl_2 produced at equilibrium when 1.0 mol of PCl_5 is heated in a 10 L vessel at 250°C.

Solution. Reaction :

	$PCl_5 \rightleftharpoons$	PCl_3 +	Cl_2
(*i*) *n* mol L^{-} at start	$\frac{1 \text{ mol}}{10 \text{ L}}$ = 0.1 mol L^{-}	0	0
(*ii*) Change by reaction	– *x*	*x*	*x*
(*iii*) *n* mol at equilibrium	0.1 – *x*	*x*	*x*

Applying law of chemical equilibrium, we get :

$$K_c = \frac{[PCl_3]\,[Cl_2]}{[PCl_5]};$$

$$0.041 = \frac{x \times x}{0.1 - x} = \frac{x^2}{0.1 - x}$$

Or $0.041(0.1 - x) = x^2$; $0.0041 - 0.041\,x = x^2$

$\therefore \quad x^2 + 0.041x + 0.0041 = 0$;

$$x = \frac{-0.041 \pm \sqrt{(0.041)^2 - 4\,(1 \times 0.0041)}}{2 \times 1}$$

Or $$x = \frac{-0.041 \pm \sqrt{1.681 \times 10^{-3} - 0.0164}}{2}$$

$$\left[\therefore \text{ for } ax^2 + bx + c = 0 \quad x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}\right]$$

$$= \frac{-0.041 \pm \sqrt{0.001681 - 0.0164}}{2}$$

$$= \frac{-0.041 + \sqrt{0.0148}}{2}$$

$$= \frac{-0.041 + 0.122}{2} \text{ (on addition)}$$

= 0.0405 mol L^{-}

= 0.0405 mol L^{-} × 10 L;

x = **0.405 mol** **Ans.**

Example 77. *In an experiment, PCl_5 was added into an evacuated chamber. The equilibrium came into being at 2 atm and 250°C. The equilibrium gas contains 40.5 % Cl_2 by volume.*

(*a*) *Calculate the partial pressures of the gaseous components at equilibrium.*

(*b*) *Calculate K_p*

(*c*) *Suppose the gaseous mixture is expanded to 0.2 atm at 250°C, then find :*

  (*i*) *% age of PCl_5 that would be dissociated at equilibrium.*

  (*ii*) *% age by volume of Cl_2 in the equilibrium gaseous mixture.*

  (*iii*) *Partial pressure of Cl_2 in the equilibrium mixture.*

Solution.

	$PCl_5 \rightleftharpoons$	PCl_3 +	Cl_2
% age by volume or mol at equilibrium	100 – (40.7 + 40.7) = 18.6	40.7	40.7

(*a*) $$p(Cl_2) = p(PCl_3) = 2 \text{ atm} \times \frac{40.7}{100}$$

= **0.814 atm.** **Ans.**

$$p\,(PCl_5) = 2 \text{ atm} \times \frac{18.6}{100} = \mathbf{0.372 \text{ atm}}$$ **Ans.**

(*b*) $$Kp = \frac{p\,(PCl_3) \times p\,(Cl_2)}{p\,(PCl_5)}$$

$$= \frac{0.814 \text{ atm} \times 0.814 \text{ atm}}{0.372 \text{ atm}}$$

= **1.78 atm.** **Ans.**

(c) $PCl_5 \rightleftharpoons PCl_3 + Cl_2$

$$\therefore K_p = \frac{p\,(PCl_3) \times p\,(Cl_2)}{p\,(PCl_5)}$$

(Law of chemical equilibrium)

or $$p(\text{PCl}_5) = \frac{p\,(\text{PCl}_3)^2}{K_P} \qquad [\because p(\text{PCl}_3) = p(\text{Cl}_2)]$$

$$p(\text{PCl}_5) = \frac{p(\text{PCl}_3)^2}{0.178 \text{ atm}} = 0.562\, p(\text{PCl}_3)^2 \qquad ...(1)$$

But $p(\text{PCl}_3) + p(\text{Cl}_2) + p(\text{PCl}_5) = 0.2$;

$p(\text{PCl}_3) + p(\text{PCl}_3) + 0.562\, p(\text{PCl}_3)^2 = 0.2$

or $0.562\, p(\text{PCl}_3)^2 + 2\, p(\text{PCl}_3) - 0.2 = 0$

$[\because p(\text{PCl}_3) = p(\text{Cl}_2)]$

$$\therefore \quad p(\text{PCl}_3) = \frac{-2 \pm \sqrt{(2)^2 - 4\,(0.562 \times -0.2)}}{2 \times 0.562}$$

$$\left[\because \text{for } ax^2 + bx + c = 0, \quad x = \frac{-b \pm \sqrt{b^2 - 4\,ac}}{2\,a}\right.$$

$$= \frac{-2 \pm \sqrt{4 + 0.4496}}{1.124} = \frac{-2 \pm \sqrt{4.4496}}{1.124}$$

$$= \frac{-2 \pm 2.11}{1.124} = \frac{+0.11}{1.124} \text{ (on adding)}$$

or $$\frac{-4.11}{1.124} \text{ (on subtraction)}$$

But negative value is not possible.

So : $p(\text{PCl}_3) = \frac{+0.11}{1.124} = \mathbf{0.097}$

Thus $p(\text{PCl}_3) = p(\text{Cl}_2) = 0.097$

From equation (1), we get ; $p(\text{PCl}_5) = 0.562 \times (0.097)^2 = 5.29 \times 10^{-3}$ atm. = 0.00529 atm.

Fraction dissociated

$$= \frac{p\,(\text{PCl}_3)}{p\,(\text{PCl}_3) + p\,(\text{PCl}_5)}$$

$$= \frac{0.097}{0.097 + 0.00529} = \frac{0.097}{0.10229} = 0.948$$

Percent dissociated

= 0.948 × 100 = 94.8 %

$$\text{Mol percent Cl}_2 = \frac{p\,(\text{Cl}_2)}{p\,(\text{Cl}_2) + p\,(\text{PCl}_3) + p\,(\text{PCl}_5)} \times 100$$

$$= \frac{0.097 \times 100}{0.097 + 0.097 + 0.00529}$$

$$= \frac{0.097}{0.19929} \times 100$$

$= \mathbf{48.6\ \%\ Cl_2}$ **Ans.**

EXAMPLE 78. *A known amount of PCl_5 was heated at 523 K in a 12 litre container. At equilibrium, the container contains 0.32 mol each of Cl_2 and PCl_3 but 0.21 mol of PCl_5, for the reaction, $PCl_5\,(g) \rightleftharpoons PCl_3(g) + Cl_2\,(g)$. Calculate equilibrium constant (K) for the dissociation of PCl_5 at 523 K when concentrations are measured in 1 mol L^{-}. Also find the value of $\Delta G°$.*

SOLUTION. Volume = 12 L

Reaction	$\text{PCl}_5 \rightleftharpoons$	PCl_3 +	Cl_2
n mol L^{-} at equilibrium	$\frac{0.21}{12}$	$\frac{0.32}{12}$	$\frac{0.32}{12}$

$$\therefore \quad K = \frac{[\text{PCl}_3]\,[\text{Cl}_2]}{[\text{PCl}_5]} = \frac{\frac{0.32}{12} \times \frac{0.32}{12}}{\frac{0.21}{12}}$$

$$= \frac{0.32}{12} \times \frac{0.32}{12} \times \frac{12}{0.21} = 0.041$$

$\therefore \quad \mathbf{K = 0.041}$

Also, $\Delta G° = -2.303 \text{ RT} \log \text{K}$;

$\Delta G° = -2.303 \times 8.314 \text{ J K}^{-} \times 523 \text{ K} \log 0.041$

$= -10{,}014 \log 0.041$

$= (-10014) \times (-1.3872)$

$= 13891 \text{ J} \simeq \mathbf{13.9\ k\ J}$

EXAMPLE 79. *One mol of Cl_2 and 3 mol of PCl_5 are placed in a 100 litre vessel heated to 277°C. The equilibrium pressure is 2.05 atmosphere. Assuming ideal behaviour, calculate the degree of dissociation of PCl_5 and K_p for the reaction,*

$$\text{PCl}_5 \rightleftharpoons \text{PCl}_3 + \text{Cl}_2 \qquad \textbf{(IIT 1984)}$$

SOLUTION. (*a*) P = 2.05 atm ; V = 100 L ;

R = 0.082 L atm (degree)$^{-}$,

T = 227 + 273 = 500 K.

But $PV = n\,RT$;

$$\boldsymbol{n} = \frac{PV}{RT} = \frac{2.05 \times 100}{0.082 \times 500} = \mathbf{5}$$

Reaction :	$\text{PCl}_5 \rightleftharpoons$	PCl_3 +	Cl_2
(*i*) n mol at start	3	0	1
(*ii*) Change by reaction	$-3\,x$	$3\,x$	$3\,x$
(*iii*) n mol at equilibrium	$3 - 3\,x$	$3\,x$	$1 + 3\,x$

∴ Total number of mol (n) at equilibrium

$= 3 - 3\,x + 3\,x + 1 + 3\,x = 3\,x + 4$

Thus $n = 3\,x + 4$ or $5 = 3\,x + 4$;

$3\,x = 1$; $x = \frac{1}{3} = 0.333.$

∴ % age of dissociation

= 0.333 × 100 = **33.3 %.**

(*b*) $$K_p = \frac{[\text{PCl}_3]\,[\text{Cl}_2]}{[\text{PCl}_5]}$$

$$= \frac{\left(\frac{3x}{3x+4} \times P\right)\left(\frac{1+3x}{3x+4} \times P\right)}{\left(\frac{3-3x}{3x+4} \times P\right)}$$

$$= \frac{3x\,(1+3x)\,P}{(3x+4)\,(3-3x)} \qquad ...(1)$$

Substituting the value of $x = \frac{1}{3}$ and P = 2.05 atm in equation (1), we get :

$$K_p = \frac{3 \times \frac{1}{3}\left(1 + 3 \times \frac{1}{3}\right) \times 2.05}{\left[\left(3 \times \frac{1}{3}\right) + 4\right]\left[3 - \left(3 \times \frac{1}{3}\right)\right]}$$

$$= \frac{4.10}{5 \times 2} = \frac{4.1}{10} = \mathbf{0.41} \qquad \textbf{Ans.}$$

EXAMPLE 80. *At 540 K, 0.1 mol of PCl_5 are heated in a 8 L flask. The pressure of the equilibrium mixture is found to be 1.0 atm. Calculate K_p and K_c for the reaction.* **(Roorkee 1998)**

SOLUTION.

	$PCl_5 \rightleftharpoons$	PCl_3 +	Cl_2 ...(1)
(*i*) *n* mol at start	0.1	0	0
(*ii*) Change by reaction	$-x$	x	x
(*iii*) n mol at equilibrium	$0.1 - x$	x	x

Total number of mol (n) = $0.1 - x + x + x = 0.1 + x$

Also, $P = 1$ atm, $V = 8$ L, $R = 0.082$ L atm K^{-} mol^{-}, $T = 540$ K

But $PV = nRT$; $P = \dfrac{nRT}{V}$;

$$1 = \frac{(0.1 + x) \times 0.082 \times 540}{8}$$

$$0.1 + x = \frac{8}{0.082 \times 540}; \quad 0.1 + x = 0.18;$$

$$x = 0.18 - 0.1 = \mathbf{0.08}$$

But $K_p = \dfrac{[PCl_3][Cl_2]}{[PCl_5]}$

$$= \frac{\left(\frac{x}{0.1 + x} \times P\right)\left(\frac{x}{0.1 + x} \times P\right)}{\frac{0.1 - x}{0.1 + x} \times P}$$

$$= \frac{x^2 P}{(0.1 - x)(0.1 + x)}$$

$$K_p = \frac{x^2 P}{0.01 - x^2}$$

Substituting, $x = 0.08$, we get : $K_p = \dfrac{(0.08)^2 \times 1}{0.01 - (0.08)^2}$

$$= \frac{0.0064}{0.01 - 0.0064} = \frac{0.0064}{0.0036} = \mathbf{1.78\ atm}$$

In reaction (1),

$$\Delta n = n_P - n_R = (1 + 1) - 1 = 1$$

$\therefore$ $K_p = K_c (RT)^{\Delta n}$

Or $K_c = \dfrac{K_p}{(RT)^{\Delta n}}$

$$= \frac{1.78 \text{ atm}}{[(0.082 \text{ L atm K}^{-}\text{mol}^{-}) \times 540 \text{ K}]}$$

$\therefore$ $K_c = \mathbf{0.0401\ mol\ L^{-}}$ **Ans.**

EXAMPLE 81. *At some temperature and under a pressure of 4 atm, PCl_5 is 10 % dissociated. Calculate the pressure at which PCl_5 will be 20 % dissociated, temperature remaining same.* **(Roorkee 1996)**

SOLUTION.

	$PCl_5 \rightleftharpoons$	PCl_3 +	Cl_2
(*i*) *n* mol at start	1	0	0
(*ii*) Change by reaction	$-x$	x	x
(*iii*) *n* mol at equilibrium	$1 - x$	x	x

Total number of mol (n)

$$= 1 - x + x + x = 1 + x$$

$$K_p = \frac{[PCl_3][Cl_2]}{[PCl_5]} = \frac{\left(\frac{x}{1+x} \times P\right)\left(\frac{x}{1+x} \times P\right)}{\left(\frac{1-x}{1+x} \times P\right)}$$

$$= \frac{x^2 P}{1 - x^2}$$

$$P = 4 \text{ atm}; \; x = 10\% = \frac{10}{100} = 0.1.$$

Substituting the values, we get :

$$K_p = \frac{(0.1)^2 \times 4}{1 - (0.1)^2} = \frac{0.01 \times 4}{1 - 0.01}$$

$$= \frac{0.04}{0.99} \simeq 0.04 \text{ atm.}$$

When $x = 20\% = \dfrac{20}{100} = 0.2$, $K_p = 0.04$ atm, then,

$$K_p' = \frac{[PCl_3][Cl_2]}{[PCl_5]} = \frac{x^2 P'}{1 - x^2} = \frac{(0.2)^2 \times P'}{1 - (0.2)^2}$$

Or $0.04 = \dfrac{0.04 \times P'}{1 - 0.04} = \dfrac{0.04 \times P'}{0.96}$;

$$P' = \frac{0.96 \times 0.04}{0.04} = \mathbf{0.96\ atm}$$

EXAMPLE 82. *At 1 atmospheric pressure and 291 K, PCl_5 gets 41.7 % dissociated. Calculate equilibrium constant as well as the fraction dissociated under three atmospheric pressure.*

SOLUTION. (*a*)

	$PCl_5 \rightleftharpoons$	PCl_3 +	Cl_2
(*i*) *n* mol at start	1	0	0
(*ii*) Change by reaction	$-x$	x	x
(*iii*) *n* mol at equilibrium	$1 - x$	x	x

$\therefore$ Total number of mol = $1 - x + x + x = 1 + x$

$$K_p = \frac{[PCl_3][Cl_2]}{[PCl_5]}$$

$$= \frac{\left(\frac{x}{1+x} \times P\right)\left(\frac{x}{1+x} \times P\right)}{\left(\frac{1-x}{1+x}\right) \times P} = \frac{x^2 P}{1 - x^2}$$

Here $P = 1$ atm ; $x = 1 \times \dfrac{41.7}{100} = 0.417$

$\therefore$ $K_p = \dfrac{(0.417)^2 \times 1}{1 - (0.417)^2} = \dfrac{0.174}{1 - 0.174} = \dfrac{0.174}{0.826}$

$= 0.21$

(*b*) $P = 3 \text{ atm}$; $K_p = 0.21$; $x = ?$

$$K_p = \frac{[PCl_3][Cl_2]}{[PCl_5]} ; \; 0.21 = \frac{x^2 P}{1-x^2} = \frac{x^2 \times 3}{1-x^2}$$

$$\therefore \; 0.21(1-x^2) = 3x^2 ; \; 0.21 - 0.21x^2 = 3x^2 ;$$

$$3x^2 + 0.21x^2 = 0.21 ;$$

$$3.21x^2 = 0.21 ; \; x^2 = \frac{0.21}{3.21} = 0.0654 ;$$

$$x = \sqrt{0.0654} \; \textbf{Or} \; x = \mathbf{0.256}$$ **Ans.**

EXAMPLE 83. *The K_p value of $PCl_5 \rightleftharpoons PCl_3 + Cl_2$ under a total pressure of 1.5 atmosphere is 0.202. Calculate the volume percent of chlorine at equilibrium.*

SOLUTION.	$PCl_5 \rightleftharpoons$	$PCl_3 +$	Cl_2
(*i*) *n* mol at start	1	0	0
(*ii*) Change by reaction	$-x$	x	x
(*iii*) *n* mol at equilibrium	$1-x$	x	x

Total number of mol = $1 - x + x + x = 1 + x$;

Pressure = 1.5 atm

$$K_p = \frac{[PCl_3][Cl_2]}{[PCl_5]}$$

$$= \frac{\left(\frac{x}{1+x} \times P\right)\left(\frac{x}{1+x} \times P\right)}{\left(\frac{1-x}{1+x} \times P\right)} = \frac{x^2 P}{1-x^2}$$

Or $$0.202 = \frac{x^2 \times 1.5}{1-x^2} ; \; 0.202 - 0.202x^2 = 1.5x^2 ;$$

$$1.5x^2 + 0.202x^2 = 0.202 ; \; 1.702x^2 = 0.202$$

$$\therefore \; x^2 = \frac{0.202}{1.702} = 0.119 ; \; x = \sqrt{0.119} = 0.345$$

But volume percent of Cl_2 = mol percent of Cl_2
= mol fraction of Cl_2 × 100

$$= \frac{x}{1+x} \times 100$$

∴ **Volume percent of Cl_2**

$$= \frac{0.345 \times 100}{1+0.345} = \frac{34.5}{1.345} = \mathbf{25.6\ \%}$$ **Ans.**

EXAMPLE 84. *2 g mol of PCl_5 are heated in a closed vessel of 2 litre capacity. When the equilibrium is reached, the pentachloride is 40 % dissociated into PCl_3 and Cl_2. Calculate the equilibrium constant.* **(Rajasthan, 1962, UP 1990)**

SOLUTION.	$PCl_5 \rightleftharpoons$	$PCl_3 +$	Cl_2
(*i*) *n* mol at start	2	0	0
(*ii*) Change by reaction	$-x$	x	x
(*iii*) *n* mol at equilibrium	$\frac{2-x}{V}$	$\frac{x}{V}$	$\frac{x}{V}$

$$K_p = \frac{[PCl_3][Cl_2]}{[PCl_5]} = \frac{\left(\frac{x}{V}\right)\left(\frac{x}{V}\right)}{\left(\frac{2-x}{V}\right)} = \frac{x^2}{(2-x)V}$$

$$V = 2\text{L} ; \; x = 40\,\%\text{ of } 2\text{ mol} = \frac{2 \times 40}{100} = 0.8$$

$$\therefore \; K_p = \frac{(0.8)^2}{(2-0.8) \times 2} = \frac{0.64}{4-1.6} = \frac{0.64}{2.4} = 0.267;$$

$$K_p = \mathbf{0.267}$$ **Ans.**

EXAMPLE 85. *Given that the degree of dissociation of PCl_5 at 523 K under atmospheric pressure is 0.798. Calculate the values of K_p and K_c.* **(Allahabad,1967)**

SOLUTION. (*a*)	$PCl_5 \rightleftharpoons$	$PCl_3 +$	Cl_2
(*i*) *n* mol at start	1	0	0
(*ii*) Change by reaction	$-x$	x	x
(*iii*) *n* mol at equilibrium	$1-x$	x	x

Total number of mol = $1 - x + x + x = 1 + x$; Pressure = P

$$K_p = \frac{[PCl_3][Cl_2]}{[PCl_5]}$$

$$= \frac{\left(\frac{x}{1+x} \times P\right)\left(\frac{x}{1+x} \times P\right)}{\left(\frac{1-x}{1+x} \times P\right)} = \frac{x^2 P}{1-x^2}$$

$$x = 0.798 ; \; P = 1 \text{ atm.}$$

$$\therefore \; K_P = \frac{(0.798)^2 \times 1}{1-(0.798)^2} = \frac{0.637}{1-0.637}$$

$$= \frac{0.637}{0.363} = 1.755 \text{ atm.}$$

(*b*) $$K_p = K_c(RT)^{\Delta n}$$

For $$\underset{1\text{ mol}}{PCl_5} \rightleftharpoons \underset{1\text{ mol}}{PCl_3} + \underset{1\text{ mol}}{Cl_2}$$

$$\Delta n = (1+1) - 1 = 1;$$

$$R = 0.0821 \text{ L atm K}^{-}\text{ mol}^{-}, \; T = 523 \text{ K}$$

$$1.755 \text{ atm} = K_c(0.0821 \text{ L atm K}^{-}\text{ mol}^{-} \times 523 \text{ K})^1$$

$$\therefore \; K_C = \frac{1.755 \text{ atm}}{0.0821 \text{ L atm K}^{-}\text{ mol}^{-} \times 523 \text{ K}}$$

$$= \mathbf{0.041\ mol\ L^{-}}$$ **Ans.**

EXAMPLE 86. *The vapour density of PCl_5 at 523 K and one atmospheric pressure is 57.9 . Calculate (i) K_p for $PCl_5 \rightleftharpoons PCl_3 + Cl_2$ reaction at 523 K (ii) Pressure at which PCl_5 is half dissociated (iii) % age dissociation when pressure is tripled. (At. wt. P = 31, Cl = 35.5).*

SOLUTION. g. mol. wt. of PCl_5 = 31 + (5 × 35.5)
= 31 + 177.5 = 208.5.

Vapour density (D) of undissociated PCl_5

$$= \frac{\text{Mol. wt.}}{2} = \frac{208.5}{2} = 104.25.$$

Observed V.D. (d) of PCl_5 at 523 K

= 57.9.

For $PCl_5 \rightleftharpoons PCl_3 + Cl_2$

1 mol 1mol $n = 1+1 = 2$

Degree of dissociation,

$$\alpha = \frac{D-d}{d\,(n-1)} = \frac{104.25-57.9}{57.9\,(2-1)} = \frac{46.35}{57.9} = \mathbf{0.8}$$

∴ %age dissociation

= 0.8 × 100 = 80 %

(*b*)	PCl_5	$\rightleftharpoons PCl_3$	$+ Cl_2$
(*i*) *n* mol at start	1		
(*ii*) Change by reaction	– 0.8	0.8	0.8
(*iii*) *n* mol at equilibrium	1 – 0.8 = 0.2	0.8	0.8

Total number of mol = 0.2 + 0.8 + 0.8 = 1.8

$$K_p = \frac{p\,(PCl_3) \times p\,(Cl_2)}{p\,(PCl_5)}$$

$$= \frac{\left(\frac{0.8}{1.8} \times p\right)\left(\frac{0.8}{1.8} \times p\right)}{\left(\frac{0.2}{1.8} \times p\right)} = \frac{\frac{0.8 \times 1}{1.8} \times \frac{0.8 \times 1}{1.8}}{\frac{0.2}{1.8} \times 1};$$

$$K_p = 1.78 \text{ atm.}$$

(*ii*) Let pressure = *p* atm. ;

degree of dissociation, α = 0.5

or % age of dissociation = 0.5 × 100 = 50

	PCl_5	$\rightleftharpoons PCl_3$	$+ Cl_2$
(*i*) *n* mol at start	1	0	0
(*ii*) Change by reaction	– 0.5	0.5	0.5
(*iii*) *n* mol at equilibrium	1 – 0.5 = 0.5	0.5	0.5

Total number of mol = 0.5 + 0.5 + 0.5 = 1.5

$$K_p = \frac{p\,(PCl_3)\, p\,(Cl_2)}{p\,(PCl_5)}$$

$$= \frac{\left(\frac{0.5}{1.5} \times p\right)\left(\frac{0.5}{1.5} \times p\right)}{\left(\frac{0.5}{1.5} \times p\right)} = \frac{p}{3}$$

$$1.78 \text{ atm} = \frac{p}{3};\ p = 3 \times 1.78 = \mathbf{5.34\ atm} \qquad \textbf{Ans.}$$

(*iii*) Pressure, *p* = 3 atm ; α = degree of dissociation :

	PCl_5	$\rightleftharpoons PCl_3$	$+ Cl_2$
(*i*) *n* mol at start	1	0	0
(*ii*) Change by reaction	– α	α	α
(*iii*) *n* mol at equilibrium	1 – α	α	α

Total number of mol = 1 – α + α + α = 1 + α

$$K_p = \frac{p\,(PCl_3) \times p\,(Cl_2)}{p\,(PCl_5)}$$

$$= \frac{\left(\frac{\alpha}{1+\alpha} \times p\right)\left(\frac{\alpha}{1+\alpha} \times p\right)}{\left(\frac{1-\alpha}{1+\alpha} \times p\right)} = \frac{\alpha^2 p}{1-\alpha^2}$$

$$1.78 = \frac{\alpha^2 \times 3}{1-\alpha^2};\ 1.78\,(1-\alpha^2) = 3\alpha^2\,;$$

$$1.78 - 1.78\,\alpha^2 = 3\,\alpha^2\,;\ 3\,\alpha^2 + 1.78\,\alpha^2 = 1.78\,;$$

$$4.78\,\alpha^2 = 1.78;\ \alpha = \frac{1.78}{4.78} = 0.372\,;$$

$$\alpha = \sqrt{0.372} = 0.6099$$

∴ % age dissociation

$$= 0.6099 \times 100 = \mathbf{60.99\ \%} \qquad \textbf{Ans.}$$

EXAMPLE 87. *In which of the following equilibrium, K_c and K_P are not equal ?*

(*a*) $2NO(g) \rightleftharpoons N_2(g) + O_2(g)$

(*b*) $SO_2(g) + NO_2(g) \rightleftharpoons SO_3(g) + NO(g)$

(*c*) $H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$

(*d*) $2C(s) + O_2(g) \rightleftharpoons 2CO_2(g)$ **(CBSE, PMT, 2010)**

SOLUTION. K_p and K_c are related as : $K_P = K_c\,(RT)^{\Delta n(g)}$ Δn(g) = no. of mol of products — no. of mol of reactants in gaseous states. K_p will not be equal to K_c if Δn(g) is not zero. For reaction (*d*),

$$\Delta n(g) = 2 \text{ mol of } CO_2 - 1 \text{ mol of } O_2 = 1.$$

So, (*d*) is correct answer.

23.20. HETEROGENEOUS EQUILIBRIA

When the species of reactants and products in an equilibrium reaction are present in two or more phases (solid, liquid, gas, aqueous), the equilibrium is called heterogeneous equilibria.

Type. Calculation of K_p from the dissociation of

$$CaCO_3\,(s) \rightleftharpoons CaO\,(s) + CO_2\,(g)$$

In such cases, the active mass (or concentration) of a solid substance is taken as unity. Thus

$$K_p = \frac{P_{CaO(s)} \times P_{CO_2\,(g)}}{P_{CaCO_3\,(s)}} = \frac{1 \times P_{CO_2}\,(g)}{1}$$

$$= P_{CO_2}\,(g)$$

EXAMPLE 88. *K_p value for the following equilibrium at 393 K*

$$M_2CO_3(s) \rightleftharpoons M_2O\,(s) + CO_2\,(g)$$

is 9.5 × 10^{-3} atm. Would 1 % CO_2 in air is sufficient to prevent any loss of M_2CO_3. How long would the partial pressure of CO_2 have to promote this reaction at 393 K?

SOLUTION. CO_2 (g) pressure of 1 % CO_2 in air $= \frac{1}{100}$ atm $= 10^{-2}$ atm.

For the reaction,

$$M_2CO_3(s) \rightleftharpoons M_2O\,(s) + CO_2(g)$$

$K_p = P_{CO_2(g)}$ because concentration of solids is taken as unity

$\therefore\ 9.5 \times 10^{-3}$ atm, $= P_{CO_2(g)}$

We know $K_p = 9.5 \times 10^{-3}$ atm and decomposition of M_2CO_3 takes place in presence of $P_{CO_2(g)}$ equal to 10^{-2} atm. Thus, practically no decomposition of M_2CO_3 takes place *i.e.*, presence of 1% CO_2 in air is sufficient to prevent any loss in mass.

From above, it is clear that $P_{CO_2(g)}$ must be less than 9.5 $\times\ 10^{-3}$ atm for the reaction to take place.

Example 89. *At 1173 K and 1273 K, the dissociation pressures of $CaCO_3$ are 790 mm and 2940 mm respectively. Calculate the heat of dissociation at this temperature range. $R = 2$ cal K^- mol^-.*

Solution.

$$CaCO_3\,(s) \rightleftharpoons CaO(s) + CO_2\,(g)$$

$K_p = p_{CO_2\,(g)}$ because

$[CaO(s)] = [CaCO_3(s)] = 1$

We know that :

$$\log K_{p_2} - \log K_{p_1} = \frac{\Delta H}{2.303\,R}\left[\frac{T_2 - T_1}{T_1\,T_2}\right]$$

Or

$$\Delta H = 2.303\,R\,(\log K_{p_2} - \log K_{p_1})\left[\frac{T_1\,T_2}{T_2 - T_1}\right]$$

$$= 2.303 \times 2\,\text{cal K}^{-}\text{mol}^{-}(\log 2940 - \log 790)\left(\frac{1173 \times 1273\ \text{K}^2}{1273 - 1173\ \text{K}}\right)$$

$$= 4.606\ \text{cal K}^{-}\ \text{mol}^{-}\,(3.4683 - 2.8976)\left(\frac{1173 \times 1273\ \text{K}}{100}\right)$$

$$= \frac{4.606\ \text{cal mol}^{-} \times 0.5707 \times 1173 \times 1273}{100}$$

$= 39252$ cal

= 39.252 K cal mol⁻ Ans.

Example 90. *The partial pressure of CO_2 obtained from the dissociation of $CaCO_3$ at 500°C is 0.8 mm (Hg) . If ΔH of the reaction is 43.2 k cal mol^- and it does not change even at 600°C, then calculate K_p at 600 °C. ($R = 2$ cal K^- mol^-).*

Solution.

$$CaCO_3\,(s) \rightleftharpoons CaO\,(s) + CO_2\,(g)$$

$\therefore\quad K_p = P_{CO_2(g)}$ because

$[CaCO_3(s)] = [CaO(s)] = 1$

We know that :

$$\log K_{p_2} - \log K_{p_1} = \frac{\Delta\,H}{2.303\,R}\left[\frac{T_2 - T_1}{T_1\,T_2}\right]$$

$T_1 = 500 + 273 = 773$ K,

$T_2 = 600 + 273 = 873$ K

$$\log K_{p_2} - \log 0.8 = \frac{43.2 \times 1000\ \text{cal}}{2.303 \times 2\ \text{cal K}^{-}\ \text{mol}^{-}}\left[\frac{873 - 773\,\text{K}}{873 \times 773\ \text{K}^2}\right]$$

$\log K_{p_2} - (-\,0.0969)$

$$= \frac{43200}{4.606} \times \frac{100}{873 \times 773} = 1.3898$$

$\log K_{p_2} = 1.3898 - 0.0969 = 1.2929$

$\therefore\quad K_{p_2} =$ antilog $1.2929 =$ **19.63 mm** **Ans.**

Example 91. *In the following chemical equilibrium reaction*

$$CaCO_3\,(s) \rightleftharpoons CaO\,(s) + CO_2\,(g)$$

at 700 K,

$\Delta G_f^\circ(CaCO_3) = -\,1129$ *k J,*

$\Delta G_f^\circ\,(CaO) = -\,604.2$ *k J*

and $\Delta G_f^\circ(CO_2) = -\,394.6$ *k J.*

Calculate the pressure of CO_2 at 700 K.

Solution. We know that,

$R = 8.314$ J K^- mol^- and :

$$\Delta\,G^\circ\,(\text{reaction}) = \Delta\,G_f^\circ\,(\text{products}) - \Delta G_f^\circ\,(\text{reactants})$$

$$= \Delta G_f^\circ\,(CaO) + \Delta G_f^\circ\,(CO_2) - \Delta G_f^\circ\,(CaCO_3)$$

$$= (-\,604.2 - 394.6 + 1129)\ \text{k J}$$

$$= 130.2\ \text{k J}$$

But $\quad \Delta G = -\,2.303\,RT\log K_p$;

$$\log K_p = \frac{-\,\Delta\,G}{2.303\,RT}$$

or

$$\log K_p = \frac{-130.2 \times 1000\ \text{J}}{2.303 \times 8.314\ \text{J K}^{-}\ \text{mol}^{-} \times 700\ \text{K}}$$

$= -9.7142$

$\therefore\quad K_p =$ antilog $-$ 9.7142

= antilog $-9 - 1 + 1 - 0.7142$

= antilog $\overline{10}.2858 = 1.93 \times 10^{-10}$ atm

Given reaction is :

$$CaCO_3\,(s) \rightleftharpoons CaO\,(s) + CO_2\,(g)$$

$\therefore\quad K_p = P_{CO_2(g)}$

Thus, $\quad \mathbf{P_{CO_2(g)} = 1.93 \times 10^{-10}}$ **atm.**

Example 92. *For the reaction, $CaCO_3(s) \rightleftharpoons CaO(s) + CO_2\,(g)$, $K_p = 1.16$ atm at 1073 K. If 15.0 g of $CaCO_3$ was put into 10 L flask heated to 1073 K, what % age of $CaCO_3$ would remain unreacted at equilibrium ?*

Solution.

$$CaCO_3\,(s) \rightleftharpoons CaO\,(s) + CO_2(g)$$

$K_p = P_{CO_2(g)}$

Wt. of $CaCO_3$ = 15 g ;

g. mol. wt. of $CaCO_3 = 40 + 12 + (3 \times 16) = 100$ g

$\therefore$ Number of mol of CO_2 at start

$$= \frac{15}{100} = 0.15\ \text{mol}$$

But $PV = nRT$ or $n_{CO_2} = \frac{PV}{RT}$

$$= \frac{1.16 \text{ atm} \times 10 \text{ L}}{0.0821 \text{ L atm K}^{-} \text{ mol}^{-} \times 1073 \text{ K}}$$

$= 0.132$ mol

% age of $CaCO_3$ decomposed

$$= \frac{0.132 \text{ mol}}{0.15} \times 100 = 88 \%$$

∴ % age of $CaCO_3$ that remained undecomposed

$= 100 - 88 =$ **12 %** **Ans.**

Example 93. *Calculate K_c for the reversible process given below if $K_p = 167$ and $T = 800°C$.*

$CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g)$.

(*a*) 1.95 (*b*) 1.85

(*c*) 1.89 (*d*) 1.60 **(West Bengal JEE, 2010)**

Solution. $K_p = K_c (RT)^{\Delta n(g)}$.

$$\underset{}{CaCO_3(s)} \rightleftharpoons CaO(s) + \underset{1 \text{ mol}}{CO_2(g)}$$

∴ $\Delta n(g) = n_p - n_r = 1 - 0 = 1$.

$R = 0.0821, T = 273 + 800$

$= 1073\ K, K_p = 167$.

So, $167 = K_c (0.0821 \times 1073)^1$.

Or $K_c = 167/(0.0821 \times 1073) = 1.89$.

So, the correct answer is (*c*).

23.21 DISSOCIATION OF HYDRAZINE (N_2H_4)

Example 94. *0.16 g of N_2H_4 are dissolved in water and total volume made up to 500 mL. Calculate the percentage of N_2H_4 that has reacted with water in this solution. The K_p value for N_2H_4 is $4.0 \times 10^{-6} M$* **(Roorkee 1998)**

Solution. g. mol. wt. of $N_2H_4 = (2 \times 14) + (4 \times 1) = 32$ g ;

wt. of $N_2H_4 = 0.16$;

volume of solution = 500 mL.

∴ Molarity of N_2H_4 solution $= \frac{0.16}{32} \times \frac{1000}{500} = 0.01\ M$

α = Amount of N_2H_4 reacted with water.

Reaction.	$N_2H_4 + H_2O$	$\rightleftharpoons N_2H_5^+$	$+ OH^-$
(*i*) *n* mol at start	0.01	0	0
(*ii*) Change by reaction	$-\alpha$	α	α
(*iii*) *n* mol at equilibrium	$0.01 - \alpha$	α	α

$$K_p = \frac{[N_2H_5^+][OH^-]}{[N_2H_4]} = \frac{\alpha \times \alpha}{0.01 - \alpha} = \frac{\alpha^2}{0.01}$$

$[\because 0.01 - \alpha \simeq 0.01]$

Or $4 \times 10^{-6} = \frac{\alpha^2}{0.01}$; $\alpha^2 = 4 \times 10^{-6} \times 0.01 = 4 \times 10^{-8}$

∴ $\alpha = (4 \times 10^{-8})^{1/2} = 2 \times 10^{-4}$

∴ % age of N_2H_4 that would react with water

$= \frac{2 \times 10^{-4}}{0.01} \times 100 = 2\%$ **Ans.**

Type involving dissociation of ammonium bisulphide (NH_4HS). Calculation of K_p from the dissociation of ammonium bisulphide, $NH_4HS(s) \rightleftharpoons NH_3(g) + H_2S(g)$

$$K_p = \frac{P\,NH_3(g) \times P\,H_2S(g)}{P\,NH_4HS(s)}$$

$$= \frac{P\,NH_3(g) \times P\,H_2S(g)}{1}$$

∴ $K_p = P\,NH_3(g) \times P\,H_2S(g)$

Example 95. *When 3.06 g of solid NH_4HS is introduced into a two litre evacuated flask at 27°C, 30% of the solid decomposes into gaseous ammonia and hydrogen sulphide.*

(*i*) *Calculate K_c and K_p for the reaction at 27°C.*

(*ii*) *What would happen to the equilibrium when more NH_4HS is introduced into the flask?* **(IIT 1999)**

Solution. Wt. of $NH_4HS = 3.06$ g ;

g. mol. wt. of $NH_4HS = 14 + (4 \times 1) + 1 + 32 = 51$ g ;

volume = 2 L

∴ mol of $NH_4HS = \frac{3.06}{51} = 0.06$; $x = 30$ %

$= \frac{30}{100} = 0.3$.

Reaction.

NH_4HS $\rightleftharpoons$	NH_3 +	H_2S
(*i*) *n* mol at start		
0.06	0	0
(*ii*) Change by reaction		
$-0.06x$	$0.06x$	$0.06x$
$-(0.06 \times 0.3)$	0.06×0.3	0.06×0.3
$= -0.018$	$= 0.018$	$= 0.018$
(*iii*) *n* mol L^- at equilibrium		
$\frac{0.06 - 0.018}{2}$	$\frac{0.018}{2}$	$\frac{0.018}{2}$
$= \frac{0.042}{2} = 0.021$	$= 0.009$	$= 0.009$

∴ $K_c = [NH_3][H_2S] = 0.009 \times 0.009$

$= 8.1 \times 10^{-5}$ mol^2 L^{-2}

But $K_p = K_c (RT)^{\Delta n}$;

$\Delta n = (1 + 1) - 0 = 2$;

$R = 0.0821$ L atm K$^-$ mol$^-$,

$T = 27 + 273 = 300$ K.

∴ $K_p = 8.1 \times 10^{-5}$ mol^2 L^{-2} (0.0821 L atm K$^-$ mol$^-$ × 300 K)^2

$= 8.1 \times 10^{-5}$ mol^2 L^{-2} × (24.63)^2 L^2 atm^2 K^{-2} mol^{-2} K^2

$K_p =$ **0.049 atm^2** **Ans.**

Example 96. *Calculate the equilibrium constant of the following reaction*

$$NH_4HS\ (s) \rightleftharpoons NH_3\ (g) + H_2S\ (g).$$

Given the observed pressure of mixture equal to 20 atmosphere.

SOLUTION. $P = 20$ atm ;

x = degree of dissociation

	$NH_4HS\ (s) \rightleftharpoons$	$NH_3\ (g)$	$+ H_2S(g)$
(*i*) n mol at start	1	0	0
(*ii*) Change by reaction	$-x$	x	x
(*iii*) n mol at equilibrium	$1-x$	x	x

Total number of mol at equilibrium = $x + x = 2x$

NH_4HS being solid, its mol are not added.

$$\therefore \quad K_p = P\ (NH_3) \times P\ (H_2S)\ ;$$

$$K_p = \left(\frac{x}{2x} \times P\right) \times \left(\frac{x}{2x} \times P\right)$$

$$= \left(\frac{1}{2} \times 20\right)\left(\frac{1}{2} \times 20\right)$$

Or $\quad K_p = 10 \times 10 = \mathbf{100\ atm^2}$. **Ans.**

EXAMPLE 97. *When solid NH_4HS is placed in an evacuated vessel at a certain temperature, it dissociates till total gas pressure is 500 torr.*

(*a*) *Find the value of K_p for the dissociation reaction.*

$$NH_4HS\ (s) \rightleftharpoons H_2S\ (g) + NH_3\ (g)$$

(*b*) *Additional NH_3 is introduced into the equilibrium mixture without change in temperature till partial pressure of NH_3 is 650 torr. Calculate the partial pressure of H_2S (g) and total pressure in the vessel under these conditions.*

SOLUTION. (*a*)$NH_4HS(s) \rightleftharpoons NH_3(g) + H_2S(g)$

n mol at start $\quad 1 \quad 1$

Since NH_3 (g) and H_2S(g) are formed in 1 : 1 ratio,

$$P\ (NH_3) = P\ (H_2S).$$

$$\text{Thus : } P\ (NH_3) = \frac{1}{1+1} \times 500 = 250 \text{ torr}$$

$$= \frac{250}{760} \text{ atm} = P(H_2S) \text{ also}$$

$$\therefore \quad Kp = P\ (NH_3) \times P\ (H_2S)$$

$$= \frac{250}{760} \text{ atm} \times \frac{250}{760} \text{ atm} = \mathbf{0.108\ atm^2}$$

(*b*) The addition of NH_3 at equilibrium will cause the reaction to shift in the backward direction as explained by Le - Chatelier's principle. But K_p value remains constant.

$$650 \text{ torr} = \frac{650}{760} \text{ atm} = P\ (NH_3)$$

$$\therefore \quad K_p = P\ (NH_3) \times P\ (H_2S)\ ;$$

$$P\ (H_2S) = \frac{K_p}{P\ (NH_3)} = \frac{0.108 \text{ atm}^2}{650/760 \text{ atm}}$$

Or $\quad P\ (H_2S) = 0.126 \text{ atm} = 0.126 \times 760 = 95.8$ torr

$\therefore$ Total pressure= $P\ (NH_3) + P\ (H_2S) = 650 + 95.8$

$= \mathbf{745.8\ torr}$ **Ans.**

EXAMPLE 98. *Some solid NH_4HS is placed in flask containing 0.5 atm of NH_3. What would be the pressures of NH_3 and H_2S when equilibrium is reached ?*

$$NH_4HS\ (s) \rightleftharpoons NH_3(g) + H_2S(g)\ ;\ K_p = 0.11$$

(MLNR, 1994)

SOLUTION.	$NH_4HS\ (s) \rightleftharpoons$	$NH_3\ (g)$	$+ H_2S\ (g)$
(*i*) n mol at start		0.5	0
(*ii*) Change by reaction		x	x
(*iii*) n mol at equilibrium		$x + 0.5$	x

$$K_p = 0.11$$

Also, $\quad K_p = P\,NH_3 \times P\,H_2S;\ 0.11 = (x + 0.5) \times x;$

$x^2 + 0.5\,x - 0.11 = 0$

$$\therefore \quad x = \frac{-0.5 \pm \sqrt{(-0.5)^2 - 4\,(1 \times -0.11)}}{2 \times 1}$$

$$= \frac{-0.5 \pm \sqrt{0.25 - 0.44}}{2}$$

$$= \frac{-0.5 \pm \sqrt{0.69}}{2} = \frac{-0.5 \pm 0.83}{2}$$

$$\text{Or} \quad x = \frac{-0.5 + 0.83}{2} \text{ or } \frac{-0.5 - 0.8}{2}$$

$$= 0.165 \text{ or } -0.65$$

The negative value is not possible. So, it is rejected.

So, $\quad x = 0.165$ atm.

$\therefore \quad P_{NH_3} = x + 0.5 = 0.165 + 0.5 = 0.665$ atm ;

$P_{H_2S} = x = \mathbf{0.165\ atm.}$ **Ans.**

Type involving dissociation of ammonium carbamate. Calculation of Kp from the dissociation of ammonium carbamate, $NH_2COONH_4\ (s) \rightleftharpoons 2NH_3\ (g) + CO_2\ (g)$

$$K_p = \frac{(p_{NH_3\,(g)})^2 \times p_{CO_2\,(g)}}{p_{NH_2COONH_4\,(s)}}$$

$$= (p_{NH_3(g)})^2 \times p_{CO_{2}(g)}$$

Let $\quad P$ = total pressure.

	$NH_2COONH_4\ (s) \rightleftharpoons$	$2NH_3\ (g)$	$+ CO_2\ (g)$
Pressure at equilibrium		2 P	P

Total pressure at equilibrium = 2 P + P = 3 P.

$$\therefore \quad p_{NH_3} = \frac{2\,P}{3\,P} \times P = \frac{2\,P}{3}\ ;$$

$$p_{CO_2} = \frac{P}{3\,P} \times P = \frac{P}{3}.$$

$$\therefore \quad K_p = [p_{NH_3\,(g)}]^2 \times p_{CO_2(g)}$$

$$= \left(\frac{2\,P}{3}\right)^2 \times \frac{P}{3}$$

$$\text{Or} \quad \boldsymbol{K_p = \frac{4\,P^3}{27}}$$

EXAMPLE 99. *In a closed vessel containing ammonium carbamate[NH_2COONH_4(s)] in equilibrium*

$$NH_2COONH_4\,(s) \rightleftharpoons 2NH_3\,(g) + CO_2\,(g)$$

ammonia is added such that partial pressure of NH_3 now equals to the original total pressure. Calculate the ratio of total pressure to original pressure.

Solution. First case.

$$NH_2COONH_4\,(s) \rightleftharpoons 2NH_3(g) + CO_2\,(g)$$

Pressure at equilibrium 2P P

∴ Total pressure at equilibrium

$$= 2P + P = 3\,P$$

$$\therefore \quad K_p = p_{(NH_3)^2} \times p_{(CO_2)} = (2P)^2 \times P = \mathbf{4P^3}$$

Second Case. When NH_3 is added, pressure of NH_3 at equilibrium = 3 P

$$\therefore \quad K_p = p_{(NH_3)2} \times p_{CO_2} = (3P)^2 \times p_{CO_2}$$

$$\textbf{or} \quad 4\,P^3 = 9P^2 \times p_{CO_2};$$

$$\therefore \quad p_{CO_2} = \frac{4\,P^3}{9\,P^2} = \frac{4\,P}{9}$$

∴ Total pressure in second equilibrium

$$= 3\,P + \frac{4}{9}P = \frac{31\,P}{9}$$

$$\therefore \textbf{Ratio of } \frac{\text{Total pressure in second case}}{\text{Total pressure in first case}}$$

$$= \frac{31\,P/9}{3\,P} = \mathbf{\frac{31}{27}} \qquad \textbf{Ans.}$$

23.22 SYNTHESIS AND DISSOCIATION OF SOME COMPOUNDS

Synthesis of H_2S gas

Example 100. *At 1,200 K, the equilibrium constant value K_p for*

$$H_2(g) + S\,(g) \rightleftharpoons H_2S\,(g)$$

is 20.2 atm. Calculate K_p at 1340 K if heat of reaction in this temperature range is – 21.23 k cal per mol.

Solution. $T_1 = 1200\,K,\ Kp_1 = 20.2$ atm,

$T_2 = 1340\,K,\ Kp_2 = ?$

$\Delta H° = -21.23\text{ k cal mol}^{-},\ R = 2\text{ cal }K^{-}\text{mol}^{-}.$

We know that :

$$\log K_{p_2} - \log K_{p_1} = \frac{\Delta H°}{2.303\,R}\left[\frac{T_2 - T_1}{T_1\,T_2}\right]$$

$$\log K_{p_2} - \log 20.2 = \frac{-21.23 \times 1000\text{ cal mol}^{-}}{2.303 \times 2\text{ cal K}^{-}\text{ mol}^{-}} \times \frac{(1340-1200)\text{ K}}{(1200 \times 1340)\text{ K}^2}$$

$$\log K_{p_2} - 1.3054 = -0.4013\,;$$

$$\log K_{p_2} = -0.4013 + 1.3054 = 0.9041$$

$$\therefore \quad K_{p_2} = \text{antilog } 0.9041 = \mathbf{8.02\ atm.} \qquad \textbf{Ans.}$$

Type. Dissociation of H_2S.

Example 101. *Calculate the percentage dissociation of H_2S (g) if 0.1 mol of H_2S is kept in 0.4 litre vessel at 100 K. For the reaction*

$$2H_2S\,(g) \rightleftharpoons 2H_2(g) + S_2\,(g)$$

the value of K_p is 1.0×10^{-6} **(Roorkee, 1994)**

Solution. Vol = 0.4 L.

$$2H_2S\,(g) \rightleftharpoons 2H_2\,(g) + S_2\,(g)$$

(*i*) *n* mol at start

$$0.1 \qquad 0 \qquad 0$$

(*ii*) Change by reaction

$$-0.1x \qquad 0.1x \qquad \frac{0.1x}{2}$$

(*iii*) *n* mol L⁻ at equilibrium

$$\frac{0.1 - 0.1x}{0.4} \qquad \frac{0.1x}{0.4} \qquad \frac{0.1x}{2 \times 0.4}$$

$$= \frac{0.1(1-x)}{0.4} = \frac{1-x}{4} \qquad = \frac{x}{4} \qquad = \frac{x}{8}$$

$$\therefore \quad K_c = \frac{[H_2]^2\,[S_2]}{[H_2S]^2} = \frac{\left(\frac{x}{4}\right)^2 \times \frac{x}{8}}{\left(\frac{1-x}{4}\right)^2} = \frac{\frac{x^2}{16} \times \frac{x}{8}}{\left(\frac{1}{4}\right)^2}$$

[∵ if x is very small, $1 - x \simeq 1$]

$$\therefore \quad K_c = \frac{x^3}{16 \times 8} \times \frac{4 \times 4}{1} = \frac{x^3}{8}\,;$$

$$1.0 \times 10^{-6} = \frac{x^3}{8}\,;$$

$$x^3 = 8 \times 10^{-6} \textbf{ Or } x = (8 \times 10^{-6})^{1/3}$$

$$= 2 \times 10^{-2}$$

∴% age dissociation

$$= 2 \times 10^{-2} \times 100 = 2\,\% \qquad \textbf{Ans.}$$

Example 102. *An equilibrium mixture for the reaction*

$$2H_2S\,(g) \rightleftharpoons 2H_2\,(g) + S_2\,(g)$$

has 1 mol of H_2S, 0.2 mol of H_2 and 0.8 mol of S_2 in a 2 litre vessel. Calculate K_c for the reaction. **(Orissa JEE 1997)**

Solution. $2\,H_2S\,(g) \rightleftharpoons 2H_2\,(g) + S_2\,(g)$

n mol L⁻ at equilibrium

$$\frac{1\text{ mol}}{2\text{ L}} \qquad \frac{0.2\text{ mol}}{2\text{ L}} \qquad \frac{0.8\text{ mol}}{2\text{ L}}$$

$$= 0.5\text{ mol L}^{-} = 0.1\text{ mol L}^{-} = 0.4\text{ mol L}^{-}$$

$$\therefore \quad K_c = \frac{[H_2]^2\,[S_2]}{[H_2S]^2} = \frac{(0.1)^2 \times 0.4}{(0.5)^2} = \frac{0.01 \times 0.4}{0.25}$$

$$K_c = \mathbf{0.016\ mol\ L^{-}}$$

Type. Dissociation of S_8.

Example 103. *When sulphur in the form of S_8 is heated at 900 K, the initial pressure of 1 atm falls by 29% at equilibrium. This is because of the conversion of some S_8 to S_2. Find the value of equilibrium constant for this reaction.* **(Roorkee, 1990)**

SOLUTION. $S_8\,(g) \rightleftharpoons 4\,S_2(g)$

(*i*) Pressure at start

$$1 \qquad\qquad 0$$

(*ii*) Change by reaction

$$-\frac{29}{100} \qquad 4\times\frac{29}{100}=\frac{116}{100}=1.16$$

(*iii*) Pressure at equilibrium

$$1-\frac{29}{100} \qquad 1.16$$

$$=\frac{71}{100}=0.71$$

$$\therefore \qquad K_p=\frac{[p_{S_2(g)}]^4}{[p_{S_8\,(g)}]}=\frac{(1.16)^4\ \text{atm}^4}{0.71\ \text{atm}}\simeq\frac{1.81}{0.71}\text{atm}^3$$

=2.55 atm^{3}Ans.

Type. Dissociation of Se$_6$

EXAMPLE 104. *At 700°C, 0.076 g of selenium vapour occupy a volume of 114 mL and exert a pressure of 185 torr (Hg). Selenium exists in the following equilibrium state.*

$$Se_6\,(g) \rightleftharpoons 3\,Se_2\,(g)$$

(*i*) *Find the value of degree of dissociation of Se and,* (*ii*) *calculate the value of K_c and K_p. (at. wt. of Se = 79 g mol$^-$).*

SOLUTION. (*a*) $P=\frac{185}{760}=0.24$ atm,

$$V=\frac{114}{1000}=0.114\ \text{L},$$

$$R=0.0821\ \text{L atm K}^-\ \text{mol}^-,$$

$$T=700+273=973\ \text{K}.$$

We know that :

$$PV=n\,RT\,;\,n=\frac{PV}{RT}$$

$$=\frac{0.24\ \text{atm}\times0.114\ \text{L}}{0.0821\ \text{L atm K}^-\ \text{mol}^-\times973\ \text{K}}$$

Or $\qquad n=3.4\times10^{-4}$ mol.

(*b*) Wt. of Se = 0.076 g ; Experimental mol. wt. of Se = M.

$$\therefore\ \text{no. of mol of Se}=\frac{0.076}{M}\,;\ 3.4\times10^{-4}=\frac{0.076}{M}$$

Or $\qquad \text{M}=\frac{0.076}{3.4\times10^{-4}}=223.5\ \text{g mol}^-$

∴ Experimental density (*d*) of Se

$$=\frac{\text{mol. wt}}{2}=\frac{223.5}{2}=111.75$$

Theoretical mol. wt. of Se

$$=6\times79\ \text{g mol}^-=474\ \text{g mol}^-$$

∴ Theoretical density D of Se

$$=\frac{474}{2}=237\ \text{g mol}^-$$

In the reaction, $Se_6\,(g) \rightleftharpoons 3\,Se_2\,(g)$

1 mol $\qquad$ 3 mol

1 mol Se_6 (g) produce Se_2 = 3 mol.

So, $n=3$

(*c*) Degree of dissociation,

$$x=\frac{D-d}{d\,(n-1)}=\frac{237-111.75}{111.75\,(3-1)}$$

Or $\qquad x=\frac{125.25}{223.50}=$ **0.5604 mol**

(*d*) $\qquad Se_6\,(g) \rightleftharpoons 3\,Se_2\,(g)$

(*i*) n mol at start $\qquad 1 \qquad 0$

(*ii*) Change by reaction $\qquad -x \qquad 3x$

(*iii*) n mol at equilibrium $\qquad 1-x \qquad 3x$

Total number of mol at equilibrium

$$=1-x+3x=1+2x;\ P=0.24\ \text{atm}.$$

$$K_p=\frac{P\,(Se_2)^3}{P\,Se_6}=\frac{\left(\frac{3x}{1+2x}\times P\right)^3}{\frac{1-x}{1+2x}\times P}$$

$$=\frac{27x^3\,P^3}{(1+2x)^3}\times\frac{1+2x}{(1-x)\,P}$$

$$=\frac{27x^3\,P^2}{(1-x)\,(1+2x)^2}$$

$$\therefore \qquad K_p=\frac{27\times(0.5604)^3\times(0.24)^2}{(1-0.5604)\times[1+(2\times0.5604)^2]}$$

$$=\frac{0.2737}{0.4396\times4.498}=0.138$$

(*e*) $\qquad K_p=K_c\,(RT)^{\Delta n}\,;$

$$\Delta n=n_p-n_R=3-1=2$$

$$R=0.0821\ \text{L atm K}^-\ \text{mol}^-,\ T=973\ \text{K}.$$

$$\therefore \qquad 0.138\ \text{atm}^2=K_c\,(0.0821\ \text{L atm K}^-\ \text{mol}^-\times973\ \text{K})^2$$

$$K_c=\frac{0.138\ \text{atm}^2}{(0.0821\ \text{L atm K}^-\ \text{mol}^-\times973\ \text{K})^2}$$

$$= \mathbf{2.162\times10^{-5}\ mol^2\ L^{-2}} \qquad \textbf{Ans.}$$

Type. Synthesis of SO$_3$.

EXAMPLE 105. *At a certain temperature, the equilibrium constant K_c is 16 for the gaseous reaction :*

$$SO_2+NO_2 \rightleftharpoons SO_3+NO$$

If we take one mol each of all the four gases in a one litre container, what would be the equilibrium concentration of NO and NO$_2$. **(IIT 1987)**

SOLUTION. Vol = 1 L

$$SO_2+NO_2 \rightleftharpoons SO_3+NO$$

(*i*) n mol at start

$$1 \quad 1 \qquad 1 \quad 1$$

(*ii*) Change by reaction

$$-x \quad -x \qquad x \quad x$$

(*iii*) n mol L^{-} at equilibrium

$$\frac{1-x}{1} \quad \frac{1-x}{1} \qquad \frac{1+x}{1} \quad \frac{1+x}{1}$$

x = Amount reacted at equilibrium.

$$\therefore \quad K_c = \frac{[SO_3][NO]}{[SO_2][NO_2]};$$

$$16 = \frac{(1+x)(1+x)}{(1-x)(1-x)} = \frac{(1+x)^2}{(1-x)^2}.$$

Taking square root of both sides, we get :

$$(16)^{1/2} = \left[\frac{(1+x)^2}{(1-x)^2}\right]^{1/2}$$

or
$$4 = \frac{1+x}{1-x} \; ; \; 4(1-x) = 1+x \; ;$$

$$4 - 4x = 1 + x \; ; \quad x + 4x = 4 - 1 \; ;$$

$$5x = 3 \; ; \; x = \frac{3}{5} = 0.6$$

$$\therefore \quad [NO] = 1 + x = 1 + 0.6 = \mathbf{1.6\ mol\ L^{-}} \; ;$$

$$[NO_2] = 1 - x = 1 - 0.6 = \mathbf{0.4\ mol\ L^{-}}$$

EXAMPLE 106. *A mixture of SO_2, SO_3 and O_2 gases is maintained in a 10 litre flask at temperature at which the equilibrium constant K_c for the reaction.*

$$2\,SO_2\,(g) + O_2\,(g) \rightleftharpoons 2\,SO_3\,(g)$$

is 100. (i) If the number of mol of SO_2 and SO_3 in the flask are equal, how many mol of O_2 are present?

(ii) If the number of mol of SO_2 in the flask is twice the number of mol of SO_3, how many mol of O_2 are present ?

(Roorkee, 1987)

SOLUTION. (*i*) $\quad 2SO_2\,(g) + O_2\,(g) \rightleftharpoons 2SO_3\,(g)$

n mol L^{-} at equilibrium

$$\frac{1\text{ mol}}{10\text{ L}} \qquad \frac{x\text{ mol}}{10\text{ L}} \qquad \frac{1\text{ mol}}{10\text{ L}}$$

$$= 0.1\text{ mol L}^{-} \quad = 0.1x\text{ mol L}^{-} \quad = 0.1\text{ mol L}^{-}$$

$$K_c = \frac{[SO_3]^2}{[SO_2]^2\,[O_2]}$$

$$= \frac{(0.1\text{ mol L}^{-})^2}{(0.1\text{ mol L}^{-})^2 \times 0.1\,x\text{ mol L}^{-}}$$

$$\therefore \quad 100 = \frac{1}{0.1\,x\text{ mol L}^{-}} = 100 \times 0.1\,x\text{ mol L}^{-} = 1$$

$$\therefore \quad x = \frac{1}{100 \times 0.1} = \mathbf{0.1\ mol.}$$

(*ii*) $\quad 2SO_2\,(g) + O_2\,(g) \rightleftharpoons 2SO_3\,(g)$

n mol L^{-} at equilibrium

$$\frac{1\text{ mol}}{10\text{ L}} \qquad \frac{2\text{ mol}}{10\text{ L}}$$

$$= 0.1\text{ mol L}^{-} \quad = 0.2\text{ mol L}^{-}$$

$$\therefore \quad K_c = \frac{[SO_3]^2}{[SO_2]^2\,[O_2]};$$

$$100 = \frac{(0.2\text{ mol L}^{-})^2}{(0.1\text{ mol L}^{-})^2\,\frac{[O_2]}{10}}$$

$$\therefore \quad \frac{[O_2]}{10} = \frac{0.04}{0.01 \times 100};$$

$$(O_2) = \frac{10 \times 4}{100} = \mathbf{0.4\ mol} \qquad \textbf{Ans.}$$

EXAMPLE 107. *The equilibrium constant K_p of the reaction*

$$2SO_2\,(g) + O_2\,(g) \rightleftharpoons 2SO_3\,(g)$$

is 900 atm at 1073 K. A mixture containing SO_3 and O_2 having initial pressure of 1 and 2 atm respectively is heated at constant volume to equilibrate. Calculate the partial pressure of each gas at 1073 K. **(IIT 1989)**

SOLUTION. $\quad 2SO_3\,(g) \rightleftharpoons 2SO_2\,(g) + O_2\,(g)$

(*i*) Pressure (atm) at start

$$1 \qquad 0 \qquad 2$$

(*ii*) Change by reaction

$$-x \qquad x \qquad \frac{x}{2}$$

(*iii*) Pressure (atm) at equilibrium

$$1-x \qquad x \qquad 2+\frac{x}{2}$$

$$K_p = \frac{p\,(SO_2)^2 \times p\,(O_2)}{p\,(SO_3)^2}$$

$$= \frac{x^2 \times \left(2+\frac{x}{2}\right)}{(1-x)^2} = \frac{2x^2 + \frac{x^3}{2}}{(1-x)^2}$$

Since K_p is very small, $x^3/2$ can be rejected

$$\therefore \quad \frac{1}{900} = \frac{2x^2}{(1-x)^2}.$$

Taking square root of both sides, we get :

$$\frac{1}{30} = \sqrt{2}\left(\frac{x}{1-x}\right); \frac{1}{30} = 1.4142\left(\frac{x}{1-x\,;}\right);$$

$$\frac{x}{1-x} = \frac{1}{30\,(1.4142)};$$

$$\frac{x}{1-x} = 0.0236\,;\, x = 0.0236\,(1-x)$$

$$= 0.0236 - 0.0236x\,;\, 1.0236x$$

$$= 0.0236$$

$$\therefore \quad x = 0.023$$

$$\therefore \quad p\,SO_2 = 0.023\text{ atm}\,;$$

$$p\,SO_3 = 1 - 0.023 = 0.977\text{ atm}\,;$$

$$p\,O_2 = 2 + \frac{x}{2} = 2 + \frac{0.023}{2} = \mathbf{2.0115\ atm.}$$

Type. Dissociation of SO_3

EXAMPLE 108. *For the reaction*

$$2SO_3\,(g) \rightleftharpoons 2SO_2\,(g) + O_2\,(g)$$

$$K_p = 1.8 \times 10^{-3}\text{ k Pa at 700 K.}$$

Calculate the value of K_c in mol per litre for this reaction at the same temperature. **(HP Board, 2007)**

SOLUTION.
$$2SO_3\,(g) \rightleftharpoons 2SO_2\,(g) + O_2\,(g)$$
$$\text{2 mol} \qquad \text{2 mol} \qquad \text{1 mol}$$

$$\therefore \quad \Delta n = n_p - n_R$$
$$= (2 + 1) - 2 = 1\,;$$
$$T = 700\text{K},$$
$$R = 8.31\,\text{J K}^{-}\text{mol}^{-}\ (= 8.31\ \text{k Pa L K}^{-}\text{mol}^{-}$$
or
$$0.0831\ \text{L bar K}^{-}\ \text{mol}^{-})$$
$$K_p = 1.8 \times 10^{-3}\ \text{k Pa.}$$
But
$$K_p = K_c\,(RT)^{\Delta n}\,;\ K_p = K_c\,(RT)^1$$
Or
$$K_c = \frac{K_p}{RT} = \frac{1.8 \times 10^{-3}\ \text{k Pa}}{8.31\ \text{k Pa L K}^{-}\ \text{mol}^{-} \times 700\ \text{K}}$$
$$= \mathbf{3.09 \times 10^{-7}\ mol\ L^{-}}.$$ **Ans.**

Note : $Pa = N\,m^{-2}\,;\,J = Nm.$

EXAMPLE 109. *At a certain temperature, $2SO_2 + O_2 \rightleftharpoons 2SO_3$ reaction was allowed to take place in a vessel of one litre capacity. The equilibrium mixture contains 24.0 g SO_3, 4.8 g O_2 and 6.4 g SO_2. Find the value of K_c.*

SOLUTION. (*a*) Wt. of SO_2 = 6.4 g ;

g. mol. wt. of $SO_2 = 32 + (2 \times 16) = 64$ g

$\therefore$ no. of mol of $SO_2 = 6.4/64 = 0.1$

(*b*) Wt. of O_2 = 4.8 g ; g. mol. wt. of O_2
$$= 2 \times 16 = 32\ \text{g}.$$
$$\therefore \text{ no. of mol of } O_2 = \frac{4.8}{32} = 0.15$$

(*c*) Wt. of SO_3 = 24 g ; g. mol. wt. of SO_3
$$= 32 + (3 \times 16) = 80\ \text{g}$$
$$\therefore \text{ no. of mol of } SO_3 = \frac{24}{80} = 0.3.$$

For the following reaction at equilibrium :
$$2SO_2 + O_2 \rightleftharpoons 2SO_3$$
$$K_c = \frac{[SO_3]^2}{[SO_2]^2\,[O_2]}$$
$$= \frac{0.3 \times 0.3}{0.1 \times 0.1 \times 0.15} = \mathbf{60}$$ **Ans.**

EXAMPLE 110. *For the following reaction at equilibrium,*
$$2\,SO_3\,(g) \rightleftharpoons 2SO_2\,(g) + O_2\,(g)$$
find the value of equilibrium constant. The partial pressures of O_2, SO_2 and SO_3 are 0.1, 0.3 and 0.5 atm respectively.

SOLUTION. $2SO_3\,(g) \rightleftharpoons 2SO_2\,(g) + O_2\,(g)$

Pressure (atm) at equilibrium
$$0.5 \qquad 0.3 \qquad 0.1$$
$$K_p = \frac{p\,(SO_2)^2 \times p\,O_2}{p\,(SO_3)^2} = \frac{(0.3)^2 \times 0.1}{(0.5)^2}$$
Or
$$K_p = \frac{0.09 \times 0.1}{0.25}$$
$$= \mathbf{0.036\ atm} \quad \text{or} \quad \mathbf{3.6 \times 10^{-2}\ atm.}$$ **Ans.**

EXAMPLE 111. *SO_3 is partially dissociated into SO_2 and O_2 gases at 1 atm pressure and 900 K. The density of mixture of gases at equilibrium is 0.925 g L^{-}. Find the degree of dissociation of SO_3 (g)*

SOLUTION. $PV = n\,RT$ (gas equation) ;
$$n = \frac{\text{wt. of substance (W)}}{\text{g. mol. wt. of substance, M}}$$
$$\therefore \quad PV = \frac{W}{M} \times RT \quad \text{or} \quad M = \frac{W}{V} \times \frac{RT}{P}$$
Or
$$M = d\,\frac{RT}{P}\ (\because \text{mass/volume} = \text{density}, d).$$
$$M = \frac{0.925\ \text{g L}^{-} \times 0.0821\ \text{L atm K}^{-}\ \text{mol}^{-} \times 900\ \text{K}}{1\ \text{atm}}$$
$$= 68.34\ \text{g mol}^{-}$$
Or Experimental g. mol. wt. of SO_3
$$= 68.34\ \text{g mol}^{-}$$
Theoretical g. mol. wt. of SO_3
$$= 32 + (3 \times 16) = 80\ \text{g mol}^{-}$$

	SO_3	$\rightleftharpoons$ SO_2	$+\ \frac{1}{2}O_2$
(*i*) *n* mol at start	1	0	0
(*ii*) Change by reaction	$-\alpha$	α	$\frac{1}{2}\alpha$
(*iii*) *n* mol at equilibrium	$1 - \alpha$	α	$\frac{1}{2}\alpha$

Total number of mol at equilibrium
$$= 1 - \alpha + \alpha + 1/2\,\alpha = 1 + 1/2\,\alpha$$
But
$$1 + \frac{\alpha}{2} = \frac{\text{Theoretical molar mass}}{\text{Experimental molar mass}}$$
$$= \frac{80}{68.34} = 1.171$$
$$\therefore \quad \frac{\alpha}{2} = 1.171 - 1 = 0.171$$
Or
$$\alpha = 2 \times 0.171 = 0.342$$
% age degree of dissociation of SO_3
$$= 0.342 \times 100 = \mathbf{34.2\ \%}$$ **Ans.**

EXAMPLE 112. *Sulphur trioxide is 50 % dissociated at 2 atmospheres and 520 K. Calculate the value of K_p.*

SOLUTION. $2SO_3 \rightleftharpoons 2SO_2 + O_2$

(*i*) *n* mol at start
$$1 \qquad 0 \qquad 0$$
(*ii*) Change by reaction
$$-\frac{1 \times 50}{100} = -\,0.5 \qquad 0.5 \qquad \frac{0.5}{2} = 0.25$$
(*iii*) *n* mol at equilibrium
$$1 - 0.5 = 0.5 \qquad 0.5 \qquad 0.25$$

Total number of mol at equilibrium

$$= 0.5 + 0.5 + 0.25 = 1.25 \text{ mol}$$

$$\therefore \qquad K_p = \frac{[SO_2]^2\,[O_2]}{[SO_3]^2}$$

$$= \frac{\left(\frac{0.5}{1.25}\times P\right)^2\left(\frac{0.25}{1.25}\times P\right)}{\left(\frac{0.5}{1.25}\times P\right)^2}$$

$$= \frac{\left(\frac{0.5}{1.25}\times 2\right)^2\left(\frac{0.25}{1.25}\times 2\right)}{\left(\frac{0.5}{1.25}\times 2\right)^2}$$

$$K_p = \frac{0.8\times 0.8\times 0.4}{0.8\times 0.8} = \mathbf{0.4} \qquad \textbf{Ans.}$$

Type. Synthesis of methanol (CH_3OH)

Example 113. *0.15 mol of CO taken in a 2.5 L flask is maintained at 750 K along with a catalyst so that the following reaction can take place.*

$$CO\,(g) + 2H_2\,(g) \rightleftharpoons CH_3OH\,(g)$$

Hydrogen is introduced until the total pressure of the system is 8.5 atmosphere at equilibrium and 0.08 mol of methanol is formed. Calculate (i) K_p and K_c and (ii) the final pressure if the same amount of CO and H_2 as before are used, but with no catalyst so that the reaction does not take place. **(IIT 1993)**

Solution. $CO\,(g) + 2H_2\,(g) \rightleftharpoons CH_3OH\,(g)$

(*i*) *n* mol at start	0.15	*a*	0
(*ii*) Change by reaction	– 0.08	– (2 × 0.08) = – 0.16	0.08
(*iii*) *n* mol at equilibrium	0.15 – 0.08 = 0.07	*a* – 0.16	0.08

Total number of mol at equilibrium

$$= 0.07 + a - 0.16 + 0.08 = a - 0.01$$

Also, $PV = nRT\,;\; n = \dfrac{PV}{RT}$

$$= \frac{8.5 \text{ atm} \times 2.5 \text{ L}}{0.0821 \text{ L atm K}^{-} \text{ mol}^{-} \times 750 \text{ K}}$$

$$\simeq 0.345 \text{ mol}$$

$\therefore$ $a - 0.01 = 0.345\,;\; \mathbf{a} = 0.345 + 0.01 = \mathbf{0.355}$

$\therefore$ mol of CO at equilibrium = 0.07

mol of H_2 at equilibrium

$$= a - 0.16 = 0.355 - 0.16 = 0.195$$

mol of CH_3OH at equilibrium = 0.08

(*a*) But $K_c = \dfrac{[CH_3OH]}{[CO]\,[H_2]^2}$

$$= \frac{\dfrac{0.08 \text{ mol}}{2.5 \text{ L}}}{\dfrac{0.07 \text{ mol}}{2.5 \text{ L}} \times \left(\dfrac{0.195 \text{ mol}}{2.5 \text{ L}}\right)^2}$$

$$= \frac{0.08 \text{ mol}}{2.5 \text{ L}} \times \frac{2.5 \text{ L}}{0.07 \text{ mol}} \times \frac{(2.5 \text{ L})^2}{(0.195 \text{ mol})^2}$$

$$K_c = 187.84 \text{ mol}^{-2} \text{ L}^2;\; K_p = K_c\,(RT)^{\Delta n}$$

where $\Delta n = n_P - n_R = 1 - (1+2) = -2;$

$$K_p = 187.84\,(0.0821 \times 750)^{-2}$$

$$= \frac{187.84}{(0.0821\times 750)^2} = \mathbf{0.049}$$

(*b*) To find final pressure :

mol of H_2 = 0.355 ; mol of CO = 0.15

$\therefore$ Total number of mol (*n*) = 0.355 + 0.15 = 0.505

But $PV = nRT\,;$

$$\therefore \qquad P = \frac{nRT}{V} = \frac{0.505 \times 0.0821 \times 750}{2.5}$$

$$\therefore \qquad P = \mathbf{12.4 \text{ atm.}}$$

Type. Reactions involving CO (g) and H_2O (g)

Example 114. *The equilibrium constant for the equation*

$$CO\,(g) + H_2O\,(g) \rightleftharpoons CO_2\,(g) + H_2\,(g)$$

is 0.63. A mixture of one mol of water vapours and 3 mol of CO is allowed to come to equilibrium at a total pressure of 2 atmosphere.

(*i*) *How many mol of hydrogen are present at equilibrium.*

(*ii*) *What is partial pressure of each gas in the equilibrium mixture.* **(Roorkee, 1992)**

Solution. $CO\,(g) + H_2O\,(g) \rightleftharpoons CO_2\,(g) + H_2(g)$

(*i*) *n* mol at start	3	1	0	0
(*ii*) Change by reaction	– *x*	– *x*	*x*	*x*
(*iii*) *n* mol at equilibrium	3 – *x*	1 – *x*	*x*	*x*

Total number of mol at equilibrium

$$= 3 - x + 1 - x + x + x = 4$$

$$K_p = \frac{[CO_2]\,[H_2]}{[CO]\,[H_2O]}\,;$$

$$0.63 = \frac{\left(\frac{x}{4}\right)\left(\frac{x}{4}\right)}{\left(\frac{3-x}{4}\right)\left(\frac{1-x}{4}\right)} = \frac{x^2}{(3-x)\,(1-x)}$$

Or $\qquad 0.63 = \dfrac{x^2}{3 - 4x + x^2};\; 0.63\,(3 - 4x + x^2) = x^2;$

$$1.89 - 2.52\,x + 0.63\,x^2 = x^2;$$

$$x^2 - 0.63\,x^2 + 2.52\,x - 1.89 = 0$$

Or $$0.37\,x^2 + 2.52\,x - 1.89 = 0$$

$$\therefore \quad x = \frac{-2.52 \pm \sqrt{(2.52)^2 - 4\,(0.37 \times -1.89)}}{2 \times 0.37}$$

$$= \frac{-2.52 \pm \sqrt{6.35 + 2.8}}{0.74}$$

$$= \frac{-2.52 \pm \sqrt{9.15}}{0.74} = \frac{-2.52 \pm 3.02}{0.74}$$

$$= \frac{0.5}{0.74}\text{ (on adding)} \quad \text{or} \quad \frac{-5.54}{0.74}\text{ (on subtraction)}$$

Since x cannot be negative, it is rejected.

$$\therefore \quad x = \frac{0.5}{0.74} = \mathbf{0.68}$$

(*i*) ∴ Mol of H_2 at equilibrium = x = 0.68

$$p_{CO_2\,(g)} = p_{H_2\,(g)} = \frac{x}{4} \times P = \frac{0.68}{4} \times 2 = \mathbf{0.34\ atm}$$

$$p\,CO(g) = \frac{(3-x)}{4} \times P = \frac{(3-0.68)}{4} \times 2 = \frac{2.32 \times 2}{4}$$

$$= \mathbf{1.16\ atm}$$

$$p\,H_2O(g) = \frac{(1-x)\,P}{4} = \frac{(1-0.68)\,2}{4} = \frac{0.32}{4} \times 2$$

$$= \mathbf{0.16\ atm.}$$

EXAMPLE 115. *H_2 (g) (0.3 mol) was injected into a one litre vessel. The composition at equilibrium is shown below.*

$$\begin{array}{cccc} CO + & H_2O & \rightleftharpoons & CO_2 + H_2 \\ 0.1 & 0.1 & & 0.40 \quad 0.1 \end{array}$$

Calculate the new concentration of CO_2 when the equilibrium establishes again.

SOLUTION. $[H_2]$ = 0.3 mol.

First case $CO + H_2O \rightleftharpoons CO_2 + H_2$

mol at equilibrium

0.1 0.1 0.4 0.1

Second case

(*i*) New mol at start

0.1 0.1 0.4; 0.1 + 0.3 = 0.4

(*ii*) Change by reaction

$+x$ $+x$ $-x$ $-x$

(*iii*) mol at equilibrium

$0.1 + x$ $0.1 + x$ $0.4 - x$ $0.4 - x$

$$K_c = \frac{[CO_2][H_2]}{[CO]\,[H_2O]} = \frac{(0.4-x)\,(0.4-x)}{(0.1+x)\,(0.1+x)}$$

Or $$4 = \frac{(0.4-x)^2}{(0.1+x)^2}.$$

Taking square root, we get :

$$2 = \frac{0.4-x}{0.1+x} \quad ; \quad 2\,(0.1+x) = 0.4 - x$$

Or $$2x + x = 0.4 - 0.2\ ;\ 3x = 0.2\ ;$$

$$x = \frac{0.2}{3} = 0.067\text{ mol}$$

∴ New molar concentration of CO_2 = 0.4 − x = 0.4 − 0.067 = **0.333 mol L^{-}** **Ans.**

EXAMPLE 116. *A mixture of 0.5 mol of each of CO and steam were put into a vessel of 2 litre capacity and heated to get the following equilibria*

$$CO\,(g) + H_2(g) \rightleftharpoons CO_2\,(g) + H_2\,(g)$$

If K_c is 4, calculate the number of mol of CO_2 at equilibrium.

SOLUTION. $CO\,(g) + H_2O\,(g) \rightleftharpoons CO_2(g) + H_2(g)$

(*i*) n mol at start

0.5 0.5 0 0

(*ii*) Change by reaction

$-x$ $-x$ x x

(*iii*) n mol L^{-} at equilibrium

$$\frac{0.5 - x\text{ mol}}{2\text{ L}} \quad \frac{0.5 - x\text{ mol}}{2\text{ L}} \quad \frac{x\text{ mol}}{2\text{ L}} \quad \frac{x\text{ mol}}{2\text{ L}}$$

$$\therefore \quad K_c = \frac{[CO_2]\,[H_2]}{[CO]\,[H_2O]}$$

$$= \frac{\frac{x}{2} \times \frac{x}{2}}{\frac{0.5-x}{2} \times \frac{0.5-x}{2}} = \frac{x^2}{(0.5-x)^2}$$

Or $$4 = \frac{x^2}{(0.5-x)^2}$$

Taking square root of both sides, we get :

$$2 = \frac{x}{0.5-x}\ ;\ 2(0.5-x) = x\ ;\ 1 - 2x = x\ ;$$

$$x + 2x = 1\ ;\ 3x = 1$$

Or $$x = \frac{1}{3} = 0.33$$

∴ number of mol of CO_2 at equilibrium

= **0.33 mol** **Ans.**

Type. Reactions involving H_2 (g) and CO_2 (g)

EXAMPLE 117. *Initially, equal number of moles of CO_2(g) and H_2(g) were put in a flask. The pressure of H_2 (g) at equilibrium is 1.2 atmosphere. If K_p for the reaction, H_2 (g) + CO_2(g) $\rightleftharpoons$ H_2O (g) + CO (g) is 16.0 at a given temperature, the partial pressure of H_2O (g) and CO (g) will be :*

(*a*) *5.0 atm each*
(*b*) *4.8 atm each*
(*c*) *2.6 atm for H_2O (g) and 3.6 atm for CO (g)*
(*d*) *2.5 atm each.*

SOLUTION. For the reaction :

$$H_2(g) + CO_2\,(g) \rightleftharpoons H_2O\,(g) + CO\,(g)$$

Conc. at equilibrium. 1.2 atm 1.2 atm

$$K_p = \frac{p_{H_2O} \times p_{CO}}{p_{H_2} \times p_{CO_2}} \quad \textbf{Or} \quad 16 = \frac{p_{H_2O} \times p_{CO}}{1.2 \times 1.2}$$

$\therefore \quad p_{H_2O} \times p_{CO} = 16 \times 1.2 \times 1.2 = 23.04$

Since $\quad p_{H_2O} = p_{CO}, (p_{H_2O})^2 = 23.04$

or $\quad p_{H_2O} = (23.04)^{1/2} = 4.8$

$\therefore \quad p_{H_2O} = p_{CO} = \mathbf{4.8\ atm.}$

So, correct answer is **(*b*)**.

EXAMPLE 118. *The value of K_p for the water gas reaction :*

$$CO + H_2O \rightleftharpoons CO_2 + H_2$$

is 1.06×10^5 at 298 K. Find the value of standard state free energy change of the reaction at the same temperature. (R = 2 cal).

SOLUTION. $R = 2$ cal, $T = 298$ K,

$K_p = 1.06 \times 10^5$. We know :

$$\Delta G° = -2.303\ RT \log K_p$$
$$= -2.303 \times 2 \times 298 \log (1.06 \times 10^5)$$
$$= -1372.588 [\log 1.06 + \log 10^5]$$
$$= -1372.588 [0.0253 + 5]$$

$\therefore \quad \Delta G° = -1372.588 \times 5.0253 \simeq$ **6898 cal. Ans.**

EXAMPLE 119. *One mol each of a mixture of H_2 and CO_2 is heated to 523 K to get the following equilibrium.*

$$CO_2\ (g) + H_2\ (g) \rightleftharpoons CO\ (g) + H_2O\ (g)$$

If total pressure is 0.1 atm, calculate K_p if final reaction mixture contains 0.16 volume percent of carbon monoxide.

SOLUTION. $CO_2(g) + H_2\ (g) \rightleftharpoons CO\ (g) + H_2O\ (g)$

(*i*) *n* mol at start

1 1 0 0

(*ii*) Change by reaction

$-x$ $-x$ x x

(*iii*) *n* mol at equilibrium

$1-x$ $1-x$ x x

Total number of mol at equilibrium

$= 1 - x + 1 - x + x + x = 2$

Here , $\Delta n = 0$, so volume is not considered.

Volume % of CO = 0.16

$\therefore$ For CO gas,

$$\frac{x}{\text{Total mol}} = \frac{0.16}{100} ; \frac{x}{2} = \frac{0.16}{100}$$

Or $\quad x = \dfrac{2 \times 0.16}{100} = 0.032$;

$$p_{CO_2} = p_{H_2} = 1 - x = 1 - 0.0032$$

Hence, $\quad K_p = \dfrac{p\,(CO) \times p\ H_2O}{p\ CO_2 \times p\ H_2}$

$$= \frac{0.0032 \times 0.0032}{(1-0.0032)^2} = \frac{1.024 \times 10^{-5}}{(0.9968)^2}$$

$K_p = \dfrac{1.024 \times 10^{-5}}{0.9936} = \mathbf{1.03 \times 10^{-5}}$ **Ans.**

EXAMPLE 120. *0.45 mol each of CO_2 and H_2 gases are heated to 700 K to get the following equilibrium.*

$$CO_2\ (g) + H_2\ (g) \rightleftharpoons CO\ (g) + H_2O\ (g)$$

Equilibrium constant for the reaction is 0.11.

(*i*) *Calculate amount of each gas at equilibrium state.*

(*ii*) *After equilibrium has attained, another 0.34 mol each of CO_2 and H_2 are added to the reaction mixture. Calculate the composition of mixture at the new equilibrium state.* **(Roorkee 1989)**

SOLUTION. First case.

$$CO_2\ (g) + H_2\ (g) \rightleftharpoons CO\ (g) + H_2O\ (g)$$

(*i*) *n* mol at start

0.45 0.45 0 0

(*ii*) Change by reaction

$-x$ $-x$ x x

(*iii*) *n* mol at equilibrium

$0.45-x$ $0.45-x$ x x

Since , $\Delta n = 0$, volume is not considered.

$$K = \frac{[CO]\,[H_2O]}{[CO_2]\,[H_2]} ;$$

$$0.11 = \frac{x \times x}{(0.45-x)\,(0.45-x)} = \frac{x^2}{(0.45-x)^2}$$

Taking square root of both sides, we get :

$$0.33 = \frac{x}{0.45-x} ;\ 0.33\,(0.45-x) = x ;$$

$0.15 - 0.33\,x = x$

Or $\quad 0.33x + x = 0.15$; $\quad 1.33x = 0.15$;

$x = 0.15/1.33 = 0.11$ mol

$\therefore \quad [CO] = x = 0.11 \text{ mol} = [H_2]$;

$[CO_2] = [H_2] = 0.45 - x = 0.45 - 0.11$

$=$ **0.34 mol.**

Second Case

$CO_2(g) + H_2\ (g) \rightleftharpoons CO\ (g) + H_2O\ (g)$

(*i*) *n* mol at start

0.34 + 0.34 0.34 + 0.34 0.11 0.11

= 0.68 = 0.68

(*ii*) Change by reaction

$-x$ $-x$ $+x$ $+x$

(*iii*) *n* mol at equilibrium

$0.68-x$ $0.68-x$ $0.11+x$ $0.11+x$

$\therefore \quad K = \dfrac{[CO]\,[H_2]}{[CO_2]\,[H_2]}$;

$$0.11 = \frac{(0.11+x)\,(0.11+x)}{(0.68-x)\,(0.68-x)} = \frac{(0.11+x)^2}{(0.68-x)^2}$$

Taking square root of both sides, we get :

$$(0.11)^{1/2} = \frac{0.11+x}{0.68-x} ; 0.33 = \frac{0.11+x}{0.68-x}$$

Or $0.33(0.68-x) = 0.11 + x$; $0.22 - 0.33\,x = 0.11 + x$;

$x + 0.33\,x = 0.22 - 0.11$; $1.33\,x = 0.11$;

$$x = 0.11/1.33 = \mathbf{0.083}$$

$$\therefore \quad [CO] = [H_2O] = 0.11 + x = 0.11 + 0.083 = \mathbf{0.193\ mol}$$

$$[CO_2] = [H_2] = 0.68 - x = 0.68 - 0.083 = \mathbf{0.597\ mol}$$

Type. Synthesis of Phosgene or Carbonyl Chloride ($COCl_2$).

Example 121. *Three moles of Cl_2 (g) and two moles of CO (g) were heated in a 5L vessel at a given temperature and allowed to reach the equilibrium, $Cl_2(g) + CO(g) \rightleftharpoons COCl_2$. If one mole of CO (g) is present at equilibrium, the value of equilibrium constant of the reaction would be :*

(*a*) 1.5 (*b*) 2

(*c*) 2.5 (*d*) 3.0

Solution. For the reaction :

	$Cl_2(g)$ +	$CO(g)$ $\rightleftharpoons$	$COCl_2(g)$
Initial conc.	3 mol	2 mol	0
Conc. at equilibrium	$\dfrac{3-1=2\text{ mol}}{\text{Vol.}(=5\text{ L})}$	$\dfrac{2-1=1\text{ mol}}{\text{Vol.}(=5\text{ L})}$	$\dfrac{1\text{ mol}}{\text{Vol.}(=5\text{ L})}$

$$\therefore \quad K_c = \frac{[COCl_2]}{[Cl_2(g)][CO(g)]}$$

$$= \frac{1/5}{2/5 \times 1/5} = \frac{5}{2} = \mathbf{2.5.}$$

Hence, correct answer is (*c*).

Example 122. *The reaction of the formation of phosgene gas from CO and Cl_2 is as follows :*

$$CO + Cl_2 \rightleftharpoons COCl_2$$

In an experiment, starting with equimolar CO and Cl_2 in 250 mL flask, the equilibrium mixture on analysis is found to contain 0.05M CO, 0.05M Cl_2 and 0.15M $COCl_2$. Calculate the equilibrium constant of the reaction. **(UP 1984)**

Solution. Volume of mixture at equilibrium = 250 mL

$$= \frac{250}{1000} = 0.25\text{ L}$$

	CO +	Cl_2 $\rightleftharpoons$	$COCl_2$
mol L^{-} at equilibrium	$\dfrac{0.05\text{ mol}}{0.25\text{ L}}$	$\dfrac{0.05\text{ mol}}{0.25\text{ L}}$	$\dfrac{0.15\text{ mol}}{0.25\text{ L}}$
	$= 0.2\text{ mol L}^{-}$	$= 0.2\text{ mol L}^{-}$	$= 0.6\text{ mol L}^{-}$

$$\therefore \quad K_p = \frac{[COCl_2]}{[CO][Cl_2]}$$

$$= \frac{0.6\text{ mol L}^{-}}{0.2\text{ mol L}^{-} \times 0.2\text{ mol L}^{-}}$$

$$= \mathbf{15\ L\ mol^{-}} \qquad \textbf{Ans.}$$

Type. Dissociation of $COCl_2$ (phosgene)

Example 123. *Phosgene ($COCl_2$) was allowed to decompose at 500°C in a one litre vessel according to the reaction :*

$$COCl_2(g) \rightleftharpoons CO(g) + Cl_2(g)$$

If 49.5 g of $COCl_2$ is used initially, find the composition of equilibrium mixture. $K_c = 1.9$.

Solution. Wt. of $COCl_2$ = 49.5 g.

$$\text{g. mol. wt. of } COCl_2 = 12 + 16 + (2 \times 35.5) = 12 + 16 + 71 = 99\text{ g}$$

$$\therefore \text{ number of mol of } COCl_2 = \frac{49.5\text{ g}}{99\text{ g}} = 0.5\text{ mol}$$

	$COCl_2(g)$ $\rightleftharpoons$	$CO(g)$ +	$Cl_2(g)$
(*i*) *n* mol at start	0.5	0	0
(*ii*) Change by reaction	$-x$	x	x
(*iii*) *n* mol at equilibrium	$\dfrac{0.5-x}{V}$	$\dfrac{x}{V}$	$\dfrac{x}{V}$

Where V = Volume of vessel = 1 L

$$\therefore \quad K_c = \frac{[CO][Cl_2]}{[COCl_2]};$$

$$1.9 = \frac{\frac{x}{V} \times \frac{x}{V}}{\frac{0.5-x}{V}} = \frac{\frac{x}{1} \times \frac{x}{1}}{\frac{0.5-x}{1}} = \frac{x^2}{0.5-x}$$

$$\therefore \quad 1.9\,(0.5 - x) = x^2 \quad ; \quad x^2 + 1.9\,x - 0.95 = 0$$

$$\therefore \quad x = \frac{-1.9 \pm \sqrt{(1.9)^2 - 4\,(1 \times -0.95)}}{2 \times 1}$$

$$\left[\because \textit{for } ax^2 + bx + c = 0,\quad x = \frac{-b \pm \sqrt{b^2 - 4\,ac}}{2\,a}\right.$$

$$\therefore \quad x = \frac{0.82}{2} = 0.41$$

$$\therefore \quad [CO] = [Cl_2] = 0.41\text{ mol L}^{-};$$

$$[COCl_2] = 0.5 - x = 0.5 - 0.41 = \mathbf{0.09\ mol\ L^{-}}\ \textbf{Ans.}$$

Type. Synthesis of CO from CO_2 and carbon

Example 124. *A gaseous mixture of CO_2 and CO at 1127 K and 1 atmosphere, in equilibrium with solid carbon has 90.55 % CO by mass in the reaction*

$$CO_2(g) + C(s) \rightleftharpoons 2\,CO(g)$$

Calculate the value of K_c for this reaction at the same temperature.

Solution. 90.55 % CO by mass in a mixture of CO and CO_2 gases means :

$$\text{Mass of CO (g)} = 90.55\text{ g};$$

$$\text{mass of } CO_2\text{ (g)} = 100 - 90.55 = 9.45\text{ g}$$

$$\text{g. mol. mass of CO} = 12 + 16 = 28\text{ g}$$

$$\text{g. mol. mass of } CO_2 = 12 + (2 \times 16) = 44\text{ g.}$$

$$\therefore \quad \text{no. of mol CO} = \frac{\text{Mass of CO}}{\text{g. mol. mass of CO}}$$

$$= \frac{90.55}{28} = \mathbf{3.234}$$

$$\text{no. of mol of } CO_2 = \frac{\text{mass of } CO_2}{\text{g. mol. mass of } CO_2}$$

$$= \frac{9.45}{44} = \mathbf{0.215}$$

In the reaction, carbon being a solid, it is not considered. Since the reaction involves change in volume, total number of mol are needed.

$\therefore$ Total number of mol of CO and

CO_2 gases = 3.234 + 0.215 = 3.449

$\therefore$ In the reaction,

$$CO_2\,(g) + C(s) \rightleftharpoons 2CO\,(g)$$

$$p_{CO} = \frac{3.234}{3.449} \times 1 \text{ atm} = 0.938 \text{ atm}\ ;$$

$$p_{CO_2} = \frac{0.215}{3.449} \times 1 \text{ atm} = 0.0623 \text{ atm}$$

$$\therefore \quad K_p = \frac{(p_{CO})^2}{p_{CO_2}} = \frac{(0.938 \text{ atm})^2}{0.0623 \text{ atm}}$$

$$= 14.19 \text{ atm.}$$

$$\Delta n = n_P - n_R = 2 - 1 = 1$$

But $\quad K_p = K_c\,(RT)^{\Delta n} = K_c\,(RT)^1$

Or $\quad K_c = \dfrac{K_p}{RT}$

$$= \frac{14.19 \text{ atm}}{0.0821 \text{ L atm K}^{-} \text{ mol}^{-} \times 1127 \text{ K}}$$

$$= 0.153 \text{ L}^{-} \text{ mol}$$

Example 125. *At 817° C, K_p for the reaction between $CO_2(g)$ and excess hot graphite (C) is 10 atm.*

(*a*) *What are the equilibrium concentrations of the gases at 817°C and a total pressure of 5 atm?*

(*b*) *At what total pressure, the gas contains 5 % CO_2 by volume.* **(Roorkee, 2000)**

Solution. K_p = 10 atm.,

α = degree of dissociation.

$$CO_2\,(g) \quad + \quad C\,(s) \quad \rightleftharpoons \quad 2CO\,(g)$$

(*i*) *n* mol at start

1 $\qquad\qquad$ 0

(*ii*) Change by reaction

$-\alpha$ $\qquad\qquad$ 2α

(*iii*) *n* mol at equilibrium

$1-\alpha$ $\qquad\qquad$ 2α

Total number of mol at equilibrium

$$= 1 - \alpha + 2\alpha = 1 + \alpha$$

$$\therefore \quad K_p = \frac{p\,(CO)^2}{p\,CO_2} = \frac{\left(\dfrac{2\alpha}{1+\alpha} \times P\right)^2}{\dfrac{1-\alpha}{1+\alpha} \times P}$$

$$= \frac{4\alpha^2 P^2}{(1+\alpha)^2} \times \frac{1+\alpha}{(1-\alpha)\,P} = \frac{4\alpha^2 P}{1-\alpha^2}$$

Or $\quad 10 = \dfrac{4\alpha^2 \times 5}{1-\alpha^2}$

$$= \frac{20\,\alpha^2}{1-\alpha^2}\ ;\ 10\,(1-\alpha^2) = 20\,\alpha^2\ ;$$

$$1 - \alpha^2 = \frac{20\,\alpha^2}{10} = 2\,\alpha^2$$

Or $\quad 2\alpha^2 + \alpha^2 = 1 \ ;\ 3\alpha^2 = 1\ ;$

$$\alpha^2 = \frac{1}{3} \text{ or } \alpha = \left(\frac{1}{3}\right)^{1/2} = (0.33)^{1/2}$$

$\therefore \quad \alpha$ = 0.577 mol

(*a*) At equilibrium,

$[CO_2] = 1 - \alpha = 1 - 0.577 = 0.423$ mol

$[CO] = 2\,\alpha = 2 \times 0.577 = 1.154$ mol.

(*b*) $\quad CO_2$ = 5 % by volume ;

CO = 100 – 5 = 95 % by volume.

$$\therefore \quad p_{CO_2} = \frac{5}{100} \times P = 0.05\,P\ ;$$

$$p_{CO} = \frac{95}{100} \times P = 0.95\,P$$

$$K_P = \frac{p\,(CO)^2}{p\,CO_2}\ ;$$

$$10 = \frac{(0.95\,P)^2}{0.05\,P} = \frac{0.9025\,P^2}{0.05\,P}$$

Or $\quad 10 \times 0.05 = 0.9025$ P ;

$$P = \frac{10 \times 0.05}{0.9025} = \mathbf{0.554\ atm} \qquad \textbf{Ans.}$$

Type. Dissociation of Carbon dioxide

Example 126. *When the following reaction;*

$$2CO_2\,(g) \rightleftharpoons 2\,CO\,(g) + O_2\,(g)$$

was allowed to take place at 3000 K, the value of K_p was found as 0.15 atm at equilibrium. Calculate the partial pressure of CO_2 at this temperature, if CO and CO_2 gases at partial pressures of 8 and 7 atmosphere at 300 K were brought to equilibrium at 3000 K.

Solution. $\quad 2\,CO_2\,(g) \quad \rightleftharpoons \quad 2\,CO\,(g) + O_2(g)$

(*i*) Pressure at start

7 $\qquad\qquad$ 8

(*ii*) Change by reaction

$-x$ $\qquad\qquad$ $+x$ $\qquad$ $+\dfrac{x}{2}$

(*iii*) Pressure at equilibrium

$7-x$ $\qquad\qquad$ $8+x$ $\qquad$ $\dfrac{x}{2}$

$$\therefore \qquad K_p = \frac{[CO]^2\,[O_2]}{[CO_2]^2} \;;\; 0.15 = \frac{(8+x)^2}{(7-x)^2}\times\frac{x}{2}$$

$$0.15\times 2 = \frac{(8+x)^2\,x}{(7-x)^2} = \frac{(64+x^2+16x)\times x}{49+x^2-14\,x}$$

$$= \frac{64\,x + x^3 + 16\,x^2}{49+x^2-14\,x}$$

Or $0.3\,(49 + x^2 - 14\,x) = 64\,x + x^3 + 16\,x$;
$14.7 + 0.3\,x^2 - 4.2\,x = 64\,x + x^3 + 16x^2$

Neglecting x^3, we have
$15.7\,x^2 + 68.2\,x - 14.7 = 0$. Hence

$$x = \frac{-68.2 \pm \sqrt{(68.2)^2 - (4\times 15.7\times -14.7)}}{2\times 15.7}$$

or $$x = 0.207 \left[\because \text{ for } ax^2+bx+c=0,\; x = \frac{-b\pm\sqrt{b^2-4ac}}{2a}\right]$$

∴ Partial pressure of CO_2, $p\,CO_2\,(g)$ = **0.207 atm.**

Type. Synthesis of methane.

Example 127. *A gaseous mixture contains 0.3 mol CO, 0.1 mol H_2 and 0.02 mol H_2O plus an unknown amount of CH_4 in each litre. This mixture is in equilibrium at 1200 K*

$$CO\,(g) + 3H_2 \rightleftharpoons CH_4\,(g) + H_2O\,(g)$$

What is the concentration of CH_4 in this mixture ? The equilibrium constant $K_c = 3.92$ **(Bihar,CEE.,1995)**

Solution. $CO\,(g) + 3\,H_2\,(g) \rightleftharpoons CH_4\,(g) + H_2O\,(g)$

	$CO\,(g)$	$3\,H_2\,(g)$	$CH_4\,(g)$	$H_2O\,(g)$
n mol at equilibrium	0.3	0.1	x	0.02

$$K_c = \frac{[CH_4]\,[H_2O]}{[CO]\,[H_2]^3} \;;\; 3.92 = \frac{x\times 0.02}{0.3\times(0.1)^3}$$

Or $3.92(0.3)\times(0.1)^3 = 0.02\,x$
$1.176\times 10^{-3} = 0.02\,x\,;\, x = (1.176\times 10^{-3})/0.02$
$= \mathbf{0.0588}$ **Ans.**

Type. Dissociation of I_2

Example 128. *Iodine dissociates as*

$$I_2 \rightleftharpoons 2\,I$$

at 1273 K. As a result, a pressure of 0.112 atm was developed. The expected pressure is, however, 0.074 atm. Find the value of K_p.

Solution. Experimental pressure = 0.112 atm ;
Calculated pressure = 0.074 atm.

	I_2	$\rightleftharpoons$	2I
(*i*) n mol at start	1		0
(*ii*) Change by reaction	$-x$		$2\,x$
(*iii*) n mol at equilibrium	$1-x$		$2\,x$

Total number of mol at equilibrium

$$= 1 - x + 2\,x = 1 + x$$

But $$\frac{1+x}{1} = \frac{\text{Experimental pressure}}{\text{Calculated pressure}} \;;$$

$$1 + x = \frac{0.112}{0.074} = 1.51$$

$$\therefore \qquad x = 1.51 - 1 = 0.51$$

Also, $$K_p = \frac{p\,(I)^2}{p_{I_2}} = \frac{\left(\frac{2\,x}{1+x}\times P\right)^2}{\frac{1-x}{1+x}\times P}$$

$$= \frac{4\,x^2\,P^2}{(1+x)^2}\times\frac{1+x}{(1-x)\,P} = \frac{4\,x^2\,P}{1-x^2}$$

$$K_p = \frac{4\times(0.51)^2\times 0.112}{1-(0.51)^2} = \frac{0.116}{0.7399}$$

$= \mathbf{0.157\ atm.}$

Example 129. *What is the value of K_c for the reaction :*

$$I_2\,(g) \rightleftharpoons 2\,I\,(g)$$

at 1473 K, when one mol of iodine gas introduced into an evacuated one litre flask such that only 5% of it gets dissociated.

(BIT Mesra; Ranchi, 1992)

Solution.	$I_2\,(g)$	$\rightleftharpoons$	$2\,I\,(g)$
(*i*) n mol at start	1		0
(*ii*) Change by reaction	$\frac{-5}{100}$ $= -0.05$		0.05×2 $= 0.1$
(*iii*) n mol at equilibrium	$1 - 0.05$ $= 0.95$		0.1

$$K_c = \frac{[I]^2}{[I_2]} = \frac{(0.1)^2}{0.95} = \frac{0.01}{0.95} = 0.0105$$

$= \mathbf{1.05\times 10^{-2}\ mol\ L^{-}}$

Example 130. *Iodine is highly soluble in KI solution because of the following equilibrium*

$$I_2 + I^- \rightleftharpoons I_3^-$$

But its saturated solution in water is 0.33 g L^-. It is observed that M/10 KI solution (i.e., M/10 I^-) actually dissolves 12.5 g L^- I_2, most of which gets converted to I_3^-. If it is assumed that concentration of I_2 in all saturated solutions is same, what would be the equilibrium constant for the above reaction. Also, describe the effect of adding water to a clear saturated solution of I_2 in KI solution. (at. wt. of I = 127).

Solution. (*a*) Wt. of I_2 in water = 0.33 g ;

g. mol. wt. of I_2 = $2\times 127 = 254$ g mol^-

$$\therefore \text{ Number of mol of } I_2 = \frac{0.33\text{ g}}{254\text{ g mol}^-}$$

$$= 1.3\times 10^{-3}\text{ mol} = 0.0013\text{ mol.}$$

Wt. of I_2 in KI solution = 12.5 g ;
g. mol. wt. of I_2 = 2 × 127 = 254 g mol^-
∴ no. of mol of I_2 in KI solution

$$= \frac{12.5\text{ g}}{254\text{ g mol}^-} = 0.0492\text{ mol}$$

$$\frac{M}{10} I_2 = 0.1\text{ mol } I_2$$

	I_2	$+$	I^-	$\rightleftharpoons$	I_3^-
(*i*) *n* mol at start			0.1		0.0492
(*ii*) Change by reaction			− (0.0492–0.0013) = − 0.0479		− 0.0013
(*iii*) *n* mol at equilibrium	0.0013		0.1 − 0.0479 = 0.0521		0.0492–0.0013 = 0.0479

$$K_p = \frac{[I_3^-]}{[I^-][I_2]} = \frac{0.0479}{0.0521 \times 0.0013} = 707$$

(*b*) If water is added to the saturated solution of I_2 in KI, backward reaction is favoured.

Type. Calculation of K_c and K_p for homogeneous gaseous equilibrium reactions involving synthesis (or formation) of product with **'no change in volume** or having same number of mol of reactants and products'.

In order to understand it, consider the following reactions.

1. Synthesis of HI.

(*a*) **Determination of K_c**

	H_2	$+$	I_2	$\rightleftharpoons$	2HI
Initial conc.	a mol		b mol		0
Conc. at equilibrium	$\frac{a-x}{V}$ mol		$\frac{b-x}{V}$ mol		$\frac{2x}{V}$ mol

Let us start with *a* mol of H_2 and *b* mol of I_2 in a closed vessel having volume of '*V*' litre.

V = Volume of closed vessel in which reaction takes place.
x = Number of mol of each of H_2 and I_2 that are used to form 2 *x* mol of HI at equilibrium.

Molar concentration at equilibrium are :

$$[H_2] = \frac{a-x}{V} \;;\; [I_2] = \frac{b-x}{V} \;;\; [HI] = \frac{2x}{V}$$

Applying law of mass action, we get :

$$K_c = \frac{[HI]^2}{[H_2][I_2]} = \frac{\left(\frac{2x}{V}\right)^2}{\left(\frac{a-x}{V}\right)\left(\frac{b-x}{V}\right)}$$

$$= \frac{4x^2}{V^2} \times \frac{V}{a-x} \times \frac{V}{b-x} = \frac{4x^2}{(a-x)(b-x)}$$

$$\therefore \quad K_c = \frac{4x^2}{(a-x)(b-x)}$$

(*b*) **Determination of K_p.**

$K_p = K_c$ (shown above) because the reaction involves no change in volume.

(*c*) **Synthesis of NO.**

(*a*) **Determination of K_c.**

	N_2	$+$	O_2	$\rightleftharpoons$	2NO
Initial conc.	a mol		b mol		0
Conc. at equilibrium	$\frac{a-x}{V}$ mol		$\frac{b-x}{V}$ mol		$\frac{2x}{V}$ mol

Note. (*a*) To find K_c proceed as shown in synthesis of HI above
(*b*) $K_p = K_c$.

EXAMPLE 131. *One mol of H_2, 2 mol of I_2 and 3 mol of HI are injected in a one litre flask. What will be the concentration of H_2, I_2 and HI at equilibrium at 500°C ? K_c for reaction, $H_2 + I_2 \rightleftharpoons 2HI$ is 45.9.* **(UP SEAT, 1995, MLNR, 1995, Roorkee, 1988)**

SOLUTION. Reaction	H_2	$+$	I_2	$\rightleftharpoons$	2HI
no. of mol at t = 0	1		2		3
no. of mol at equilibrium	1 − *x*		2 − *x*		3 + 2*x*

If volume of container is *V* litre, then :

[∵ *x* = no. of mol dissociated. For 2 HI, HI formed = 2*x*

$$K_c = \frac{[HI]^2}{[H_2][I_2]} = \frac{\left(\frac{3+2x}{V}\right)^2}{\left(\frac{1-x}{V}\right)\left(\frac{2-x}{V}\right)};$$

$$45.9 = \frac{(3+2x)^2}{(1-x)(2-x)};$$

$$45.9 = \frac{9+4x^2+12x}{2-3x+x^2};$$

$$45.9(2-3x+x^2) = 9+4x^2+12x$$
$$= 91.8 - 137.07x + 45.9x^2$$
$$= 9 + 4x^2 + 12x$$

$$41.9x^2 - 149.7x + 82.8 = 0$$

After solving, we find

$$x = 0.684\text{ mol L}^-$$

∴ $[H_2]$ = 1 − 0.684 = **0.316 mol L^-** **Ans.**

[∵ *V* = 1 L]

$[I_2]$ = 2 − 0.684 = **1.316 mol L^-** **Ans.**

$$\left[\begin{array}{l} \because x = \dfrac{-b \pm (b^2 - 4ac)^{1/2}}{2a} \\ \text{for a quadratic equation} \\ ax^2 + bx + c = 0 \end{array}\right]$$

$$[HI] = 3 + 2\,(0.684) = 3 + 1.368$$

$$= \mathbf{4.368\ mol\ L^{-}} \qquad \textbf{Ans.}$$

EXAMPLE 132. *25 cc hydrogen and 18 cc of iodine vapours were heated in a sealed tube at 456°C when at equilibrium 30.8 cc of HI are formed. Calculate the value of equilibrium constant.*

(Modified MLNR, 1984, AIPMT, 2009)

SOLUTION. The reaction is :

$$\begin{array}{lccccc} \textbf{At equilibrium} & H_2 & + & I_2 & \rightleftharpoons & 2HI \\ & \dfrac{a-x}{V} & & \dfrac{b-x}{V} & & \dfrac{2x}{V} \end{array}$$

$$K_c = \frac{[HI]^2}{[H_2][I_2]} = \frac{\left(\dfrac{2x}{V}\right)^2}{\left(\dfrac{a-x}{V}\right)\left(\dfrac{b-x}{V}\right)}$$

$$= \frac{4x^2}{(a-x)(b-x)} \qquad \ldots (1)$$

$$2x = \text{Vol of HI} = 30.8 \text{ cc}$$

$$\therefore \quad x = 30.8/2 = 15.4 \text{ cc;}$$

$$a = \text{Vol. of } H_2 = 25 \text{ cc}$$

$$\therefore \quad a - x = 25 - 15.4 = 9.6 \text{ cc;}$$

$$b = \text{Vol of } I_2 = 18 \text{ cc}$$

$$\therefore \quad b - x = 18 - 15.4 = 2.6 \text{ cc}$$

Substituting these values in equation (1) above, we have :

$$K_c = \frac{4 \times (15.4)^2}{9.6 \times 2.6} = \frac{4 \times 237.16}{9.6 \times 2.6} = 38$$

EXAMPLE 133. *The K_p value for the reaction : $H_2 + I_2 \rightleftharpoons 2\,HI$ at 460° C is 49. If the partial pressure of each of H_2 and I_2 is 0.5 atm, determine the partial pressure of each gas at equilibrium.* **(Roorkee , 1999)**

SOLUTION.

	H_2	+	I_2	$\rightleftharpoons$	2HI
(*i*) *n* atm at start	0.5		0.5		0
(*ii*) Change by reaction	$-x$		$-x$		$2x$
(*iii*) *n* atm at equilibrium	$0.5-x$		$0.5-x$		$2x$

Applying law of chemical equilibrium, we have :

$$K_p = \frac{(p_{HI})^2}{p_{H_2} \times p_{I_2}} = \frac{(2x)^2}{(0.5-x)(0.5-x)};$$

$$49 = \frac{(2x)^2}{(0.5-x)^2}$$

Taking square root of both sides, we get :

$$7 = \frac{2x}{0.5-x}; \; 3.5 - 7x = 2x \; ; 9x = 3.5$$

$$\therefore \quad x = 3.5/9 = 0.389 \text{ atm.}$$

$$\therefore \quad p_{H_2} = 0.5 - x = 0.5 - 0.389 = \mathbf{0.111\ atm\ Ans.}$$

$$p_{I_2} = 0.5 - x = 0.5 - 0.389 = \mathbf{0.111\ atm\ Ans.}$$

$$p_{HI} = 2x = 2 \times 0.389 = \mathbf{0.778\ atm} \qquad \textbf{Ans.}$$

EXAMPLE 134. *The equilibrium constant for the reaction $H_2(g) + I_2(g) \rightleftharpoons 2\,HI(g)$ is 0.35 at 298 K. Has the equilibrium been reached ? If not, state on which side of the equilibrium, the system is.*

(*i*) *p_{H_2} = 0.55 bar ; p_{HI} = 0.44 bar ; there is solid I_2 in the container.*

(*ii*) *p_{H_2} = 2.5 bar ; p_{HI} = 0.15 bar; there is solid I_2 in the container.*

(*iii*) *p_{H_2} = 0.10 bar ; p_{HI} = 0.80 bar ; there is solid I_2 in the container.*

SOLUTION. The reaction is :

$$H_2\,(g) + I_2\,(g) \rightleftharpoons 2HI\,(g)$$

(*i*) p_{H_2} = 0.55 bar, p_{I_2} = 1 (being solid) ;

p_{HI} = 0.44 bar.

$\therefore$ Concentration quotient,

$$Q = \frac{(p_{HI})^2}{p_{H_2} \times p_{I_2}} = \frac{(0.44)^2}{0.55 \times 1} = \frac{0.1936}{0.55} = \mathbf{0.35}$$

K = 0.35 (given). Since the value of *Q* = *K*, *equilibrium has been reached.*

(*ii*) p_{H_2} = 2.5 bar ; p_{I_2} = 1 ; p_{HI} = 0.15 bar

$$\therefore \quad Q = \frac{(p_{HI})^2}{p_{H_2} \times p_{I_2}} = \frac{0.15 \times 0.15}{2.5}$$

$$= \frac{0.0225}{2.5} = 0.009$$

K = 3.5. Since the value of *Q* is much less than that of *K*, the *equilibrium has not been reached* and the reaction will proceed in the *forward direction*.

(*iii*) p_{H_2} = 0.1 bar, p_{I_2} = 1 ; p_{HI} = 0.8 bar

$$\therefore \quad Q = \frac{(p_{HI})^2}{p_{H_2} \times p_{I_2}} = \frac{0.8 \times 0.8}{0.1} = 6.4$$

K = 3.5. Since the value of *Q* is much higher than that of *K*, the *equilibrium has not been reached* and the reaction will proceed in the backward direction.

EXAMPLE 135. *A mixture containing H_2 and I_2 in the molar ratio 2 : 3 was heated at 713 K till the reaction $H_2 + I_2 \rightleftharpoons 2\,HI$ reached at the equilibrium state. Calculate the percentage of iodine converted into HI (K_c at 713 K = 0.02).* **(Bihar CEE, 1987)**

SOLUTION. Reaction	H_2	+	I_2	$\rightleftharpoons$	2HI
(*i*) *n* mol at start	2		3		0
(*ii*) Change by reaction	$-x$		$-x$		$2x$
(*iii*) *n* mol at equilibrium	$2-x$		$3-x$		$2x$

Applying law of chemical equilibrium, we have

$$K = \frac{[HI]^2}{[H_2][I_2]} \quad ; \quad 0.02 = \frac{(2x)^2}{(2-x)(3-x)}$$

$$0.02 = \frac{4x^2}{6-5x+x^2} \;;$$

$$= 0.12 - 0.1x + 0.02x^2 = 4x^2 \;;$$

$$4x^2 - 0.02x^2 + 0.1x - 0.12 = 0 \;;$$

$$3.98x^2 + 0.1x - 0.12 = 0$$

$$\therefore \quad x = \frac{-(+0.1) \pm \sqrt{(+0.1)^2 - 4(3.98 \times -0.12)}}{2 \times 3.98}$$

$$\left[\because \text{for } ax^2 + bx + c = 0, \quad x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}\right]$$

$$x = \frac{-0.1 \pm \sqrt{0.01 + 1.91}}{7.96} = \frac{-0.1 \pm \sqrt{1.92}}{7.96}$$

$$= \frac{-0.1 \pm 1.38}{7.96}$$

$$= \frac{1.28}{7.96} = \mathbf{0.16} \text{ or } \frac{-1.48}{7.96}$$

x cannot be negative, so $\frac{-1.48}{7.96}$ value is rejected.

Total mol of I_2 = 3

$\therefore$ % age of I_2 converted to HI

$$= \frac{0.16 \times 100}{3} = \mathbf{5.33\ \%} \qquad \textbf{Ans.}$$

EXAMPLE 136. *In a 10 L evacuated chamber, 0.5 mol H_2 and 0.5 mol I_2 are reacted at 448°C. At which temperature K = 50 for*

$$H_2(g) + I_2(g) \rightleftharpoons 2\,HI(g)$$

For concentration in mol per litre :

(a) What is the value of K_p ?

(b) What is total pressure in the chamber ?

(c) How many mol of iodine remain unreacted at equilibrium ?

(d) What is partial pressure of each component in the equilibrium mixture ?

(e) What is the concentration of each substance at equilibrium ? **(Roorkee, 1985, 1989)**

SOLUTION. (*a*) Since Δn = 0 in this reaction, volume is not considered in this reaction to calculate *K*. Hence,

$$K_p = K_c = 50$$

$$n = \text{Total mol of } H_2 \text{ and } I_2$$

$$= 0.5 + 0.5 = 1.0.$$

$$V = 10\text{ L} \;; \quad R = 0.0821 \text{ L atm mol}^{-} \text{ K}^{-} \;;$$

$$T = 448 + 273 = 721 \text{ K} \quad P = ?$$

(*b*) We know $PV = nRT$;

$$P = \frac{nRT}{V}$$

$$= \frac{1\text{ mol} \times 0.0821 \text{ L atm mol}^{-} \text{ K}^{-} \times 721\text{ K}}{10\text{ L}}$$

$$\therefore \quad P = \mathbf{5.9\ atm = Total\ pressure.} \qquad \textbf{Ans.}$$

Given reaction :	$H_2(g)$ +	$I_2(g)$ $\rightleftharpoons$	$2HI(g)$
(*i*) n mol at start	0.5	0.5	0
(*ii*) Change by reaction	$-x$	$-x$	$2x$
(*iii*) n mol at equilibrium	$0.5-x$	$0.5-x$	$2x$

Applying law of chemical equilibrium, we have.

$$K = \frac{[HI]^2}{[H_2][I_2]} \;;$$

$$50 = \frac{(2x)^2}{(0.5-x)(0.5-x)} = \frac{(2x)^2}{(0.5-x)^2}$$

Taking square root, we get :

$$(50)^{1/2} = \frac{2x}{0.5-x} \;; \quad 7.07 = \frac{2x}{0.5-x}$$

$$3.53 - 7.07x = 2x \;; \quad 2x + 7.07x = 3.53$$

$$9.07x = 3.53 \;; \quad x = \frac{3.53}{9.07} = 0.39$$

(*c*) mol of I_2 remained unreacted at equilibrium

$$= 0.5 - 0.39 = \mathbf{0.11\ mol} \qquad \textbf{Ans.}$$

(*d*)

$$p_{H_2} = \frac{\text{Mol of } H_2}{\text{Total mol}} \times \text{total pressure}$$

$$= \frac{0.11 \times 5.9}{1} = 0.649 \text{ atm}$$

$$p_{I_2} = p_{H_2} = 0.649 \text{ atm}$$

$$p_{HI} = \text{Total pressure} - (p_{H_2} + p_{I_2})$$

$$= 5.9 - (0.649 + 0.649)$$

$$= \mathbf{4.66\ atm}$$

(*e*) $\therefore$

$$[H_2] = [I_2] = 0.5 - 0.39 = 0.11 \text{ mol}$$

$$= \frac{0.11 \text{ mol}}{10 \text{ L}} = \mathbf{0.011\ mol\ L^{-}}$$

Also, $[HI] = 2x = 2 \times 0.39 = \mathbf{0.78\ mol\ L^{-}}$

EXAMPLE 137. *15 g mol of H_2 reacts with 5.2 g mol of I_2 to give 10 g mol of HI. Calculate the equilibrium constant of the reaction $H_2 + I_2 \rightleftharpoons 2HI$.* **(UP, 1980)**

SOLUTION. Reaction :	H_2 +	I_2 $\rightleftharpoons$	2 HI
(*i*) n mol at start	15	5.2	10
(*ii*) Change by reaction	$-x$	$-x$	$2x$
(*iii*) n mol at equilibrium	$15-x$	$5.2-x$	$2x$

$$2x = 10. \quad \text{So,} \quad x = 10/2 = 5$$

$$\therefore \quad [H_2] = 15 - x = 15 - 5 = 10 \;;$$

$$[I_2] = 5.2 - x = 5.2 - 5.0 = 0.2, \quad [HI] = 10$$

Applying law of chemical equilibrium, we get :

$$K = \frac{[HI]^2}{[H_2][I_2]} = \frac{10 \times 10}{10 \times 0.2} = 50$$

$$\therefore \quad K = \mathbf{50} \qquad \textbf{Ans.}$$

EXAMPLE 138. *25 mL of H_2 and 18 mL of I_2 vapours are heated in a sealed glass tube at 465°C, when at equilibrium, 30.8 mL of HI was formed. Calculate the percentage degree of dissociation of pure 2 mol HI at 465°C.* **(MLNR, 1984)**

SOLUTION. (*a*) K_c = 38 (see example 132...)

(*b*) For $H_2 + I_2 \rightleftharpoons 2HI$,

$$K_c = 38 \qquad \text{...(1)}$$

∴ For $2HI \rightleftharpoons H_2 + I_2,\; K_c' = \dfrac{1}{38}$ ... (2)

For reaction :	$2HI$	$\rightleftharpoons$	H_2	+	I_2, we have
(*i*) *n* mol at start	2		0		0
(*ii*) Change for reaction	-2α		$2\alpha/2 = \alpha$		$2\alpha/2 = \alpha$
(*iii*) *n* mol at equilibrium	$2 - 2\alpha$		α		α

Applying law of chemical equilibrium to equation (2), we have :

$$K_c' = \frac{[H_2][I_2]}{[HI]^2};$$

$$\frac{1}{38} = \frac{\alpha \times \alpha}{(2 - 2\alpha)^2} = \frac{\alpha^2}{4 + 4\alpha^2 - 8\alpha}$$

Or $38\alpha^2 = 4 + 4\alpha^2 - 8\alpha;$

$38\alpha^2 - 4\alpha^2 + 8\alpha - 4 = 0$

Or $34\alpha^2 + 8\alpha - 4 = 0;$

$$\therefore \quad \alpha = \frac{-8 \pm \sqrt{(8)^2 - 4(34 \times -4)}}{2 \times 34}$$

$$\left[\because \text{ for } ax^2 + bx + c = 0,\; x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}\right]$$

$$\alpha = \frac{-8 \pm \sqrt{64 + 544}}{68} = \frac{-8 \pm \sqrt{608}}{68} = \frac{-8 \pm 24.65}{68}$$

$$\alpha = \frac{-8 \pm 24.65}{68} = \frac{16.65}{68} = 0.244$$

(on addition), $\dfrac{-32.65}{68}$ (on subtraction)

Since α cannot be negative, negative value is neglected.

∴ % age degree of dissociation = 0.244 × 100

= **24.4 %** **Ans.**

> **Note.** According to Avogadro's law, equal volume of all gases contain equal number of molecules under similar conditions of temperature and pressure.

EXAMPLE 139. *At a certain temperature, the value of equilibrium constant of the reaction*

$$H_2 + I_2 \rightleftharpoons 2HI$$

is 6.0. If the system is equilibrated at [HI] = 1.23, $[H_2]$ = 0.50 and $[I_2]$ = 0.5 in a one litre flask and suddenly 0.6 mol of HI is removed, calculate the concentration of all species when equilibrium is attained.

SOLUTION. Reaction.	H_2	+	I_2	$\rightleftharpoons$	$2HI$
(*i*) *n* mol at start	0.5		0.5		1.23
(*ii*) Change by reaction	$-x$		$-x$		$+2x - 0.6$
(*iii*) *n* mol at equilibrium	$0.5 - x$		$0.5 - x$		$1.23 + 2x - 0.6 = 0.63 + 2x$

Applying law of chemical equilibrium, we get :

$$K = \frac{[HI]^2}{[H_2][I_2]}; \quad 6 = \frac{(0.63 + 2x)^2}{(0.5 - x)(0.5 - x)}$$

Taking square root of both sides, we get :

$$\sqrt{6} = \frac{0.63 + 2x}{0.5 - x}; \quad 2.45 = \frac{0.63 + 2x}{0.5 - x};$$

$2.45\,(0.5 - x) = 0.63 + 2x$

$1.225 - 2.45\,x = 0.63 + 2x;$

$2x + 2.45\,x + 0.63 - 1.225 = 0$

Or $4.45x - 0.595 = 0;\quad x = \dfrac{0.595}{4.45} = 0.13$

∴ $[H_2] = [I_2] = 0.50 - 0.13 =$ **0.37 mol.** **Ans.**

$[HI] = 0.63 + 2(0.13) = 0.63 + 0.26$

= **0.89 mol.** **Ans.**

EXAMPLE 140. *One mol each of H_2 and I_2 are heated in an evacuated chamber of 30 L capacity to 470°C. If K = 50.*

(*a*) *How many mol of I_2 remain unreacted when equilibrium is established?*

(*b*) *Find the partial pressures of HI and I_2 in the equilibrium mixture.*

(*c*) *Now if one additional mol of H_2 is introduced into this equilibrium mixture, how many mol of the original iodine will remain unreacted ?*

SOLUTION. Reaction :	H_2	+	I_2	$\rightleftharpoons$	$2HI$
(*i*) *n* mol at start	1		1		0
(*ii*) Change by reaction	$-x$		$-x$		$2x$
(*iii*) *n* mol at equilibrium	$1 - x$		$1 - x$		$2x$

Applying law of chemical equilibrium, we get :

$$K = \frac{[HI]^2}{[H_2][I_2]} = \frac{(2x)^2}{(1 - x)(1 - x)} = \frac{(2x)^2}{(1 - x)^2}$$

(*a*) ∴ $$50 = \frac{(2x)^2}{(1 - x)^2}$$

Taking square root of both sides, we get :

$$\sqrt{50} = \frac{2x}{1 - x}; \quad 7.07 = \frac{2x}{1 - x};$$

$7.07 - 7.07\,x = 2x;$

$2x + 7.07\,x = 7.07 \quad ; \quad 9.07x = 7.07;$

Thus $x = 7.07/9.07$

Or $x = 0.78$ mol I_2 reacted.

∴ Mol of I_2 remain unreacted

$= 1 - x = 1 - 0.78 =$ **0.22 mol** **Ans.**

(*b*) Since the number of moles of the gas do not change as the reaction proceeds at 470°C, hence number of mol (*n*) of gas that remains at equilibrium = 1 + 1 = 2.

$P = ?,\quad n = 2,\quad R = 0.0821$ L atm K^{-} mol^{-},

$T = 470 + 273$ K = 743 K and $V = 30$ L.

But $PV = nRT;$

So, $$P = \frac{n\,RT}{V}$$

$$= \frac{2\text{ mol} \times 0.0821\text{ L atm K}^{-}\text{ mol}^{-} \times 743\text{ K}}{30\text{ L}}$$

∴ $P =$ **4.1 atm.**

$$P_{I_2} = \frac{0.22\text{ mol} \times 0.0821\text{ L atm K}^{-}\text{ mol}^{-} \times 743\text{ K}}{30\text{ L}}$$

$=$ **0.45 atm.** **Ans.**

no. of mol of HI $= 2\,x = 2 \times 0.78 = 1.56$ mol

∴ $$p_{HI} = \frac{1.56\text{ mol} \times 0.0821\text{ L atm K}^{-}\text{ mol}^{-} \times 743\text{ K}}{30\text{ L}}$$

$=$ **3.17 atm.** **Ans.**

(*c*) H_2	+	I_2 $\rightleftharpoons$	2HI
(*i*) *n* mol at start	$1 + 1$ $= 2$	1	0
(*ii*) Change by reaction	$-x$	$-x$	$2\,x$
(*iii*) *n* mol at equilibrium	$2 - x$	$1 - x$	$2\,x$

Applying law of chemical equilibrium, we have :

$$K = \frac{[HI]^2}{[H_2][I_2]}\ ;$$

$$50 = \frac{(2x)^2}{(2-x)(1-x)} = \frac{4x^2}{2 - 3x + x^2}\ ;$$

$$100 - 150\,x + 50\,x^2 = 4\,x^2 \quad ; \quad 50x^2 - 4x^2 - 150x + 100 = 0$$

$$\therefore\ 46x^2 - 150x + 100 = 0\ ;$$

$$x = \frac{-(-150) \pm \sqrt{(-150)^2 - 4\,(46 \times 100)}}{2 \times 46}$$

$$\left[\because \text{ for } ax^2 + bx + c = 0,\quad x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}\right.$$

∴ $$x = \frac{150 \pm \sqrt{22500 - 18400}}{92}$$

$$= \frac{150 \pm \sqrt{4100}}{92} = \frac{150 \pm 64.03}{92}$$

$$= \frac{214.03}{92} \text{ or } \frac{85.97}{92}$$

$= 2.33$ or 0.93.

Here 2.33 is rejected according to given data. So, $x = 0.93$ mol of I_2 reacted.

∴ Mol of I_2 remained unreacted

= Initial mol of I_2 – mol of I_2 reacted

$= 1.00 - 0.93 =$ **0.07 mol** **Ans.**

EXAMPLE 141. *When one gram of H_2 is heated with 46 g of I_2 at 470°C, the equilibrium mixture contains 1.9 g I_2.*

(*a*) *Calculate the value of equilibrium constant*

(*b*) *How many mol of each gas are present in the equilibrium mixture ?*

SOLUTION. Wt. of $H_2 = 1$ g ;

g. mol. wt. of $H_2 = 2 \times 1 = 2$ g

∴ no. of mol of $H_2 = \frac{1}{2} = 0.5$ mol ;

Wt. of $I_2 = 46$ g ;

g. mol. wt. of $I_2 = 2 \times 127 = 254$ g.

∴ $$\text{no. of mol of } I_2 = \frac{\text{Wt. of } I_2}{\text{g. mol. wt. of } I_2}$$

$$= \frac{46}{254} = 0.181\text{ mol}$$

no. of mol of I_2 produced at equilibrium

$$= \frac{\text{Wt. of } I_2}{\text{g. mol. wt. of } I_2}$$

$$= \frac{1.9\text{ g}}{254\text{ g}} = 0.0075$$

For H_2	+ I_2	$\rightleftharpoons$ 2HI
(*i*) *n* mol at start		
0.5	0.181	0
(*ii*) *n* mol used up		
$0.181 - 0.0075$ $\simeq 0.174$	$0.181 - 0.0075$ $\simeq 0.174$	—
(*iii*) *n* mol produced		
—	—	$2(0.174) = 0.348$
(*iv*) *n* mol at equilibrium		
$0.5 - 0.174$ $= 0.326$	0.0075	0.348

Applying law of chemical equilibrium, we get :

$$K = \frac{[HI]^2}{[H_2][I_2]} = \frac{(0.348)^2}{0.326 \times 0.0075} = 49.5$$

Or $K =$ **49.5** **Ans.**

Type. ΔG° = – 2.303 RT log K

ΔG° is not the free energy change at equilibrium. It is the free energy change when all the reactants and products are taken at a concentration of 1 Mol L^{-}. ΔG° is related to K_c or K_p as $\Delta G° = -RT \ln K_c$ or $\Delta G° = -RT \ln Kp$. The units of ΔG° depend upon units of R. When R is used as 8.314 J $mol^{-}\ K^{-}$, ΔG° will be in joules. When R is used as 1.99 cal $mol^{-} K^{-}$, ΔG° will be in calories. But K_p must always be in $(atm)^{\Delta n}$.

EXAMPLE 142. *The value of equilibrium constant K is 45.9 at 490°C for the reaction :*

$$H_2 + I_2 \rightleftharpoons 2HI$$

Calculate the value of ΔG° for the reaction at that temperature.

SOLUTION. $\Delta G° = ?$, $R = 1.987$ cal K^{-},

$T = 490 + 273 = 763$ K, $K = 45.9$.

We know that : $\Delta G° = -2.303\text{ RT} \log K$

$$= -2.303 \times 1.987\text{ cal K}^{-} \times 763\text{ K} \log 45.9$$

$$= -3490 \times 1.6618 = -5.79 \times 10^3\text{ cal}$$

$$= \frac{-5.79 \times 10^3}{10^3}\text{ k cal}$$

$\Delta G° =$ **– 5.79 k cal.** **Ans.**

EXAMPLE 143. *When an experiment was performed at 763 K, the following equilibrium composition was obtained for the reaction :* $H_2 + I_2 \rightleftharpoons 2HI + heat$; $[H_2] = 8.62 \times 10^{-4}$ *mol* L^{-} ; $[I_2] = 2.63 \times 10^{-3}$ *mol* L^{-} ; $[HI] = 1.02 \times 10^{-2}$ *mol* L^{-}.

(*a*) *Find equilibrium constant, K*

(*b*) *Find* $\Delta G°$

(*c*) *Predict the effect of increasing temperature on equilibrium*

(*d*) *Predict the effect of increasing volume on the equilibrium.*

SOLUTION. (*a*) Reaction :

$$H_2 \quad + \quad I_2 \quad \rightleftharpoons \quad 2HI + \text{heat}$$

n mol at equilibrium

$$8.62 \times 10^{-4} \qquad 2.63 \times 10^{-3} \qquad 1.02 \times 10^{-2}$$

Applying law of chemical equilibrium, we get :

$$K = \frac{[HI]^2}{[H_2][I_2]}$$

$$= \frac{(1.02 \times 10^{-2})^2}{8.62 \times 10^{-4} \times 2.63 \times 10^{-3}} = \mathbf{45.9} \textbf{ Ans.}$$

(*b*)

$$\Delta G° = -2.303 \text{ RT} \log \text{K}$$

$$= -2.303 \times 1.987 \text{ cal K}^{-} \times 763 \text{ K} \log 45.9$$

$$= -3490 \times 1.6618 = -5.79 \times 10^3 \text{ cal}$$

$$= \mathbf{-5.79 \text{ k cal}} \qquad \textbf{Ans.}$$

(*c*) Since the reaction is exothermic, increase in temperature will favour the backward reaction.

(*d*) Since number of mol of reactants is equal to number of mol of products, volume will have no effect on equilibrium.

EXAMPLE 144. *The value of equilibrium constant for the reaction* $H_2 + I_2 \rightleftharpoons 2HI$ *at 700°C is 54.8. If 0.5 mol* L^{-} *of HI (g) is present at equilibrium at 700°C, what are the concentrations of* H_2 *(g) and* I_2 *(g) assuming that we initially started with HI (g) and allowed it to reach equilibrium at 700 K.*

(Problem from NCERT Text book)

SOLUTION. For $H_2 + I_2 \rightleftharpoons 2 \text{ HI}$, K = 54.8 . Thus, for $2HI \rightleftharpoons H_2 + I_2$ *i.e.*, reverse reaction, $K' = 1/K_c = 1/54.8$

$\therefore$ For the reaction : $\quad 2 \text{ HI} \rightleftharpoons H_2 + I_2$

n mol at equilibrium $\quad 0.5 \qquad x \qquad x$

Applying law of chemical equilibrium, we get :

$$K = \frac{[H_2][I_2]}{[HI]^2} \ ; \quad \frac{1}{54.8} = \frac{x \times x}{(0.5)^2} = \frac{x^2}{0.25}$$

$$\therefore \qquad 54.8\, x^2 = 0.25 \ ;$$

$$x = \sqrt{\frac{0.25}{54.8}} = \sqrt{0.00456}$$

$$= \mathbf{0.068 \text{ mol L}^{-}} \qquad \textbf{Ans.}$$

EXAMPLE 145. *In the reaction,*

$$H_2 + I_2 \rightleftharpoons 2HI$$

the equilibrium concentration of H_2, I_2 *and HI at 400°C are 0.2 mol, 0.2 mol and 1.6 mol* L^{-} *respectively. Calculate*

(*a*) K_c *and* K_p *for the reaction*

(*b*) *The equilibrium concentrations if 1 mol of* H_2, *2 mol of* I_2 *and 3 mol of HI are heated in a 10 litre flask and 400°C and*

(*c*) *Equilibrium concentrations if one mol of HI is added.*

SOLUTION. (*a*) $\qquad H_2 \quad + \quad I_2 \quad \rightleftharpoons \quad 2 \text{ HI}$

n mol at equilibrium $\quad 0.2 \qquad 0.2 \qquad 1.6$

Applying law of chemical equilibrium, we get :

$$K_c = \frac{[HI]^2}{[H_2][I_2]} = \frac{(1.6)^2}{0.2 \times 0.2} = 64$$

Since , $\quad \Delta n = 0, \quad K_c = K_p = 64.$

(*b*) Reaction $\qquad H_2 \quad + \quad I_2 \quad \rightleftharpoons \quad 2 \text{ HI}$

(*i*) *n* mol at start $\qquad 1 \qquad 2 \qquad 3$

(*ii*) Change by reaction $\qquad -x \qquad -x \qquad 2x$

(*iii*) *n* mol at equilibrium $\qquad \frac{1-x}{10} \qquad \frac{2-x}{10} \qquad \frac{2x+3}{10}$

Applying law of chemical equilibrium, we get :

$$K_c = \frac{[HI]^2}{[H_2][I_2]} = \frac{\left(\frac{2x+3}{10}\right)^2}{\left(\frac{1-x}{10}\right)\left(\frac{2-x}{10}\right)}$$

$$= \frac{(2x+3)^2}{(1-x)(2-x)}$$

$$64 = \frac{4x^2 + 9 + 12x}{2 - 3x + x^2} \ ;$$

$$128 - 192x + 64x^2 = 4x^2 + 9 + 12x$$

Or $\quad 64x^2 - 4x^2 - 192x - 12x + 128 - 9 = 0 \quad ;$

$$60x^2 - 204x + 119 = 0$$

$$\therefore \qquad x = \frac{-(-204) \pm \sqrt{(-204)^2 - 4(60 \times 119)}}{2 \times 60}$$

$$\left[\because \text{ for } ax^2 + bx + c = 0, \quad x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}\right]$$

$$= \frac{204 \pm \sqrt{41616 - 28560}}{120}$$

$$= \frac{204 \pm \sqrt{13056}}{120} = \frac{204 \pm 114}{120}$$

$$= \frac{318}{120} \text{ or } \frac{90}{120} = 2.65 \text{ or } 0.75$$

Since the value cannot be 2.65, we have, $x = 0.75$

$$\therefore \qquad [H_2] = \frac{1-x}{10} = \frac{1-0.75}{10} = \frac{0.25}{10}$$

$$= 0.025 \text{ mol L}^{-}$$

$$I_2 = = \frac{2-x}{10} = \frac{2-0-75}{10} = \frac{1.25}{10} = 0.125 \text{ mol L}^{-}$$

$$[\text{HI}] = \frac{2x+3}{10} = \frac{(2\times 0.75)+3}{10}$$

$$= \frac{1.5+3}{10} = \frac{4.5}{10} = 0.45 \text{ mol L}^{-}$$

	H_2	+	I_2	$\rightleftharpoons$	2HI
(*c*) Reaction	H_2	+	I_2	$\rightleftharpoons$	2HI
(*i*) *n* mol at start	0.2		0.2		1.6
(*ii*) Change by reaction	$-x$		$-x$		$2x$
(*iii*) *n* mol at equilibrium	$0.2-x$		$0.2-x$		$2x+1+1.6$ $= 2x+2.6$

Applying law of chemical equilibrium, we get :

$$K_c = \frac{[\text{HI}]^2}{[H_2][I_2]} ;$$

$$64 = \frac{(2x+2.6)^2}{(0.2-x)(0.2-x)} = \frac{(2x+2.6)^2}{(0.2-x)^2}$$

Taking square root of both sides, we get :

$$8 = \frac{2x+2.6}{0.2-x} ; \; 1.6 - 8x = 2x + 2.6 ;$$

$$2x + 8x + 2.6 - 1.6 = 0$$

Or $\quad 10x = -1 \;;\; x = \frac{-1}{10} = -0.1$

$\therefore \quad [H_2] = [I_2] = 0.2 - x = 0.2 - (-0.1)$

$= \mathbf{0.3 \text{ mol L}^{-}}$

$[\text{HI}] = 2x + 2.6 = 2(-0.1) + 2.6 = -0.2 + 2.6$

$= \mathbf{2.4 \text{ mol L}^{-}}$

EXAMPLE 146. *At 700 K, hydrogen and bromine react to form hydrogen bromide. The value of equilibrium constant for this reaction is 5 × 10^8. Calculate the amount of H_2, Br_2 and HBr at equilibrium if a mixture of 0.6 mol of H_2 and 0.2 mol of Br_2 is heated to 700 K.* **(Roorkee, 1995)**

SOLUTION. Reaction

	H_2	+	Br_2	$\rightleftharpoons$	2HBr
(*i*) *n* mol at start	0.6		0.2		0
(*ii*) Change by reaction	$-x$		$-x$		$2x$
(*iii*) *n* mol at equilibrium	$0.6-x$		$0.2-x$		$2x$

Applying law of chemical equilibrium, we have :

$$K_c = \frac{[\text{HBr}]^2}{[H_2][Br_2]} = \frac{2x \times 2x}{(0.6-x)(0.2-x)}$$

$$= \frac{4x^2}{0.12 - 0.8x + x^2}$$

$$\therefore \quad 5\times 10^8 = \frac{4x^2}{x^2 - 0.8x + 0.12} ; \; 5 \times 10^8 x^2 - 5 \times 10^8 \times 0.8x + 5\times 10^8 \times 0.12 = 4x^2 ;$$

$$5 \times 10^8 x^2 - 4x^2 - 4 \times 10^8 x + 0.6 \times 10^8 = 0;$$

$$10^8 (5x^2 - 4 \times 10^{-8} x^2 - 4x + 0.6) = 0$$

Or $5x^2 - 4x + 0.6 = 0;$

[$4 \times 10^{-8} x^2$ being very small, is neglected]

$$x = \frac{-(-4) \pm \sqrt{(-4)^2 - 4(5\times 0.6)}}{2\times 5}$$

$$\left[\because \text{ for } ax^2 + bx + c = 0, \; x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}\right.$$

Or $$x = \frac{4 \pm \sqrt{16-12}}{10} = \frac{4\pm 2}{10} = 0.6 \text{ or } 0.2.$$

But according to given data, *x* cannot be equal to 0.6.

So, $\quad x = 0.2 \;\; \therefore [H_2] = 0.6 - x = 0.6 - 0.2$

$= \mathbf{0.4 \text{ mol}}$ **Ans.**

$[Br_2] = 0.2 - x = 0.2 - 0.2 \quad = \mathbf{0.0 \text{ mol}}$ **Ans.**

$[\text{HBr}] = 2x = 2 \times 0.2 = \mathbf{0.4 \text{ mol}}$ **Ans.**

Type. Calculation of K_c for homogeneous gaseous **dissociation** reversible reaction involving **"no change in volume or having same number of mol in reactants and products."** In order to understand it, let us consider the **dissociation of HI.**

	2HI	$\rightleftharpoons$	H_2	+	I_2
(*i*) *n* mol at start	1		0		0
(*ii*) Change by reaction	$-x$		$+\frac{x}{2}$		$+\frac{x}{2}$
(*iii*) *n* mol at equilibrium	$\frac{1-x}{V}$		$\frac{x/2}{V} = \frac{x}{2V}$		$\frac{x}{2V}$

Let us start with 1 mol of HI enclosed in a vessel of volume of '*V*' litre.

V = volume of the closed vessel in which reaction takes place.

x = number of mol of HI that decompose at equilibrium to yield *x*/2 mol of H_2 and *x*/2 mol of I_2.

Applying law of mass action, we get,

$$[\text{HI}] = \frac{1-x}{V} ; [H_2] = \frac{x}{2V} ; [I_2] = \frac{x}{2V}$$

$$\therefore \quad K_c = \frac{[H_2][I_2]}{[\text{HI}]^2} = \frac{\left(\frac{x}{2V}\right)\left(\frac{x}{2V}\right)}{\left(\frac{1-x}{V}\right)^2}$$

Or $$K_c = \frac{x^2}{4V^2} \times \frac{V^2}{(1-x)^2} = \frac{x^2}{4(1-x)^2}$$

EXAMPLE 147. *In an equilibrium, 2HI $\rightleftharpoons$ $H_2 + I_2$, 819.2 g of HI, 3.9 g H_2 and 101.6 g I_2 were present in a 4 litre flask. Find the value of K_c. If all the reactants and products are transferred to a 2.5 L flask, calculate the amount of reactants and products at equilibrium. (at. wt. H = 1, I = 127).*

SOLUTION. Reaction. $\quad 2\text{HI} \rightleftharpoons H_2 + I_2$

no. of mol at equilibrium = wt/mol. wt.

2HI	H_2	I_2
$\frac{819.2}{128}$	$\frac{3.9}{2}$	$\frac{101.6}{254}$
$= 6.4$	$= 1.95$	$= 0.4$

If volume of container is *V* litre, then :

$$[\text{HI}] = \frac{6.4}{V} ; [H_2] = \frac{1.95}{V} ; [I_2] = \frac{0.4}{V}$$

$$\therefore \quad K_c = \frac{[H_2][I_2]}{[\text{HI}]^2} = \frac{\frac{1.95}{V} \times \frac{0.4}{V}}{\left(\frac{6.4}{V}\right)^2} = \mathbf{0.019} \;\; \textbf{Ans.}$$

In the given reaction, $\Delta n = 2 - (1 + 1) = 0$. So, if the matter is transferred to attain equilibrium in 2.5 L flask, there will be no effect on equilibrium concentration of reactants and products.

Type. Calculations of **equilibrium constant** (K_c and K_p) for **gaseous reactions** involving "**Change in volume**". To understand it, consider the **dissociation** of AB(g) into A(g) and B(g).

$$AB\,(g) \rightleftharpoons A\,(g) + B\,(g)$$

***(I)* Calculation of K_C.**

Let, 1 = Initial molar concentration of AB, x = Degree of dissociation of AB

V = Total volume of vessel (in litre) in which reaction takes place.

Thus, at equilibrium, we have :

	AB	⇌	A	+	B
Initial conc.	1		0		0
Conc. at equilibrium	$1 - x$		x		x

$$[AB] = \frac{1-x}{V}\text{ mol L}^{-}\,;$$

$$[A] = \frac{x}{V}\text{ mol L}^{-}\,;\,[B] = \frac{x}{V}\text{ mol L}^{-}$$

Applying law of chemical equilibrium, we have :

$$K_c = \frac{[A]\,[B]}{[AB]} = \frac{\left(\frac{x}{V}\text{ mol L}^{-}\right)\times\left(\frac{x}{V}\text{ mol L}^{-}\right)}{\frac{1-x}{V}\text{ mol L}^{-}}$$

$$= \frac{x^2}{(1-x)\,V}\text{ mol L}^{-}$$

Thus K_c value involves also the volume of the vessel in which reaction takes place.

***(II)* Calculation of K_p; $K_p = K_c\,(RT)^{\Delta n}$**

Type. **Calculation** of K_p, pressure, degree of **dissociation for reactions** involving change in volume or **number of mol.** To understand it, consider the dissociation of AB (g) into A (g) and B (g).

I. Calculation of K_p AB (g) ⇌ A (g) + B (g)

Let
1 = Initial molar concentration of AB
x = Degree of dissociation of AB
P = Pressure of vessel (in bar or atm) in which reaction takes place.

Thus, at equilibrium, we have :

	AB (g)	⇌	A (g)	+	B (g)
Initial conc.	1		0		0
Conc. at equilibrium	$1 - x$		x		x

Total number of mol at equilibrium

$$= 1 - x + x + x = 1 + x$$

$$[AB] = \frac{1-x}{1+x}\times P\;;\;[A] = \frac{x}{1+x}\times P\;;$$

$$[B] = \frac{x}{1+x}\times P$$

Applying law of chemical equilibrium, we have :

$$K_p = \frac{[A]\,[B]}{[AB]} = \frac{\left(\frac{x}{1+x}\times P\right)\left(\frac{x}{1+x}\times P\right)}{\left(\frac{1-x}{1+x}\times P\right)}$$

$$= \frac{x^2\,P}{(1+x)\,(1-x)}$$

or $$K_p = \frac{x^2\,P}{1-x^2} \qquad \ldots (1)$$

II. Calculation of pressure (P'). From relation (1), we have :

$$K_p = \frac{x^2\,P'}{1-x^2} \quad or \quad P' = \frac{K_p\,(1-x^2)}{x^2}$$

III. Calculation of degree of dissociation, x. From relation (I), we have :

$$K_p = \frac{x^2\,P'}{1-x^2} \quad or \quad \frac{K_P}{P'} = \frac{x^2}{1-x^2}.$$

So, x can be calculated from this relation.

EXAMPLE 148. *Calculate the degree of dissociation of hydriodic acid if equilibrium constant for $H_2 + I_2 \rightleftharpoons 2HI$ reaction is 38.*

SOLUTION. Let 1 = Initial molar concentration of HI
x = degree of dissociation of HI

This reaction involves no change in volume. So, at equilibrium, we have :

	2HI	⇌	H_2	+	I_2
Initial conc.	1		0		0
Conc. at equilibrium	$1 - x$		$\frac{x}{2}$		$\frac{x}{2}$

$$\left[\begin{array}{llll} \because HI \rightleftharpoons & \frac{1}{2}H_2 & + & \frac{1}{2}I_2 \\ \therefore 1-x & \frac{x}{2} & & \frac{x}{2} \end{array}\right.$$

$$[HI] = 1 - x \;;\; [H_2] = x/2 \;;\; [I_2] = x/2$$

Applying law of chemical equilibrium, we have :

$$K_c = \frac{[H_2]\,[I_2]}{[HI]^2} = \frac{\frac{x}{2}\times\frac{x}{2}}{(1-x)^2} = \frac{x^2}{4\,(1-x)^2}$$

$$\frac{1}{38} = \frac{x^2}{4\,(1-x)^2}$$

Taking square root of both sides, we get :

$$\left(\frac{1}{38}\right)^{1/2} = \frac{x}{2\,(1-x)} \quad \textbf{or} \quad \frac{1}{6.16} = \frac{x}{2\,(1-x)}$$

$$6.16\,x = 2\,(1-x)$$

or $$\frac{6.16}{2}x = 1 - x\,;\,3.08\,x = 1 - x$$

$$\therefore \quad x + 3.08\,x = 1 \quad \text{or} \quad 4.08\,x = 1$$

Hence $$x = \frac{1}{4.08} = 0.245$$

∴ Degree of dissociation

$= 0.245 \times 100 =$ **24.5 %**

23.23 MISCELLANEOUS EXAMPLES

Type. Calculations of *equilibrium constant (K_c and K_p) for gaseous reactions* involving formation (or synthesis) of products with **"no change in volume"**. To understand it, consider the formation of AB (g) from A_2 (g) and B_2 (g).
$A_2 + B_2 \rightleftharpoons 2\,AB$

Let a = Initial molar concentration of A_2

b = Initial molar concentration of B_2

x = no. of mol of A_2 and B_2 that combine to form $2\,x$ mol of AB

V = Total volume of the vessel (in litre) in which reaction takes place.

∴ Thus, at equilibrium, we have :

$$\begin{array}{ccc} A_2 + B_2 & \rightleftharpoons & 2\,AB \\ a-x \quad b-x & & 2\,x \end{array} \qquad \text{...(1)}$$

$$[A_2] = \frac{a-x}{V}\,\text{mol L}^{-}\;;\;[B_2] = \frac{b-x}{V}\,\text{mol L}^{-}$$

$$[AB] = \frac{2\,x}{V}\,\text{mol L}^{-}$$

Applying law of chemical equilibrium to reaction (1), we have :

$$K_c = \frac{[AB]^2}{[A_2][B_2]} = \frac{\left(\frac{2x}{V}\,\text{mol L}^{-}\right)^2}{\frac{a-x}{V}\,\text{mol L}^{-} \times \frac{b-x}{V}\,\text{mol L}^{-}}$$

Or $$K_c = \frac{4\,x^2}{(a-x)(b-x)}$$

Thus K_c is independent of volume of vessel for reactions involving no change in volume.

Calculation of Kp.

$$K_p = K_c (RT)^{\Delta n} \qquad \text{...(2)}$$

Where , Δn = (no. of mol of gaseous products) – (no. of mol of gaseous reactants)

For reactions involving no change in volume, $\Delta n = 0$.

So, in reaction (2)

$$K_p = K_c \qquad [\because (RT)^{\circ} = 1]$$

Here R = gas constant = 0.081 L atm K^{-} mol^{-}

= 0.081 L bar K^{-} mol^{-} and T is absolute temperature in kelvin (K)

EXAMPLE 149. *The equilibrium constant of the reaction :*

$$A_2\,(g) + B_2\,(g) \rightleftharpoons 2AB(g)$$

at 100°C is 50. If one litre flask containing one mol of A_2 is connnected to a two litre flask containing 2 mol of B_2, how many mol of AB will be formed at 373 K. **(IIT, 1985)**

SOLUTION.

	$A_2\,(g)$ +	$B_2\,(g) \rightleftharpoons$	$2\,AB(g)$
(*i*) *n* mol at start	1	2	0
(*ii*) Change by reaction	$-x$	$-x$	$2\,x$
(*iii*) *n* mol at equilibrium	$1-x$	$2-x$	$2\,x$

Total number of mol at equilibrium

$= 1 - x + 2 - x + 2\,x = 3$

$$\therefore \quad K_c = \frac{[AB]^2}{[A_2][B_2]} = \frac{\left(\frac{2\,x}{3}\right)^2}{\left(\frac{1-x}{3}\right)\left(\frac{2-x}{3}\right)}$$

$$= \frac{4\,x^2}{(1-x)(2-x)}$$

Or $$50 = \frac{4\,x^2}{(1-x)(2-x)} = \frac{4\,x^2}{2-3\,x+x^2}\,;$$

$50\,(2 - 3\,x + x^2) = 4\,x^2\,;$

$100 - 150\,x + 50\,x^2 = 4\,x^2\;;$

$46\,x^2 - 150\,x + 100 = 0$

Or $23\,x^2 - 75\,x + 50 = 0$

$$\therefore \quad x = \frac{-(-75) \pm \sqrt{(-75)^2 - 4\,(23 \times 50)}}{2 \times 23}$$

$$\left[\because \text{ for } ax^2 + bx + c = 0,\; x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}\right]$$

$$x = \frac{+75 \pm 32}{46} = 2.32 \quad \text{or} \quad 0.934.$$

Since x cannot be 2.32, so, $x = 0.934$.

∴ Number of mol of AB formed

$= 2\,x = 2 \times 0.934 =$ **1.868 mol**

EXAMPLE 150. *The value of equilibrium constant for the reaction:*

$$N_2 + 2\,O_2 \rightleftharpoons 2\,NO_2$$

at a certain temperature is 50. Write down the expression for the equilibrium constant in each of the following reactions and also calculate the values of the constants in the two cases.

(*a*) $2\,NO_2 \rightleftharpoons N_2 + 2\,O_2$ (*b*) $NO_2 \rightleftharpoons \frac{1}{2}N_2 + O_2$

(UP, 1989, AIEEE, 2012)

SOLUTION. (*a*) $N_2 + 2\,O_2 \rightleftharpoons 2\,NO_2$ ... (1)

$$K_c = \frac{[NO_2]^2}{[N_2]\,[O_2]^2}\;;\;50 = \frac{[NO_2]^2}{[N_2]\,[O_2]^2} \quad \textbf{Ans.}$$

(*b*) $2\,NO_2 \rightleftharpoons N_2 + 2\,O_2$ ...(2)

This reaction is reverse of reaction (1).

So, $$K_c' = \frac{1}{K_c}$$

Or $$K_c' = \frac{[O_2]^2\,[N_2]}{[NO_2]^2} = \frac{1}{50} = \mathbf{0.02} \qquad \textbf{Ans.}$$

(*c*) $NO_2 \rightleftharpoons \frac{1}{2}N_2 + O_2$

The number of mol of this equation is 1/2 of that of equation (2). So :

$$K_c'' = \frac{[N_2]^{1/2}\,[O_2]}{[NO_2]}$$

or $\quad K_c'' = (K_c')^{1/2} = (0.02)^{1/2} = 0.1414$

∴ $\quad K_c'' = \mathbf{0.1414}$ **Ans.**

Type. To calculate k_p from the given value of ΔG°, use the relation :

$$\Delta G° = -2.303\ RT \log K_p$$

EXAMPLE 151. *Calculate the value of K_p for the reaction :*

$$N_2 + O_2 \rightleftharpoons 2NO$$

at 2000 K. The standard free energy change ΔG° for the reaction is given by

$$\Delta G° = 22{,}000 - 2.5\ T,\ (R = 1.98\ \text{cal})$$

SOLUTION. $\Delta G° = 22{,}000 - 2.5\ T$ (given)

∴ $\quad \Delta G° = 22{,}000 - (2.5 \times 2{,}000)$

$\quad = 22{,}000 - 5{,}000 = 17{,}000$

But $\quad \Delta G° = -2.303\ RT \log K_p$

$\quad 17{,}000 = -2.303 \times 1.98 \times 2{,}000 \log K_p$

∴ $\quad \log K_p = -\dfrac{17{,}000}{2.303 \times 1.98 \times 2{,}000} = -1.86$

∴ $\quad K_p = \text{antilog} - 1.86 = \text{antilog} -1 -1 +1 -0.86$

$\quad = \text{antilog}\ \bar{2}.14 = \mathbf{0.014}$ **Ans.**

EXAMPLE 152. *A sample of air consisting of N_2 and O_2 was heated at 2,500 K until the equilibrium*

$$N_2 + O_2 \rightleftharpoons 2NO$$

was established with an equilibrium constant, $K_c = 2.1 \times 10^{-3}$. At equilibrium, the mol % age of NO was 1.8. Estimate the initial concentration of air in mol fraction of N_2 and O_2. **(IIT, May 1997)**

SOLUTION.	N_2	+ O_2	$\rightleftharpoons$ 2NO
(*i*) *n* mol at start	a	$100 - a$	0
(*ii*) Change by reaction	$-x$	$-x$	$2x$
(*iii*) *n* mol at equilibrium	$a - x$	$100 - a - x$	$2x$

But $\quad \dfrac{2x}{100} = \dfrac{1.8}{100}$ or $2x = 1.8$; ∴ $x = \dfrac{1.8}{2} = 0.9$

Applying law of chemical equilibrium, we get :

$$K = \frac{[NO]^2}{[N_2][O_2]};$$

$$2.1 \times 10^{-3} = \frac{(2x)^2}{(a-x)(100-a-x)};$$

$$2.1 \times 10^{-3} = \frac{(2 \times 0.9)^2}{(a-0.9)(100-a-0.9)}$$

$$= \frac{3.24}{(a-0.9)(99.1-a)}$$

$$= \frac{3.24}{99.1\,a - a^2 - 89.19 + 0.9a}$$

$$0.0021\,(-a^2 - 100\,a - 89.19) = 3.24 \quad ;$$

$$-a^2 + 100\,a - 89.19 = \frac{3.24}{0.0021} = 1543$$

Or– $a^2 + 100\,a - 89.19 - 1543 = 0$; $a^2 - 100\,a + 1632.19 = 0$

∴ $$a = \frac{-(-100) \pm \sqrt{(-100)^2 - 4\,(1 \times 1632.19)}}{2 \times 1}$$

$$= \frac{-(-100) \pm \sqrt{10{,}000 - 6528.76}}{2}$$

$$\left[\because \text{ for } ax^2 + bx + c = 0,\quad x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}\right]$$

$$= \frac{-100 \pm \sqrt{3471.24}}{2}$$

$$a = \frac{+100 \pm 58.9}{2}$$

$$= \frac{158.9}{2} \text{ or } \frac{41.1}{2} = 79.4 \text{ or } 20.55$$

So, $\quad a = 79.4\ \%$ *i.e.,* % age of N_2 = 79.4 %

% age of O_2 = 100 – 79.4 = 20.6 %.

Since $\dfrac{1.8}{100}$ *i.e.,* 0.018 mol NO is formed at equilibrium, $\dfrac{0.018}{2}$ *i.e.,* 0.009 mol of each N_2 and O_2 have reacted.

Hence, initially,

$O_2 = \dfrac{20.6}{100}$ *i.e.,* 0.206 mol + 0.009 = 0.215 mol.

$N_2 = \dfrac{79.4}{100}$ *i.e.,* 0.794 mol + 0.009 = 0.803 mol.

EXAMPLE 153. *5 moles of SO_2 and 5 moles of O_2 are allowed to react. At equilibrium, it was found that 60 % SO_2 is used up. If the partial pressure of the equilibrium mixture is one atmosphere, the partial pressure of O_2 is :*

(*a*) *0.52 atm* (*b*) *0.21 atm*

(*c*) *0.41 atm* (*d*) *0.82 atm*

(Karnataka CET, 2009)

SOLUTION. Given :	$2SO_2(g)$	+ $O_2(g)$	$\rightleftharpoons$ $2SO_3(g)$
Initial no. of mol.	5	5	0
no of mol reacted	$5 \times \dfrac{60}{100} = 3$	$3 \times \dfrac{1}{2} = 1.5$*	3
no. of mol at equi.	5 – 3 = 2	5 – 1.5 = 3.5	3

$$*\left[\begin{array}{l} \because 2\ \text{mol}\ SO_2 = 1\ \text{mol}\ O_2 \\ 3\ \text{mol}\ SO_2 = \dfrac{3}{2}\text{mol}\ O_2 \\ \qquad = 1.5\ \text{mol} \end{array}\right]$$

Total no. of mol = 2 + 3.5 + 3 = 8.5

∴ $$p_{O_2} = \frac{\text{no. of mol of } O_2}{\text{Total mol}} \times P_{\text{total}},$$

$$p_{O_2} = \frac{3.5 \times 1}{8.5} = 0.41$$

So, the correct answer is (*c*).

EXAMPLE 154. *For the reaction*

$$N_2(g) + O_2(g) \rightleftharpoons 2NO(g)$$

at 1500°C, the equilibrium constant K_p is 120. If N_2 and O_2 gases at an initial pressure of 0.25 atm each are maintained at 1500°C till equilibrium is established, calculate the partial pressure of N_2, O_2 and NO in the equilibrium.

SOLUTION.

	$N_2(g)$	+ $O_2(g)$	$\rightleftharpoons 2NO(g)$
(*i*) *n* atm at start	0.25	0.25	0
(*ii*) Change by reaction	$-x$	$-x$	$2x$
(*iii*) *n* atm at equilibrium	$0.25-x$	$0.25-x$	$2x$

Applying law of chemical equilibrium, we get :

$$K_p = \frac{(p_{NO})^2}{p_{N_2} \times p_{O_2}} ;$$

$$120 = \frac{(2x)^2}{(0.25-x)(0.25-x)} = \frac{(2x)^2}{(0.25-x)^2}$$

Taking square root of both sides, we get :

$$\sqrt{120} = \frac{2x}{0.25-x} \quad ; \quad 10.95 = \frac{2x}{0.25-x} ;$$

$$2.74 - 10.95\,x = 2x$$

Or $2x + 10.95\,x = 2.74$; $12.95\,x = 2.74$

$$\therefore \quad x = \frac{2.74}{12.95} = 0.21 \text{ atm}$$

$$\therefore \quad p_{N_2} = p_{O_2} = 0.25 - x = 0.25 - 0.21 = \mathbf{0.04\ atm}$$

$$p_{NO} = 2x = 2 \times 0.21 \text{ atm} = \mathbf{0.42\ atm.}$$

EXAMPLE 155. *Bodenstein found that starting with 10.5 mol of HI initially, only 8.2 mol were left at 448°C when equilibrium was attained. Calculate the equilibrium constant for the dissociation of HI. Also calculate how much HI will be obtained when eight mol of H_2 and 27.5 mol of I_2 are heated together for a sufficiently long time at 448°C.*

SOLUTION.

	2 HI	$\rightleftharpoons H_2$	+ I_2
(*i*) *n* mol at start	10.5	0	0
(*ii*) Change by reaction	$-10.5\,x$	$\frac{10.5\,x}{2}$	$\frac{10.5\,x}{2}$
(*iii*) *n* mol at equilibrium	$10.5 - 10.5\,x$	$\frac{10.5\,x}{2}$	$\frac{10.5\,x}{2}$

But $10.5 - 10.5\,x = 8.2$

$$\therefore \quad 10.5\,x = 10.5 - 8.2 = 2.3; \quad x = 2.3/10.5 = 0.219.$$

$$[H_2] = \frac{10.5\,x}{2} = \frac{10.5 \times 0.219}{2} ;$$

$$[I_2] = [H_2] = \frac{10.5 \times 0.219}{2}$$

$$[HI] = 10.5 - 10.5\,x$$

$$= 10.5 - (10.5 \times 0.219) = 10.5\,(1 - 0.219)$$

$$= 10.5 \times 0.781$$

Applying law of chemical equilibrium, we get :

$$K_c = \frac{[H_2][I_2]}{[HI]^2}$$

$$= \frac{\frac{10.5 \times 0.219}{2} \times \frac{10.5 \times 0.219}{2}}{(10.5 \times 0.781)^2} = \mathbf{0.0196}$$

Second Case.

	H_2	+ I_2	$\rightleftharpoons$ 2HI
(*i*) *n* mol at start	8	27.5	0
(*ii*) Change by reaction	$-x$	$-x$	$2x$
(*iii*) *n* mol at equilibrium	$8-x$	$27.5-x$	$2x$

Applying law of chemical equilibrium, we get :

$$K_c' = \frac{1}{K_c} = \frac{[HI]^2}{[H_2][I_2]} ;$$

$$\frac{1}{0.00196} = \frac{(2x)^2}{(8-x)(27.5-x)} = \frac{4x^2}{(8-x)(27.5-x)}$$

Or $0.0196 \times 4x^2 = 220.0 - 8x - 27.5\,x + x^2$

$$0.0784\,x^2 = x^2 - 35.5\,x + 220 \quad ;$$

$$x^2 - 0.0784\,x^2 - 35.5\,x + 220 = 0$$

Or $0.9216\,x^2 - 35.5\,x + 220 = 0$;

$$x = \frac{-(-35.5) \pm \sqrt{(-35.5)^2 - 4\,(0.9216 \times 220)}}{2 \times 0.9216}$$

Or

$$x = \frac{+35.5 \pm \sqrt{1260.25 - 811}}{1.8432}$$

$$= \frac{35.5 \pm \sqrt{449.5}}{1.8432} = \frac{35.5 \pm 21.2}{1.8432}$$

$$\left[\because \text{For } ax^2 + bx + c = 0, x = \frac{-b \pm (b^2 - 4ac)^{1/2}}{2a}\right]$$

$$= \frac{56.7}{1.8432}$$

or $\frac{14.3}{1.8432} = 30.76$ or 7.76

Out of these only 7.76 is possible.

So, $x = 7.76.$

$\therefore$ $[HI] = 2x = 2 \times 7.76 = \mathbf{15.52\ mol}$ **Ans.**

EXAMPLE 156. *Hydriodic acid undergoes 25 % dissociation at equilibrium. Compare its K_c value with its K_p value for the reaction, $HI \rightleftharpoons \frac{1}{2}H_2 + \frac{1}{2}I_2$.*

SOLUTION.

	HI	$\rightleftharpoons \frac{1}{2}H_2$	+ $\frac{1}{2}I_2$
(*i*) n mol at start	1	0	0
(*ii*) Change by reaction	$\frac{-25}{100}$ $= -0.25$	$\frac{+25}{200}$ $= +0.125$	$\frac{+25}{200}$ $= +0.125$
(*iii*) *n* mol at equilibrium	$1 - 0.25$ $= 0.75$	0.125	0.125

Applying law of chemical equilibrium, we get :

$$K_c = \frac{[H_2]^{1/2}[I_2]^{1/2}}{[HI]} = \frac{(0.125)^{1/2}\times(0.125)^{1/2}}{0.75}$$

$$= \frac{0.125}{0.75} = 0.167$$

∴ $K_c = 0.167$

For the given reaction,

$$\Delta n = \left(\frac{1}{2}+\frac{1}{2}\right) - 1 = 0 \quad i.e., \quad \text{zero.}$$

But $K_p = K_c\,(RT)^{\Delta n} = 0.167\,(RT)^{\circ} = 0.167$

∴ $\mathbf{K_p = K_c}$.

Type. Calculation of dissociation of HI involving titration of I_2 from HI at equilibrium with sodium thiosulphate

The degree of dissociation

$$= \frac{\text{mol of HI dissociated}}{\text{mol of HI taken}}$$

EXAMPLE 157. *A known quantity (0.96 g) of HI was heated to get following equilibrium.*

$$2HI \rightleftharpoons H_2 + I_2$$

The reaction mixture on titration consumed 15.7 mL of 0.1 N sodium thiosulphate solution. Calculate the degree of dissociation of HI. **(Agra, 1961)**

SOLUTION. Wt. of HI = 0.96 g ;

g. mol. wt. of HI = 1 + 127 = 128 g

∴ no. of mol of HI = 0.96/128 = 7.5×10^{-3} mol.

Reaction	$2HI \rightleftharpoons$	H_2 +	I_2
(i) *n* mol at start	7.5×10^{-3}	0	0
(*ii*) Change by reaction	$-x$	$x/2$	$x/2$
(*iii*) *n* mol at equilibrium	$7.5 \times 10^{-3} - x$	$x/2$	$x/2$

1000 m L of 1N - $Na_2S_2O_3$ = g. eq. wt. of I_2 = 127 g

Or 1000 m L of 0.1 N $Na_2S_2O_3$ = 127 × 0.1 = 12.7 g I_2

∴ 15.7 mL of 0.1 N $Na_2S_2O_3$

$$= \frac{12.7}{1000} \times 15.7 \text{ g } I_2$$

But g. mol. wt. of I_2 = 2 × 127 = 254 g

$$\therefore \text{ no. of mol of } I_2 \text{ formed} = \frac{12.7 \times 15.7}{1000 \times 254} = 7.85 \times 10^{-4}$$

$$[H_2] = [I_2] = \frac{x}{2} = 7.85 \times 10^{-4} ;$$

$$x = 2 \times 7.85 \times 10^{-4}$$
$$= 15.70 \times 10^{-4} \text{ mol}$$

no. of mol of HI dissociated = x = 15.7×10^{-4} mol

$$\therefore \quad \text{HI dissociated} = \frac{15.7 \times 10^{-4}}{7.5 \times 10^{-3}} \times 100 = \mathbf{20.93\%}$$

EXAMPLE 158. *In an experiment, the amount of H_2, I_2 and HI in the equilibrium state of the reaction, $2HI \rightleftharpoons H_2 + I_2$ were found to be 7.8 g, 203.2g and 1638.4 g respectively. Calculate the equilibrium constant (H = 1, I = 127)* **(UP, 1982)**

SOLUTION. Wt. of H_2 = 7.8 g ;

g. mol. wt of H_2 = 2 × 1 = 2 g

∴ no. of mol of H_2 = wt. of H_2/g. mol. wt. of H_2

$$= \frac{7.8 \text{ g}}{2 \text{ g}} = 3.9 ;$$

Wt. of I_2 = 203.2 g ;

g. mol. wt. of I_2 = 2 × 127 = 254 g

$$\therefore \quad \text{no. of mol of } I_2 = \frac{203.2 \text{ g}}{254 \text{ g}} = 0.8 ;$$

Wt. of HI = 1638. 4 g ;

g. mol. wt. of HI = 1 + 127 = 128 g

$$\therefore \quad \text{no. of mol of HI} = \frac{1638.4 \text{ g}}{128 \text{ g}} = 12.8$$

Applying law of chemical equilibrium, to the following reaction

$$2\,HI \rightleftharpoons H_2 + I_2$$

$$K = \frac{[H_2][I_2]}{[HI]^2} = \frac{3.9 \times 0.8}{(12.8)^2} ;$$

K = **0.019** **Ans.**

EXAMPLE 159. *One mol of HI, when heated at 723 K until equilibrium was attained in a volume of one litre, the resultant iodine required 49.6 mL of 5 M $Na_2S_2O_3$ for the reaction. Calculate K_c for $2HI \rightleftharpoons H_2 + I_2$ reaction.*

SOLUTION.	$2HI \rightleftharpoons$	H_2 +	I_2
(*i*) *n* mol at start	1	0	0
(*ii*) Change by reaction	$-x$	$\frac{x}{2}$	$\frac{x}{2}$
(*iii*) *n* mol at equilibrium	$1-x$	$\frac{x}{2}$	$\frac{x}{2}$

Applying law of chemical equilibrium, we get :

$$K_c = \frac{[H_2][I_2]}{[HI]^2} = \frac{\frac{x}{2}\times\frac{x}{2}}{(1-x)^2} = \frac{x^2}{4(1-x)^2} \quad ...(1)$$

Reaction : $2Na_2S_2O_3 + I_2 \longrightarrow Na_2S_4O_6 + 2\,NaI$
(2 mol) (1mol)

Using above reaction, we have :

$$\frac{(M_1 V_1) \text{ of } I_2}{(M_2 V_2) \text{ of } Na_2S_2O_3} = \frac{1}{2}$$

∴ 49.6 m L of 5 M

$$Na_2S_2O_3 = \frac{1}{2} \times 49.6 \text{ m L of 5 M } I_2$$
$$= 24.8 \text{ mL of 5 M } I_2$$

But 1000 mL of 1 M I_2 = 1 mol of I_2

$$\therefore \quad 24.8 \text{ m L of 5M } I_2 = \frac{1}{1000} \times 24.8 \times 5$$

$$= 0.124 \text{ mol } I_2$$

Or $\frac{x}{2}$ = 0.124 ; x = 2 × 0.124 = 0.248

Substituting the value of x in equation (1), we get :

$$K_c = \frac{(0.248)^2}{4\,(1-0.248)^2} = \frac{(0.248)^2}{4\,(0.752)^2}$$

$$= \frac{0.062}{2.262} = 0.027$$

∴ K_c = **0.027** **Ans.**

EXAMPLE 160. *HI (20 g) was heated to 600 K in a one litre capacity vessel. Calculate the volume percentage of H_2, I_2 and HI at equilibrium. The value of equilibrium constant of the reaction*

$$2\,HI \rightleftharpoons H_2 + I_2$$

is 0.056 at the same temperature when the concentrations are expresssed in mol L^{-}.

SOLUTION. wt. of HI = 20 g ;

g. mol. wt. of HI = 1 + 127 = 128 g

∴ no. of mol of HI = $\frac{20}{128} = 0.156$

	$2HI$	$\rightleftharpoons H_2$	$+\ I_2$
(*i*) *n* mol at start	0.156	0	0
(*ii*) Change by reaction	$-x$	$\frac{x}{2}$	$\frac{x}{2}$
(*iii*) *n* mol at equilibrium	$0.156 - x$	$\frac{x}{2}$	$\frac{x}{2}$

Applying law of chemical equilibrium, we get :

$$K_c = \frac{[H_2][I_2]}{[HI]^2} \;;$$

$$0.056 = \frac{\frac{x}{2} \times \frac{x}{2}}{(0.156 - x)^2} = \frac{x^2}{4\,(0.156 - x)^2}$$

Taking square root of both sides, we get :

$$\sqrt{0.056} = \frac{x}{2\,(0.156 - x)} \,;$$

$$0.237 = \frac{x}{0.312 - 2x} \,;\ 0.237\,(0.312 - 2\,x) = x$$

Or $0.074 - 0.474\,x = x \quad ; \quad x + 0.474\,x = 0.074$

Or $1.474\,x = 0.074$;

∴ $x = \frac{0.074}{1.474} = 0.05$

∴ HI dissociated = x = **0.05 mol**;

$[H_2] = [I_2] = \frac{x}{2} = \frac{0.05}{2} = \mathbf{0.025\ mol}$

Amount of HI left behind

$= 0.156 - x = 0.156 - 0.05 = 0.106$ mol.

According to Avogadro's law, equal volume of all gases contain equal number of mol under similar conditions of temperature and pressure. So, ratio by mol will be the ratio by volume.

∴ % age of H_2 and I_2 both by volume

$$= \frac{0.025}{0.156} \times 100 = 16\ \%$$

% age of HI by volume

$$= \frac{0.106}{0.156} \times 100 = 67.9\ \%$$

EXAMPLE 161. *For the reaction : $2\,HI\,(g) \rightleftharpoons H_2\,(g) + I_2\,(g)$ the value of equilibrium constant at 764 K and 667 K are 2.18×10^{-2} and 1.64×10^{-2} respectively. Calculate the value of ΔH° for the given reaction.*

SOLUTION. $T_1 = 667$ K, $K_1 = 1.64 \times 10^{-2}$; $T_2 = 764$ K, $K_2 = 2.18 \times 10^{-2}$, ΔH° = ?, R = 2 cal. We know that :

$$\log K_2 - \log K_1 = \frac{-\Delta H^\circ}{2.303\,R}\left[\frac{1}{T_2} - \frac{1}{T_1}\right]$$

$$\log 2.18 \times 10^{-2} - \log 1.64 \times 10^{-2}$$

$$= \frac{-\Delta H^\circ}{2.303 \times 2}\left(\frac{1}{764} - \frac{1}{667}\right)$$

$$= \frac{-\Delta H^\circ}{4.606}\left(\frac{667 - 764}{764 \times 667}\right)$$

$$\log 2.18 + \log 10^{-2} - (\log 1.64 + \log 10^{-2})$$

$$= \frac{-\Delta H^\circ}{4.606}\left(\frac{-97}{764 \times 667}\right)$$

$$0.3384 - 2 - 0.2148 + 2$$

$$= \frac{-\Delta H^\circ}{4.606}\left(\frac{-97}{764 \times 667}\right) = 4.13 \times 10^{-5}\ \Delta H^\circ$$

Or $0.1236 = 4.13 \times 10^{-5}\,\Delta H^\circ$;

∴ $\Delta H^\circ = \frac{0.1236}{4.13 \times 10^{-5}}$ = **2998 cal** **Ans.**

EXAMPLE 162. *At 1024 K, the value of equilibrium constant for the reaction $H_2\,(g) + Br_2\,(g) \rightleftharpoons 2HBr\,(g)$ is 1.6×10^5. Calculate the equilibrium pressure of all gases at 10.0 bar if HBr is introduced into a sealed container at the same temperature.*

SOLUTION. For the reaction, $H_2\,(g) + Br_2\,(g) \rightleftharpoons 2HBr$; $K_p = 1.6 \times 10^5$

∴ For the reaction, $2HBr \rightleftharpoons H_2\,(g) + Br_2\,(g)$;

2 Vol 1Vol 1 Vol

$$K_p' = \frac{1}{1.6 \times 10^5}$$

Let p = Equilibrium pressure.

Since the reaction does not involve change in volume, so total number of mol are not required.

	2HBr (g)	$\rightleftharpoons H_2$ (g) +	Br_2 (g)
Initial conc.	10 bar	0	0
Conc. at equilibrium	$10 - p$	$\frac{p}{2}$	$\frac{p}{2}$

p_{HBr} or $[HBr] = 10 - p$; p_{H_2} or $[H_2] = p/2$; p_{Br_2} or $[Br_2] = p/2$

Applying law of chemical equilibrium, we have :

$$K_p = \frac{[H_2]\,[Br_2]}{[HBr]^2} = \frac{\frac{p}{2} \times \frac{p}{2}}{(10 - p)^2}$$

or $$\frac{1}{1.6 \times 10^5} = \frac{p^2}{4\,(10 - p)^2}$$

Taking square root of both sides, we get :

$$\frac{1}{4\times 10^2} = \frac{p}{2(10-p)} \quad ; \quad \frac{1}{2\times 10^2} = \frac{1}{10-p};$$

$$200\,p = 10 - p \;;\; 200\,p + p = 10$$

or $$201\,p = 10 \quad ; \quad p = \frac{10}{201} = 0.0498$$

$$\therefore \quad P_{\text{HBr}} = 10 - p = 10 - 0.0498 = \mathbf{9.95\ bar}$$

$$p_{\text{H}_2} = \frac{p}{2} = \frac{0.0498}{2} = \mathbf{0.0249\ bar}\;;$$

$$p_{\text{Br}_2} = \frac{p}{2} = \frac{0.0498}{2} = \mathbf{0.0249\ bar}$$

Type. Calculation of K_c and K_p for homogeneous gaseous dissociation reversible reaction involving **"Change in volume or having different number of mol of reactants and products".**

In order to understand it, let us consider :

1. Dissociation of PCl_5

(*a*) **Determination of K_c.**

	PCl_5 ⇌	PCl_3 +	Cl_2
Original conc.	1 mol	0	0
Conc. at equilibrium	$\frac{1-x}{V}$ mol	$\frac{x}{V}$ mol	$\frac{x}{V}$ mol

Let us start with 1 mol of PCl_5 enclosed in a vessel of volume of '*V*' litre.

V = Volume of the closed vessel in which reaction takes place.

x = Number of mol of PCl_5 that decompose at equilibrium to yield *x* mol of PCl_3 and *x* mol of Cl_2.

Molar concentrations at equilibrium are :

$$[PCl_5] = \frac{1-x}{V} \quad ; \quad [PCl_3] = \frac{x}{V} \quad ; \quad [Cl_2] = \frac{x}{V}$$

Applying law of mass action, we get :

$$K_c = \frac{[PCl_3][Cl_2]}{[PCl_5]} = \frac{\left(\frac{x}{V}\right)\left(\frac{x}{V}\right)}{\left(\frac{1-x}{V}\right)} = \frac{x^2}{V^2} \times \frac{V}{1-x}$$

$$K_c = \frac{x^2}{V(1-x)} \qquad \text{... (1)}$$

(*b*) **Determination of K_p.**

Total number of mol

$$= 1 - x + x + x = 1 + x$$

Let *P* = Total pressure of the system.

$$\therefore \quad p_{PCl_5} = \frac{(1-x)P}{1+x};\; p_{PCl_3} = \frac{xP}{1+x};\; p_{Cl_2} = \frac{xP}{1+x}$$

$$\therefore \quad K_p = \frac{(p_{PCl_3})(p_{Cl_2})}{p_{PCl_5}} = \frac{\frac{xP}{1+x}\times\frac{xP}{1+x}}{\frac{(1-x)P}{1+x}}$$

$$= \frac{x^2P^2}{(1+x)(1+x)} \times \frac{1+x}{P(1-x)}$$

$$K_p = \frac{x^2P}{1-x^2} \qquad \text{...(2)}$$

(*c*) From equation (2),

$$K_p(1-x^2) = x^2P\;;\; K_p - K_px^2 = x^2P\;;$$

$$x^2P\,z + K_px^2 = K_p\;;\; x^2(P + K_p) = K_p;$$

or $$x^2 = K_p/(P + K_p)$$

$$\therefore \quad x = \sqrt{\frac{K_p}{P+K_p}} \quad \text{or} \quad \left[\frac{K_p}{(P+K_p)}\right]^{1/2}$$

$$x = \left(\frac{K_p}{P+K_p}\right)^{1/2}$$

EXAMPLE 163. *For $PCl_5 \rightleftharpoons PCl_3 + Cl_2$,*

prove that $x = \left(\frac{K_p}{P+K_p}\right)^{1/2}$

Where x is the degree of dissociation at a temperature when equilibrium constant is K_p.

SOLUTION. See derivation in the above given type.

EXAMPLE 164. *At 1 bar pressure and at a certain temperature, the degree of dissociation of PCl_5 is 0.2. Calculate the pressure at which it will be half dissociated at the same temperature.*

SOLUTION. Dissociation of PCl_5 is :

$$\underset{1\ \text{Vol}}{PCl_5} \rightleftharpoons \underset{1\ \text{Vol}}{PCl_3} + \underset{1\ \text{Vol}}{Cl_2}$$

Since the reaction involves change in volume, and pressure is given, so we have to know total number of mol at equilibrium.

Let 1 = Initial molar concentration of PCl_5

P = 1 bar ; *x* = 0.2

Thus, at equilibrium, we have :

	PCl_5 ⇌	PCl_3 +	Cl_2
Initial conc.	1	0	0
Conc. at equilibrium	$1-x$	x	x

Total number of mol at equilibrium

$$= 1 - x + x + x = 1 + x$$

$$[PCl_5] = \frac{1-x}{1+x}\times P\;;\; [PCl_3] = \frac{x}{1+x}\times P\;;$$

$$[Cl_2] = \frac{x}{1+x}\times P$$

Applying law of chemical equilibrium, we have :

$$K_p = \frac{[PCl_3][Cl_2]}{[PCl_5]} = \frac{\left(\frac{x}{1+x}\times P\right)\left(\frac{x}{1+x}\times P\right)}{\frac{1-x}{1+x}\times P}$$

$$= \frac{x^2P}{1-x^2} \qquad \text{... (1)}$$

Substituting the values in equation (1), we get :

$$K_p = \frac{0.2\times0.2\times1}{1-(0.2)^2} = \frac{0.04}{1-0.04} = \frac{0.04}{0.96} = 0.041$$

Calculation of pressure, P′. Here, *x* = ½ or 0.5 *i.e.*, half dissociation from relation(1) we have :

$$K_p = \frac{x^2 P'}{1-x^2} \quad \text{or} \quad P' = \frac{K_p(1-x^2)}{x^2}$$

$$= \frac{0.041[1-(0.5)^2]}{0.5 \times 0.5}$$

$$\therefore \quad p' = \frac{0.041 \times (1-0.25)}{0.25} = \frac{0.041 \times 0.75}{0.25}$$

$$= \mathbf{0.123\ bar}$$ **Ans.**

EXAMPLE 165. *The reaction $PCl_5\,(g) \rightleftharpoons PCl_3\,(g) + Cl_2\,(g)$ on heating at 473 K and at 523 K gave density of the mixture 70.2 and 57.9 respectively at equilibrium. What will be the dissociation of PCl_5 at 473 K and 523 K respectively ?*

SOLUTION. V.D. = Mol. Wt/2. Initial vapour density (V.D.) of PCl_5 at 473 K and 523 K will be same and equal to half of the Mol. Wt. of PCl_5.

$$\therefore \quad \text{Initial V.D. of } PCl_5 = \frac{31 + (5 \times 35.5)}{2} = \mathbf{104.25}$$

	$PCl_5\,(g)$	$\rightleftharpoons$	$PCl_3\,(g)$	+	$Cl_2\,(g)$
Initial conc.	1		0		0
Conc. at equilibrium	$1-\alpha$		α		α

[∵ α = degree of dissociation]

Total moles at equilibrium

$$= 1 - \alpha + \alpha + \alpha = 1 + \alpha.$$

$$\therefore \frac{\text{Total moles at equilibrium}}{\text{Initial moles}} = \frac{\text{Initial V.D.}}{\text{V.D. at equilibrium}}$$

$$\frac{1+\alpha}{1} = \frac{104.25}{70.2}$$

or $\alpha = 1.485 - 1 = \mathbf{0.485}$

∴ Dissociation of PCl_5 at 473 K = **0.485** **Ans.**

Similarly at 523 K, $1 + \alpha = \frac{104.25}{57.9} = 1.8$

$$\alpha = 1.8 - 1 = 0.8$$

∴ Dissociation of PCl_5 at 523 K = 0.8 **Ans.**

EXAMPLE 166. *One mol of $PCl_3\,(g)$ and 2 mol of $Cl_2\,(g)$ were placed in a 3 litre vessel at a certain temperature. When equilibrium reached, only 0.7 mol of PCl_3 remained. Find the value of equilibrium constant for the reaction*

$$PCl_3 + Cl_2 \rightleftharpoons PCl_5$$

at the same temperature.

SOLUTION.	PCl_3	+	Cl_2	$\rightleftharpoons$	PCl_5
(*i*) *n* mol L^{-} at start	$\frac{1}{3} = 0.333$		$\frac{2}{3} = 0.667$		0
(*ii*) Change by reaction	-0.1		-0.1		$\frac{1.0-0.7}{3} = 0.1$
(*iii*) *n* mol L^{-} at equilibrium	$0.333-0.1$ $= 0.233$		$0.667-0.1$ $= 0.567$		0.1

[∵ Volume = 3L]

Applying law of chemical equilibrium, we get :

$$K_c = \frac{[PCl_5]}{[PCl_3][Cl_2]} = \frac{0.1}{0.233 \times 0.567}$$

$$= \mathbf{0.757}$$ **Ans.**

EXAMPLE 167. *Under what pressure must an equimolar mixture of phosphorus trichloride and chlorine be placed at 250°C in order to obtain 80 % conversion of PCl_3 into PCl_5. K_p for dissociation of $PCl_5 = 1.78$*

SOLUTION.	$PCl_3 + Cl_2$		$\rightleftharpoons$	PCl_5
Initial conc.	1	1		0
At. equilibrium	$1-x$	$1-x$		x

Total no. of mol at equilibrium $= 1-x+1-x+x = 2-x$

Applying law of mass action, we have

$$K_p = \frac{p_{PCl_5}}{p_{PCl_3} \times p_{Cl_2}}$$

$$\text{or} \quad 1.78 = \frac{\frac{x}{2-x}P}{\frac{1-x}{2-x}P \times \frac{1-x}{2-x}P} = \frac{x(2-x)}{(1-x)^2 P}$$

$$1.78 = \frac{0.8(2-0.8)}{(1-0.8)^2 P}$$

$$\left[\because x = 80\,\% = \frac{80}{100} = 0.8\right.$$

∴ $P = \mathbf{13.48\ atm.}$

EXAMPLE 168. *The equilibrium composition for the reaction is :*

$PCl_3 + Cl_2$		$\rightleftharpoons$	PCl_5
0.2	0.1		0.4 mol L^{-}

If 0.2 mol of Cl_2 is added at the same temperature, then the equilibrium concentration of PCl_5 will be :

(*a*) *0.46 or 0.08* (*b*) *0.23 or 0.04*

(*c*) *0.86 or 0.49* (*d*) *none of these*

SOLUTION. For	PCl_3	+	Cl_2	$\rightleftharpoons$	PCl_5
	0.2		0.1		0.4 mol L^{-}

$$K_c = \frac{[PCl_5]}{[PCl_3][Cl_2]} = \frac{0.4}{0.2 \times 0.1} = 20$$

when 0.2 mol of Cl_2 is added, then ; $[Cl_2] = 0.1 + 0.2 =$ 0.3 mol

Thus :	PCl_3	+	Cl_2	$\rightleftharpoons$	PCl_5
(*i*) *n* mol at start	0.2		0.3		0.4
(*ii*) Change by reaction	$-x$		$-x$		x
(*iii*) *n* mol at equilibrium	$0.2-x$		$0.3-x$		$0.4+x$

Applying law of chemical equilibrium, we get :

$$K_c = \frac{[PCl_5]}{[PCl_3][Cl_2]} = \frac{0.4+x}{(0.2-x)(0.3-x)}\ ;$$

$$20 = \frac{0.4+x}{0.06 - 0.5\,x + x^2}$$

Or $20x^2 - 10x + 1.2 = 0.4 + x$;

$20x^2 - 10x - x + 1.2 - 0.4 = 0$

Or $20x^2 - 11x + 0.8 = 0$;

$$\therefore \quad x = \frac{-(-11) \pm \sqrt{(-11)^2 - 4(20 \times 0.8)}}{2 \times 20}$$

$$\text{Or} \quad x = \frac{11 \pm \sqrt{121 - 64}}{40}$$

$$= \frac{11 \pm \sqrt{57}}{40} = \frac{11 \pm 7.5}{40}$$

$$= \frac{18.5}{40} \text{ or } \frac{3.5}{40} = 0.46 \text{ or } 0.09$$

∴ Concentration of PCl_5 at equilibrium

$= 0.4 + x = (0.4 + 0.46) =$ **0.86**

Or $(0.4 + 0.09) =$ **0.49** **Ans.**

So, the correct answer is (*c*).

Example 169. *Determine the concentration of NH_3 solution whose one litre can dissolve 0.1 mol AgCl. K_{sp} of AgCl and K_f of $[Ag(NH_3)_2]^+$ are 1.0×10^{-10} M^2 and 1.6×10^7 M^{2-} respectively.*

(Roorkee, 1999)

Solution. (*a*) NH_3 dissolves AgCl(s) as follows.

$$AgCl(s) + 2\,NH_3 \rightleftharpoons Ag(NH_3)_2]^+ + Cl^- \quad ...(1)$$

$$\therefore \quad K_{eq} = \frac{[Ag(NH_3)_2]^+\,[Cl^-]}{[NH_3]^2} \quad ...(2)$$

(*b*) $[Ag(NH_3)_2]^+$ is formed as follows.

$$Ag^+ + 2NH_3 \rightleftharpoons [Ag(NH_3)_2]^+$$

$$\therefore \quad K_f = \frac{[Ag(NH_3)_2]^+}{[Ag^+][NH_3]^2} \quad ...(3)$$

$K_f = 1.6 \times 10^7\ M^{-2}$;

$K_{sp} = 1.0 \times 10^{-10}\ M^2$

$\therefore \quad K_{eq} = K_f \times K_{sp} = 1.6 \times 10^7\ M^{2-} \times 1.0 \times 10^{-10} M^2$

$= 1.6 \times 10^{-3}$

$$AgCl(s) + 2\,NH_3 \rightleftharpoons [Ag(NH_3)_2]^+ + Cl^-$$

n mol at equilibrium 0.1 0.1

$$\therefore \quad K_{eq} = \frac{[Ag(NH_3)_2]^+\,[Cl^-]}{[NH_3]^2} \ ;$$

$$1.6 \times 10^{-3} = \frac{0.1 \times 0.1}{[NH_3]^2}$$

$$\text{Or} \quad [NH_3]^2 = \frac{0.1 \times 0.1}{1.6 \times 10^{-3}} = 6.25\ ;$$

$[NH_3] = (6.25)^{1/2} = 2.5$ M

Since 0.1×2 (= 0.2) mol of NH_3 is used to dissolve AgCl, so :

Necessary concentration of $NH_3 = 2.5 + 0.2$

= **2.7 M** **Ans.**

Example 170. *For the following reactions*

(*i*) $2NO(g) \rightleftharpoons N_2(g) + O_2(g)$ *and*

(*ii*) $NO(g) + 1/2\, Br_2(g) \rightleftharpoons NOBr(g)$

the value of K_c for reactions (i) and (ii) are 2.4×10^{30} and 1.4 respectively at 300 K. Calculate the value of K_c for the reaction

$$\frac{1}{2}N_2(g) + \frac{1}{2}O_2(g) + \frac{1}{2}Br_2(g) \rightleftharpoons NOBr(g).$$

Solution. (*i*) $2\,NO(g) \rightleftharpoons N_2(g) + O_2(g)$;

$K_c = 2.4 \times 10^{30}$

(*ii*) $NO(g) + \frac{1}{2}Br_2(g) \rightleftharpoons NOBr(g)$; $K_c' = 1.4$

(*iii*) $\frac{1}{2}N_2(g) + \frac{1}{2}O_2(g) + \frac{1}{2}Br_2(g) \rightleftharpoons NOBr(g)$; $K_c'' = ?$

In order to get equation (iii), we have

Equation (ii) $-\frac{1}{2}$ equation (*i*). So, we have :

$$NO(g) + \frac{1}{2}Br_2(g) \rightleftharpoons NOBr(g) - \frac{1}{2}N_2(g) - \frac{1}{2}O_2(g)\ ; \quad -\frac{1}{2}(2\,NO)$$

$$K''_C = K'_C \times \left(\frac{1}{K_c}\right)^{1/2}$$

$$\therefore \quad \frac{1}{2}N_2(g) + \frac{1}{2}O_2(g) + \frac{1}{2}Br_2(g) \rightleftharpoons NOBr(g)\ ;$$

$$K''_c = 1.4 \times \left(\frac{1}{2.4 \times 10^{30}}\right)^{1/2}$$

Or $K''_c = 1.4 \times 0.646 \times 10^{-15}$

= $\mathbf{0.904 \times 10^{-15}}$ **Ans.**

Example 171. *For a reaction $Br_2(g) + 2NO(g) \rightleftharpoons 2NOBr(g)$, the partial pressure of Br_2 is 41.3 torr while that of NO is 98.3 torr, at 27°C. Calculate the value of standard free energy change and equilibrium constant at the same temperature if the total pressure was 110.5 torr at equilibrium (R = 2.0 cal mol$^-$ K$^-$)*

Solution. T = 273 + 27 = 300 K ; R = 2.0 cal mol$^-$ K$^-$. Let α is the degree of dissociation. For one mol of the given reaction, we have :

$$\frac{1}{2}Br_2(g) + NO(g) \rightleftharpoons NOBr(g)$$

Co-efficients	$\frac{1}{2}$	1	1
Pressure (atm)	41.3	98.3	0

At equilibrium.

p_{Br_2} = Given pressure of Br_2 – (coeff. of Br_2 × α)

$$= 41.3 - \left(\frac{1}{2} \times \alpha\right) = 41.3 - \frac{\alpha}{2}$$

p_{NO} = Given pressure of NO – (coeff. of NO × α)

$$= 98.3 - (1 \times \alpha) = 98.3 - \alpha$$

$$p_{\text{NOBr}} = 0 + (\text{coeff. of NOBr} \times \alpha)$$

$$= 0 + (1 \times \alpha) = \alpha$$

Total pressure = 110.5 torr

$$\therefore 41.3 - \frac{\alpha}{2} + 98.3 - \alpha + \alpha = 110.5\ ;$$

$$\frac{\alpha}{2} = 41.3 + 98.3 - 110.5 = 29.2$$

$$\therefore \quad \alpha = 2 \times 29.2 = 58.4 \text{ torr} = \frac{58.4}{760.4}$$

$$= 7.68 \times 10^{-2} \text{atm.} (\because 760.4 \text{ torr} = 1 \text{ atm})$$

$$\therefore \quad p_{\text{Br}_2} = 41.3 - \frac{58.4}{2} = 12.1 \text{ torr} = \frac{12.1}{760.4} \text{ atm}$$

$$= 1.59 \times 10^{-2} \text{ atm}$$

$$p_{\text{NO}} = 98.4 - 58.4 = 40.0 \text{ torr} = \frac{40}{760.4} \text{ atm}$$

$$= 5.26 \times 10^{-2} \text{ atm}$$

$$p_{\text{NOBr}} = \alpha = 58.4 \text{ torr} = \frac{58.4}{760.4} \text{ atm}$$

$$= 5.26 \times 10^{-2} \text{ atm}$$

But
$$K_p = \frac{[\text{p}_{\text{NOBr}}]^2}{[\text{p}_{\text{Br}_2}]\,[\text{p}_{\text{NO}}]^2}$$

$$= \frac{(7.68 \times 10^{-2})^2}{(1.59 \times 10^{-2})\,(5.26 \times 10^{-2})^2}$$

$$= \frac{58.9824 \times 10^{-4} \text{ atm}}{43.99 \times 10^{-6} \text{ atm}^2}$$

$$= 134.1 \text{ atm}^{-}$$

$$\therefore \quad \Delta G^\circ = -2.303 \text{ RT} \log K_p$$

$$= -2.303 \times 2 \times 300 \times \log 134.1$$

$$= -2.303 \times 2 \times 300 \times 2.1274$$

$$= -2939.6 \text{ cal} = -2939.6 \times 4.184 \text{ J}$$

$$= 12299 \text{ J} = 12.299\text{k J}$$

[When R is used as 8.314 J mol^{-} K^{-}, ΔG° will be in joule and K_p will be in (atm)$^{\Delta n}$].

EXAMPLE 172. *When sulphur is treated with sulphide ions in an alkaline medium, polyvalent sulphide ions are formed. The equilibrium constants for the formation of* S_2^{2-} *and* S_3^{2-} *from S and* S^{2-} *are shown along with the following equilibria reactions.*

(*i*) $S(s) + S^{2-} \rightleftharpoons S_2^{2-}\ ;\ K_{c_1} = 1.7$

(*ii*) $2\,S(s) + S^{2-} \rightleftharpoons S_3^{2-}\ ;\ K_{c_2} = 5.1$

Calculate the equilibrium constant for the following reaction.

$$S(s) + S_2^{2-} \rightleftharpoons S_3^{2-}$$

SOLUTION. (*i*) $\text{S(s)} + \text{S}^{2-} \rightleftharpoons \text{S}_2^{2-}\ ;$

$$K_{C1} = \frac{[\text{S}_2^{2-}]}{[\text{S}^{2-}]}\ ;\ 1.7 = \frac{[\text{S}_2^{2-}]}{[\text{S}^{2-}]} \qquad ...(1)$$

(*ii*) $2\,\text{S(s)} + \text{S}^{2-} \rightleftharpoons \text{S}_3^{2-}\ ;$

$$K_{C_2} = \frac{[\text{S}_3^{2-}]}{[\text{S}^{2-}]}\ ;\ 5.1 = \frac{[\text{S}_3^{2-}]}{[\text{S}^{2-}]} \qquad ...(2)$$

Dividing equation (2) by (1), we get :

$$K_{C_3} = \frac{K_{C_2}}{K_{C_1}} = \frac{[\text{S}_3^{2-}]}{[\text{S}^{2-}]} \times \frac{[\text{S}^{2-}]}{[\text{S}_2^{2-}]} = \frac{5.1}{1.7} = 3$$

EXAMPLE 173. *When 500 mL of 1.09 M* Fe^{2+} *ion were mixed with exact 500 ml of 0.15 M* $AgNO_3$ *solution, following equilibrium was established.*

$$Fe^{2+} + Ag^{+} \rightleftharpoons Fe^{3+} + Ag$$

If 25 mL solution required 30 mL of 0.083 M $KMnO_4$ *at equilibrium for complete oxidation, calculate* K_c *at 298 K.*

SOLUTION. $\text{Fe}^{2+} + \text{Ag}^{+} \rightleftharpoons \text{Fe}^{3+} + \text{Ag(s)}$

	Fe^{2+}	Ag^{+}	Fe^{3+}	Ag(s)
(*i*) milli.equiv. at start	500×1.09 $= 545$	500×0.15 $= 75$	0	0
(*ii*) Change by reaction	$-x$	$-x$	x	x
(*iii*) milliequiv. at equilibrium	$545 - x$	$75 - x$	x	x

Total volume of solution at equilibrium

= 500 + 500 = 1000 mL

$$K_C = \frac{[\text{Fe}^{3+}]}{[\text{Fe}^{2+}]\,[\text{Ag}^{+}]} = \frac{\frac{x}{1000}}{\frac{545 - x}{1000} \times \frac{75 - x}{1000}}$$

$$= \frac{x}{1000} \times \frac{1000}{545 - x} \times \frac{1000}{75 - x}$$

$$= \frac{1000\,x}{(545 - x)\,(75 - x)}$$

In terms of milliequivalents, molarity should be changed into normality.

$\therefore$ Normality of KMnO_4 = Molarity × 5

$= 0.083 \times 5 = 0.415$ N

$\left[\begin{array}{l}\because \text{5 is valence factor} \\ (= \text{Mol. wt. of KMnO}_4/\text{Eq. wt. of KMnO}_4)\end{array}\right]$

Using normality equation, we have :

Fe^{2+} KMnO_4;

$$\text{N}_1 \times 25 = 0.415 \times 30$$

$$\therefore \quad \text{N}_1 = \frac{0.415 \times 30}{25} = 0.498$$

$\therefore$ Milliequivalents of Fe^{2+}

$= 0.498 \times 1000 = 498$

$\therefore$ At equilibrium, milliequivalents of Fe^{2+} left = 498

Or $498 = 545 - x\ ;\ x = 545 - 498 = 47$

$$\therefore \quad K_c = \frac{1000\,x}{(545 - x)\,(75 - x)} = \frac{1000 \times 47}{(545 - 47)\,(75 - 47)}$$

$$= \frac{47000}{497 \times 28}$$

$\therefore$ K_c = **3.38** **Ans.**

EXAMPLE 174. *120 mL solution was prepared by mixing 15 mL of 4.8 M La(NO$_3$)$_3$, 40 mL of 15 M HNO$_3$, 0.1 mol of La (OH)$_3$ and rest water. Calculate the concentration of each ion in the solution so prepared.*

SOLUTION. $$\begin{array}{lcccc} (i) & La(OH)_3 & \rightleftharpoons & La^{3+} & + \quad 3OH^- \\ n \text{ mol at start} & 0.1 & & 0.1 & 0.1 \times 3 = 0.3 \\ \text{no. of millimol } (= \text{mol} \times 1000) & & & & \\ & 0.1 \times 1000 & & 0.1 \times 1000 & 0.3 \times 1000 \\ & = 100 \text{ m mol} & & = 100 \text{ m mol} & = 300 \text{ m mol} \\ (ii) & La(NO_3)_3 & \rightleftharpoons & La^{3+} & + \quad 3NO_3^- \\ m \text{ mol at start} & 15 \times 4.8 & & 72 \text{ m mol} & 3 \times 72 \\ (= \text{Vol in mL} \times \text{molarity}) & & & & \\ & = 72 \text{ m mol} & & & = 216 \text{ m mol} \\ (iii)\ m \text{ mol at start} & HNO_3 & \rightleftharpoons & H^+ & + \quad NO_3^- \\ (= \text{Vol in mL} \times \text{molairty}) & & & & \\ & 40 \times 15 & & 600 \text{ m mol} & 600 \text{ m mol} \\ & = 600 \text{ m mol} & & & \end{array}$$

Total m mol of H$^+$ ions

$= 600$; OH$^-$ ions $= 300$

$\therefore$ 300 m mol of OH$^-$ react with 300 m mol of H$^+$ to form H$_2$O.

$\therefore$ m mol of H$^+$ ions unreacted

$= 600 - 300$ m mol

$$\therefore \quad \mathbf{M_{H^+}} = \frac{300}{120} = \mathbf{2.5\ m\ mol}\ ;$$

$$\mathbf{M_{La^{3+}}} = (100 + 72)/120 = \mathbf{1.43\ m\ mol.}$$

$$\mathbf{M_{NO_3^-}} = (216 + 600)/120 = \mathbf{6.8\ m\ mol.}$$

EXAMPLE 175. *Calculate the pressure at which CuSO$_4$. 5H$_2$O undergoes efflorescent at 298 K. At 298 K, vapour pressure of water is 23.8 mm Hg. How good CuSO$_4$. 3H$_2$O is a drying agent at the same temperature.At 298 K, the K_p for the reaction*

CuSO$_4$. 5H$_2$O(s) $\rightleftharpoons$ CuSO$_4$. 3H$_2$O(s) + 2H$_2$O(g) is 1.086 $\times$ 10^{-4} atm^2.

SOLUTION.

$$CuSO_4.\ 5H_2O(s) \rightleftharpoons CuSO_4.\ 3H_2O(s) + 2H_2O(g)$$

$\therefore$ $K_p = p(H_2O)^2$ because concentration of solids is taken as unity.

$$\therefore\ 1.086 \times 10^{-4}\ \text{atm}^2 = p(H_2O)^2;$$

$$pH_2O = (1.086 \times 10^{-4}\ \text{atm}^2)^{1/2}$$

$$\therefore \quad pH_2O = 1.042 \times 10^{-2}\ \text{atm}.$$

But $1\ \text{atm} = 760$ mm Hg.

$$\therefore \quad pH_2O = 1.042 \times 10^{-2} \times 760\ \text{mm}$$

$= 7.92$ mm Hg at 298 K.

Vapour pressure of H$_2$O at 298 K

$= 23.8$ mm Hg. So, CuSO$_4$. 3H$_2$O can absorb mixture when P_{H_2O} is above 7.92 mm Hg, in air.

EXAMPLE 176. *At 40°C, $K_p = 9$ atm^2 for the following equilibrium.*

LiCl. 3NH$_3$(s) $\rightleftharpoons$ LiCl. NH$_3$(s) + 2NH$_3$(g)

The reaction was started with 0.1 mol LiCl. NH$_3$ in a 5 L vessel. Calculate the number of mol of NH$_3$ that should be added to the vessel at this temperature so that backward reaction becomes completed.

SOLUTION. The backward reaction will be :

$$\begin{array}{lccc} & LiCl.\ NH_3(s) + & 2NH_3(g) \rightleftharpoons & LiCl.\ 3NH_3(s) \\ (i)\ n \text{ mol at start} & & & \\ & 0.1 & a + (0.1 \times 2) = a + 0.2 & 0 \\ (ii) \text{ Change by reaction} & & & \\ & -0.1 & -0.1 \times 2 = -0.2 & 0.1 \\ (iii)\ n \text{ mol at equilibrium} & & & \\ & 0.1 - 0.1 & a + 0.2 - 0.2 & 0 + 0.1 \\ & = 0 & = a & = 0.1 \end{array}$$

$$\therefore \quad K_p = \frac{1}{P_{(NH_3)^2}}$$

because the partial pressures of solids are taken as unity.

$$\therefore \quad \frac{1}{9\ \text{atm}^2} = \frac{1}{P_{(NH_3)^2}}.$$

Taking square root of both sides,we get :

$$\frac{1}{3\ \text{atm}} = \frac{1}{p_{NH_3}}\ ; \quad p_{NH_3} = 3\ \text{atm}$$

But $PV = n\,RT$ (gas equation) ;

$P = 3$ atm, $V = 5$ L, $n = ?$

$R = 0.0821$ L atm K$^-$ mol$^-$,

$T = 40 + 273 = 313$ K

$$\therefore \quad 3\ \text{atm} \times 5\ \text{L} = n \times 0.0821\ \text{L atm K}^-\ \text{mol}^- \times 313\ \text{K}$$

$$\therefore \quad n = \frac{15\ \text{atm L}}{0.821\ \text{L atm K}^-\ \text{mol}^- \times 313\ \text{K}} = 0.584$$

Or $a = 0.584$

$\therefore$ mol of NH$_3$ to be added at start $= a + 0.2 = 0.584 + 0.2 =$ **0.784 mol Ans.**

EXAMPLE 177. *The composition of the equilibrium mixture (Cl$_2$ $\rightleftharpoons$ 2 Cl) which is attained at 1200°C, is determined by measuring the rate of effusion through a pin-hole. It is observed that at 1.80 mm Hg pressure, the mixture effuses 1.16 times as fast as krypton effuses under the same conditions. Calculate the fraction of chlorine molecules dissociated into atoms (at. wt. of Kr = 84)* **(IIT, 1995)**

SOLUTION. Let $x =$ Fraction of Cl$_2$ molecules dissociated.

$$\frac{r_{mix}}{r_{Kr}} = \left(\frac{M_{Kr}}{M_{mix}}\right)^{½}$$

(Graham's law of diffusion)

$$\frac{1.16}{1} = \left(\frac{84}{M_{mix}}\right)^{1/2}$$

Squaring both sides, we get :

$$(1.16)^2 = \frac{84}{M_{mix}}\ ; \quad M_{Mix} = \frac{84}{(1.16)^2} = 62.42$$

	$Cl_2 \rightleftharpoons$	$2Cl$
(*i*) *n* mol at start	1	0
(ii) Change by reaction	$-x$	$2x$
(iii) *n* mol at equilibrium	$1-x$	$2x$

Total number of mol at equilibrium

$$= 1 - x + 2x = 1 + x$$

$$M_{mix} = \left(\frac{2x}{1+x} \times \text{at. wt. of Cl}\right) + \frac{1-x}{1+x} \times (\text{mol. wt. of } Cl_2)$$

$$= \left(\frac{2x}{1+x} \times 35.5\right) + \frac{1-x}{1+x} \times (2 \times 35.5)$$

$$= \frac{71x}{1+x} + \frac{71}{1+x} - \frac{71x}{1+x}$$

$$62.42 = \frac{71}{1+x}\ ;\ 62.42\,(1+x) = 71\ ;$$

$$1 + x = \frac{71}{62.42} = 1.137$$

$\therefore$ $x = 1.137 - 1 = \mathbf{0.137}$ **Ans.**

Example 178. *For the reaction :*

$$A + B \rightleftharpoons C$$

the equilibrium concentration of A and B at a particular temperature are 15 mol L^{-} *each. When volume is doubled, the reaction has equilibrium concentration of A as 10 mol* L^{-}*. Calculate (i) Kc for reaction (ii) [C] in the original equilibrium obtained.*

Solution. First Case.	A	+	B	$\rightleftharpoons$	C
n mol at equilibrium	15		15		*a*
			(When volume = *V*)		
Second Case	A	+	B	$\rightleftharpoons$	C
			(When Volume = 2 *V*)		
(*i*) *n* mol at start	$\frac{15}{2}$		$\frac{15}{2}$		$\frac{a}{2}$
	$= 7.5$		$= 7.5$		$= 0.5\,a$
(*ii*) Change by reaction	$+x$		$+x$		$-x$
(*iii*) *n* mol at equilibrium	$7.5 + x$		$7.5 + x$		$0.5\,a - x$

We know that when volume is doubled, the pressure becomes one half. So, the reaction will proceed in a direction where there is an increase in the number of mol, *i.e.*, it will proceed in the backward direction.

Since $7.5 + x = 10\ ;\ \mathbf{x = 10 - 7.5 = 2.5}$

For first case. $K_p = \frac{[C]}{[A][B]} = \frac{a}{15 \times 15} = \frac{a}{225}$

For second case.

$$K_p = \frac{[C]}{[A][B]} = \frac{0.5\,a - x}{(7.5 + x)(7.5 + x)}$$

$$= \frac{0.5\,a - 2.5}{(7.5 + 2.5)^2}$$

Or $\frac{a}{225} = \frac{0.5\,a - 2.5}{100}\ ;\ 100\,a = 225\,(0.5\,a - 2.5)$

$$100\,a - 112.5\,a = -562.5\ ;\ -12.5\,a = -562.5$$

Hence $\mathbf{a = 45\ mol}$

$\therefore$ $K_C = \frac{a}{225} = \frac{45}{225} = \mathbf{0.2\ mol\ L^{-}}$ **Ans.**

Type. *Calculation of concentration of monomers/polymers when equilibrium constant value is given.*

Example 179. *The equilibrium constant for the polymerisation of formaldehyde, HCHO to glucose* $C_6H_{12}O_6$*, in aqueous solution is* 6×10^{22}*.*

$$6\ HCHO \rightleftharpoons C_6H_{12}O_6$$

If 1.0 M solution of glucose were to reach the dissociation equilibrium with respect to the above equation, what would be the concentration of formaldehyde in the solution ?

(MP PMT, 2002)

Solution. Given reaction :

$$6\ HCHO \rightleftharpoons C_6H_{12}O_6$$

$$[C_6H_{12}O_6] = 1.0\ M\ ;\ K = 6 \times 10^{22}$$

For the above reaction :

$$K = \frac{[C_6H_{12}O_6]}{[HCHO]^6}\ ;$$

$$6 \times 10^{22} = \frac{1}{[HCHO]^6}\ ;\ [HCHO]^6 = \frac{1}{6 \times 10^{22}}$$

$$\therefore\quad [HCHO] = \left(\frac{1}{6 \times 10^{22}}\right)^{1/6} = (0.167 \times 10^{-22})^{1/6}$$

Taking logs of both sides, we get :

$$\log [HCHO] = \log (0.167 \times 10^{-22})^{1/6}$$

$$= \frac{1}{6}[\log 0.167 - 22]$$

$$= \frac{1}{6}[-0.7772 - 22] = -3.7962$$

Taking antilogs, we get

$$[HCHO] = \text{antilog} - 3.7962$$

$$= \text{antilog} -3 -1 + 1 - 0.7962$$

$$= \text{antilog}\ \bar{4}.2038 = \mathbf{1.6 \times 10^{-4}}$$ **Ans.**

Example 180. *The equilibrium constant for the reaction*

$$\text{Glycerol} + H_3BO_3 \rightleftharpoons H_3BO_3 - \text{glycerol complex}$$

is 0.90. How much glycerol should be added per litre of 0.1 M H_3BO_3 *solution, so that 70 % of the* H_3BO_3 *is converted to* (H_3BO_3 *– glycerol) complex.*

Solution.

H_3BO_3 + glycerol $\rightleftharpoons$ H_3BO_3 – glycerol complex

n mol at equilibrium

30 70

Applying law of chemical equilibrium, we get :

$$K = \frac{[H_3BO_3 - \text{glycerol}]\ \text{Complex}}{[H_3BO_3]\ [\text{glycerol}]}$$

$$0.9 = \frac{70}{30 \times [\text{glycerol}]}\ ;$$

$$[\text{glycerol}] = \frac{70}{30 \times 0.9} = \mathbf{2.59\ M}$$ **Ans.**

EXAMPLE 181. *For $X_2(g) + Y_2(g) \rightleftharpoons 2XY(g)$ at 373 K, the value of $K_c = 50$. If 1 L vessel containing 1 mol of X_2 is connected with a 2 L flask containing 2 mol of Y_2, calculate the number of mol of XY formed at 373 K.*

SOLUTION. Reaction

Reaction	$X_2(g)$ +	$Y_2(g)$ ⇌	$2XY(g)$
no. of mol at $t = 0$	1	2	0
no. of mol at equilibrium	$1 - x$	$2 - x$	$2x$

Total volume after connecting vessels

$$= 1\text{ L} + 2\text{ L} = 3\text{ L}$$

$$[X_2] = \frac{1-x}{3}, [Y_2] = \frac{2-x}{3}; [XY] = \frac{2x}{3}$$

$$\therefore \quad K_c = \frac{[XY]^2}{[X_2][Y_2]} = \frac{\left(\frac{2x}{3}\right)^2}{\frac{1-x}{3} \times \frac{2-x}{3}}$$

$$= \frac{4x^2}{x^2 - 3x + 2}$$

$$50 = \frac{4x^2}{x^2 - 3x + 2};$$

$$50x^2 - 150x + 100 = 4x^2 \quad ; \quad 46x^2 - 150x + 100 = 0$$

After solving, we get $x = 0.93$ and 2.326. But the value 2.326 is not correct because x cannot be greater than 2.

$\therefore$ no. of mol of XY

$= 2x = 2 \times 0.93 =$ **1.86** **Ans.**

EXAMPLE 182. *The value of K_c at 25°C for the reaction*

$$Hg_2^{2+} + 2\,Fe^{3+} \rightleftharpoons 2Hg^{2+} + 2\,Fe^{2+}$$

is *9.14×10^{-6}. Calculate the concentration of ions at equilibrium if concentrations at the start are, $Hg_2^{2+} = Fe^{3+} = 0.5$ M ; $Hg^{2+} = Fe^{2+} = 0.03$ M.*

SOLUTION.

	Hg_2^{2+} +	$2Fe^{3+}$ ⇌	$2Hg^{2+}$ +	$2Fe^{2+}$
(*i*) *n* mol at start	0.5	0.5	0.03	0.03
(*ii*) Change by reaction	$\frac{-x}{2}$	$-x$	x	x
(*iii*) *n* mol at equilibrium	$0.5 - \frac{x}{2}$	$0.5 - x$	$0.03 + x$	$0.03 + x$

$$K_c = \frac{[Hg^{2+}]^2\,[Fe^{2+}]^2}{[Hg_2^{2+}]\,[Fe^{3+}]^2};$$

$$9.14 \times 10^{-6} = \frac{[Hg^{2+}]^2\,[Fe^{2+}]^2}{[Hg_2^{2+}]\,[Fe^{3+}]^2}$$

$$= \frac{(0.03 + x)^2\,(0.03 + x)^2}{0.5 - (x/2) \times (0.5 - x)^2}$$

After solving the above equation, we get,

$$x = 0.0027$$

$$\therefore \quad [Hg_2^{2+}] = 0.5 - \frac{0.0027}{2} = 0.5 - 0.00135$$

$= \mathbf{0.4986\ M}$ **Ans.**

$[Fe^{3+}] = 0.5 - 0.0027 = \mathbf{0.4973\ M}$ **Ans.**

$[Hg^{2+}] = 0.03 + 0.0027 = \mathbf{0.0327\ M}$ **Ans.**

$[Fe^{2+}] = 0.03 + 0.0027 = \mathbf{0.0327\ M}$ **Ans.**

EXAMPLE 183. *The dissociation equilibrium of a gas AB_2 can be represented as $2AB_2(g) \rightleftharpoons 2AB(g) + B_2(g)$. The degree of dissociation is x and is small compared to 1. The expression relating the degree of dissociation (x) with equilibrium constant K_p and total pressure P is :*

(a) $(2K_p/P)1/2$ *(b)* K_p/P

(c) $2K_p/P$ *(d)* $(2K_p/P)^{1/3}$

(CBSE–PMT, 2008 Prelims)

SOLUTION.

Given :	$2AB_2(g)$ ⇌	$2AB(g)$ +	$B_2(g)$
Initial conc.	2	0	0
Conc. at equilibrium	$2(1-x)$ *i.e.,* $2 - 2x$	$2x$	x

No. of mol at equilibrium

$$= 2(1-x) + 2x + x = 2 + x$$

$$\text{But} \quad K_p = \frac{(P_{AB})^2\left[P_{B_2}\right]}{\left[P_{AB_2}\right]^2} = \frac{\left(\frac{2x}{2+x} \times P\right)^2 \left(\frac{x}{2+x} \times P\right)}{\left[\frac{2(1-x)}{2+x} \times P\right]^2}$$

$$= \frac{\frac{4x^3}{2+x} \times P}{4(1-x)^2}$$

$$= \frac{4x^3 \times P}{2} \times \frac{1}{4}$$

[$\because$ $1 - x = 1$ and $2 + x = 2$, x being very small]

$$\therefore \quad x = \left(\frac{8K_p}{4P}\right)^{1/3} \quad \text{or} \quad x = \left(\frac{2K_p}{P}\right)^{1/3}.$$

So, the correct answer is (*d*).

EXAMPLE 184. *For the reaction*

$$Ag(CN)_2^- \rightleftharpoons Ag^+ + 2CN^-.$$

the K_c at 25°C is 4×10^{-19}. Calculate $[Ag^+]$ in solution which was originally 0.1 M in KCN and 0.03 M in $AgNO_3$.

(IIT 1994)

SOLUTION.

	2KCN +	$AgNO_3$ ⇌	$Ag(CN)_2^-$ +	KNO_3 +	K^+
(*i*) *n* mol at start	0.1	0.03	0	0	0
(*ii*) Change by reaction	$-(2 \times 0.03)$ $= -0.06$	0	$\frac{0.06}{2}$ $= 0.03$	$\frac{0.06}{2}$ $= 0.03$	$\frac{0.06}{2}$ $= 0.03$
(*iii*) *n* mol at equilibrium	$0.1 - 0.06$ $= 0.04$	0	0.03	0.03	0.03

$\therefore$ $[Ag(CN)_2]^- = 0.03.$

$$[Ag(CN)_2]^- \rightleftharpoons Ag^+ + 2CN^-$$

(*i*) *n* mol at start	0.03	0	0.04
(*ii*) Change by reaction	$-x$	x	$0.04+x$
(*iii*) *n* mol at equilibrium	$0.03-x$	x	$0.04+x$

Since the value of K_c is very small and dissociation of $[Ag(CN)_2]^-$ is very small, $0.03-x=0.03$; $0.04+x=0.04$

But $$K_c=\frac{[Ag^+][CN^-]^2}{[Ag(CN)_2]^-}\ ;\ 4\times10^{-19}=\frac{x\times(0.04)^2}{0.03}\ ;$$

$$4\times10^{-19}(0.03)=x\times(0.04)^2\ ;$$

$$x=\frac{4\times10^{-19}\times0.03}{(0.04)^2}=\mathbf{7.5\times10^{-18}}\quad \textbf{Ans.}$$

EXAMPLE 185. *For the equilibrium*

$$AB\,(g) \rightleftharpoons A\,(g)+B\,(g),$$

K_p is equal to four times of total pressure. Calculate the number of mol of A formed. **(BIT Mesra ; Ranchi, 1990)**

SOLUTION.

	AB (g)	A (g)	B (g)
(*i*) *n* mol at start	1	0	0
(*ii*) Change by reaction	$-x$	x	x
(*iii*) *n* mol at equilibrium	$1-x$	x	x

Total number of mol at equilibrium

$$=1-x+x+x=1+x$$

$$\therefore\quad K_p=\frac{P_{(B)}\times P_{(A)}}{P_{(AB)}}=\frac{\left(\frac{x}{1+x}\times P\right)\left(\frac{x}{1+x}\times P\right)}{\left(\frac{1-x}{1+x}\times P\right)}$$

$$=\frac{x^2\,P}{1-x^2}$$

Since pressure $=P$, $K_p=4\times P$ (given) $=4$ P

$$\therefore\quad 4\,P=\frac{x^2\,P}{1-x^2}\ ;\ 4(1-x^2)=x^2\ ;$$

$$4-4\,x^2=x^2\ ;\ 5x^2=4$$

$$\therefore\quad x=\left(\frac{4}{5}\right)^{1/2}=0.894$$

Hence number of mol of A formed $=x=$ **0.894 mol.**

EXAMPLE 186. *In the preparation of CaO from $CaCO_3$ using the equilibrium $CaCO_3(s) \rightleftharpoons CaO(s)+CO_2(g)$, K_p is expressed as*

$$\log K_p=7.282-8500/T$$

For the complete decomposition of $CaCO_3$, the temperature in celsius to be used is :

(*a*) *1167* (*b*) *892*

(*c*) *8500* (*d*) *850* **[AMU (engg) 2011]**

SOLUTION. In order to have complete decomposition, $K_p=1$. So, $\log K_p=\log 1=0$. Thus :

$$0=7.282-8500/T\ ;$$

$$T=(8500/7.282)=1167\ K$$

So, the correct answer is (*a*).

EXAMPLE 187. *The value of K_p is 1×10^{-3} atm^- at 25°C for the reaction*

$$2\,NO+Cl_2 \rightleftharpoons 2\,NOCl$$

A flask contains NO at 0.02 atm and at 25°C. Calculate the mol of Cl_2 that must be added if 1 % of the NO is to be converted to NOCl at equilibrium. The volume of flask is such that 0.2 mol of the gas produces 1 atm pressure at 25°C. (Ignore the probable association of NO to N_2O_2). **(Roorkee, 2001)**

SOLUTION. Let initial pressure of Cl_2 = P; $K_p=10^{-3}$

	2NO	Cl_2	2NOCl
(*i*) Pressure (atm) at start	0.02	P	0
(*ii*) Change by reaction	$-\frac{0.02\times1}{100}$ $=-2\times10^{-4}$	$-\frac{1}{2}\times\frac{0.02}{100}$ $=-10^{-4}$	$0.02\times\frac{1}{100}$ $=2\times10^{-4}$
(*iii*) Pressure (atm) at equilibrium	$0.02-2\times10^{-4}$ $=2\times10^{-2}-2\times10^{-4}$ $=2\times10^{-4}(100-1)$ $=198\times10^{-4}$	$P-10^{-4}$ $P-10^{-4}$	2×10^{-4} 2×10^{-4}

$$\therefore\quad K_p=\frac{P(NOCl)^2}{P(NO)^2\times PCl_2}$$

$$=\frac{(2\times10^{-4})^2}{(198\times10^{-4})^2\times(P-10^{-4})}$$

Or $$10^{-3}=\frac{4}{198\times198}\times\frac{1}{P-10^{-4}}\ ;$$

$$P-10^{-4}=\frac{4}{198\times198}\times\frac{1}{10^{-3}}=0.102$$

Or $$P=0.102+10^{-4}=0.102+0.0001$$

$$=0.1021\ \text{atm}$$

But $PV=n\,RT$ (ideal gas equation) ,

$V=$ Volume of vessel.

$$\therefore\quad V=\frac{n\,RT}{P}$$

$$=\frac{0.2\ \text{mol}\times0.082\ \text{L atm K}^-\ \text{mol}^-\times(25+273)\ \text{K}}{1\ \text{atm}}=4.887\ \text{L}$$

Again $$PV=n\,RT\ ;\ n=\frac{PV}{RT}$$

$$=\frac{0.1021\ \text{atm}\times4.877\ \text{L}}{0.082\ \text{L atm K}^-\ \text{mol}^-\times298\ \text{K}}$$

Or $n=$ **0.0204 mol** **Ans.**

EXAMPLE 188. *For a reaction $A(s)+B(g) \rightleftharpoons C(s)+D(g)$ at equilibrium, the value of K_p at 1000°C is 0.45. If B(g) at a pressure of 1 atmosphere and excess C(s) are placed in a container at the same temperature, what will be the pressure of B(g) and D(g), when equilibrium is attained ?*

SOLUTION. The given reaction is :

A(s)	B(g)	C(s)	D(g)
1 mol	1 mol	1 mol	1mol

Here, number of moles of B(g) consumed = Number of moles of D(g) formed. Considering ideal gas behaviour, partial pressures of gases are proportional to number of moles present. Hence, drop in pressure of B(g) will be equal to the partial pressure of D(g) formed. Suppose, partial pressure of D(g) at equilibrium = a atm.

$\therefore$ Partial pressure of B(g) at equilibrium = $(1 - a)$ atm.

But $$K_p = \frac{p_D}{p_B} = \frac{a}{1-a} = 0.45$$

Or $a + 0.45\,a = 0.45$

or $a = 0.31$

Hence $p_B = 1 - a = 1 - 0.31 = \mathbf{0.69\ atm.}$ **Ans.**

and $p_D = \mathbf{0.31 atm.}$ **Ans.**

23.24 AIEEE PATTERN EXAMPLES

Example 189. *A reaction is $A + B \rightleftharpoons C + D$. Initially, we start with equal concentrations of A and B. At equilibrium, we find that the moles of C are two times of A. What is the equilibrium constant of the reaction ?*

(*a*) 1/2 (*b*) 1/4

(*c*) 2 (*d*) 4 **(Karnataka CET, 2000)**

Solution. Given reaction : $A + B \rightleftharpoons C + D$ ...(1)

	A	B	C	D
Initial conc. (mol)	1	1	0	0
At equilibrium, conc.	$1 - x$	$1 - x$	x	x

But at equilibrium no. of mol of C

= 2 × no. of mol of A **Or** $x = 2(1 - x)$

$\therefore \quad x + 2x = 2 \; ; \; x = \frac{2}{3}$

For reaction (1),

$$K_c = \frac{[C][D]}{[A][B]} ; K_C = \frac{x \times x}{(1-x)(1-x)}$$

Or $$K_c = \frac{\frac{2}{3} \times \frac{2}{3}}{\left(1-\frac{2}{3}\right) \times \left(1-\frac{2}{3}\right)} = \frac{2}{3} \times \frac{2}{3} \times \frac{3}{1} \times \frac{3}{1} = \mathbf{4.0.}$$

So, the correct answer is (*d*).

Example 190. *At 1273 K, the value of K_c for the following reactions is given side by side.*

(*i*) $COCl_2(g) \rightleftharpoons CO(g) + Cl_2(g); K_1 = 0.33$

(*ii*) $2CO(g) + O_2(g) \rightleftharpoons 2CO_2(g); \; K_2 = 2.2 \times 10^{22}$

The value of K_c for (iii) $2COCl_2(g) + O_2(g) \rightleftharpoons 2CO_2(g) + 2Cl_2(g)$ is :

(*a*) 10^{21} (*b*) 2.3958×10^{21}

(*c*) 239.5×10^{23} (*d*) 4

Solution. For reaction

(*i*) $$K_1 = \frac{[CO(g)][Cl_2(g)]}{[COCl_2(g)]} = 0.33$$

(*ii*) $$K_2 = \frac{[CO_2(g)]^2}{[CO(g)]^2\,[O_2(g)]} = 2.2 \times 10^{22}$$

(*iii*) $$K = \frac{[CO_2(g)]^2\,[Cl_2(g)]^2}{[COCl(g)]^2\,[O_2(g)]} = ?$$

In order to get K, we have $K_1^2 \times K_2$.

So : $$K = \frac{[CO(g)]^2\,[Cl_2(g)]^2}{[COCl_2(g)]^2} \times \frac{[CO_2(g)]^2}{[CO(g)]^2\,[O_2(g)]}$$

$$= (0.33)^2 \times (2.20 \times 10^{22})$$

$$= \mathbf{2.3958 \times 10^{21}}$$ **Ans.**

So, the correct answer is, (*b*).

Example 191. *Equilibrium constants K_1 and K_2 for the following equilibria*

$$NO(g) + ½\,O_2 \xrightleftharpoons{K_1} NO_2(g) \text{ and}$$

$$2NO_2(g) \xrightleftharpoons{K_2} 2NO(g) + O_2(g) \text{ are related as}$$

(*a*) $K_2 = 1/K_1^2$ (*b*) $K_2 = K_1^2$

(*c*) $K_2 = 1/K_1$ (*d*) $K_2 = K_1/K_2$

[CBSE-PMT (Prelim), 2005]

Solution. (*a*) $NO(g) + \frac{1}{2}O_2(g) \xrightleftharpoons{K_1} NO_2(g)$

(*b*) $2NO_2(g) \xrightleftharpoons{K_2} 2NO(g) + O_2(g)$

$$\therefore \quad K_1 = \frac{P_{(NO_2)}}{P_{(NO)} \times P_{(O_2)^{1/2}}} \quad ...(1)$$

$$K_2 = \frac{P_{(NO)^2} \times P_{O_2}}{P_{(NO_2)^2}} \quad ...(2)$$

Equation (*b*) is reverse of equation (*a*) multiplied by 2. So, taking square root on both sides in equation (2), we get :

$$(K_2)^{1/2} = \frac{P_{(NO)} \times P(O_2)^{½}}{P_{(NO_2)}} ;$$

$$(K_2)^{1/2} = \frac{1}{K_1} \quad \textbf{Or} \quad K_2 = \frac{1}{K_1^2}$$

(after squaring both sides).

So, the correct answer is (*a*).

Example 192. *For the reaction, $CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g)$, partial pressure of CO_2 at 1000 K is 0.003 atm. $\Delta G^o = 27.2$ k cal. Calculate the value of ΔG.*

(*a*) 12.6 k cal (*b*) 15.6 k. cal

(*c*) 13.4 k. cal (*d*) 14.2 k. cal **(Orissa JEE, 2011)**

Solution. Since in the reaction, $CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g)$, only CO_2 is a gas, so $K_p = P_{CO_2} = 0.003$ atm.

But $$\Delta G = \Delta G^o + 2.303\,RT \log K_p$$

$$= 27.2 + 2.303 \times 2 \times 1000 \times \log 0.003$$

$(\because R = 2 \text{ cal mol}^{-} \text{ K}^{-})$

$$= \mathbf{15.6\ k\ cal}$$

So, the correct answer is (*b*).

Example 193. *You are provided with the reaction, $2NO(g) \rightleftharpoons N_2(g) + O_2(g)$; $\Delta H = -43.5$ k cal. Which out of the following will be true for $N_2(g) + O_2(g) \rightleftharpoons 2NO(g)$?*

(*a*) *K varies with the addition of NO*
(*b*) *K is independent of T*
(*c*) *K decreases with the decrease in T*
(*d*) *K increases with the decrease in T.*

Solution. The given reaction is exothermic. So, the given reverse reaction will be endothermic. According to Le-Chatelier's principle, high temperature would favour the forward reaction. It means K increases with increase in T or K decreases with decrease in T. So, the answer is (*c*).

Example 194. *At 5°C, K value of equilibrium constant for the reaction,* $Cu(s) + 2\,Ag^+(aq) \rightleftharpoons 2Cu^{2+}(aq) + 2Ag(s)$ *is* 2.0×10^{15}*. In a solution in which the copper has displaced some silver ions from the solution, concentration of* Ag^+ *ions is* 3.0×10^{-9} *mol* L^- *and of* Cu^{2+} *ions is* 1.8×10^{-2} *mol* L^-*. The system will be :*

(*a*) *At equilibrium*
(*b*) *More to-wards forward*
(*c*) *More to-wards backward*
(*d*) *Can not be predicted.*

Solution.

$[Cu^{2+}(aq)]^{2+} = 1.8 \times 10^{-2}$ mol L^- ;

$[Ag^+(aq)] = 3.0 \times 10^{-9}$ mol L^-. Molar conc. of solids = 1

Applying law of chemical equilibrium for the reaction.

$Cu(s) + 2Ag^+(aq) \rightleftharpoons Cu^{2+}(aq) + 2Ag(s)$, we have :

$$Q = \frac{[Cu^{2+}(aq)]\,[Ag(s)]^2}{[Cu(s)]\,[Ag^+(aq)]^2}$$

$$= \frac{1.8 \times 10^{-2} \times 1}{1 \times 3.0 \times 10^{-9} \times 3.0 \times 10^{-9}}$$

$$= \mathbf{2.0 \times 10^{15}} \qquad \textbf{Ans.}$$

The value of Q being same as that of K_c, so the correct answer is, (*a*).

Example 195. *For a reaction,* $X + Y \rightleftharpoons Z + E + 50k$ *cal, the value of equilibrium constant at 596K is 900. The value of K in presence of catalyst in the forward reaction would be :*

(*a*) *900 × 596* (*b*) *900*
(*c*) $\dfrac{900}{\textit{conc. of catalyst}}$ (*d*) *Cannot be calculated.*

Solution. Since the value of K varies with temperature only and not by a catalyst, the value will remain same *i.e.*, 900. So, the correct answer is (*b*).

Example 196. *The equilibrium constant, K for the reaction,* $2HI(g) \rightleftharpoons H_2(g) + I_2(g)$ *at room temperature is 2.85 and that at 698 K is* 1.4×10^{-2}*. This implies that :*

(*a*) *HI is resonance stabilised*
(*b*) *HI is an exothermic compound*
(*c*) *HI is relatively less stable than* I_2 and H_2
(*d*) *HI is extremely stable at room temperature.*

Solution. The value of K being less (= 1.4×10^{-2}) at high temperature (698K) than (2.85) at room temperature, so the given reaction is exothermic. In other words, the backward reaction is exothermic. So, HI is an endothermic compound. Since the energy of HI is greater than that of constituent elements H_2 and I_2, so HI is relatively unstable. So, the correct answer is, (*c*).

Example 197. *If Henry's law constant for* O_2 *is* 1.28×10^{-3} *mol* L^- *atm*$^-$*, the solubility of* O_2 *in water at a partial pressure of* O_2 *of 190 torr at 298 K will be :*

(*a*) 1.6×10^{-4} *mol* L^- (*b*) 3.2×10^{-4} *mol* L^-
(*c*) 4.8×10^{-6} *mol* L^- (*d*) 10^{-5} *mol* L^- *only.*

Solution. P = 190 torr = 190/760 = 0.25 atm ;
$k = 1.28 \times 10^{-3}$ mol L^- atm$^-$.

According to Henry's law,

$$C = k\,P$$

$$\therefore \quad C = 1.28 \times 10^{-3} \text{ mol } L^- \text{ atm}^- \times 0.25 \text{ atm}$$

$$= \mathbf{3.2 \times 10^{-4}\ mol\ L^-}.$$

So, the correct answer is (*b*).

Example 198. *For a reaction,* $N_2(g) + O_2(g) \rightleftharpoons 2NO(g)$*, the value of* K_c *at 127°C is* 4.0×10^{-6}*. The value of* K_p *for the same reaction will be :*

(*a*) 4.0×10^{-2} (*b*) 2.0×10^{-4}
(*c*) $2 \times 10^{-6}\,RT$ (*d*) *none of these.*

Solution. For $N_2(g) + O_2(g) \rightleftharpoons 2NO(g)$

1 mol 1 mol 2 mol

$\Delta n = 2 - (1 + 1)$ = zero

We know $K_p = K_c\,(RT)^{\Delta n} = K_c\,(RT)^{\circ} = K_c$

or $K_p = K_c$.

Hence the true answer is (*d*).

Example 199. *At 673 K and 10 atmospheric pressure, ammonia was found to be dissociated to 96 % in the equilibrium mixture.*

$$2NH_3 \rightleftharpoons N_2 + 3H_2$$

The K_p *for the reaction will be :*

(*a*) *1.1 atm* (*b*) $\simeq 2.3328 \times 10^4$ *atm*^{2}
(*c*) 1.421×10^3 *atm* (*d*) *4 atm.*

Solution.	$2\,NH_3$ $\rightleftharpoons$	$1N_2$ +	$3H_2$
(*i*) *n* mol at start	1	0	0
(*ii*) Change by reaction	$-96\,\% = \frac{-96}{100}$ $= -0.096$	$\frac{1}{2} \times 0.96$ $= 0.48$	$\frac{3}{2} \times 0.96$ $= 1.44$
(*iii*) *n* mol at equilibrium	$(1 - 0.96)$ $= 0.04$	0.48	1.44

Total number of mol

$$= 0.04 + 0.48 + 1.44 = 1.96$$

$$K_p = \frac{p(H_2)^3 \times p_{N_2}}{p(NH_3)^2}$$

$$= \frac{\left(\frac{1.44}{1.96}\times P\right)^3 \left(\frac{0.48}{1.96}\times P\right)}{\left(\frac{0.04}{1.96}\times P\right)^2}$$

But $P =$ 10 atm. Hence.

$$K_p = \frac{\left(\frac{1.44\times 10}{1.96}\right)^3 \left(\frac{0.48\times 10}{1.96}\right)}{\left(\frac{0.04}{1.96}\times 10\right)^2}$$

$$= \frac{(1.44\times 10)^3}{(1.96)^3}\times\frac{0.48}{1.96}\times 10\times\frac{(1.96)^2}{(0.04\times 10)^2}$$

$$= \frac{2985.98\times 4.8}{3.84\times 0.16} = \mathbf{23328} = 2.3328\times 10^4$$

So, the correct answer is (*b*).

Example 200. *One mol of NH_3 was heated in presence of a catalyst in a half-litre capacity vessel to get equilibrium. The resultant mixture contained 0.7 mol of NH_3. The equilibrium constant at the temperature of experiment will be*

(*a*) *0.1* (*b*) *0.2*

(*c*) *0.8* (*d*) *0.33.*

Solution. mol of NH_3 at equilibrium = 0.7

Volume $= \frac{1}{2}L = 0.5\ L$

	NH_3 $\rightleftharpoons$	$\frac{1}{2}N_2$ +	$\frac{3}{2}H_2$
(*i*) *n* mol at start	1	0	0
(*ii*) Change by reaction	$1 - 0.7 = 0.3$	$0.3\times\frac{1}{2} = 0.15$	$0.3\times\frac{3}{2} = 0.45$
(*iii*) *n* mol L^- at equilibrium	$\frac{1-0.3}{0.5} = 1.4$	$\frac{0.15}{0.5} = 0.3$	$\frac{0.45}{0.5} = 0.9$

$\because V = 0.5\ L$

$$K_p = \frac{p(N_2)^{1/2}\times p(H_2)^{3/2}}{p(NH_3)}$$

$$= \frac{(0.3)^{1/2}\times(0.9)^{3/2}}{1.4} = \frac{(0.3)^{1/2}\times\sqrt{(0.9)^3}}{1.4}$$

$$= \frac{0.55\times(0.729)^{1/2}}{1.4} = \frac{0.55\times 0.85}{1.4} = \mathbf{0.33}$$

So, the correct answer is (*d*).

Example 201. *One mol of NH_3 was heated in presence of a catalyst in a one litre capacity flask to get $NH_3 \rightleftharpoons \frac{1}{2}N_2 + \frac{3}{2}H_2$ equilibrium. At equilibrium 0.3 mol of H_2 was left behind. The concentrations of N_2 and NH_3 at equilibrium are respectively :*

(*a*) *0.05, 1 mol* (*b*) *0.1 mol, 0.2 mol*

(*c*) *0.2 mol, 0.1 mol* (*d*) *none of these.*

Solution.

	NH_3 $\rightleftharpoons$	$\frac{1}{2}N_2$ +	$\frac{3}{2}H_2$
(*i*) *n* mol at start	1	0	0
(*ii*) *n* mol at equilibrium	$0.3\times 1\times\frac{2}{3}$	$0.3\times\frac{1}{2}\times\frac{2}{3}$	0.3
	= 0.2	= 0.1	0.3

$\therefore$ $[N_2]$ = 0.1 mol ; $[NH_3]$ = 0.2 mol.

So, the correct answer is (*b*).

Example 202. *1 mol of N_2O_4 is heated in a flask with a volume of 10 dm^3. At equilibrium, 1.708 mol of NO_2 and 0.146 mol of N_2O_4 were found at 407 K. The equilibrium constant value will be :*

(*a*) *200 mol^{-3} dm* (*b*) *2.0 mol dm^{-3}*

(*c*) *100 mol dm^{-3}* (*d*) *50 mol dm^{-3}.*

Solution.

	N_2O_4 $\rightleftharpoons$	$2NO_2$
(*i*) *n* mol at start	1	0
(*ii*) *n* mol dm^{-3} at equilibrium	$\frac{0.146\ \text{mol}}{10\ dm^3}$	$\frac{1.708\ \text{mol}}{10\ dm^3}$
	= 0.0146 mol dm^{-3}	0.1708 mol dm^{-3}

$$\therefore \quad K_c = \frac{[NO_2]^2}{[N_2O_4]}$$

$$= \frac{(0.1708\ \text{mol dm}^{-3})^2}{0.0146\ \text{mol dm}^{-3}}$$

$$= \frac{0.0292\ \text{mol}^2\ \text{dm}^{-6}}{0.0146\ \text{mol dm}^{-3}}$$

$$= \mathbf{2\ mol\ dm^{-3}}$$

So, the correct answer is (*b*).

Example 203. *The concentrations of N_2O_4 and NO_2 for the reaction $N_2O_4 \rightleftharpoons 2NO_2$ are 0.044 mol L^- and 0.015 mol L^- respectively. The equilibrium constant K_c for this reaction at equilibrium will be :*

(*a*) *5.1 × 10^{-3} mol L^-* (*b*) *1.5 × 10^{-4} mol L^-*

(*c*) *10^{-3} mol L^-* (*d*) *10.2 × 10^{-3} mol L^-*

Solution.

$[N_2O_4]$ = 0.044 mol L^- ;

$[NO_2]$ = 0.015 mol L^-.

For the reaction

$$N_2O_4 \rightleftharpoons 2NO_2$$

$$K_c = \frac{[NO_2]^2}{[N_2O_4]} = \frac{(0.015\ \text{mol L}^-)^2}{0.044\ \text{mol L}^-}$$

$$= \frac{0.000225\ \text{mol}^2\ \text{L}^{-2}}{0.044\ \text{mol L}^-}$$

$$K_c = \mathbf{5.1\times 10^{-3}\ mol\ L^-}$$

So, the correct answer is (*a*).

Example 204. *A closed vessel contains one mol of $N_2O_4(g)$ at 27°C and one atmospheric pressure. On heating to 327°C, 20% by mass of this gas decomposed to brown coloured $NO_2(g)$. The resultant pressure will be :*

(*a*) *0.24 atm* (*b*) *2.4 atm*

(*c*) *0.024 atm* (*d*) *0.48 atm.*

SOLUTION. g. mol. mass (= 1 mol) of $N_2O_4(g) = (2 \times 14) + (4 \times 16) = 28 + 64 = 92$ g.

g. mol. mass of $2NO_2 = 2[14 + (2 \times 16)] = 92$ g.
At equilibrium, mass of $N_2O_4(g)$

$$= 92 - \left(92 \times \frac{20}{100}\right) = 92 - 18.4 = 73.6 \text{ g}$$

∴ no. of mol of N_2O_4 (g)

$$= \frac{\text{mass of } N_2O_4}{\text{g. mol. mass of } N_2O_4}$$

$$= \frac{73.6 \text{ g}}{92 \text{ g}} = 0.8 \text{ mol}$$

In the reaction,

$$N_2O_4 \rightleftharpoons 2NO_2 \text{ g}$$

no. of mol of NO_2

$$= \frac{1}{2} \times \text{mol of } N_2O_4 = \frac{1}{2} \times 0.8 \text{ mol}$$

$$= \mathbf{0.4 \text{ mol}}$$

$$T_1 = 27 + 273 = 300\text{K};$$

$$T_2 = 327 + 273 = 600 \text{ K}$$

Total no. of mol = 0.8 + 0.4 = 1.2 mol
Since the volume (V) is constant, thus

(*i*) $P_1 = 0.8$ mol, $V_1 = V$; $T_1 = 300$K, $n_1 = 1$ mol

(*ii*) $P_2 = 0.4$ mol, $V_2 = V$; $T_2 = 600$K, $n_2 = 1.2$ mol

But $$\frac{P_1V_1}{n_1 RT_1} = \frac{P_2V_2}{n_2 RT_2}$$

Or $$\frac{P_1}{n_1T_1} = \frac{P_2}{n_2T_2}; \frac{1}{1 \times 300} = \frac{P_2}{1.2 \times 600}$$

∴ $$P_2 = \frac{1.2 \times 600}{300} = \mathbf{2.4 \text{ atm.}}$$

So, the correct answer is, (*b*).

EXAMPLE 205. *At 27°C and one atmospheric pressure, the equilibrium mixture of* N_2O_4 *(g) and* $NO_2(g)$ *contains 19.8 %* NO_2 *by volume. The value of* K_p *for the equilibrium* N_2O_4 *(g)* $\rightleftharpoons 2NO_2(g)$ *will be :*

(a) 8.49	*(b) 2.22*
(c) 2.89	*(d) 0.0489.*

SOLUTION. Let concentration of N_2O_4 (g) = 1 mol.
concentration of NO_2 at equilibrium

$$= 19.8\ \% = \frac{19.8}{100} = 0.198 \text{ mol}$$

Concentration of N_2O_4 (g) at equilibrium

$$= 1 - \frac{19.8}{100} = 0.802 \text{ mol}$$

Total number of mol of NO_2 and N_2O_4

$$= 0.198 + 0.802 = 1 \text{ mol},$$

Pressure, $P = 1$ atm.

K_p for the reaction $N_2O_4 \text{ (g)} \rightleftharpoons 2NO_2(g)$ is given as:

$$K_p = \left(\frac{p_{NO_2} \times P}{\text{total mol} = 1}\right)^2 \Big/ \left(\frac{p_{N_2O_4} \times P}{\text{total mol} = 1}\right)$$

∴ $$K_p = \frac{0.198 \times 0.198 \times 1}{0.802 \times 1} = 0.0489$$

So, the correct answer is (*d*).

EXAMPLE 206. The dissociation constant of N_2O_4 if it dissociates to the extent of 53% at 60°C and one atmospheric pressure will be :

(*a*) 2.39	(*b*) 9.32
(*c*) 239	(*d*) 23.9

SOLUTION. Dissociation of N_2O_4 = 53 % .

Let initial concentration of N_2O_4 = 1 mol.

P = 1 atm. Thus for the following reaction we have:

	$N_2O_4 \rightleftharpoons$	$2NO_2$
Initial conc.	1 mol	0
Conc. at. equilibrium	$1 - \frac{53}{100}$	$2 \times \frac{53}{100}$
	= 0.47 mol	= 1.06 mol

$$K_p = \frac{\left(p_{NO_2} \times P\right)^2}{(p_{N_2O_4} \times P)} = \frac{(1.06 \times 1)^2}{(0.47 \times 1)}$$

$$= \frac{(1.06)^2}{0.47} = \mathbf{2.39}$$

So, the correct answer is (*a*).

EXAMPLE 207. *One mol of acetic acid and one mol of ethyl alcohol were mixed at 298 K. At equilibrium, 0.333 mol of acetic acid was found unreacted. The value of equilibrium constant will be :*

(*a*) 2.006	(*b*) 4.012
(*c*) 12.036	(*d*) 1.003

SOLUTION. Concentration of CH_3COOH = 1 mol ;
Concentration of ethyl alcohol = 1 mol ;
mol of CH_3COOH unreacted = 0.333 mol.
Thus for the following reaction, we have :

$$CH_3COOH\,(l) + C_2H_5OH\,(l) \rightleftharpoons CH_3COOC_2H_5\,(l) + H_2O\,(l)$$

(*i*) no. of mol at start

1 mol	1mol	0	0

(*ii*) Change for reaction

0.333 mol	0.333 mol	– 0.333 mol	–0.333mol

(*iii*) no. of mol at equilibrium

0.333 mol	0.333 mol	1 – 0.333 = 0.667 mol	1 – 0.333 =0.667mol

K_c for the reaction is given as :

$$K_c = \frac{[CH_3COOC_2H_5][H_2O]}{[CH_3COOH][C_2H_5OH]}$$

$$= \frac{0.667 \times 0.667}{0.333 \times 0.333} = \mathbf{4.012} \qquad \textbf{Ans.}$$

So, the correct answer is, (*b*).

Example 208. *The equilibrium constant of the reaction*

$$CH_3OH + CH_3COOH \rightleftharpoons CH_3COOCH_3 + H_2O$$

at 298K is 65. The weight of methyl acetate in equilibrium mixture, if 2 mol of methyl alcohol were originally mixed with one mol of acetic acid is :

(*a*) *36.5 g* (*b*) *34.4 g*
(*c*) *72.9 g* (*d*) *17.7 (g)*

Solution. mol of $CH_3COOH = x$. Initial concentration of CH_3OH = 2 mol ; CH_3COOH = 1 mol ; $K_c = 65$. For the following reaction, we have :

$$\begin{array}{lcccc} & CH_3OH + & CH_3COOH & \rightleftharpoons CH_3COOCH_3 + & H_2O \\ (i)\ n \text{ mol at start} & & & & \\ & 2\text{ mol} & 1\text{ mol} & 0 & 0 \\ (ii) \text{ Change for reaction} & & & & \\ & x\text{ mol} & x\text{ mol} & x\text{ mol} & x\text{ mol} \\ (iii)\ n \text{ mol at equilibrium} & & & & \\ & 2-x\text{ mol} & 1-x\text{ mol} & x\text{ mol} & x\text{ mol} \end{array}$$

$$\therefore \qquad K_c = \frac{[CH_3COOCH_3][H_2O]}{[CH_3OH][CH_3COOH]}$$

$$65 = \frac{x \times x}{(2-x)\times(1-x)} = \frac{x^2}{2-3x+x^2}$$

$$130 - 195x + 65x^2 = x^2 \quad ; \quad 65x^2 - x^2 - 195x + 130 = 0$$

$$\therefore\ 64x^2 - 195x + 130 = 0$$

$$\therefore \qquad x = \frac{-(-195) \pm [(-195)^2 - (4 \times 64 \times 130)]^{1/2}}{2 \times 64}$$

$$= \frac{+195 \pm (38025 - 33280)^{1/2}}{128}$$

$$= \frac{+195 \pm (4745)^{1/2}}{128}$$

$$\left[\begin{array}{l} \text{For quadratic equation,} \\ ax^2 + bx + c = 0 \\ x = \dfrac{-b \pm (b^2 - 4\,ac)^{1/2}}{2a} \end{array}\right.$$

$$= \frac{+195 - 68.88}{128} = \frac{126.12}{128}$$

$$x = 0.985 \text{ mol.}$$

$$\left[\begin{array}{l} \text{g. mol. wt. of } CH_3COOCH_3 \\ = 12 + (3 \times 1) + 12 + (2 \times 16) \\ + 12 + (3 \times 1) = 74 \text{ g} \end{array}\right.$$

g. mol. of methyl acetate,

CH_3COOCH_3 weigh = 74 g

Thus 1 mol of CH_3COOCH_3 weigh = 74 g

0.985 mol of CH_3COOCH_3 weigh

$$= 74 \times 0.985 = \mathbf{72.9\ g} \quad \textbf{Ans.}$$

So, the correct answer is, (*c*).

Example 209. *At 427°C, the value of K_c for the reaction, $H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$ is 54.8. If at the same temperature, 0.5 mol L^- of HI (g) is present at equilibrium, the concentration of $H_2(g)$ and $I_2(g)$ assuming that we initially started with HI(g) and allowed it to reach equilibrium at same temperature is :*

(*a*) *6.8 mol L^-* (*b*) *68 mol L^-*
(*c*) *0.068 mol L^-* (*d*) *0.34 mol L^-*

Solution. At equilibrium,

$$[H_2] = [I_2] = x \text{ (say) ; [HI] = 0.5 mol}$$

For the reaction,

$$H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$$

$$K_c = \frac{[HI]^2}{[H_2][I_2]} = \frac{0.5 \text{ mol L}^- \times 0.5 \text{ mol L}^-}{x^2}$$

$$54.8 = 0.25/x^2$$

$$\text{Or} \qquad 54.8\,x^2 = 0.25 \text{ mol}^2\text{ L}^{-2}$$

$$\text{Or} \qquad x = \left[\frac{0.25 \text{ mol}^2 \text{ L}^{-2}}{54.8}\right]^{1/2}$$

$$\therefore \qquad x = (0.00456 \text{ mol}^2 \text{ L}^-)^{1/2}$$

$$= \mathbf{0.068\ mol\ L^-} \qquad \textbf{Ans.}$$

So, the correct answer is, (*c*).

Example 210. *0.12 mol of PCl_3 are mixed with 0.9 mol of PCl_5 in a one litre vessel. The vessel contains 0.72 mol of PCl_5 at equilibrium. The value of K_c for the reaction is :*

(*a*) *0.1 mol L^-* (*b*) *0.04 mol L^-*
(*c*) *0.075 mol L^-* (*d*) *0.75 mol L^-*

Solution. Initial no. of mol of PCl_5 = 0.90 ; PCl_3 = 0.12 mol; no. of mol of PCl_5 at equilibrium = 0.72

∴ At equilibrium (*i*) no. of mol of PCl_3 = 0.12 + (0.90 – 0.72) = 0.12 + 0.18 = 0.30 mol

(*ii*) no. of mol of Cl_2

$$= 0.90 - 0.72 = 0.18 \text{ mol}$$

∴ K_c for the reaction, $PCl_5 \rightleftharpoons PCl_3 + Cl_2$ is :

$$K_c = \frac{[PCl_3][Cl_2]}{[PCl_5]} = \frac{0.3 \times 0.18}{0.72}$$

$$= \mathbf{0.075\ mol\ L^-} \qquad \textbf{Ans.}$$

So, the correct answer is, (*c*).

Example 211. *Phosphorus penta chloride is 82% dissociated into phosphorus trichloride and chlorine, all gaseous at 250°C and 1 atmospheric pressure. The equilibrium constant of dissociation is :*

(*a*) *2.577* (*b*) *3.577*
(*c*) *0.202* (*d*) *2.05*

Solution.	PCl_5 $\rightleftharpoons$	PCl_3 +	Cl_2
(*i*) *n* mol at start	1	0	0
(*ii*) Change by reaction	$-x$	x	x
(*iii*) *n* mol at equilibrium	$1-x$	x	x

Total number of mol

$$= 1 - x + x + x = 1 + x$$

$$K_p = \frac{[PCl_3][Cl_2]}{[PCl_5]}$$

$$= \frac{\left(\frac{x}{1+x}\times P\right)\left(\frac{x}{1+x}\times P\right)}{\left(\frac{1-x}{1+x}\right)P} = \frac{x^2\,P}{1-x^2}$$

$$x = 82\ \%\ \text{of 1 mol} = \frac{82}{100} \times 1 = 0.82\ ;$$

$$P = 1\ \text{atmosphere}$$

$$\therefore \quad K_p = \frac{(0.82)^2}{1-(0.82)^2} \times 1 = \frac{0.6724}{1-0.6724}$$

$$= \frac{0.6724}{0.3276} = \mathbf{2.05} \qquad \textbf{Ans.}$$

So, the correct answer is (*d*).

Example 212. *Pure PCl_5 was transferred into an evacuated vessel at 473 K. After the attainment of equilibrium, concentration of PCl_5 was found to be 0.05 mol L^{-}. If value of K_c is 8.3×10^{-3}, the concentration of Cl_2 and PCl_3 at equilibrium will be :*

(*a*) *24 mol L^{-}* (*b*) *0.24 mol L^{-}*

(*c*) *0.024 mol L^{-}* (*d*) *0.0024 mol L^{-}*

Solution. $[Cl_2] = [PCl_3] = x$ (say) ; $[PCl_5] = 0.05\ \text{mol}^{-}$

For the reaction, $PCl_5 \rightleftharpoons PCl_3 + Cl_2$, we have

Conc. at equilibrium : 0.05 mol L^{-} $\quad x \quad x$

$$\therefore \quad K_C = \frac{[PCl_3][Cl_2]}{[PCl_5]} = \frac{x \times x}{0.05}$$

$$8.3 \times 10^{-3} = \frac{x^2}{0.05}\ ;\ x^2 = 8.3 \times 10^{-3} \times 0.05$$

$$= 4.15 \times 10^{-4}$$

$$\therefore \quad x = (4.15 \times 10^{-4})^{1/2} = \mathbf{0.024\ mol\ L^{-}}$$

So, the correct answer is, (*c*).

Example 213. *The equilibrium*

$$H_2(g) + S(s) \rightleftharpoons H_2S(g),\ K = 6.8 \times 10^{-2}$$

exists at 363 K. If 0.2 mol of H_2 and 1.0 mol of sulphur are heated to 363 K in a 1.0 L vessel, the partial pressure of H_2S gas at equilibrium will be :

(*a*) *0.21 atm* (*b*) *0.21 atm^2*

(*c*) *0.42 atm* (*d*) *0.42 atm^2.*

Solution.	$H_2(g) + S(s)$ $\rightleftharpoons$	$H_2S(g)$
(*i*) *n* mol at start	0.2	0
(*ii*) Change by reaction	$-x$	x
(*iii*) *n* mol L^{-} at equilibrium	$0.2 - x$ mol/1 L = 0.2 mol L^{-}	x

($\because$ x is very small and can be rejected)

$$K_p = \frac{pH_2S}{pH_2} = \frac{x}{0.2}\ ;\ 6.8 \times 10^{-2} = \frac{x}{0.2}$$

$$\therefore \quad x = 6.8 \times 10^{-2} \times 0.2 = 1.4 \times 10^{-2}\ \text{mol L}^{-}$$

$$P(H_2S) = \left(\frac{n}{V}\right)RT = 1.4 \times 10^{-2}\ \text{mol L}^{-} \times 0.0821$$

$$\text{L atm K}^{-}\ \text{mol}^{-} \times 363\ \text{K}$$

$$P(H_2S) = \mathbf{0.42\ atm} \qquad \textbf{Ans.}$$

So, the correct answer is (*c*).

Example 214. *A container contains CO_2 gas at 0.5 atm pressure and 1000K. On the addition of some graphite, some of the $CO_2(g)$ converted into carbon monoxide. If total pressure at equilibrium is 0.8 atm, the value of equilibrium constant will be:*

(*a*) *0.8 atm* (*b*) *1.8 atm*

(*c*) *2.8 atm* (*d*) *None of these.* **(AIEEE, 2011)**

Solution. Initial pressure of CO_2 = 0.5 atm

At equilibrium ; we have :

$CO_2(g)$ +	$C(s)$ $\rightleftharpoons$	$2CO(g)$
Initial pressure		
0.5 atm	Graphite	0
Conc. at equilibrium		
$0.5 - x$	0	$2x$

Total pressure at equilibrium

$$= 0.5 - x + 2x = 0.5 + x$$

$$0.8 = 0.5 + x\ ;\ \therefore\ x = 0.8 - 0.5 = 0.3$$

$\therefore$ Partial pressure of CO_2 (g), p_{CO_2}

$$= 0.5 - x = 0.5 - 0.3 = \mathbf{0.2\ atm.}$$

Partial pressure of CO(g), p_{CO}

$$= 2x = 2 \times 0.3 = \mathbf{0.6\ atm.}$$

$$\therefore \quad K_p = \frac{(p_{CO})^2}{p_{CO_2}} = \frac{(0.6\ atm)^2}{0.2\ atm} = \frac{0.36\ \text{atm}^2}{0.2\ \text{atm}}$$

$$= \mathbf{1.8\ atm} \qquad \textbf{Ans.}$$

So, the correct answer is, (*b*).

Example 215. *If the equilibrium constants of the following equilibria, $SO_2 + 1/2\ O_2 \rightleftharpoons SO_3$ and $2SO_3 \rightleftharpoons 2SO_2 + O_2$ are given by K_1 and K_2 respectively, which of the following reactions are correct ?*

(*a*) *$K_2 = (1/K_1)^2$* (*b*) *$K_1 = (1/K_2)^3$*

(*c*) *$K_2 = 1/K_1$* (*d*) *$K_2 = (K_1)^2$.* **(WB-JEE, 2011)**

Solution. For $SO_2 + \frac{1}{2}O_2 \rightleftharpoons SO_3$, $K_1 = [SO_3]/[SO_2][O_2]$ ...(1)

For $\quad 2SO_3 \rightleftharpoons 2SO_2 + O_2$,

$$K_2 = [SO_2]^2\,[O_2]/[SO_3]^2 \qquad ...(2)$$

From (1) and (2), $K_2 = \dfrac{1}{K_1^2}$ or $K_2 = (1/K_1)^2$

So, the correct answer is (*a*).

EXAMPLE 216. *For the reaction, $N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$ at 400 K, $K_p = 41$. Find the value of K_p for the following reaction.*

$1/2\ N_2(g) + 3/2\ H_2(g) \rightleftharpoons NH_3(g)$

(a) 6.4 *(b)* 0.02

(c) 50 *(d)* 4.6 **(J and K CET, 2010)**

SOLUTION. For $N_2(g) + 3\ H_2(g) \rightleftharpoons 2NH_3$

$$K_p = [p_{NH_3}]^2/[p_{N_2}]\ [p_{H_2}]^3 = 41\ ;$$

$$p_{NH_3} = K_p\ [p_{N_2}]\ [p_{H_2}]^3 \qquad ...(1)$$

For $1/2\ N_2(g) + 3/2\ H_2(g) \rightleftharpoons NH_3(g)$

$$K_p' = [p_{NH_3}]/[p_{N_2}]^{1/2}[p_{H_2}]^{3/2} \qquad ...(2)$$

Putting value of (1) in (2), we get :

$$K_p' = (K_p\ p_{N_2} p_{H_2}^3)^{1/2}/p_{N_2}^{1/2}\ p_{H_2}^{3/2} = (41)^{1/2}$$

$= 6.4$. So, correct answer is *(a)*.

EXAMPLE 217. *The value of K_c for the reaction $H_2O\ (g) + CO(g) \rightleftharpoons CO_2(g) + H_2(g)$ at 298 K from the following data*

$$2CO(g) + O_2(g) \rightleftharpoons 2CO_2(g)\ ;\ K_{c_1} = 3.3 \times 10^{91}$$

$$2H_2(g) + O_2(g) \rightleftharpoons 2H_2O(g)\ ;$$

$$K_{c_2} = 9.1 \times 10^{80} \text{ at } 298K \text{ is :}$$

(a) 2.3×10^4 *(b)* 1.9×10^5

(c) 3.1×10^2 *(d)* 1.9×10^{17}

SOLUTION. Given :

$$2CO(g) + O_2(g) \rightleftharpoons 2CO_2(g) \qquad ...(1)$$

$$2H_2(g) + O_2(g) \rightleftharpoons 2H_2O(g) \qquad ...(2)$$

In order to get $H_2O(g) + CO(g) \longrightarrow CO_2(g) + H_2(g)$, we have :

$$2CO(g) + O_2(g) \rightleftharpoons 2CO_2(g)\ ;$$

$$K_{C_1} = 3.3 \times 10^{91}$$

Or $$CO(g) + \frac{1}{2}O_2(g) \rightleftharpoons CO_2(g)\ ;$$

$K_C' = (K_{C_1})^{½}$ because

When an equation is divided by 2,

new K_C' value $= (K_{C_1})^{½}$

Similarly, write equation (ii) in the reverse direction. So,

$$2H_2O(g) \rightleftharpoons 2H_2(g) + O_2(g)\ ;$$

$$K_{C_2}'' = \frac{1}{K_{C_2}}$$

Or $$H_2O(g) \rightleftharpoons H_2(g) + \frac{1}{2}O_2(g)\ ;$$

$$K_C'' = \left(\frac{1}{K_{C_2}}\right)^{1/2}$$

because when an equation is divided by 2,

new K_c'' value $= \left(\frac{1}{K_{C_2}}\right)^{1/2}$

Hence net K value is given as :

$$K = K_C' \times K_C'' = \left(\frac{1}{K_{C_1}}\right)^{1/2} \times \left(\frac{1}{K_{C_2}}\right)^{1/2}$$

$$= \left(\frac{3.3 \times 10^{91}}{9.1 \times 10^{80}}\right)^{1/2}$$

$K =$ antilog 5.28 $=$ **1.9×10^5** **Ans.**

So, the correct answer is *(b)*.

EXAMPLE 218. *Iodine vapours contain 40 % by volume of iodine atoms at total pressure of 10^5 Pa and at a certain temperature. The value of K_p for the equilibrium $I_2(g) \rightleftharpoons 2I(g)$ will be :*

(a) 2.67×10^4 *(b)* 0.267×10^4

(c) 5.34×10^8 *(d)* 53.4×10^7

SOLUTION. Iodine vapours contain I–atoms. So, partial pressure of I– atoms

$$= \frac{40}{100} \times 10^5\ Pa = 4.0 \times 10^4\ Pa$$

Also : partial pressure of I_2 – molecules

$$= \frac{(100 - 40)}{100} \times 10^5\ Pa$$

$$= \frac{60}{100} \times 10^5\ Pa$$

$$= 6.0 \times 10^4\ Pa.$$

For the reaction

$$I_2(g) = 2I(g),$$

$$K_p = \frac{[p_I(g)]^2}{(p_{I_2})} = \frac{(4.0 \times 10^4)^2}{6.0 \times 10^4} = \frac{16 \times 10^8}{6.0 \times 10^4}$$

$= \mathbf{2.67 \times 10^4}$ **Ans.**

So, the correct answer is, *(a)*.

EXAMPLE 219. *At 500K, bromine monochloride (BrCl) decomposes to give bromine and chlorine according to the following equilibrium*

$$2BrCl \rightleftharpoons Br_2(g) + Cl_2(g)\ ;\ K_c = 32 \text{ at } 500K$$

If the concentration of BrCl in the beginning was 3.3×10^{-3} mol L^-, its concentration in the mixture at equilibrium will be :

(a) 2.92×10^{-3} *(b)* 2.0×10^{-4}

(c) 6.0×10^{-8} *(d)* 2.92×10^{-4}

SOLUTION. For the following reaction, we have :

2BrCl ⇌	$Br_2(g)$ +	$Cl_2(g)$
Initial conc.		
3.3×10^{-3}	0	0
Conc. at equilibrium		
x	$\frac{1}{2} \times 3.3 \times 10^{-3}$	$\frac{1}{2} \times 3.3 \times 10^{-3}$
	$= 1.65 \times 10^{-3}$	$= 1.65 \times 10^{-3}$

Where $x =$ molar concentration of the mixture at equilibrium.

$$\therefore \quad K_C = \frac{[Br_2]\ [Cl_2]}{[BrCl]^2}$$

$$= \frac{(1.65 \times 10^{-3}) \times (1.65 \times 10^{-3})}{x^2}$$

$$32 = \frac{1.65\times10^{-3}\times1.65\times10^{-3}}{x^2}\ ;$$

$$32x^2 = 1.65\times10^{-3}\times1.65\times10^{-3}$$

$$\therefore \qquad x^2 = \frac{(1.65\times10^{-3})^2}{32}\ ;\ x = \frac{[(1.65\times10^{-3})^2]^{1/2}}{(32)^{1/2}}$$

$$= \frac{1.65\times10^{-3}}{5.656}$$

$$= \mathbf{2.92\times10^{-4}\ mol} \qquad \textbf{Ans.}$$

So, the correct answer is, (*d*).

EXAMPLE 220. *At a total pressure of one atmosphere, SO_2Cl_2 decomposes to the extent of 91.2 % at 102°C according to the reaction.*

$$SO_2Cl_2(g) \rightleftharpoons SO_2(g) + Cl_2(g)$$

The value of K_p for the reaction would be :

(*a*) 494 (*b*) 49.4

(*c*) 4.94 (*d*) 0.494

SOLUTION. Total pressure = 1 atm ; % age decomposition of SO_2Cl_2 = 91.2. Initial concentration of SO_2Cl_2 = 1 mol. Thus for the following reaction, we have :

	$SO_2Cl_2(g) \rightleftharpoons$	$SO_2(g)$	$+Cl_2(g)$
Initial conc.	1 mol	0	0
Conc. at equilibrium	$1-\frac{91.2}{100}$ = 0.088	$1\times\frac{91.2}{100}$ = 0.912	$\frac{1\times91.2}{100}$ = 0.912

Total number of mol

$$= 0.08 + 0.912 + 0.912 = 1.912$$

$$K_p = \frac{\left(\dfrac{p_{SO_2}\times P}{\text{Total mol}}\right)\times\left(\dfrac{P_{Cl_2}\times P}{\text{Total mol}}\right)}{\left(\dfrac{p_{SO_2Cl_2}\times P}{\text{Total mol}}\right)}$$

$$= \frac{\dfrac{0.912\times1}{1.912}\times\dfrac{0.912\times1}{1.912}}{\dfrac{0.088\times1}{1.912}}$$

$$= \frac{0.477\times0.477}{0.046} = \mathbf{4.94} \qquad \textbf{Ans.}$$

So, the correct answer is, (*c*).

EXAMPLE 221. *For a reaction of the type, $AB \rightleftharpoons A + B$, the total pressure at which AB gets 50% dissociated will be numerically equal to*

(*a*) 2 Kp (*b*) 3 Kp

(*c*) 4 Kp (*d*) 0.5 Kp.

(Modified PUPET 1986)

SOLUTION. For the following reaction,

total pressure = P (say).

	AB $\rightleftharpoons$	A +	B
no. of mol at equilibrium	$\frac{50}{100}=\frac{1}{2}$	$\frac{50}{100}=\frac{1}{2}$	$\frac{50}{100}=\frac{1}{2}$

$$\text{Total no. of mol} = \frac{1}{2}+\frac{1}{2}+\frac{1}{2}=\frac{3}{2}$$

Partial pressure of a component in a mixture

$$= \frac{\text{no. of mol of component}}{\text{Total no. of mol at equilibrium}}\times P \text{ total}$$

$$\therefore \qquad p_A = \frac{\frac{1}{2}}{\frac{3}{2}}\times P = \frac{1}{2}\times\frac{2}{3}\times P = \frac{1}{3}P$$

Since $\qquad p_A = p_B,$ so $\ p_B = \frac{1}{3}P$;

$$p_{AB} = \frac{\frac{1}{2}}{\frac{3}{2}}\times P = \frac{1}{2}\times\frac{2}{3}\times P = \frac{1}{3}P$$

But $\qquad K_p = \dfrac{[A][B]}{[AB]} = \dfrac{\frac{P}{3}\times\frac{P}{3}}{\frac{P}{3}} = \dfrac{P}{3}$

$$\therefore \qquad P = \mathbf{3\ Kp} \qquad \textbf{Ans.}$$

So, the correct answer is, (*b*).

EXAMPLE 222. *For the reaction at equilibrium, $N_2O_4(g) \rightleftharpoons 2NO_2(g)$, the concentrations of N_2O_4 and NO_2 at equilibrium are 4.8×10^{-2} and 1.2×10^{-2} mol L^{-} respectively. The value of K_c for the reaction is :*

(*a*) 3×10^{3} mol L^{-} (*b*) 3.3×10^{2} mol L^{-}

(*c*) 3×10^{-1} mol L^{-} (*d*) 3×10^{-3} mol L^{-} **(AIEEE, 2003)**

SOLUTION. $N_2O_4(g) \rightleftharpoons 2NO_2(g)$

Rate of forward reaction, $K_f \propto [N_2O_4]$ ...(1)

Rate of backward reaction, $K_b \propto [NO_2]^2$ ...(2)

At equilibrium,

$$K_f = K_b$$

$$K_c = \frac{[\text{Products}]}{[\text{Reactants}]} = \frac{[NO_2]^2}{[N_2O_4]}$$

Substituting the values we get :

$$K_c = \frac{1.2\times10^{-2}\text{ mol } L^{-}\times1.2\times10^{-2}\text{ mol } L^{-}}{4.8\times10^{-2}\text{ mol } L^{-}}$$

$$= \mathbf{3.0\times10^{-3}\ mol\ L^{-}} \qquad \textbf{Ans.}$$

Hence, the correct answer is (*d*).

EXAMPLE 223. *For the reaction, $CO(g) + \frac{1}{2}O_2(g) \longrightarrow CO_2(g)$, K_p/K_c* is :

(*a*) *RT* (*b*) $(RT)^{-1}$

(*c*) $(RT)^{-1/2}$ (*d*) $(RT)^{1/2}$ **(AIEEE, 2002)**

SOLUTION.

$$CO(g) + \frac{1}{2}O_2(g) \longrightarrow CO_2(g)$$

$$1\text{ mol} \qquad \frac{1}{2}\text{ mol} \qquad 1\text{ mol}\ ;$$

$$\Delta n = 1-\left(1+\frac{1}{2}\right) = 1-1-\frac{1}{2} = -\frac{1}{2}$$

But $K_p = K_c\,(RT)^{\Delta n}$ or $\dfrac{K_p}{K_c} = (RT)^{\Delta n}$

$$\therefore \quad \frac{K_p}{K_c} = (RT)^{-1/2}$$

So, the correct answer is, (*c*).

EXAMPLE 224. *4 moles of CO_2 were heated in 1 dm^3 vessel under conditions which produced at equilibrium 25 % dissociation into carbon monoxide and oxygen. The number of moles of carbon monoxide produced was :*

(a) 0.5 *(b) 1.0*
(c) 1.5 *(d) 2.0*

SOLUTION. Reaction.

$$\begin{array}{llll} & CO_2(g) & \rightleftharpoons CO(g) & + \frac{1}{2}O_2(g) \\ \text{Initial conc.} & 4 \text{ mol} & 0 & 0 \\ \text{At equilibrium} & 4 - \left(4 \times \frac{25}{100}\right) & 4 \times \frac{25}{100} = 1.0 & \end{array}$$

From above we see that number of carbon monoxide produced = 1 mol.

So, the correct answer is, (*b*).

EXAMPLE 225. *For a reaction, $SO_2(g) + \frac{1}{2}O_2(g) \longrightarrow SO_3(g)$, $K_p = 1.7 \times 10^{12}$ at 20°C and 1 atmospheric pressure. The value of K_c will be :*

(a) 7.0×10^{11} *(b) 7.98×10^{12}*
(c) 8.33×10^{9} *(d) 8.33×10^{12}*

SOLUTION. T = 20 + 273 = 293 K ; R = 0.0821 L atm (degree)⁻ mol⁻

$$\begin{array}{llll} \text{For} & SO_2(g) + \frac{1}{2}O_2(g) & \longrightarrow SO_3(g) \\ & 1 \text{ mol} \quad \frac{1}{2}\text{mol} & 1\text{mol} \end{array}$$

$$\Delta n = n_P - n_R = 1 - \left(1 + \frac{1}{2}\right) = -\frac{1}{2}\text{ mol}$$

we know $K_p = K_c(RT)^{\Delta n}$

$$\therefore \quad K_c = \frac{K_p}{(RT)^{\Delta n}} = \frac{1.7 \times 10^{12}}{(0.0821 \times 293)^{-1/2}}$$

$$= 1.7 \times 10^{12} \times (0.0821 \times 293)^{1/2}$$

$$= 1.7 \times 10^{12} \times 4.9 = \mathbf{8.33 \times 10^{12}}\ \textbf{Ans.}$$

So, the correct answer is, (*d*).

EXAMPLE 226. *For which of the following shall the ratio of K_p/K_c is unity at 300 K and 1 atmospheric pressure ?*

(a) $N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$
(b) $N_2(g) + O_2(g) \rightleftharpoons 2NO(g)$
(c) $SO_2(g) + \frac{1}{2}O_2(g) \rightleftharpoons SO_3(g)$
(d) $PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$

SOLUTION. We know

$$K_p = K_c\,(RT)^{\Delta n} \quad \text{or} \quad K_p/K_c = (RT)^{\Delta n}$$

K_p/K_c will be equal to unity (*i.e.*, 1) when

$$\Delta n = \text{zero}$$

$\Delta n = n_P - n_R$ for reaction (*a*)

$$= 2 - (1 + 3) = -2\,;$$

for reaction (*b*), $\Delta n = 2 - (1 + 1) = 0$; for reaction (*c*),

$\Delta n = 1 - \left(1 + \frac{1}{2}\right) = -\frac{1}{2}$ and for reaction(*d*),

$$\Delta n = 1 + 1 - 1 = 1.$$

So, for reaction (*b*),

$$K_p/K_c = (RT)^{\circ} = 1.$$

Hence, the correct answer is (*b*).

EXAMPLE 227. *A mixture of NO_2 and N_2O_4 has vapour density 38.5. How many mol of NO_2 are present in 100 g of mixture.*

(a) 0.42 *(b) 4.4*
(c) 33.4 *(d) 3.34*

SOLUTION. Mol. wt. of NO_2 and N_2O_4

$$= 2 \times \text{V.D.} = 2 \times 38.5 = 77$$

Mass of NO_2 in the mixture = *a* g

∴ Mass of N_2O_4 in the mixture = (100 – *a*) g;

Mol. wt. of NO_2 = 14 + (2 × 16) = 46 ;

∴ no. of mol of $NO_2 = \dfrac{a}{46}$

Mol. wt. of N_2O_4 = (2 × 14) + (4 × 16) = 92

∴ no. of mol of $N_2O_4 = \dfrac{100 - a}{92}$

Total no. of mol of mixture $= \dfrac{\text{wt.}}{\text{mol. wt.}} = \dfrac{100}{77}$

$$\therefore \quad \frac{a}{46} + \frac{100 - a}{92} = \frac{100}{77}$$

$$\frac{92a + 4600 - 46a}{46 \times 92} = \frac{100}{77}\ ;\ 46a = \left(\frac{100 \times 46 \times 92}{77}\right)$$

$$-4600 = 5496 - 4600 = 896$$

$$\therefore \quad a = \frac{896}{46} = 19.48$$

$$\therefore \quad \text{No. of mol of } NO_2 = \frac{19.48}{46} = \mathbf{0.42}$$

So, the correct answer is (*a*).

EXAMPLE 228. *For $2A_2(g) + 2B_2(g) \rightleftharpoons 2A_2B_2(g)$, the heat is evolved. The mass of A_2B_2 increases at equilibrium by :*

(a) increasing the total pressure
(b) increasing the temperature
(c) using a catalyst
(d) decreasing the total pressure.

SOLUTION. The reaction $2A_2(g) + 2B_2(g) \rightleftharpoons 2A_2B_2(g)$ is exothermic and is accompanied by decrease in the number of moles from 4(= 2 + 2) to 2 moles. So, low temperature and increase in total pressure will favour the forward reaction. Hence, correct answer is (*a*).

EXAMPLE 229. *For any two reactions, activation energies are E_1 and E_2 respectively. If $E_1 > E_2$, and temperature of the reacting system is increased from T_1 to T_2, then the correct answer is:*

(*a*) $\frac{K_1}{K'_1} = \frac{K_2}{K'_2}$ (*b*) $\frac{K'_1}{K_1} < \frac{K'_2}{K_2}$

(*c*) $\frac{K'_1}{K_1} > \frac{K'_2}{K_2}$ (*d*) $\frac{K'_1}{K_1} = \frac{K'_2}{K_2}$

SOLUTION. The value of equilibrium constant K depends upon temperature. Since $E_1 > E_2$, the first reaction is endothermic. By increase of temperature from T_1 to T_2, the value of K is also increased. So, K'_2/K_2 will become more than K'_1/K if temperature is increased by equal values. So, $(K'_1/K_1) < (K'_2/K_2)$ and correct answer is (*b*).

EXAMPLE 230. *In the reaction $AB(g) \rightleftharpoons A(g) + B(g)$ at 30°C, K_p for the dissociation equilibrium is 2.56×10^{-2} atm. If the total pressure at equilibrium is 1 atm, then the percentage dissociation of AB is*

(*a*) *87 %* (*b*) *13 %*

(*c*) *43.5 %* (*d*) *6 %*

(*e*) *16 %* **(Kerala PMT, 2011)**

SOLUTION.

Given reaction	$AB(g) \rightleftharpoons$	$A(g)$ +	$B(g)$
At start	P	0	0
Change by reaction	$-P\alpha$	$P\alpha$	$P\alpha$
At equilibrium	$P - P\alpha$	$P\alpha$	$P\alpha$
	$= P(1-\alpha)$		

$$\therefore \quad K_p = \frac{[A(g)][B(g)]}{[AB(g)]} = \frac{P\alpha \times P\alpha}{P(1-\alpha)} = \frac{P\alpha^2}{1-\alpha}$$

Substituting the values, we get :

$$2.56 \times 10^{-2} = 1 \times \alpha^2$$

[α being very small, it can be neglected in the denominator]

or $\alpha = [2.56 \times 10^{-2}]^{1/2} = 0.16$

% age dissociation

$$= 0.16 \times 100 = 16\ \%.$$

So, the correct answer is (*e*).

EXAMPLE 231. *The equilibrium constant for the reaction*

$$SO_3(g) \rightleftharpoons SO_2(g) + \frac{1}{2}O_2(g)$$

is $K_c = 4.9 \times 10^{-2}$. The value of K_c for the reaction

$$2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g) \text{ will be}$$

(*a*) *416* (*b*) *2.40×10^{-3}*

(*c*) *9.8×10^{-2}* (*d*) *4.9×10^{-2}* **(AIEEE, 2006)**

SOLUTION. K_c for $SO_3(g) \rightleftharpoons SO_2(g) + \frac{1}{2}O_2(g)$ is given as :

$$K_c = \frac{[SO_2][O_2]^{1/2}}{[SO_3]} = 4.9 \times 10^{-2} \qquad ...(1)$$

$$K'_c \text{ for } SO_2(g) + \frac{1}{2}O_2(g) \rightleftharpoons SO_3(g) \text{ will be } \frac{1}{4.9 \times 10^{-2}} \qquad ...(2)$$

$\therefore$ For $2SO_2 + O_2 \rightleftharpoons 2SO_3(g)$

$$(K'_1)^2 = \frac{[SO_3]^2}{[SO_2]^2[O_2]} = \left(\frac{1}{4.9 \times 10^{-2}}\right)^2$$

$$= \frac{10^4}{24.01} = \mathbf{416.49}$$

So, the correct answer is (*a*).

EXAMPLE 232. *$2HI(g) \rightleftharpoons H_2(g) + I_2(g)$*

The equilibrium constant for the above reaction is 6.4 at 300 K. If 0.25 mole each of H_2 and I_2 are added to the system, the equilibrium constant will be :

(*a*) *0.8* (*b*) *3.2*

(*c*) *1.6* (*d*) *6.4* **(Karnataka CET, 2009)**

SOLUTION. The value of equilibrium constant does not change even on changing the concentration of the reaction system. So, the correct answer is (*d*).

EXAMPLE 233. *For the reaction $C(s) + CO_2(g) \longrightarrow 2CO(g)$, $K_p = 63$ atm at 1000 K. If at equilibrium, $P_{CO} = 10\ P_{CO_2}$, then the total pressure of the gases at equilibrium is*

(*a*) *6.3 atm* (*b*) *6.93 atm*

(*c*) *0.63 atm* (*d*) *0.693 atm*

(*e*) *69.3 atm* **(Kerala PMT, 2011)**

SOLUTION. Given reaction : $C(s) + CO_2(g) \longrightarrow 2CO(g)$

$$\therefore \quad K_p = \frac{(P_{CO})^2}{[P_{CO_2}]};\ 63 = \frac{(10\ P_{CO_2})^2}{P_{CO_2}};$$

$$63 = \frac{100\ P_{CO_2}^2}{P_{CO_2}}$$

Or $63 = 100\ P_{CO_2};\ P_{CO_2} = \frac{63}{100} = 0.63$ atm.

$$P_{CO} = 10\ P_{CO_2} = 10 \times 0.63 = 6.3 \text{ atm.}$$

$$\therefore \quad P_{total} = P_{CO} + P_{CO_2} = 0.63 + 6.3 = 6.93 \text{ atm.}$$

So, the correct answer is (*b*).

EXAMPLE 234. *Given that the equilibrium constant for the reaction:*

$$2SO_2(g) + O_2(g) \rightleftharpoons 2\ SO_3(g)$$

has a value of 278 at a particular temperature. What is the value of equilibrium constant for the following reaction at the same temperature?

$$SO_3(g) \rightleftharpoons SO_2(g) + \frac{1}{2}O_2(g)$$

(*a*) *1.8×10^{-3}* (*b*) *3.6×10^{-3}*

(*c*) *6.0×10^{-2}* (*d*) *1.3×10^{-5}*

(AIPMT Mains, 2012)

SOLUTION. For $2SO_2(g) + O_2(g) \rightleftharpoons 2\ SO_3(g)$ ...(*i*), $K = 278$

On reversing the above equation, we get:

$$2SO_3(g) \rightleftharpoons 2SO_2(g) + O_2(g) \qquad ...(ii)$$

K' for this reaction $= 1/K = 1/278$

On dividing equation (*ii*) by 2, we get:

$$SO_3(g) \rightleftharpoons SO_2(g) + \frac{1}{2}O_2(g) \qquad ...(iii)$$

∴ The value of K for this reaction will be:

$$K'' = (K')^{1/2} = \left(\frac{1}{K}\right)^{1/2} = \left(\frac{1}{278}\right)^{1/2} = 0.06 = 6 \times 10^{-2}.$$

So, the correct answer is (*c*).

EXAMPLE 235. *Given the reaction between two gases represented by A_2 and B_2 to give the compound AB(g).*

$A_2(g) + B_2(g) \rightleftharpoons 2AB(g)$

At equilibrium, the concentration of $A_2 = 3.0 \times 10^{-3}$ M; of $B_2 = 4.2 \times 10^{-3}$ M and of AB = 2.8×10^{-3}M. If the reaction takes place in a sealed vessel at 527°C, then the value of K_c will be:

(*a*) 2.0 (*b*) 1.9

(*c*) 0.62 (*d*) 4.5

(AIPMT, Mains, 2012)

SOLUTION. $A_2(g) + B_2(g) \rightleftharpoons 2AB(g)$

$$\therefore K_c = \frac{[AB]^2}{[A_2][B_2]} \qquad ...(i)$$

Substituting the values in equation (*i*), we get:

$$K_c = \frac{(2.8 \times 10^{-3})^2}{(3.0 \times 10^{-3})(4.2 \times 10^{-3})} = \frac{2.8 \times 2.8}{3.0 \times 4.2} = 0.62.$$

So, the correct answer is (*c*).

EXAMPLE 236. *In the equilibrium $2A \rightleftharpoons B + C$, the equilibrium concentrations of A, B and C at 300K are 3×10^{-4} M, 1×10^{-4} M and 4.5×10^{-4} respectively. The value of Kc for the above equilibrium at 300 K is:*

(*a*) 0.5 (*b*) 0.05

(*c*) 5.0 (*d*) 1.5

(*e*) 0.2 **(Kerala PMT, 2012)**

SOLUTION. Given equilibrium is: $2A \rightleftharpoons B + C$. So:

$$K_c = \frac{[B][C]}{[A]^2};\ [A] = 3 \times 10^{-4}\ M;\ [B] = 1 \times 10^{-4}\ M;$$

$$[C] = 4.5 \times 10^{-4}\ M$$

Substituting these values, we get:

$$K_c = \frac{10^{-4} \times 4.5 \times 10^{-4}}{3 \times 10^{-4} \times 3 \times 10^{-4}} = 0.5.$$

So, the correct answer is (*a*).

EXAMPLE 237. *In the following equilibrium reaction,*

$$2A \rightleftharpoons B + C$$

the equilibrium concentrations of A, B and C are 1×10^{-3} M, 2×10^{-3} M and 3×10^{-3} M respectively at 300 K. The value of K_c for this equilibrium at the same temperature is:

(*a*) 1/6 (*b*) 6

(*c*) 1/36 (*d*) 36

(*e*) 1/24 **(Kerala PET, 2012)**

SOLUTION. For $2A \rightleftharpoons B + C$, $K_c = \frac{[B][C]}{[A]^2}$ ...(1)

Substituting the values of

A (= 10^{-3}), B (= 2×10^{-3}) and C (= 3×10^{-3}) in equation (1), we get:

$$K_c = \frac{2 \times 10^{-3} \times 3 \times 10^{-3}}{(10^{-3})^2} = 6.$$

So, the correct answer is (*b*).

EXAMPLE 238. *Calculate the solubility of lead chloride in water, if its solubility product is 1.7×10^{-5}.*

(ISC, 2012)

SOLUTION. $PbCl_2 \rightleftharpoons Pb^{2+} + 2\,Cl^-$

Solubility S S 2S

∴ Solubility product, $K_{sp} = [Pb^{2+}]\,[Cl^-]^2$

$$1.7 \times 10^{-5} = S \times (2S)^2 = 4S^3$$

$$\therefore S = \left(\frac{1.7 \times 10^{-5}}{4}\right)^{1/3}$$. Taking logs of both sides,

We get:

$$\log S = \log\left(\frac{1.7 \times 10^{-5}}{4}\right)^{1/3} = \frac{1}{3}\left[\log 1.7 + \log 10^{-5} - \log 4\right]$$

$$= \frac{1}{3}[0.2304 - 5 - 0.6020] = \frac{1}{3} \times -5.3716 = 1.7905$$

$$= +1 - 1 - 1 - 0.7905 = \bar{2}.2095$$

Taking antilog of both sides, we get:

$S = \text{antilog}\ \bar{2}.2095 = 0.0162\ g\ L^-$ **Ans.`**

PROBLEMS FOR PRACTICE

1. Give the conditions under which the following reaction proceeds in the forward direction.

(*i*) $PCl_5\,(g) + x\,k\,cal \rightleftharpoons PCl_3\,(g) + Cl_2\,(g)$

(*ii*) $N_2(g) + 3H_2\,(g) \rightleftharpoons 2NH_3\,(g) + 23\ k\ cal$

(*iii*) $2SO_2\,(g) + O_2\,(g) \rightleftharpoons 2\,SO_3\,(g) + 45\ k\ cal$

(*iv*) $N_2\,(g) + O_2\,(g) \rightleftharpoons 2\,NO\,(g) - 43.2\ k\ cal.$

Ans. (*i*)Low *P*, high *T*, excess of PCl_5 (g)

(*ii*) High *P*, low *T*, excess of N_2 and H_2

(*iii*) High *P*, low *T*, excess of SO_2 and O_2

(*iv*) Any *P*, high *T*, excess of O_2 and N_2

2. When 1 mol of ethyl alcohol is mixed with 2.0 mol of acetic acid, 0.428 mol of ester is formed. Will the equilibrium be reached ? K = 4

[Ans. Q = 0.2. So, equilibrium will not reach].

3. What is the percentage decomposition of H_2S if 1.0 mol of H_2S is introduced into a 1.1 litre vessel at 1000°C. K_c for the reaction, $2H_2S\,(g) \rightleftharpoons 2H_2\,(g) + S_2\,(g)$ is 1.0×10^{-6}

[Ans. % age dissociation = 1.3 %] **(Roorkee, 1984)**

4. 16.2 g mol of H_2 and 5.88 g mol of I_2 were heated at constant volume at 444°C, when at equilibrium 11.28 mol of HI are formed. Calculate the equilibrium constant of the reaction. **(UP, 1983)**

[Ans. K = 50.2]

5. For a gaseous phase reaction, $A + 2B \rightleftharpoons AB_2$, $K_c = 0.3475\ L^2\ mol^{-2}$ at 573 K. When 2.0 mol of B are mixed with one mol of A, what total pressure would be needed to convert 60% of A to AB_2 ?

[Hint and Ans.	A	$+\ 2B \rightleftharpoons$	AB_2
no. of mol at $t = 0$	1	2	0
no. of mol at equilibrium	$1 - x$	$2 - 2x$	x

Total no. of mol at equilibrium = $1 - x + 2 - 2x + x = 3 - 2x$

Let P = Pressure at equilibrium

$$\therefore \qquad P'_{AB_2} = \frac{xP}{3-2x};\ P'_A = \frac{(1-x)P}{3-2x};\ P'_B = \frac{(2-2x)P}{3-2x}$$

$$\therefore \qquad K_p = \frac{[AB_2]}{[A][B]}$$

$$= \frac{\dfrac{xP}{3-2x}}{\dfrac{(1-x)P}{3-2x} \times \left(\dfrac{2-2x}{3-2x}\right)^2 P^2}$$

$$= \frac{(3-2x)^2\, x}{(1-x)(2-2x)^2\, P^2} \qquad \textbf{Ans.}$$

6. If the weight of KI and KI_3 at equilibrium in the reaction $KI + I_2 \rightleftharpoons KI_3$ are 1.326g and 0.105g respectively, then calculate the value of K_C. The number of mol of free I_2 at equilibrium is 0.0025 and the volume of solution is $10^3\ cm^3$. (At. wt. K = 39, I = 127). **[Ans. 0.0323]**

Since KI has fully reacted with I_2 and free I_2 will be in the solid state, so $[I_2]$ is taken as constant.

7. Consider the equilibrium reaction $X + Y \rightleftharpoons P + Q$. X and Y are mixed in a vessel at temperature, T. The concentration of X at $t = 0$ is twice the concentration of Y. After the equilibrium has been reached, the concentration of P was three times the equilibrium concentration of Y. Find the value of K_c.

[Ans. $K_c = 1.8$]

8. One mole of FeO(s) and one mole of CO(g) were treated in a closed vessel at 1000°C and the value of Kp was found to be 0.4. The products were $CO_2(g)$ and Fe(s). If CO(g) at one atm and excess FeO(s) are placed in a container at 1000°C, calculate the pressure of CO(g) and $CO_2(g)$ when equilibrium is established.

[Ans. $p_{CO} = 0.714$ atm ; $p_{CO_2} = 0.286$ atm.**]**

9. For which of the reactions, $K_p = K_c$?

(*a*) $H_2 + I_2 \rightleftharpoons 2HI$ (*b*) $PCl_3 + Cl_2 \rightleftharpoons PCl_5$

(*c*) $2SO_2 + O_2 \rightleftharpoons 2SO_3$ (*d*) $N_2 + 3H_2 \rightleftharpoons 2NH_3$

[Bihar CECE, 2010] (Ans. (a))

10. Calculate the value of K_c for the equilibrium reaction:

$2NOCl(g) \rightleftharpoons 2NO(g) + Cl_2(g), K_p = 1.8 \times 10^{-2}$ at 500 K.

11. Find the value of K_p for the equilibrium reaction :

$CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g), K_c = 1.87$ at 1073 K.

[Ans. 164.7]

12. One litre of a solution contains 30 g acetic acid. Calculate its active mass. **[UP 1989]**

[Ans. 0.5 g mol L^{-}]

13. Consider the following gaseous equilibria with equilibrium constants K_1 and K_2 respectively.

$$SO_2(g) + 1/2\, O_2(g) \rightleftharpoons SO_3(g)\ ;$$
$$2SO_3(g) \rightleftharpoons 2SO_2(g) + O_2(g).$$

The equilibrium constants are related as:

(*a*) $K_1^2 = 1/K_2$ (*b*) $2K_1 = K_2^2$

(*c*) $K_2 = 2/K_1^2$ (*d*) $K_2^2 = 1/K_1$

[Kerala CET, 2010]

[Ans. (*a*)]

14. For a reaction, $A + 2B \longrightarrow C$, the amount of C formed by starting the reaction with 5 mol of A and 8 mol of B is :

(*a*) 5 mol (*b*) 8 mol

(*c*) 16 mol (*d*) 4 mol

(*e*) 1 mol **[Kerala PMT, 2010]**

24

CHAPTER

Ionic Equilibrium

24.1 SOLUBILITY

Maximum amount of one phase (solute) dissolved by another (solvent) under specified temperature and pressure is called the solubility of the solute.

Type. The solubility of a solute per 100 g of the solvent

$$= \frac{\text{wt. of solute}}{\text{wt. of solvent}} \times 100 .$$

EXAMPLE 1. *A saturated solution weighing 15.2 g gave 3.2g of dry solute. Calculate the solubility of salt.*

SOLUTION. wt. of solute = 3.2 g ; wt. of salt + water (solvent) = 15.2 g

$\therefore$ wt. of solvent = 15.2 – 3.2 = 12.0 g.

$\therefore$ Solubility of salt in 100 g solvent

$$= \frac{3.2}{12} \times 100 = \mathbf{26.7\ g} \qquad \textbf{Ans.}$$

EXAMPLE 2. *A solution of sodium carbonate weighs 6.0 g at 30°C. This solution required 32.8 mL of $\frac{N}{5}$ HCl for complete neutralisation. Calculate the solubility of sodium carbonate at this temperature.*

SOLUTION. 6.0 g Na_2CO_3 (aq) ≡ 32.8 mL of N/5 HCl.

$\therefore$ 32.8 mL of N/5 HCl ≡ 32.8 mL N/5 Na_2CO_3

But 1000 mL of 1N Na_2CO_3 ≡ 53 g Na_2CO_3

$$\left[\because \text{Eq. wt. of } Na_2CO_3 = \frac{\text{Mol. wt}}{2} = \frac{106}{2} = 53\right]$$

$$\therefore \quad 32.8 \text{ mL of N/5 } Na_2CO_3 \equiv \frac{53}{1000} \times 32.8 \times \frac{1}{5} = 0.348 \text{ g}$$

$\therefore$ wt. of Na_2CO_3 in solution = 0.348 g

wt. of Na_2CO_3 solution = 6.0 g

$\therefore$ wt. of solvent = 6.0 – 0.348 = 5.652 g

$\therefore$ Solubility of Na_2CO_3 in 100 g solvent

$$= \frac{0.348}{5.652} \times 100 = \mathbf{6.16\ g} \qquad \textbf{Ans.}$$

EXAMPLE 3. *15.0 g of a solution of $FeSO_4.7H_2O$ is diluted with water to 100 mL. 20 mL of this solution required 22.1 mL of 0.1 N $KMnO_4$ for complete oxidation. Calculate the solubility of $FeSO_4.7H_2O$. (At. wt. Fe = 56, S = 32, O = 16, H = 1)*

SOLUTION. g. eq. wt. of $FeSO_4.7H_2O$

$$= \frac{56 + 32 + (4 \times 16) + 7(18)}{1} = 278 \text{ g}$$

20 mL of dilute $FeSO_4.7H_2O$ solution

≡ 22.1 mL of N/10 $KMnO_4$.

$\therefore$ 100 mL of dilute $FeSO_4.7H_2O$ solution

$$\equiv \frac{22.1}{20} \times 100 = 110.5 \text{ mL of N/10 } KMnO_4$$

$\therefore$ 15 g solution of $FeSO_4.7H_2O$

≡ 110.5 mL of N/10 $KMnO_4$

Also,110.5 mL N/10 $KMnO_4$

≡ 110.5 mL of N/10 $FeSO_4.7H_2O$.

But1000 mL of 1N $FeSO_4$. $7H_2O$

= 278 g $FeSO_4.7H_2O$

$\therefore$ 110.5 mL of N/10 $FeSO_4$. $7H_2O$

$$= \frac{278}{1000} \times 110.5 \times \frac{1}{10} = 3.072 \text{ g}$$

$\therefore$ wt. of $FeSO_4.7H_2O$ = 3.072 g

wt. of $FeSO_4.7H_2O$ solution = 15.0 g

$\therefore$ wt. of solvent = 15.0 – 3.072 = 11.928 g

$\therefore$ Solubility of $FeSO_4.7H_2O$ in 100 g solvent

$$= \frac{3.072}{11.928} \times 100 = \mathbf{25.75 g.} \quad \textbf{Ans.}$$

EXAMPLE 4. *The solubilities of a solute in 120 g of the solvent are given below*

Temperature	*Solubility*
350 K	*140.0 g*
300 K	*85.0 g*

Calculate the amount of crystals of the solute when 100 g of the saturated solution is cooled from 350 K to 300 K.

Solution. (*i*) At 350 K. Solubility of solute = 140 g

wt. of saturated solution = 120 + 140 = 260 g

260 g saturated solution contain solute = 140 g

100 g saturated solution contain solute

$$= \frac{140}{260} \times 100 = 53.85 \text{ g}$$

$\therefore$ wt. of solvent (H_2O) in 100 g saturated solution

$$= 100 - 53.85 = 46.15 \text{ g}$$

Thus, wt. of solute that would be retained by 46.15 g water at 300 K

$$= \frac{85 \times 46.15}{100} = 39.23 \text{ g}$$

$\therefore$ wt. of solute that separates on cooling from 350 K to 300 K

$$= 53.85 - 39.23 = \mathbf{14.62 \text{ g}} \quad \textbf{Ans.}$$

24.2 OSTWALD'S DILUTION LAW

The application of law of chemical equilibrium to **weak electrolytes** is called Ostwald dilution law. Consider the dissociation of weak electrolyte AB in water.

	AB $\rightleftharpoons$	A^+ +	B^-
(1) n. mol at start	C	0	0
(2) Change by reaction	$-C\alpha$	$C\alpha$	$C\alpha$
(α = degree of dissociation at equilibrium)			
(3) n mol at equilibrium	$C - C\alpha$	$C\alpha$	$C\alpha$

Applying law of chemical equilibrium, we get :

$$K_c = \frac{[A^+][B^-]}{[AB]} = \frac{C\alpha \times C\alpha}{C(1-\alpha)}$$

$$= \frac{C\alpha^2}{1-\alpha}$$

K_c is called dissociation (or ionisation) constant and the expression $[K_c = C\alpha^2/(1-\alpha)]$ is the mathematical form of Ostwald dilution law. If α *is very small as compared to unity (= 1),* α *can be neglected.* For such cases, $1 - \alpha = 1$. Thus :

$$K_c = C\alpha^2 \quad \text{Or} \quad \boldsymbol{\alpha = [K_c/C]^{1/2}}$$

where C is molarity.

(*i*) For a *weak monobasic acid* (*HA*), $\alpha = [K_a/C]^{1/2}$ and H^+ ion concentration, $[H^+] = C\alpha = (K_a.C)^{1/2}$; pH = $-\log(C\alpha)$; pH = $-\log(Ka.C)^{1/2}$

(*ii*) For a weak monoacidic base (BOH), $\alpha = (K_b/C)^{1/2}$ and OH^- ion concentration, $[OH^-] = C\alpha$; pOH = $-\log(C\alpha)$

$\therefore$ pOH = $-\log(K_b.C)^{1/2}$

(*iii*) Greater the value of K_a or K_b, greater the strength of acid or base respectively. The values of K_a and K_b depend upon temperature.

Example 5. *Calculate the dissociation constant of a monobasic maleic acid having molarity 0.25 and degree of dissociation 0.95%.* **(Dumet, 2010 modified)**

Solution. Degree of dissociation, $\alpha = 0.95\% = \frac{0.95}{100}$ $= 0.0095$; concentration, $C = 0.25$ mol L^-.

Dissociation constant,

$$\boldsymbol{K_a} = C\alpha^2 = 0.25 \times (0.0095)^2$$

$$= \mathbf{2.26 \times 10^{-5}}$$

Type. To find K_a when normality of a solution is given, use,

$$K_a = \frac{\alpha^2}{(1-\alpha)V}$$

Example 6. *The degree of dissociation of a monobasic acid is 4.5% in N/20 solution at 288 K. Calculate the dissociation constant of the given acid at the same temperature.*

Solution. Degree of dissociation (α)

$$= 4.5\% = \frac{4.5}{100} = 0.045$$

N/20 or 0.05 N solution means that dilution

$$= \frac{L}{0.05} = V \text{ (say).}$$

But, $K_a = \dfrac{\alpha^2}{(1-\alpha)V}$ (Ostwald dilution law)

$$\therefore \qquad K_a = \frac{(0.045)^2 \times 0.05}{(1-0.045)}$$

$$= \frac{2.025 \times 10^{-3} \times 0.05}{0.955}$$

$$= \mathbf{1.06 \times 10^{-4}} \quad \textbf{Ans.}$$

Example 7. *A weak monobasic acid is 1% ionised in 0.1 M solution at 25°C. The percentage ionisation in its 0.025 M solution is :*

(a) 1 *(b)* 2 *(c)* 3 *(d)* 4 *(e)* 5 **(Kerala PET, 2011).**

Solution. Let acid H A ionises as; $HA \rightleftharpoons H^+ + A^-$.

α is the degree of ionisation. Thus:

$$\begin{array}{ccc} HA & \rightleftharpoons & H^+ + A^- \\ C & & C\alpha \quad C\alpha \end{array}$$

$$\therefore \qquad K = \frac{[H^+][A^-]}{[HA]} = \frac{C\alpha \times C\alpha}{C} = C\alpha^2$$

Or $\qquad K = 0.1 \times (1/100)^2; K = 10^{-5}$

Since $\qquad K = C\alpha^2, 10^{-5} = 0.025 \times \alpha^2$

$\therefore \qquad \alpha^2 = 10^{-5}/0.025; \alpha = (4 \times 10^{-3})^{1/2} = 0.02$

$\therefore$ Percentage of ionisation = 0.02 × 100 = 2.

So, the correct answer is (*b*).

Example 8. *The given solution is 1.5 N of HCN. Find the H^+ ion concentration if $K_{HCN} = 4.0 \times 10^{-10}$.*

Solution. HCN solution = 1.5N. So, dilution volume (V) = 1.5 L^-.

But $\qquad K = \dfrac{\alpha^2}{(1-\alpha)V}$

(Ostwald dilution law; α is neglected from denominator because α is very small)

Or $$K = \frac{\alpha^2}{V}\ ;\ \alpha^2 = KV\ ;\ \alpha = (KV)^{1/2}$$

Or $$\alpha = \left(4.0\times10^{-10}\times\frac{1}{1.5}\right)^{1/2}$$
$$= (2.67\times10^{-10})^{1/2} = 1.63\times10^{-5}$$

But $$(H^+) = \frac{\alpha}{V}\ ;\ [H^+] = \frac{1.63\times10^{-5}}{1/1.5}$$
$$= 2.4\times10^{-5}\text{ g. ion L}^-.$$

Type. For Isohydric solution, use, $\frac{\alpha_1^2}{\alpha_2^2} = \frac{V_1}{V_2}$ where as according to Ostwald's dilution law, $\alpha^2 = KV$ Or $\alpha^2 = K/C$

EXAMPLE 9. *At 293 K, dissociation constant of cyanoacetic acid is 0.0037 and that of acetic acid is 0.000018. Calculate the relative dilution of the above acids so that both solutions become isohydric.*

SOLUTION. For isohydric solutions, $$\frac{\alpha_1^2}{\alpha_2^2} = \frac{V_1}{V_2} \qquad ...(1)$$

Where α_1 = dissociation constant of cyanoacetic acid and

α_2 = dissociation constant of acetic acid.

$\therefore$ $\alpha_1^2 = KV_1\ ;\ \alpha_1^2 = 0.0037\times V_1$ ...(2)
[Ostwald dilution law]

$\alpha_2^2 = KV_2\ ;\ \alpha_2^2 = 0.000018\times V_2$ ...(3)
[Ostwald dilution law]

Dividing (2) and (3), we get :

$$\frac{\alpha_1^2}{\alpha_2^2} = \frac{0.0037V_1}{0.000018V_2} \qquad ...(4).$$

Comparing (1) and (4), we get :

$$\frac{V_1}{V_2} = \frac{3700}{18} = 205.56$$

$\therefore$ Relative dilution of cyanoacetic acid and acetic acid is, **205.56 : 1** **Ans.**

EXAMPLE 10. *Calculate the concentration of H_2CO_3, HCO_3^- and CO_3^{2-} in a 0.01M aqueous solution of H_2CO_3 (carbonic acid), having pH 3.98; $K_1 = 4.5\times10^{-7}$; $K_2 = 4.7\times10^{-11}$.*

SOLUTION. $pH = 3.98\ ;\ -\log(H^+) = 3.98\ ;\ \log[H^+] = -3.98 = -3-1+1-0.98 = \bar{4}.02$

$\therefore$ $[H^+] = \text{antilog } \bar{4}.02 = 1.05\times10^{-4}\text{ mol L}^-$

(*a*) H_2CO_3 being a weak acid, its concentration *i.e.*,
$[H_2CO_3] = 0.01M = 10^{-2}$ M **Ans.**

(*b*) $H_2CO_3 \rightleftharpoons H^+ + HCO_3^-$ (Ionisation);

$$K_1 = \frac{[H^+][HCO_3^-]}{[H_2CO_3]}$$

Or $$[HCO_3^-] = \frac{K_1\,[H_2CO_3]}{[H^+]}$$
$$= \frac{4.5\times10^{-7}\times10^{-2}}{1.05\times10^{-4}}$$
$$= 4.28\times10^{-5}\text{ mol L}^- \qquad \textbf{Ans.}$$

(*c*) $HCO_3^- \rightleftharpoons H^+ + CO_3^{2-}$;

$$K_2 = \frac{[H^+][CO_3^{2-}]}{[HCO_3^-]}\ ;$$

$$[CO_3^{2-}] = \frac{K_2\,[HCO_3^-]}{[H^+]}$$

$\therefore$ $$[CO_3^{2-}] = \frac{4.7\times10^{-11}\times4.28\times10^{-5}}{1.05\times10^{-4}}$$
$$= 1.9\times10^{-11}\text{ mol L}^- \qquad \textbf{Ans.}$$

EXAMPLE 11. *If 0.1 M aqueous solution of acetic acid is 1.32 percent ionised, then calculate the following.*

(*i*) *Concentration of $[H_3O^+]$ (ii) Concentration of $[CH_3COO^-]$ (iii) Conc. of acetic acid (iv) Ionisation constant of acetic acid.*

SOLUTION. If M and α represent the molarity and degree of ionisation of ionic substance, then :

	$CH_3COOH + H_2O$	$\rightleftharpoons$ CH_3COO^-	$+ H_3O^+$
(*i*) n mol at start	0.1	0	0
(*ii*) Change by reaction	$-0.1\times\frac{1.32}{100}$	$0.1\times\frac{1.32}{100}$	$0.1\times\frac{1.32}{100}$
	$=-0.1\times0.0132$	$=0.1\times0.0132$	0.1×0.0132
(*ii*) n mol at equilibrium	$0.1-0.1\times0.0132$	0.1×0.0132	$0.1\times0.0.132$

$$K_c = \frac{[CH_3COO^-][H_3O^+]}{[CH_3COOH]}$$
$$= \frac{(0.1\times0.0132)\times(0.1\times0.132)}{0.1(1-0.0132)}$$
$$= \frac{0.1(0.0132)^2}{0.9868}$$
$$= \mathbf{1.77\times10^{-5}} \quad \textbf{Ans.}$$

EXAMPLE 12. *The ionisation constant of formic acid (HCOOH) is 1.8×10^{-4}. Calculate the ionisation constant of its corresponding base.*

SOLUTION. $HCOOH \rightleftharpoons H^+ + HCOO^-$
conjugate acid conjugate base

Conjugate acid and its conjugate base differ by H^+ only. K_a for HCOOH $= 1.8\times10^{-4}$; K_b for conjugate base $HCOO^-$ = ? $K_w = 10^{-14}$. For conjugate acid – conjugate base pair :

$$K_a\times K_b = K_w$$

Or $$K_b = \frac{K_w}{K_a} = \frac{10^{-14}}{1.8\times10^{-4}}$$
$$= \mathbf{5.6\times10^{-11}} \quad \textbf{Ans.}$$

EXAMPLE 13. *The electrolytic dissociation constants of two acids CH_3COOH and HCOOH are 1.8×10^{-5} and 2.1×10^{-4} respectively. Calculate the relative strength of these acids.* **(UP 1981)**

Solution. Both acids are weak acids. So, their relative strengths can be found by the relation :

$$\frac{\text{Strength of CH}_3\text{COOH}}{\text{Strength of HCOOH}} = \left(\frac{K_{CH_3COOH}}{K_{HCOOH}}\right)^{1/2}$$

$$= \left(\frac{1.8\times10^{-5}}{2.1\times10^{-4}}\right)^{1/2}$$

$$= (0.0857)^{1/2}$$

$$= 0.293$$

∴ Strength of CH_3COOH = 0.293 × strength of HCOOH

Or Strength of HCOOH is $\frac{1}{0.293}$ times or 3.413 times the strength of CH_3COOH.

Example 14. *If in the beginning of the reaction*

$$NH_4OH \rightleftharpoons NH_4^+ + OH^-$$

there are 25 molecules and only 5 molecules out of these dissociate, then calculate the degree of dissociation. **(UP 1983)**

Solution. Degree of dissociation

$$= \frac{\text{no. of molecules which dissociate}}{\text{Total no. of molecules taken}}$$

$$= \frac{5}{25} = 0.2$$

Or *degree of dissociation* = 0.2 × 100 = **20%** **Ans.**

Example 15. *What will be the dissociation constant of 0.1N aqueous ammonia in terms of the degree of dissociation, α. What will be the value if the concentration is 0.01N?* **(DSC, 1988)**

Solution. (*a*)

	NH_4OH	$\rightleftharpoons$ NH_4^+	+ OH^-
Conc. at start	0.1	0	0
Conc. at equilibrium	$0.1 - 0.1\alpha$	0.1α	0.1α

$= 0.1(1-\alpha)$

$= 0.1$

[∵ α is very small, it is neglected]

$$K_b = \frac{[NH_4^+][OH^-]}{[NH_4OH]} = \frac{0.1\alpha \times 0.1\alpha}{0.1(1-\alpha)}$$

$$= \frac{\alpha^2}{10(1-\alpha)}$$ **Ans.**

(*b*) For 0.01 N solution ;

$C = 0.01$ N

But $$K_b = \frac{C\alpha^2}{1-\alpha} = \frac{0.01\times\alpha^2}{(1-\alpha)}$$

$$= \frac{\alpha^2}{100(1-\alpha)}$$ **Ans.**

Example 16. *Nicotinic acid ($K_a = 1.4\times10^{-5}$) is represented by the formula HNiC. Calculate its percentage dissociation in a solution which contains 0.1 mol of nicotinic acid per 2.0 litre of solution.*

Solution.

	HNiC	$\rightleftharpoons$ H^+	+ NiC^-
(*i*) n mol at start	$\frac{0.1}{2}$	0	0
(*ii*) Change by reaction	$\frac{-0.1\alpha}{2}$	$\frac{0.1\alpha}{2}$	$\frac{0.1\alpha}{2}$
(*iii*) n mol at equilibrium	$(0.1-0.1\alpha)/2$	$\frac{0.1\alpha}{2}$	$\frac{0.1\alpha}{2}$

[∵ For 2L, [HNiC] = 0.1

$= [0.1(1-\alpha)]/2$

∴ For 1L, $[HNiC] = \frac{0.1}{2}$

$$K_a = \frac{[H^+][NiC^-]}{[HNiC]} ;$$

$$1.4\times10^{-5} = \frac{\frac{0.1\alpha}{2}\times\frac{0.1\alpha}{2}}{\frac{0.1(1-\alpha)}{2}} = \frac{\left(\frac{0.1}{2}\right)^2\alpha^2}{\frac{0.1}{2}}$$

[∵ α is very small, so, 1 − α = 1]

$$\alpha^2 = \frac{1.4\times10^{-5}}{\left(\frac{0.1}{2}\right)} = 2.8\times10^{-4}$$

or $$\alpha = (2.8\times10^{-4})^{1/2} = 1.67\times10^{-2}$$

∴ % age of degree of ionisation

$= 1.67\times10^{-2}\times100 =$ **1.67%** **Ans.**

Example 17. *An aqueous solution contains 10% ammonia and has a density of 0.99 g cm^{-3}. Calculate hydroxyl and hydrogen ion concentration in this solution. K_a for $NH_4^+ = 5.0\times10^{-10}$ M.* **(Roorkee, 1995)**

Solution. (*i*) Mass of NH_3 = 10%

$$= \frac{10}{100} = 0.1 \text{ g} ;$$

g. mol. wt. of NH_3 = 14 + (3 × 1) = 17g

$$\text{Volume of NH}_3 = \frac{\text{Mass}}{\text{density}} = \frac{0.1 \text{ g}}{0.99 \text{ g cm}^{-3}}$$

$$= \frac{10}{99}\text{cm}^3$$

$$\text{Molarity of NH}_3 = \frac{\text{wt. of NH}_3}{\text{g. mol. wt. of NH}_3} \times \frac{1000}{\text{Volume of solution in cm}^3}$$

$$= \frac{0.1}{17}\times\frac{1000}{10/99} = 58.2$$

(*ii*)

	$NH_3 + H_2O$	$\rightleftharpoons$ NH_4^+	+ OH^-
(*i*) *n* mol at start	*C*	0	0
(*ii*) Change by reaction	$-C\alpha$	$C\alpha$	$C\alpha$
(*iii*) *n* mol at equilibrium	$C - C\alpha$	$C\alpha$	$C\alpha$

$= C(1-\alpha)$

α being very small, it is rejected. Thus $C(1-\alpha) = C$

$$K_b = \frac{[NH_4^+][OH^-]}{[NH_3]} = \frac{C\alpha\times C\alpha}{C}$$

$$= C\alpha^2 ; \quad K_b = \frac{K_w}{K_a} = \frac{10^{-14}}{5\times10^{-10}}$$

$$= 0.2\times10^{-4}.$$

Thus $C\alpha^2 = 0.2 \times 10^{-4}$;

$$58.2\,\alpha^2 = 0.2 \times 10^{-4};$$

$$\alpha = \left(\frac{0.2 \times 10^{-4}}{58.2}\right)^{1/2}$$

$$= (0.344 \times 10^{-6})^{1/2}$$

$$= \mathbf{0.586 \times 10^{-3}}$$ **Ans.**

EXAMPLE 18. *Calculate the* $[H_3O^+]$ *and percentage ionisation of 0.1M acetic acid if its ionisation constant value is* 1.8×10^{-5}.

SOLUTION. (*a*) Acetic acid ionises as

$$CH_3COOH + H_2O \rightleftharpoons H_3O^+ + CH_3COO^-$$

(*i*)	n mol at start	0.1	0	0
(*ii*)	Change by reaction	$-x$	x	x
	(x = Amount of CH_3COOH ionised)			
(*iii*)	n mol at equilibrium	$0.1 - x$	x	x

$$K_c = \frac{[H_3O^+][CH_3COO^-]}{[CH_3COOH]}$$

$$= \frac{x \times x}{0.1 - x} = \frac{x^2}{0.1 - x} \qquad ...(1)$$

Substituting these values in equation (1) above, we get

$$K_c = \frac{x \times x}{0.1 - x} = 1.8 \times 10^{-5} \text{ (given)}$$

Since x is extremely small, it can be neglected in the denominator. So, we have :

$$\frac{x^2}{0.1} = 1.8 \times 10^{-5};\ x^2 = 1.8 \times 10^{-6};$$

$$x = (1.8 \times 10^{-6})^{1/2}$$

$\therefore$ $x = 1.34 \times 10^{-3}$

Hence $[H_3O^+] = 1.34 \times 10^{-3}$ g mol L$^-$

(*b*) Ionic concentration = gross concentration × fraction ionised (α).

$$1.34 \times 10^{-3} = 0.1 \times \alpha$$

$\therefore$ $\alpha = 1.34 \times 10^{-2} = 0.0134$

Hence percent ionisation

$= 0.0134 \times 100 =$ **1.34%**

EXAMPLE 19. *Calculate the hydrogen ion concentration of an aqueous solution of formic acid containing 0.92 g of the acid per litre. The ionisation constant of the acid is* 2.4×10^{-4} *at 298 K.*

SOLUTION. Gram molecular weight of formic acid (HCOOH) = 1 + 12 + 16 + 16 + 1 = 46 g

weight of formic acid per litre = 0.92 g

$\therefore$ Molarity of formic acid $= \frac{0.92}{46} = 0.02$ M

= 0.02 g mol L$^-$

HCOOH ionises in water as

$$(HCOOH + H_2O \rightleftharpoons H_3O^+ + HCOO^-)$$

(1)	n g. mol L$^-$ at start	0.02	0	0
(2)	Change by reaction	$-x$	x	x
(3)	n g. mol L$^-$ at equilibrium	$0.02 - x$	x	x

x = mol of formic acid ionised.

$\therefore$ Ionisation constant

$$K_C = \frac{[H_3O^+][HCOO^-]}{[HCOOH]} \qquad ...(1)$$

Substituting these values in equation (1), we get

$$K_C = \frac{x \times x}{0.02 - x} = 2.4 \times 10^{-4} \text{ (given)}$$

Since, 'x' is extremely small, it can be neglected in the denominator. So, we have $\frac{x^2}{0.02} = 2.4 \times 10^{-4}$

$$x^2 = 0.02 \times 2.4 \times 10^{-4};$$

$$x = \sqrt{0.02 \times 2.4 \times 10^{-4}}$$

$$= 2.19 \times 10^{-2}$$

$\therefore$ $[H_3O^+] = \mathbf{2.19 \times 10^{-2}}$ **g mol L$^-$**

EXAMPLE 20. *Find the molar concentration of* $[OH^-]$ *and percentage ionisation of 0.02 M ammonia solution if its ionisation constant value is* 1.8×10^{-5}.

SOLUTION. Ammonia (NH_3) ionises in water as follows.

$$NH_3 + H_2O \rightleftharpoons NH_4^+ + OH^-$$

(1)	n mol at start	0.02	0	0
(2)	Change by reaction	$-x$	x	x
(3)	n mol at equilibrium	$0.02 - x$	x	x

x = mol of NH_3 ionised

$$\therefore \qquad K_c = \frac{[NH_4^+][OH^-]}{[NH_4OH]} \qquad ...(1)$$

Substituting these values in equation (1), we get $K = \frac{x \times x}{0.02 - x} = 1.8 \times 10^{-5}$ (given)

Since 'x' is very small, it can be ignored in the denominator. So, we have :

$$\frac{x^2}{0.02} = 1.8 \times 10^{-5};\ x^2 = 0.02 \times 1.8 \times 10^{-5}$$

$$= 0.02 \times 18 \times 10^{-6}$$

$$x = \sqrt{0.36 \times 10^{-6}} = 0.6 \times 10^{-3}$$

$\therefore$ $[OH^-] = 0.6 \times 10^{-3}$

But ionic concentration

= gross concentration × fraction ionised (α)

$\therefore$ $0.6 \times 10^{-3} = 0.02 \times \alpha;\ \alpha = 0.6 \times 10^{-3}/0.02$

$= 3.0 \times 10^{-2} = 0.03$

or Percent ionisation = 0.03 × 100 = **3.0**

Type. Solution of weak base and salt of a weak base with strong acid.

EXAMPLE 21. *Calculate the percentage ionisation of 0.02M ammonia solution containing 0.02 M NH_4Cl. Also calculate the $[OH^-]$, if K (ionisation constant) of ammonia solution is 1.8 × 10^{-5} and NH_4Cl is 100% ionised with $[OH^-]$ concentration be less or more when no NH_4Cl solution is added in ammonia solution?*

SOLUTION. (*a*) Ammonia solution in water ionises as

	$NH_3 + H_2O \rightleftharpoons$	NH_4^+ +	OH^-
(*i*) n mol at start	0.02	0.02	0.
	$\because$ In $NH_4Cl \rightleftharpoons$	NH_4^+ +	Cl^-
(*ii*) Change by reaction	$-x$	x	x
	common ion $[NH_4^+] = 0.02M$		
(*iii*) n mol at equilibrium	$0.02 - x$	$0.02 + x$	x

x = Degree of ionisation of 0.02 M ammonia.

$$\therefore \quad K_c = \frac{[NH_4^+][OH^-]}{[NH_4OH]} \quad ...(1)$$

Substituting the values in equation (1), we get :

$$K_c = \frac{(0.02 + x)(x)}{0.02 - x} = 1.8 \times 10^{-5} \text{ (given)}$$

Since x is very small, it can be ignored with respect to 0.02 from numerator as well as denominator. So, we have

$$\frac{0.02x}{0.02} = 1.8 \times 10^{-5}\ ;\ x = 1.8 \times 10^{-5}$$

$$\therefore \quad [OH^-] = 1.8 \times 10^{-5}$$

But degree of ionisation (α)

$$= \frac{\text{Gross ionisation}}{\text{Molar concentration}}$$

$$= 1.8 \times 10^{-5}/0.02 = 9 \times 10^{-4}$$

$\therefore$ % age ionisation in the presence of NH_4Cl = 9 × 10^{-4} × 100 = 0.09%

(*b*)The concentration of OH^- ions will be more when NH_4Cl is not added to NH_4OH because the common ions (NH_4^+) from NH_4Cl suppress the ionisation of NH_4OH due to common ion effect. See previous example for $[OH^-]$ in pure NH_4OH solution.

Type. Weak acid + salt of weak acid with strong base.

EXAMPLE 22. *How will the degree of dissociation of 0.1M solution of CH_3COOH change if 8.2 g of CH_3COONa (mol mass 82 g mol^-) is added to one litre of the solution. (K_a = 1.8 × 10^{-5})* **(WBEngg. 1993)**

SOLUTION. (*a*) wt. of CH_3COONa = 8.2 g ; g. mol. wt. of CH_3COONa = 82 g.

Hence no. of mol of CH_3COONa $= \frac{8.2}{82} = 0.1$ M

	$CH_3COOH \rightleftharpoons$	CH_3COO^- +	H^+
conc in mol L^-	0.1		
conc in mol L^-	$0.1 - 0.1\alpha$		
after change	$= 0.1(1 - \alpha)$	$0.1\alpha'$	$0.1\alpha'$

$\therefore \quad [H^+] = 0.1\alpha'$

Total conc. of CH_3COO^- = $0.1 + 0.1\alpha' = \mathbf{0.1\,(1 + \alpha')}$

$$K_a(CH_3COOH) = \frac{[CH_3COO^-][H^+]}{[CH_3COOH]}$$

$$1.8 \times 10^{-5} = \frac{0.1(1+\alpha') \times 0.1\alpha'}{0.1(1-\alpha')}$$

$$= \frac{(\alpha')^2 + 0.1\alpha'}{1 - \alpha'} = 0.1\alpha'$$

$$\left[\begin{array}{l}\alpha^2 \text{ is neglected because } 0.1\,\alpha \text{ and} \\ \alpha' \text{ are very small as compared to 1}\end{array}\right]$$

$$\therefore \quad \alpha' = \frac{1.8 \times 10^{-5}}{0.1} = 1.8 \times 10^{-4}$$

(*b*) Also, for a weak acid,

$$\alpha = \left(\frac{K_a}{C}\right)^{1/2} = \left(\frac{1.8 \times 10^{-5}}{0.1}\right)^{1/2}$$

$$= (1.8 \times 10^{-4})^{1/2} \therefore \alpha = 1.34 \times 10^{-2}$$

$\therefore$ Decrease in the degree of dissociation = $\alpha - \alpha'$

$$= (1.34 \times 10^{-2}) - (1.8 \times 10^{-4})$$

$$= 10^{-4}(1.34 \times 10^2 - 1.8)$$

$$= 132.2 \times 10^{-4}$$

$$= \mathbf{1.322 \times 10^{-2}} \quad \textbf{Ans.}$$

Type. To calculate rate constant (K) for proton transfer from water to a base (say, NH_3), use the relation

$$K_{(\text{base}-NH_3)} = \frac{K_f}{K_b} = \frac{K_w}{K_{\text{acid}\,(NH_4^+)}}$$

$$[\because K_w = K_{\text{acid}} \times K_{\text{base}}].$$

Here, *f* and *b* represent forward nad backward reactions respectively.

EXAMPLE 23. *The ionisation constant of NH_4^+ in water is 5.6 × 10^{-10} at 25°C. The rate constant for the reaction of NH_4^+ and OH^- to form NH_3 and H_2O at 25°C is 3.4 × 10^{10} lit mol^- s^-. Calculate the rate constant for proton transfer from water to ammonia.* **(I.I.T. 1996)**

SOLUTION.

$$NH_3 + H_2O \underset{K_b}{\overset{K_f}{\rightleftharpoons}} NH_4^+ + OH^-\ ;\ K_b = 3.4 \times 10^{10}$$

$$NH_4^+ + H_2O \rightleftharpoons NH_4OH + H^+\ ;\ K_a = 5.6 \times 10^{-10}$$

Equilibrium reaction

$$K_{(\text{base}-NH_3)} = \frac{K_f}{K_b}$$

or

$$\frac{K_w}{K_{\text{acid}\,(NH_4^+)}} = \frac{K_f}{K_b}$$

$$\left[\because K_w = K_{\text{acid}} \times K_{\text{base}}\ ;\ K_{\text{base}} = \frac{K_w}{K_{\text{acid}}}\right]$$

or

$$\frac{10^{-14}}{5.6 \times 10^{-10}} = \frac{K_f}{3.4 \times 10^{10}}\ ;$$

$$K_f = \frac{10^{-14} \times 3.4 \times 10^{10}}{5.6 \times 10^{-10}}$$

$$= \mathbf{6.07 \times 10^5} \quad \textbf{Ans.}$$

Type. Calculation of ionisation constant when vapour pressure of solution is given.

Example 24. *The vapour pressure of 0.01 molal solution of a weak base BOH in water at 293 K is 17.536 torr. What will be the value of K_b of this base if it is assumed that the molality and molarity of this solution are same? (Aqueous tension at 293 K = 17.54 torr).*

Solution. (*a*). We know, molality

$$= \frac{\text{wt}\,(w)}{\text{g.mol.wt.}(m)} \times \frac{1000}{\text{wt}\,(W)\text{ of solvent}}$$

$$= \left(\frac{w}{mW} \times 1000\right)$$

But $\frac{p - ps}{p} = \frac{wM}{mW}$ (Raoult's law)

$$\therefore \quad \frac{w}{mW} = \frac{p - ps}{p\,M} = \frac{17.54 - 17.536}{17.54 \times 18}$$

[∵ mol. wt. of H_2O solvent = (2 × 1) + 16 = 18]

$$\text{or} \quad \frac{w}{mW} = \frac{4 \times 10^{-3}}{17.54 \times 18} = 1.267 \times 10^{-5}$$

$$\therefore \quad \text{Molality} = \text{molarity} = 1.267 \times 10^{-5} \times 1000$$

$$= 1.26 \times 10^{-2} = 0.01267$$

(*b*)

	$BOH \rightleftharpoons$	B^+	+ OH^-
Conc. at start	1	0	0
Conc. at equilibrium	$1 - \alpha$	α	α

∴ Total no. of mol at equilibrium

$$= 1 - \alpha + \alpha + \alpha = 1 + \alpha$$

$$\text{But} \quad 1 + \alpha = \frac{\text{Experimental molarity}}{\text{Theoretical molarity}} = \frac{0.01267}{0.01}$$

$$= 1.267$$

Or $\alpha = 1.267 - 1 = 0.267$. For a weak base,

$$\therefore \quad K_b = \frac{C\alpha^2}{1 - \alpha} = \frac{0.01 \times (0.0267)^2}{1 - 0.267}$$

$$= \frac{0.01 \times (0.0267)^2}{0.733} = 9.7 \times 10^{-4}$$

Example 25. *How much concentration of ethanoic acid should be added to 0.5M methanoic acid solution so that the ionisation of both the acids is the same? (K_a for ethanoic acid and methanoic acid are 1.8×10^{-5} and 2.4×10^{-4} respectively.*

Solution. Ethanoic acid = CH_3COOH ; Methanoic acid = $HCOOH$. K_{a_1} (CH_3COOH) = 1.8×10^{-5} ; K_{a_2} ($HCOOH$) = 2.4×10^{-4}. C_1 = ? ; C_2 = 0.5M.

But $\alpha_1 = (K_{a1}C_1)^{1/2}$; $\alpha_2 = (K_{a_2}C_2)^{1/2}$

$HCOOH \rightleftharpoons HCOO^- + H^+$; $CH_3COOH \rightleftharpoons CH_3COO^- + H^+$

Since the ionisation of both the acids is same, $\alpha_1 = \alpha_2$

$$\therefore \quad (K_{a_2}C_1)^{1/2} = (K_{a_1}C_2)^{1/2} \textbf{ Or } K_{a_1}C_1 = K_{a_2}C_2$$

$$\therefore \quad C_1 = \frac{K_{a_2}C_2}{K_{a_1}} = \frac{2.4 \times 10^{-4} \times 0.5}{1.8 \times 10^{-5}}$$

$$= \mathbf{6.67M} \qquad \textbf{Ans.}$$

Example 26. *An aqueous solution of aniline of concentration 0.24M is prepared. What concentration of NaOH is needed in this solution so that anilinium ion concentration remains at 1×10^{-8}M? (K_a for $C_6H_5NH_3^+ = 2.4 \times 10^{-5}$).* **(Roorkee 1996).**

Solution. Reaction

	$C_6H_5NH_2 + H_2O \rightleftharpoons$	$C_6H_5NH_3^+$	$+ OH^-$ ...(1)
Initial conc.	0.24	0	x
Conc. after reaction	$0.24 - \alpha$	α	$x + \alpha$

Where x = Amount of NaOH or OH^- needed to maintain 10^{-8}M concentration of $C_6H_5NH_3^+$. We know :

$$K_b = \frac{K_w}{K_a} = \frac{10^{-14}}{2.4 \times 10^{-5}}$$

$$= 4.17 \times 10^{-10}.$$

$$\text{But for reaction (1),} \quad K_b = \frac{[C_6H_5NH_3^+][OH^-]}{[C_6H_5NH_2]}$$

$$= \frac{\alpha\,(x + \alpha)}{0.24 - \alpha} = \frac{10^{-8}\,(x + 10^{-8})}{0.24 - 10^{-8}}$$

$$\textbf{Or} \quad 4.17 \times 10^{-10} = \frac{10^{-8}\,(x + 10^{-8})}{0.24}$$

[∵ 10^{-8} is very small, it is neglected from the denominator]

$$\frac{4.17 \times 10^{-10} \times 0.24}{10^{-8}} = x + 10^{-8} \text{ or } x = 10^{-2}\text{M}$$

Hence $[OH^-] = 10^{-2}$M

Example 27. *0.16 g of N_2H_4 are dissolved in water and the total volume made up to 500 mL. Calculate the percentage of N_2H_4 that has reacted with water in this solution. (K_b for N_2H_4 is 4.0×10^{-6}M)* **(Roorkee, Entrance 1998)**

Solution. wt. of N_2H_4 = 0.16 g ;

g. mol. wt. of N_2H_4 = (2 × 14) + (4 × 1) = 32 g

$$\text{Molarity of } N_2H_4 = \frac{\text{wt.}}{\text{g. mol. wt.}} \times \frac{1000}{\text{volume in mL}}$$

$$= \frac{0.16}{32} \times \frac{1000}{500} = 0.01$$

	$N_2H_4 + H_2O \rightleftharpoons$	$N_2H_5^+$	$+ OH^-$
(*i*) n mol at start	0.01	0	0
(*ii*) Change by reaction	$- 0.01\alpha$	0.01α	0.01α
(*iii*) n mol at equilibrium	$0.01 - 0.01\alpha$ $= 0.01$		

(∵ α is small, it is neglected)

$$\therefore \quad K_b = \frac{[N_2H_5^+][OH^-]}{[N_2H_4]} ;$$

$$4.0 \times 10^{-6} = \frac{0.01\alpha \times 0.01\alpha}{0.01}$$

$$\textbf{Or} \quad 0.01\alpha^2 = 4 \times 10^{-6} ; \alpha = \left(\frac{4 \times 10^{-6}}{0.01}\right)^{1/2}$$

$$= (4 \times 10^{-4})^{1/2} = 2 \times 10^{-2}$$

or Percentage of dissociation

$$= 2 \times 10^{-2} \times 100 = \mathbf{2\%}$$ **Ans.**

24.3 ACIDS AND BASES

According to arrhenius, an acid is that substance which when dissolved in water, gives H^+ ions. A base is a substance which when dissolved in water, gives OH^- ions.

*p*H of a solution is defined as the negative logarithm of its H^+ ion concentration: Mathematically :

$$pH = -\log[H^+] \;\textbf{or}\; pH = \frac{1}{\log[H^+]}$$

Or $\log[H^+] = -pH$

Taking antilog of both sides, we get : $[H^+] = {}_{10}{-}pH$

∴ pH may also be defined as the negative power to which 10 must be raised to equal the hydrogen ion concentration.

(*a*) $[H^+] > 10^{-7}$ or $pH < 7$, the solution is **acidic.**

(*b*) $[H^+] < 10^{-7}$ or $pH > 7$, the solution is **basic.**

(*c*) $[H^+] = 10^{-7}$ or $pH = 7$, the solution is **neutral.**

Sorenson (1909) devised a scale called pH scale (pH = 1 to pH = 14) to represent H^+ ion concentration. Here '*p*' stands for power (French Puissance, German Potenz). pH can be negative also. It will happen when $[H^+]$ (rather the activity) is more than one.

pOH. The pOH of a solution is defined as the negative logarithm of its OH^- ions concentration.

$$\therefore \quad pOH = -\log[OH^-]$$

Ionic product of water, K_w. For :

$H_2O \rightleftharpoons H^+(aq) + OH^-(aq)$ **Or**

$2H_2O \rightleftharpoons H_3O^+(aq) + OH^-(aq)$

$$\therefore \quad K = \frac{[H^+][OH^-]}{[H_2O]} ;$$

$$K = \frac{[H_3O^+][OH^-]}{[H_2O]} ;$$

$$K[H_2O] = [H^+][OH^-] \text{ or}$$

$$K_w = [H^+][OH^-]$$

{∵ H_2O is slightly ionised, $[H_2O]$ is constant. *i.e.*, molar concentration of water, $[H_2O] = \frac{1000}{18} = 55.5 \text{ mol } L^-$

[∵ density of water = 1 g (mL$^-$)]}.

Where K_w is ionic product of water. $\mathbf{pK_w = -\log K_w}$.

At 22°C, $K_w = 1.0 \times 10^{-14} ; K_w = [H^+][OH^-]$;

$$10^{-14} = [H^+][H^+] \; [\because [H^+] = [OH^-] ;$$

$$[H^+] = (10^{-14})^{1/2}$$

$$\therefore \quad [H^+] = 10^{-7}.$$

Hence $[H^+] = [OH^-]$

$$= 10^{-7}.$$

$$pH + pOH = 14.$$

$$pK_w = -\log K_w = -\log 10^{-14} = 14$$

But $[H^+][OH^-] = K_w$. Taking negative log of both sides, we get :

$$-\log H^+ + (-\log OH^-) = -\log K_w \; i.e., -\log 10^{-14} = 14$$

$$\therefore \; pH + pOH = 14.$$

$pK_a + pK_b = pK_w$. Since $K_a \times K_b = K_w$ (where K_a and K_b are the values of conjugate acids and bases respectively), $pK_a + pK_b = pK_w = 14$

24.4 IONIC PRODUCT OF WATER, K_w

Type. To find K_w, use the relation : $K_w = [H^+][OH^-]$

EXAMPLE 28. *A centinormal solution of KOH has pH equal to 12. If KOH is 100% dissociated, calculate the ionic product of water.*

SOLUTION. (*a*) Centinormal (N/100) KOH = 10^{-2}N or 10^{-2}M KOH

$$\underset{10^{-2}\,M}{KOH} \rightleftharpoons K^+ + \underset{10^{-2}\,M}{OH^-}$$

$$\therefore \quad [OH^-] = 10^{-2} \text{ M} \quad \text{...(A)}$$

(*b*) $pH = 12$ (given)

But $pH = -\log(H^+)$

$$\therefore \quad [H^+] = 10^{-12} M; K_w = [H^+][OH^-] \text{...(B)}$$

$$= 10^{-12} \times 10^{-2} = \mathbf{10^{-14}}$$

[From equations (A) and (B)]

EXAMPLE 29. *What is the ionic product of water? If the pH of a solution is 5.5, find out its pOH.* **(UP 1984)**

SOLUTION. Ionic product of water, $K_w = [H^+][OH^-] = 10^{-14}$ at 298K. We know that :

$$pH + pOH = 14 ;$$

$$\therefore \quad pOH = 14 - 5.5 = \mathbf{8.5}$$ **Ans.**

24.5 pH OF SOLUTIONS

EXAMPLE 30. *Calculate the pH of a 1.0×10^{-7} molar solution of HCl. The ionic product of water = 10^{-14}.*

SOLUTION. $K_w = [H^+][OH^-] ; 10^{-14} = [H^+][OH^-]$ ...(1)

$$HCl \rightleftharpoons H^+ + Cl^- \quad \text{(ionisation).}$$

A mass balance on Cl^- ion combined with the charge balance gives the following proton (H^+) condition.

$$[OH^-] = [H^+] - 10^{-7} \quad \text{...(2)}$$

The given HCl solution is very dilute. So, $[OH^-]$ can not be ignored as compared to 10^{-7}. Thus, the equations have to be solved exactly. Thus by substituting the value of $[OH^-]$ from (2) in (1), we get :

$$10^{-14} = [H^+] \times \{[H^+] - 10^{-7}\} = [H^+]^2 - 10^{-7}[H^+]$$

Or $[H^+]^2 - 10^{-7}[H^+] - 10^{-14} = 0$

$$[H^+] = \frac{-(-10^{-7}) \pm \left\{(-10^{-7})^2 - (4 \times 1 \times -10^{-14})\right\}^{1/2}}{2 \times 1}$$

$$\left[\because \text{for } ax^2 + bx + c,\; x = \frac{-b \pm (b^2 - 4ac)^{1/2}}{2a}\right]$$

$$= \frac{+10^{-7} \pm \left\{10^{-14} + (4 \times 10^{-14})\right\}^{1/2}}{2}$$

$$= \frac{+10^{-7} \pm \left\{10^{-14}\,(1+4)\right\}^{1/2}}{2}$$

$$= \frac{+10^{-7} + 2.24 \times 10^{-7}}{2}$$

$$[H^+] = \frac{10^{-7}\,(2.24+1)}{2} = 1.62 \times 10^{-7}$$

(To avoid –ve result out of ±, we take + sign)

$\therefore \quad pH = -\log [H^+] = -\log 1.62 \times 10^{-7}$

$= -(\log 1.62 + \log 10^{-7})$

$pH = -(0.209 - 7) \simeq$ **6.79** **Ans.**

EXAMPLE 31. *At 333K, K_w for $2H_2O \rightleftharpoons H_3O^+ + OH^-$ is 9.62×10^{-14}. Calculate the pH of water at this temperature. What happens to its neutrality?*

SOLUTION. $K_w = [H^+]\,[OH^-]$. For pure water,

$[H^+] = [OH^-]$

$\therefore \quad K_w = [H^+]\,[H^+]\,;\ 9.62 \times 10^{-14} = [H^+]^2.$

Hence : $[H^+] = (9.62 \times 10^{-14})^{1/2} = 3.1 \times 10^{-7}$

$\therefore \quad pH = -\log [H^+] = -\log 3.1 \times 10^{-7}$

$= -(\log 3.1 + \log 10^{-7})$

$= -(0.49 - 7) = 6.51$

Though *p*H of H_2O at 333K has become 6.51 (of acidic solution) yet its nature will remain neutral.

Type. To calculate H^+ ion concentration from the given value of *p*H or *p*OH, use the following relations

(*i*) $pH = -\log [H^+]$ (*ii*) $pH = 14 - pOH$

EXAMPLE 32. *Calculate the H^+ ion concentration of a solution having (i) pH 12.8 and (ii) pOH = 5.7*

SOLUTION. (*i*) Given

$pH = 12.8 \quad \therefore [H^+] = 10^{-12.8}$

$[\because pH = -\log [H^+]]$

Taking logs of both sides, we get

$\log [H^+] = -12.8$ (log 10 = 1

$= -12 - 1 + 1 - 0.8 = \overline{13}.2$

[∵ Mantissa must be positive]

Taking antilogs of both sides, we get

$[H^+] = \text{antilog}\,\overline{13}.2$

$= 1.585 \times 10^{-13}$ g mol L^-

(*ii*) $pOH = 5.7$ (given)

$\therefore \quad pH = 14 - 5.7 = 8.3 \quad [\because pH = 14 - pOH]$

$[H^+] = 10^{-8.3} \quad [\because pH = -\log (H^+)]$

Taking logs of both sides, we get

$\log [H^+] = -8.3 = -8 - 1 + 1 - 0.3 = \overline{9}.7$

(∵ Mantissa must be positive)

Taking antilogs of both sides, we get $[H^+]$

$= \text{antilog}\,\overline{9}.7 \simeq 5.0 \times 10^{-9}$

EXAMPLE 33. *Find the pH of 0.05 M H_2SO_4 solution.*

SOLUTION.

$$\begin{array}{lccc} & H_2SO_4 & \rightleftharpoons 2H^+ + & SO_4^{2-} \\ \text{Conc. before ionisation} & 0.05 \rightleftharpoons & 0 & 0 \\ \text{Conc. after ionisation} & 0 & 2 \times 0.05 & 0.05 \end{array}$$

$\therefore \quad [H^+] = 2 \times 0.05 = 0.1\ M;$

$pH = -\log [H^+] = -\log 0.1$ or 10^{-1}

$= -(-1) \log 10 = +1 \times 1 =$ **1 Ans.**

EXAMPLE 34. *Calculate the pH of 0.2 M $Ca(OH)_2$ which is found to be 90% ionised at 298K.*

SOLUTION. $Ca(OH)_2$ ionises as

$$Ca(OH)_2 \rightleftharpoons Ca^{2+} + 2OH^-$$

Since $Ca(OH)_2$ is 90% ionised, the degree of ionisation of $Ca(OH)_2 = \frac{90}{100} = 0.9$

$\therefore \quad [OH^-] = 0.9 \times 2 \times 0.2 = 0.36M$

But $\quad [H^+]\,[OH^-] = K_w = 1.0 \times 10^{-14}$

$\therefore \quad [H^+] = 10^{-14}/[OH^-] = \frac{10^{-14}}{0.36}$

$= 2.78 \times 10^{-14} = 2.78 \times 10^{-14}$

$pH = -\log[H^+] = -[\log 2.78 \times 10^{-14}]$

$= -[\log 2.78 - 14 \log 10$ *i. e.* $- 14]$

$= 14 - \log 2.78 = 14 - 0.44$

$= 13.56$ or **$pH = 13.56$**

I Strong acids such as HCl, HNO_3, H_2SO_4 etc.

Important. *When $[H^+]_{acid} < 10^{-6}$ M, water contribution should be taken. When $[H^+]_{acid} \geq 10^{-6}$ M, water contribution should not be taken.*

EXAMPLE 35. *Calculate the pH of 10^{-8} M HCl.*

(Kanpur IET, 1998, BCECE, Bihar 2005)

SOLUTION.

$$\begin{array}{ccc} HCl & \rightleftharpoons & H^+ + Cl^- \\ 10^{-8}\,M & & 10^{-8}\,M \end{array}$$

Since $(H^+)_{acid} < 10^{-6}$ M, so water contribution should be taken.

$$\therefore \quad \begin{array}{ccc} H_2O & \rightleftharpoons & H^+ + OH^- \\ & & x \quad\ \ x \end{array}$$

[Let $x = [H^+]$ derived from water]

$\therefore \quad K_w = [H^+]_T \times [OH^-]_T$ **or**

$10^{-14} = (10^{-8} + x) \times (x)$

Or $\quad x^2 + 10^{-8}x - 10^{-14} = 0$

$\therefore \quad x = 9.51 \times 10^{-8}$

$\therefore \quad [H^+] = 10^{-8} + x$

$= 10^{-8} + 9.51 \times 10^{-8}$

$= 10^{-8}\,[1 + 9.51]$

$= 10.51 \times 10^{-8}$ g ion L^- **Ans.**

Also, $\quad pH = -\log [H^+]_T$

$= -\log [10.51 \times 10^{-8}]$

$= -[\log 10.51 - 8 \log 10]$

$pH = -[1.0216 - 8]$

$=$ **6.9784** **Ans.**

For general equation $ax^2 + bx + c = 0$,

$$x = \frac{-b+\left[\left(b^2-4ac\right)^{1/2}\right]}{2a}$$

$$\therefore \quad x = \frac{-10^{-8} \pm\left[\left(-10^{-8}\right)^2-\left(4\times1\times-10^{-14}\right)\right]^{½}}{2\times1}$$

$$x = \frac{-10^{-8}+(10^{-16}+4\times10^{-14})^{1/2}}{2}$$

$$= \frac{-10^{-8}+2.002\times10^{-7}}{2}$$

$$= \frac{1.902}{2}\times10^{-7}$$

$$= 0.951\times10^{-7} = 9.51\times10^{-8}$$

Example 36. *Calculate the pH of 10^3 M HCl.*

$$\underset{10^3\text{ M}}{\text{HCl}} \rightleftharpoons \underset{10^3\text{ M}}{\text{H}^+} + \text{Cl}^-$$

$[H^+] = 10^3$ (M) **Or** pH = − log 10^3

= − [3 log 10] = **− 3**

But pH = − 3 is not possible because pH range is from 0 to 14.

∴ pH = − log a_{H^+} × activity coefficient

Hence, unless activity coefficient is given, it is not possible to calculate pH of the solution.

Example 37. *Calculate the pH of a solution containing 0.365 g HCl per litre of water.* **(UP1983).**

Solution. wt. of HCl = 3.65 g ;

g. mol. wt. of HCl = 1 + 35.5 = 36.5 g.

Hence, no. of mol of HCl

$$= \frac{0.365}{36.5} = 0.01 = 10^{-2}$$

$$\text{HCl} \rightleftharpoons \text{H}^+ + \text{Cl}^-$$

Conc. (mol L⁻) 10^{-2}

∴ pH = − log [H⁺] = − (log 10^{-2})

= − (− 2 log 10)

= − (−2 × 1) = **+ 2** **Ans.**

II. Strong Bases such as NaOH, KOH etc.

To find pH of such solutions, having $[OH^-] < 10^{-7}$ *i. e.*, $10^{-8}, 10^{-9}$ etc, add $[OH^-]$ of H_2O ($H_2O \rightleftharpoons H^+ + OH^-$) to given $[OH^-]$. For example, in case of 10^{-8}M NaOH, $[OH^-] = 10^{-8} + x$.

Example 38. *Calculate the pH of 10^{-6} M NaOH.*

Solution. NaOH ⇌ Na⁺ + OH⁻

Conc. after ionisation 10^{-6}

∴ $[OH^-] = 10^{-6}$;

$$[H^+] = \frac{K_w}{[OH^-]} = \frac{10^{-14}}{10^{-6}} = 10^{-8}$$

∴ pH = − log [H⁺] = − log 10^{-8}

= − (− 8) log 10

= + 8 × 1 = **+ 8** **Ans.**

III Weak bases

Example 39. *Calculate the pH of 0.01N Ba(OH)$_2$.*

Solution. $Ba(OH)_2 \rightleftharpoons Ba^{2+} + 2OH^-$

Initial conc. 0.01 N or 10^{-2} N 0 0

Conc. at equilibrium 10^{-2} 10^{-2}

∴ $[OH^-] = 10^{-2}$

∴ pH = − log [H⁺]

$$\left[\begin{array}{l} [H^+][OH^-] = 10^{-14} \\ [H^+]\times10^{-2} = 10^{-14} \\ \therefore\ [H^+] = \dfrac{10^{-14}}{10^{-2}} = 10^{-12} \end{array}\right]$$

= − log 10^{-12} = − [− 12 log 10] = **12**

But pH + pOH = 14

∴ ***p*OH** = 14 − pH = 14 − 12 = **2** **Ans.**

Example 40. *2.5 ml of 10N HCl is diluted with water to 500 mL. Calculate the pH of the solution.*

Solution. To find normality of diluted acid, we use normality equation.

∴ Given acid Diluted acid

$N_1V_1 = N_2V_2$; 10 × 2.5 = N_2 × 500

∴ N_2 = 10 × 2.5/500 = 0.50 N

HCl is a strong acid. It ionises completely in water.

∴ [H⁺] = 0.05 g ion L⁻ = 5 × 10^{-2} g ion L⁻

pH = − log [H⁺] = − log 5 × 10^{-2}

= − [log 5 − 2 log 10]

= 2 − log 5 = 2 − 0.699

Or *p*H = 1.301 **Ans.**

Example 41. *Calculate the percentage ionisation of an acid having molarity and pH equal to 0.01 M and 4 respectively.*

Solution. pH = 4.0 (given)

∴ [H⁺] = 10^{-4} g ion L⁻ [∵ pH = − log [H⁺]]

But degree of ionisation,

$$\alpha = \frac{\text{Gross concentration}}{\text{molar concentration}} = \frac{10^{-4}}{0.01} = 10^{-2}$$

∴ Percent ionisation = 10^{-2} × 100 = 1.0

Example 42. *Calculate the pH of a solution which contains 2.01 × 10^{-7} moles of H⁺ ion concentration in 100 ml of the solution.*

Solution. 100 ml solution contains moles of H⁺ ions = 2.01 × 10^{-7}

1000 ml solution contains moles of H⁺ ions =

$$2.01\times10^{-7}\times\frac{1000}{100} = 2.01\times10^{-6}$$

∴ [H⁺] = 2.01 × 10^{-6}; pH = − log [H⁺]

= − log 2.01 × 10^{-6}

$$= -[\log 2.01 - 6 \log 10]$$

$$= -[\log 2.01 - 6]$$

$$pH = 6 - \log 2.01 = 6 - 0.303 = 5.697$$

IV. Weak acids.

A weak acid is that which does not ionise completely in water. For example, acetic acid (CH_3COOH), HCN etc. The equilibrium constant, K_a for $CH_3COOH \rightleftharpoons CH_3COO^- + H^+$ is given as :

$$K_a = \frac{[CH_3COOH^-][H^+]}{[CH_3COOH]}$$

	CH_3COOH $\rightleftharpoons$	CH_3COO^- +	H^+
Initial conc.	C	0	0

[Where α = degree of dissociation]

Conc. at equilibrium	$C - C\alpha$ $= C(1 - \alpha)$	$C\alpha$	$C\alpha$

$$\therefore \quad K_a = \frac{[CH_3COOH^-][H^+]}{[CH_3COOH]}$$

$$= \frac{C\alpha \times C\alpha}{C(1-\alpha)} = \frac{C\alpha^2}{1-\alpha}$$

> **Note.** If α is ≤ 0.1, α can be ignored in comparison to 1. If α is > 0.1, α can not be ignored and has to be calculated by the use of quadratic equation.

For weak acids, α is very small and can be ignored. Thus :

$$K_a = C\alpha^2 \quad \text{or} \quad \alpha = \left(\frac{K_a}{C}\right)^{1/2}$$

$$[H^+]_{acid} = C\alpha = C\left(\frac{K_a}{C}\right)^{1/2} = \left(\frac{C^2K_a}{C}\right)^{1/2}$$

$$= (K_a.C)^{1/2}$$

If $[H^+]_{acid} < 10^{-6}$ M, H^+ ions coming from water must be taken into consideration. It is clear from following example.

EXAMPLE 43. *(a) Calculate the pH of 10^{-6} M CH_3COOH, with $K_a = 1.8 \times 10^{-5}$.*

$$[H^+]_{acid} = (K_aC)^{1/2} = [(1.8 \times 10^{-5}) \times 10^{-6}]^{1/2}$$

$$= 4.24 \times 10^{-6}$$

$$\therefore \quad pH = -\log 4.24 \times 10^{-6}$$

$$= -[\log 4.24 - 6 \log 10]$$

$$= -(0.6274 - 6) = 5.3726.$$

But pH of 10^{-6} HCl = $-\log 10^{-6} = 6$

This pH value is more than that of CH_3COOH (= 5.3726) having same concentration. It means CH_3COOH gives more H^+ ions than HCl having the same concentration. It is not possible because CH_3COOH is weaker acid than HCl. Hence, we must have done some error.

(*b*) Now, let us calculate degree of dissociation, α.

$$\alpha = (K_a/C)^{1/2} = [(1.8 \times 10^{-5})/10^{-6}]^{1/2}$$

$$= \mathbf{4.24}.$$

But α can not be more than 1. It means we have committed an error by neglecting α from the denominator of $K_a = C\alpha^2/1 - \alpha$. It is because without knowing the value of α, the latter can not be neglected in comparison to 1. Hence α present in denominator must be considered and calculated by using quadratic equation.

$$10^{-6}\alpha^2 + 1.8 \times 10^{-5}\alpha - 1.8 \times 10^{-5} = 0$$

$$\left[\because K_a = \frac{C\alpha^2}{1-\alpha} \textbf{ Or } C\alpha^2 + K_a\alpha - K_a = 0\right]$$

$$\therefore \quad \alpha =$$

$$\frac{-1.8 \times 10^{-5} \pm \left[(1.8 \times 10^{-5})^2 - 4 \times 10^{-6} \times -1.8 \times 10^{-5}\right]^{1/2}}{2 \times 10^{-6}}$$

$$\left[\because \text{for } ax^2 + bx + c = 0,\ x = \frac{-b \pm (b^2 - 4ac)^{1/2}}{2a}\right]$$

$$\alpha = \frac{-1.8 \times 10^{-5} \pm \left[(3.24 \times 10^{-10}) + (7.2 \times 10^{-11})\right]^{1/2}}{2 \times 10^{-6}}$$

$$= \frac{(-1.8 \times 10^{-5}) + \left[10^{-10} \times 3.96\right]^{1/2}}{2 \times 10^{-6}}$$

$$= \frac{-1.8 \times 10^{-5} + 1.9899 \times 10^{-5}}{2 \times 10^{-6}}$$

$$= 0.95$$

$$\therefore \quad \alpha = 0.95. \quad \text{Hence } [H^+]_A$$

$$= C\alpha = 0.95 \times 10^{-6}$$

$$\therefore \quad pH = -\log [H^+]_A = -[\log 0.95 + \log 10^{-6}]$$

$$= -[-0.02227 - 6] = 6.02$$

EXAMPLE 44. *At what molar concentration, the pH of nitrous acid would be 2.0? (K_a of nitrous acid = 4.5×10^{-4}).*

(Dhanbad, 1990)

SOLUTION.	HNO_2 $\rightleftharpoons$	H^+ +	NO_2^-
Conc. at start	*C*	*0*	*0*
Change by ionisation	$-C\alpha$	$C\alpha$	$C\alpha$
Conc. at equilibrium	$C - C\alpha$	$C\alpha$	$C\alpha$.

$$\text{But} \quad \alpha = \left(\frac{K_c}{C}\right)^{1/2} \quad \text{...(1)}$$

(By Ostwald dilution law)

$$\text{Also,} \quad [H^+] = C\alpha \quad \text{...(2)}$$

From relations (1) and (2), we get :

$$[H^+] = C\left(\frac{K_c}{C}\right)^{1/2} = \left(\frac{C^2K_c}{C}\right)^{1/2} = (CK_c)^{1/2}$$

But $pH = 2.0 ; -\log [H^+] = 2.0 ; [H^+] = 10^{-2}$.

Hence : $10^{-2} = (CK_c)^{1/2} ; (10^{-2})^2 = CK_c$

$$\text{Or} \quad C = \frac{(10^{-2})^2}{K_c} \quad \therefore C \frac{10^{-4}}{4.5 \times 10^{-4}}$$

$= \mathbf{0.222\ M}$ **Ans.**

EXAMPLE 45. *The dissociation constant of HCN is 4×10^{-10}. What will be the concentration of H^+ ions in 1N HCN solution?* **(U.P. 1990)**

SOLUTION. For weak electrolytes, $K = C\alpha^2 ; C = 1N$

$$\therefore \quad 4 \times 10^{-10} = 1 \times \alpha^2 ; \alpha = \left(\frac{4 \times 10^{-10}}{1}\right)^{1/2}$$

$= 2 \times 10^{-2}$ g ion L^-. **Ans.**

EXAMPLE 46. *The pH value of a solution of NaOH is 10. Assuming complete dissociation, calculate the concentration of OH^- ions.* **(UP1990)**

SOLUTION. $pH = 10 ; -\log [H^+] = 10 ; \log [H^+] = -10; [H^+] = 10^{-10}$.

But $[H^+][OH^-] = K_w ; [OH^-] = K_w/[H^+]$

$= 10^{-14}/10^{-10} = 10^{-4}$

Or $[OH^-] = \mathbf{0.0001\ g\ ion\ L^-}$ **Ans.**

EXAMPLE 47. *You are provided with a solution having pH 0.35. Calculate its $[H_3O^+]$ and $[OH^-]$.*

SOLUTION. We know

$$pH = -\log [H^+] \text{ or } -\log [H_3O^+]$$

$\therefore \quad [H_3O^+] = 10^{-pH} = 10^{-0.35}$ $[\because pH = 0.35$ (given)]

$$[OH^-] = \frac{K_w}{[H_3O^+]} = \frac{10^{-14}}{10^{-0.35}} = 10^{-14+0.35}$$

$= 10^{-13.65}$ g ion L^-

EXAMPLE 48. *How many grams of nitric acid should be dissolved per litre to get its pH 2.6 ?*

SOLUTION. $pH = 2.6$ (given)

$[H^+] = 10^{-2.6}$ $[\because pH = -\log [H^+]]$

Taking logs of both sides, we get $\log H^+ = -2.6$

$= -2 - 1 + 1 - 0.6 = \bar{3}.4$

[$\because$ Mantissa must be positive]

Taking antilogs of both sides, we get

$[H^+] = \text{antilog } \bar{3}.4 = \mathbf{2.5 \times 10^{-3}\ g\ ion\ L^-}$

$= 0.0025$ M

HNO_3 is a strong electrolyte and is supposed to ionise completely in aqueous solution. Hence strength of HNO_3 which corresponds to 0.0025 M $[H^+]$ will be 0.0025 M

$\therefore$ Strength in gL^- = Molecular weight × molarity

$= 63 \times 0.0025\ gL^-$

[$\because$ Mol. wt. of $HNO_3 = 1 + 14 + 3 \times 16 = 63$]

$= 0.1575\ gL^-$

EXAMPLE 49. *Calculate the weight of sodium hydroxide that must be dissolved in 500 ml of solution to give it a pH of 10.*

SOLUTION. $pH = 10$ (given)

$\therefore \quad [H^+] = 10^{-10} ; [pH = -\log [H^+]] ;$

$K_w = [H^+][OH^-]$

$$\therefore \quad [OH^-] = \frac{K_w}{[H^+]} = \frac{10^{-14}}{10^{-10}} = 10^{-4} \text{ g ion } L^-$$

Since NaOH is a strong electrolyte, it is supposed to be 100% ionised. Hence the solution containing 10^{-4} g L^- of OH^- ions, will be 10^{-4} M.

Strength in gL^- = Mol. wt. × molarity $= 40 \times 10^{-4} gL^-$

[$\because$ Mol. wt. of NaOH = 23 + 16 + 1 = 40]

$= 0.0040\ gL^-$

$\because$ 1000 ml solution contain NaOH = 0.004 g

$\therefore$ 500 ml solution would contain NaOH

$$= \frac{0.004 \times 500}{1000} = \mathbf{0.002\ g}$$

EXAMPLE 50. *Calculate the concentration of H_3O^+ and OH^- ions in 0.01 M HNO_3 and 0.01 M KOH solution.*

SOLUTION. (*a*) HNO_3 is a strong electrolyte. It ionises completely in 0.01 M solution.

$$\underset{0.01\,M}{HNO_3} \xrightleftharpoons{H_2O} \underset{0.01M}{H_3O^+} + NO_3^-$$

$\therefore \quad [H_3O^+] = 0.01\ M = 0.01$ g mol L^-

$= 1.0 \times 10^{-2}$ g mol L^-

But $[OH^-] = K_w/[H_3O^+]$ $[\because K_w = [H_3O^+][OH^-]]$

$= 1.0 \times 10^{-14}/1.0 \times 10^{-2}$

$= \mathbf{10^{-12}\ g\ mol\ ion\ L^-}$

(*b*)KOH is a strong electrolyte. It ionises completely in 0.01 M solution

$$\underset{0.01\,M}{KOH} \xrightleftharpoons{H_2O} K^+ + \underset{0.01\,M}{OH^-}$$

$\therefore \quad [OH^-] = 0.01\ M = 1.0 \times 10^{-2}$ g mol L^-

But $K_w = [H_3O^+][OH^-]$

$1.0 \times 10^{-14} = [H_3O^+][1.0 \times 10^{-2}]$

$\therefore \quad [H_3O^+] = 10^{-12}$

Note : From above calculations we see that an acid (HNO_3) solution contains OH^- ions and an alkaline solution (KOH) contains H_3O^+ ions though to very small extent.

Type. To calculate $[H^+]$, K_a or molarity of a solution,

Use $$[H^+] = (K_a \times \text{molarity})^{1/2}$$

EXAMPLE 51. *The pH of a 0.1 M hydrocyanic acid solution is 5.2. What is the value of K_a for hydrocyanic acid?*

(Roorkee entrance, 1988)

SOLUTION. $$pH = 5.2 \text{ (given)}$$

$$\therefore \quad [H^+] = 10^{-5.2} \quad [\because pH = -\log [H^+]]$$

But $$[H^+] = \sqrt{K_a \times \text{Molarity}}$$

Squaring both sides, we get

$$[H^+]^2 = K_a \times \text{Molarity}$$

$$\therefore \quad K_a = [H^+]^2/\text{molarity} = (10^{-5.2})^2/0.1$$

$$K_a = 10^{-10.4} \times 10^1 = 10^{-9.4}$$

Taking logs of both sides, we get

$$\log K_a = \log 10^{-9.4} = -9.4 \log 10 = -9.4$$

$$= -9 - 1 + 1 - 0.4 = \overline{10}.6$$

Taking antilogs, we get

$$K_a = \text{antilog } \overline{10}.6$$

$$\therefore \quad K_a = 3.98 \times 10^{-10}$$

V Strong acid + Weak acid. Let strong acid (HA) and weak acid (HB) have concentrations C_1 and C_2 respectively. Let dissociation of weak acid HB is K_a. Thus, we have

$$\underset{C_1}{HA} \rightleftharpoons H^+ + B^- \quad \text{(complete ionisation)}$$

$$\underset{\substack{C_2 - C_2\alpha \\ = C_2(1-\alpha)}}{HB} \rightleftharpoons \underset{C_2\alpha + C_1}{H^+} + \underset{C_2\alpha}{B^-}$$

(α = degree of dissociation of HB)

$$\therefore \quad K_a = \frac{[H^+][B^-]}{[HB]}$$

$$= \frac{(C_2\alpha + C_1) \times C_2\alpha}{C_2(1-\alpha)} = \frac{(C_2\alpha + C_1)\alpha}{1-\alpha} \quad ...(1)$$

By solving equation (1), α can be calculated. From the value of α, $[H^+]$ and then pH can be calculated.

EXAMPLE 52. *Calculate the pH of a solution obtained by mixing 200 mL of 0.1 M HCl with 800 mL of 0.125 M CH_3COOH. (K_a for $CH_3COOH = 1.8 \times 10^{-5}$).*

SOLUTION. $$\underset{1 \text{ mol}}{HCl} \rightleftharpoons H^+ + Cl^-$$

$$200 \text{ mL of } 0.1 \text{ M HCl} = \frac{200 \times 0.1 \times 1}{1000} = 0.02 \text{ M} = C_1$$

[∵ Total volume of mixture = 200 + 800 = 1000 mL]

$$CH_3COOH \rightleftharpoons CH_3COO^- + H^+ ; K_a = 1.8 \times 10^{-5}$$

800 mL of 0.125 M CH_3COOH

$$= \frac{800 \times 0.125 \times 1}{1000} = 0.1 \text{ M} = C_2$$

For a mixture of a strong acid (HCl) and weak acid (CH_3COOH),

$$K_a = \frac{[H^+][CH_3COO^-]}{[CH_3COOH]}$$

$$= \frac{(C_2\alpha + C_1) \times \alpha}{1-\alpha} \quad ...(1)$$

or $$1.8 \times 10^{-5} = \frac{(0.1\alpha + 0.02) \times \alpha}{(1-\alpha)}$$

$$= \frac{(0.1\alpha + 0.02)\alpha}{1-\alpha}$$

$$\therefore \quad 1.8 \times 10^{-5}(1-\alpha) = (0.1\alpha + 0.02)\alpha ;$$

$$1.8 \times 10^{-5} - 1.8 \times 10^{-5}\alpha = 0.1\alpha^2 + 0.02\alpha$$

$$\therefore \quad 0.1\alpha^2 + 0.02\alpha + 1.8 \times 10^{-5}\alpha - 1.8 \times 10^{-5} = 0$$

Or $$0.1\alpha^2 + 10^{-5}\alpha(2 \times 10^3 + 1.8) - 1.8 \times 10^{-5} = 0$$

$$0.1\alpha^2 + 0.02\alpha - 1.8 \times 10^{-5} = 0$$

$$\therefore \quad \alpha = \frac{-0.02 \pm \left[(0.02)^2 - 4(0.1 \times -1.8 \times 10^{-5})\right]^{1/2}}{2 \times 0.1}$$

$$\left[\because \textit{for } ax^2 + bx + c = 0,\ x = \frac{-b \pm (b^2 - 4ac)^{½}}{2a}\right]$$

$$= \frac{-0.02 \pm (4 \times 10^{-4} + 0.72 \times 10^{-5})^{1/2}}{0.2}$$

$$= \frac{-0.02 \pm \left[10^{-4}(4 + 0.072)^{1/2}\right]}{0.2}$$

$$= \frac{-0.02 \pm 2.02 \times 10^{-2}}{0.2}$$

$$= \frac{-0.02 + 0.0202}{0.2} = \frac{0.002}{0.2}$$

(–ve sign is rejected because α can not be negative)

$$\alpha = 0.01$$

But $$[H^+] = C_2\alpha + C_1 \quad \text{[from equation (1)]}$$

$$= 0.1 \times 0.01 + 0.02$$

$$= 0.001 + 0.02 = \mathbf{0.021\ M}$$

$$\therefore \quad pH = -\log [H^+] = -\log 0.021$$

$$= -(-1.68) = \mathbf{+1.68}$$ **Ans.**

EXAMPLE 53. *K_a for HA is 4.9×10^{-8}. After making the necessary approximation, calculate for its decinormal solution (i) percentage dissociation (ii) OH^- ion conc. and pH.*

(IIT 1983, Kanpur I.I.T 1997)

SOLUTION. (*i*) $K_a = 4.9 \times 10^{-8}$; Degree of dissociation = α = ? Conc, C = N/10 = 0.1 *or* 0.1 M

$$HA \rightleftharpoons H^+ + A^-$$

But $$\alpha = \left(\frac{K_a}{C}\right)^{1/2} = \left(\frac{4.9 \times 10^{-8}}{0.1}\right)^{1/2}$$

$= (49 \times 10^{-8})^{1/2} = 7 \times 10^{-4}$

∴ % age degree of ionisation

$= 7 \times 10^{-4} \times 100 = 7 \times 10^{-2}$

$=$ **0.07% Ans.**

(*ii*) $[H^+] = C\alpha = 0.1 \times 7 \times 10^{-4} = 7 \times 10^{-5}$

(*iii*) $[OH^-] = \dfrac{K_w}{[H^+]} = \dfrac{10^{-14}}{7 \times 10^{-5}}$

$= \mathbf{1.43 \times 10^{-10}}$ **Ans.**

(*iv*) $pH = -\log [H^+] = -\log 7 \times 10^{-5}$

$= -[\log 7 + \log 10^{-5}]$

$= -[0.8451 - 5] = \mathbf{4.155}$ **Ans.**

Example 54. *Find the pH of a solution obtained by mixing 15 mL of 0.126 M NaOH and 21.0 mL of 0.051 M H_2SO_4. (Assume that the volume of the mixture is simply the sum of volumes mixed).*

Solution. Total volume of mixture = 15 + 21 = 36 mL

(*i*) 15 mL of 0.126 M NaOH $= 15 \times 0.126$

$= 1.89$ m.eq. NaOH

(*ii*) 21.0 mL of 0.051 M $H_2SO_4 = 21 \times 2 \times 0.051$

$= 2.142$ m.eq. H_2SO_4

[∵ H_2SO_4 in dibasic]

∴ $H_2SO_4 \rightleftharpoons 2H^+ + SO_4^{2-}$

But 1.89 m. eq. of H_2SO_4 exactly neutralise 1.89 m. eq. NaOH.

∴ H_2SO_4 left behind $= 2.142 - 1.89$

$= 0.252$ m. eq.

∴ $[H_2SO_4]$ or $[H^+] = \dfrac{0.252}{36} \times 1000$ m.eq. L^-

$= \dfrac{0.252}{36} \times \dfrac{1000}{1000}$

$= 7 \times 10^{-3}$ M

∴ $pH = -\log [H^+]$

$= -\log [7 \times 10^{-3}]$

$= -[0.845 - 3] = \mathbf{2.15}$ **Ans.**

Type. To find pH of a solution (obtained by mixing a weak acid with a strong base and vice-versa) and K_a or K_b is given, use :

(*i*) $\alpha = (K_a/C$ or molarity$)^{1/2}$ and find molarity *i. e.*, $[H^+]$.
(*ii*) $pH = -\log [H^+]$.

Example 55. *25 mL of 1.0 M acetic acid are completely mixed with 25 mL of 0.5 M caustic potash. Calculate the pH of the mixture ($K_a = 1.8 \times 10^{-5}$).*

Solution. Total volume of mixed solution = 25 + 25 = 50 mL.

(*i*) 25 mL of 1.0 M acetic acid $= 25 \times 1.0 = 25$ m. mol

(*ii*) 25 mL of 0.5 M KOH $= 25 \times 0.5 = 12.5$ m. mol

But 12.5 m. mol acetic acid completely neutralise 12.5 m. mol KOH.

∴ Acetic acid left behind $= 25 - 12.5 = 12.5$ m. mol.

∴ $[CH_3COOH]$ or $[H^+] = \dfrac{12.5}{50} \times 1000$ m. mol L^-

$= \dfrac{12.5}{50} \times \dfrac{1000}{1000}$ mol L^-

$= 0.25$ M

But degree of ionisation,

$\alpha = (K_c/C$ i.e., molarity$)^{½}$

$= \left(\dfrac{1.8 \times 10^{-5}}{0.25}\right)^{1/2}$

$= (72 \times 10^{-6})^{1/2}$

$= 8.48 \times 10^{-3}$

But ionic concentration $= \alpha \times$ molarity

∴ $[H_3O^+] = 8.48 \times 10^{-3} \times 0.25$

$= 2.12 \times 10^{-3}$ g ion L^-

∴ $pH = -\log [H_3O^+]$

$= -[\log 2.12 \times 10^{-3}]$

$= -[0.3263 - 3]$

$= 3 - 0.3263$

∴ $\mathbf{pH = 2.6737}$ **Ans.**

Example 56. *Calculate the pH of a solution of 0.1 M acetic acid. ($K_a = 1.8 \times 10^{-5}$).*

Solution. (*a*) Reaction : $CH_3COOH \rightleftharpoons CH_3COO^- + H^+$

Conc. at start	0.1 M	0	0
Conc. at equilibrium	$0.1 - x \simeq 0.1$	x	x

$0.1 - x = 0.1$ because x is very small as compared to 0.1 and hence neglected.

∴ $K_a = \dfrac{[CH_3COO^-][H^+]}{[CH_3COOH]}$;

$1.8 \times 10^{-5} = \dfrac{x \times x}{0.1}$

∴ $x = (1.8 \times 10^{-5} \times 0.1)^{1/2}$

$= 1.34 \times 10^{-3}$;

$[H^+] = 1.34 \times 10^{-3}$

or $[H^+] = (K_a \times \text{molarity})^{1/2}$

$= (1.8 \times 10^{-5} \times 0.1)^{1/2}$

$= 1.34 \times 10^{-3}$

∴ $pH = -\log 1.34 \times 10^{-3}$

$= -(\log 1.34 \times 10^{-3})$

$= -(\log 1.34 + \log 10^{-3})$

$pH = -(0.127 - 3) = 2.873$ **Ans.**

Type. To find *p*H of solutions containing weak acid and strong bases but the resulting solution after reaction is **neutral or alkaline**. In other words, at the end point and beyond that, however, [HA] *i.e.*, weak acid concentration, can not be set equal to zero but must be solved for ionic equilibrium conditions.

(*i*) For neutral solution at end point, write hydrolysis reaction of salt and find $[OH^-]$ by supposing $[OH^-] = x$ and, then find H^+, *p*H.

(*ii*) If the resulting solution at end point is basic (*i.e.*, contain excess of OH^- ion), then find $[OH^-]$ and then H^+ and hence *p*H.

EXAMPLE 57. *A 40 mL sample of 0.01 M CH_3COOH is titrated with 0.02 M NaOH. Calculate the pH after the addition of (i) 20 mL (ii) 30.0 mL NaOH solution. ($K_a = 1.8 \times 10^{-5}$)*

SOLUTION. (*i*) Amount of base added (L) = 20 mL = $\frac{20}{1000}$ = 0.02 L

$$\text{Total volume} = \frac{40}{1000} + 0.02$$
$$= 0.04 + 0.02 = 0.06 \text{ L}$$

no. of mol of CH_3COOH before neutralisation

$$= \frac{40}{1000} \times 0.01 = 4 \times 10^{-4}$$

no. of mol of OH^- added

$$= 0.02 \times 0.02 = 4 \times 10^{-4}$$

no. of mol of CH_3COO^- formed = 4×10^{-4}

no. of mol of CH_3COOH left behind

$$= (4 \times 10^{-4}) - (4 \times 10^{-4}) = \text{zero.}$$

Since, neither H^+ nor OH^- ions are present because no. of mol of CH_3COOH left = 0,

$$\therefore \quad M(CH_3COO^-) = \frac{4 \times 10^{-4} \text{ mol}}{\text{Total volume}}$$
$$= \frac{4 \times 10^{-4} \text{ mol}}{0.06 \text{ L}}$$
$$= 6.7 \times 10^{-3} \text{ mol L}^-$$

The solution at the end point is the same as 6.7×10^{-3} M CH_3COONa. Consider the hydrolysis of CH_3COONa.

$$CH_3COO^- + HOH \rightleftharpoons CH_3COOH + OH^-$$

Conc. (mol L^-) 6.7×10^{-3}

Conc. at equilibrium $6.7 \times 10^{-3} - x$ $\quad x \quad x$

But $6.7 \times 10^{-3} - x \simeq 6.7 \times 10^{-3}$ because x is very small as compared to 6.7×10^{-3} and hence neglected.

$$\therefore \quad K_b = \frac{[CH_3COOH][OH^-]}{[CH_3COO^-]} \quad \text{...(1)}$$

$$\text{Also,} \quad K_b = \frac{K_w}{K_a} = \frac{10^{-14}}{1.8 \times 10^{-5}} \quad \text{...(2)}$$

From (1) and (2), we get :

$$\frac{[CH_3COOH][OH^-]}{[CH_3COO^-]} = \frac{10^{-14}}{1.8 \times 10^{-5}};$$

$$\frac{x \times x}{6.7 \times 10^{-3}} = \frac{10^{-14}}{1.8 \times 10^{-5}};$$

$$x = \left(\frac{10^{-14} \times 6.7 \times 10^{-3}}{1.8 \times 10^{-5}}\right)^{1/2}$$
$$= (3.7 \times 10^{-12})^{1/2}$$

$$\therefore \quad x = 1.9 \times 10^{-6} \text{ or}$$

$$[OH^-] = 1.9 \times 10^{-6}$$

$$\therefore \quad [H^+] = \frac{10^{-14}}{1.9 \times 10^{-6}} = 5.26 \times 10^{-9};$$

$$pH = -\log[H^+]$$
$$= -(\log 5.26 + \log 10^{-9});$$
$$\mathbf{pH} = -(0.72 - 9) = \mathbf{8.28} \qquad \textbf{Ans.}$$

(*ii*) Amount of base added = 30 mL = $\frac{30}{1000}$ = 0.03 L

$$\text{Total volume} = \frac{40}{1000} \text{ L} + 0.03 \text{ L}$$
$$= 0.04 + 0.03 = 0.07 \text{ L.}$$

no. of mol of CH_3COOH before neutralisation

$$= \frac{40}{1000} \times 0.01 = 4 \times 10^{-4}$$

no. of mol of OH^- added

$$= 0.03 \times 0.02 = 0.0006 = 6 \times 10^{-4}$$

no. of mol of CH_3COO^- formed = 4×10^{-4}

∴ no. of mol of OH^- left behind

$$= (6 \times 10^{-4}) - (4 \times 10^{-4})$$
$$= 2 \times 10^{-4}$$

From above, it is clear that there are excess of OH^- ions beyond that needed for neutralising CH_3COOH. For such a case, we know that :

$$M[OH^-] = \frac{2 \times 10^{-4} \text{ mol}}{\text{Total volume (L)}}$$
$$= \frac{2 \times 10^{-4}}{0.07}$$
$$= 2.86 \times 10^{-3} \text{ mol L}^-$$

$$\therefore \quad [OH^-] = 2.86 \times 10^{-3};$$

$$[H^+] = \frac{K_w}{[OH^-]} = \frac{10^{-14}}{2.86 \times 10^{-3}}$$
$$= 3.5 \times 10^{-12}$$

$$\therefore \quad pH = -\log[H^+] = -\log(3.5 \times 10^{-12})$$
$$= -(\log 3.5 + \log 10^{-12})$$

$$\textbf{or} \quad \mathbf{pH} = -(0.54 - 12) = \mathbf{11.46} \qquad \textbf{Ans.}$$

EXAMPLE 58. *Calculate the $[OH^-]$ and pH of the following solution : 10 mL of 0.2 M $Ca(OH)_2$ + 25 mL of 0.1 M HCl.*

(CBSE-PMT, 2009)

SOLUTION. Total volume of mixture solution = 10 + 25 = 35 ml

(*i*) 10 mL of 0.2 M $Ca(OH)_2$

$$= 10 \times (2 \times 0.2)$$
$$= 4 \text{ m mol of } Ca(OH)_2$$

$$[\because Ca(OH)_2 \rightleftharpoons Ca^{2+} + 2OH^- \ (\textit{i.e.}, 2 \text{ mol } OH^-)].$$

(*ii*) 25 mL of 0.1 M HCl = 25 × 0.1 = 2.5 m. mol of HCl

But 2.5 m. mol of $Ca(OH)_2$ completely neutralise 2.5 m mol of HCl.

So, m. mol of $Ca(OH)_2$ left behind

$$= 4 - 2.5 = 1.5$$

$$\therefore \quad [Ca(OH)_2] = [OH^-]$$

$$= \frac{1.5}{\text{Total volume}} \times 1000 \text{ m. mol L}^-$$

$$[OH^-] = \frac{1.5}{35} \times \frac{1000}{1000} \text{ mol L}^- = 0.0428 \text{ M}$$

$$\text{But} \quad [H^+] = \frac{K_w}{[OH^-]} = \frac{10^{-14}}{0.0428}$$

$$= 2.34 \times 10^{-13} \text{ M}$$

$$\therefore \quad pH = -\log [H^+] = -\log [2.34 \times 10^{-13}]$$

$$= -[0.3692 - 13] = 13 - 0.3692$$

$$\boldsymbol{pH = 12.63} \qquad \textbf{Ans.}$$

EXAMPLE 59. *Calculate the pH of a solution made by mixing 50 mL of 0.01 M $Ba(OH)_2$ solution with 50 mL water.*

(MLNR 1988)

SOLUTION. Total volume of solution = 50 + 50 = 100 mL

Original $Ba(OH)_2$ solution; Diluted $Ba(OH)_2$ solution

$$M_1V_1 = M_2V_2$$

$$0.01 \text{ M} \times 50 \text{ mL} = M_2 \times 100 \text{ mL}$$

$$M_2 = \frac{0.01 \text{ M} \times 50 \text{ mL}}{100 \text{ mL}} = 0.005 \text{ M}$$

$$\underset{1 \text{ mol}}{Ba(OH)_2} \rightleftharpoons Ba^{2+} + \underset{2 \text{ mol}}{2OH^-}$$

$$\therefore \quad [Ba(OH)_2] = [OH^-] = 2 \times 0.005 = 0.01 \text{ M}$$

$$\therefore \quad [H^+] = \frac{K_w}{[OH^-]} = \frac{10^{-14}}{0.01} = 10^{-12} \text{ M}$$

$$\therefore \quad pH = -\log 10^{-12} = -[-12 \log 10]$$

$$= -[-12 \times 1] = \mathbf{12} \qquad \textbf{Ans.}$$

Type. *p*H of a solution obtained by **mixing strong acid and strong base.** Use the relation.

no. of mol = Vol (is litre) × molarity (mol L⁻)

EXAMPLE 60. *40 cm³ of a 0.1 molar NaOH was added to 10 cm³ of 0.45 molar HCl. What is the pH of the resulting solution? Both NaOH and HCl are strong electrolytes.* ($K_w = 10^{-14}$ *mol^2L^{-2}*).

SOLUTION. For NaOH, $[OH^-] = 0.1$ M ;

Volume = 40 cm³.

1000 cm³ solution contain $[OH^-] = 0.1$ M

40 cm³ solution contain $[OH^-]$

$$= \frac{0.1}{1000} \times 40 = 0.004 \text{ M.}$$

$$\text{Or} \quad \text{no. of mol of } OH^- = \frac{40}{1000} \times 0.1 = 0.004 \text{ M}$$

For HCl, $[H^+] = 0.45$ M ; Volume = 10 cm³

1000 cm³ solution contain

$$[H^+] = 0.45 \text{ M}$$

10 cm³ solution contain $[H^+]$

$$= \frac{0.45 \times 10}{1000} = 0.0045 \text{ M.}$$

$$\text{Or} \quad \text{no. of mol of } H^+ = \frac{10}{1000} \times 0.45 = 0.0045 \text{ M.}$$

Total volume of mixing = 40 + 10 = 50 cm³

∴ Mol of H^+ ions left unused

$$= 0.0045 - 0.004 = 0.0005 \text{ M.}$$

Mol of H^+ ions in 50 cm³ solution = 0.0005 M

Mol of H^+ ions in 1000 cm³ solution

$$= \frac{0.0005}{50} \times 1000 = 0.01$$

$$= 10^{-2} \text{ M}$$

$$\therefore \quad [H^+] = 10^{-2} \text{ M}$$

$$\text{Hence,} \quad pH = -\log [H^+] = -\log (10^{-2})$$

$$\text{Or} \quad pH = -(-2 \log 10) = -(-2 \times 1)$$

$$= \mathbf{+2} \qquad \textbf{Ans.}$$

EXAMPLE 61. *The pH of a solution prepared by mixing 2.0 mL of HCl solution of pH 3.0 and 3.0 mL of NaOH of pH 10.0 is:*

(a) 2.5 (b) 3.5 (c) 5.5 (d) 6.5

(I.I.T., 1998, AMU med. 2010, J&KCET, 2010)

SOLUTION. (*i*) For HCl, pH = 3. So, $[H^+] = 10^{-3} = M_1$, $V_1 = 2.0$ mL

(*ii*) For NaOH, pH = 10; But $p_H + p_{OH} = 14$, so, 10 + *p*OH = 14 or $p_{OH} = 14 - 10 = 4$; $[OH^-] = 10^{-4} = M_2$, $V_2 = 3.0$ mL; M_R = resultant molarity

$\therefore M_1V_1 - M_2V_2 = M_R(V_1 + V_2)$; $(10^{-3} \times 2) - (10^{-4} \times 3) = M_R(2 + 3)$; $10^{-3}(2 - 0.3) = 5\,M_R$.

or $M_R \times 5 = 1.7 \times 10^{-3}$. So, $M_R = 3.4 \times 10^{-4} = [H^+]$

Hence, pH = $-\log (3.4 \times 10^{-4}) = [\log 3.4 + \log 10^{-4}] = 4 - 0.53 = 3.47 \simeq 3.5$. So, correct answer is (*b*).

EXAMPLE 62. *The pk_{a_1} and pk_{a_2} of an amino acid are 2.3 and 9.7 respectively. The isoelectric point of the amino acid is:*

(a) 12. 0 (b) 7.4 (c) 6.0 (d) 3.7 **(AMUMed.2010)**

SOLUTION. Isoelectric point = 2.3 + 9.7/2 = 6. So, correct answer is (*c*).

EXAMPLE 63. *Calculate the pH of a solution containing 20 mL of 0.1 M H_2SO_4 and 40 mL of 0.2 M HCl.*

SOLUTION. $HCl \rightleftharpoons H^+ + Cl^-$ (ionisation).

∴ Milliequivalent of 40 mL of 0.2 M HCl

$$= 40 \times 0.2 \times 1 = 8$$

$$H_2SO_4 \rightleftharpoons 2H^+ + SO_4^{2-}$$

∴ Milliequivalent of 20 mL 0.1M H_2SO_4

$$= 20 \times 0.1 \times 2 = 4$$

Total number of milliequivalent of H^+ ions (from HCl and H_2SO_4) = 8 + 4 = 12

Total volume of solution

$$= 20 + 40 = 60 \text{ mL}$$

$\therefore \quad [H^+] = \frac{12}{60} = 0.2$

$\therefore \quad pH = -\log [H^+] = -[\log 0.2]$

$= -[-0.6989]$

$= \mathbf{+0.6989}$ **Ans.**

EXAMPLE 64. *Calculate the pH of a solution obtained by mixing 0.063 g nitric acid dissolved in 250 mL solution and 0.049 g sulphuric acid dissolved in 250 mL solution.*

SOLUTION. (*a*) g. mol. wt. of HNO_3

$= 1 + 14 + (3 \times 16) = 63$ g.

Total volume of solution

$= 250 + 250 = 500$ mL

500 mL solution contain HNO_3

$= 0.063$ g

1000 mL HNO_3 contain HNO_3

$= \frac{0.063}{500} \times 1000 = 0.126$ g

$\therefore$ no. of mol of $HNO_3 = \frac{0.126}{63} = 2 \times 10^{-3}$

$\therefore \quad [H^+] = [HNO_3] = 2 \times 10^{-3}\ M \times 1$

$= 2 \times 10^{-3}$ M

$[\because HNO_3 \rightleftharpoons H^+ \text{(1 mol)} + NO_3^-]$

(*b*) g. mol. wt. of $H_2SO_4 = (2 \times 1) + 32 + (4 \times 16) = 98$ g

500 mL solution contain $H_2SO_4 = 0.049$ g

1000 mL solution contain H_2SO_4

$= \frac{0.049}{500} \times 1000 = 0.098$ g

But $\quad H_2SO_4 \rightleftharpoons 2H^+ \text{(2 mol)} + SO_4^{2-}$

$\therefore$ no. of mol of H_2SO_4 or $[H^+]$

$= \frac{0.098}{98} \times 2 = 2 \times 10^{-3}$

$\therefore \quad [H^+] = 2 \times 10^{-3}$ M

$\therefore \quad$ Total $[H^+] = (2 \times 10^{-3}) + (2 \times 10^{-3})$

$= 2 [10^{-3} + 10^{-3}]$

$= 2 \times 2 \times 10^{-3} = 4 \times 10^{-3}$ M

$\therefore \quad pH = -\log [H^+] = -\log 4 \times 10^{-4}$

$= -[\log 4 - 3 \log 10]$

$= -[0.602 - 3]$

$pH = 3 - 0.602 = \mathbf{2.398}$ **Ans.**

EXAMPLE 65. *Calculate the pH of the solution obtained by mixing equal volumes of the solution having pH 2 and 6.*

SOLUTION. (1) $\quad pH = 2 ;\ \therefore\ [H^+] = 10^{-2}$ M

(2) $\quad pH = 6 ;\ [H^+] = 10^{-6}$

Since the resulting solution is obtained by mixing equal volumes of two solutions :

$$[H^+] = \frac{10^{-2} + 10^{-6}}{2} = \frac{10^{-2}[1 + 10^{-4}]}{2}$$

$$= \frac{10^{-2} \times 1.0004}{2}$$

$= 0.5002 \times 10^{-2}$ M

$= 5.002 \times 10^{-3}$ M

$\therefore \quad pH = -\log [H^+]$

$= -\log [5.002 \times 10^{-3}]$

$= -[\log 5.002 + \log 10^{-3}]$

$= -[0.6991 - 3] = \mathbf{2.33}$ **Ans.**

EXAMPLE 66. *How much volume (in mL) of 0.001 M HNO_3 (aq) should be added to 100 cm^3 of 0.001 M KOH to change its pH by one unit ?*

SOLUTION. $\quad KOH \rightleftharpoons K^+ + OH^-$;

$[KOH] = [OH^-] = 0.001M = 10^{-3}$ M

But $\quad [H^+] = \frac{K_w}{[OH^-]} = \frac{10^{-14}}{10^{-3}} = 10^{-14+3}$

$= 10^{-11}$

$\therefore \quad pH = -\log [H^+] = -\log 10^{-11} = \mathbf{11}$

Change in pH required = 1

$\therefore$ Required pH after adding $HNO_3 = 11 - 1 = \mathbf{10}$

$\therefore \quad [H^+] = 10^{-10}\ M ;\ [OH^-] = \frac{K_w}{[H^+]} = \frac{10^{-14}}{10^{-10}}$

$= 10^{-14+10} = 10^{-4}$

$\therefore$ no. of mol of KOH in 100 cm^3 of 10^{-3} M

$= \frac{10^{-3} \times 100}{1000} = 10^{-4}$

no. of mol of KOH in 100 cm^3 of 10^{-4}M

$= \frac{10^{-4} \times 100}{1000} = 10^{-5}$

no. of mol of KOH to be neutralised by HNO_3

$= 10^{-4} - 10^{-5} = 10^{-5} (10 - 1)$

$= 9 \times 10^{-5}$

Volume of 0.001M HNO_3 containing 9×10^{-5} mol

$HNO_3 = \frac{1000 \times 9 \times 10^{-5}}{0.001} = 90$

$\therefore$ Volume of 0.001 M HNO_3 to be added

$= \mathbf{90\ mL.}$ **Ans.**

EXAMPLE 67. *500 mL of a solution contain 0.28 g of KOH (a) How much water should be added to it to change its original pH by unity?*

(b) How much water should be evaporated from it to change its original pH by unity?

SOLUTION. 500 solution contain KOH = 0.28 g

$\therefore$ 1000 mL solution contain

$KOH = \frac{0.28}{500} \times 1000 = 0.56$ g

g. mol. wt. of KOH = 39 + 16 + 1 = 56 g

$$\therefore \quad [KOH] = [OH^-(aq)] = \frac{0.56}{56} = 10^{-2} M;$$

$$[H^+(aq)] = \frac{K_w}{[OH^-(aq)]} = \frac{10^{-14}}{10^{-2}} = 10^{-12}$$

$$\therefore \quad pH = -\log 10^{-12} = (-)(-12 \log 10)$$
$$= +12 \times 1 = +12$$

(*i*) When KOH solution is diluted, it becomes less concentrated and $[OH^-(aq)]$ decreases *i.e.*, $[H^+(aq)]$ increases and hence pH decreases.

Thus : Desired pH = 12 – 1 = 11.

So, $[H^+(aq)] = 10^{-11}$ M ;

$$[OH^-(aq)] = \frac{K_w}{[H^+(aq)]} = \frac{10^{-14}}{10^{-11}} = 10^{-3}$$

Original $[OH^-(aq)]$ Diluted $[OH^-(aq)]$

$$M_1V_1 = M_2V_2$$

$$10^{-2} \times 500 = 10^{-3} \times V_2\,;\; V_2 = \frac{10^{-2} \times 500}{10^{-3}}$$
$$= 5000 \text{ mL}$$

∴ Volume of water to be added

= 5000 – 500 = 4500 mL

$= \frac{4500}{1000} =$ **4.5 L** **Ans.**

(*ii*) When KOH solution is evaporated, it becomes concentrated and $[OH^-(aq)]$ increases *i.e.*, $[H^+(aq)]$ decreases and hence pH increases.

Desired pH = 12 + 1 = 13.

So, $[H^+(aq)] = 10^{-13}$ M ;

$$[OH^-(aq)] = \frac{K_w}{[H^+(aq)]} = \frac{10^{-14}}{10^{-13}} = 10^{-1}$$

Original $[OH^-(aq)]$ $[OH^-(aq)]$ after evaporation

$$M_3V_3 = M_4V_4$$

$$10^{-2} \times 500 = 10^{-1} \times V_4;\; V_4 = \frac{10^{-2} \times 500}{10^{-1}}$$
$$= 50 \text{ mL}$$

∴ Volume of water to be evaporated

= 500 – 50 = 450 ml

$= \frac{450}{1000} =$ **0.45 L** **Ans.**

EXAMPLE 68. *Calculate the pH value of a solution obtained by mixing 600 mL of 0.1 M NaOH and 400 mL of 0.1M* $Ca(OH)_2$.

SOLUTION. (*i*) 600 mL of 0.1 M NaOH $= \frac{600 \times 0.1}{1000} = 0.06$ M

$$NaOH \xrightleftharpoons{H_2O} Na^+(aq) + OH^-(aq);$$

$[OH^-(aq)] = 0.06$M.

$$Ca(OH)_2 \rightleftharpoons Ca^{2+}(aq) + \underset{2 \text{ mol}}{2OH^-(aq)}$$

∴ 400 mL of 0.1M $Ca(OH)_2$

$$= \frac{400 \times 0.1 \times 2}{1000} = 0.8 \text{ M}$$
$$= [OH^-(aq)]$$

∴ Total $[OH^-(aq)] = 0.06 + 0.08 = 0.14$ M

But
$$[H^+(aq)] = \frac{K_w}{[OH^-(aq)]} = \frac{10^{-14}}{0.14}$$
$$= 7.1 \times 10^{-14}$$

$$\therefore \quad pH = -\log [H^+] = -\log 7.1 \times 10^{-14}$$
$$= -[\log 7.1 + \log 10^{-14}]$$

pH = – (0.85 – 14) = 13.15 Ans.

EXAMPLE 69. *A solution has been prepared by mixing 50 mL of 0.05 M* H_2SO_4, *50 mL of 0.05N* HNO_3, *100 mL of 0.1N HCl, 100 mL of 0.2N NaOH and 100 mL of 0.2M* $Ba(OH)_2$. *Calculate the pH of the resulting solution.*

SOLUTION. (*i*) 50 mL of 0.05 M H_2SO_4 = 50 × 0.05 of 1M H_2SO_4 = 2.5 mL of 1M H_2SO_4

= 2.5 × 2 *i.e.*, **5 mL** of 1 N $H^+(aq)$ ions.

$(\because H_2SO_4 \rightleftharpoons 2H^+ + SO_4^{2-})$

(*ii*) 50 mL of 0.05 N HNO_3 = 50 × 0.05 *i.e.*,

2.5 mL of 1N HNO_3 = **2.5 mL** of 1 N HNO_3

(*iii*) 100 mL of 0.1N HCl = 100 × 0.1 *i.e.*,

10 mL of 1N HCl = **10 mL** of 1N HCl.

(*iv*) 100 mL of 0.2N NaOH = 100 × 0.2 *i.e.*,

20 mL of 1N NaOH = **20 mL** of 1N NaOH

(*v*) 100 mL of 0.2 M $Ba(OH)_2$ = 100 × 0.2 *i.e.*,

20 mL of 1 M $Ba(OH)_2$ = 20 × 2 *i.e.*, **40 mL** of 1N. $Ba(OH)_2$

$[\because Ba(OH)_2 \rightleftharpoons Ba^{2+} + \mathbf{2OH^-}]$

Total volume of 1N $H^+(aq)$ ions

= 5 + 2.5 + 10 = 17.5 mL

Total volume of 1N $OH^-(aq)$ ions

= 20 + 40 = 60 mL

∴ 17.5 mL of 1N $OH^-(aq)$ ions = 17.5 mL of 1N, $H^+(aq)$ ions.

∴ Volume of 1N $OH^-(aq)$ ions left unused

= 60 – 17.5 = 42.5 mL

Actual volume of solution = 50 + 50 + 100 + 100 + 100 = 400 mL

Unused $[OH^-(aq)]$ Mixture $[OH^-(aq)]$

$$N_1V_1 = N_2V_2;\; 1 \times 42.5 = N_2 \times 400$$

$$\therefore \quad N_2 = \frac{42.5}{400}$$

Or $$[OH^-(aq)] = \frac{42.5}{400}\text{ N}$$

∴ $$[H^+] = \frac{K_w}{[OH^-]} = \frac{10^{-14}}{42.5} \times 400$$

$$= 9.4 \times 10^{-14}$$

∴ $$pH = -\log [H^+]$$

$$= -\log 9.4 \times 10^{-14}$$

$$= -[\log 9.4 + \log 10^{-14}]$$

$$pH = -(0.97 - 14)$$

$$= \mathbf{13.03}$$ **Ans.**

EXAMPLE 70. *Calculate the pH of a solution obtained by dissolving 0.28 g of potassium hydroxide in 1.0 L of water.*

(NCERT Book problem)

SOLUTION. g. mol. wt. of KOH = 39 + 16 +1 = 56 g ; wt. of KOH = 0.28 g; 1L = 100 mL.

$$\text{Molarity of KOH} = \frac{\text{wt. (g)}}{\text{g. mol. wt}} = \frac{0.28}{56\text{ g}}$$

$$= 5.0 \times 10^{-3}\text{ M};$$

$$[OH^-] = 5 \times 10^{-3}\text{ M}$$

∴ $$[H^+] = \frac{K_w}{[OH^-]} = \frac{10^{-14}}{5 \times 10^{-3}} = 2 \times 10^{-12}$$

∴ $$pH = -\log [H^+] = -(\log 2 \times 10^{-12})$$

$$= -(\log 2 + \log 10^{-12})$$

$$= -(0.301 - 12) = \mathbf{11.699}$$ **Ans.**

EXAMPLE 71. *Calculate pH for 0.0008 $Mg(OH)_2$*

(Roorkee, 1992)

SOLUTION. 0.0008 M $Mg(OH)_2$ = 8×10^{-4} M $Mg(OH)_2$

	$Mg(OH)_2 \rightleftharpoons$	Mg^{2+} +	$2OH^-$
Original concentration	8×10^{-4} M	0	0
Concentration after ionisation		8×10^{-4} M	$2 \times 8 \times 10^{-4}$ N $= 16 \times 10^{-4}$ N

∴ $$[OH^-] = 16 \times 10^{-4}\text{ N}$$

∴ $$pOH = -\log 16 \times 10^{-4}$$

$$= -[\log 16 + \log 10^{-4}]$$

$$pOH = -(1.204 - 4) = 2.796.$$

Hence $$\mathbf{pH} = 14 - pOH = 14 - 2.796$$

$$= \mathbf{11.204}$$ **Ans.**

EXAMPLE 72. *A solution contains 0.1 M H_2S and 0.3 M HCl. Calculate the concentration of S^{2-} and HS^- ions in solution. Given Ka_1 and Ka_2 for H_2S are 10^{-7} and 1.3×10^{-13} respectively.*

(Roorkee, 1992)

SOLUTION. Ionisation.

$$H_2S \rightleftharpoons H^+ + HS^-;\ Ka_1 = 10^{-7}$$

$$HS^- \rightleftharpoons H^+ + S^{2-};\ Ka_2 = 1.3 \times 10^{-13}$$

$$HCl \rightleftharpoons H^+ + Cl^-;\ [H^+] = 0.3\text{ M}$$

H^+ ions are common ions. So, due to addition of HCl, ionisation of H_2S is suppressed. So, $[H^+]$ is due to HCl and thus, $[H^+] = 0.3$.

(*a*) *To find $[HS^-]$.*

$$Ka_1 = \frac{[H^+][HS^-]}{[H_2S]};$$

$$10^{-7} = \frac{0.3 \times [HS^-]}{0.1}$$

∴ $$[HS^-] = \frac{0.1 \times 10^{-7}}{0.3}$$

$$= \mathbf{3.3 \times 10^{-8}\ M}$$ **Ans.**

(*b*) *To find $[S^{2-}]$.* $$Ka_2 = \frac{[H^+][S^-]}{[HS^-]};$$

$$13 \times 10^{-13} = \frac{0.3 \times [S^{2-}]}{3.3 \times 10^{-8}}$$

∴ $$[S^{2-}] = \frac{1.3 \times 10^{-13} \times 3.3 \times 10^{-8}}{0.3}$$

$$= \mathbf{1.43 \times 10^{-20}\ M}$$ **Ans.**

EXAMPLE 73. *Calculate the approximate pH of a 0.1M aqueous H_2S solution. K_1 and K_2 for H_2S are 10^{-7} and 1.3×10^{-13} respectively at 298K.* **(Roorkee,1986)**

SOLUTION. The value of K_1 (= 10^{-7}) is >>> than K_2 (= 1.3×10^{-13}) value. So, $[H^+]$ will be due to first ionisation of H_2S.

$$H_2S \xrightleftharpoons{H_2O} H^+(aq) + HS^-(aq)\text{(First ionisation)}$$

∴ $$K_1 = \frac{[H^+(aq)][HS^-(aq)]}{[H_2S]};$$

$$10^{-7} = \frac{[H^+(aq)][H^+(aq)]}{[H_2S]}$$

$$[\because [H^+(aq)] = [HS^-(aq)]]$$

Or $$10^{-7} = \frac{[H^+(aq)]^2}{0.1};$$

$$[H^+(aq)] = (10^{-7} \times 0.1)^{1/2} = \mathbf{10^{-4}\ M}$$ **Ans.**

$$pH = -\log [H^+] = -\log 10^{-4}$$

$$= -(-4)\log 10 = \mathbf{4}$$ **Ans.**

EXAMPLE 74. *If 0.4 molar aqueous solution of $Ca(OH)_2$ is 85% ionised at 298 K, what will be the pH of this solution at the same temperature ?*

SOLUTION. Degree of ionisation of $Ca(OH)_2$ = 85% = $\frac{85}{100}$ = 0.85

$$Ca(OH)_2 \rightleftharpoons Ca^{2+} + \underset{2 \times 0.4 \times 0.85 = 0.68}{2OH^-}$$

∴ $$[OH^-] = 0.68;$$

∴ $$[H^+] = \frac{K_w}{[OH^-]} = \frac{10^{-14}}{0.68}$$

$$= 1.47 \times 10^{-14}$$

$$\therefore \quad pH = -\log 1.47 \times 10^{-14}$$

$$= -(\log 1.47 + \log 10^{-14})$$

$$= -(0.167 - 14)$$

$$\boldsymbol{pH} = 14 - 0.167 = \mathbf{13.833} \qquad \textbf{Ans.}$$

EXAMPLE 75. *0.1 millimol of $CdSO_4$ are present in 10 mL acid solution of 0.08N HCl. Now H_2S is passed to precipitate all the Cd^{2+} ions. What would be the pH of the solution after filtering off precipitate, boiling of H_2S and making the solution 100 mL by adding H_2O?* **(IIT1984)**

SOLUTION. Reaction :

$$CdSO_4 + HCl + H_2S \rightleftharpoons CdS\downarrow + H_2SO_4 + HCl$$

	$CdSO_4$	HCl	H_2S	CdS↓	H_2SO_4	HCl
Millimol at start	0.1	10×0.08 $= 0.8$				
Millimol after reaction	0	0.8			0.1	0.1

$[H^+]$ left in HCl = 0.8 ;

$[H^+]$ in $H_2SO_4 = 2 \times 0.1 = 0.2$

$$[\because H_2SO_4 \rightleftharpoons 2H^+ + SO_4^{2-}]$$

$\therefore$ Total millimol of H^+ ions left = 0.8 + 0.2 = 1.0

Total volume = 100 mL.

Hence : 100 mL solution contain H^+ ions = 1 millimol

$\therefore$ 1000 mL solution contain H^+ ions

$$= \frac{1}{100} \times 1000 = 10 \text{ millimol}$$

But $\quad 10 \text{ millimol} = \dfrac{10}{1000} \text{ mol} = 10^{-2} \text{ mol.}$

$$\therefore \quad [H^+] = 10^{-2}\text{ M} \ \textbf{Or}$$

$$pH = -\log 10^{-2} = -(-2 \log 10)$$

$$= -(-2 \times 1) = \mathbf{2} \qquad \textbf{Ans.}$$

EXAMPLE 76. *Twenty ml of 0.2 M sodium hydroxide is added to 50 ml of 0.2 M acetic acid to give 70 ml of the solution. What is the pH of the solution? Calculate the additional volume of 0.2 M NaOH required to make the pH of the solution 4.74. The ionisation constant of acetic acid is 1.8×10^{-5}.* **(IIT 1982)**

SOLUTION. (*a*) We know that

$$pH = -\log K_a + \log \frac{[\text{salt}]}{[\text{acid}]} \qquad ...(1)$$

Since 20 ml of 0.2 M NaOH will completely neutralise 20 ml of 0.2M acetic acid, we shall be left with 30 mL (50 – 20 = 30) of acetic acid. The total volume of solution after mixing is 70 ml. Thus in the mixture :

$$[\text{acid}] = 30 \times 0.2/70 = 0.085;$$

$$[\text{salt}] = 20 \times 0.2/70 = 0.057.$$

Substituting the respective values in equation (1), we get

$$pH = -\log(1.8 \times 10^{-5}) + \log \frac{0.057}{0.085}$$

$$= -[\log 1.8 + \log 10^{-5}]$$

$$+ \log 57 - \log 85$$

$$= -[0.26 - 5] + 1.7559 - 1.9294$$

$$= 5 - 0.26 + 1.7559 - 1.9294$$

$$= 4.74 + 1.7559 - 1.9294$$

$$\mathbf{pH = 4.57}$$

(*b*) To calculate the volume of 0.2 M NaOH to be added to get pH, 4.74. In order to get pH = 4.74, the [salt] should be equal to [acid]. For this purpose, 50/2 ml (= 25 ml) of 0.2M acetic acid must be equal to 50/2 ml (= 25ml) of 0.2 M NaOH.

Volume of 0.2 M NaOH already added = 20 ml

Volume of 0.2 M NaOH to be added for complete neutralisation = 25 ml.

$\therefore$ Additional volume of 0.2 M NaOH to be added for getting pH (4.74) = 25 – 20 = **5 ml**

EXAMPLE 77. *The concentration of hydrogen ions in a 0.2 molar solution of formic acid is 6.4×10^{-3} mole per litre. To this solution sodium formate is added so as to adjust the concentration of sodium formate to one mole per litre. What will be the pH of this solution? The dissociation constant of formic acid is 2.4×10^{-4} and degree of dissociation of sodium formate is 0.75.* **(IIT, 1985)**

SOLUTION. (*a*) K_a for formic acid

$$= 2.4 \times 10^{-4} \text{ mol L}^{-};$$

$$[H^+] = 0.2 \text{ M (given)}$$

Let $\quad x = [H^+]$ after the addition of HCOONa.

Formic acid (HCOOH) ionises as :

$$HCOOH \rightleftharpoons H^+ + HCOO^-$$

Applying law of mass action, we get

$$K_a = \frac{[H^+][HCOO^-]}{[HCOOH]} \qquad ...(1)$$

Here $\quad [HCOOH]_{\text{final}} = 0.2 - x$

$[HCOO^-]_{\text{final}}$ = $[HCOO^-]$ available from dissociation of HCOONa + $[HCOO^-]$ available from dissociation of HCOOH = $0.75 - x$

Substituting the values in equation (1), we get

$$2.4 \times 10^{-4} = \frac{x \times (0.75 - x)}{0.2 - x}$$

$$2.4 \times 10^{-4} \times 0.2 - 2.4 \times 10^{-4}x = 0.75x - x^2$$

x being small, x^2 and $2.4 \times 10^{-3}x$ are hence neglected.

$$\therefore \quad 0.75x = 0.48 \times 10^{-4} \ x = \frac{0.48 \times 10^{-4}}{0.75}$$

$$= 0.64 \times 10^{-4} \text{ mol L}^{-}$$
$$= 6.4 \times 10^{-5}$$

(*b*) $$pH = -\log[H^+] = -\log(6.4 \times 10^{-5})$$
$$= -(\log 6.4 - 5 \log 10)$$
$$= -0.8062 + 5$$
$$\mathbf{pH = 4.1938 \simeq 4.2}$$

EXAMPLE 78. *What is the pH of a 1.0M solution of acetic acid? To what volume must one litre of its solution be diluted so that the pH of the resulting solution will be twice the original volume? Given $K_a = 1.8 \times 10^{-5}$.* **(IIT, 1990)**

SOLUTION. Acetic acid ionises as,

$$CH_3COOH \rightleftharpoons CH_3COO^- + H^+$$

Applying law of mass action, we have

$$K_a = \frac{[CH_3COO^-][H^+]}{[CH_3COOH]} = \frac{[H^+]^2}{[CH_3COOH]}$$
$$[\because [H^+] = [CH_3COO^-]]$$
$$[H^+]^2 = K_a[CH_3COOH]$$
$$= 1.8 \times 10^{-5} \times 1$$
$$\therefore \quad [H^+] = \sqrt{18 \times 10^{-6}} = 4.24 \times 10^{-3}$$
$$\therefore \quad pH = -\log[H^+] = -\log(4.24 \times 10^{-3})$$
$$= -(\log 4.24 - 3 \log 10)$$
$$= -\log 4.24 + 3$$
$$pH = -0.6274 + 3 = \mathbf{2.3726}$$

Required pH of diluted solution

$$= 2 \times 2.3726 = 4.7452 \simeq 4.74$$
$$\therefore \quad \text{pH required} = 4.74 - \log[H^+] = 4.74$$
$$\log[H^+] = -4.74 = -4 - 1 + 1 - 0.74$$
$$= \bar{5}.26$$

Taking antilogs of both sides,

we get $[H^+] = \text{antilog } \bar{5}.26 = 1.82 \times 10^{-5}$

Substituting $[H^+]$ in the expression K_a

$$= \frac{[H^+]^2}{[CH_3COOH] - [H^+]}$$
$$1.8 \times 10^{-5} = \frac{(1.82 \times 10^{-5})^2}{[CH_3COOH] - 1.82 \times 10^{-5}}$$
$$\therefore \quad [CH_3COOH] \times 1.8 \times 10^{-5} - 1.82 \times 10^{-5} \times 1.8 \times 10^{-5}$$
$$= (1.82 \times 10^{-5})^2$$
$$[CH_3COOH] = \frac{(1.82 \times 10^{-5})^2 + 1.82 \times 10^{-5} \times 1.8 \times 10^{-5}}{1.8 \times 10^{-5}}$$
$$= 3.66 \times 10^{-5}$$

∴ Volume of dil. CH_3COOH containing one mole of

$$\text{acid} = \frac{1}{3.66 \times 10^{-5}} = 2.732 \times 10^4 \text{ L}$$

∴ 1 litre solution should be diluted to 2.732×10^4 litre.

EXAMPLE 79. *A solution of HCl has a pH = 6. If one mL of it is diluted to one litre, what will be the pH of the resulting solution?*

SOLUTION. pH = 6 ; ∴ $[HCl] = 10^{-6}$; original volume= 1.0 mL ; required volume = 1000 mL

Original solution Diluted solution

$$N_1V_1 = N_2V_2 \text{ (normality equation)}$$
$$10^{-6} \times 1 = N_2 \times 1000$$
$$\therefore \quad N_2 = \frac{10^{-6} \times 1}{1000} = 10^{-9};$$
$$\therefore \quad [HCl] = 10^{-9}\text{M}.$$

$$H_2O \rightleftharpoons H^+ + OH^-$$

At start : x M xM

At equilibrium, total $[H^+]$: $(x + 10^{-9})$ M xM

But $K_w = [H^+][OH^-]$; ∴ $10^{-14} = (x + 10^{-9})(x)$

Or $x^2 + 10^{-9}x - 10^{-14} = 0$;

$$\therefore \quad x = \frac{-10^{-9} \pm \left[(10^{-9})^2 - 4(1 \times -10^{-14})\right]^{1/2}}{2 \times 1}$$
$$\because \text{ for } ax^2 + bx + c = 0, \; x = \frac{-b \pm (b^2 - 4ac)^{1/2}}{2a}$$

Or $$x = \frac{-10^{-9} \pm (10^{-18} + 4 \times 10^{-14})^{1/2}}{2}$$
$$= \frac{-10^{-9} \pm (10^{-18}(1 + 40000)^{1/2}}{2}$$
$$= \frac{-10^{-9} + 10^{-9} \times 200}{2}$$

(– ive sign of ± is ignored because x can not be negative)

$$= \frac{10^{-9}(-1 + 200)}{2} = 9.95 \times 10^{-8}$$
$$\therefore \quad [H^+] = (x + 10^{-9})\text{ M} = 9.95 \times 10^{-8} + 10^{-9}$$
$$= 10^{-9}(9.95 \times 10 + 1) = 10^{-9}(99.5 + 1)$$
$$= 10^{-9} \times 100.5$$
$$\therefore \quad pH = -\log[H^+] = -\log 10^{-9} \times 100.5$$
$$= -(\log 10^{-9} + \log 100.5)$$
$$pH = -(-9 \log 10 + 2.002)$$
$$= 9 - 2.002 = \mathbf{6.998}$$

Ans.

EXAMPLE 80. *Calculate the pH of a solution which contains 3.01×10^{12} H^+ ions per cm^3 solution.*

SOLUTION. 1 Mol H^+ ions = 6.02×10^{23}

Given : 1 cm^3 solution contains H^+ ions = 3.01×10^{12}

∴ 1000 cm^3 *i.e.*, one litre solution contain H^+ ions

$$= \frac{3.01 \times 10^{12}}{1} \times 1000$$

$$= 3.01 \times 10^{15}$$

$\therefore$ no. of mol of H^+ ions

$$= \frac{3.01 \times 10^{15}}{6.02 \times 10^{23}} = 0.5 \times 10^{-8}$$

$$\therefore \quad pH = -\log [H^+] = -\log 0.5 \times 10^{-8}$$
$$= -(\log 0.5 + \log 10^{-8})$$
$$pH = -(-0.301 - 8) = 8 - 0.301$$
$$= \mathbf{7.699} \qquad \textbf{Ans.}$$

EXAMPLE 81. *The pH value of 0.1M solution of cyanic acid (HCNO) is 2.34. Calculate the ionisation constant of the acid and its degree of ionisation in the solution.*

SOLUTION. (*a*) pH = 2.34 ; $\therefore$ – log [H^+] = 2.34 ;

Or [H^+] = antilog (– 2.34)

$$= \text{antilog} - 2 - 1 + 1 - 0.34 = \bar{3}.66 = 4.57 \times 10^{-3}$$

$$HCNO \rightleftharpoons H^+ + CNO^-$$
$$0.1 \qquad C\alpha \qquad C\alpha$$

$$C\alpha = [H^+]; \alpha = \frac{[H^+]}{C} = \frac{4.57 \times 10^{-3}}{0.1}$$
$$= \mathbf{4.57 \times 10^{-2}}$$

But
$$K_a = C\alpha^2 = 0.1 \times (4.57 \times 10^{-2})^2$$
$$= \mathbf{2.09 \times 10^{-4}} \qquad \textbf{Ans.}$$

EXAMPLE 82. *From the equilibrium $HCO_3^- \rightleftharpoons H^+ + CO_3^{2-}$ ($K_a = 4.8 \times 10^{-11}$), $[HCO_3^-] = 9.8 \times 10^{-2}$ M, $[CO_3^{2-}] = 1.1 \times 10^{-3}$M, calculate the pH of the solution.*

SOLUTION. $HCO_3^- \rightleftharpoons H^+ + CO_3^{2-}$

n mol at equilibrium 9.8×10^{-2} ? 1.1×10^{-3}

$$K_a = \frac{[H^+][CO_3^{2-}]}{[HCO_3^-]};$$

$$4.8 \times 10^{-11} = \frac{[H^+] \times 1.1 \times 10^{-3}}{9.8 \times 10^{-2}}$$

$$\therefore \quad [H^+] = \frac{4.8 \times 10^{11} \times 9.8 \times 10^{-2}}{1.1 \times 10^{-3}}$$
$$= 4.28 \times 10^{-9}$$

$$\therefore \quad pH = -\log [H^+] = -\log 4.28 \times 10^{-9}$$
$$= -[\log 4.28 + \log 10^{-9}]$$
$$pH = -[0.6314 - 9] = \mathbf{8.3686} \quad \textbf{Ans.}$$

EXAMPLE 83. *Calculate the pH value of 0.002 M HBr.*

(HP Board, 2007)

SOLUTION. $HBr \rightleftharpoons H^+ + Br^-$ (ionisation)

Conc. mol L^- 0.002 0.002

$$\therefore \quad (H^+) = 0.002 = \frac{2}{1000} = 2 \times 10^{-3}$$

$$\therefore \quad pH = -\log [H^+] = -\log (2 \times 10^{-3})$$
$$= -[\log 2 + \log 10^{-3}]$$
$$= -[0.301 - 3] = 3 - 0.301$$
$$pH = \mathbf{2.699} \qquad \textbf{Ans.}$$

EXAMPLE 84. *Calculate the molar concentration at which the pH of nitrous acid is 3.0. K_a for nitrous acid = 4.5 × 10^{-4}.*

SOLUTION. pH of HNO_2 = 3 ; $\therefore$ [H^+] = 10^{-3} M.

$$HNO_2 \rightleftharpoons H^+ + NO_2^-$$
$$x \qquad 10^{-3}\,M \quad 10^{-3}\,M$$

$$K_a = \frac{[H^+][NO_2^-]}{[HNO_2]};$$

$$4.5 \times 10^{-4} = \frac{10^{-3} \times 10^{-3}}{x}$$

$$\therefore \quad x = \frac{10^{-3} \times 10^{-3}}{4.5 \times 10^{-4}} = 2.22 \times 10^{-3}\,M$$

$\therefore$ Molar concentration of HNO_2

$$= \mathbf{2.22 \times 10^{-3}\,M} \qquad \textbf{Ans.}$$

EXAMPLE 85. *Will pH value of water be same at temperature 25°C and 4°C. Justify it in not more than 2 or 3 sentences?*

SOLUTION. The pH value of a solution depends upon the hydrogen ion concentration which in turn depends upon the value of K_w. But K_w is a function of temperature. Thus, the change in temperature changes the pH value for a given sample of water.

EXAMPLE 86. *Find the pH, [H^+], [OH^-], [Na^+] and [Cl^-] of a solution obtained by mixing 40 mL of 0.3 M NaOH and 40 mL of 0.6 M HCl.*

SOLUTION. Reaction

$$NaOH + HCl \rightleftharpoons NaCl + H_2O$$

(1) m. equiv (= N_1V_1)

	NaOH	HCl	NaCl	H_2O
(1) m. equiv (= N_1V_1)	40 × 0.3 = 12	40 × 0.6 = 24	0	0
(2) m. equiv. after reaction	12 – 12 = 0	24 – 12 = 12	12	12

Total volume = 40 + 40 = 80 mL

Since both electrolytes (NaOH and HCl) are monovalent,

$$\text{hence molarity} = \text{normality} = \frac{\text{m. equiv.}}{\text{Total volume}}$$

$$\therefore \quad [Na^+] = \frac{12}{40} = 0.3\,M; [Cl^-] = \frac{12 + 12}{40}$$
$$= 0.6\,M$$

$$[H^+] = \frac{12}{40} = \mathbf{0.3\,M};$$

$$[OH^-] = \frac{K_w}{[H^+]} = \frac{10^{-14}}{0.3}$$
$$= \mathbf{3.3 \times 10^{-14}\,M}$$

$$pH = -\log [H^+] = -\log 0.3$$
$$= -(-0.52) = \mathbf{0.52} \qquad \textbf{Ans.}$$

EXAMPLE 87. *60 cm^3 of HCl gas at 298 K and 740 mm pressure were dissolved in 500 cm^3 of water. If vapour pressure of water at 298 K is 23.7 mm, calculate the pH of the solution.*

SOLUTION. $$P(\text{HCl}) = \frac{740 - 23.7}{760} = 0.9425 \text{ atm.}$$

500 cm^3 water dissolves HCl gas = 60 cm^3

$\therefore$ 1000 cm^3 (= 1L) water dissolves HCl gas

$$= \frac{60}{500} \times 1000 = 120 \text{ cm}^3$$

Or $$V = \frac{120}{1000} = 0.12 \text{ L}$$

$$T = 298 \text{ K},$$

$$R = 0.0821 \text{ L atm K}^{-} \text{mol}^{-}$$

But $$PV = nRT\,; n = \frac{PV}{RT}$$

$$= \frac{0.9425 \text{ atm} \times 0.12 \text{ L}}{0.0821 \text{ L atm K}^{-}\text{mol}^{-} \times 298 \text{ K}}$$

$$= 4.6 \times 10^{-3} \text{ mol}$$

$$\therefore \quad \text{Molarity of HCl} = \frac{n}{\text{Volume of solution}}$$

$$= \frac{4.6 \times 10^{-3} \text{ mol}}{1 \text{ L}}$$

$$= 4.6 \times 10^{-3} \text{ mol L}^{-}$$

$$\therefore \quad [H^+] = [\text{HCl}] = 4.6 \times 10^{-3}$$

$$\therefore \quad pH = -\log [H^+] = -\log 4.6 \times 10^{-3}$$

$$= -(\log 4.6 + \log 10^{-3})$$

$$\mathbf{pH} = -(0.66 - 3) = 3 - 0.66$$

$$= \mathbf{2.34}$$ **Ans.**

EXAMPLE 88. *pH of a saturated solution of Ba (OH)$_2$ is 12. The value of solubility product (K_{sp}) of Ba(OH)$_2$ is:*

(a) 3.3 × 10^{-7} *(b) 5.0 × 10^{-7}*
(c) 4.0 × 10^{-6} *(d) 5.0 × 10^{-6}*

(AIPMT (Pre.) 2012)

SOLUTION. pH = 12 (given) . So, $[H^+] = 10^{-12}$

$$\therefore [OH^-] = \frac{K_w}{[H^+]} = \frac{10^{-14}}{10^{-12}} = 10^{-2}$$

$$Ba(OH)_2 \rightleftharpoons Ba^{2+} + 2OH^-$$

Solubility: S 2S

$$\therefore 2S = 10^{-2}; \quad S = \frac{10^{-2}}{2}$$

$$K_{sp} = [Ba^{2+}]\,[OH^-]^2; K_{sp} = S \times (2S)^2 = 4S^3$$

$$= 4 \times \left(\frac{10^{-2}}{2}\right)^3 = \frac{4 \times 10^{-6}}{8} = 5 \times 10^{-7}.$$

So, the correct answer is (*b*).

EXAMPLE 89. *How many mol of calcium hydroxide must be dissolved to produce 250 mL of aqueous solution of pH 10.65? Assume complete dissociation.* **(Roorkee Entrance, 1987)**

SOLUTION. Given. $$\text{pH} = 10.65\,; \mathbf{pOH} = 14 - \text{pH}$$

$$= 14 - 10.65$$

$$= \mathbf{3.35}; \mathbf{pOH} = -\log [OH^-]$$

Or $$-\log [OH^-] = 3.35\,; \log [OH^-] = -3.35$$

$$= -3 - 1 + 1 - 0.35$$

$= \bar{4}.65$. Taking antilog of both sides, we get :

$$[OH^-] = \text{antilog } \bar{4}.65 = 4.47 \times 10^{-4}.$$

Mol of OH$^-$ ion in 1000 mL solution = 4.47×10^{-4}

Mol of OH$^-$ ion in 250 ml (= 1L) solution

$$= \frac{4.47 \times 10^{-4}}{1000} \times 250$$

$$= 1.12 \times 10^{-4} \text{ M}$$

$$\underset{1\text{ mol}}{Ca(OH)_2} \rightleftharpoons Ca^{2+} + \underset{2\text{ mol}}{2OH^-}$$

2 mol OH$^-$ ions ≡ 1 mol Ca(OH)$_2$

1.12×10^{-4} mol OH$^-$ ions

$$\equiv \frac{1}{2} \times 1.12 \times 10^{-4}$$

$$= \mathbf{5.6 \times 10^{-5}\ mol}$$

$\therefore$ mol of Ca(OH)$_2$ produced

$$= \mathbf{5.6 \times 10^{-5}\ mol}$$ **Ans.**

EXAMPLE 90. *The pH of 0.05 M aqueous solution of diethyl amine is 12. Calculate its K_b.* **(Roorkee entrance, 1993)**

SOLUTION. $[(C_2H_5)_2NH] = 0.05M\,; pH = 12.$

So, $$pOH = 14 - 12 = 2$$

$$\therefore \quad -\log [OH^-] = 2\,; [OH^-] = \text{antilog} - 2 = 0.01$$

$$(C_2H_5)_2NH + H_2O \rightleftharpoons (C_2H_5)_2NH_2^+ + OH^-$$

(1) Conc. at start	0.05 M	0	0
(2) Change by reaction	− 0.01	0.01	0.01
(3) Conc. at equilibrium	0.05 − 0.01 = 0.04	0.01	0.01

$$\therefore \quad K_b = \frac{[(C_2H_5)_2NH_2^+]\,[OH^-]}{[(C_2H_5)_2NH]}$$

$$= \frac{0.01 \times 0.01}{0.04}$$

$$= \mathbf{2.5 \times 10^{-3}}$$ **Ans.**

EXAMPLE 91. *An aqueous solution of aniline of concentration 0.24 M is prepared. What concentration of sodium hydroxide is needed in this solution so that anilium ion concentration remains at 1 × 10^{-8} M? K_a for $C_6H_5NH_3^+$ is 2.4 × 10^{-5} M.*

(Roorkee 1996)

SOLUTION. Anilium ion conc. *i.e.*, $[C_6H_5NH_3^+] = 10^{-8}$; $[C_6H_5NH_2] = 0.24M$

For the reaction :

$$C_6H_5NH_2 + H_2O \rightleftharpoons C_6H_5NH_3^+ + OH^-$$

$$K_b = \frac{[C_6H_5NH_3^+]\,[OH^-]}{[C_6H_5NH_2]}$$

$$= \frac{10^{-8} \times [OH^-]}{0.24} \qquad ...(1)$$

Also, $$K_b\,(C_6H_5NH_2) = \frac{K_w}{K_a\,[C_6H_5NH_3^+]}$$

$$= \frac{10^{-14}}{2.4 \times 10^{-5}} \qquad ...(2)$$

From (1) and (2),L.H.S. = L.H.S. ; so , R.H.S. = R.H.S.

$$\therefore \quad \frac{10^{-8}\,[OH^-]}{0.24} = \frac{10^{-14}}{2.4 \times 10^{-5}}\,;$$

$$[OH^-] = \frac{10^{-14} \times 0.24}{2.4 \times 10^{-5} \times 10^{-8}} = 0.01$$

$\therefore$ $[OH^-] = [NaOH] = \mathbf{0.01}$ **Ans.**

24.6 INDICATOR

Example 92. *Find the value of pH at which an acid indicator with $K_a = 10^{-5}$ changes colour when the indicator is 10^{-3} M.*

Solution. *Reaction:* $H\,Ind + H_2O \rightleftharpoons Ind^- + H_3O^+$

Concentration $10^{-3}M$ $10^{-3}M$ x

$$\therefore \quad K_a \text{ or } K_{ind} = \frac{[Ind^-]\,[H_3O^+]}{[H\,Ind]}\,;$$

$$10^{-5} = \frac{10^{-3} \times x}{10^{-3}}$$

[At the colour change, $[Ind^-] = [H\,Ind]$]

$\therefore$ $x = [H_3O^+] = 10^{-5}$;

$pH = -\log [H_3O^+] = -\log 10^{-5}$

or **pH** $= -(-5 \log 10) = -(-5 \times 1)$

$= \mathbf{+5}$ **Ans.**

Example 93. *At what pH will a 10^{-3}M solution of an indicator with $K_b = 10^{-10}$ change colour?*

Solution. $Ind + H_2O \rightleftharpoons H\,Ind^+ + OH^-$

Conc. $10^{-3}M$ $10^{-3}M$ x

$$K_b = \frac{[H\,Ind^+]\,[OH^-]}{[Ind]}\,;$$

$$10^{-10} = \frac{10^{-3} \times [OH^-]}{10^{-3}}$$

$\therefore$ $[OH^-] = 10^{-10}$;

$pOH = -\log [OH^-] = -\log 10^{-10}$

$= -(-10 \log 10)$

Or $pOH = -(-10 \times 1) = +10.$

But $pH + pOH = 14$

$\therefore$ $pH = 14 - 10 = \mathbf{4}$ **Ans.**

pH ranges of some indicators

Indicator	pH range	Indicator	pH range
Cresol red (acid)	0.2 – 1.8	Cresol red (base)	7.0 – 9.1
Methyl orange	2.8 – 3.8	Thymol blue	0.8 – 1.8
Congo red	2.8 – 4.8		and 7.6 – 9.2
Methyl red	3.8 – 6.1	Phenolphthalein	8.0 – 9.6
Bromothymol blue	6.0 – 7.9	Thymolphthalein	10.2 – 11.7
Litmus	5.0 – 8.1	Tropeolin O	11.1 – 12.6
Phenol red	6.8 – 8.6		

Example 94. *Find the value of pH at which an indicator with $pK_b = 4$, changes colour.*

Solution. Reaction. $Ind + H_2O \rightleftharpoons H\,Ind^+ + OH^-$

At the colour change, $[H\,Ind^+] = [Ind]$

$$\therefore \quad K_b = \frac{[H\,Ind^+]\,[OH^-]}{[Ind]}\,;\ pK_b = 4.$$

Hence $pK_b = -\log K_b\,; 4 = -\log K_b\,;$

$K_b = 10^{-4}$

$$\therefore \quad 10^{-4} = \frac{[H\,Ind^+]\,[OH^-]}{[Ind]}$$

$= [OH^-]\,;\ pOH = -\log [OH^-]$

$pOH = -\log 10^{-4} = -(-4 \log 10) = 4.$

So, $pH = 14 - pOH = 14 - 4 = 10$

Hence **pH = 10** **Ans.**

Example 95. *The pH range for congo red and methyl red is 2.8 to 4.8 and 3.8 to 6.1 respectively. What indicator should be used for the titration of KH_2BO_3 with 0.1M HCl? ($K_a = 7.3 \times 10^{-10}$).*

Solution. ***Reaction.*** $H_2BO_3^- + H_3O^+ \rightleftharpoons H_3BO_3 + H_2O$

At the equivalence point, concentration of H_3BO_3 produced would be 0.1/2 = 0.05M. Only the first ionisation step of H_3BO_3 is important to the pH determination.

$$H_3BO_3 + H_2O \rightleftharpoons H_2BO_3^- + H_3O^+$$

Conc. at equivalence

point 0.05 x x

$$\therefore \quad K_a = \frac{[H_2BO_3^-]\,[H_3O^+]}{[H_3BO_3]}$$

$$7.3 \times 10^{-10} = \frac{x \times x}{0.05}\,;$$

$x = (7.3 \times 10^{-10} \times 0.05)^{1/2}$

$= (36.5 \times 10^{-12})^{1/2}$

$x = 6 \times 10^{-6}\,;\ [H_3O^+] = 6 \times 10^{-6}$

$\therefore$ $pH = -\log [H_3O^+] = -\log 6 \times 10^{-6}$

$= -(\log 6 + \log 10^{-6})$

$pH = -(0.78 - 6) = 5.22.$

This pH range is the middle of pH range of methyl red indicator. Hence indicator used should be methyl red.

EXAMPLE 96. *At what pH does an indicator change colour if the indicator is a weak acid ? $K_{ind} = 4 \times 10^{-4}$. For which one (s) of the following neutralisations would the indicator be useful? Explain.*

(*i*) $HCl + NH_3 \rightarrow$ (*ii*) $NaOH + HCl \rightarrow$

(*iii*) $NaOH + CH_3COOH \rightarrow$

SOLUTION. Reaction.

$$\underset{\text{conjugate acid}}{H\,Ind} + H_2O \rightleftharpoons \underset{\text{conjugate base}}{Ind} + H_3O^+$$

At colour change,

$$[\text{conjugate acid}] = [\text{conjugate base}]$$

$$\therefore \qquad K_{\text{ind}} = \frac{[Ind^-][H_3O^+]}{[H\,Ind]};$$

$$4 \times 10^{-4} = [H_3O^+]$$

$$\therefore \qquad pH = -\log [H_3O^+]$$

$$= -\log 4 \times 10^{-4};$$

$$-(\log 4 + \log 10^{-4})$$

$$= -(0.6 - 4) \ \textbf{Or}\ \boldsymbol{pH = 3.4.}$$

The indicator is a weak acid (given). In reaction (*i*), NH_4Cl (acidic) is formed and in reaction (*ii*), NaCl (neutral) is formed at the equivalence point. So, the indicator used will be useful. In reaction (*iii*), CH_3COONa (basic) is formed and its pH will be more than 7. So, the indicator which changes colour in acid would not be suitable.

EXAMPLE 97. Name the suitable indicator which indicates the equivalence point when 50 mL of 0.1 M HCN is titrated with 0.1 M NaOH. pH range of indicator for thymolphthalein = 10.2 to 11.7 ; Cresol red = 7.0 to 9.1. $K_a = 6.2 \times 10^{-10}$.

SOLUTION. At the equivalence point, NaCN is formed.

no. of m mol of NaCN, if equal number of m mol NaOH and HCN react completely

$$= 50 \times 0.1 = 5 \text{ m mol}$$

So, the solution is the equivalent of a 0.1/2 or 0.05M solution of HCN. Hence, we have:

$$CN^- + H_2O \rightleftharpoons HCN + OH^-$$

Conc. at equivalence point $\quad 0.05 - x \simeq 0.05 \qquad x \qquad x$

$$0.05 - x \simeq 0.05$$

because x is very small as compared to 0.05 and hence ignored.

$$\therefore \qquad K_h = \frac{[HCN][OH^-]}{[CN^-]} \qquad \ldots (1)$$

$$\text{Also,} \qquad K_h = \frac{K_w}{K_a} \qquad \ldots (2)$$

From (1) and (2), we get :

$$\frac{K_w}{K_a} = \frac{[HCN][OH^-]}{[CN^-]};$$

$$\frac{10^{-14}}{6.2 \times 10^{-10}} = \frac{x \times x}{0.05};$$

$$x = \left(\frac{10^{-14} \times 0.05}{6.2 \times 10^{-10}}\right)^{1/2}$$

$$= (80.6 \times 10^{-8})^{1/2} = 8.9 \times 10^{-4}$$

$$\text{or} \qquad [OH^-] = 8.9 \times 10^{-4}; pOH = -\log [OH^-]$$

$$= -\log 8.9 \times 10^{-4}$$

$$= -(\log 8.9 + \log 10^{-4});$$

$$pOH = -(0.95 - 4) = 3.05$$

$$\therefore \qquad pH = 14 - pOH = 14 - 3.05 = \mathbf{10.95}$$

This pH lies in the middle of pH range of thymolphthalein indicator. So suitable indicator is thymolphthalein.

EXAMPLE 98. *The K_a value of an acid indicator, bromophenol blue is 5.84×10^{-5}. Calculate the % age of this indicator in its basic form at a pH of 4.84.*

SOLUTION. $pH = 4.84; -\log [H_3O^+] = 4.84;$

$$\log [H_3O^+] = -4.84$$

$$= -4 - 1 + 1 - 0.84\ \bar{5}.16;$$

$$\therefore \qquad [H_3O^+] = \text{antilog}\ \bar{5}.16 = 1.44 \times 10^{-5}.$$

Reaction $\quad H\,Ind + H_2O \rightleftharpoons Ind^- + H_3O^+$

$$\therefore \qquad K_a = \frac{[Ind^-][H_3O^+]}{[H\,Ind]};$$

$$5.84 \times 10^{-5} = \frac{[Ind^-][H_3O^+]}{[H\,Ind]}$$

$$\therefore \qquad \frac{[Ind^-]}{[H\,Ind]} = \frac{5.84 \times 10^{-5}}{1.44 \times 10^{-5}} = \frac{4.05}{1}$$

$\therefore$ % age of basic form

$$= \frac{[Ind^-]}{[Ind^-] + [H\,Ind]} \times 100$$

$$= \frac{4.05}{4.05 + 1} \times 100$$

$$= \mathbf{80\%}$$

Ans.

EXAMPLE 99. *The K_a value of an indicator is 3.0×10^{-5}. The acidic and basic forms of this indicator have red and blue colour respectively. By how much the pH would change in order to change the indicator from 75% red to 75% blue?*

SOLUTION. (*a*) $\qquad K_a = 3.0 \times 10^{-5};$

[acid] for 75% red = 75 and [base] = 100 − 75 = 25

$$\text{But} \qquad [H^+] = \frac{K_a\,[\text{acid}]}{[\text{base}]}.\ \text{75\% red:}$$

$$[H^+] = \frac{3.0 \times 10^{-5} \times 75}{25} = 9.0 \times 10^{-5}$$

$$\therefore \qquad pH = -\log [H^+]\ -\log 9.0 \times 10^{-5}$$

$$= -(\log 9 + \log 10^{-5})$$

$$= -(0.95 - 5);\ \mathbf{pH = 4.05}$$

(*b*) $K_a = 3.0 \times 10^{-5}$;

[acid] for 75% blue = 100 – 75 = 25, [base] = 75

$$\therefore \quad [H^+] = \frac{K_a\,[\text{acid}]}{[\text{base}]};$$

$$[H^+] = \frac{3.0 \times 10^{-5} \times 25}{75} = 10^{-5}$$

$$\therefore \quad pH = -\log [H^+] = -\log 10^{-5}$$
$$= -(\log 10^{-5}) = -(-5 \log 10)$$
$$= +5.0$$

$\therefore$ Change in $pH = 5.0 - 4.05 = 0.95$.

Example 100. *The pH range of an indicator (weak acid) at which it changes its colour is 3.1 to 4.5. If the neutral point of the given indicator is in the centre of this pH range, calculate the ionisation constant of the indicator.*

Solution. We know that pH values are exponential in form. So, centre of the range may not be calculated by averaging the pH value. Hence, centre of range can be obtained by averaging the corresponding H^+ ion concentration. Hence, we have :

(*a*) $pH = 3.1 ; -\log [H^+] = 3.1$;

$$\log [H^+] = -3.1 = -3 - 1 + 1 - 0.1 = \bar{4}.9$$

$$\therefore \quad [H^+] = \text{antilog } \bar{4}.9 = 7.9 \times 10^{-4}$$

(*b*) $pH = 4.5 ; -\log [H^+] = 4.5 ; \log [H^+]$

$$= -4.5 = -4 - 1 + 1 - 0.5 = \bar{5}.5$$

$$\therefore \quad [H^+] = \text{antilog } \bar{5}.5 = 3.16 \times 10^{-5}$$
$$= 0.316 \times 10^{-4}$$

$\therefore$ Average value of $[H^+] = (7.9 \times 10^{-4} + 0.316 \times 10^{-4})/2$

$$= \frac{10^{-4}\,(7.9 + 0.316)}{2}$$

$[H^+] \simeq 4.1 \times 10^{-4}$. But $[H^+] = K$.

Hence, $\boldsymbol{K = 4.1 \times 10^{-4}}$ **= Ionisation constant.**

Example 101. *An acid type indicator H In differs in colour from its conjugate base (In^-). The human eye is sensitive to colour differences only when the ratio $[In^-]/[HIn]$ is greater than 10 or smaller than 0.1. What should be the minimum change in the pH of the solution to observe a complete colour change ($K_a = 1.0 \times 10^{-5}$)?* **(IIT 1997, Re-exam)**

Solution. $\dfrac{[In]^-}{[H\,In]} = 10 \text{ or } 0.1 \quad (i.e., 10^{-1})$

But $pH = pK_{In} \pm 1$ ...(1)

$(\because \log 10 = 1 \text{ and } \log 10^{-1} = -1)$

Also, $pK_{In} = -\log K_{In} = -\log 10^{-5} = -(-5)$
$= +5$

$\therefore$ From equation (1),

$pH = 5 \pm 1$ *i.e.*, 6 or 4.

$\therefore$ **pH interval** = 6 or 4.

Hence, minimum pH change

= **6 – 4 = 2 pH unit** **Ans.**

Example 102. *Find the pH of a solution obtained at the equivalence point when 0.2M , 20mL CH_3COOH was titrated with 0.1M NaOH solution, K_a (CH_3COOH) = 1.8×10^{-5}.*

Solution. Molarity (M_1) of CH_3COOH = 0.2M ; Volume (V_1) = 20 mL. Molarity (M_2) of NaOH = 0.1M ; Volume (V_2) =?

We know : CH_3COOH NaOH

$$M_1V_1 = M_2V_2$$

$$\therefore \quad 0.2 \times 20 = 0.1 \times V_2$$

Or $V_2 = (0.2 \times 20)/0.1 = 40$ mL.

Concentration of salt formed

$$= \frac{\text{Millimoles of acid}}{\text{Total volume}}$$

$$= \frac{20 \times 0.2}{20 + 40\,(= 60)} = \frac{0.2}{3}$$

We know, $K_w = 10^{-14}$

$$\therefore \quad [H^+] = \left(\frac{K_w . K_a}{C}\right)^{1/2}$$

$$= \left(\frac{10^{-14} \times 1.8 \times 10^{-5}}{0.2/3}\right)^{1/2}$$

$$= (2.7 \times 10^{-18})^{1/2} = 1.6432 \times 10^{-9}$$

$$\therefore \quad pH = -\log [H^+]$$
$$= -(\log 1.6432 \times 10^{-9})$$
$$= [0.2157 - 9] = \mathbf{8.7843} \quad \textbf{Ans.}$$

24.7 COMMON ION EFFECT

Type. For solutions containing common ion, use the relations :

(1) $K_c = \dfrac{C\alpha^2}{1 - \alpha}$;

(2) $\dfrac{\text{Ionic concentration}}{\text{of common ion}}$ = $\dfrac{\text{Gross con-}}{\text{centration}}$ × $\dfrac{\text{fraction}}{\text{ionised}(\alpha)}$

Example 103. *0.1 g mol of ammonium acetate has been dissolved in one litre of 0.1M acetic acid. Calculate $[H_3O^+]$ in this solution. [K (ionisation of acetic acid = 1.8×10^{-5} ; effective ionisation of ammonium acetate = 80%).*

Solution. 0.1 g mol L^- of ammonium acetate in solution = 0.1M

Gross concentration of acetic acid in solution = 0.1M

Acetic acid ionises as

$$(CH_3COOH + H_2O \rightleftharpoons H_3O^+ + CH_3COO^-)$$

(1) n mol at start

0.1 – 0 0

(2) Change by reaction

$-x$ x x

(3) n mol at equilibrium

$0.1 - x$ x x

x = mol *i.e.*, amount of CH_3COOH ionised.

$$\therefore \qquad K_c = \frac{[H_3O^+][CH_3COO^-]}{[CH_3COOH]} \qquad ...(1)$$

Substituting these values in equation (1), we get

$$K_c = \frac{x \times x}{0.1 - x} = 1.8 \times 10^{-5} \text{ (given)}$$

$$\frac{x^2}{0.1 - x} = 1.8 \times 10^{-5}$$

x being very small, is ignored in the denominator. So, we get :

$$x^2 = 0.1 \times 1.8 \times 10^{-5} = 1.8 \times 10^{-6}$$

$$\therefore \qquad x = \sqrt{1.8 \times 10^{-6}} = 1.3 \times 10^{-3} \qquad ...(2)$$

Ammonium acetate CH_3COONH_4 also ionises to give CH_3COO^- (common ion)

$\therefore$ Ionic concentration of CH_3COO^- = gross concentration × Fraction ionised (α)

$$= 0.1 \times 0.8 = 0.08 \text{ g mol L}^-$$

$$\left[\because 80\% = \frac{80}{100} = 0.8\right]$$

$\therefore$ Total concentration of CH_3COO^- ions in solution

$$= \mathbf{0.8} + x$$

Substituting this value in equation (1), we get

$$K_c = \frac{x \times (0.8 + x)}{0.1 - x} = 1.8 \times 10^{-5} \text{ (given)}$$

In order to avoid quadratic equation in x, x (being very small) is avoided from denominator as well as numerator (*i.e.*, $0.08 + x \simeq 0.08$)

$$\text{So, we have } \frac{x \times 0.08}{0.1} = 1.8 \times 10^{-5};$$

$$x = \frac{0.1 \times 1.8 \times 10^{-5}}{0.08}$$

Or $\qquad x = \mathbf{2.2 \times 10^{-5}}$

Hence $\quad [H_3O^+] = 2.2 \times 10^{-5}$ g mol L$^-$

This value of x is a reduced value of $[H_3O^+]$ (see equation, 2 in acetic acid solution in the presence of ammonium acetate having common ion, CH_3COO^- with acetic acid, (CH_3COO^- + H^+). This reduction value is about one fifty ninth of the original value, 1.3×10^{-3}. The reduction of ionisation of acetic acid in presence of common ion, CH_3COO^- is called common ion effect.

Type Weak acid + salt of weak acid with a strong base.

Example 104. *A 100 mL solution contains 0.01 mol of acetic acid and 0.01 mol of sodium acetate. Calculate its hydronium ion concentration in mol L⁻ if K_a (CH_3COOH) = 1.8×10^{-5}.*

Solution. $[CH_3COOH]$ in mol L$^-$

$$= \frac{0.01}{100} \times 1000 = 0.1 \text{ M}$$

[$\because$ Volume of solution = 100 mL]

$$[CH_3COONa] \text{ in mol L}^- = \frac{0.01}{100} \times 1000 = 0.1 \text{ M}$$

	$CH_3COOH + H_2O$	$\rightleftharpoons$ CH_3COO^-	$+ H_3O^+$
(1) n. mol at start	0.1	0.1	0
(2) Change by reaction	$-x$	x	x
(3) n mol at equilibrium	$0.1 - x$	$0.1 + x$	x

x = Degree of ionisation of CH_3COOH

$$\therefore \qquad K_a = \frac{[CH_3COO^-][H_3O^+]}{[CH_3COOH]};$$

$$1.8 \times 10^{-5} = \frac{(0.1 + x) \times x}{0.1 - x} = \frac{0.1x}{0.1} = x$$

[Since x is very small as compared to 0.1, $0.1 + x \simeq 0.1$ and $0.1 - x \simeq 0.1$] **Or** $x = 1.8 \times 10^{-5}$.

Hence $\qquad [H_3O^+] = x = \mathbf{1.8 \times 10^{-5}}$ **Ans.**

Example 105. *In case of 2×10^{-2}M H_3PO_4, what will be the value of $[H^+]$, $[H_2PO_4^-(aq)]$, $[HPO_4^{2-}(aq)]$ and* $[PO_4^{3-}]$ *K_1, K_2 and K_3 respectively are 8.5×10^{-3}, 7.2×10^{-8} and 5.4×10^{-13}.*

Solution. (*i*) $H_3PO_4 \xrightleftharpoons{H_2O} H^+(aq) + H_2PO_4^-(aq)$;

$$[H_3PO_4] = 2 \times 10^{-2};$$

$$K_1 = \frac{[H^+(aq)][H_2PO_4^-(aq)]}{[H_3PO_4]};$$

$$8.5 \times 10^{-3} = \frac{[H^+(aq)][H^+(aq)]}{[H_3PO_4]};$$

$$[\because [H^+(aq)]] = [H_2PO_4^-(aq)]$$

Or $\quad [H^+(aq)]^2 = 8.5 \times 10^{-3} \times [H_3PO_4]$

$$= 8.5 \times 10^{-3} \times 2 \times 10^{-2}$$

$$\therefore \qquad [H^+(aq)] = (8.5 \times 10^{-3} \times 2 \times 10^{-2})^{1/2}$$

$$= (1.7 \times 10^{-4})^{1/2} = \mathbf{1.3 \times 10^{-2}}$$

Or $\quad [H^+(aq)] = [H_2PO_4^-(aq)] = \mathbf{1.3 \times 10^{-2}}$ **Ans.**

(*ii*) $H_2PO_4^-(aq) \xrightleftharpoons{H_2O} H^+(aq) + HPO_4^{2-}(aq)$

$$\therefore \qquad K_2 = \frac{[H^+(aq)][HPO_4^{2-}(aq)]}{[H_2PO_4^-(aq)]};$$

$$7.2 \times 10^{-8} = [HPO_4^{2-}(aq)]$$

$$[\because [H^+(aq)] = [H_2PO_4^-(aq)]]$$

$\therefore \quad [HPO_4^{2-}(aq)] = \mathbf{7.2 \times 10^{-8}}$ **Ans.**

(*iii*) $HPO_4^{2-}(aq) \xrightleftharpoons{H_2O} H^+(aq) + PO_4^{3-}(aq)$

$$K_3 = \frac{[H^+(aq)][PO_4^{3-}(aq)]}{[HPO_4^{2-}(aq)]};$$

$$5.4 \times 10^{-13} = \frac{1.3 \times 10^{-2} \times [PO_4^{3-}(aq)]}{7.2 \times 10^{-8}}$$

$$\therefore \quad [PO_4^{3-}(aq)] = \frac{5.4 \times 10^{-13} \times 7.2 \times 10^{-8}}{1.3 \times 10^{-2}}$$

$$= \mathbf{2.99 \times 10^{-18}}$$ **Ans.**

IV Weak acid + weak acid. Let weak acid (HA) and weak acid (HB) have concentrations C_1 and C_2 respectively. Let dissociation constants of weak acid HA is Ka_1 and weak acid HB is Ka_2. Thus we have :

	HA	$\rightleftharpoons$	H^+	A^-
Conc. at	$C_1 - C_1\alpha_1$		$C_1\alpha_1$	$C_1\alpha_1$
equilibrium	$= C_1(1-\alpha_1)$			
	HB	$\rightleftharpoons$	H^+	B^-
Conc. at	$C_2 - C_2\alpha_2$		$C_1\alpha_1$	$C_2\alpha_2$
equilibrium	$= C_2(1-\alpha_2)$		$+ C_2\alpha_2$	$+ C_2\alpha_2$

$$\therefore \quad Ka_1 = \frac{[A^-][H^+]}{[HA]}$$

$$= \frac{(C_1\alpha_1)(C_1\alpha_1 + C_2\alpha_2)}{C_1(1-\alpha_1)} \quad ...(1)$$

$$Ka_2 = \frac{[B^-][H^+]}{[HB]}$$

$$= \frac{(C_2\alpha_2)(C_1\alpha_1 + C_2\alpha_2)}{C_2(1-\alpha_2)} \quad ...(2)$$

By solving equations (1) and (2), α can be calculated. From the value of α, $[H^+]$ and then pH can be calculated.

EXAMPLE 106. *500 mL each of two weak monobasic organic acids HA and HB having molarity 1M each were mixed to give one litre solution. Ka_1 for HA = 1.5×10^{-5} and Ka_2 for HB = 1.8×10^{-5}. Calculate the pH of the mixed solution.*

SOLUTION. Since equal volumes (500 mL) of acids HA and HB are mixed to give one litre solution, the concentration of HA and HB in the mixture = 0.5M = C (suppose)

$$\therefore \quad HA \rightleftharpoons \underset{C_1}{H^+} + \underset{C_1}{A^-}$$

$$HB \rightleftharpoons \underset{C_2}{H^+} + \underset{C_2}{B^-}$$

$$\therefore \quad [H^+]_{total} = C_1 + C_2$$

$$K_{HA} = \frac{[H^+][A^-]}{[HA]} = \frac{(C_1 + C_2) \times C_1}{C}; \quad ...(1)$$

$$K_{HB} = \frac{[H^+][B^-]}{[HB]} = \frac{(C_1 + C_2) \times C_2}{C}; \quad ...(2)$$

$$\therefore \quad \frac{K_{HA}}{K_{HB}} = \frac{(C_1 + C_2)C_1}{C} \times \frac{C}{(C_1 + C_2)C_2} = \frac{C_1}{C_2}$$

$$\frac{1.5 \times 10^{-5}}{1.8 \times 10^{-5}} = \frac{C_1}{C_2} \text{ or } 18C_1 = 15C_2 \text{ or } 6C_1 = 5C_2$$

$$\therefore \quad C_1 = \frac{5}{6}C_2.$$

Substituting the value of C_1 is (1), we get :

$$1.5 \times 10^{-5} = \frac{\left(\frac{5}{6}C_2 + C_2\right) \times \frac{5}{6}C_2}{0.5}$$

$$= \frac{\frac{25}{36}C_2^2 + \frac{5}{6}C_2^2}{0.5} = \frac{\frac{25C_2^2 + 30C_2^2}{36}}{0.5}$$

$$1.5 \times 10^{-5} \times 0.5 \times 36 = 55C_2^2$$

$$\text{Or} \quad C_2^2 = \frac{1.5 \times 10^{-5} \times 0.5 \times 36}{55} = 4.909 \times 10^{-6}$$

$$\therefore \quad C_2 = (4.909 \times 10^{-6})^{1/2} = \mathbf{2.21 \times 10^{-3}}$$

$$\text{Since} \quad 6C_1 = 5C_2, 6C_1 = 5 \times 2.21 \times 10^{-3}$$

$$\text{Or} \quad C_1 = \frac{5 \times 2.21 \times 10^{-3}}{6} \quad \therefore \; C_1 = \mathbf{1.84 \times 10^{-3}}$$

$$\text{But} \quad [H^+] = C_1 + C_2 = 1.84 \times 10^{-3} + 2.21 \times 10^{-3}$$

$$= 10^{-3}[1.84 + 2.21] = 10^{-3} \times 4.05$$

$$\therefore \quad pH = -\log[H^+] = -[\log 10^{-3} \times 4.05]$$

$$= -[\log 10^{-3} + \log 4.05]$$

$$\mathbf{pH} = -[-3 + 0.6074] = 3 - 0.6074$$

$$= \mathbf{2.3926}$$ **Ans.**

Type. Weak acid + weak acid

EXAMPLE 107. *A solution contains 0.15M CH_3COOH and 0.25M HCN. Calculate $[H^+]$, $[CN^-]$ and $[CH_3COO^-]$ if K_a $[CH_3COOH] = 1.8 \times 10^{-5}$ and K_a (HCN) = 6.2×10^{-10}.*

SOLUTION.

$$(a) \quad CH_3COOH \xrightleftharpoons{H_2O} CH_3COO^-(aq) + H^+(aq)$$

	CH_3COOH	$CH_3COO^-(aq)$	$H^+(aq)$
(1) n mol at start	0.15	0	0
(2) Change by reaction	$-x$	x	x
(3) n mol at equilibrium	$0.15 - x$	x	x

x = degree of ionisation

$$K_a = \frac{[CH_3COO^-(aq)][H^+(aq)]}{[CH_3COOH]};$$

$$1.8 \times 10^{-5} = \frac{x \times x}{0.15 - x} \text{ or } \frac{x^2}{0.15}$$

$$\therefore \quad x = (1.8 \times 10^{-5} \times 0.15)^{1/2};$$

$$x = (2.7 \times 10^{-6})^{1/2} = 1.64 \times 10^{-3}$$

$$\therefore \quad [H^+(aq)] = [CH_3COO^-(aq)]$$

$$x = \mathbf{1.64 \times 10^{-3}M}$$ **Ans.**

$$(b) \quad HCN \xrightleftharpoons{H_2O} H^+(aq) + CN^-(aq)$$

(1)n mol at start

0.25 $\quad 1.64 \times 10^{-3} \quad$ 0

(2)Change by reaction

$y \quad y \quad y$

(3)n mol at equilibrium

$0.25 + y \quad (1.64 \times 10^{-3}) + y \quad y$

y = degree of ionisation

$$\therefore \quad K_a = \frac{[H^+(aq)][CN^-(aq)]}{[HCN]};$$

$$6.2 \times 10^{-10} = \frac{\left[(1.64 \times 10^{-3}) + y\right] \times y}{0.25 + y};$$

$$6.2 \times 10^{-10} = \frac{1.64 \times 10^{-3} y}{0.25}$$

[$\because$ y being very small, it can be neglected]

Or $$y = \frac{6.2 \times 10^{-10} \times 0.25}{1.64 \times 10^{-3}} = 9.45 \times 10^{-8}$$

$\therefore$ $[CN^-(aq)] = y =$ **9.45×10^{-8}M Ans.**

24.8 BUFFER SOLUTIONS

A buffer solution is that which resists the change in pH of a solution when a small amount of an acid, base or water is added to it. Three types of buffers are :

1. **Acid buffer.** It is solution of weak acid and the salt of this weak acid with a strong base. *e.g.*, $CH_3COOH + CH_3COONa$. The $[H^+]$ and pH of such solutions can be calculated with the help of following relations.

$$[H^+] = K_a \frac{[Acid]}{[Salt]};$$

$$pH = pK_a + \log \frac{[salt]}{[acid]}$$

2. **Basic buffer.** It is a solution of a weak base and the salt of this weak base with a strong acid. *e.g.*, $NH_4OH + NH_4Cl$. The pOH and pH of such solutions can be calculated with the help of following relations.

$$pOH = pK_b + \log \frac{[salt]}{[base]};$$

$$pH = 14 - pK_b - \log \frac{[salt]}{[base]}$$

3. **Salt buffer.** It is a solution of a salt which itself acts as a buffer. The salt is of a weak acid with a weak base. *e.g.*, CH_3COONH_4.

Note. When water is added to a buffer solution, no change in the pH of the solution takes place. It is because the volume change caused by the addition of water effects both the concentration of acid and the salt and the volumes, actually cancel each other.

EXAMPLE 108. *Write a relation (a) between pH and pK_a of an acid buffer solution (b) between pH and pK_b of a basic buffer.*

SOLUTION. (*a*) **For acid buffer,**

$$pH = pK_a + \log \frac{[salt]}{[acid]}$$

(*b*) **For basic buffer,** $pH = 14 - pK_b - \log \dfrac{[salt]}{[base]}$

Or $\quad p_{OH} = pK_b + \log \dfrac{[salt]}{[base]}$

EXAMPLE 109. *If 100 mL of 0.1 M CH_3COOH is mixed with 200 mL of 0.5 M CH_3 COONa, what will be the pH of the resulting solution? K_a for CH_3 COOH = 1.75×10^{-5}* **(ISC, 2011)**

SOLUTION. (*a*) Total volume of solution = 100 mL + 200 mL = 300 mL; K_a for $CH_3COOH = 1.75 \times 10^{-5}$.

(i) 100 mL of 0.1 M $CH_3COOH = 100 \times 0.1 = 10$ m mol.

(ii) 200 mL of 0.5 M $CH_3COOH = 200 \times 0.5 = 100$ m mol.

$$\therefore \quad [CH_3COOH] = [H^+] = \frac{10}{300} \times \frac{1000}{1000} = \frac{1}{30}$$

$$[CH_3COONa] = \frac{100}{300} \times \frac{1000}{1000} = \frac{1}{3}$$

But $\quad pK_a = -\log K_a = -[\log 1.75 \times 10^{-5}]$

$= -[\log 1.7 - 5 \log 10\ (=1)]$

$= -0.2430 + 5 = 4.757$

$$\therefore \quad pH = pK_a + \log \frac{[salt]}{[acid]};$$

$$pH = 4.757 + \log \frac{1/3}{1/30} \ (= 10)$$

$= 4.757 + 1 = 5.757$ **Ans**

[$\because$ log 10 = 1].

EXAMPLE 110. *Calculate the pH of (i) a solution obtained by mixing (i) 40 mL of 0.05 M NaOH and 40 mL of 0.1N CH_3COOH ($K_a = 1.8 \times 10^{-5}$) (ii) 40 mL of 0.05M HCl and 40mL of 0.1M NH_4OH. ($K_b = 1.8 \times 10^{-5}$)*

SOLUTION. (*i*)Number of millimoles of NaOH

$= 40 \times 0.05 = 2$

Number of millimoles of CH_3COOH

$= 40 \times 0.1 = 4$

$\therefore$ Millimoles of CH_3COOH reacted

= millimoles of NaOH = 2

($\because$ 2 < 4)

$$NaOH + CH_3COOH \longrightarrow CH_3COONa + H_2O$$

Millimoles before

reaction : $\quad 2 \quad 4$

Millimoles after

reaction : $\quad 4 - 2 = 2 \quad 2$

Total volume of solution

= 40 mL + 40 mL = 80 mL.

$$\therefore \quad [CH_3COOH] = \frac{2}{80} M \ ; [CH_3COONa, salt]$$

$$= \frac{2}{80}\,\text{M}.$$

$$\text{Hence, pH} = \text{p}K_a + \log\frac{[\text{salt}, CH_3COONa]}{[\text{acid}, CH_3COOH]} \quad ...(1)$$

$$K_a = 1.8 \times 10^{-5};$$

$$\therefore \quad \text{p}K_a = -\log K_a = -[\log 1.8 + \log 10^{-5}]$$
$$= -[0.2552 - 5]$$
$$\simeq 4.74.$$

Substituting the values in equation (1), we have :

$$\text{pH} = 4.74 + \log\frac{2/80}{2/80}$$
$$= 4.74 + \log 1$$
$$= 4.74 + 0 = \mathbf{4.74} \qquad \textbf{Ans.}$$

(*ii*) Number of millimoles of NH_4OH

$$= 40 \times 0.1 = 4$$

Number of millimoles of HCl

$$= 40 \times 0.05 = 2$$

∴ Millimoles of NH_4OH reacted = number of millimoles of HCl = 2

Total volume of solution = 40 mL + 40 mL = 80 mL.

	NH_4OH +	HCl $\longrightarrow$	NH_4Cl +	H_2O
Millimoles before reaction	4	2		
Millimoles after reaction	4 − 2 = 2		2	

$$\therefore \quad [NH_4OH] = \frac{2}{80}\,\text{M};$$

$$[NH_4Cl\ \text{salt}] = \frac{2}{80}\,\text{M}.$$

$$K_b = 1.8 \times 10^{-5};\ \text{p}K_b = -\log K_b$$
$$= -\log 1.8 \times 10^{-5}$$
$$= -[\log 1.8 + \log 10^{-5}]$$
$$= -[0.2552 - 5] = 4.74$$

Substituting the values in pOH

$$= \text{p}K_b + \log\frac{[\text{salt}]}{[\text{base}]}, \text{ we have}$$

$$\text{pOH} = 4.74 + \log\frac{2/80}{2/80}$$
$$= 4.74 + \log 1 = 4.74 + 0 = 4.74$$

$$\text{But} \quad \mathbf{pH} = 14 - \text{pOH}$$
$$\textbf{Or} \quad \text{pH} = 14 - 4.74 = \mathbf{9.26} \qquad \textbf{Ans.}$$

EXAMPLE 111. *What is the $[H^+]$ in mol L^- of a solution that is 0.20 M in CH_3COONa and 0.10 M in CH_3COOH? K_a for acetic acid is 1.8×10^{-5}* **(CBSE, PMT 2010)**

(*a*) 3.5×10^{-4} (*b*) 1.1×10^{-5} (*c*) 1.8×10^{-5} (*d*) 9.0×10^{-6}

SOLUTION.

$$\begin{array}{ccc} CH_3COOH & \rightleftharpoons & CH_3COO^- + H^+ \\ C - x & & x \qquad x \\ CH_3COONa & \rightleftharpoons & CH_3COO^- + Na^+ \\ 0.2\,M & & 0.2M \quad 0.2M \end{array}$$

$$[CH_3COOH] = C - x = 0.1\,M;$$
$$[CH_3COO^-] = 0.2 + x = 0.2\,M$$
$$\therefore \quad [H^+] = K_a \times [CH_3COOH]/[CH_3COO^-]$$
$$= 1.8 \times 10^{-5} \times 10^{-1}/2 \times 10^{-1}$$
$$= 9 \times 10^{-6}\,M.$$

So, correct answer is (*d*).

Note: CH_3COOH being weak, dissociates to least extent.

EXAMPLE 112. *How will you prepare a buffer solution of pH 4.70 using acetic acid and sodium acetate? K_a for $CH_3COOH = 1.75 \times 10^{-5}$.* **(Kanpur I.E.T. 1996)**

SOLUTION. $K_a = 1.75 \times 10^{-5}$. For buffer solution of a weak acid with sodium salt of this weak acid :

$$\text{pH} = \text{p}K_a + \log\frac{[\text{salt}]}{[\text{acid}]}$$
$$= -\log K_a + \log\frac{[\text{salt}]}{[\text{acid}]}$$
$$4.7 = -\log(1.75 \times 10^{-5}) + \log\frac{[\text{salt}]}{[\text{acid}]}$$
$$4.7 = -[\log 1.75 + \log 10^{-5}] + \log\frac{[\text{salt}]}{[\text{acid}]}$$
$$4.7 = -[0.24 - 5] + \log\frac{[\text{salt}]}{[\text{acid}]}$$
$$\textbf{Or} \quad \log\frac{[\text{salt}]}{[\text{acid}]} = 4.7 + 0.24 - 5 = -0.06$$
$$= -1 + 1 - 0.06 = \bar{1}.94$$
$$\text{or} \quad \frac{[\text{salt}]}{[\text{acid}]} = \text{antilog}\ \bar{1}.94 = 8.7 \times 10^{-1} = \frac{0.87}{1}$$
$$\text{or} \quad \frac{[\text{acid}]}{[\text{salt}]} = \frac{1}{0.87} = 1.15$$

i.e., the ratio in which concentration of acetic acid and sodium acetate should be used is 1 : 1.15.

EXAMPLE 113. *Suppose one litre of a buffer (pH = 5.4) has to be prepared from NH_4Cl and NH_4OH. If 0.1 mol of NH_4Cl is used, how many mol of NH_3 should be added to the solution? Assume an activity co-efficient of one. ($K_b = 1.8 \times 10^{-5}$ mol L^-)*

SOLUTION. $NH_4Cl \rightleftharpoons NH_4^+ + Cl^-;\ [NH_4^+] = 0.1\text{M}$ (given)

$$\text{Also,} \quad \text{pH} = 5.4. \text{ But pH} + \text{pOH} = 14$$
$$\therefore \quad \text{pOH} = 14 - \text{pH} = 14 - 5.4 = 8.6;$$
$$-\log[OH^-] = 8.6.$$
$$\text{Hence :} \quad \log[OH^-] = -8.6 = -8 - 1 + 1 - 0.6 = \bar{9}.4;$$
$$[OH^-] = \text{antilog}\ \bar{9}.4 = \mathbf{2.5 \times 10^{-9}}$$

	NH_4OH $\rightleftharpoons$	NH_4^+ +	OH^-
Conc. (mol L^-) at equilibrium	x	0.1 + 2.5×10^{-9}	2.5×10^{-9}

$$\therefore \quad K_b = \frac{[NH_4^+][OH^-]}{[NH_4OH]} = 0.1$$

(∵ 2.5×10^{-9} is very small as compared to 0.1, it is neglected).

Or $$1.8 \times 10^{-5} = \frac{0.1 \times 2.5 \times 10^{-9}}{x};$$

$$x = \frac{0.1 \times 2.5 \times 10^{-9}}{1.8 \times 10^{-5}} = 1.39 \times 10^{-5}$$

∴ Adding 2.5×10^{-9} and 1.39×10^{-5} we get,
13902.5×10^{-9} mol NH_3. **Ans.**

EXAMPLE 114. *Calculate the pH of a solution obtained by mixing 6.0 g of acetic acid and 12.3 g of sodium acetate and making the volume of solution to 500 mL. K_a (CH_3COOH) = 1.8×10^{-5}.*

SOLUTION. g. mol. wt. of CH_3COOH = 12 + (3 × 1) + 12 + (2 × 16) + 1 = 60 g

g. mol. wt. of CH_3COONa

= 12 + (3 × 1) + 12 + (2 × 16) + 23 = 82 g

(*i*) Molarity of CH_3COOH (acid)

$$= \frac{\text{wt.}}{\text{g. mol. wt}} \times \frac{1000}{\text{Volume of solution in mL}}$$

$$= \frac{6}{60} \times \frac{1000}{500} = 0.2\text{M}$$

(*ii*) Molarity of CH_3COONa (salt)

$$= \frac{\text{wt.}}{\text{g. mol. wt}} \times \frac{1000}{\text{Volume of solution in mL}}$$

$$= \frac{12.3}{82} \times \frac{1000}{500} = 0.3\text{M}$$

But $$p\text{H} = \text{p}K_a + \log\frac{[\text{salt}]}{[\text{acid}]}$$

$$= -\log K_a + \log\frac{[\text{salt}]}{[\text{acid}]}$$

$$= -\log(1.8 \times 10^{-5}) + \log\frac{0.3}{0.2}$$

$$= -[\log 1.8 + \log 10^{-5}] + \log 1.5$$

$$p\text{H} = -[0.2552 - 5] + 0.1761$$

$$= 5 - 0.2552 + 0.1761 = 4.92$$

EXAMPLE 115. *Calculate the pH of a buffer solution containing 0.45 moles of NH_4OH and 0.75 mole of NH_4Cl. K_b for NH_4OH is 1.8×10^{-5}.* **(ISC, 2010)**

SOLUTION. Let volume of buffer solution = one litre. Then: $[NH_4OH] = 0.45\,M$; $[NH_4Cl] = 0.75\,M$. But for a basic buffer solution:

$$p\text{OH} = pK_b + \log_{10}\frac{[\text{Salt}]}{[\text{Base}]}$$

$$= -\log_{10}(1.8 \times 10^{-5}) + \log_{10}\frac{0.75}{0.45}$$

or $$p\text{OH} = 4.7447 + [-0.1249 + 0.3467]$$

$$= 4.7447 + 0.2218 = 4.9665$$

But $$\text{pH} = 14 - p\text{OH} = 14 - 4.9665$$

$$= 9.0335$$ **Ans.**

EXAMPLE 116. *Calculate the pH of a solution obtained by mixing equal volumes of 0.016N NH_4OH and 0.16N NH_4Cl. K_b (NH_4OH) = 1.8×10^{-5}.*

SOLUTION. Since equal volume of two solutions is mixed, the concentration of each solution becomes one half *i.e.*, 1/2.

∴ $$[NH_4OH] = [\text{Base}] = \frac{0.016}{2} = 0.008\text{N}$$

$$[NH_4Cl] = [\text{Salt}] = \frac{0.16}{2} = 0.08\text{N}$$

For a basic buffer, $$p\text{OH} = \text{p}K_b + \log\frac{[\text{salt}]}{[\text{base}]}$$

$$= -\log K_b + \log\frac{0.008}{0.08}$$

Or $$p\text{OH} = -\log(1.8 \times 10^{-5}) + \log 10$$

$$= -[\log 1.8 + \log 10^{-5}] + 1$$

$$= -[0.2552 - 5] + 1$$

$$= 5 - 0.2552 + 1 = 5.7448$$

But $$\text{pH} + p\text{OH} = 14;$$

∴ $$p\text{H} = 14 - \text{pOH} = 14 - 5.7448$$

Or $$\boldsymbol{p\text{H} = 8.2552}$$ **Ans.**

EXAMPLE 117. *Calculate the amount of $(NH_4)_2SO_4$ in gram which must be added to 500 mL of 0.2M NH_3 to yield a solution with pH = 9.35 (K_b for NH_3 = 1.78×10^{-5}).* **(MLNR 1992)**

SOLUTION. 1000 mL solution contain NH_3 = 0.2M

∴ 500 mL solution contain NH_3

$$= \frac{0.2}{1000} \times 500 = 0.1\text{M}$$

∴ $$[\text{Base}] = [NH_3] = 0.1\text{M}.$$

$$p\text{OH} = 14 - \text{pH} = 14 - 9.35$$

$$= 4.65;\ [(NH_4)_2SO_4] = ?$$

But $$p\text{OH} = pK_b + \log\frac{[\text{salt}]}{[\text{Base}]}$$

(Henderson's equation)

∴ $$4.65 = -\log 1.78 \times 10^{-5} + \log\frac{[\text{salt}]}{0.1};$$

$$4.65 = -[\log 1.78 + \log 10^{-5}] + \log[\text{salt}] - \log 0.1$$

$$4.65 = -[0.25 - 5] + \log[\text{salt}] - (-1);$$

$$\log[\text{salt}] = 4.65 + 0.25 - 5 - 1 = -1.1$$

Or $$\log[\text{salt}] = -1 - 1 + 1 - 0.1 = \bar{2}.9.$$

Taking antilog of both sides we get :

$$[\text{salt}] = 7.9 \times 10^{-2}\ \text{mol};$$

g. mol. wt. of $(NH_4)_2SO_4$ = 2(18) + 32 + (4 × 16) = 132 g

∴ Amount of $(NH_4)_2SO_4$ to be added

= 7.9×10^{-2} mol × Mol. wt. of $(NH_4)_2SO_4$.

= $7.9 \times 10^{-2} \times 132$ g

= **10.5 g** **Ans.**

EXAMPLE 118. *Calculate the pH of a solution prepared by mixing 0.1 mol of sodium acetate with enough water to make 1.0 litre of solution. Assume the activity co-efficient equal to unity* ($K_a = 1.9 \times 10^{-5}$).

SOLUTION.

$$CH_3COO^- + Na^+ + HOH \rightleftharpoons CH_3COOH + Na^+ + OH^-$$

Or $$CH_3COO^- + HOH \rightleftharpoons CH_3COOH + OH^-$$

	CH_3COO^-	CH_3COOH	OH^-
Conc. (mol L⁻)	0.1	0	0
Conc. at equilibrium	$0.1 - x = 0.1$	x	x

($\because$ x is very small as compared to 0.1, it is neglected)

$$\therefore \quad K_h = \frac{[CH_3COOH][OH^-]}{[CH_3COO^-]} \quad \text{...(1)}$$

Also, $$K_h = \frac{K_w}{K_a} \quad \text{...(2)}$$

From (1) and (2), we get :

$$\frac{K_w}{K_a} = \frac{[CH_3COOH][OH^-]}{[CH_3COO^-]}$$

Or $$\frac{10^{-14}}{1.9 \times 10^{-5}} = \frac{x \times x}{0.1} ; x = \left(\frac{10^{-14} \times 0.1}{1.9 \times 10^{-5}}\right)^{1/2}$$

$$= (53 \times 10^{-12})^{1/2} = 7.3 \times 10^{-6}$$

$$\therefore \quad [OH^-] = 7.3 \times 10^{-6} ;$$

$$[H^+] = \frac{10^{-14}}{7.3 \times 10^{-6}} = 1.37 \times 10^{-9}$$

$$\therefore \quad pH = -\log [H^+] = -(\log 1.37 \times 10^{-9})$$

$$= -(\log 1.37 + \log 10^{-9})$$

$$= -(0.14 - 9) = \mathbf{8.84} \quad \textbf{Ans.}$$

EXAMPLE 119. *A buffer solution was obtained by mixing 8.3 g of acetic acid and 16.0 g of sodium acetate. The buffer is diluted to one litre. Calculate the pH of the solution if mL of 1M HCl is added to it. The dissociation constant of acetic acid is* 1.8×10^{-5}. *(At. wt., C = 12, H = 1, O = 16, Na = 23).*

SOLUTION.

(*a*) wt. of CH_3COOH = 8.3 g ;

g. mol. wt. of CH_3COOH

$$= 12 + (3 \times 1) + 12 + (2 \times 16) + 1 = 60 \text{ g.}$$

$\therefore$ no. of mol of CH_3COOH

$$= \frac{8.3 \text{ g}}{60 \text{ g}} = 0.138 ;$$

$$[CH_3COOH] = \mathbf{0.138}$$

Volume of 1N HCl added = 7 mL

$\therefore$ no. of mol of HCl or H^+ added

$$= \frac{7}{1000} = 0.007 \text{ mol}$$

$$\therefore \quad \text{Total [acid]} = 0.138 + 0.007 = 0.1\,45 \text{ mol L}^-$$

(*b*) wt. of CH_3COONa = 16.0 g.

g. mol. wt. of CH_3COONa

$$= 12 + (3 \times 1) + 12 + (2 \times 16) + 23 = 82$$

$\therefore$ no. of mol L⁻ of CH_3COONa

$$= \frac{16 \text{ g}}{82 \text{ g}} = 0.195$$

$$\therefore \quad [CH_3COONa] = 0.195 \text{ mol} = [\text{salt}]$$

But pH for a mixture of weak acid and salt of weak acid with a strong base is given as:

$$pH = pK_a + \log \frac{[\text{salt}]}{[\text{acid}]}$$

$$= -\log K_a + \log \frac{0.195}{0.145}$$

$$= -\log 1.8 \times 10^{-5} + \log 1.345$$

Or $$pH = -[\log 1.8 + \log 10^{-5}] + 0.129$$

$$= -[0.255 - 5] + 0.129$$

$$pH = 5 - 0.255 + 0.129 = \mathbf{4.874} \quad \textbf{Ans.}$$

24.9 BUFFER CAPACITY OR BUFFER INDEX (β)

It is defined as the rate of change of pH with number of mol of acid or base added.

Mathematically : Buffer capacity (Q)

$$= \frac{d_{\text{pH}}}{d_n \text{ acid or base}} \quad \text{Where } d_{\text{pH}} = \text{Change in pH}$$

d_n acid or base = number of mol of acid or base added.

> **Note.** (1) Buffer capacity or buffer index (β) is always positive.
>
> (2) Buffer capacity is maximum near pK_a provided the total number of mol of acid or base remain constant.

EXAMPLE 120. *On adding 0.0012 mol of an acid to 100 mL of a buffer solution, the pH of the solution decreases by 0.04 units. Calculate the buffer capacity of the system.*

SOLUTION. Number of mol of acid added to 100 mL solution = 0.0012

Number of mol of acid added to 1000 mL (= 1L)

$$\text{solution} = \frac{0.0012 \times 1000}{100} = 0.012$$

$\therefore$ Buffer capacity

$$= \frac{\text{no. of mol of acid added per litre}}{\text{Change in pH}}$$

$$= \frac{0.012}{0.04}$$

$$= 0.3 \quad \textbf{Ans.}$$

Example 121. *The value of ionisation constant of formic acid is 1.8 × 10⁻⁴. Calculate the pH value at which its mixture with sodium formate gives a buffer solution of higher capacity. Also, calculate the ratio of sodium formate and formic acid in a buffer of pH 4.32.*

Solution. We know that buffer capacity is maximum near pK_a provided the total number of mol of acid or base remain constant.

(*i*) *To find* pK_a.

$$pK_a = -\log K_a = -\log 1.8 \times 10^{-4}$$
$$= -[\log 1.8 + \log 10^{-4}]$$
$$= -[0.255 - 4] = 3.745$$

∴ pH of high capacity buffer = 3.745.

In order to get buffer solution of pH equal to 4.32, we have

$$\text{pH} = pK_a + \log\frac{[\text{salt}]}{[\text{acid}]};$$
$$4.32 = 3.745 + \log\frac{[\text{salt}]}{[\text{acid}]}$$
$$\therefore \quad \log\frac{[\text{salt}]}{[\text{acid}]} = 4.32 - 3.745 = 0.575.$$

Taking antilog of both sides, we get :

$$\frac{[\text{salt}]}{[\text{acid}]} = \text{antilog } 0.575 = \mathbf{3.76} \qquad \textbf{Ans.}$$

Example 122. *Calculate the pH of a buffer solution that contains 0.2M NH_4OH and 0.02 M NH_4Cl per litre ($K_w = 1.0 \times 10^{-14}$, $K_b = 1.8 \times 10^{-5}$).*

Solution. Hint. $[NH_4OH]$ = [Base] = 0.2M ;
$[NH_4Cl]$ = [salt] = 0.02 M

$$p\text{OH} = pK_b + \log\frac{[\text{salt}]}{[\text{base}]}$$
$$= -\log K_b + \log\frac{[\text{salt}]}{[\text{base}]}$$
$$= -\log(1.8 \times 10^{-5}) + \log\frac{0.02}{0.2}$$
$$\therefore \quad \text{pH} = 14 - p\text{OH} = 14 - 3.745$$
$$= \mathbf{10.26} \qquad \textbf{Ans.}$$

Example 123. *Calculate the composition of a buffer solution of sodium acetate and acetic acid having a total molarity of 0.3 and pH approximately 4.7. [K_a (CH_3COOH) = 1.8 × 10⁻⁵].*

Solution. [salt] + [acid] = 0.3 ; pH = 4.7 ; $K_a = 1.8 \times 10^{-5}$

$$p\text{H} = pK_a + \log\frac{[\text{salt}]}{[\text{acid}]};$$
$$4.7 = -\log K_a + \log\frac{[\text{salt}]}{[\text{acid}]}$$

Or
$$4.7 = [\log 1.8 \times 10^{-5}] + \log\frac{[\text{salt}]}{[\text{acid}]};$$
$$4.7 = -[\log 1.8 + \log 10^{-5}] + \log\frac{[\text{salt}]}{[\text{acid}]};$$
$$4.7 = -[0.255 - 5] + \log\frac{[\text{salt}]}{[\text{acid}]};$$
$$\log\frac{[\text{salt}]}{[\text{acid}]} = 4.7 - 5 + 0.255 = -0.045$$
$$= -1 + 1 - 0.045 = \bar{1}.955$$

Taking antilogs of both sides, we get :

$$\frac{[\text{salt}]}{[\text{acid}]} = \text{antilog } \bar{1}.955 = 0.9$$

Or
$$\frac{[\text{salt}]}{[\text{acid}]} + 1 = 1 + 0.9 ; \frac{[\text{salt}] + [\text{acid}]}{[\text{acid}]} = 1.9$$

Or
$$\frac{\text{Total molarity of buffer}}{[\text{acid}]} = 1.9$$

Substituting the values, we get : $\frac{0.3}{[\text{acid}]} = 1.9$;

$$[\text{acid}] = \frac{0.3}{1.9} = \mathbf{0.158} \qquad \textbf{Ans.}$$

Hence **[salt] = 0.3 – 0.158 = 0.142** **Ans.**

Example 124. *A buffer solution with pH 9 is to be prepared by mixing NH_4Cl and NH_4OH. Calculate the number of mol of NH_4Cl that should be added to one litre of 1.0M NH_4OH. ($K_b = 1.8 \times 10^{-5}$)* **(MLNR 1991)**

Solution. $p\text{H} = 9 ; p\text{OH} = 14 - p\text{H} = 14 - 9 = 5$

$[\text{salt}] = [NH_4Cl] = ?$;
$[\text{Base}] = [NH_4OH] = 1.0\text{M}$.

We know :
$$p\text{OH} = pK_b + \log\frac{[\text{salt}]}{[\text{base}]};$$
$$5 = -\log K_b + \log[\text{salt}] - \log 1$$

Or
$$5 = -\log(1.8 \times 10^{-5}) + \log[\text{salt}] - 0$$
$$= -[\log 1.8 + \log 10^{-5}] + \log[\text{salt}]$$

Or
$$5 = -[0.255 - 5] + \log[\text{salt}]$$
$$= 4.745 + \log[\text{salt}]$$
$$\therefore \quad \log[\text{salt}] = 5 - 4.745 = 0.255.$$

Taking antilog, we get :

$$[\text{salt}] = \mathbf{1.8\ mol\ L^{-}} \qquad \textbf{Ans.}$$

Example 125. *Calculate the change in pH of one litre of buffer solution containing 0.1 mol each of NH_3 and NH_4Cl upon addition of (i) 0.02 mol of dissolved gaseous HCl (ii) 0.02 mol of dissolved NaOH (K_b for $NH_3 = 1.8 \times 10^{-5}$).* **(Roorkee, 1992)**

Solution. $[NH_3]$ = [base] = 0.1 ; $[NH_4Cl]$ = [salt] = 0.1 ;
$K_b = 1.8 \times 10^{-5}$

But
$$p\text{OH} = pK_b + \log\frac{[\text{salt}]}{[\text{base}]}$$
$$= -[\log 1.8 \times 10^{-5}] + \log\frac{0.1}{0.1}$$

$$= -[\log 1.8 + \log 10^{-2}] + \log 1$$

$$= -[0.255 - 5] + 0 = 4.745$$

$$\therefore \quad pH = 14 - pOH = 14 - 4.745 = \mathbf{9.255.}$$

(*i*) When 0.02 mol HCl is added, we have :

	$NH_3 + HCl \rightleftharpoons$	NH_4Cl
Resulting concentration.	$0.1 - 0.02$ $= 0.08$ mol	$0.1 + 0.02$ $= 0.12$ mol

$$\therefore \quad pOH = pK_b + \log\frac{[\text{salt}]}{[\text{base}]}$$

$$= -\log K_b + \log\frac{0.12}{0.08}$$

$$= -(\log 1.8 \times 10^{-5}) + \log 12 - \log 8$$

$$= -(0.255 - 5) + 1.079 - 0.903$$

$$= 4.921$$

$$\therefore \quad pH = 14 - pOH = 14 - 4.921$$

$$= \mathbf{9.079} \qquad \textbf{Ans.}$$

$\therefore$ Decrease in $pH = 9.255 - 9.079 = \mathbf{0.176}$ **Ans.**

(*ii*) When 0.02 mol NaOH is added, we have :

$$NaOH + NH_4Cl \rightleftharpoons NaCl + NH_3 + H_2O.$$

$$[NH_4Cl] = [\text{salt}] = 0.1 - 0.02 = 0.08 \text{ mol};$$

$$[NH_3] = [\text{base}] = 0.1 + 0.02 = 0.12 \text{ mol}$$

$$pOH = pK_a + \log\frac{[\text{salt}]}{[\text{base}]}$$

$$= -\log K_a + \log[\text{salt}] - \log[\text{base}]$$

$$= -\log 1.8 \times 10^{-5} + \log 0.08 - \log 0.12$$

$$= -(\log 1.8 + \log 10^{-5}) - 1.097 + 0.92$$

$$pOH = -(0.255 - 5) - 1.097 + 0.92$$

$$= 5 - 0.255 - 1.097 + 0.92 = 4.568$$

$$\therefore \quad \mathbf{pH} = 14 - 4.568 = \mathbf{9.432} \qquad \textbf{Ans.}$$

Example 126. *The buffers of (X) and (Y) of pH 4.0 and 6.0 are prepared from acid HA and the salt NaA. Both the buffers are 0.50M in HA. What would be the pH of the solution obtained by mixing equal volumes of two buffers.* ($K_{HA} = 1.0 \times 10^{-5}$)

(Roorkee Entrance, 1999)

Solution. K_{HA} or $K_a = 10^{-5}$; $pK_a = -\log K_a = -(\log 10^{-5})$

$$= -(-5 \log 10) = +5$$

$$[\text{salt}] = ? ; [\text{acid}] = 0.5M ; pK_a = 5$$

(*a*) In buffer (*X*),

$$\therefore \quad pH = pK_a + \log\frac{[\text{salt}]}{[\text{base}]};$$

$$4 = 5 + \log[\text{salt}] - \log[\text{acid}]$$

$$4 = 5 + \log[\text{salt}] - \log 0.5$$

$$= 5 + \log[\text{salt}] - (-0.301)$$

$$\therefore \quad \log[\text{salt}] = 4 - 5 - 0.301 = -1.301$$

$$= -1 - 1 + 1 - 0.301 = \bar{2}.699$$

Or $[\text{salt}] = \text{antilog } \bar{2}.699 = 5 \times 10^{-2}$

$$= \mathbf{0.05M} \qquad \textbf{Ans.}$$

(*b*) In buffer (*Y*),

$$pH = pK_a + \log[\text{salt}] - \log[\text{acid}];$$

$$6 = 5 + \log[\text{salt}] - \log 0.5$$

$$= 5 + \log[\text{salt}] - (-0.301)$$

Or $\log[\text{salt}] = 6 - 5 - 0.301 = 0.699$

$$\therefore \quad [\text{salt}] = \text{antilog } 0.699 = 5M$$

$$\therefore \quad [\text{salt}] \text{ in mixture} = \frac{0.05 + 5}{2} = 2.525$$

Hence
$$pH = pK_a + \log\frac{[\text{salt}]}{[\text{acid}]}$$

$$= 5 + \log\frac{2.525}{0.5}$$

$$= 5 + \log 2.525 - \log 0.5$$

$$pH = 5 + 0.4 - (-0.301)$$

$$= 5 + 0.4 + 0.301 = \mathbf{5.701} \ \textbf{Ans.}$$

Example 127. *The dissociation constant of an acid HA is 1.34×10^{-5}. How many mol of sodium salt of this acid should be added to one litre of an aqueous solution containing 0.02 mol of this acid to obtain a buffer solution of pH 4.75 ? What will be the pH if 0.01 mol of hydrogen chloride is dissolved in the above buffer solution?*

(MLNR1993)

Solution. (*a*) $K_a = 1.34 \times 10^{-5}$; pH = 4.75 ;

$$[\text{acid}] = 0.02M$$

We know :
$$pH = pK_a + \log\frac{[\text{salt}]}{[\text{acid}]};$$

$$4.75 = -\log Ka + \log[\text{salt}] - \log[\text{acid}]$$

$$4.75 = -\log(1.34 \times 10^{-5}) + \log[\text{salt}] - \log 0.02$$

$$= -(\log 1.34 + \log 10^{-5}) + \log[\text{salt}] - (-1.699)$$

$$= -(0.127 - 5) + \log[\text{salt}] + 1.699;$$

$$\log[\text{salt}] = 4.75 + 0.127 - 5 - 1.699$$

$$= -1.822$$

$$\therefore \quad \log[\text{salt}] = -1 - 1 + 1 - 0.822 = \bar{2}.178.$$

Taking antilogs, we get :

$$[\text{salt}] = \text{antilog}\ \bar{2}.178 = 1.5 \times 10^{-2}$$
$$= 0.015\ \text{M}$$

∴ no. of mol of sodium salt to be added

$$= \mathbf{0.015\ mol\ L^{-}} \qquad \textbf{Ans.}$$

(*b*) When HCl is added to salt, we have :

		HCl +	NaA	$\rightleftharpoons$ NaCl + HA
(1)	n mol at start	0.01	0.015	0.02
(2)	Change by reaction	– 0.01	– 0.01	+ 0.01
(3)	n mol at equilibrium	0.01 – 0.01 = 0	0.015 – 0.01 = 0.005	0.02 + 0.01 = 0.03

$$\therefore \quad \text{pH} = pK_a + \log \frac{[\text{salt}]}{[\text{acid}]}$$
$$= -\log(1.34 \times 10^{-5}) + \log[\text{salt}] - \log[\text{acid}]$$
$$= -(\log 1.34 + \log 10^{-5}) + \log 0.005 - \log 0.03$$
$$= -(0.127 - 5) + (-2.3) - (-1.523) = 4.096$$

$$\therefore \quad \boldsymbol{p}\mathbf{H} = \mathbf{4.096} \qquad \textbf{Ans.}$$

Example 128. *0.15 mol of pyridinium chloride has been added into 500 cm^3 of 0.2M pyridine solution. Calculate pH and hydroxyl ion concentration in resulting solution assuming no change in volume. (K_b for pyridine = 1.5×10^{-9} M)*

(Roorkee Entrance, 1995)

Solution. [Pyridinium chloride]

$$= \frac{\text{no. of mol} \times 1000}{\text{Vol in mL}}$$
$$= \frac{0.15 \times 1000}{500} = 0.3\text{M}$$

[Pyridine] = 0.2M (given)

Since pyridine and pyridinium chloride form a **basic buffer,** we have :

$$\text{pOH} = pK_b + \log \frac{[\text{salt}]}{[\text{base}]}$$
$$= -\log K_b + \log[\text{salt}] - \log[\text{base}]$$
$$= -\log(1.5 \times 10^{-9}) + \log 0.3 - \log 0.2$$
$$= -(\log 1.5 + \log 10^{-9}) + (-0.523) - (-0.699)$$
$$\text{pOH} = -(0.176 - 9) - 0.523 + 0.699$$
$$= 9$$

But $\quad \text{pH} = 14 - p\text{OH}$ **Or**

$$\text{pH} = 14 - 9 = \mathbf{5} \qquad \textbf{Ans.}$$

Example 129. *The freshly precipitated aluminium and magnesium hydroxides are stirred vigorously in a buffer containing 0.25M of NH$_4$Cl and 0.05 M of NH$_4$OH. Calculate the concentration of Al^{3+} and Mg^{2+} ions in a solution. K_b for NH$_4$OH = 1.8×10^{-5}; K_{sp} of Mg(OH)$_2$ = 6×10^{-10}; K_{sp} of Al(OH)$_3$ = 6×10^{-32}.*

(IIT 1989)

Solution. Since NH$_4$Cl (0.25M) and NH$_4$OH (0.05M) form a buffer solution, so :

$$\text{pOH} = pK_b + \log \frac{[\text{NH}_4\text{Cl}]}{[\text{NH}_4\text{OH}]};$$
$$\text{pOH} = -\log K_b + \log \frac{[\text{NH}_4\text{Cl}]}{[\text{NH}_4\text{OH}]};$$
$$\text{pOH} = -\log(1.8 \times 10^{-5}) + \log \frac{0.25}{0.05};$$
$$\text{pOH} = -(\log 1.8 + \log(10^{-5})) + \log 5$$
$$\text{pOH} = -(0.255 - 5) + 0.699 = 5.444$$

Or $\quad -\log[\text{OH}^-] = 5.444 ; \log[\text{OH}^-] = -5.444$

$$= -5 - 1 + 1 - 0.444 = \bar{6}.556$$

$$\therefore \quad [\text{OH}^-] = \text{antilog}\ \bar{6}.556 = 3.6 \times 10^{-6}.$$

(*i*) $\quad \text{Al(OH)}_3 \rightleftharpoons \text{Al}^{3+} + 3\text{OH}^-;$

$$[\text{Al}^{3+}][\text{OH}^-]^3 = K_{\text{sp}}\ i.e., 6 \times 10^{-32}$$
$$\therefore \quad [\text{Al}^{3+}] = \frac{6 \times 10^{-32}}{[\text{OH}^-]^3} = \frac{6 \times 10^{-32}}{(3.6 \times 10^{-6})^3}$$
$$= \mathbf{1.286 \times 10^{-15}} \qquad \textbf{Ans.}$$

(*ii*) $\quad \text{Mg(OH)}_2 \rightleftharpoons \text{Mg}^{2+} + 2\text{OH}^-;$

$$[\text{Mg}^{2+}][\text{OH}^-]^2 = K_{\text{sp}}\ i.e., 6 \times 10^{-10}$$
$$\therefore \quad [\text{Mg}^{2+}] = \frac{6 \times 10^{-10}}{[\text{OH}^-]^2} = \frac{6 \times 10^{-10}}{(3.6 \times 10^{-6})^2}$$
$$= \mathbf{46.296M} \qquad \textbf{Ans.}$$

Example 130. *How many moles of sodium propionate should be added to one litre of an aqueous solution containing 0.020 mole of propionic acid to obtain buffer solution at pH 4.75? What will be the pH if 0.010 mole of hydrogen chloride is dissolved in the above buffer solution? Compare the last pH value with the pH of 0.010 molar HCl solution. Dissociation constant of propionic acid, K_a at 25°C = 1.34×10^{-5}.* **(IIT, 1981)**

Solution. (*a*) Let moles of sodium propionate (salt) added = *x*

$$p\text{H} = -\log K_a + \log \frac{[\text{salt}]}{[\text{acid}]}$$
$$4.75 = -\log(1.34 \times 10^{-5}) + \log \frac{x}{0.02}$$
$$= -(\log 1.34 + \log 10^{-5}) + \log x - \log 0.02$$
$$= -0.1271 + 5 + \log x - (\log 2 \times 10^{-2})$$
$$= -0.1271 + 5 + \log x - [\log 2 + (-2)\log 10]$$
$$4.75 = -0.1271 + 5 + \log x - \log 2 + 2$$
$$4.75 = -0.1271 + 5 + \log x - 0.3010 + 2$$
$$\log x = 4.75 + 0.1271 - 5 + 0.3010 - 2$$
$$= -1.8219$$

$$= \bar{1}.8219 = \bar{2}.1781$$

Taking antilogs of both sides, we get

$$x = \text{anti log } \bar{2}.1781 = 1.5 \times 10^{-2} \text{ mole} = 0.015 \text{ mole}$$

∴ Number of moles of sodium propionate

$$= x = 1.5 \times 10^{-2}$$

(*b*) When 0.01 mole of HCl is added, we get 0.03 mole (0.01 + 0.02 = 0.03) of propionic acid and 0.005 mole (0.015 – 0.010 = 0.005) of sodium propionate (salt)

$$\therefore \quad p\text{H} = -\log K_a + \log \frac{[\text{salt}]}{[\text{acid}]}$$

$$= -\log (1.34 \times 10^{-5}) + \log \frac{0.005}{0.030}$$

$$= -\log 1.34 + 5 + \log 5 - \log 30$$

$$= -0.1271 + 5 + 0.6990 - 1.4771$$

$$\boldsymbol{p\text{H} = 4.09}$$

(*c*) pH of 0.01M HCl or 10^{-2}M HCl

$$= -\log 10^{-2} \qquad \left[\begin{array}{l} \because \text{HCl} \rightleftharpoons \text{H}^+ + \text{Cl}^- \\ \quad 0.01\text{M} \qquad 0.01\text{M} \end{array}\right]$$

$$\boldsymbol{p\text{H}} = -(-2) \log 10 = \mathbf{+2}$$

EXAMPLE 131. *What is the pH of a solution when 0.20 mole of hydrochloric acid is added to one litre of a solution containing*

(*i*) *1M each of acetic acid and acetate ion?*

(*ii*) *0.1M each of acetic acid and acetate ion?* **(IIT, 1987)**

Assume total volume as one litre and K_a of acetic acid = 1.8 × 10^{-5}.

SOLUTION. HCl ionises as :

$$\underset{0.2 \text{ mole}}{\text{HCl}} \rightleftharpoons \underset{0.2 \text{ mole}}{\text{H}^+ + \text{Cl}^-}$$

$$\therefore \quad [\text{H}^+] = 0.20 \text{ mole} = 0.2 \text{ g L}^-$$

(*i*) Consider $CH_3COOH + CH_3COO^-$ solution.

When HCl *i.e.*, H^+ ions (common ion) are added to above solution, the $[CH_3COO^-]$ will be reduced

$$\therefore \quad \mathbf{[CH_3COO^-] = 1.0 - 0.2 = 0.8 \text{ mole}}$$

The H^+ ions from added HCl will combine with CH_3COO^- ions from CH_3COOH

$$\therefore \quad [CH_3COOH] = 1.0 + 0.2 = 1.2 \text{ mole}$$

We know that : $p\text{H} = -\log K_a + \log \dfrac{[\text{salt}]}{[\text{acid}]}$

Substituting the values, we get

$$p\text{H} = -\log (1.8 \times 10^{-5}) + \log \frac{[CH_3COO^-]}{[CH_3COOH]}$$

$$= -\log (1.8 - 5 \log 10) + \log \frac{0.8}{1.2}$$

$$= -(\log 1.8 - 5) + \log 8 - \log 12$$

$$= -(0.2552 - 5) + 0.9031 - 1.0791$$

$$= -0.2552 + 5 + 0.9031 - 1.0791$$

$$\boldsymbol{p\text{H} = 4.5688}$$

(*ii*) When 0.2 mole of HCl (*i.e.*, H^+ ions) are added to 0.1 mole of CH_3COO^- ions present, only 0.1 mole of H^+ ions (from HCl) combine with 0.1 mole of CH_3COO^- ions to form 0.2 mole (0.1 + 0.1 = 0.2) of acetic acid.

$$\therefore \quad [CH_3COOH] = 0.1 + 0.1 = 0.2 \text{ mole};$$

$$[\text{H}^+] = 0.2 - 0.1 = 0.1 \text{ mole}$$

Since CH_3COOH remains unionised due to the presence of H^+ ions, pH of the solution will be due to 0.1 mole HCl.

$$\therefore \quad \boldsymbol{p\text{H}} = -\log [\text{H}^+] = -\log 10^{-1} = \mathbf{1}$$

EXAMPLE 132. *How many gram moles of HCN will be required to prepare one litre of a buffer solution (containing NaCN and HCN) of pH 8.5 using 0.01 gram formula weight of NaCN?* **(IIT 1988)**

[*K dissociation (HCN) = 4.1 × 10^{-10}*]

SOLUTION. $p\text{H} = 8.5$ (given)

But $p\text{H} = -\log [\text{H}^+]$

$$\therefore \quad [\text{H}^+] = 10^{-8.5}$$

Taking logs of both sides, we get

$$\log [\text{H}^+] = \log 10^{-8.5} = -8.5 \log 10 = -8.5$$

$$= -8 - 1 + 1 - 0.5$$

$$= \bar{9}.5$$

[∵ mantissa must be positive]

Taking antilogs of both sides, we get $[\text{H}^+]$ = antilog $\bar{9}.5 = 3.16 \times 10^{-9}$ mol L^-

HCN ionises as : $HCN \rightleftharpoons H^+ + CN^-$

Applying law of mass action, we get

$$K_{\text{dissociation}} = [\text{H}^+][\text{CN}^-]/[\text{HCN}]$$

$$4.1 \times 10^{-10} = 3.16 \times 10^{-9} \times \frac{[\text{CN}^-]}{[\text{HCN}]}$$

$$\therefore \quad \frac{[\text{CN}^-]}{[\text{HCN}]} = \frac{4.1 \times 10^{-10}}{3.16 \times 10^{-9}} = 0.129 \qquad ...(1)$$

Let $[\text{HCN}] = C$

$$\therefore \quad [\text{CN}^-] = 0.01 - C$$

[∵ g. formula weight of NaCN = 0.01]

$$\therefore \quad \frac{[\text{CN}^-]}{[\text{HCN}]} = \frac{0.01 - C}{C}$$

$$0.129 = \frac{0.01 - C}{C};$$

$$0.129C = 0.01 - C; \; 1.129C = 0.01$$

$$\therefore \quad C = 0.0089$$

Hence gram mole of HCl required to be added = 0.0089

EXAMPLE 133. *A 40 ml solution of a weak base, BOH is titrated with 0.1N HCl solution. The pH of the solution is found to be 10.04 and 9.14 after the addition of 5.0 ml and 20.0 mL of the acid respectively. Find out the dissociation constant of the base.* **(IIT,1991)**

SOLUTION. Let normality of BOH = N

pH of solution = 10.04 and 9.14 (given)

We know that

$$pOH = 14 - pH$$

$$pOH = pK_b + \log \frac{[\text{salt}]}{[\text{base}]}$$

$$14 - 10.04 = pK_b + \log \frac{[5.0 \times 0.1]}{[40.0 \times N - 5.0 \times 0.1]} \quad ...(1)$$

$$14 - 9.14 = pK_b + \log \frac{[20.0 \times 0.1]}{[40.0 \times N - 20.0 \times 0.1]} \quad ...(2)$$

From expressions (1) and (2), we get

$$pK_b = 3.96 - \log \frac{0.5}{40N - 0.5} \quad ...(3)$$

$$pK_b = 4.86 - \log \frac{2}{40N - 2} \quad ...(4)$$

Equating equations (3) and (4), we get

$$3.96 - \log \frac{0.5}{40N - 0.5} = 4.86 - \log \frac{2}{40N - 2}$$

$$4.86 - 3.96 = \log \frac{2}{40N - 2} - \log \frac{0.5}{40N - 0.5}$$

$$0.9 = \log \frac{2}{40N - 2} \times \log \frac{40N - 0.5}{0.5}$$

$$= \log \frac{4\,(40N - 0.5)}{40N - 2}$$

Taking antilogs of both sides, we get

$$7.943 = \frac{4\,(40N - 0.5)}{40N - 2} \quad \therefore \quad N = 0.088$$

Substituting this value of N in equation (3), we get

$$pK_b = 3.96 - \log \frac{0.5}{40 \times 0.088 - 0.5}$$

$$= 3.96 - \log \frac{0.5}{3.02} = 3.96 - \log \frac{50}{302}$$

$$= 3.96 - [\log 50 - \log 302]$$

$$= 3.96 - 1.6990 + 2.48 = 4.741$$

Or $-\log K_b = 4.74$ or $\log K_b = -4.741$

$$= -4 - 1 + 1 - 0.741 = \bar{5}.259$$

Taking antilogs of both sides we get : $\mathbf{K_b = 1.82 \times 10^{-5}}$

EXAMPLE 134. *The pH of blood stream is maintained by a proper balance of H_2CO_3 and $NaHCO_3$ concentrations. What volume of 5M $NaHCO_3$ solution should be mixed with a 10 mL sample of blood which in 2M is H_2CO_3 in order to maintain a pH of 7.4? K_a for H_2CO_3 in blood is 7.8×10^{-7}.* **(IIT,1993)**

SOLUTION. Let V = Volume in litres of 5M $NaHCO_3$ to be added to 10 ml (= 0.01 litre) of blood to maintain pH, 7.4

Moles of $NaHCO_3 = 5 \times V = 5V$

Moles of $H_2CO_3 = 2 \times 0.01 = 0.02$

We know that : $pH = -\log K_a + \log \dfrac{[\text{salt}]}{[\text{acid}]}$

Substituting the values, we get

$$7.4 = -\log 7.8 \times 10^{-7} + \log \frac{5V}{0.02}$$

$$= -[\log 7.8 - 7 \log 10] + \log 5V - \log 2 \times 10^{-2}$$

$$= -[\log 7.8 - 7] + \log 5V - [\log 2 - 2 \log 10]$$

$$7.4 = -0.89 + 7 + \log 5V - 0.301 + 2$$

$$\log 5V = 7.4 + 0.89 - 7 + 0.301 - 2$$

$$= -0.409$$

$$= -1 + 1 - 0.409 = \bar{1}.591$$

Taking antilogs of both sides, we get $5V$

$$= \text{antilog } \bar{1}.591 = 3.9 \times 10^{-1}$$

$$\therefore \quad V = 3.9 \times 10^{-1}/5$$

$$= 0.078 \text{ litre} = \mathbf{78\ mL}$$

EXAMPLE 135. *A buffer solution contains 0.04 mol of Na_2HPO_4 per litre and 0.02 mol of NaH_2PO_4 per litre (i) Calculate pH using $pK_a = 6.84$ (ii) if 1 mL of 1.0 N HCl is added to the buffer, what will be the change in pH? (iii) if the same quantity of HCl is added to one litre of water (having pH = 7), calculate the change in pH.*

SOLUTION. (*i*) $pK_a = 6.84$; [salt] = 0.04 mol L$^-$;

[acid] = 0.02 mol L$^-$

But $pH = pK_a + \log \dfrac{[\text{salt}]}{[\text{acid}]}$;

$$pH = 6.84 + \log \frac{0.04}{0.02} \text{ i.e., } 2$$

$$\therefore \quad \mathbf{pH} = 6.84 + 0.301 \simeq \mathbf{7.14}$$

(*ii*) Original solution Dilute solution

$$N_1V_1 = N_2V_2$$

$$1 \times 1 = N_2 \times 1000 \, ; N_2 = \frac{1}{1000} = 10^{-3}$$

$$[\text{salt}] = 0.04 - 10^{-3} ; [\text{acid}] = 0.02 - 10^{-3}$$

$$\therefore \quad pH = pK_a + \log \frac{[\text{salt}]}{[\text{acid}]} ;$$

$$pH = 6.84 + \log \frac{0.04 - 10^{-3}}{0.02 - 10^{-3}}$$

$$pH = 6.84 + \log \frac{0.039}{0.019}\ ;$$

$$pH = 6.84 + \log 39 - \log 19$$

$$= 6.84 + 1.591 - 1.279$$

$$\therefore \quad \mathbf{pH = 7.15.}$$

Thus, **change in pH** = 7.15 – 7.11 = **0.04**

(*iii*) When 1mL of 1N HCl is added to one litre water, $[H^+] = 10^{-3}$ as shown in (*ii*)

$$\therefore \quad pH = -\log [H^+] = -\log 10^{-3}$$

$$= -(-3) = +3$$

$\therefore$ **Change in pH = 7 – 3 = 4** **Ans.**

EXAMPLE 136. *Calculate the amount of NH_3 and NH_4Cl required to prepare a buffer solution of pH 9.0 when total concentration of buffering reagents is 0.6 mol L^-. pK_b for NH_3 = 4.7, log 2 = 0.30.* **(Roorkee 1997)**

SOLUTION. $[\text{salt}] = [NH_4Cl] = x\ ;$

$$[\text{base}] = [NH_3] = 0.6 - x$$

We know, $pOH = pK_b + \log \frac{[\text{salt}]}{[\text{base}]}.$

Hence $14 - pH = pK_b + \log \frac{[\text{salt}]}{[\text{base}]} \log \frac{[\text{salt}]}{[\text{base}]}$

$$= 14 - pK_b - pH$$

$$= 14 - 4.7 - 9 = 0.3.$$

Taking antilogs, we get : $\frac{[\text{salt}]}{[\text{base}]}$ = antilog 0.3 = 2

Or $\frac{x}{0.6 - x} = 2\ ;\ x = 1.2 - 2x\ ;$

$$3x = 1.2\ ;\ x = \mathbf{0.4}$$

$\therefore$ Amount of salt, $NH_4Cl = x$ = **0.4 mol L⁻** **Ans.**

Amount of base, NH_3 = 0.6 – 0.4 = **0.2 mol L⁻** **Ans.**

EXAMPLE 137. *Calculate the pH of a buffer solution prepared by dissolving 28 g Na_2CO_3 in 500 mL of an aqueous solution containing 150 mL of 1M HCl. (K_a for HCO_3^- = 5.63 × 10^{-11}).*

SOLUTION. g. eq. wt. of Na_2CO_3

$$= \frac{(2 \times 23) + 12 + (3 \times 16)}{2}$$

$$= 53 \text{ g}$$

Reaction $Na_2CO_3 + HCl \rightleftharpoons NaCl + NaHCO_3$

(*i*) m. equiv. $\frac{28 \times 1000}{53}$ 1×150

before reaction = 528 = 150

(2) m. equiv. 528 – 150

after reaction = 378 0 150 150

The above solution is a buffer solution because it contains Na_2CO_3 and $NaHCO_3$.

Hence $pH = pK_a + \log \frac{[\text{salt}]}{[\text{acid}]}\ ;$

$$pH = -\log K_a + \log \frac{[\text{salt}]}{[\text{acid}]}$$

$$\therefore \quad pH = -\log 5.63 \times 10^{-11} + \log \frac{378}{150}$$

$$= -(\log 5.63 + \log 10^{-11}) + \log 378 - \log 150$$

$$\mathbf{pH} = -(0.75 - 11) + 2.58 - 2.18$$

$$= \mathbf{10.65}$$ **Ans.**

EXAMPLE 138. *During a titration of a weak acid (HA) with a strong base (NaOH), the end point was obtained by the addition of 36.0 mL of 0.1N NaOH. After this, 18.0 mL of 0.1N HCl was added to the titrated solution. As a result, pH of solution became 4.5. Find the value of K_a of the weak acid.*

SOLUTION. Reaction. $NaOH + HA \rightleftharpoons NaA + H_2O.$

(*i*) no. of milliequivalent of NaOH

$$= N_1V_1 = 0.1 \times 36 = 3.6$$

no. of milliequivalent of HCl at end point

$$= 0.1 \times 36 = 3.6$$

$\therefore$ no. of milliequivalent of NaA formed

$$= 0.1 \times 36 = 3.6.$$

(*ii*) When 18 mL of 0.1N HCl was added after the end point, we have :

$$NaA + HCl \rightleftharpoons NaCl + HA$$

no. of milliequivalent of NaA

$$= N_2V_2 = 0.1 \times 18 = 1.8$$

no. of milliequivalent of NaCl (= HA) = 1.8

Since weak acid HA and salt (NaA) of weak acid with strong base NaOH is a buffer solution :

$$pH = pK_a + \log \frac{[\text{salt}]}{[\text{acid}]}$$

$$= -\log K_a + \log \frac{[\text{salt}]}{[\text{acid}]}$$

$$\log K_a = \log \frac{[\text{salt}]}{[\text{acid}]} - pH$$

$$= \log \frac{1.8}{1.8} - 4.5 = 0 - 4.5$$

Or $\log \boldsymbol{K_a} = -4.5 = -4 - 1 + 1 - 0.5 = \bar{5}.5$

$\therefore$ $\boldsymbol{K_a}$ = antilog $\bar{5}.5$ = **3.16 × 10^{-5}** **Ans.**

Type. pH of weak acid + strong alkali

EXAMPLE 139. *To 30 cm^3 of 0.02 mol dm^{-3} acetic acid were added 10 cm^3 of 0.05 mol dm^{-3} potassium hydroxide. Calculate the pH of the solution. pK_a of acetic acid = 4.74.*

SOLUTION. Total volume = 30 + 10 = 40 cm^3

Reaction. $CH_3COOH + KOH \rightleftharpoons CH_3COOK + H_2O.$

m. mol of acetic acid = 30 × 0.02 = 0.6.

m. mol of KOH = 10 × 0.05 = 0.5

(fully ionised because KOH is a strong base)

m. mol of acetic acid left unreacted

= 0.6 – 0.5 = 0.1

$$\therefore \quad [CH_3COOK] = [\text{salt}] = \frac{0.5 \times 40}{1000} = 0.02$$

$$[CH_3COOH] = [\text{acid}] = \frac{0.1 \times 40}{1000} = 0.004$$

Since the reaction is between weak acid and strong base :

$$pH = pK_a + \log \frac{[\text{salt}]}{[\text{acid}]}$$

$$= 4.74 + \log \frac{0.02}{0.004}$$

$$= 4.74 + \log 5 = 4.74 + 0.7$$

Or $pH = \mathbf{5.44}$ **Ans.**

Note.	$1\ cm^3 = 1\ mL$; $mol\ dm^{-3} = mol\ L^-$

EXAMPLE 140. *A solution of 0.1M CH_3COOH (having pH = 3) was titrated against 0.05N NaOH solution. Calculate the pH at 25% and 75% stage of neutralisation of acid.*

SOLUTION. First Case. When 25% or $\frac{25}{100}$ *i.e.*, 1/4th acid is neutralised.

$$CH_3COOH + NaOH \rightleftharpoons CH_3COONa\ (\text{salt}) + H_2O.$$

(1) Conc. at start $0.1 \quad 0 \quad 0 \quad 0$

(2) Conc. after adding NaOH to have 1/4th neutralisation $0.1 \times \frac{3}{4} = 0.075 \quad 0.1 \times \frac{1}{4} = 0.025$

$$pH = 3 ; -\log [H^+] = 3 ;$$

$$\log [H^+] = -3 ; [H^+] = 10^{-3}.$$

Since $[CH_3COOH] = 0.1\ M, C = 0.1\ M.$

Here $[H^+] = C\alpha$

$$\therefore \quad 10^{-3} = 0.1 \times \alpha ; \alpha = \frac{10^{-3}}{0.1} = 10^{-2}.$$

Also : $K_a = C\alpha^2 ; K_a = 0.1 \times (10^{-2})^2 = 10^{-5}$

$$\therefore \quad pH = pK_a + \log \frac{[\text{salt}]}{[\text{acid}]}$$

$$= -\log K_a + \log \frac{0.025}{0.075} \text{ or } \log 0.33$$

$$pH = -\log 10^{-5} - 0.48$$

$= -(-5) - 0.48 = \mathbf{4.52}$ **Ans.**

Second Case

$$CH_3COOH + NaOH \rightleftharpoons CH_3COONa + H_2O$$

(1) Conc. at start $0.1 \quad 0 \quad 0$

(2) Conc. after adding NaOH to have 3/4th neutralisation $0.1 \times \frac{1}{4} = 0.025 \quad 0.1 \times \frac{3}{4} = 0.075$

$K_a = 10^{-5}$ as explained in first case.

$$\therefore \quad pH = pK_a + \log \frac{[\text{salt}]}{[\text{acid}]}$$

$$= \log K_a + \log \frac{0.075}{0.025} \text{ or } \log 3$$

$$pH = -\log 10^{-5} + 0.477$$

$= -(-5) + 0.477 = \mathbf{5.477}$ **Ans.**

EXAMPLE 141. *50 mL of 0.2M CH_3COOH is added to 20 mL of 0.2 M NaOH solution to get exact 70 mL solution. Calculate the pH of solution. Also calculate the additional volume of 0.2M NaOH solution needed to make the pH of the solution equal to 4.71. Ionisation constant of acid = 1.8×10^{-5}.*

SOLUTION. (*a*) Total volume = 50 + 20 = 70 mL.

Reaction :

$$CH_3COOH + NaOH \rightleftharpoons CH_3COONa + H_2O$$

m. mol of CH_3COOH = 50 × 0.2 = 10

m. mol of NaOH = 20 × 0.2 = 4

(fully ionised because NaOH is a strong base)

m. mol of CH_3COOH left unreacted

= 10 – 4 = 6

$$\therefore \quad [CH_3COONa] = \frac{4 \times 70}{1000} = 0.28M = [\text{salt}]$$

$$[CH_3COOH] = \frac{6 \times 70}{1000} = 0.42\ M = [\text{acid}]$$

Since the reaction is between strong base and weak acid,

$$pH = pK_a + \log \frac{[\text{salt}]}{[\text{acid}]}$$

$$= -\log K_a + \log \frac{0.28}{0.42}$$

$$= -\log 1.8 \times 10^{-5} + \log 0.67$$

$$= -(\log 1.8 + \log 10^{-5}) - 0.174$$

$$pH = -(0.255 - 5) - 0.174 = 4.571$$

(*b*) After the addition of 0.2M NaOH, *p*H of solution = 4.71

$$\therefore \quad pH = pK_a + \log \frac{[\text{salt}]}{[\text{acid}]}$$

$$= -\log K_a + \log \frac{[\text{salt}]}{[\text{acid}]}$$

$$4.71 = -(\log 1.8 \times 10^{-5}) + \log \frac{[\text{salt}]}{[\text{acid}]}$$

$$= -(0.255 - 5) + \log \frac{[\text{salt}]}{[\text{acid}]}$$

$$\therefore \quad \log \frac{[\text{salt}]}{[\text{acid}]} = 4.71 + 0.255 - 5 = -0.035$$

$$= -1 + 1 - 0.035 = \bar{1}.965$$

$$\therefore \quad \frac{[\text{salt}]}{[\text{acid}]} = \text{antilog } \bar{1}.965$$

$$= \frac{9.2 \times 10^{-1}}{1} \quad \ldots(1)$$

Let volume of 0.2 M NaOH added to get pH 4.71 = x mL

It means, this NaOH solution will neutralise further x mL of 0.2M CH_3COOH and produce x mL of 0.2M CH_3COONa.

$\therefore$ Resulting volume of solution = $(70 + x)$ mL.

This solution would contain :

(i) $(20 + x)$ mL of CH_3COONa

(ii) $(30 - x)$ mL of 0.2M CH_3COOH $\quad (\because 50 - 20 = 30)$

$\therefore$ no. of mol of CH_3COONa $(20 + x)$ mL solution

$$= \frac{0.2\,(20 + x)}{1000}$$

no. of mol CH_3COOH in $(30 - x)$ mL solution

$$= \frac{0.2\,(30 - x)}{1000}$$

$$\frac{[CH_3COONa]}{[CH_3COOH] \text{ or } [\text{acid}]} = \frac{0.2\,(20 + x)/1000}{0.2\,(30 - x)/1000}$$

$$= \frac{20 + x}{30 - x} \quad \ldots(2)$$

From (1) and (2), we get :

$$\frac{9.2 \times 10^{-1}}{1} = \frac{20 + x}{30 - x};$$

$$(30 - x) \times 9.2 \times 10^{-1} = 20 + x$$

$$27.6 - 0.92x = 20 + x;$$

$$1.92x = 7.6 \quad \text{Hence } x = \frac{7.6}{1.92} = 3.96.$$

Thus 3.96 mL of 0.2M NaOH is needed to make pH of solution equal to 4.71.

EXAMPLE 142. *Calculate the ratio of the concentration of salt and the acid to prepare a buffer solution of an acid and its sodium salt, having pH 4.5.* $K_a = 1.7 \times 10^{-5}$ *mol* L^{-}.

SOLUTION. For a buffer solution of an acid and its sodium salt,

$$p\text{H} = pK_a + \log \frac{[\text{salt}]}{[\text{acid}]}$$

(Henderson's equation)

$$\therefore \quad \log \frac{[\text{salt}]}{[\text{acid}]} = p\text{H} - pK_a$$

$$= 4.5 - (-\log K_a) = 4.5 + \log K_a$$

$$= 4.5 + (\log 1.7 \times 10^{-5})$$

$$= 4.5 + (\log 1.7 + \log 10^{-5})$$

$$= 4.5 + 0.23 - 5 = -0.27$$

$$\therefore \quad \log \frac{[\text{salt}]}{[\text{acid}]} = -0.27 = -1 + 1 - 0.27 = \bar{1}.73$$

$$\therefore \quad \frac{[\text{salt}]}{[\text{acid}]} = \text{antilog } \bar{1}.73 = 5.37 \times 10^{-1} = \frac{0.537}{1}.$$

$$\text{Thus} \quad \frac{[\text{salt}]}{[\text{acid}]} = \frac{0.537}{1}$$ **Ans.**

EXAMPLE 143. *Calculate the weight in g of potassium acetate that should be added to one litre of 0.45M* CH_3COOH *solution so that the* $[H^+]$ *of resultant solution is* 1.5×10^{-4} *g ion* L^{-}. $[K_a(CH_3COOH) = 1.8 \times 10^{-5}]$

SOLUTION. [acid] = 0.45 ; [salt] = ?,

g. mol. wt. of CH_3COOK

$$= 12 + (3 \times 1) + 12 + (2 \times 16) + 39 = 98 \text{ g};$$

$$[H^+] = 1.5 \times 10^{-4}$$

For a buffer solution of CH_3COOH and CH_3COOK,

$$p\text{H} = pK_a + \log \frac{[\text{salt}]}{[\text{acid}]}$$

$$= -\log K_a + \log \frac{[\text{salt}]}{[\text{acid}]}$$

$$-\log [H^+] = -\log (1.8 \times 10^{-5}) + \log \frac{[\text{salt}]}{0.45}$$

$$\therefore \quad \log \frac{[\text{salt}]}{0.45} = \log (1.8 \times 10^{-5}) - \log [H^+]$$

$$= \log 1.8 + \log 10^{-5} - \log 1.5 \times 10^{-4}$$

$$= 0.255 - 5 - (\log 1.5 + \log 10^{-4})$$

$$= 0.255 - 5 - (0.176 - 4)$$

$$= 0.255 - 5 - 0.176 + 4 = -0.921$$

$$= 0 - 1 + 1 - 0.921 = \bar{1}.079$$

$$\therefore \quad \frac{[\text{salt}]}{0.45} = \text{antilog } \bar{1}.079 = 1.2 \times 10^{-1}$$

$$= 0.12 \therefore [\text{salt}] = 0.12 \times 0.45$$

$$= 0.054 \text{ mol L}^{-}$$

$\therefore$ Amount of salt required in g = 0.054×98 g

[$\because$ g. mol. wt. of CH_3COOK = 98 g]

= **5.292 g** **Ans.**

EXAMPLE 144. *Assuming effective ionisation of* CH_3COONH_4 *as 8.0%, calculate the* $[H_3O^+]$ *of a solution containing 0.1 mol of* CH_3COONH_4 *and 0.1M* CH_3COOH. K_a $(CH_3COOH) = 1.8 \times 10^{-5}$.

SOLUTION.

$$CH_3COOH + H_2O \rightleftharpoons CH_3COO^- + H_3O^+ \ldots(1)$$

	CH_3COOH	CH_3COO^-	H_3O^+
Conc. at start (mol L^-)	0.1		
Conc. after reaction	$0.1 - x$	x	x

$$CH_3COONH_4 \rightleftharpoons CH_3COO^- + NH_4^+ ...(2)$$

$$\text{Conc. (mol L}^-) \quad 80\% = \frac{8}{100} = 0.08$$

$\therefore$ Total $[CH_3COO^-] = x + 0.08$;

$[H_3O^+] = x$; $[CH_3COOH] = 0.1 - x$

From equation (1), $K = \dfrac{[CH_3COO^-][H_3O^+]}{[CH_3COOH]}$

$$\therefore \quad 1.8 \times 10^{-5} = \frac{(x + 0.08) \times x}{0.1 - x}$$

$$= \frac{x^2 + 0.08\,x}{0.1 - x} = \frac{0.08x}{0.1}$$

($\because$ x is very small as compared to 0.1, it is rejected from the denominator. Also, x^2 being very small, is rejected).

$$\therefore \quad x = \frac{1.8 \times 10^{-5} \times 0.1}{0.08}$$

$$= 2.25 \times 10^{-5} \text{ g ion L}^-$$

or $\quad$ $\mathbf{[H_3O^+] = x = 2.25 \times 10^{-5}}$ **g ion L⁻Ans.**

Example 145. If *the addition of a small amount of solid does not cause the dilution of a solution, what will be the* $[OH^-]$ *in a solution prepared by dissolving 0.02 mol of* NH_4Cl *in 100 mL of 0.15M ammonia.* (K_{eq} *for this reaction* = 1.8×10^{-5})

Solution. $\quad NH_4Cl \rightleftharpoons NH_4^+ + Cl^-$

100 mL solution contain $[NH_4^+] = 0.02$ M

1000 mL solution contain $[NH_4^+]$

$$= \frac{0.02 \times 1000}{100} = 0.2 \text{ mol L}^-$$

Reaction $\quad NH_3 + H_2O \rightleftharpoons NH_4^+ + OH^-$

Conc. (mol L⁻) $\quad$ 0.15M $\quad$ 0.02M

$$K_{eq} = \frac{[NH_4^+][OH^-]}{[NH_3]};$$

$$1.8 \times 10^{-5} = \frac{0.02 \times [OH^-]}{0.15}$$

$$\therefore \quad \mathbf{[OH^-]} = \frac{1.8 \times 10^{-5} \times 0.15}{0.02}$$

$$= \mathbf{1.35 \times 10^{-4}\ M} \qquad \textbf{Ans.}$$

Example 146. *Calculate the number of mol of NaOH which can be added to one litre of a solution of 0.1M in* NH_4Cl *and 0.1M in* NH_3 *without changing pOH by more than one unit. Assume that volume does not change.* ($K_b = 1.8 \times 10^{-5}$; $pK_b = 4.75$).

Solution. (*a*) $\quad [NH_4Cl] = [NH_4^+] = 0.1$; $[NH_3] = 0.1$.

We know : $\quad pOH = pK_b + \log \dfrac{[NH_4^+]}{[NH_3]}$;

$$pOH = 4.75 + \log \frac{0.1}{0.1} = 4.75 + \log 1$$

$$\therefore \quad pOH = 4.75 + 0 = 4.75$$

(*b*) Since pOH should not change by more than one unit, so pOH after the addition of NaOH can not be less than 3.75. $\quad$ ($\because$ 4.75 – 1 = 3.75)

$$\therefore \quad pOH = pK_b + \log \frac{[NH_4^+]}{[NH_3]};$$

$$3.75 = 4.75 + \log \frac{[NH_4^+]}{[NH_3]}$$

$$\therefore \quad \log \frac{[NH_4^+]}{[NH_3]} = 3.75 - 4.75 = -1 = \bar{1}$$

$$\therefore \quad \frac{[NH_4^+]}{[NH_3]} = \text{antilog } \bar{1} = 10^{-1} = 0.1 \quad ...(1)$$

$\therefore$ NaOH can be added till the ratio of $[NH_4^+]$ and $[NH_3]$ is 0.1

At start, $[NH_4^+] + [NH_3] = 0.1 + 0.1 = 0.2 \quad ...(2)$

From relation (1), $[NH_4^+] = 0.1 \times [NH_3]$.

Substituting this value in relation (2), we get :

$$0.1 \times [NH_3] + [NH_3] = 0.2 \; ; \; [NH_3]\,[0.1 + 1] = 0.2$$

$$\therefore \quad \mathbf{[NH_3]} = \frac{0.2}{1.1} = \mathbf{0.182M}$$

$\therefore$ From relation (2), $[NH_4^+] + 0.182 = 0.2$

$\therefore$ $[NH_4^+] = 0.2 - 0.182 = \mathbf{0.018}$

Assuming no change in volume, hence :

$$\left.\begin{array}{l}\text{no. of mol of NaOH that should}\\ \text{be added without changing } pOH\\ \text{by one unit}\end{array}\right]$$

$$= 0.182 - 0.1 = \mathbf{0.082M.}$$

Example 147. *The concentration of HCN and NaCN in a solution is 0.01M each. Calculate the concentration of hydrogen ad hydroxyl ions if the dissociation constant of HCN is* 7.2×10^{-10}.

(Roorkee, 1991)

Solution. (*a*) $\quad [\text{salt}] = [NaCN] = 0.01M$;

$[\text{acid}] = [HCN] = 0.01M$.

We know that for a solution of weak acid with a strong base :

$$pH = pK_a + \log \frac{[\text{salt}]}{[\text{acid}]};$$

$$pH = pK_a + \log \frac{0.01}{0.01}$$

Or $\quad pH = pK_a + 0 = pK_a$;

$$-\log [H^+] = -\log K_a$$

$$= -\log 7.2 \times 10^{-10}$$

$$\therefore \quad \mathbf{[H^+] = 7.2 \times 10^{-10}} \qquad \textbf{Ans.}$$

(*b*) We know $[H^+][OH^-] = K_w$; $7.2 \times 10^{-10} \times [OH^-] = 10^{-14}$

Hence : $\quad [OH^-] = \dfrac{10^{-14}}{7.2 \times 10^{-10}}$

$$= \mathbf{1.39 \times 10^{-5}} \qquad \textbf{Ans.}$$

EXAMPLE 148. *How many mol of calcium hydroxide must be dissolved to produce 250 mL of an aqueous solution of pH 10.65. Assume complete dissociation.* **(Roorkee,1989)**

SOLUTION. $pH = 10.65.$

We know $pH + pOH = 14\ ;\ pOH = 14 - pH$

Or $pOH = 14 - 10.65 = 3.35\ ;$

$$-\log [OH^-] = -3.35$$
$$= -3 - 1 + 1 - 0.35 = \bar{4}.65$$

$\therefore$ $[OH^-] = \text{antilog } \bar{4}.65$
$$= 4.47 \times 10^{-4} \text{ mol } L^-$$
$$= 4.47 \times 10^{-4} \text{ mol } (1000 \text{ mL})^-$$

$\therefore$ $[OH^-]$ in 250 mL solution
$$= \frac{4.47 \times 10^{-4} \times 250}{1000} = 1.12 \times 10^{-4} \text{ mol } (250 \text{ mL})^-$$

$\therefore$ no. of mol of $Ca(OH)_2$ dissolved
$$= \frac{1.12 \times 10^{-4}}{2}$$
[$\because$ $Ca(OH)_2$ gives $2OH^-$ ions on dissolution]
$$= \mathbf{0.56 \times 10^{-4} \text{ mol } (250 \text{ mL})^-}$$
Ans.

EXAMPLE 149. *What happens to the 500 mL of solution that is 0.1 molar in sodium acetate and 0.1 molar in acetic acid when 10 mL of 0.1M sodium hydroxide is added? ($K_a = 1.8 \times 10^{-5}$)* **(ISC, 1989)**

SOLUTION. (*a*) Given : 500 mL solution contains 0.1M $CH_3COO^- Na^+$ + 0.1M CH_3COOH.

Hence :

$$[CH_3COO^-] = 0.1 + 0.1 = 0.2 \text{ mol}\ ;$$
$$[CH_3COOH] = 0.1 + 0.1 = 0.2 \text{ mol}$$

Reaction

$$CH_3COOH \rightleftharpoons CH_3COO^- + H^+$$

$$\therefore \quad K = \frac{[CH_3COO^-][H^+]}{[CH_3COOH]}\ ;$$

$$1.8 \times 10^{-5} = \frac{(0.2) \times [H^+]}{0.2}$$

Or $[H^+] = 1.8 \times 10^{-5}\ ;\ pH = -\log 1.8 \times 10^{-5}$
$$= -(\log 1.8 + \log 10^{-5})$$

Or $pH = -(0.255 - 5) = \mathbf{4.745}$

(*b*) $NaOH \rightleftharpoons Na^+ + OH^-$

Conc. (mol L^-) 0.1 ; $[OH^-] = 0.1 = 10^{-1}$

$$\therefore \quad [H^+] = \frac{K_w}{[OH^-]} = \frac{10^{-14}}{10^{-1}} = 10^{-13}\ ;$$

$$pH = -\log 10^{-13} = 13$$

When 10 mL of 0.1 M NaOH is added, the pH of the solution will increase because the pH of 0.1 M NaOH is 13 as explained above.

EXAMPLE 150. *Calculate the pH of an aqueous solution of 1.0M ammonium formate assuming complete dissociation (pK_a of formic acid = 3.8 and pK_b of ammonia = 4.8).* **(IIT 1995)**

SOLUTION. Ammonium formate is a salt of weak acid and weak base. pH of such a salt is given as :

$$pH = 0.5[pK_w + pK_a - pK_b]$$
$$= 0.5\,(-\log K_w + 3.8 - 4.8)$$
$$pH = 0.5[-\log 10^{-14} + 3.8 - 4.8]$$
$$= 0.5\,(14 + 3.8 - 4.8) = \mathbf{6.5}$$
Ans.

Type. Weak acid + strong acid

EXAMPLE 151. *500 mL of 0.2M aqueous solution of acetic acid is mixed with 500 mL of 0.2M HCl at 25°C.*

(*i*) *Calculate the degree of dissociation of acetic acid in the resulting solution and pH of the solution.*

(*ii*) *If 6g of NaOH is added to the above solution, determine the final pH (Assume there is no change in volume on mixing ; K_a of acetic acid is 1.75×10^{-5} mol L^-).* **(IIT 2002 Mains)**

SOLUTION. (*i*) Total volume of solution
$$= 500 + 500 = 1000 \text{ mL}$$

500 mL of 0.2M acetic acid
$$= 500 \times 0.2 = 100 \text{ m mol}$$

$$\therefore \quad [CH_3COOH] = [H^+] = \frac{100}{1000} \times \frac{1000}{1000} = 0.1 \text{ M}$$

500 mL of 0.2M HCl = 500 × 0.2 = 100 m mol

$$\therefore \quad [HCl] = [H^+] = \frac{100}{1000} \times \frac{1000}{1000} = 0.1\text{M}.$$

Let x = degree of dissociation of acetic acid, CH_3COOH

	$CH_3COOH \rightleftharpoons$	CH_3COO^- +	H^+
(1) n mol at start	0.1	0	0.1(of HCl)
(2) Change by reaction	$-x$	x	$x + 0.1$
(3) n mol at equilibrium	$0.1 - x$	x	$x + 0.1$

$$\therefore \quad K_a = \frac{[CH_3COO^-][H^+]}{[CH_3COOH]}\ ;$$

$$1.75 \times 10^{-5} = \frac{x\,(x + 0.1)}{0.1 - x}$$

Since acetic acid is a weak acid, take $x + 0.1 = 0.1$ and $0.1 - x = 0.1$.

Hence $1.75 \times 10^{-5} = \dfrac{x \times 0.1}{0.1}$; **Or** $\mathbf{x = 1.75 \times 10^{-5}}$

For 0.1M, degree of dissociation of CH_3COOH
$$= 1.75 \times 10^{-5}$$

For 1M, degree of dissociation of CH_3COOH

$$= \frac{1.75 \times 10^{-5}}{0.1} \times 1 = 1.75 \times 10^{-4}$$

(*ii*) wt. of NaOH = 6.0 g ;

g. mol. wt. of NaOH = 23 + 16 + 1 = 40 g

Total volume of mixture solution

= 500 + 500 = 1000 mL

$$\therefore \text{ Molarity of NaOH} = \frac{\text{wt. of NaOH}}{\text{g. mol. wt. of NaOH}} \times \frac{1000}{\text{Vol of solution in mL}}$$

$$= \frac{6}{40} \times \frac{1000}{1000} = \mathbf{0.15M}$$

Molarity of CH_3COOH = 0.1M (found above)

Molarity of NaOH that react with

CH_3COOH = 0.15 – 0.1 = 0.05M

Thus :

$$CH_3COOH + NaOH \rightleftharpoons CH_3COONa + H_2O$$

(1) n mol at start	0.1	0.05	0	0
(2) Change by reaction	– 0.05	+ 0.05		
(3) n mol at equilibrium	0.1 – 0.05 = 0.05	0.05		

Since $CH_3COOH + CH_3COONa$ forms a buffer solution, *p*H of solution can be obtained by the use of Henderson– Hasselbalch equation

$$pH = pK_a + \log \frac{[\text{salt}]}{[\text{Acid}]}$$

Or

$$pH = -\log K_a + \log \frac{[CH_3COONa]}{[CH_3COOH]}$$

$$= -\log (1.75 \times 10^{-5}) + \log \frac{0.05}{0.05}$$

$$= -[\log 1.75 + \log 10^{-5}] + 0$$

$$= -[0.243 - 5] = \mathbf{4.757}$$ **Ans.**

Example 152. *What volume of 5M KCN solution must be added to 10mL of 2M HCN solution to maintain pH equal to 9? [K_a(HCN) = 5 × 10^{-10} at 298K].*

Solution. (*a*) HCN + KCN form a buffer solution. For an acidic buffer solution :

$$pH = pK_a + \log \frac{[\text{salt}]}{[\text{acid}]} ;$$

$$9 = -\log K_a + \log \frac{[\text{salt}]}{[\text{acid}]}$$

$$9 = -[\log 5 \times 10^{-10}] + \log \frac{[\text{salt}]}{[\text{acid}]}$$

$$= -[\log 5 + \log 10^{-10}] + \log \frac{[\text{salt}]}{[\text{acid}]}$$

Or

$$9 = -[0.699 - 10] + \log \frac{[\text{salt}]}{[\text{acid}]} ;$$

$$\log \frac{[\text{salt}]}{[\text{acid}]} = 9 + 0.699 - 10 = -0.3010 ;$$

$$\therefore \quad \frac{[\text{salt}]}{[\text{acid}]} = \text{antilog}(-0.3010)$$

$$= \text{antilog}(-1 + 1 - 0.301 = \bar{1}.699)$$

$$= 5 \times 10^{-1} = 0.5$$

Let volume of 5M KCN to be added = *V* mL

∴ Total volume of KCN + HCN = (*V* + 10)mL

Original KCN KCN in mixture;

$$M_1V_1 = M_2V_2$$

$$5 \times V = M_2 \times (10 + V) ; M_2 = \frac{5V}{10+V} \quad ...(i)$$

Original HCN HCN in mixture

$$M_3V_3 = M_4V_4$$

$$2 \times 10 = M_4 \times (10 + V) ; M_4 = \frac{20}{10+V} \quad ...(ii)$$

But $$\frac{[\text{salt}]}{[\text{acid}]} = \frac{\frac{5V}{10+V}}{\frac{20}{10+V}} \textbf{ Or } 0.5 = \frac{5V}{20}$$ (from (*i*) and (*ii*) above).

Hence $$5V = 20 \times 0.5 \textbf{ Or } V = \frac{20 \times 0.5}{5}$$

Or V = 2 mL.

Hence volume of 5M KCN required to be added to 10 mL of 2M HCN = **2 mL** **Ans.**

Example 153. *Find the value of pH of a solution containing 3.2 mL of 0.1N NaOH and 60mL of 0.01N acetic acid. The effect due to dilution may be neglected. [K_a (CH_3COOH) = 1.7 × 10^{-5} at 298 K]*

Solution. (*i*) 3.2 mL of 0.1N NaOH = $\frac{3.2 \times 0.1}{1000}$ g. eq.

$= 3.2 \times 10^{-4}$ g. eq.

(*ii*) 60 mL of 0.01N CH_3COOH = $\frac{60 \times 0.01}{1000} = 6 \times 10^{-4}$

$$CH_3COOH + NaOH \rightleftharpoons CH_3COONa + H_2O$$

	3.2×10^{-4} g. eq.	3.2×10^{-4} g. eq. (formed)	

∴ Amount of CH_3COOH left behind after neutralisation

$$= (6 \times 10^{-4}) - (3.2 \times 10^{-4})$$

$$= 2.8 \times 10^{-4} \text{ g. eq.}$$

$$\therefore \quad [CH_3COONa] = 3.2 \times 10^{-4} \text{ g. eq} ;$$

$$[CH_3COOH] = 2.8 \times 10^{-4} \text{ g. eq.}$$

But $$pH = pK_a + \log \frac{[\text{salt}]}{[\text{acid}]}$$

$$= -\log K_a + \log \frac{3.2 \times 10^{-4}}{2.8 \times 10^{-4}}$$

$$= -\log(1.7 \times 10^{-5}) + \log 3.2 - \log 2.8$$

$$= -[\log 1.7 + \log 10^{-5}] + \log 3.2 - \log 2.8$$

$$p\textbf{H} = -[0.2304 - 5] + 0.5051 - 0.4471 = \mathbf{4.8276} \qquad \textbf{Ans.}$$

24.10 CALCULATION OF pH OF SALTS AND SOLUTIONS DUE TO HYDROLYSIS

When a salt is dissolved in water, ions are formed. If these ions are treated chemically with water, hydrolysis takes place. The salts which undergo hydrolysis are :

(*i*) salts of weak acids and strong bases (*e.g.*, CH_3COONa)

(*ii*) salts of weak bases and strong acids (*e.g.*, NH_4Cl)

(*iii*) salts of weak acids and weak bases (*e.g.*, CH_3COONH_4)

Types : Salts of weak acids and strong bases.

$$\underset{\text{Weak acid}}{CH_3COOH} + \underset{\text{Strong base}}{NaOH} \longrightarrow \underset{\substack{\text{salt of weak acid}\\ \text{and strong base}}}{CH_3COONa} + H_2O.$$

$$CH_3COONa \longrightarrow CH_3COO^- + Na^+ \qquad ...(1)$$

$$\underset{\substack{\text{Ion}\\ C - C\alpha}}{CH_3COO^-} + H_2O \rightleftharpoons \underset{C\alpha}{CH_3COOH} + \underset{\substack{\text{(hydrolysis)}\\ C\alpha}}{OH^-} \qquad ...(2)$$

[α = degree of hydrolysis]

$$= C(1 - \alpha)$$

Na^+ does not hydrolyse because it reacts with H_2O to give NaOH which ionises completely to give Na^+ and OH^- ions.

∴ Hydrolysis constant,

$$K_h = \frac{[CH_3COOH][OH^-]}{[CH_3COO^-]} \qquad ...(3)$$

[from equation (2)]

Also,
$$K_a = \frac{[CH_3COO^-] \times [H^+]}{[CH_3COOH]}$$

$$[\because CH_3COOH \rightleftharpoons CH_3COO^- + H^+]$$

and
$$K_w = [H^+][OH^-][\because H_2O \rightleftharpoons H^+ + OH^-]$$

$$\therefore \quad \frac{K_w}{K_a} = \frac{[H^+][OH^-] \times [CH_3COOH]}{[CH_3COO^-][H^+]}$$

$$= \frac{[OH^-][CH_3COOH]}{[CH_3COO^-]} = K_h$$

$$\therefore \quad \frac{K_w}{K_a} = \frac{C\alpha \times C\alpha}{C(1-\alpha)} = \frac{C\alpha^2}{1-\alpha} = C\alpha^2$$

$$\left[\because \alpha << 1, \alpha \text{ can be neglected in the denominator}\right]$$

$$\therefore \quad \alpha = \left(\frac{K_w}{K_a.C}\right)^{1/2}. \text{ But } [OH^-] = C\alpha\ ;$$

$$\therefore \quad [OH^-] = C\left(\frac{K_w}{K_aC}\right)^{1/2} = \left(\frac{C^2K_w}{K_aC}\right)^{1/2} = \left(\frac{CK_w}{K_a}\right)^{1/2}$$

Also,
$$[H^+] = \frac{K_w}{[OH^-]} = \frac{K_w}{(CK_w/K_a)^{1/2}}$$

$$= \left(\frac{K^2{}_w \times K_a}{CK_w}\right)^{1/2} = \left(\frac{\boldsymbol{K_wK_a}}{\boldsymbol{C}}\right)^{1/2}$$

Thus, hydrolysis of CH_3COO^- ion gives OH^- ions and hence solution of salts of weak acids and strong bases is **basic** in nature.

EXAMPLE 154. *Calculate the amount of NH_4Cl required to dissolve in 500 mL water to have pH 4.7 of the solution. K_b for $NH_4OH = 1.8 \times 10^{-5}$.*

SOLUTION. Reaction $\quad NH_4Cl + H_2O \rightleftharpoons NH_4OH + HCl$

Conc. at equilibrium $\quad C - Ch \qquad Ch \qquad Ch$

$$p\text{H} = 4.7\ ; -\log[H^+] = 4.7\ ;$$

$$\log[H^+] = -4.7 = -4 - 1 + 1 - 0.7 = \bar{5}.3$$

Or
$$\log[H^+] = \bar{5}.3\ ; [H^+] = \text{antilog } \bar{5}.3$$

$$= 1.99 \times 10^{-5}$$

Also, $[H^+] = hC$ where h is degree of hydrolysis.

But
$$h = \left(\frac{K_w}{K_bC}\right)^{1/2};$$

Hence
$$[H^+] = \left(\frac{K_w \times C^2}{K_bC}\right)^{1/2} = \left(\frac{K_wC}{K_b}\right)^{1/2}$$

Squaring both sides, we get :

$$[H^+]^2 = \frac{K_wC}{K_b} \text{ Or } C = \frac{[H^+]^2 K_b}{K_w}$$

Hence
$$C = \frac{(1.99 \times 10^{-5})^2 \times 1.8 \times 10^{-5}}{10^{-14}}$$

$$= 0.71 \text{ mol L}^-$$

Thus 1000 mL solution contain NH_4Cl = 0.71 mol

∴ 500 mL solution contain NH_4Cl

$$= \frac{0.71 \times 500}{1000} = 0.355 \text{ mol}$$

g. mol. wt. of NH_4Cl = 14 + (4 × 1) + 35.5 = 53.5 g

∴ Amount of NH_4Cl = 0.355 × 53.5 g = **18.99 g**

Some important formulae on hydrolysis of salts

	Salt of	Examples	Hydrolysis constant, K_h	Degree of hydrolysis, h	pH of solution
1.	Strong acid and strong base	KCl, $NaNO_3$ Na_2SO_4 etc	No hydrolysis takes place		

2.	Strong acid and weak base	NH_4NO_3, NH_4Cl	$\frac{K_w}{K_b}$	$\left(\frac{K_w}{K_bC}\right)^{1/2}$ $= \left(\frac{K_h}{C}\right)^{1/2}$	.5[$pK_w - pK_b -$ log C] Or 7 – 0.5 pK_b – 0.5logC
3.	Weak acid and strong base	Na_2CO_3, CH_3COOK etc	$\frac{K_w}{K_a}$	$\left(\frac{K_w}{K_b.C}\right)^{1/2}$ $= \left(\frac{K_h}{C}\right)^{1/2}$	7 + 0.5 pK_a + 0.5 log COr 0.5 [$pK_w + pK_a$ + log C] Or – log $\left(\frac{K_a.K_w}{C}\right)^{1/2}$
4.	Weak acid and weak base	CH_3COONH_4, NH_4CN	$\frac{K_w}{K_a.K_b}$	$\left(\frac{K_w}{K_a.K_b}\right)^{1/2}$	7 + 0.5 pK_a – 0.5 pK_b Or 0.5[$pK_w + pK_a - pK_b$] Or – log $\left(\frac{K_a.K_w}{K_b}\right)^{1/2}$

Note. (1) $pK_w = -\log K_w$; $pK_a = -\log K_a$; $pK_b = -\log K_b$.

(2) *For salt of weak acid and weak base,* if K_h is not small, then :

(*i*) $$h = \frac{(K_h)^{1/2}}{1+(K_h)^{1/2}}$$

(*ii*) $pH = pK_a - \log h + \log (1-h)$

(3) $$[H^+] = \left(\frac{K_wK_a}{C}\right)^{1/2}$$

(4) $$[OH^-] = \left(\frac{CK_w}{K_a}\right)^{1/2}$$

Type. Salt of strong base and weak acid.

Example 155. *Calculate the amount of potassium cyanide in gram that must be dissolved in 250 mL water to give a solution with a pH of 10.9. K_a (HCN) = 4.0 × 10^{-10}.*

Solution. (*a*) $KCN + H_2O \rightleftharpoons KOH + HCN$

Conc. at equilibrium $C - Ch = C(1-h)$ $\quad Ch \quad Ch$

$$\text{Hydrolysis constant, } K_h = \frac{[KOH][HCN]}{[KCN]};$$

$$K_h = \frac{Ch \times Ch}{C(1-h)} = \frac{(Ch)^2}{C} = \frac{[OH^-]^2}{C}$$

Or $$C = \frac{[OH^-]^2}{K_h} = \frac{[OH^-]^2 \times K_a}{K_w}$$

Or $$C = \frac{K_a[OH^-]^2}{K_w} \quad ...(1)$$

(*b*) $pH = 10.9$; $pOH = 14 - pH$
$= 14 - 10.9 = 3.1$

Or $-\log [OH^-] = 3.1$; $\log [OH^-] = -3.1$
$= -3 - 1 + 1 - 0.1 = \bar{4}.9$

Taking antilog of both sides, we get : $[OH^-]$ =

antilog $\bar{4}.9 = 7.9 \times 10^{-4}$

Substituting the values of $[OH^-]$ in (1), we get :

$$C = \frac{4.0 \times 10^{-10} \times (7.9 \times 10^{-4})^2}{10^{-14}}$$

$= 0.025$

$[KCN] = 0.025$ mol L^-

g. mol. wt. of KCN = 39 + 12 + 14 = 65 g

∴ $[KCN] = 0.025 \times 65 = 1.625$ g L^-

∴ Amount of KCN in 250 mL

$$= \frac{1.625 \times 250}{1000} = \mathbf{0.406\ g} \quad \textbf{Ans.}$$

Example 156. *If the dissociation constant of H_3PO_4 is 1.3 × 10^{-12}, what will be the pH of 0.2M solution of potassium orthophosphate ?*

Solution. Reaction : $PO_4^{3-} + H_2O \rightleftharpoons HPO_4^{2-} + OH^-$

But $$K_h = \frac{K_w}{K_a} = \frac{10^{-14}}{1.3 \times 10^{-12}} = 7.7 \times 10^{-5}$$

Also,degree of hydrolysis,

$$h = \left(\frac{K_h}{C}\right)^{1/2} = \left(\frac{7.7 \times 10^{-5}}{0.2}\right)^{1/2}$$

$= (385 \times 10^{-6})^{1/2} = 19.6 \times 10^{-3}$

Also, $[OH^-] = hC$.

Hence $[OH^-] = 19.6 \times 10^{-3} \times 0.2$

∴ $$[H^+] = \frac{K_w}{[OH^-]} = \frac{10^{-14}}{19.6 \times 10^{-3} \times 0.2}$$

$= 2.55 \times 10^{-12}$

∴ $pH = -\log [H^+] = -\log 2.55 \times 10^{-12}$

$= -(\log 2.55 + \log 10^{-12})$

$= -(0.4065 - 12)$ pH

$= \mathbf{11.59}$ **Ans.**

Example 157. *Calculate the pH of 0.03M sodium nitrite solution and also its degree of hydrolysis (ionisation constant of nitrous acid = 4.5 × 10^{-4}).*

Solution.

$K_a(HNO_2) = 4.5 \times 10^{-4}$; $K_w = 10^{-14}$

But hydrolysis constant, $K_h = \frac{K_w}{K_a}$

∴ $$K_h = \frac{10^{-14}}{4.5 \times 10^{-4}} = 2.2 \times 10^{-11}$$

Let h = Degree of hydrolysis

∴ $$K_h = \frac{Ch^2}{1-h} \text{ or } Ch^2$$

[because h being very small, it is ignored from the denominator]

$$2.2 \times 10^{-11} = 0.03\,h^2\,;\,h^2 = \frac{2.2 \times 10^{-11}}{0.03}$$

$$= 7.3 \times 10^{-10}$$

$$\therefore \quad h = (7.3 \times 10^{-10})^{1/2} = 2.7 \times 10^{-5}$$

But $pH = 0.5\,[pK_w + pK_a + \log C]$

$= 0.5\,[-\log K_w - \log K_a + \log C]$

$= 0.5\,[-\log 10^{-14} - [\log 4.5 \times 10^{-4}] + \log 0.03]$

$pH = 0.5\,[14 - 0.6532 + 4 - 1.5229]$

$= 0.5 \times 15.8239$

$= 7.9$ **Ans.**

EXAMPLE 158. *What is the pH of a 0.50M aqueous NaCN solution ? pK_b of CN^- is 4.70.* **(IIT 1996)**

SOLUTION. Concentration of NaCN = 0.5 ; $pK_w = 14$

But $pK_a + pK_b = 14\,;\, pK_a + 4.7 = 14\,;$

$pK_a = 14 - 4.7 = 9.3$

We know that for a salt of weak acid and strong base:

$pH = 0.5\,[pK_w + pK_a + \log C]$

$\therefore \quad pH = 0.5\,[14 + 9.3 + \log 0.5]$

$= 0.5\,[23.3 - 0.301]$

$\boldsymbol{pH = 11.5}$ **Ans.**

EXAMPLE 159. *The pH value of a 0.05 M solution of potassium formate is 9.25 at 25°C. Calculate the degree of hydrolysis, hydrolysis constant and also the dissociation constant of formic acid. (Take K_w at 25°C as 10^{-14}).*

SOLUTION.

(*a*) $K^+ + HCOO^- + H_2O \rightleftharpoons HCOOH + K^+ + OH^-$ (hydrolysis)

Or $\quad HCOO^- + H_2O \rightleftharpoons HCOOH + OH^-$

$C = 0.05M$. In case of salt of a weak acid and strong base :

$$pH = -\log\left(\frac{K_w.K_a}{C}\right)^{1/2}$$

$$= -\frac{1}{2}\,[\log K_w + \log K_a - \log C]$$

$$9.25 = -\frac{1}{2}\,[\log 10^{-14} + \log K_a - \log 0.05]$$

$$= -\frac{1}{2}[-14 + \log K_a - (-1.301)]$$

Or $\quad 2 \times 9.25 = -[-14 + \log K_a + 1.301]$

$= 14 - \log K_a - 1.301$

Or $\quad \log K_a = 14 - 1.301 - 18.5 = -5.801$

$= -5 - 1 + 1 - 0.801 = \bar{6}.199$

$\therefore \quad K_a = \text{antilog}\ \bar{6}.199 = 1.581 \times 10^{-6}$

= Dissociation constant of formic acid.

(*b*) Hydrolysis constant,

$$K_h = \frac{K_w}{K_a} = \frac{10^{-14}}{1.581 \times 10^{-6}}$$

$$= 6.32 \times 10^{-9}$$

(*c*) Degree of hydrolysis,

$$h = \left(\frac{K_h}{C}\right)^{1/2} = \left(\frac{6.32 \times 10^{-9}}{0.05}\right)^{1/2}$$

$$= (12.64 \times 10^{-8})^{1/2}$$

$$= 3.56 \times 10^{-4}$$

Or $\quad h = 3.56 \times 10^{-4} \times 100$

$= \mathbf{0.0356\%}$ **Ans.**

EXAMPLE 160. *Calculate the degree of hydrolysis, hydrolysis constant and pH of a 0.04M solution of sodium acetate. $K_w = 10^{-14}$, $K_a\,(CH_3COOH) = 1.8 \times 10^{-5}$.*

SOLUTION.

$CH_3COO^- + Na^+ + H_2O \rightleftharpoons CH_3COOH + Na^+ + OH^-$

Or $\quad CH_3COO^- + H_2O \rightleftharpoons CH_3COOH + OH^-$ (hydrolysis)

$C = 0.04M;\ K_w = 10^{-14},\ K_a = 1.8 \times 10^{-5}.$

(*a*)For the salt of a weak acid and strong base :

$$K_h = \frac{K_w}{k_a} = \frac{10^{-14}}{1.8 \times 10^{-5}} = \mathbf{5.56 \times 10^{-10}}$$

(*b*) $\quad h = \text{Hydrolysis constant} = \left(\dfrac{K_w}{k_a C}\right)^{1/2}$

$$= \left(\frac{10^{-14}}{1.8 \times 10^{-5} \times 0.04}\right)^{1/2}$$

$$= (1.39 \times 10^{-8})^{1/2}$$

$$= 1.18 \times 10^{-4}$$

(*c*) $\quad pH = \dfrac{1}{2}\,[pK_w + pK_a + \log C]$

$$= -\frac{1}{2}\,[\log K_w + \log K_a - \log C]$$

$$= -\frac{1}{2}\,[\log 10^{-14} + \log 1.8 \times 10^{-5} - \log 0.04]$$

$$= -\frac{1}{2}\,[-14 + \log 1.8 + \log 10^{-5} - \log 0.04]$$

$$= -\frac{1}{2}\,[-14 + 0.255 - 5 - (-1.398)]$$

$\boldsymbol{pH} = -\dfrac{1}{2}\,[-17.347] = \mathbf{+\,8.674}$ **Ans.**

Type. Salts of strong acids and weak bases

$$\underset{\text{Weak base}}{NH_4OH} + \underset{\text{Strong acid}}{HCl} \longrightarrow \underset{\text{Salt of weak base and strong acid}}{NH_4Cl} + H_2O$$

$$NH_4Cl \rightleftharpoons NH_4^+ + Cl^- \qquad ...(1)$$

$$NH_4^+ + H_2O \rightleftharpoons NH_4OH + H^+ \ldots(2) \text{ (hydrolysis)}$$

conc.

at eqbm. $C - C\alpha = C(1-\alpha) \qquad C\alpha \qquad C\alpha$

(α = degree of hydrolysis)

Cl^- does not hydrolyse because it reacts with H_2O to give HCl, which ionises completely to give H^+ and Cl^- ions.

Hydrolysis constant,

$$K_h = \frac{[NH_4OH][H^+]}{[NH_4^+]} \qquad \ldots(3)$$

$$K_b = \frac{[NH_4^+][OH^-]}{[NH_4OH]}$$

$$(\because NH_4OH \rightleftharpoons NH_4^+ + OH^-)$$

$$K_w = [H^+][OH^-] (\because H_2O \rightleftharpoons H^+ + OH^-)$$

$$\therefore \quad \frac{K_w}{K_b} = \frac{[H^+][OH^-] \times [NH_4OH]}{[NH_4^+] \times [OH^-]}$$

$$= \frac{[H^+][NH_4OH]}{[NH_4^+]} = K_h$$

$$\frac{K_w}{K_b} = \frac{C\alpha \times C\alpha}{C(1-\alpha)} = \frac{C\alpha^2}{1-\alpha} = C\alpha^2$$

[$\because \alpha << 1$, α can be neglected from the denominator]

$$\therefore \quad \alpha = \left(\frac{K_w}{CK_b}\right)^{1/2}$$

$$\text{But} \quad [H^+] = C\alpha = \left(\frac{C^2K_w}{CK_b}\right)^{1/2} = \left(\frac{CK_w}{K_b}\right)^{1/2}$$

The hydrolysis of salt of a weak base and a strong acid gives an acidic solution.

Type. ***Salt of strong acid and weak base***

EXAMPLE 161. *Calculate the hydrolysis constant, degree of hydrolysis and hydrogen ion concentration in 0.15N NH_4NO_3 solution. [K_b for $NH_4OH = 1.8 \times 10^{-5}$, $K_w = 1 \times 10^{-14}$]*

SOLUTION. $NH_4^+ + H_2O \rightleftharpoons NH_4OH + H^+$

Concentration at equilibrium $C - C\alpha = C(1-\alpha) \qquad C\alpha \qquad C\alpha$

$$\text{Degree of hydrolysis, } h = \left(\frac{K_h}{C}\right)^{1/2} \quad \ldots(1)\ ;\ C = 0.15N$$

$$K_h = \frac{K_w}{K_b}\ ;\ K_h = \frac{10^{-14}}{1.8 \times 10^{-5}}$$

$$= 5.6 \times 10^{-10}$$

Where K_h = Hydrolysis constant.

$\therefore$ From equation (1), we have :

$$h = \left(\frac{5.6 \times 10^{-10}}{0.15}\right)^{1/2} = 6.1 \times 10^{-5}$$

But $[H^+] = Ch\ ;\ [H^+] = 0.15 \times 6.1 \times 10^{-5}$

$= 9.15 \times 10^{-6}$

And $pH = -\log[H^+] = -\log[9.15 \times 10^{-6}]$

$= -[\log 9.15 + \log 10^{-6}]$

$pH = -[0.9614 - 6] = \mathbf{5.04}$ **Ans.**

EXAMPLE 162. *Calculate the hydrolysis constant, pH value and the $[OH^-]$ for NH_4Cl in 0.1M NH_4Cl solution. $K_w = 10^{-14}$ and K (NH_4OH) = 1.75×10^{-5}.* **(CBSE-PMT,2009)**

SOLUTION. (*i*) NH_4Cl is a salt of weak base (NH_4OH) and strong acid (HCl). Thus, the hydrolysis constant :

$$K_h = \frac{K_w}{K_b} = \frac{10^{-14}}{1.75 \times 10^{-5}}$$

$= \mathbf{5.7 \times 10^{-10}}$ **Ans.**

(*ii*) $pH = 0.5\,[pK_w - pK_b - \log C]$

$= 0.5\,[14 - (-\log 1.75 - \log 10^{-5}) - \log 0.1]$

$pH = 0.5\,[14 + 0.243 - 5 - (-1)]$

$= \mathbf{5.12}$ **Ans.**

$\therefore \quad -\log[H^+] = 5.12\ ;\ \log[H^+] = -5.12$

$= -5 - 1 + 1 - 0.12 = \bar{6}.88$

$\therefore \quad [H^+] = \text{antilog } \bar{6}.88 = 7.58 \times 10^{-6}$

$$\therefore \quad [OH^-] = \frac{K_w}{[H^+]} = \frac{10^{-14}}{7.58 \times 10^{-6}}$$

$= \mathbf{1.32 \times 10^{-9}}$ **Ans.**

EXAMPLE 163. *Calculate the percentage of hydrolysis in 0.003M aqueous solution of NaOCN (K_a of HOCN = 3.33×10^{-4}M).* **(Roorkee 1996)**

SOLUTION. NaOCN is a salt of strong base NaOH and weak acid HOCN.

Reaction : $OCN^- + H_2O \rightleftharpoons OH^- + HOCN$

Conc. at start 0.003M

Conc. at equilibrium $0.003 - \alpha \qquad \alpha \qquad \alpha$

For such a salt,

$$\alpha = \left(\frac{K_w}{K_aC}\right)^{1/2}$$

$$= \left(\frac{10^{-14}}{3.33 \times 10^{-4} \times 0.003}\right)^{1/2}$$

$$= (10^{-8})^{1/2} = 10^{-4}$$

Or % age hydrolysis = $10^{-4} \times 100 = \mathbf{0.01\%}$ **Ans.**

EXAMPLE 164. *Calculate the ionisation constant of a weak base B, if the pH of its 0.4M BNO_3 solution is 5.*

SOLUTION. $K_b = ?,\ K_w = 10^{-14}\ ;\ pH = 5.$

Hence $[H^+] = 10^{-5}$

Hydrolysis. $BNO_3 + H_2O \rightleftharpoons BOH + HNO_3$

Or $$B^+ + H_2O \rightleftharpoons BOH + \underset{10^{-5}}{H^+}$$

BNO_3 being a salt of a strong acid with a weak base, so hydrolysis constant, K_h is given as:

$$K_h = \frac{K_w}{K_b} \qquad ...(1)$$

But $$K_h = \frac{[BOH][H^+]}{[B^+]}$$

$$= \frac{[H^+][H^+]}{[B^+]} = \frac{[H^+]^2}{[B^+]}$$

$$= \frac{(10^{-5})^2}{0.4} = \frac{10^{-10}}{0.4}$$

Substituting the value of K_h in equation (1), we get :

$$\frac{10^{-10}}{0.4} = \frac{10^{-14}}{K_b} \text{ Or } K_b = \frac{10^{-14} \times 0.4}{10^{-10}}$$

$$= \mathbf{4.0 \times 10^{-5}} \qquad \textbf{Ans.}$$

EXAMPLE 165. *At 298K, how much of a 0.25M solution of sodium acetate should be diluted to get double the degree of hydrolysis?*

SOLUTION. $CH_3COONa \rightleftharpoons CH_3COO^- + Na^+$

$$CH_3COO^- + H_2O \rightleftharpoons CH_3COOH + OH^-$$

(hydrolysis)

At equilibrium $C - Ch$ $\quad Ch \quad Ch$

$= C(1 - h)$

($\because$ h = degree of hydroysis)

$$\therefore \quad K_h = \frac{[CH_3COOH][OH^-]}{[CH_3COO^-]}$$

$$= \frac{Ch \times Ch}{C(1-h)} = \frac{Ch^2}{1-h} = Ch^2 \; ...(1)$$

($\because$ h is very small, it is neglected in the denominator).

Suppose at concentration, C_1, degree of hydrolysis = $2h$.

Hence : $$K_h = C_1(2h)^2 = 4C_1h^2 \qquad ...(2)$$

From equations (1) and (2), we get :

$$4C_1h^2 = Ch^2 \; ; \; C_1 = \frac{C}{4}.$$

Hence solution should be diluted four times.

EXAMPLE 166. *Find out the value of pH of 0.001M $Zn(NO_3)_2$ solution (K_b for $Zn(OH)_2 = 2.2 \times 10^{-12}$).*

SOLUTION. *Reaction :*

$$Zn(NO_3)_2 + 2H_2O \rightleftharpoons Zn(OH)_2 + 2HNO_3$$

Or $$Zn^{2+} + 2H_2O \rightleftharpoons Zn(OH)_2 + 2H^+ \qquad ...(1)$$

	Zn^{2+}	$Zn(OH)_2$	$2H^+$
Conc. at start	C	0	0
Conc. after the reaction	$C - Ch$	Ch	$2Ch$

Where h = degree of hydrolysis ;

C = 0.001 mol L^-

$$\therefore \quad K_h = \frac{[Zn(OH)_2][H^+]^2}{[Zn^{2+}]} \qquad ...(2)$$

$$= \frac{Ch \times (2Ch)^2}{C - Ch \text{ or } C(1-h)}$$

$$= \frac{4C^3h^3}{C(1-h)} = 4C^2h^3$$

[$\because$ h is very small as compared to 1, so, it is neglected in the denominator]

$$\therefore \quad h = \left(\frac{K_h}{4C^2}\right)^{1/3} \qquad ...(3)$$

Also : $$Zn(OH)_2 \rightleftharpoons Zn^{2+} + 2OH^-$$

$$\therefore \quad K_b = \frac{[Zn^{2+}][OH^-]^2}{[Zn(OH)_2]} \qquad ...(4)$$

From equations (2) and (4), we get

$$K_h \times K_b = [H^+]^2[OH^-]^2 = \{[H^+][OH^-]\}^2$$

$$= K_w^{\,2} \; ; \; K_h = \frac{K_w^2}{K_b}$$

Or $$K_h = \left(\frac{(10^{-14})^2}{2.2 \times 10^{-12}}\right) = 4.5 \times 10^{-17}.$$

Substituting the value of K_h and C in equation (3), we get :

$$h = \left(\frac{4.5 \times 10^{-17}}{4 \times (0.001)^2}\right)^{\frac{1}{3}}$$

$$= (1.125 \times 10^{-11})^{1/3}.$$

Thus, $$\log h = \log (1.125 \times 10^{-11})^{1/3}$$

$$= \frac{1}{3} [\log 1.125 + \log 10^{-11}]$$

$$= \frac{1}{3}(0.051 - 11) = \frac{1}{3} - 10.979$$

$$= -3.6497$$

$$= -3 - 1 + 1 - 0.6497 = \bar{4}.3503$$

Or $$h = \text{antilog } \bar{4}.3503 = \mathbf{2.24 \times 10^{-4}}.$$

But $$[H^+] = 2Ch \text{ [from equation (1)]}$$

$$= 2 \times 0.001 \times 2.24 \times 10^{-4}$$

$$= 4.48 \times 10^{-7}$$

$$\therefore \quad pH = -\log [H^+] = -\log 4.48 \times 10^{-7}$$

$$= -(\log 4.48 \times 10^{-7})$$

$$\boldsymbol{p}\mathbf{H} = -(0.6513 - 7) \simeq \mathbf{6.35} \qquad \textbf{Ans.}$$

Type. Salt of a weak acid and weak base.

EXAMPLE 167. *Find the value of hydrolysis constant, degree of hydrolysis and pH of a 0.02M ammonium cyanide solution at 298K. $K_w = 10^{-14}$, $K_a(HCN) = 4.99 \times 10^{-10}$, K_b (NH_4OH) $= 1.77 \times 10^{-5}$.*

SOLUTION. (*a*) Ammonium cyanide (NH_4CN) is a salt of weak acid and weak base.

Hence : $$K_h = \left(\frac{K_w}{K_aK_b}\right)^{1/2}$$

$$= \left(\frac{10^{-14}}{(4.99 \times 10^{-10}) \times 1.77 \times 10^{-5}}\right)^{1/2}$$

$$= (1.32)^{1/2} = \mathbf{1.06}$$

(*b*) Since the value of K_h is not small :

$$h = \text{degree of hydrolysis} = \frac{(K_h)^{1/2}}{1 + (K_h)^{1/2}}$$

$$= \frac{(1.06)^{1/2}}{1 + (1.06)^{1/2}}$$

$$= \frac{1.03}{1 + 1.03} = \frac{1.03}{2.03} = 0.51$$

(*c*) Since h is very small as compared to unity :

$$pH = pK_a - \log h + \log (1 - h)$$

$$= -\log K_a - \log h + \log (1 - h)$$

$$= -\log (4.99 \times 10^{-10}) - \log 0.51 + \log (1 - 0.51)$$

$$= -[\log 4.99 + \log 10^{-10}] - (-0.29) + (-0.31)$$

$$= -[0.698 - 10] + 0.29 - 0.31$$

$$pH = 9.302 + 0.29 - 0.31 = \mathbf{9.28}$$ **Ans.**

EXAMPLE 168. *Calculate the pH of an aqueous solution of 1.0M ammonium formate assuming complete dissociation. pK_a of formic acid = 3.8 and pK_b of ammonia = 4.8.* **(IIT1995)**

SOLUTION. Ammonium formate is a salt of weak acid (formic acid) and weak base (NH_4OH). For such a solution,

$$pH = 0.5[pK_w + pK_a - pK_b]$$

$$= 0.5[14 + 3.8 - 4.8]$$

$[\because$ Given : $pK_a = 3.8, pK_b = 4.8]$

$$= \mathbf{6.5}$$ **Ans.**

EXAMPLE 169. *Calculate the degree of hydrolysis of ammonium acetate if $K_w = 10^{-14}$, $K\ (NH_4OH) = 1.8 \times 10^{-5}$ and $K\ (CH_3COOH) = 1.8 \times 10^{-5}$.*

SOLUTION. Ammonium acetate (CH_3COONH_4) is a salt of weak acid (CH_3COOH) and weak base (NH_4OH).

So, hydrolysis constant,

$$K_h = \frac{K_w}{K_aK_b} = \frac{10^{-14}}{1.8 \times 10^{-5} \times 1.8 \times 10^{-5}}$$

Or $K_h = 3.09 \times 10^{-5}$

Hydrolysis of salt is given below :

$$\underset{\frac{1-h}{V}}{CH_3COO} + \underset{\frac{1-h}{V}}{NH_4^+} + H_2O \rightleftharpoons \underset{\frac{h}{V}}{CH_3COOH} + \underset{\frac{h}{V}}{NH_4OH}$$

$$\therefore \quad K_h = \frac{[CH_3COOH][NH_4OH]}{[CH_3COO^-][NH_4^+]}$$

(law of chemical equilibrium)

$$K_h = \frac{\frac{h}{V} \times \frac{h}{V}}{\frac{1-h}{V} \times \frac{1-h}{V}} = \frac{h^2}{(1-h)^2}.$$

But $$K_h = \frac{K_w}{K_aK_b} = \frac{10^{-14}}{1.8 \times 10^{-5} \times 1.8 \times 10^{-5}}$$

Or $K_h = 3.09 \times 10^{-5}$

$$\therefore \quad \frac{h^2}{(1-h)^2} = 3.09 \times 10^{-5};$$

$$\frac{h}{1-h} = (3.09 \times 10^{-5})^{1/2} = 5.56 \times 10^{-3}$$

Or $h = 5.56 \times 10^{-3} - 5.56 \times 10^{-3}h$;

$h + 5.56 \times 10^{-3}h = 5.56 \times 10^{-3}$ **Or** $h = 5.56 \times 10^{-3}$

$[\because 5.56 \times 10^{-3}$ is very small, it can be neglected$]$

Hence $h = \mathbf{0.00556}$ **Ans.**

EXAMPLE 170. *At 298K, the values of ionisation constants of water, acetic acid and aniline are respectively 1.008×10^{-14}, 1.75×10^{-5} and 3.83×10^{-10}. Calculate the % age hydrolysis of aniline acetate in the 0.1N and 0.2N solution.*

SOLUTION. Aniline acetate is a salt of weak base and weak acid.

Given $K_w = 1.008 \times 10^{-14}, K_a = 1.75 \times 10^{-5},$
$K_b = 3.83 \times 10^{-10}$

So, we have : Degree of hydrolysis,

$$h = \left(\frac{K_w}{K_aK_b}\right)^{1/2}$$

$$= \left(\frac{1.008 \times 10^{-14}}{1.75 \times 10^{-5} \times 3.83 \times 10^{-10}}\right)^{1/2}$$

$$= 1.22$$

But h cannot be greater than 1. So, above formula for h cannot be used. So :

$$h = \frac{(K_h)^{1/2}}{1 + (K_h)^{1/2}}$$

Where $$K_h = \frac{K_w}{K_aK_b}$$

$$= \frac{1.008 \times 10^{-14}}{1.75 \times 10^{-5} \times 3.83 \times 10^{-10}} = 1.5$$

$$\therefore \qquad h = \frac{(1.5)^{1/2}}{1+(1.5)^{1/2}} = \frac{1.22}{1+1.22}$$

$$= \frac{1.22}{2.22} = 0.5495$$

∴ % age degree of hydrolysis

$$= 0.5495 \times 100 = \mathbf{54.95\%} \qquad \textbf{Ans.}$$

We see that in the above case, the degree of hydrolysis (h) is independent of concentration. So, 'h' remains equal to 0.5495 in 0.1 and 0.2N solution.

EXAMPLE 171. *Calculate the dissociation constant of aniline from the given data. (i) K (acetic acid) =* 1.8×10^{-5} *(ii)* $K_w = 10^{-14}$ *(iii) Degree of hydrolysis of 0.01N aniline acetate is 55% at 291K.*

SOLUTION. *Aniline acetate is a salt of weak acid (acetic acid) and weak base (aniline). So,* $K_b = ?$ $K_a = 1.8 \times 10^{-5}$; $h = 55\% = 55/100 = 0.55$.

But (a) $$K_h = \frac{h^2}{(1-h)^2} \qquad \text{...(1)}$$

(b) $$K_h = \frac{K_w}{K_a \times K_b} \qquad \text{...(2)}$$

From equations (1) and (2), we get

$$\frac{h^2}{(1-h)^2} = \frac{K_w}{K_a \times K_b}\,;\; K_b = \frac{K_w \times (1-h)^2}{K_a h^2}$$

Or $$K_b = \frac{10^{-14}\,(1-0.55)^2}{1.8 \times 10^{-5} \times (0.55)^2} = \frac{10^{-9} \times (0.45)^2}{1.8\,(0.55)^2}$$

$$= \mathbf{3.7 \times 10^{-10}} \qquad \textbf{Ans.}$$

EXAMPLE 172. *Calculate for 0.01N solution of sodium acetate (i) hydrolysis constant (ii) degree of hydrolysis (iii) pH* ($K_a = 1.9 \times 10^{-5}$). **(MLNREC Allahabad, 1991)**

SOLUTION. $K_w = 10^{-14}$; C = 0.01N

$$CH_3COONa + H_2O \rightleftharpoons CH_3COOH + Na^+ + OH^-$$

Concentration $\qquad Ch$

(i) $$K_h = \text{hydrolysis constant}$$

$$= \frac{K_w}{K_a} = \frac{10^{-14}}{1.9 \times 10^{-5}}$$

$$= \mathbf{5.26 \times 10^{-10}} \qquad \textbf{Ans.}$$

(ii) Degree of hydrolysis,

$$h = \left(\frac{K_h}{C}\right)^{1/2}$$

$$= \left(\frac{5.26 \times 10^{-10}}{0.01}\right)^{1/2}$$

$$= (5.26 \times 10^{-8})^{1/2}$$

$$\therefore \qquad h = 2.29 \times 10^{-4} \qquad \textbf{Ans.}$$

(iii) $\qquad pH = ?$;

$$[OH^-] = Ch = 0.01 \times 2.29 \times 10^{-4}$$

$$= 0.0229 \times 10^{-4} M$$

$$\therefore \qquad [H^+] = \frac{K_w}{[OH^-]} = \frac{10^{-14}}{0.0229 \times 10^{-4}}$$

$$= 4.37 \times 10^{-9}$$

$$\therefore \qquad pH = -\log [H^+] = -\log 4.37 \times 10^{-9}$$

$$= -[\log 4.37 + \log 10^{-9}]$$

$$= -[0.64 - 9]$$

$$\mathbf{pH = 8.36} \qquad \textbf{Ans.}$$

EXAMPLE 173. *When 0.2M acetic acid is neutralised with 0.2M NaOH in a 0.5 litre of water, the resulting solution is slightly alkaline. Calculate the pH of the resulting solution.* *(K_a for acetic acid =* 1.8×10^{-5}*).* **(Roorkee, 1989)**

SOLUTION.

$$CH_3COOH + NaOH \rightleftharpoons CH_3COONa + H_2O$$

Volume of water = 0.5 L = 0.5 × 1000 = 500 ml

0.2M CH_3COOH is neutralised by 0.2 M NaOH in 500 mL water.

$$\therefore \qquad [CH_3COONa] = \frac{0.2\text{ M} \times 500\text{ mL}}{1000\text{ mL}} = 0.1\text{ M}$$

	$CH_3COO^- + H_2O$	$\rightleftharpoons CH_3COOH$	$+ OH^-$
(1) Conc. at start	0.1M	x	x
(2) Change by reaction	$-x$	x	x
(3) Conc. at equilibrium	$0.1 - x$ $= 0.1$	x	x

(∵ x is very small, $0.1 - x = 0.1$)

$$\therefore \qquad K_h = \frac{[CH_3COOH][OH^-]}{[CH_3COO^-]}$$

$$= \frac{x \times x}{0.1} = \frac{x^2}{0.1} \qquad \text{...(1)}$$

But $$K_h = \frac{K_w}{K_a} = \frac{10^{-14}}{1.8 \times 10^{-5}} = 5.5 \times 10^{-10} \qquad \text{...(2)}$$

From (1) and (2), we get :

$$\frac{x^2}{0.1} = 5.5 \times 10^{-10}$$

$$\therefore \qquad x = (5.5 \times 10^{-10} \times 0.1)^{1/2}$$

$$= (55 \times 10^{-12})^{1/2} = 7.4 \times 10^{-6}$$

Or $$[OH^-] = 7.4 \times 10^{-6}$$

$$\therefore \qquad [H^+(aq)] = \frac{K_w}{[OH^-(aq)]} = \frac{10^{-14}}{7.4 \times 10^{-6}}$$

$$= 1.35 \times 10^{-9}$$

$$pH = -\log [H^+] = -\log 1.35 \times 10^{-9}$$

$$= -[\log 1.35 + \log 10^{-9}]$$

$$= -(0.13 - 9) = \mathbf{8.87} \qquad \textbf{Ans.}$$

EXAMPLE 174. *Calcium lactate is a salt of weak acid and is represented as $Ca(LaC)_2$. A saturated solution of $Ca(LaC)_2$ contains 0.13 mol of salt in 0.5 litre solution. The pOH of this is 5.6. Assuming complete dissociation of salt, calculate K_a of lactic acid.* **(Roorkee Entrance 1991)**

SOLUTION. $Ca(LaC)_2 + 2H_2O \rightleftharpoons Ca(OH)_2 + 2HLaC$

Or $2LaC^- + 2H_2O \rightleftharpoons 2OH^- + 2HLaC$.hydrolysis

Conc. after hydrolysis $C - Ch$ $\quad Ch \quad Ch$

$$[OH^-] = Ch = C\left(\frac{K_h}{C}\right)^{1/2}$$

$$= \left(C^2 \frac{K_w}{K_a C}\right)^{1/2} = \left(\frac{K_w C}{K_a}\right)^{1/2}$$

0.5L solution contain $Ca(LaC)_2 = 0.13M$

$\therefore$ 1L solution contain $Ca(LaC)_2 = \frac{0.13}{0.5} \times 1 = 0.26M.$

$\therefore$ C = Concentration of $2LaC^-$ anion that undergoes hydrolysis = 0.26M × 2 = 0.52 M

We know $$[OH^-] = \left(\frac{CK_w}{K_a}\right)^{1/2};$$

$$[OH^-] = \left(\frac{0.52 \times 10^{-14}}{K_a}\right)^{1/2} \qquad ...(1)$$

But $\quad pOH = 5.6$ (given) ;

$- \log [OH^-] = 5.6$;

$\log [OH^-] = -5.6 = -5 - 1 + 1 - 0.6 = \bar{6}.4.$

Taking antilog of both sides, we get :

$[OH^-] = 2.5 \times 10^{-6}.$

Substituting the value $[OH^-]$ in equation (1), we get :

$$2.5 \times 10^{-6} = \left(\frac{0.52 \times 10^{-14}}{K_a}\right)^{1/2}$$

Squaring both sides, we get

$$(2.5 \times 10^{-6})^2 = \frac{0.52 \times 10^{-14}}{K_a};$$

$$K_a = \frac{0.52 \times 10^{-14}}{2.5 \times 10^{-6} \times 2.5 \times 10^{-6}}$$

$\therefore$ $\mathbf{K_a = 8.32 \times 10^{-4}}$ **Ans.**

EXAMPLE 175. *Calculate the pH at the equivalence point when a solution of 0.1M acetic acid is titrated with a solution of 0.1M NaOH. K_a for acetic acid is 1.9×10^{-5}.* **(Roorkee Entrance, 1990)**

SOLUTION. $[CH_3COOH] = [NaOH] = 0.1M$ (given)

Let V ml of 0.1M CH_3COOH and V mL of 0.1M NaOH are used.

$\therefore$ Total volume of solution = $V + V = 2V$ mL

$\therefore$ Initial concentration of CH_3COOH

$$= \frac{0.1 \times V}{2V} = 0.05M = C$$

Also, Initial concentration of NaOH

$$= \frac{0.1 \times V}{2V} = 0.05M \backsimeq C$$

Reactions :

$CH_3COOH + NaOH \rightleftharpoons CH_3COONa + H_2O$ [neutralisation]

$CH_3COONa + H_2O \rightleftharpoons CH_3COOH + Na^+ + OH^-$ [Hydrolysis]

Concentration after reaction, $C \quad Ch \quad Ch$

$$\therefore \quad [OH^-] = Ch = C\left(\frac{K_h}{C}\right)^{1/2}$$

$$= \left(\frac{CK_w}{K_a}\right)^{1/2} = \left(\frac{0.05 \times 10^{-14}}{1.9 \times 10^{-5}}\right)$$

$= (26.3 \times 10^{-12})^{1/2}$ or

$[OH^-] = 5.13 \times 10^{-6}$

$\therefore$ $pOH = -\log [OH^-]$

$= -[\log 5.13 \times 10^{-6}]$

$= -[\log 5.13 + \log 10^{-6}]$

$= -[0.71 - 6]; pOH = 5.29$

$\therefore$ **pH** $= 14 - pOH = 14 - 5.29$

$= \mathbf{8.71}$ **Ans.**

EXAMPLE 176. *What is the pH of a 0.5M aqueous NaCN solution? pK_b of $CN^- = 4.70$.* **(IIT 1996)**

SOLUTION.	$NaCN + H_2O$	$\rightleftharpoons$ NaOH	+ HCN
(1) n mol at start	C	0	0
(2) Change by reaction	$-Ch$	Ch	Ch
(3) n mol after hydrolysis	$C - Ch$	Ch	Ch

$\therefore$ $[OH^-] = Ch$

$$[OH^-] = (K_h.C)^{1/2} = \left(\frac{K_w.C}{K_a}\right)^{1/2} \qquad ...(1)$$

But $\quad pOH = 0.5 [pK_w - pK_a - \log C]$

$= 0.5 [-\log K_w - pK_a - \log C]$

$= 0.5 [-\log 10^{-14} - 9.3 - \log 0.5]$

$= 0.5 [14 - 9.3 - (-0.301)]$

$\because$ $pK_a = 14 - pK_b = 14 - 4.7 = 9.3$

Also, $C = 0.5$ M

$pOH = 2.5$

$\therefore$ **pH** $= 14 - pOH = 14 - 2.5$

$= \mathbf{11.5}$ **Ans.**

Example 177. *A certain weak acid has $K_a = 1.0 \times 10^{-4}$. Calculate the equilibrium constant for its reaction with a strong base.* **(IIT 1984)**

Solution. Let weak acid = HA ; strong base = BOH

For weak acid,

$$HA \underset{}{\overset{H_2O}{\rightleftharpoons}} H^+(aq) + A^-(aq) ;$$

$$K_a = \frac{[H^+(aq)]\,[A^-(aq)]}{[HA]}$$

Reaction of weak acid with strong base is :

$$HA + B^+(aq) + OH^-(aq) \rightleftharpoons H_2O + B^+(aq) + A^-(aq)$$

$$\therefore \quad K_{eq} = \frac{[A^-(aq)]}{[HA]\,[OH^-(aq)]}$$

Or $$K_{eq} = \frac{[A^-(aq)]}{[HA]\,[OH^-(aq)]} \times \frac{H^+(aq)}{H^+(aq)}$$

$$= \frac{[A^-(aq)]\,[H^+(aq)]}{[HA]} \times \frac{1}{[OH^-(aq)]\,[H^+(aq)]} = \frac{K_a}{K_w}$$

Or $$K_{eq} = \frac{K_a}{K_w} \text{ which is reverse of } K_h$$

$$\left[\because K_h = \frac{K_w}{K_a}\right]$$

$$\therefore \quad K_{eq} = \frac{10^{-4}}{10^{-14}} = 10^{-4+14} = \mathbf{10^{10}}$$ **Ans.**

Example 178. *K_a for ascorbic acid (HAsc) is 5×10^{-5}. Calculate the hydrogen ion concentration and percentage of hydrolysis in an aqueous solution in which the concentration of the AsC^- ions is 0.02M.* **(Roorkee, 1997)**

Solution. We know $K_b = \frac{K_w}{K_a}$; $K_b = \frac{10^{-14}}{5 \times 10^{-5}} = 2 \times 10^{-10}$

Reaction : $AsC^- + H_2O \rightleftharpoons HAsC + OH^-$

Conc. at start 0.02M 0 0

Conc. after reaction $0.02 - x$ x x

$$\therefore \quad K_b = \frac{[HAsC]\,[OH^-]}{[AsC^-]}$$

$$= \frac{x \times x}{0.02 - x} = \frac{x^2}{0.02}$$

[$\because$ x is very small as compared to 0.02, it is rejected in the denominator]

Or $$\frac{x^2}{0.02} = 2 \times 10^{-10}$$

($\because$ $K_b = 2 \times 10^{-10}$ found above)

$$\therefore \quad x = (2 \times 10^{-10} \times 0.02)^{1/2}$$

$$= 0.2 \times 10^{-5} ; \textbf{ Or}$$

$$[OH^-] = 0.2 \times 10^{-5}$$

$$\therefore \quad [H^+] = \frac{K_w}{[OH^-]} = \frac{10^{-14}}{0.2 \times 10^{-5}}$$

$$= 5 \times 10^{-9} M$$

$$\therefore \quad \text{Degree of hydrolysis} = \frac{0.2 \times 10^{-5}}{0.02} \times 100$$

$$= \mathbf{0.01\%}$$ **Ans.**

Example 179. *The sodium salt of a weak acid is hydrolysed to the extent of 3.5% in 0.1M solution in water at 298K. Calculate the ionic product of water. (K_a of acid = 1.3×10^{-10}).*

Solution. ionic, C = 0.1M ; x = degree of hydrolysis = $3.5\% = \frac{3.5}{100} = 0.035$.

But hydrolysis constant,

$$K_h = Cx^2 ; K_h = 0.1 \times (0.035)^2$$

$$= 1.2 \times 10^{-4} \qquad \text{...(1)}$$

Also, $$K_h = \frac{K_w}{K_a} = \frac{K_w}{1.3 \times 10^{-10}} \qquad \text{...(2)}$$

Equating (1) and (2), we get :

$$\frac{K_w}{1.3 \times 10^{-10}} = 1.2 \times 10^{-4} ;$$

$$K_w = 1.2 \times 10^{-4} \times 1.3 \times 10^{-10}$$

$$= \mathbf{1.56 \times 10^{-14}}$$ **Ans.**

Example 180. *Calculate the amount of sodium acetate in gram that must be added to 500 mL water to give a pH of 8.4. ($K_a = 1.8 \times 10^{-5}$)*

Solution. We know that for a salt of weak acid (acetic acid) and strong base (NaOH):

$$pH = 0.5\,(pK_w + pK_a + \log C) ;$$

$$8.4 = 0.5\,\{14 + (-\log K_a) + \log C\}$$

$$8.4 = 0.5\,\{14 - (\log 1.8 \times 10^{-5}) + \log C\}$$

$$= 0.5\,\{\log 1.8 + \log 10^{-5} + \log C\}$$

$$8.4 = 0.5\,\{14 - (0.26 - 5) + \log C\} ;$$

$$\frac{8.4}{0.5} = 14 - 0.26 + 5 + \log C$$

$$16.8 - 14 + 0.26 - 5 = \log C$$

or $$\log C = -0.94$$

$$= -1 - 1 + 1 - 1.94 = \bar{2}.06$$

$$\therefore \quad C = \text{antilog } \bar{2}.06 = 1.15 \times 10^{-2} \text{ mol L}^-$$

$$= 1.15 \times 10^{-2} \text{ mol } (1000 \text{ mL})^-.$$

g. mol. wt. of CH_3COONa

$$= 12 + (3 \times 1) + 12 + (2 \times 16) + 23$$

$$= 82 \text{ g.}$$

$\therefore$ Amount of CH_3COONa in 500 mL

$$= \frac{1.15 \times 10^{-2} \times 500 \times 82}{1000} = \mathbf{0.472 \text{ g}}$$ **Ans.**

Example 181. *Calculate the pH of a 0.2M solution of NH_4Cl. The ionisation constant of $NH_4^+ = 1.8 \times 10^{-5}$.*

Solution. Hydrolysis reaction.

$$\begin{array}{lcccc} & NH_4^+ + HOH & \rightleftharpoons & NH_3 + & H_3O^+ \\ \text{Conc. (mol L}^-\text{)} & 0.2\text{M} & & & \\ \text{Conc. at} & & & & \\ \text{equilibrium} & 0.2 - x & & x & x \end{array}$$

But $0.2 - x \simeq 0.2$ because as compared to 0.2, x is very small and hence neglected.

$$\therefore \quad K_h = \frac{[NH_3][H_3O^+]}{[NH_4^+]} \qquad \text{...(1)}$$

$$\text{Also,} \quad K_h = \frac{K_w}{K_b} \qquad \text{...(2)}$$

From (1) and (2) we get :

$$\frac{[NH_3][H_3O^+]}{[NH_4^+]} = \frac{K_w}{K_b}; \frac{x \times x}{0.2}$$

$$= \frac{10^{-14}}{1.8 \times 10^{-5}}; x = \left(\frac{10^{-14} \times 0.2}{1.8 \times 10^{-5}}\right)^{1/2}$$

$$\textbf{Or} \quad x = (1.1 \times 10^{-10})^{1/2}$$

$$= 1.05 \times 10^{-5} = [H_3O^+]$$

$$\therefore \quad pH = -\log 1.05 \times 10^{-5}$$

$$= -(\log 1.05 + \log 10^{-5})$$

$$= -(0.02 - 5) = \mathbf{4.98} \qquad \textbf{Ans.}$$

Example 182. *Calculate the percent hydrolysis of 1N solution of sodium acetate. K_a (CH_3COOH) = 1.8×10^{-5} at 298K. K_w at 298K = 1.2×10^{-14}.*

Solution. Sodium acetate is a salt of strong base (NaOH) and weak acid (CH_3COOH). Hence, hydrolysis constant :

$$K_h = \frac{K_w}{K_a} = \frac{1.2 \times 10^{-14}}{1.8 \times 10^{-5}} = 6.67 \times 10^{-10}.$$

$$h = \left(\frac{K_h}{C}\right)^{1/2} \Rightarrow h = \left(\frac{6.67 \times 10^{-10}}{1}\right)^{1/2}$$

$$= 2.58 \times 10^{-5}$$

$\therefore$ % age hydrolysis

$$= 2.58 \times 10^{-5} \times 100 = 2.58 \times 10^{-3}$$

$$= \mathbf{0.00258\%} \qquad \textbf{Ans.}$$

Example 183. *K_a for butyric acid is 2×10^{-5}. Calculate pH and hydroxyl ion concentration of 0.2M aqueous solution of sodium butyrate.* **(Roorkee Entrance, 1994)**

Solution. *Sodium butyrate is a salt of strong base (NaOH) and weak acid (butyric acid).*

$$\text{So :} \quad pOH = 0.5\,[pK_w - pK_a - \log C]$$

$$\text{But} \quad pH = 14 - pOH.$$

$$\text{Hence :} \quad pH = 14 - 0.5\,[-\log K_w - (-\log K_a) - \log C]$$

$$= 14 - 0.5\,[-\log 10^{-14} - (-\log 2 \times 10^{-5})]$$

$$- \log C$$

$$\therefore \quad pH = 14 - 0.5\,[14 - (\log 2 - \log 10^{-5}) - \log 0.2]$$

$$= 14 - 0.5\,[14 - (-0.301 + 5) - (-0.699)]$$

$$pH = 14 - 0.5\,[14 + 0.301 - 5 + 0.699]$$

$$= 14 - 5 = 9 \qquad \textbf{Ans.}$$

$$\text{Since} \quad pH = 9; -\log[H^+] = 9; [H^+] = 10^{-9}$$

$$\text{But} \quad [OH^-] = \frac{K_w}{[H^+]} = \frac{10^{-14}}{10^{-9}} = 10^{-14+9} = \mathbf{10^{-5}} \qquad \textbf{Ans.}$$

24.11 SOLUBILITY AND SOLUBILITY PRODUCT

Solubility. The concentration (mol L⁻) of a saturated solution of a salt at a given temperature is called solubility of a salt.

Solubility product and ionic product. Suppose AgCl salt is dissolved in water to get its saturated solution. It ionises as $AgCl(s) \rightleftharpoons Ag^+(aq) + Cl^-(aq)$. Applying law of chemical equilibrium we have :

$$K = \frac{[Ag^+][Cl^-]}{[AgCl(s)]}$$

$$\textbf{Or} \quad K \times [AgCl(s)] = [Ag^+][Cl^-]$$

$$\textbf{Or} \quad K_c, \text{ called } K_{sp} = [Ag^+][Cl^-];$$

K_{sp} = solubility product while $[Ag^+][Cl^-]$ is called ionic product.

(*i*) If ionic product > K_{sp}, precipitation takes place

(*ii*) If ionic product < K_{sp}, no precipitation takes place and more of the salt dissolves.

(*iii*) If ionic product = K_{sp}, the solution is saturated.

I. *Calculation of solubility of a salt of a strong base and a strong acid in pure water e.g.,* AgCl

Let solubility of salt = s mol L⁻,

$$\begin{array}{lcc} & AgCl \rightleftharpoons Ag^+ + & Cl^- \\ \text{Solubility (mol L}^-\text{)} & s & s \end{array}$$

$$\therefore \quad K_{sp} = [Ag^+][Cl^-] = s \times s = s^2$$

$$\text{then,} \quad \mathbf{s = (K_{sp})^{1/2}}$$

II. Calculation of solubility of a salt of a strong base and strong acid in a solution which already contains a common ion. *e.g.*, {[Ag^+] common ion = '*a*' mol L⁻} in AgCl solution.

$$\begin{array}{lcc} \text{Thus :} & AgCl \rightleftharpoons Ag^+ + & Cl^- \\ & s' + a & s' \end{array}$$

Here, $K_{sp} = [Ag^+][Cl^-]$

Or $K_{sp} = (s' + a) \times s'$

III. *Calculation of solubility of a salt of a weak acid with a strong base in* ***pure water****. e.g.,* CH_3COOAg.

Since the salt is of weak acid and strong base, it will get hydrolysed. Suppose, solubility of $CH_3COOAg = x$ mol L^-; amount of CH_3COO^- that gets hydrolysed = y mol L^-.

Thus :
$$CH_3COOAg \rightleftharpoons \underset{x-y}{CH_3COO^-} + \underset{x}{Ag^+} \quad ...(1)$$
$$\underset{x-y}{CH_3COO^-} + H_2O \rightleftharpoons \underset{y}{CH_3COOH} + \underset{y}{OH^-} \quad ...(2)$$

$\therefore$ From equation (1),
$$K_{sp} = [CH_3COO^-][Ag^+]$$
$$= (x-y) \times x = x(x-y) \quad ...(3)$$

Similarly from equation (2) :
$$K_h (= K_w/K_a) = \frac{[CH_3COOH][OH^-]}{[CH_3COO^-]}$$
$$= \frac{y \times y}{x-y} = \frac{y^2}{x-y} \quad ...(4)$$

After solving equations (3) and (4), the volume of x can be calculated.

IV. *Calculation of solubility of a salt (e.g., CH_3COOAg) of a weak acid (e.g., CH_3COOH) and a strong base (e.g., AgOH) in an* ***acidic buffer*** *solution.* CH_3COOAg ionises as :
$$CH_3COOAg \rightleftharpoons CH_3COO^- + Ag^+$$

The given condition is that the solution is acidic. So, CH_3COO^- ions would react with H^+ ions to form CH_3COOH

Suppose solubility of CH_3COOAg = x mol L^- and
Concentration of CH_3COO^- combined with H^+ ions $= y$
$$\underset{x}{CH_3COOAg} \rightleftharpoons \underset{x-y}{CH_3COO^-} + \underset{x}{Ag^+} \quad ...(1)$$
$$\underset{x-y}{CH_3COO^-} + H^+ \rightleftharpoons \underset{y}{CH_3COOH} \quad ...(2)$$

$\therefore$ From equation (1),
$$K_{sp} = [CH_3COO^-][Ag^+]$$
$$= (x-y) \times x = x(x-y) \quad ...(3)$$

Similarly, from equation (2) :
$$K_a = \frac{[CH_3COOH]}{[CH_3COO^-][H^+]}$$
$$= \frac{y}{(x-y)[H^+]} \quad ...(4)$$

Solving equation (3) and (4), value of x can be calculated. This value of x will be more than that of x, found in pure water.

V. *Calculation of solubility of a salt of a weak acid (e.g., CH_3COOH) and a strong base (e.g., AgOH) in a* ***basic buffer****.* CH_3COOAg ionises as :
$$CH_3COOAg \rightleftharpoons CH_3COO^- + Ag^+ \quad ...(1)$$

Since the solution is basic (given), the $[H^+]$ will be less and very less amount of CH_3COO^- would react with H^+ ions. Also, the hydrolysis would get suppressed by already existing OH^- ions.

Let solubility of $CH_3COOAg = x$ mol L^-.

So, from equation (1),
$$[CH_3COO^-] = [Ag^+] = x \text{ mol } L^-.$$

Hence $K_{sp} = [CH_3COO^-][Ag^+]$
$$= x \times x = x^2 \text{ mol}^2 \text{ L}^{-2}.$$

> **Note 1.** The decreasing order of solubility of such salts is :
>
> In acidic solution > in pure water> in basic solution.
>
> **2.** For salts (*e.g.*, $C_6H_5NH_3^+Cl^-$) of a strong acid (*e.g.*, HCl) with a weak base (*e.g.*, aniline, $C_6H_5NH_2$), the decreasing order of solubility of such salts is :
>
> In basic solution > in pure water > in acidic solution.

VI. *Calculation of solubility of a salt of weak acid (e.g., HCN) with a weak base (e.g., NH_4OH), in pure water. NH_4CN ionises as :*
$$NH_4CN \rightleftharpoons \underset{x-y}{NH_4^+} + \underset{x-y}{CN^-} \quad \text{(Ionisation)}...(1)$$
$$\underset{x-y}{NH_4^+} + \underset{x-y}{CN^-} + H_2O \rightleftharpoons \underset{y}{NH_4OH} + \underset{y}{HCN} \quad \text{(Hydrolysis)} \quad ...(2)$$

$\therefore$ From equation (1), we have :
$$K_{sp} = [NH_4^+][CN^-] = (x-y)(x-y)$$

Or $K_{sp} = (x-y)^2$ ...(3)

From equation (2), we have :
$$\frac{K_w}{K_aK_b} = \frac{[NH_4OH][HCN]}{[NH_4^+][CN^-][H_2O]}$$
$$= \frac{y \times y}{(x-y) \times (x-y)} = \frac{y^2}{(x-y)^2}$$

or
$$\frac{K_w}{K_aK_b} = \frac{y^2}{(x-y)^2} \quad ...(4)$$

Solving equations (3) and (4), solubility of salt can be found.

VII. *Calculation of solubility of a salt (e.g., NH_4CN) of a weak acid (e.g., HCN) and weak base (e.g., NH_4OH) in an acidic buffer and in a basic buffer.*

In acidic buffer medium
$$NH_4CN \rightleftharpoons \underset{x}{NH_4^+} + \underset{x-y}{CN^-} \quad ...(1)$$
$$\underset{x-y}{CN^-} + H^+ \rightleftharpoons \underset{y}{HCN} \quad ...(2)$$

Where solubility of salt = x mol L$^-$ and concentration of CN$^-$ combined with H$^+$ is $x - y$.

$\therefore$ $[CN^-] = x - y$; $[HCN] = y$; $[NH_4^+] = x$

$\therefore$ From equation (1) we have :

$$K_{sp} = [NH_4^+]\,[CN^-] = x\,(x - y)$$

From equation (2) using CN$^-$ of product of equation (1), we have :

$$K_a^{-1} = \frac{[HCN]}{[CN^-]\,[H^+]} = \frac{y}{(x-y)\,(H^+)}$$

In basic buffer medium

$$NH_4CN \rightleftharpoons \underset{x-y}{NH_4^+} + \underset{x}{CN^-} \qquad ...(1)$$

$$\underset{x-y}{NH_4^+} + OH^- \rightleftharpoons \underset{y}{NH_4OH} \qquad ...(2)$$

Where solubility of salt = x mol L$^-$ and concentration of NH$_4^+$ combined with OH$^-$ is $x - y$.

$\therefore$ $[NH_4^+] = x - y$; $[CN^-] = x$;

$[NH_4OH] = y$

$\therefore$ From equation (1) we have :

$$K_{sp} = [NH_4^+]\,[CN^-] = (x - y)x$$

From equation (2) using NH$_4^+$ of product of equation (1), we have :

$$K_b^{-1} = \frac{[NH_4OH]}{[NH_4^+]\,[OH^-]} = \frac{y}{(x-y)\,(OH^-)}$$

EXAMPLE 184. *A cation A$^+$ and anion B$^-$ react to give salts of the type (i) AB (ii) AB$_2$ and A$_2$B (iii) A$_3$B$_2$ and A$_2$B$_3$. If S is the solubility of the salt in mol L$^-$, calculate the value of solubility product of these types of salts.*

SOLUTION. (*i*) AB ionises as : $AB \rightleftharpoons A^+ + B^-$

Solubility $\quad S \quad S$

$\therefore$ $K_{sp} = [A^+]\,[B^-] = S\ mol\ L^- \times S\ mol\ L^-$
$= S^2\ mol^2\ L^{-2}$

(*ii*) AB$_2$ ionises as : $AB_2 \rightleftharpoons A^+ + 2B^-$

Solubility $\quad$ S mol L$^-$ $\quad$ 2 S mol L$^-$

$\therefore$ $K_{sp} = [A^+]\,[B^-]^2$
$= (S\ mol\ L^-) \times (2\ S\ mol\ L^-)^2$
$= 4S^3\ mol^3\ L^{-3}$

(*iii*) A$_2$B ionises as : $A_2B \rightleftharpoons 2A^+ + B^-$

Solubility $\quad$ 2S mol L$^-$ $\quad$ S mol L$^-$

$\therefore$ $K_{sp} = [A^+]^2\,[B^-]$
$= (2\ S\ mol\ L^-)^2 \times (S\ mol\ L^-)$
$= 4S^3\ mol^3\ L^{-3}$

(*iv*) A$_3$B$_2$ ionises as : $A_3B_2 \rightleftharpoons 3A^+ + 2B^-$

Solubility $\quad$ 3 S mol L$^-$ $\quad$ 2 S mol L$^-$

$\therefore$ $K_{sp} = [A^+]^3\,[B^-]^2$
$= (3\ S\ mol\ L^-)^3 \times (2\ S\ mol\ L^-)^2$
$= \mathbf{108\ S^5\ mol^5\ L^{-5}}$

(*v*) A$_2$B$_3$ ionises as : $A_2B_3 \rightleftharpoons 2A^+ + 3B^-$

Solubility]$\rightarrow$ $\quad$ 2S mol L$^-$ $\quad$ 3S mol L$^-$

$\therefore$ $K_{sp} = [A^+]^2\,[B^-]^3$
$= (2S\ mol\ L^-)^2 \times (3S\ mol\ L^-)^3$
$= \mathbf{108\ S^5\ mol^5\ L^{-5}}$

EXAMPLE 185. *Calculate the solubility of strontium fluoride in 0.1M NaF solution. K$_{sp}$ for SrF$_2$ in water = 8 × 10^{-10}.*

(Roorkee, 1997)

SOLUTION. SrF$_2$ ionises as :

$$SrF_2 \xrightleftharpoons{\text{in 0.1 M NaF}} Sr^{2+} + 2F^-$$

Solubility $\quad$ S mol L$^-$ $\quad$ 2S mol L$^-$

NaF ionises as $\quad NaF \rightleftharpoons Na^+ + F^-$

Concentration $\quad$ 0.1M $\quad$ 0.1M

$\therefore$ $[Sr^{2+}] = S\ mol\ L^-$; $[F^-] = 2S + 0.1$

Hence, $K_{sp} = [Sr^{2+}]\,[F^-]^2 = S\,(2S + 0.1)^2$

$8 \times 10^{-10} = S \times (0.\ 1)^2$

[Since $S << 0.1$, $(2S + 0.1)^2 = (0.1)^2$]

$= S \times (0.1)^2 = S \times 10^{-2}$

or $\quad S = \dfrac{8 \times 10^{-10}}{10^{-2}} = 8 \times 10^{-10+2}$

$= \mathbf{8 \times 10^{-8}}$ **Ans.**

EXAMPLE 186. *Calculate the maximum pH of a given solution of 0.1M Mg^{2+} ions from which Mg(OH)$_2$ is not precipitated [K$_{sp}$ of Mg(OH)$_2$ = 1.2 × 10^{-11}].*

SOLUTION. $[Mg(OH)_2] = 0.1$ M (given) ;

$K_{sp} = 1.2 \times 10^{-11}$

For $\quad Mg(OH)_2 \rightleftharpoons Mg^{2+} + 2OH^-$

Concentration $\quad$ 0.1M $\quad$ x

$K_{sp} = [Mg^{2+}]\,[OH^-]^2$;

$1.2 \times 10^{-11} = 0.1\,[OH^-]^2$

$\therefore$ $[OH^-] = \left(\dfrac{1.2 \times 10^{-11}}{0.1}\right)^{1/2}$

$= (1.2 \times 10^{-10})^{1/2} = 1.1 \times 10^{-5}$

But $\quad [H^+] = \dfrac{K_w}{[OH^-]} = \dfrac{10^{-14}}{1.1 \times 10^{-5}}$

$= 9.09 \times 10^{-10}$ M

$\therefore$ $pH = -\log 9.09 \times 10^{-10}$
$= -[\log 9.09 + \log 10^{-10}]$
$= -[0.9586 - 10]$

$pH = 10 - 0.9586 = \mathbf{9.04}$ **Ans.**

EXAMPLE 187. *The solubility product of PbF$_2$ is 3.2 × 10^{-8}. Calculate the solubility of PbF$_2$ in (i) mol L$^-$ or mol dm^{-3} (ii) in gL$^-$ (at. wt. Pb = 207, F = 19).*

SOLUTION. (*i*) K_{sp} $\therefore$ 3.2×10^{-8} ; (*i*) Solubility of

$PbF_2 = S = ?$ (*ii*) in gL^-

g. mol. wt. of $PbF_2 = 207 + (2 \times 19) = 245$ g.

$$PbF_2 \rightleftharpoons Pb^{2+} + 2F^-$$

Solubility S mol S mol 2S mol

$$K_{sp} = [Pb^{2+}][F^-]^2;$$

$$3.2 \times 10^{-8} = S \times (2S)^2 = 4S^3$$

$$\therefore \quad S = (3.2 \times 10^{-8})^{1/3}.$$

Taking logs, we get :

$$\log S = \log (3.2 \times 10^{-8})^{1/3}$$

$$= \frac{1}{3}[\log 3.2 + \log 10^{-8}]$$

$$= \frac{1}{3}[0.505 - 8] = 2.498$$

$$= -2 - 1 + 1 - 0.498 = \bar{3}.502$$

Taking antilogs of both sides, we get :

$$S = 3.18 \times 10^{-3} \text{ mol L}^-$$

$(\text{or } 3.18 \times 10^{-3} \text{ mol dm}^{-3})$ **Ans.**

(*ii*) Solubility in gL^- = no. of mol × g. mol. wt. of PbF_2

$$= 3.18 \times 10^{-3} \times 245 \text{ g}$$

$= \mathbf{0.779\ g\ L^-}$ **Ans.**

EXAMPLE 188. *At 25°C, the solubility product of Hg_2Cl_2 in water is 3.2×10^{-17} mol^3 dm^{-9}. What is the solubility of Hg_2Cl_2 in water at 25 ° C?*

(a) 1.2×10^{-12} M (b) 3.0×10^{-6} M (c) 2×10^{-6} M

(d) 1.2×10^{-16} M (e) 5.2×10^{-6} M

(MLNR 1985, HP Board 2007, UP 1986, 89 Kerala PMT, 2011)

SOLUTION. $Hg_2Cl_2 \rightleftharpoons Hg_2^{2+} + 2Cl^-$

Concentration 2 x $2x$

$$\therefore \quad K_{sp} = [Hg_2^{2+}][Cl^-]^2; 3.2 \times 10^{-17}$$

$$= x \times (2x)^2 = 4x^3$$

$$\therefore \quad x = \left[\frac{3.2 \times 10^{-17}}{4}\right]^{1/3}$$

$$= (8 \times 10^{-18})^{1/3}$$

$$= [2^3 \times (10^{-6})^3]^{1/3} = 2 \times 10^{-6}.$$

So, the correct answer is (*c*)

EXAMPLE 189. *If the solubility product of $BaSO_4$ at 25°C be 1×10^{-10}, find out the solubility is gL^-. (Mol. wt. = 233.3).*

(UP 1989, H.P. Board 2012)

SOLUTION. $BaSO_4 \rightleftharpoons Ba^{2+} + SO_4^{2-}$

Solubility, mol L^- S S

$$K_{sp} = [Ba^{2+}][SO_4^{2-}];$$

$$10^{-10} = S \times S ; S = (10^{-10})^{1/2}$$

$$= 10^{-5} \text{ mol L}^-$$

Or $S = 10^{-5} \times 233.3$

$= \mathbf{2.333 \times 10^{-3}\ g\ L^-}$ **Ans.**

EXAMPLE 190. *Calculate the solubility of $BaSO_4$ in 0.05 M $BaCl_2$ solution, K_{sp} of $BaSO_4 = 1.1 \times 10^{-10}$.* **(HP Board, 2007)**

SOLUTION. $BaSO_4 \rightleftharpoons Ba^{2+} + SO_4^{2-}$ (ionisation)

Solubility, (mol L^-) S S

$$BaCl_2 \rightleftharpoons Ba^{2+} + 2Cl^-$$

Conc. (mol L^-) 0.05

$$\therefore \quad [Ba^{2+}] = S + 0.05; SO_4^{2-} = S$$

Hence $K_{sp} = [Ba^{2+}][SO_4^{2-}] = (S + 0.05) \times S$

$$1.1 \times 10^{-1} = 0.05\,S$$

$$[\because S << 0.12, K_{sp} = 0.05\,S]$$

$$\therefore \quad S = \frac{1.1 \times 10^{-10}}{0.05}$$

$= \mathbf{2.2 \times 10^{-9}}$ **Ans.**

TYPE. *To predict precipitation or non-precipitation of a compound when two different solutions are mixed.*

EXAMPLE 191. *In 1L solution of AgCl [K_{sp} (AgCl) = 1.6×10^{-10}], 0.1 mol of CuCl [K_{sp} (CuCl)] = 1.0×10^{-6}] is added. The resultant concentration of Ag^+ in the solution is 1.6×10^{-x}. The value of x is :* **(IIT-JEE, 2011)**

SOLUTION. (*i*) Suppose, solubility of AgCl = *a* mol L^-

$$AgCl \rightleftharpoons Ag^+ + Cl^- \quad \ldots(1)$$

a a

(*ii*) Suppose solubility of CuCl = *b* mol L^-

$$CuCl \rightleftharpoons Cu^+ + Cl^-$$

b b ...(2)

$$\therefore \quad K_{sp} \text{ of AgCl} = [Ag^+][Cl^-]$$

$$1.6 \times 10^{-10} = a(a + b) \quad \ldots(3)$$

[from equations (1) and (2)]

Similarly, K_{sp} of CuCl = $[Cu^+][Cl^-]$

$$1.0 \times 10^{-6} = b(a + b) \quad \ldots(4)$$

Solving equations (3) and (4) by dividing, we get :

$$\frac{1.6 \times 10^{-10}}{1.0 \times 10^{-6}} = \frac{a(a+b)}{b(a+b)};$$

$$1.6 \times 10^{-4} = \frac{a}{b}; \; a = b\,(1.6 \times 10^{-4}) \quad \ldots(5)$$

Substituting the value of *a* in equation (3), we get :

$$1.6 \times 10^{-10} = b(1.6 \times 10^{-4})\,[b(1.6 \times 10^{-4}) + b];$$

$$\frac{1.6 \times 10^{-10}}{1.6 \times 10^{-4}} = b^2(1.6 \times 10^{-4}) + b^2$$

or $10^{-6} = b^2\,(1.6 \times 10^{-4} + 1);$

$$b = \sqrt{10^{-6} / (1.6 \times 10^{-4} + 1)}$$

$$= 10^{-3}$$

Substituting the value of $b (= 10^{-3})$ in equation (5), we get:

$$\therefore \quad a = 10^{-3}\,(1.6 \times 10^{-4}) = 1.6 \times 10^{-7}$$

$$\therefore \quad [Ag^+] = a = 1.6 \times 10^{-7} \quad \ldots(6)$$

Thus from 1.6×10^{-x} (given) and 1.6×10^{-7}, the value of ***x* is 7**.

EXAMPLE 192. *Will a precipitate exist at equilibrium if 1/2 litre of a 4×10^{-3}M solution of NaOH and 1/2 litre of 2×10^{-3}M* *solution of $AlCl_3$ are mixed and diluted to 10^3 litre with water at room temperature (K_{sp} for $Al(OH)_3 = 5 \times 10^{-33}$)?*

SOLUTION. $K_{sp} = 5 \times 10^{-33}$; Total volume = 10^3 L

For NaOH $M_1V_1 = M_2V_2$; $4 \times 10^{-3} \times \frac{1}{2} = M_2 \times 10^3$

$$\therefore \quad M_2 = \frac{4 \times 10^{-3} \times \frac{1}{2}}{10^3} = 2 \times 10^{-6}$$

Since $\quad NaOH \rightleftharpoons Na^+ + OH^-$

$\therefore \quad [OH^-] = 2 \times 10^{-6} M$

For $AlCl_3$ $M_3V_3 = M_4V_4$

$$2 \times 10^{-3} \times \frac{1}{2} = M_4 \times 10^3$$

$$\therefore \quad M_4 = \frac{2 \times 10^{-3}}{10^3} \times \frac{1}{2} = 10^{-6} M$$

$$AlCl_3 \rightleftharpoons \underset{10^{-6}M}{Al^{+3}} + 3Cl^-$$

$\therefore \quad [Al^{+3}] = 10^{-6}$ M.

$$AlCl_3 + 3NaOH \longrightarrow Al(OH)_3 + 3NaCl$$

$$Al(OH)_3 \rightleftharpoons Al^{+3} + 3OH^-$$

$$\text{Ionic Product} = [Al^{+3}][OH^-]^3 = (10^{-6})(2 \times 10^{-6})^3 = 8.0 \times 10^{-24}$$

Since ionic product (= 8.0×10^{-24}) is greater than solubility product (= 5×10^{-33}), so precipitation will take place.

EXAMPLE 193. *The solubility of $Ca_3(PO_4)_2$ in water is y mol L^-. Its solubility product is:*

(a) 6 y^4 (b) 36 y^4 (c) 64 y^5 (d) 108 y^5

[WB-JEE, 2011, Karnataka CET, 2011]

SOLUTION. $Ca_3(PO_4)_2$ ionises as:

$$Ca_3(PO_4)_2 \rightleftharpoons 3Ca^{2+} + 2PO_4^{3-}$$

Concentration : $\quad 3y \quad 2y$

$\therefore$ Solubility product,

$$K_{sp} = (3y)^3 (2y)^2 = 27y^3 \times 4y^2 = 108\, y^5.$$

So, the correct answer is (*d*).

EXAMPLE 194. *Decide if a precipitation occurs on mixing together, 10 mL of 0.02M solution of $CaCl_2$ and 5mL of 0.1M solution of K_2CrO_4. (K_{sp} for $CaCrO_4 = 2.3 \times 10^{-2}$).*

(WB Engg. 1993)

SOLUTION. Total volume = 10 + 5 = 15 mL

For $CaCl_2$: $M_1V_1 = M_2V_2$;

$$10 \times 0.02 = M_2 \times 15 \,; M_2 = \frac{10 \times 0.02}{15} = 0.013$$

$\therefore \quad [Ca^{2+}] = 0.013$

$$[\because CaCl_2 \rightleftharpoons Ca^{2+} + 2Cl^-]$$

For K_2CrO_4 :

$$M_3V_3 = M_4V_4$$

$$5 \times 0.1 = M_4 \times 15 \,; M_4 = \frac{5 \times 0.1}{15} = 0.03M$$

$\therefore \quad K_2CrO_4 \rightleftharpoons 2K^+ + CrO_4^{2-}$; $[CrO_4^{2-}] = 0.03M$

$\therefore$ Ionic product of $CaCrO_4$

(*i.e.*, $CaCrO_4 \rightleftharpoons Ca^{2+} + CrO_4^{2-}$)

$$= [Ca^{2+}][CrO_4^{2-}] = 0.013 \times 0.03 = 3.9 \times 10^{-4}$$

Since ionic product (= 3.9×10^{-4}) is less than solubility product (= 2.3×10^{-2}), no precipitation of $CaCrO_4$ will take place.

Type. To calculate percentage error in washing of precipitate with (*i*) water (*ii*) acid solution.

EXAMPLE 195. *The solubility of $BaSO_4$ in water is 2.3×10^{-3} g L^-. Calculate the percentage loss/or error in washing 0.25 g of $BaSO_4$ with (i) 1L H_2O and (ii) N/250 H_2SO_4.*

SOLUTION. (*i*) Solubility of $BaSO_4 = 2.3 \times 10^{-3}$ gL^-.

It means, 0.25 g of $BaSO_4$ must be less from 2.3×10^{-3} g when dissolved in 1L pure water.

$$\text{Hence : } \quad \%\text{ age error} = \frac{2.3 \times 10^{-3}\text{ g}}{0.25\text{ g}} \times 100 = 0.92\%$$

(*ii*) Solubility of $BaSO_4 = 2.3 \times 10^{-3}$ g L^- ;

g. mol. wt. of $BaSO_4$ = 137 + 32 + (4 × 16) = 233 g mol^-

$$\therefore \quad \text{Solubility of } BaSO_4 = \frac{2.3 \times 10^{-3}\text{ g}L^-}{233\text{ g mol}^-} = 9.87 \times 10^{-6}\text{ mol L}^-$$

$\therefore \quad BaSO_4 \rightleftharpoons Ba^{2+} + SO_4^{2-}$

$$\therefore \quad K_{sp}(BaSO_4) = [Ba^{2+}][SO_4^{2-}] = (9.87 \times 10^{-6})(9.87 \times 10^{-6})$$

$$[\because [Ba^{2+}] = [SO_4^{2-}]]$$

$$= 97.4 \times 10^{-12}$$

Suppose solubility of $BaSO_4$ in 1L N/250 H_2SO_4 = xg $= \frac{x}{233}$ g mol.

$$\therefore \quad [Ba^{2+}] = [SO_4^{2-}] = \frac{x}{233}$$

$$H_2SO_4 \rightleftharpoons 2H^+ + SO_4^{2-}$$

$$\text{Molarity} \quad \frac{1}{250} \times \frac{1}{2} = 0.002$$

$$\therefore \quad \text{Total } [SO_4^{2-}] = \frac{x}{233} + 0.002$$

But $\quad K_{sp} = [Ba^{2+}][SO_4^{2-}]$;

$$97.4 \times 10^{-12} = \frac{x}{233}\left(\frac{x}{233} + 0.002\right)$$

$$= \frac{x}{233} \times 0.002$$

[∵ Value of $\frac{x}{233}$ is very small as compared to 0.002, it is rejected]

$$\therefore \quad x = \frac{97.4 \times 10^{-12} \times 233}{0.002}$$

$$= 1.13 \times 10^{-5}$$

$$\therefore \quad \%\text{ age loss} = \frac{1.13 \times 10^{-5}}{0.25} \times 100$$

$$= 4.52 \times 10^{-3} = \mathbf{0.00452\%}$$

EXAMPLE 196. *Calculate the solubility of $BaSO_4$ in (i) pure water and (ii) is 0.1M $BaCl_2$ [K_{sp} ($BaSO_4$) = 1.5×10^{-9}].*

(Roorkee, 1989)

SOLUTION. (*i*) $BaSO_4 \rightleftharpoons Ba^{2+} + SO_4^{2-}$ ...(1)

Solubility in pure water (mol L^{-}) S S S

$$\therefore \quad K_{sp} = [Ba^{2+}]\,[SO_4^{2-}]\,;$$

$$1.5 \times 10^{-9} = S \times S = S^2$$

$$\therefore \quad S = (1.5 \times 10^{-9})^{1/2}$$

$$= (15 \times 10^{-10})^{1/2} = 3.87 \times 10^{-5}.$$

∴ Solubility of $BaSO_4$ in pure water = 3.87×10^{-5} mol L^{-}.

(*ii*) $BaCl_2 \rightleftharpoons Ba^{2+} + 2Cl^-$ ...(2)

Conc. (mol L^{-}) 0.1

∴ From equations (1), and (2),

$$[Ba^{2+}] = S + 0.1\,;\ [SO_4^{2-}] = S$$

$$\therefore \quad K_{sp} = [Ba^{2+}]\,[SO_4^{2-}]\,;$$

$$1.5 \times 10^{-9} = (S + 0.1)\,(S)$$

$$= S^2 + 0.1\,S$$

$$= 0.1S$$

(∵ S being very small, S^2 is neglected).

$$\text{or} \quad S = \frac{1.5 \times 10^{-9}}{0.1}$$

$$= 1.5 \times 10^{-8}\ \text{mol L}^{-}$$

∴ Solubility of $BaSO_4$ in 0.1M $BaCl_2$ = 1.5×10^{-8} mol L^{-}

EXAMPLE 197. *In qualitative analysis, the metals of group 1 can be separated from other ions by precipitating them as chloride salts. A solution initially contains Ag^+ and Pb^{2+} at a concentration of 0.10 M. Aqueous HCl is added to this solution until the Cl^- concentration is 0.10 M. What will be the concentrations of Ag^+ and Pb^{2+} be at equilibrium? (K_{sp} for AgCl = 1.8×10^{-10}; K_{sp} for $PbCl_2$ = 1.7×10^{-5})*

(a) $[Ag^+] = 1.8 \times 10^{-7}$ M, $Pb^{2+} = 1.7 \times 10^{-6}$ M

(b) $[Ag^+] = 1.8 \times 10^{-11}$ M, $[Pb^{2+}] = 8.5 \times 10^{-5}$ M

(c) $[Ag^+] = 1.8 \times 10^{-9}$ M, $[Pb^{2+}] = 1.7 \times 10^{-3}$ M

(d) $[Ag^+] = 1.8 \times 10^{-11}$ M, $[Pb^{2+}] = 1.7 \times 10^{-4}$ M

(AI PMT, 2011)

SOLUTION. (*i*) For AgCl, K_{sp} [AgCl] = $[Ag^+][Cl^-]$

$$[Ag^+] = \frac{K_{sp}[AgCl]}{[Cl^-]} = \frac{1.8 \times 10^{-10}}{10^{-1} = 0.1}$$

$$= \mathbf{1.8 \times 10^{-9}\ M}$$

(*ii*) For $PbCl_2$, K_{sp} $[PbCl_2] = [Pb^{2+}][Cl^-]^2$

$$\therefore \quad [Pb^{2+}] = \frac{K_{sp}[PbCl_2]}{[Cl^-]^2} = \frac{1.7 \times 10^{-5}}{0.1 \times 0.1}$$

$$= 1.7 \times 10^{-3}\ \text{M}$$

So, the correct answer is (*c*).

EXAMPLE 198. *Calculate the minimum volume of water needed to dissolve 1.5 g of calcium sulphate at 298K. $K_{sp}(CaSO_4) = 9.1 \times 10^{-6}$. (at. wt., Ca = 40, S = 32, O = 16)*

SOLUTION. $CaSO_4 \rightleftharpoons Ca^{2+} + SO_4^{2-}$

Solubility (mol L^{-}) S S S

$$K_{sp} = [Ca^{2+}]\,[SO_4^{2-}]\,;$$

$$9.1 \times 10^{-6} = S \times S = S^2$$

$$\therefore \quad S = (9.1 \times 10^{-6})^{1/2}$$

$$= 3.017 \times 10^{-3}\ \text{mol L}^{-}$$

g. mol. wt. of $CaSO_4$ = 40 + 32 + (4 × 16) = 136 g

∴ Solubility in gL^{-} = no. of mol × g. mol. wt. of $CaSO_4$

$$= 3.017 \times 10^{-3} \times 136 = 0.41\ \text{gL}^{-}$$

Volume of water used to dissolve 0.41 g $CaSO_4$ = 1L

∴ Volume of water used to dissolve 1.5 g $CaSO_4$

$$= \frac{1}{0.41} \times 1.5 = \mathbf{3.66\ L} \quad \textbf{Ans.}$$

EXAMPLE 199. *The values of solubility product of AgBr and Ag_2CrO_4 are 5.0×10^{-13} and 1.1×10^{-12} respectively. Calculate the ratio of the molarities of their saturated solutions.*

SOLUTION. (*i*) For AgBr $AgBr \rightleftharpoons Ag^+ + Br^-$

Solubility (mol L^{-}) S S S

$$K_{sp} = [Ag^+]\,[Br^-]\,;$$

$$5.0 \times 10^{-13} = S \times S = S^2$$

$$\therefore \quad S = (5.0 \times 10^{-13})^{1/2}$$

$$= (50 \times 10^{-14})^{1/2}$$

$$= 7.07 \times 10^{-7}\ \text{mol L}^{-}$$

(*ii*) For Ag_2CrO_4. $Ag_2CrO_4 \rightleftharpoons 2Ag^+ + CrO_4^{2-}$

Solubility (mol L^{-}) S $2S$ S

$$K_{sp} = [Ag^+]^2\,[CrO_4^{2-}]\,;$$

$$1.1 \times 10^{-12} = (2S)^2 \times S = 4S^3$$

$$\therefore \quad S = \left(\frac{1.1 \times 10^{-12}}{4}\right)^{1/3}$$

$$= (0.275 \times 10^{-12})^{1/3}.$$

Taking logs, we get :

$$\begin{aligned}
\log S &= \log (0.275 \times 10^{-4})^{1/3} \\
&= \frac{1}{3} \log (0.275 \times 10^{-4}) \\
&= \frac{1}{3} (\log 0.275 + \log 10^{-4}) \\
&= \frac{1}{3} (0.561 - 4) \\
&= -1.52 = -1 - 1 + 1 - 0.52 \\
&= \bar{2}.48 \\
\therefore \quad S &= \text{antilog } \bar{2}.48 = 3.02 \times 10^{-2}
\end{aligned}$$

$$\therefore \quad \text{Ratio of molarities} = \frac{3.02 \times 10^{-2}}{7.07 \times 10^{-7}} = \frac{42715}{1}$$

EXAMPLE 200. *Calculate the solubility product of Ag_2CrO_4 if its solubility at 85°C is 8.0×10^{-5} mol L^{-}.*

SOLUTION. $Ag_2CrO_4 \rightleftharpoons 2Ag^+ + CrO_4^{2-}$

Solubility (mol L^-) $\quad S \quad 2S \quad S$

$$\begin{aligned}
K_{sp} &= [Ag^+]^2 [CrO_4^{2-}] \\
&= [2S]^2 \times S = 4S^3 \\
&= 4 \times (8.0 \times 10^{-5})^3 \\
K_{sp} &= \mathbf{2.048 \times 10^{-12}\ mol^3\ L^{-3}} \quad \textbf{Ans.}
\end{aligned}$$

EXAMPLE 201. 0.*00094 g of AgCl is dissolved in 500 cm^3 water at 298K to form saturated solution. Calculate the solubility product of AgCl (At. wt. Ag = 108, Cl = 35.5).*

SOLUTION. 500 mL solution contain AgCl = 0.00094 g

∴ 1000 mL (= 1L) solution contain

$$AgCl = \frac{0.00094}{500} \times 1000 = 0.00188 \text{ g.}$$

g. mol. wt. of AgCl = 108 + 35.5 = 143.5 g.

143.5 g AgCl ≡ 1 mol AgCl

$$\begin{aligned}
0.00188 \text{ g AgCl} &\equiv \frac{1}{143.5} \times 0.00188 \\
&= 1.31 \times 10^{-5} \text{ mol}
\end{aligned}$$

$$AgCl \rightleftharpoons Ag^+ + Cl^-$$

Solubility (mol L^-) $\quad 1.31 \times 10^{-5} \quad 1.31 \times 10^{-5}$

$$\begin{aligned}
K_{sp} &= [Ag^+][Cl^-] \\
&= (1.31 \times 10^{-5}) \times (1.31 \times 10^{-5}) \\
&= \mathbf{1.71 \times 10^{-10}} \quad \textbf{Ans.}
\end{aligned}$$

EXAMPLE 202. H*ow much KBr should be added to one litre of 0.05M $AgNO_3$ solution just to start the precipitation of AgBr ? K_{sp} (AgBr) = 5×10^{-13}. (at. wt., K = 39, Br = 80)*

SOLUTION. Precipitation will start if ionic product $[Ag^+][Br^-] > K_{sp}$ value.

$$AgNO_3 \rightleftharpoons Ag^+ + NO_3^-$$

Solubility (mol L^-) $\quad 0.05$

$$\begin{aligned}
K_{sp} &= [Ag^+][Br^-] \\
\therefore \quad [Br^-] &= \frac{K_{sp}}{[Ag^+]} = \frac{5 \times 10^{-13}}{0.05} \\
&= 10^{-11} \text{ mol } L^-
\end{aligned}$$

g. mol. wt. of KBr = 39 + 80 = 119 g.

∴ Amount of KBr = $10^{-11} \times 119 = 11.9 \times 10^{-9}$ g L^-

Type. To know *p*H at which precipitation would start.

EXAMPLE 203. *Calculate the pH at which $Mg(OH)_2$ starts precipitating from a solution containing 0.1M Mg^{2+} ions. K_{sp} for $Mg(OH)_2 = 10^{-11}$.* **(Roorkee Entrance 1992)**

SOLUTION. $[Mg^{2+}] = 0.1M$, $K_{sp} = 10^{-11}$

$$Mg(OH)_2 \rightleftharpoons Mg^{2+} + 2OH^-$$

$$0.1 \qquad ?$$

$$K_{sp} = [Mg^{2+}][OH^-]^2 \,;\; 10^{-11} = 0.1 \times [OH^-]^2 \,;$$

$$\therefore \quad [OH^-] = \left(\frac{10^{-11}}{0.1}\right)^{1/2} = 10^{-5} \text{ M}$$

$$\text{But} \quad [H^+] = \frac{K_w}{[OH^-]} = \frac{10^{-14}}{10^{-5}} = 10^{-14+5} = 10^{-9} \text{ M}$$

$$\begin{aligned}
\therefore \quad pH &= -\log [H^+] = -\log 10^{-9} \\
&= -(-9) \log 10 = \mathbf{+9} \quad \textbf{Ans.}
\end{aligned}$$

EXAMPLE 204. *The solubility product of AgCl is 1.8×10^{-10}. Calculate the concentration of Cl^- ions when one drop of $AgNO_3$ solution is added to one litre of N/50 HCl solution.*

SOLUTION. (*a*) $\quad AgCl \rightleftharpoons Ag^+ + Cl^-$

Solubility $\quad x \quad x \quad x$

$$\begin{aligned}
\therefore \quad K_{sp} &= [Ag^+][Cl^-] \,; \\
1.8 \times 10^{-10} &= x \times x \,;\; x^2 = 1.8 \times 10^{-10} \\
\therefore \quad x &= (1.8 \times 10^{-10})^{1/2} = 1.342 \times 10^{-5} \\
\text{Or} \quad [Ag^+] &= x = 1.342 \times 10^{-5}
\end{aligned}$$

∴ $[Ag^+]$ before adding HCl

$$= 1.342 \times 10^{-5} \text{ g ion } L^-$$

(*b*) $[Cl^-]$ ion in 1L of N/50 HCl

$$= 1 \times \frac{1}{50} = 0.02 \text{ g ion } L^-$$

$$AgCl \rightleftharpoons Ag^+ + Cl^-$$

Solubility (g ion L^-) $\quad 0.02$

$$\begin{aligned}
\therefore \quad K_{sp} &= [Ag^+][Cl^-] \,; \\
1.8 \times 10^{-10} &= [Ag^+] \times 0.02 \\
\therefore \quad [Ag^+] \text{ on adding HCl} &= \frac{1.8 \times 10^{-10}}{0.02} \\
&= 9.0 \times 10^{-9} \text{ g ion } L^-
\end{aligned}$$

$$AgNO_3 \rightleftharpoons \underset{\text{Common ion}}{Ag^+} + NO_3^-$$

Since ion added to AgCl is common ion Cl^-, the ionisation of AgCl is suppressed. Hence, concentration of Ag^+ on the addition of one drop of N/50 HCl = 9.0×10^{-9} g ion L^-.

EXAMPLE 205. *If a metal (II) fluoride salt is 60% dissociated in its saturated solution, calculate its solubility product. (At. wt.*

of metal = 40, K_{sp} of metal fluoride = 3.6×10^{-11}).

SOLUTION. $MF_2 \rightleftharpoons M^{2+} + 2F^-$

Solubility mol L^- $\quad x \quad x \quad 2x$

$$\therefore \quad K_{sp} = [M^{2+}][F^-]^2 ;$$

$$3.6 \times 10^{-11} = x \times (2x)^2 = 4x^3$$

$$\therefore \quad x^3 = \frac{3.6 \times 10^{-11}}{4} = 0.9 \times 10^{-11} ;$$

$$x = (0.9 \times 10^{-11})^{1/3}$$

Taking logs of both sides, we get :

$$\log x = \log (0.9 \times 10^{-11})^{1/3}$$

$$= \frac{1}{3} [\log 0.9 + \log 10^{-11}]$$

$$= \frac{1}{3} [-0.046 - 11]$$

$$= -3.682 = -3 - 1 + 1 - 0.682$$

$$= \bar{4}.318$$

Taking antilog of both sides we get :

$$x = 2.08 \times 10^{-4}$$

$\therefore$ Solubility of MF_2 = $x = 2.08 \times 10^{-4}$ mol L^-

g. mol. wt. of MF_2 = $40 + (2 \times 19) = 78$ g.

$\therefore$ Solubility of MF_2 = $2.08 \times 10^{-4} \times 78$

$= 162.24 \times 10^{-4}$ g L^-

Since MF_2 is 60% dissociated. so :

$$\text{solubility of } MF_2 = 162.24 \times 10^{-4} \times \frac{60}{100}$$

$= \mathbf{9.7 \times 10^{-3}}$ **g L^-** **Ans.**

EXAMPLE 206. *A solution of Mn salt is mixed with 0.025 M $(NH_4)_2S$ solution. Calculate the amount of Mn^{2+} that will remain unprecipitated in 15 mL of the solution (K_{sp} of Mn S = 3.0×10^{-22}).*

SOLUTION. $(NH_4)_2S \rightleftharpoons 2NH_4^+ + S^{2-}$

Conc. (mol L^-) $\quad 0.025 \quad 0.025$

$MnS \rightleftharpoons Mn^{2+} + S^{2-}$

Conc. (mol L^-) $\quad 0.025$

$$K_{sp} = [Mn^{2+}][S^{2-}] ;$$

$$3.0 \times 10^{-22} = [Mn^{2+}] \times 0.025$$

$$\therefore \quad [Mn^{2+}] = 1.2 \times 10^{-20} \text{ M.}$$

At. wt. of Mn = 55

$\therefore$ Mn^{2+} ions left in solution = $1.2 \times 10^{-20} \times 55$

$= 6.6 \times 10^{-19}$ g

$\therefore$ 15 mL solution will contain Mn^{2+} ions

$$= \frac{6.6 \times 10^{-19}}{1000} \times 15$$

$$= 9.9 \times 10^{-21} \text{ g}$$

EXAMPLE 207. *Calculate the highest concentration of iodide ions that can exist in equilibrium with 0.02M of Ag^+ ions. [K_{sp} (AgI) = 8.3×10^{-17}].*

SOLUTION. $AgI(s) \xrightleftharpoons{\text{water}} Ag^+(aq) + I^-(aq)$

Conc. mol L^- $\quad 0.02 \quad x$

$$K_{sp} = [Ag^+][I^-] ;$$

$$8.3 \times 10^{-17} = 0.02 \times x$$

$$\therefore \quad x = \frac{8.3 \times 10^{-17}}{0.02} = 4.15 \times 10^{-15}$$

$\therefore$ $[I^-] = x = \mathbf{4.15 \times 10^{-15}}$ **mol L^- Ans.**

EXAMPLE 208. *A saturated solution of a mixture of silver chromate and silver oxalate was prepared. Calculate the [Ag^+] in this solution. (K_{sp} of silver chromate = 1.2×10^{-12} and that of silver oxalate = 6×10^{-12}).*

SOLUTION. Solubility of Ag_2CrO_4 = x mol$^-$; that of $Ag_2C_2O_4$ = y mol L^-

$$Ag_2CrO_4(s) \xrightleftharpoons{\text{water}} 2Ag^+(aq) + CrO_4^{2-}(aq)$$

Solubility $\quad 2x \quad x$

$$Ag_2C_2O_4(s) \xrightleftharpoons{\text{water}} 2Ag^+(aq) + C_2O_4^{2-}(aq)$$

Solubility $\quad 2y \quad y$

Total $[Ag^+] = 2x + 2y$

(*a*) For Ag_2CrO_4 ; $K_{sp} = [Ag^+]^2 [CrO_4^{2-}]$

$$1.2 \times 10^{-12} = (2x + 2y)^2 \times x ;$$

$$(2x + 2y)^2 = \frac{1.2 \times 10^{-12}}{x} \qquad ...(1)$$

For $Ag_2C_2O_4$; $K_{sp} = [Ag^+]^2 [C_2O_4^{2-}]$;

$$6 \times 10^{-12} = (2x + 2y)^2 \times y$$

$$\therefore \quad (2x + 2y)^2 = \frac{6 \times 10^{-12}}{y} \qquad ...(2)$$

In equations (1) and (2), L.H.S = L.H.S., so, R.H.S. = R.H.S.

$$\therefore \quad \frac{1.2 \times 10^{-12}}{x} = \frac{6 \times 10^{-12}}{y} \text{ or } y = \frac{6 \times 10^{-12} x}{1.2 \times 10^{-12}}$$

$$= 5x$$

Substituting the value of $y = 5x$ in equation (1), we get:

$$(2x + 10x)^2 = \frac{1.2 \times 10^{-12}}{x} ;$$

$$144x^3 = 1.2 \times 10^{-12} ;$$

$$x = \left(\frac{1.2 \times 10^{-12}}{144}\right)^{1/3}$$

Taking logs of both sides, we get :

$$\log x = \frac{1}{3} [\log 1.2 + \log 10^{-12} - \log 144]$$

$$= \frac{1}{3} [0.079 - 12 - 2.158]$$

$$= -4.693$$

$$= -4 - 1 + 1 - 0.693 = \bar{5}.307$$

Taking antilog of both sides, we get :

$$\mathbf{x = 2.03 \times 10^{-5}}$$

But $y = 5x$. So, $y = 5 \times 2.03 \times 10^{-5}$

$$= 10.15 \times 10^{-5}$$

$$\therefore \quad [Ag^+(aq)] = 2x + 2y = (2 \times 2.03 \times 10^{-5}) + (2 \times 10.15 \times 10^{-5})$$

$$[Ag^+(aq)] = 4.06 \times 10^{-5} + 20.3 \times 10^{-5}$$

$$= \mathbf{24.36 \times 10^{-5}}$$ **Ans.**

EXAMPLE 209. *A solution has 0.05M Mg^{2+} and 0.05M NH_3. Calculate the concentration of NH_4Cl required to prevent the formation of $Mg(OH)_2$ in the solution. K_{sp} of $Mg(OH)_2$ is 9.0×10^{-12} and ionisation constant of NH_3 is 1.8×10^{-5}.* **(Roorkee Entrance 1993)**

SOLUTION. $NH_3 + H_2O \rightleftharpoons NH_4^+ + OH^-$ ...(1)

$$Mg^{2+} + 2OH^- \rightleftharpoons Mg(OH)_2 \quad ...(2)$$

$$\therefore \quad K_{sp} = [Mg^{2+}]\,[OH^-]^2 ;$$

$$9 \times 10^{-12} = 0.05\,[OH^-]^2$$

Or $$[OH^-] = \left(\frac{9 \times 10^{-12}}{0.05}\right)^{1/2}$$

$$= (180 \times 10^{-12})^{1/2} = 13.4 \times 10^{-6}$$

From equation (1), $$K_b = \frac{[NH_4^+]\,[OH^-]}{[NH_3]}$$

$$\therefore \quad [NH_4]^+ = \frac{K_b\,[NH_3]}{[OH^-]}$$

$$= \frac{1.8 \times 10^{-5} \times 0.05}{13.4 \times 10^{-6}} = 0.067M$$

$$[\because [NH_3] = 0.05M \text{ (given)}]$$

$\therefore$ 0.067M NH_4^+ ions must be produced by 0.067M NH_4Cl ($NH_4Cl \rightleftharpoons NH_4^+ + Cl^-$) to prevent the formation of NH_4^+ ions and hence OH^- ions from NH_3.

EXAMPLE 210. *Saccharin ($K_a = 2 \times 10^{-12}$) is a weak acid represented by the formula HSaC. A 4×10^{-4} mol amount of Saccharin is dissolved in 200 cm^3 water of pH 3. Assuming no change in volume, calculate the concentration of SaC^- ions in the resulting solution at equilibrium.* **(Roorkee, 1994)**

SOLUTION. [HSaC] no. of mol $\times \dfrac{1000}{\text{vol in mL}}$

$$= \frac{4 \times 10^{-4} \times 1000}{200}$$

$$= 2 \times 10^{-3}\text{ M}$$

$$pH = 3 ; -\log[H^+] = 3 ;$$

$$\log[H^+] = -3 ;$$

$$[H^+] = \text{antilog}(-3) = 10^{-3}$$

$$HSaC \rightleftharpoons H^+ + SaC^-$$

Concentration 2×10^{-3} M 10^{-3} M

H^+ ions are common ions. So, due to common ion effect, the dissociation of HSaC is almost negligible.

Hence : $$[H^+] = \frac{[H^+]\,[SaC^-]}{[HSaC]} ;$$

$$2 \times 10^{-12} = \frac{10^{-3}\,[SaC^-]}{2 \times 10^{-3}}$$

$$\therefore \quad [SaC^-] = \frac{2 \times 10^{-12} \times 2 \times 10^{-3}}{10^{-3}}$$

$$= \mathbf{4.0 \times 10^{-12}\ M}$$ **Ans.**

EXAMPLE 211. *Calculate the pH value of a saturated solution of $Mg(OH)_2$. K_{sp} for $Mg(OH)_2 = 10^{-11}$.*

SOLUTION. $Mg(OH)_2 \rightleftharpoons Mg^{2+} + 2OH^-$

Solubility (mol L^-) S S $2S$

$$K_{sp} = [Mg^{2+}]\,[OH^-]^2 = S \times (2S)^2$$

$$= 4S^3 ; 10^{-11} = 4S^3$$

Hence $$S = \left(\frac{10^{-11}}{4}\right)^{1/3} ;$$

$$\log S = \log(0.25 \times 10^{-11})^{1/3}$$

$$= \frac{1}{3}[\log 0.25 + \log 10^{-11}]$$

$$= \frac{1}{3}(-0.6 - 11) = -3.87$$

$$= -3 - 1 + 1 - 0.87 = \bar{4}.13$$

$$\therefore \quad S = \text{antilog}\,\bar{4}.13 = 1.35 \times 10^{-4}\text{ M.}$$

$$\therefore \quad [OH^-] = 2S = 2 \times 1.35 \times 10^{-4}$$

$$= 2.7 \times 10^{-4}$$

$$[H^+] = \frac{K_w}{[OH^-]} = \frac{10^{-14}}{2.7 \times 10^{-4}}$$

$$= 3.7 \times 10^{-11}$$

Hence $$pH = -\log 3.7 \times 10^{-11}$$

$$= -(\log 3.7 + \log 10^{-11})$$

$$= -(0.57 - 11)$$

$$\mathbf{pH = 10.43}$$ **Ans.**

EXAMPLE 212. *If we increase the solubility of $Mg(OH)_2$ by the addition of ammonium ions, then calculate :*

(i) K_c for the reaction,

$$Mg(OH)_2 + 2NH_4^+ \rightleftharpoons Mg^{2+} + 2NH_3 + 2H_2O$$

(ii) Solubility of $Mg(OH)_2$ in a solution containing 0.6M NH_4Cl before $Mg(OH)_2$ has been added. [K_b for $NH_3 = 1.8 \times 10^{-5}$; K_{sp} for $Mg(OH)_2 = 10^{-11}$].

SOLUTION. $Mg(OH)_2 \rightleftharpoons Mg^{2+} + 2OH^-$;

$$\therefore \quad K_{sp} = [Mg^{2+}]\,[OH^-]^2 \quad ...(1)$$

For $NH_4OH \rightleftharpoons NH_4^+ + OH^-$;

$$K_b = \frac{[NH_4^+]\,[OH^-]}{[NH_4OH]}$$

For $Mg(OH)_2 + 2NH_4^+ \rightleftharpoons Mg^{2+} + 2NH_3 + 2H_2O$;

$$K_c = \frac{[Mg^{2+}]\,[NH_3]^2}{[NH_4^+]^2}$$

$$= \frac{[Mg^{2+}]\,[NH_4OH]^2}{[NH_4^+]^2}$$

$$\therefore \quad K_c \times K_b^2 = \frac{[Mg^{2+}]\,[NH_4OH]^2}{[NH_4^+]^2} \times \frac{[NH_4^+]^2\,[OH^-]^2}{[NH_4OH]^2}$$

$$= [Mg^{2+}]\,[OH^-]^2$$

$$K_c \times K_b^2 = K_{sp} \quad \text{[see equation (1)]}$$

$$\therefore \quad K_c = \frac{K_{sp}}{K_b^2} = \frac{10^{-11}}{(1.8 \times 10^{-5})^2} = 0.03$$

Let $Mg(OH)_2$ dissolved in presence of 0.6M NH_4Cl = x mol L^-

$$\therefore \quad Mg(OH)_2 + 2NH_4^+ \rightleftharpoons Mg^{2+} + 2NH_3 + 2H_2O$$

(1) Conc. at start	0.6	0	0
(2) Change by reaction	$-2x$	$\frac{2x}{2} = x$	$2x$
(3) Conc. at equilibrium	$0.6 - 2x$	x	$2x$

$$\therefore \quad K_c = \frac{[Mg^{2+}]\,[NH_3]^2}{[NH_4^+]^2}$$

$$= \frac{x(2x)^2}{(0.6 - 2x)^2} = \frac{4x^3}{0.6}$$

[2x is neglected from the denominator because it is very small as compared to 0.6]

$$\therefore \quad 0.03 = \frac{4x^3}{0.6}\ ;\ x = \left(\frac{0.03 \times 0.36}{4}\right)^{1/3}$$

$$= (2.7 \times 10^{-3})^{1/3}$$

$$\therefore \quad \log x = \log (2.7 \times 10^{-3})^{1/3}$$

$$= \frac{1}{3}\,[\log 2.7 + \log 10^{-3}]$$

$$= \frac{1}{3}\,[0.43 - 3] = -0.86$$

$$= -1 + 1 - 0.86 = \bar{1}.14$$

$$\therefore \quad x = \text{antilog } 1.14 = 1.38 \times 10^{-1}$$

$$= \mathbf{0.138\ M}$$ **Ans.**

EXAMPLE 213. *Determine the number of mol of AgI which may be dissolved in 1.0M CN^- solution. K_{sp} for AgI and K_c for $Ag(CN)_2^-$ are 1.2×10^{-17} M^2 and 7.1×10^{19} M^{2-} respectively.*

(Roorkee Entrance 1998)

SOLUTION. $[CN^-] = 1.0M$

(*i*) $$AgI(s) \underset{}{\overset{H_2O}{\rightleftharpoons}} Ag^+(aq) + I^-(aq) \quad \text{(given)}$$

$$\therefore \quad K_{sp} = [Ag^+(aq)]\,[I^-(aq)]$$

$$= 1.2 \times 10^{-17}\ M^2$$

(*ii*) $Ag^+(aq) + 2CN^-(aq) \rightleftharpoons [Ag(CN)_2]^-$

(formation process)

$$\therefore \quad K_f = \frac{[Ag(CN)_2]^-}{[Ag^+(aq)]\,[CN^-(aq)]^2}$$

$$= 7.1 \times 10^{19}\ M^{2-}$$

But $$K_{eq} = K_{sp} \times K_f$$

$$\therefore \quad K_{eq} = \frac{[Ag^+(aq)]\,[I^-(aq)]\,[Ag(CN)_2]^-}{[Ag^+(aq)]\,[CN^-(aq)]^2}$$

$$= \frac{[I^-(aq)]\,[Ag(CN)_2]^-}{[CN^-(aq)]^2}$$

Or $$K_{eq} = 1.2 \times 10^{-17} \times 7.1 \times 10^{19} = 852$$

Let x = no. of mol of AgI that dissolve in CN^- solution.

Thus : $$AgI(s) + 2CN^- \rightleftharpoons [Ag(CN)_2]^- + I^-$$

(1) n mol at start	1	0	0
(2) Change by reaction	$-2x$	x	x
(3) n mol after reaction	$1 - 2x$	x	x

$$\therefore \quad K_{eq} = \frac{[Ag(CN)_2]^-\,[I^-]}{[CN^-]^2}$$

$$= \frac{x \times x}{(1 - 2x)^2} = \frac{x^2}{(1 - 2x)^2}$$

Or $$852 = \frac{x^2}{(1 - 2x)^2}$$

Taking square root of both sides, we get :

$$(852)^{1/2} = \frac{x}{1 - 2x}\ ;$$

$$29.19 = \frac{x}{1 - 2x}\ ;\ 29.19\,(1 - 2x) = x$$

$$29.19 - 58.38x = x\ ;\ 59.38x = 29.19\ ;$$

$$x = \frac{29.19}{59.38} = 0.49 \text{ mol}$$

∴ no. of mol of AgI which may be dissolved in 1.0M CN^- = **0.49 mol.**

EXAMPLE 214. *A solution contains a mixture of Ag^+(0.1M) and Hg_2^{2+} (0.1M) which are to be separated by relative precipitation. Calculate the maximum concentration of iodide ions at which one of these gets precipitated almost completely. What percentage of metal ion is precpitated? K_{sp} of AgI and Hg_2I_2 are 8.5×10^{-17} and 2.5×10^{-26} respectively.* **(IIT 1984)**

SOLUTION. (*i*) $$AgI(s) \overset{H_2O}{\rightleftharpoons} Ag^+(aq) + I^-(aq)$$

(dissociation)

$$\therefore \quad K_{sp} = [Ag^+(aq)]\,[I^-(aq)]\ ;$$

$$8.5 \times 10^{-17} = [Ag^+(aq)]\,[I^-(aq)]$$

or $$8.5 \times 10^{-17} = 0.1\,[I^-(aq)]\ ;$$

$$\therefore \quad [I^-(aq)] = \frac{8.5 \times 10^{-17}}{0.1} = 8.5 \times 10^{-16}$$

(*ii*) $Hg_2I_2(s) \xrightleftharpoons{H_2O} Hg_2^{2+}(aq) + 2I^-(aq)$ (dissociation)

$$\therefore \qquad K_{sp} = [Hg_2^{2+}(aq)]\,[I^-(aq)]^2\,;$$

$$2.5 \times 10^{-26} = 0.1\,(I^-(aq))^2$$

$$\text{or} \qquad [I^-(aq)] = \left(\frac{2.5 \times 10^{-26}}{0.1}\right)^{1/2}$$

$$= (25 \times 10^{-26})^{1/2} = 5 \times 10^{-13}$$

Since $[I^-(aq)]$ required to precipitate AgI is less ($= 8.5 \times 10^{-16}$) than that of Hg_2I_2 ($= 5 \times 10^{-13}$), AgI gets precipitated first. During the precipitation of AgI, Hg_2I_2 exists is solution and for which maximum concentration of I^- ions is 5×10^{-13} M found above. This concentration of I^- ions exist until Hg_2I_2 gets precipitated.

(*iii*)To find % age of Ag^+ ion precipitated.

To find $[Ag^+(aq)]$ left in solution when

$$[I^-(aq)] = 5 \times 10^{-13}\ \text{M},$$

$$\text{We have} \qquad K_{sp} = [Ag^+(aq)]\,[I^-(aq)]\,;$$

$$8.5 \times 10^{-17} = [Ag^+(aq)] \times 5 \times 10^{-13}$$

$$\therefore \qquad [Ag^+(aq)] = \frac{8.5 \times 10^{-17}}{5 \times 10^{-13}} = 1.7 \times 10^{-4}\ \text{M}.$$

Since 0.1M $Ag^+(aq)$ will leave 1.7×10^{-4} M Ag^+ ions in solution :

$\therefore$ 100 M $Ag^+(aq)$ leave $Ag^+(aq)$ ions in solution

$$= \frac{1.7 \times 10^{-4}}{0.1} \times 100 = 0.17\ \text{M}$$

$\therefore$ % age of Ag^+ ions precipitated

$$= 100 - 0.17 = \mathbf{99.83\ M} \qquad \textbf{Ans.}$$

EXAMPLE 215. *The K_{sp} of $Ag_2C_2O_4$ at 25°C is 1.29×10^{-11} mol^3L^{-3}. A solution of $K_2C_2O_4$ containing 0.152 mol in 500 mL water is shaken at 25°C with excess of Ag_2CO_3 till the equilibrium is reached. $Ag_2CO_3 + K_2C_2O_4 \rightleftharpoons Ag_2C_2O_4 + K_2CO_3$.*

At equilibrium, the solution contains 0.0358 mol of K_2CO_3. Assuming degree of dissociation of $K_2C_2O_4$ and K_2CO_3 to be same, calculate K_{sp} of Ag_2CO_3. **(IIT1991)**

SOLUTION. *Reaction*

(*a*)	$Ag_2CO_3 +$	$K_2C_2O_4 \rightleftharpoons$	$Ag_2C_2O_4 +$	K_2CO_3
(1) n mol at start	Excess	0.152	0	0
(2) Change by reaction		− 0.0358	+ 0.0358	+0.0358
(3) n mol at equilibrium		0.152 − 0.0358 = 0.1162	0.0358	0.0358

(*i*) 500 mL solution contain $K_2C_2O_4$ = 0.1162 M

$\therefore$ 1000 mL solution contain

$$K_2C_2O_4 = \frac{0.1162}{500} \times 1000 = 0.2324\ \text{M}$$

Similarly, $[CO_3^{2-}]$ in 1000 mL

$$= \frac{0.0358 \times 1000}{500} = 0.0716\ \text{M}$$

(*ii*) 500 mL solution contain $K_2C_2O_4$ = 0.152 mol

$\therefore$ 1000 mL solution contain $K_2C_2O_4$

$$= \frac{0.152 \times 1000}{500} = 0.304\ \text{mL}^-$$

(*b*)	$Ag_2C_2O_4 \rightleftharpoons$	$2Ag^+$ +	$C_2O_4^{2-}$
Concentration		2×0.0716	0.304

$$\therefore \qquad \text{Ionic product} = [Ag^+]^2\,[C_2O_4^{2-}]$$

$$= (2 \times 0.0716)^2 \times 0.304$$

$$= 6.23 \times 10^{-3}$$

Since ionic product $[Ag^+]^2\,[C_2O_4^{2-}]$ ($= 6.23 \times 10^{-3}$) is greater than solubility product [$= 1.29 \times 10^{-11}$ (given)], $Ag_2C_2O_4$ will be precipitated.

Since $Ag_2C_2O_4$ is almost precipitated and Ag_2CO_3 is solid, for the precipitation of $Ag_2C_2O_4$.

$$[Ag^+]^2\,[C_2O_4^{2-}] = K_{sp}\,(Ag_2C_2O_4)\,;$$

$$[Ag^+]^2 \times 0.2324 = 1.29 \times 10^{-11}$$

$$\text{or} \qquad [Ag^+] = \left(\frac{0.129 \times 10^{-11}}{0.2324}\right)^{1/2}$$

$$= (56 \times 10^{-12})^{1/2} = 7.48 \times 10^{-6}$$

$$(c) \qquad Ag_2CO_3 \rightleftharpoons 2Ag^+ + CO_3^{2-}$$

$$K_{sp} = (Ag^+)^2\,[CO_3^{\,2-}]$$

$$= (7.48 \times 10^{-6})^2 \times 0.0716$$

$$= \mathbf{4.0 \times 10^{-12}\ mol^3\ L^{-3}} \qquad \textbf{Ans.}$$

EXAMPLE 216. *Given $[Ag(NH_3)_2]^+ \rightleftharpoons Ag^+ + 2NH_3\,;\ K_c = 6.2 \times 10^{-8}$ and K_{sp} of AgCl $= 1.8 \times 10^{-10}$ at 298 K. Calculate the concentration of the complex in 1.0 M aqueous ammonia.*

(IIT, 1998)

SOLUTION. $[Ag(NH_3)_2^+] = ?\ ;\ [NH_3] = 1.0$ M

$$Ag(NH_3)_2^+(aq) \rightleftharpoons Ag^+(aq) + 2NH_3(aq) \quad ...(1)$$

n mol at start		$a + b$	$2a$M = 1M (given)

$$AgCl(s) \xrightleftharpoons{water} Ag^+(aq) + Cl^-(aq) \qquad ...(2)$$

$$a + b \qquad b$$

$[Ag^+] = a + b$ because the solution contains Ag^+ ions due to $Ag(NH_3)_2^+(aq)$ and AgCl(s). In case of simultaneous solubility, Ag^+ ions remain same in solution.

$$\therefore \qquad K_c = \frac{[Ag^+(aq)]\,[NH_3(aq)]^2}{[Ag(NH_3)_2(aq)]^+}$$

$$= \frac{(a+b) \times 1^2}{b}$$

$$\because [Ag(NH_3)_2^+(aq)] = [Cl^-(aq)] = b$$

Also, K_{sp} for equation (2) = $[Ag^+(aq)]\,[Cl^-(aq)]$ $= (a + b) \times b$

$$\text{Hence} \qquad \frac{K_c}{K_{sp}} = \frac{a+b}{b} \times \frac{1}{(a+b) \times b}$$

$$= \frac{1}{b^2} ; \frac{6.2 \times 10^{-8}}{1.8 \times 10^{-10}} = \frac{1}{b^2}$$

Or $b^2 = 29 \times 10^{-4} ; b = 5.38 \times 10^{-2}$

$= 0.538$

Or $[Ag(NH_3)_2^+(aq)] = \mathbf{0.0538}$ **Ans.**

EXAMPLE 217. *For the reaction* $[Ag(CN)_2]^- \rightleftharpoons Ag^+ + 2CN^-$*, the equilibrium constant at 25°C is* 4×10^{-19}*. Calculate the silver ion concentration in a solution which was originally 0.1 molar in KCN and 0.03 molar in* $AgNO_3$*.* **(IIT JEE. 1994)**

SOLUTION. (*a*) $Ag^+ + 2CN^- \rightleftharpoons [Ag(CN)_2^-]$ ...(1)

$[CN^-] = 0.1\ M ; [CN^-]$ used

$= 2\,[CN^-] = 2 \times 0.03 = 0.06$

$\therefore$ $[CN^-]$ left in solution $= 0.1 - 0.06 = 0.04$ M

Also, $[Ag(CN)_2^-]$ formed in solution = 0.03M

Since reaction (1) is reverse of reaction

$[Ag(CN)_2^-] \rightleftharpoons Ag^+ + 2CN^-$, so :

$$K' = \frac{1}{K} = \frac{1}{4.0 \times 10^{-19}}$$

Hence
$$\frac{1}{4.0 \times 10^{-19}} = \frac{[Ag(CN)_2^-]}{[Ag^+][CN^-]^2}$$

$$= \frac{0.03}{[Ag^+] \times (0.04)^2}$$

$$\therefore \quad [Ag^+] = \frac{0.03 \times 4 \times 10^{-19}}{(0.04)^2}$$

$= \mathbf{7.5 \times 10^{-18}\ M}$ **Ans.**

EXAMPLE 218. *A sample of AgCl was treated with 5.0 mL of 1.5 M* Na_2CO_3 *solution to give* Ag_2CO_3*. The remaining solution contained 0.0026 g of* Cl^- *per litre. Calculate the solubility product of AgCl* (K_{sp} *of* $Ag_2CO_3 = 8.2 \times 10^{-12}$). **(IIT 1997)**

SOLUTION. (*i*) *To find* $[Ag^+]$.

$Ag_2CO_3 \rightleftharpoons 2Ag^+ + CO_3^{2-}$

$\therefore$ $K_{sp} = [Ag^+]^2\,[CO_3^{2-}]$;

$$[Ag^+]^2 = \frac{K_{sp}}{[CO_3^{2-}]} = \frac{8.2 \times 10^{-12}}{1.5}$$

$= 5.47 \times 10^{-12}$

$\therefore$ $[Ag^+] = (5.47 \times 10^{-12})^{1/2}$

$= 2.34 \times 10^{-6}$ M

(2) wt. of Cl^- = 0.0026 g ;

g. at. wt. of Cl^- = 35.5 g

$$\therefore \quad [Cl^-] = \frac{\text{wt.}}{\text{g. at. wt}} = \frac{0.0026\ \text{g}}{35.5\ \text{g}}$$

$= 7.32 \times 10^{-5}$

$\therefore$ K_{sp} of AgCl $= [Ag^+]\,[Cl^-]$

$= 2.34 \times 10^{-6} \times 7.32 \times 10^{-5}$

$= \mathbf{1.7 \times 10^{-10}}$ **Ans.**

EXAMPLE 219. *The* K_{sp} *of* $Ca(OH)_2$ *is* 4.42×10^{-5} *at 25°C. A 500 mL of saturated solution of* $Ca(OH)_2$ *is mixed with equal volume of 0.4M NaOH. How much* $Ca(OH)_2$ *in mg is precipitated.* **(IIT 1992)**

SOLUTION. Let s = Solubility of $Ca(OH)_2$

$Ca(OH)_2 \rightleftharpoons Ca^{2+} + 2OH^-$

Solubility s $2s$

$\therefore$ $K_{sp} = [Ca^{2+}]\,[OH^-]^2$;

$4.42 \times 10^{-5} = s \times (2s)^2 = 4s^3$

$$\therefore \quad s = \left(\frac{4.42 \times 10^{-5}}{4}\right)^{1/3}$$

$= (1.105 \times 10^{-5})^{1/3}$

Taking logs of both sides, we get :

$\log s = \log (1.105 \times 10^{-5})^{1/3}$

$= \frac{1}{3}\,[\log 1.105 + \log 10^{-5}]$

$= \frac{1}{3}\,(0.043 - 5) = -1.652$

$\log s = -1 - 1 + 1 - 0.652 = \bar{2}.348.$

Taking antilogs, we get :

$s = \text{antilog}\ \bar{2}.348 = 2.23 \times 10^{-2}$

$= 0.0223$ M

When $Ca(OH)_2$ is mixed with NaOH solution, some Ca^{2+} ions are precipitated.

On mixing (*i*)
$$[Ca^{2+}] = \frac{0.0223\ M \times 500\ mL}{1000\ mL}$$

$= 0.01115$ M

$$[OH^-] = \frac{0.0223\ M \times 2 \times 500}{1000} + \frac{0.4\ M \times 500}{1000}$$

$= 0.2223$ M

$\therefore$ $K_{sp} = [Ca^{2+}\ (\text{left})]\,[OH^-]^2$

$$\therefore \quad Ca^{2+}\ (\text{left}) = \frac{K_{sp}}{[OH^-]^2} = \frac{4.42 \times 10^{-5}}{(0.2223)^2}$$

$= 8.84 \times 10^{-4}$ mol L^-.

$\therefore$ mol of $Ca(OH)_2$ precipitated

$= \text{Total}\ [Ca^{2+}] - [Ca^{2+}\ (\text{left})]$

$= 111.5 \times 10^{-4} - 8.84 \times 10^{-4}$

$= 10^{-4} \times (111.5 - 8.84)$

$= 102.56 \times 10^{-4}$ mol L^-

g. mol. wt. of $Ca(OH)_2 = 40 + 2\,(16 + 1) = 74$ g

$= 74 \times 1000 = 74000$ mg

$\therefore$ wt. of $Ca(OH)_2$ precipitate in 1L solution

$= 102.56 \times 10^{-4} \times 74000$

$= \mathbf{758.9\ mg}$ **Ans.**

EXAMPLE 220. *The solubility of* $Mg(OH)_2$ *in pure water is* 9.57×10^{-3} *g*L^-*. Calculate its solubility in g*L^- *in 0.02M* $Mg(NO_3)_2$*.* **(IIT 1986)**

SOLUTION. g. mol. wt. of $Mg(OH)_2$

$$= 24 + 2\,(16 + 1) = 58 \text{ g mol}^{-}$$

$$\therefore \quad [\text{Mg(OH)}_2] = \frac{9.57 \times 10^{-3}}{58}$$

$$= 1.65 \times 10^{-4} \text{ mol L}^{-}$$

$$\text{Mg(OH)}_2 \rightleftharpoons \text{Mg}^{2+} + 2\text{OH}^-$$

$$\therefore \quad [\text{OH}^-] = \frac{2 \times 9.57 \times 10^{-3}}{58}$$

$$= 3.30 \times 10^{-4} \text{ mol L}^{-}$$

$$\therefore \quad K_{\text{sp}} = [\text{Mg}^{2+}]\,[\text{OH}^-]^2$$

$$= (1.65 \times 10^{-4})\,(3.3 \times 10^{-4})^2$$

$$= 1.797 \times 10^{-11}$$

In presence of $\text{Mg(NO}_3)_2$, let solubility of Mg(OH)_2 = x mol L$^-$

$$\therefore \quad [\text{Mg}^{2+}]\,[\text{OH}^-]^2 = K_{\text{sp}} \textit{ i.e., } 1.797 \times 10^{-11}$$

$$\therefore \quad (0.02 + x)\,(2x)^2 = 1.797 \times 10^{-11}$$

$$[\because \text{Mg(OH)}_2 \rightleftharpoons \text{Mg}^{2+} + 2\text{OH}^-]$$

$$0.08x^2 + 4x^3 = 1.797 \times 10^{-11}$$

or
$$0.08x^2 = 1.797 \times 10^{-11}$$

$$[\because x \text{ is very small, } x^3 \text{ is neglected}]$$

$$\therefore \quad x = \left(\frac{1.797 \times 10^{-11}}{0.08}\right)^{1/2}$$

$$= (2.246 \times 10^{-10})^{1/2}$$

$$\log x = \frac{1}{2} \log 2.246 \times 10^{-10}$$

$$= \frac{1}{2} (\log 2.246 + \log 10^{-10})$$

$$= \frac{1}{2} (0.351 - 10) = -4.824$$

$$= -4 - 1 + 1 - 0.824 = \bar{5}.176$$

$$\therefore \quad x = \text{antilog } \bar{5}.176 \simeq 1.5 \times 10^{-5}$$

$$\therefore \quad \text{Solubility of Mg(OH)}_2 = 1.5 \times 10^{-5} \times \text{mol. wt.}$$

$$= 1.5 \times 10^{-5} \times 58$$

$$= \mathbf{87 \times 10^{-5} \text{ g L}^{-}} \qquad \textbf{Ans.}$$

EXAMPLE 221. *Calculate the solubility of AgCl in 0.2 M solution of sodium chloride. K_{sp} of AgCl = 1.2×10^{-10}.*

(ISC, 2007)

SOLUTION. AgCl ionises as: $\text{AgCl} \rightleftharpoons \text{Ag}^+ + \text{Cl}^-$

Solubility (mol L$^-$) $\quad S \quad S$

NaCl ionises as : $\text{NaCl} \rightleftharpoons \text{Na}^+ + \text{Cl}^-$

Concentration $\quad$ 0.2M $\quad$ 0.2M

$$\therefore \quad [\text{Ag}^+] = S;\ [\text{Cl}^-] = S + 0.2$$

$$= 0.2 \quad \because S <<< 0.2, S + 0.2 \simeq 0.2)$$

Hence
$$K_{\text{sp}} = [\text{Ag}^+]\,[\text{Cl}^-]$$

$$1.2 \times 10^{-10} = S \times 0.2; \quad S = \frac{1.2 \times 10^{-10}}{0.2}$$

$$= 6.0 \times 10^{-10} \text{ mol L}^{-}$$

$$\therefore \quad \text{Solubility of AgCl} = \mathbf{6.0 \times 10^{-10} \text{ mol L}^{-}} \qquad \textbf{Ans.}$$

EXAMPLE 222. *The values of equilibrium constant for the dissociation of H_2S are as follows :*

(*i*) $H_2S \rightleftharpoons H^+ + HS^-$; $Ka_1 = 9.0 \times 10^{-8}$

(*ii*) $HS^- \rightleftharpoons H^+ + S^{-2}$; $Ka_2 = 10^{-12}$

Find the maximum concentration of Zn^{2+} ions in water (at 27°C) that is saturated with H_2S (0.1 M at 27°C) and maintained at pH 3 with HCl. K_{sp} (ZnS) = 4.51×10^{-24}.

SOLUTION. We know, overall dissociation constant, K_a is equal to multiple of dissociation constants of step wise reactions. Thus :

$$K_a = Ka_1 \times Ka_2\,;$$

$$K_a = 9.0 \times 10^{-8} \times 10^{-12} = 9.0 \times 10^{-20}$$

Also,
$$\text{H}_2\text{S} \rightleftharpoons 2\text{H}^+ + \text{S}^{2-};$$

$$\therefore \quad K_a = \frac{[\text{H}^+]^2\,[\text{S}^{2-}]}{[\text{H}_2\text{S}]} \qquad \text{...(1)}$$

Given $\quad pH = 3$; $\therefore\ -\log\,[\text{H}^+] = 3$;

Or $\quad [\text{H}^+] = 10^{-3}$

From equation (1), we have :

$$9.0 \times 10^{-20} \simeq \frac{(10^{-3})^2\,[\text{S}^{2-}]}{0.1}\,;$$

$$[S^{2-}] = \frac{9.0 \times 10^{-20} \times 0.1}{(10^{-3})^2}$$

Or $\quad [\text{S}^{2-}] = 9.0 \times 10^{-15}$

Also, $\quad \text{ZnS} \rightleftharpoons \text{Zn}^{2+} + \text{S}^{2-}$

$$K_{\text{sp}} = [\text{Zn}^{2+}]\,[\text{S}^{2-}]\,;$$

$$[\text{Zn}^{2+}] = \frac{K_{sp}}{[\text{S}^{2-}]} = \frac{4.51 \times 10^{-24}}{9.0 \times 10^{-15}}$$

Or $\quad [\text{Zn}^{2+}] = \mathbf{5.01 \times 10^{-10}\ M} \qquad$ **Ans.**

EXAMPLE 223. *The given nickel sulphide solution contains concentration of Ni^{2+} ions as 0.18×10^{-5} mol L$^-$. Calculate the minimum concentration of S^{2-} ions that could cause the precipitation of nickel sulphide. K_{sp} for nickel sulphide is 1.4×10^{-14}.*

SOLUTION. $\quad \text{NiS} \rightleftharpoons \text{Ni}^{2+} + \text{S}^{2-}$

Conc. (mol L$^-$) $\quad 0.18 \times 10^{-5}$

But $\quad K_{\text{sp}} = [\text{Ni}^{2+}]\,[\text{S}^{2-}]\,;$

$$[\text{S}^{2-}] = \frac{K_{sp}}{[\text{Ni}^{2+}]} = \frac{1.4 \times 10^{-14}}{0.18 \times 10^{-5}}$$

$$= 7.7 \times 10^{-9} \text{ mol L}^{-}.$$

So any value of concentration of S^{2-} ions greater than 7.7×10^{-9} mol L$^-$ will cause NiS to get precipitated.

EXAMPLE 224. *When a lead salt was dissolved in HCl, it was found to ionise up to 90%. It contains H^+ and Pb^{2+} ions respectively as 0.25 M and 0.12 M respectively. The solution is saturated with H_2S. Find the amount of Pb^{2+} ions those could not be precipitated. K_{sp} (H_2S) = 10^{-22} ; K_{sp} (PbS) = 4×10^{-29}.*

SOLUTION. HCl ionises to 90%.

So, $$[H^+] = \frac{0.25 \times 90}{100} = 0.225 \text{ M}$$

(*i*) $$H_2S \rightleftharpoons 2H^+ + S^{2-}$$

∴ $$K_{sp} = [H^+]^2\,[S^{2-}]\,;$$

$$[S^{2-}] = \frac{K_{sp}}{[H^+]^2} = \frac{10^{-22}}{(0.225)^2}$$

$$= 1.98 \times 10^{-21} \text{ M}$$

(*ii*) $$PbS \rightleftharpoons Pb^{2+} + S^{2-}$$

∴ $$K_{sp} = [Pb^{2+}]\,[S^{2-}]\,;$$

$$[Pb^{2+}] = \frac{K_{sp}}{[S^{2-}]} = \frac{4 \times 10^{-29}}{1.98 \times 10^{-21}}$$

$$= \mathbf{2 \times 10^{-8}\ mol\ L^{-}}$$ **Ans.**

EXAMPLE 225. *The dissociation constant of carbonic acid is 4.31×10^{-7} and the solubility product of silver carbonate is 6.15×10^{-12}. What will happen to the concentration of hydrogen ions in a 0.01 molar carbonic acid solution and also its pH if 10^{-3} mol of silver nitrate powder is added to the solution ? Why ?* **(ISC 1996)**

SOLUTION. (*a*) $Ag_2CO_3 \rightleftharpoons 2Ag^+ + CO_3^{2-}; [Ag^+] = 10^{-3}$ M

$$K_{sp} = [Ag^+]^2\,[CO_3^{2-}]\,;$$

$$[CO_3^{2-}] = \frac{K_{sp}}{[Ag^+]^2} = \frac{6.15 \times 10^{-12}}{(10^{-3})^2}$$

$$= 6.15 \times 10^{-6}$$

(*b*) $$H_2CO_3 \rightleftharpoons 2H^+ + CO_3^{2-}\,;\ [H_2CO_3] = 0.01$$

∴ $$K = \frac{[H^+]^2\,[CO_3^{2-}]}{[H_2CO_3]}\,;$$

$$[H^+]^2 = \frac{K \times [H_2CO_3]}{[CO_3^{2-}]}$$

$$= \frac{4.31 \times 10^{-7} \times 0.01}{6.15 \times 10^{-6}}$$

∴ $$[H^+]^2 = 7 \times 10^{-4}\,;\ \therefore\ [H^+] = (7 \times 10^{-4})^{1/2}$$

$$= 2.646 \times 10^{-2}$$

∴ $$pH = -\log\,[H^+]$$

$$= -\log\,(2.646 \times 10^{-2})$$

$$= -(\log 2.646 + \log 10^{-2})$$

$$pH = -(0.422 - 2) = \mathbf{1.578}$$ **Ans.**

Type. Calculation of simultaneous solubilities of salts when their solubility products are given and when their K_{sp} values are very near to each other.

EXAMPLE 226. *Calculate the simultaneous solubility of AgSCN and AgBr. The solubility products of AgSCN and AgBr are 1.0×10^{-12} and 5.0×10^{-13} respectively.* **(MLNR 1995)**

SOLUTION. Data of K_{sp} values indicate that the solubilities of AgSCN and AgBr are very close to each other. So, the contribution of AgBr (less soluble) can not be ignored.

(*a*) For $AgSCN \rightleftharpoons Ag^+ + SCN^-\,;\ K_{sp} = [Ag^+]\,[SCN^-]\,;$

$$10^{-12} = [Ag^+]\,[SCN^-] \qquad ...(i)$$

(*b*) For $AgBr \rightleftharpoons Ag^+ + Br^-\,;\ K_{sp} = [Ag^+]\,[Br^-]\,;$

$$5 \times 10^{-13} = [Ag^+]\,[Br^-] \qquad ...(ii)$$

Dividing (*i*) by (*ii*), we get

$$\frac{[SCN^-]}{[Br^-]} = \frac{10^{-12}}{5 \times 10^{-13}} = 2 \qquad ...(iii)$$

Because of the need to balance electrical charge :

$$[SCN^-] + [Br^-] = [Ag^+] \qquad ...(iv)$$

Dividing (*iv*) by $[Br^-]$, we get :

$$\frac{[SCN^-]}{[Br^-]} + \frac{[Br^-]}{[Br^-]} = \frac{[Ag^+]}{[Br^-]}$$

Or $$2 + 1 = \frac{[Ag^+]}{[Br^-]}$$

$$\left\{\because \text{from } (iii)\,\frac{[SCN^-]}{[Br^-]} = 2\right\}$$

∴ $$[Ag^+] = 3[Br^-] \qquad ...(v)$$

Substituting the value of $[Ag^+]$ from (*v*) in (*ii*), we get :

$$5 \times 10^{-13} = 3[Br^-]\,[Br^-] = 3[Br^-]^2;$$

$$[Br^-] = \left(\frac{5 \times 10^{-13}}{3}\right)^{1/2}$$

∴ $$[Br^-] = (16.7 \times 10^{-14})^{1/2} = 4.1 \times 10^{-7}$$

(*c*) Substituting the value of $[Br^-]$ in (*iii*) and (*iv*), we get :

$$[SCN^-] + [Br^-] = 3[Br^-]\,;\ [SCN^-] = 2[Br^-]$$

$$= 2 \times 4.1 \times 10^{-7} = 8.2 \times 10^{-7}$$

$$5 \times 10^{-13} = [Ag^+] \times 4.1 \times 10^{-7}$$

∴ $$[Ag^+] = \frac{5 \times 10^{-13}}{4.1 \times 10^{-7}} = 1.2 \times 10^{-6}$$

∴ Solubility of AgSCN $= 8.2 \times 10^{-7}$ mol L^-

Solubility of AgBr $= 4.1 \times 10^{-7}$ mol L^-

EXAMPLE 227. *Assuming no hydrolysis of F^- ions, what will the $[F^-]$ in a solution saturated with respect to both SrF_2 and MgF_2. (K_{sp} of $SrF_2 = 2.8 \times 10^{-9}$ and K_{sp} of $MgF_2 = 6.5 \times 10^{-9}$)*

SOLUTION. $$\frac{K_{sp}\,[MgF_2]}{K_{sp}\,[SrF_2]} = \frac{[Mg^{2+}]\,[F^-]^2}{[Sr^{2+}]\,[F^-]^2} = \frac{[Mg^{2+}]}{[Sr^{2+}]}$$

Or $$\frac{6.5 \times 10^{-9}}{2.8 \times 10^{-9}} = \frac{[Mg^{2+}]}{[Sr^{2+}]}\,;\ 2.32 = \frac{[Mg^{2+}]}{[Sr^{2+}]}$$

∴ $$[Mg^{2+}] = 2.32\,[Sr^{2+}]$$

(*a*) $$SrF_2 \rightleftharpoons Sr^{2+} + 2F^-$$

Solubility (mol L^-) $\qquad S \qquad 2S$

$$MgF_2 \rightleftharpoons Mg^{2+} \quad + \quad 2F^-$$

Solubility (mol L^-) $\qquad 2.32S \qquad 2 \times 2.32S = 4.64S$

$$\begin{aligned} K_{sp}\,[\mathrm{SrF_2}] &= [\mathrm{Sr^{2+}}]\,[\mathrm{F^-}]^2 \\ 2.8 \times 10^{-9} &= S\,(2S + 4.64S)^2 \\ &= S\,(6.64S)^2 = 44.09S^3 \\ \therefore \quad S &= \left(\frac{2.8 \times 10^{-9}}{44.09}\right)^{1/3}; \\ \log S &= \log\,(0.063 \times 10^{-9})^{1/3} \\ &= \frac{1}{3}\,(\log 0.063 + \log 10^{-9}) \\ &= \frac{1}{3}\,(-1.2 - 9) = -3.4 \\ &= -3 - 1 + 1 - 0.4 = \bar{4}.6 \\ \therefore \quad S &= \text{antilog}\ \bar{4}.6 = 3.98 \times 10^{-4} \\ \therefore \quad [\mathrm{F^-}] &= 6.64S = 6.64 \times 3.98 \times 10^{-4} \\ &= \mathbf{2.64 \times 10^{-3}\ M} \qquad \textbf{Ans.} \end{aligned}$$

EXAMPLE 228. *You are provided with a 250 mL of a sample of hard water containing 0.0025 mol of* $CaCl_2$ *and a sample of 0.001 M* H_2SO_4*. Will this sample of* H_2SO_4 *precipitate out* Ca^{2+} *ions?* K_{sp} *of* $CaSO_4$ *in water at 298K is* 2.4×10^{-5}.

SOLUTION. (*a*) $[\mathrm{Ca^{2+}}] = \dfrac{\text{no. of mol} \times 1000}{\text{Volume of solution in mL}}$

$$= \frac{0.0025 \times 1000}{250} = 0.01\ \text{mol L}^{-}$$

(*b*) Let equal volumes of hard water and H_2SO_4 are used. As a result, the volume becomes double.

Hence : $[\mathrm{Ca^{2+}}]$ in solution after adding $H_2SO_4 = \dfrac{0.01}{2}$

$$= 0.005\ \text{mol L}^{-}$$

In $\qquad H_2SO_4 \rightleftharpoons 2H^+ + SO_4^{2-}$

Conc. mol L^- $\quad$ 0.001M $\qquad$ 0.001M

$\therefore$ $[SO_4^{2-}]$ in solution obtained after mixing

$$= \frac{0.001}{2} = 0.0005\ \text{M}$$

Hence $\quad$ *ionic product* $= [\mathrm{Ca^{2+}}]\,[\mathrm{SO_4^{2-}}]$

$$= 0.005 \times 0.0005 = 2.5 \times 10^{-6}$$

But Solubility product,

$$K_{sp} = 2.4 \times 10^{-5}\ \text{(given)}$$

Since ionic product is less than solubility product, no precipitation of $CaSO_4$ would take place.

EXAMPLE 229. *A sample of hard water contains 0.005 mol of* $CaCl_2$ *per litre. What is the maximum concentration of* Na_2SO_4 *which must be added for removing* Ca^{2+} *ions from this sample.* K_{sp} *for* $CaSO_4$ *is* 2.4×10^{-5} *at 25°C.* **(Rookee, 1986)**

SOLUTION. $\qquad CaCl_2 \xrightleftharpoons{H_2O} Ca^{2+}(aq) + 2Cl^-(aq)$

Conc. (mol L^-) $\quad$ 0.005

$$Na_2SO_4 \xrightleftharpoons{H_2O} 2Na^+(aq) + SO_4^{2-}(aq)$$

Conc. (mol L^-) $\quad x$

$$\therefore \quad K_{sp} = [\mathrm{Ca^{2+}(aq)}]\,[\mathrm{SO_4^{2-}(aq)}];$$

$$\begin{aligned} 2.4 \times 10^{-5} &= 0.005 \times x \\ \therefore \quad x = [\mathrm{SO_4^{2-}(aq)}] &= \frac{2.4 \times 10^{-5}}{0.005} \\ &= 4.8 \times 10^{-3}\ \text{mol L}^{-} \end{aligned}$$

So, maximum concentration of Na_2SO_4 to be added

$$= \mathbf{4.8 \times 10^{-3}\ mol\ L^{-}} \qquad \textbf{Ans.}$$

EXAMPLE 230. *Powdered silver nitrate solid is added bit by bit to a solution which is 0.001 M each of KCl, KBr and KI,*

(*i*) *Find the concentration of* Ag^+ *ions needed to initiate the precipitation of AgCl, AgBr and AgI.*

(*ii*) *Find the percentage of* I^- *ions precipitated before the precipitation of AgBr.*

(*iii*) *Find the % age of* I^- *ions precipitated before the precipitation of* Cl^- *ions. (*K_{sp} *AgCl, AgBr and AgI =* 1.8×10^{-10} 3.3×10^{-13} *and* 1.5×10^{-16} $mol^2\ L^{-2}$ *respectively).*

SOLUTION. (*i*) KCl, KBr and KI are strong electrolytes.

Hence, $\qquad [\mathrm{Cl^-}] = [\mathrm{Br^-}] = [\mathrm{I^-}] = 0.001$ M

(*a*) For $\quad AgCl \rightleftharpoons Ag^+ + Cl^-, K_{sp}\,[AgCl] = [Ag^+]\,[Cl^-]$.

Thus : $\qquad [\mathrm{Ag^+}] = \dfrac{K_{sp}}{[\mathrm{Cl^-}]} = \dfrac{1.8 \times 10^{-10}}{0.001}$

$$= \mathbf{1.8 \times 10^{-7}\ M} \qquad \textbf{Ans.}$$

(*b*) For $\quad AgBr \rightleftharpoons Ag^+ + Br^-, K_{sp}\,[AgBr] = [Ag^+]\,[Br^-]$.

Thus : $\qquad [\mathrm{Ag^+}] = \dfrac{K_{sp}}{[\mathrm{Br^-}]} = \dfrac{3.3 \times 10^{-13}}{0.001}$

$$= \mathbf{3.3 \times 10^{-10}\ M} \qquad \textbf{Ans.}$$

(*c*) For $\quad AgI \rightleftharpoons Ag^+ + I^-, K_{sp}\,[AgI] = [Ag^+]\,[I^-]$.

Hence : $\qquad [\mathrm{Ag^+}] = \dfrac{K_{sp}}{[\mathrm{I^-}]} = \dfrac{1.5 \times 10^{-16}}{0.001}$

$$= \mathbf{1.5 \times 10^{-13}\ M} \qquad \textbf{Ans.}$$

(*ii*) When AgBr just begins to precipitate, then, $[Ag^+] = 3.3 \times 10^{-10}$ (found above). At this stage, $[I^-]$ can be calculated as follows :

$$K_{sp}\,[AgI] = [Ag^+]\,[I^-]\,;\ [I^-] = \frac{K_{sp}\,[AgI]}{[Ag^+]}$$

$$= \frac{1.5 \times 10^{-16}}{3.3 \times 10^{-10}} = \mathbf{4.5 \times 10^{-7}}$$

$\therefore$ Percentage of I^- ions, not precipitated

$$= \frac{4.5 \times 10^{-7}}{0.001} \times 100 = 0.045\%$$

$\therefore$ Percentage of I^- ions precipitated before AgBr begins to precipitate

$$= 100 - 0.045 = \mathbf{99.955\%}\ \textbf{Ans.}$$

(*iii*) When AgCl just begins to precipitate, then, $[Ag^+] = 1.8 \times 10^{-7}$ (found above). At this stage, $[I^-]$ can be calculated as follows :

$$K_{sp}\,[AgI] = [Ag^+]\,[I^-]\,;$$

$$[I^-] = \frac{K_{sp}\,[AgI]}{[Ag^+]} = \frac{1.5 \times 10^{-16}}{1.8 \times 10^{-7}}$$

$$= \mathbf{8.3 \times 10^{-10}\ M}$$

∴ Percentage of I^- ions, not precipitated

$$= \frac{8.3 \times 10^{-10}}{0.001} \times 100$$

$$= 8.3 \times 10^{-5}\ M = 0.000083$$

∴ Percentage of I^- ions precipitated before AgCl begins to precipitate

$$= 100 - 0.000083$$

$$= \mathbf{99.999917\ \%} \qquad \textbf{Ans.}$$

EXAMPLE 231. *A given sample of hard water contains 0.03 mol L$^-$ of $CaCl_2$. Predict which of the following solutions of Na_2SO_4 will cause precipitation with hard water if equal volumes of both solutions are mixed? [K_{sp} ($CaSO_4$) = 2.4×10^{-4}].*

(*i*) *0.01 M* (*ii*) *0.008 M*

SOLUTION. Let volume of hard water ($CaCl_2$) = x mL; Volume of Na_2SO_4 = x mL

∴ Total volume of solution = $x + x = 2x$ mL

First case.

Hard water ($CaCl_2$) (before mixing) — Hard water (after mixing)

$$M_1V_2 = M_2V_2;\ 0.03 \times x = M_2 \times 2x$$

$$\therefore \quad M_2 = \frac{0.03 \times x}{2x} = 0.015\,;$$

$$[Ca^{2+}] = 0.015$$

Na_2SO_4 (before mixing) — Na_2SO_4 (after mixing)

$$M_1V_1 = M_2V_2;\ 0.01 \times x = M_2 \times 2x$$

$$\therefore \quad M_2 = \frac{0.01 \times x}{2x} = 0.005\,;$$

$$[SO_4^{2-}] = 0.005\ M$$

$$\therefore \quad \text{Ionic product} = [Ca^{2+}]\,[SO_4^{2-}] = 0.015 \times 0.005$$

$$= 7.5 \times 10^{-5}$$

Given $K_{sp} = 2.4 \times 10^{-4}$. Since ionic product is less than solubility product, **no precipitation of $CaSO_4$ will take place.**

Second Case.

Hard water ($CaCl_2$) (before mixing) — Hard water (after mixing)

$$M_1V_1 = M_2V_2;\ 0.08 \times x = M_2 \times 2x$$

$$\therefore \quad M_2 = \frac{0.08x}{2x} = 0.04 = [SO_4^{2-}]$$

$$\therefore \quad \text{Ionic product} = [Ca^{2+}]\,[SO_4^{2-}] = 0.015 \times 0.04$$

$$= 0.0060 = 6.0 \times 10^{-3}$$

Given $K_{sp} = 2.4 \times 10^{-4}$. Since ionic product is greater than solubility product, precipitation of $CaSO_4$ will take place.

EXAMPLE 232. *A few determinations of the solubility of AgCl in water at 298 K were recorded. Their average value is 0.00194 g L$^-$. Using this value, calculate the K_{sp} value of AgCl.*

SOLUTION. $AgCl(s) \rightleftharpoons Ag^+ + Cl^-\,;\ K_{sp} = [Ag^+]\,[Cl^-]$

Conc. $\qquad\qquad C \quad C$

$$\therefore \quad [Ag^+] = [Cl^-] = C\,;$$

$$\text{g. mol. wt. of AgCl} = 108 + 35.5 = 143.5\ \text{g mol}^-$$

$$= 1.435 \times 10^2\ \text{g mol}^-;$$

$$\text{wt. of AgCl} = 0.00194 = 1.94 \times 10^{-3}\ \text{g mol}^-$$

$$C = \frac{\text{wt. of AgCl}}{\text{g. mol. wt. of AgCl}}$$

$$= \frac{1.94 \times 10^{-3}}{1.435 \times 10^{+2}}$$

$$= 1.35 \times 10^{-5}\ \text{mol L}^-$$

$$\therefore \quad K_{sp} = [Ag^+]\,[Cl^-]$$

$$= (1.35 \times 10^{-5}) \times 1.35 \times 10^{-5}$$

$$= 1.82 \times 10^{-10}$$

$$K_{sp} = -\log Ks$$

$$= -(\log 1.82 + \log 10^{-10})$$

$$= -(0.26 - 10) = \mathbf{9.74} \qquad \textbf{Ans.}$$

EXAMPLE 233. *Silver nitrate is slowly added to a 0.02 M solution. of $NaC_2H_3O_2$.*

(*a*) *Will a precipitate of $AgC_2H_3O_2$ form when concentration of Ag^+ ions = 0.5×10^{-2}M?*

(*b*) *Calculate the approximate [Ag^+] at which precipitate starts forming. [K_{sp} ($AgC_2H_3O_2$)] = 2×10^{-3}.*

SOLUTION. (*a*) $NaC_2H_3O_2$ or CH_3COONa (sodium acetate) ionises as :

$CH_3COONa \rightleftharpoons CH_3COO^- + Na^+\ ;\ [CH_3COO^-] = 0.02M$

$AgC_2H_3O_2$ Or

$CH_3COOAg \rightleftharpoons CH_3COO^- + Ag^+\,;\ [Ag^+] = 0.5 \times 10^{-2}$

∴ Ionic product, $[Ag^+]\,[CH_3COO^-]$

$$= (0.5 \times 10^{-2}) \times (0.02) = 1 \times 10^{-4}$$

$$K_{sp} = 2 \times 10^{-3}.$$

Since ionic product is less than K_{sp}, no precipitate of silver acetate is formed.

(*b*) Since, we need precipitate to begin with, ionic product $[Ag^+]\,[CH_3COO^-]$ should be equal to K_{sp} *i.e.*, equilibrium value. So, we have :

$$K_{sp} = [Ag^+]\,[CH_3COO^-]\,;$$

$$2 \times 10^{-3} = [Ag^+] \times 0.02$$

$$\therefore \quad [Ag^+] = \frac{2 \times 10^{-3}}{0.02} = 0.1\ M$$

Hence the minimum concentration of Ag^+ ion at which precipitate of silver acetate would start forming is 0.1 M. At concentration, higher than 0.1M, precipitation of silver acetate will occur and sufficient amount of CH_3COO^- ions will be removed from solution to maintain K_{sp} value.

Example 234. *A litre of a solution contains 0.1 mol of Ag^+ and 0.1 mol of Hg_2^{2+} ion/litre. Calculate the concentration of I^- ions at which, one of them gets precipitated most completely. What %age of that metal ion is precipitated?*

$(K_{sp}\,(AgI) = 8.5 \times 10^{-17} = ;\ K_{sp}\,(Hg_2I_2) = 2.5 \times 10^{-26})$

(IIT, 1984)

Solution. (*a*) $AgI \rightleftharpoons Ag^+ + I^-\ ;\ K_{sp} = [Ag^+]\,[I^-]\ ;$

$$[I^-] = \frac{K_{sp}}{[Ag^+]}$$

$$\therefore \quad [I^-] = \frac{8.5 \times 10^{-17}}{0.1}$$

$$= 8.5 \times 10^{-16} \text{ g ion L}^-$$

(*b*) $Hg_2I_2 \rightleftharpoons Hg_2^{+2} + 2I^-\ ;\ K_{sp} = [Hg_2^{2+}]\,[I^-]^2\ ;$

$$[I^-] = \left[\frac{K_{sp}}{[Hg_2^{2+}]}\right]^{1/2} \left(\frac{2.5 \times 10^{-26}}{0.1}\right)^{1/2}$$

$$\therefore \quad [I^-] = 5 \times 10^{-13} \text{ g ion L}^-.$$

Since ionic product of AgI is greater than its K_{sp}, so AgI will precipitate first.

(*c*) When $[I^-] = 5 \times 10^{-13}$ g ion L^-, *i.e.*, when Hg_2I_2 starts precipitating out, then :

$$[Ag^+] = \frac{K_{sp}\,[AgI]}{[I^-]\text{ of }Hg_2I_2} = \frac{8.5 \times 10^{-17}}{5 \times 10^{-13}}$$

$$= 1.7 \times 10^{-4}\text{M}$$

$$\therefore \quad \%\text{ age of } Ag^+ \text{ left} = \frac{1.7 \times 10^{-4}}{0.1} \times 100 = 0.17$$

% age of Ag^+ precipitated

= 100 – 0.17 = 99.83 Ans.

Example 235. *The given solution of one litre contains 0.01 mol $Cr_2O_7^{2-}$ ions and 0.01 mol Cl^- ions. If Ag^+ ions are added dropwise, will AgCl or $Ag_2Cr_2O_7$ be precipitated first? $[K_{sp}\,(AgCl) = 1.56 \times 10^{-10}\ ;\ K_{sp}\,(Ag_2Cr_2O_7) = 2.83 \times 10^{-11}]$.*

Solution. (*a*) $AgCl \rightleftharpoons Ag^+ + Cl^-\ ;\ K_{sp} = [Ag^+]\,[Cl^-]\ ;$

$$[Ag^+] = \frac{K_{sp}}{[Cl^-]}$$

$$\text{Or} \quad [Ag^+] = \frac{1.56 \times 10^{-10}}{0.01} = 1.56 \times 10^{-8} \text{ g ion L}^-$$

(*b*) $Ag_2Cr_2O_7 \rightleftharpoons 2Ag^+ + Cr_2O_7^{2-}\ ;\ K_{sp} = [Ag^+]^2\ Cr_2O_7^{2-}]\ ;$

$$[Ag^+] = \left[\frac{K_{sp}}{[Cr_2O_7]^{2-}}\right]^{1/2}$$

$$\textbf{Or} \quad [Ag^+] = \left(\frac{2.83 \times 10^{-11}}{0.01}\right)^{1/2}$$

$$= (0.283 \times 10^{-8})^{1/2} = 0.53 \times 10^{-4} \text{ g ion L}^-.$$

Since the concentration of Ag^+ ions required to precipitate as AgCl (= 1.56×10^{-8} g ion L^-) is much less than that of Ag^+ ion in $Ag_2Cr_2O_7$ (= 0.53×10^{-4}), AgCl will precipitate first.

Example 236. *The pH of a 0.1M solution of monoprotic weak acid is 4.0. Calculate its $[H^+]$ and K_a value.*

Solution. Let HA = monoprotic acid ; α = degree of dissociation.

	HA ⇌	H^+	+ A^-
(1) n mol at start	0.1	0	0
(2) Change by reaction	–0.1α	0.1α	0.1α
(3) n mol after ionisation	0.1 – 0.1α	0.1α	0.1α

$$pH = 4\ ;\ -\log\,[H^+] = 4$$

$$\log\,[H^+] = -4$$

$$\therefore \quad [H^+] = \mathbf{10^{-4}} \qquad \textbf{Ans.}$$

$$\therefore \quad \text{But} \quad [H^+] = 0.1\alpha\ ;\ 10^{-4} = 0.1\alpha\ ;$$

$$\alpha = \frac{10^{-4}}{0.1} = 10^{-3}$$

$$\text{But} \quad K_a = \frac{[H^+]\,[A^-]}{[HA]} = \frac{0.1\alpha \times 0.1\alpha}{0.1 - 0.1\alpha}$$

$$= \frac{0.1 \times 0.1\alpha^2}{0.1(1-\alpha)} = 0.1\alpha^2$$

[∵ α is very small as compared to 1, so, α is rejected from the denominator]

$$\text{Or} \quad K_a = 0.1 \times (10^{-3})^2 = \mathbf{10^{-7}} \qquad \textbf{Ans.}$$

Example 237. *Find the value of equilibrium constant at 298K for the disproportionation of 3 mol HNO_2 to yield NO (g) and aqueous NO_3^-. The standard potential for the reduction of HNO_2 to NO is 0.99 V ; that for the reduction of NO_3^- to HNO_2 is 0.94V. Also, comment on the stability of HNO_2.*

Solution. The given reduction reactions are as follows.

(*i*) $HNO_2 + H_3O^+ + e^- \rightarrow NO + 2H_2O\ ;\ E° = +\,0.99V$

(*ii*) $NO_3^- + 3H_3O^+ + 2e^- \rightarrow HNO_2 + 4H_2O\ ;\ E° = +\,0.94V.$

In order to get the required equation,

$3HNO_2 \rightarrow 2NO + NO_3^- + H_3O^+;\ E° = ?$

we have 2 × Equation (*i*) – Eqation (*ii*). Thus

$2HNO_2 + 2H_3O^+ + 2e^- - NO_3^- \rightarrow 2NO + 4H_2O$

$\quad - 3H_3O^+ - 2e^- \qquad\qquad - HNO_2 - 4H_2O$

$E° = +\,0.099V - 0.94\text{ V} = +\,0.05V$

$$\text{Or} \quad 3HNO_2 \rightarrow 2NO + NO_3^- + H_3O^+\ ;$$

$$E° = +\,0.05V$$

$$\text{But} \quad E°nF = 2.303RT/\log K$$

$$\text{where} \quad n = \text{no. of electrons} = 2\ ;$$

$$R = 8.31\ JK^-$$

$$\text{Or} \quad \log K = \frac{2.303\,RT}{E^{\circ}\,nF}$$

$$= \frac{2.303 \times 8.31\text{ J K}^- \times 298\text{ K}}{0.05\text{ V} \times 2\text{ F} \times 96500\text{ CF}}$$

$$= 0.59$$

$$\text{Or} \quad K = \text{antilog } 0.59 = 3.89$$

The value of *K* being very small, HNO_2 is not very stable and decomposes on standing.

EXAMPLE 238. *The pH of hydrogen electrode is made 10. What will be its electrode potential?*

SOLUTION. $pH = \frac{E_{cell}}{0.0591}$; $E_{cell} = 0.0591 \times 10 = 0.591$

EXAMPLE 239. *An ammonia solution gives the following values of equivalent conductivity at different dilutions.*

V (in litre)	8	16	32	64	∞
g $(\text{ohm}^{-}\ \text{cm}^2\ (\text{equiv})^{-}$	3.2	4.45	6.62	8.9	2.37

From the above data, calculate the ionisation constant of ammonia.

SOLUTION. Let α = degree of ionisation ; K = ionisation constant = ?

Expt. no	Volume (V)	$\alpha = \frac{\alpha/\lambda_V}{\lambda_\infty}$	$K = \frac{\alpha^2}{(1-\alpha)V}$
(*i*)	8	$\frac{3.2}{237} = 0.0135$	$\frac{(0.0135)^2}{(1-0.0135)8} = 2.31 \times 10^{-5}$
(*ii*)	16	$\frac{4.45}{237} = 0.0188$	$\frac{(0.0188)^2}{(1-0.0188)16} = \frac{(0.0188)^2}{0.9812 \times 16}$ $= 2.25 \times 10^{-5}$
(*iii*)	32	$\frac{6.62}{237} = 0.0279$	$\frac{(0.0279)^2}{(1-0.0279)32} = \frac{(0.0279)^2}{0.9721 \times 32}$ $= 2.5 \times 10^{-5}$
(*iv*)	64	$\frac{8.9}{2.37} = 0.0375$	$\frac{(0.0375)^2}{(1-0.0375) \times 64} = \frac{(0.0375)^2}{0.9625 \times 64}$ $= 2.28 \times 10^{-5}$

$$\therefore \text{ Average value of } K = \frac{10^{-5}(2.31 + 2.25 + 2.5 + 2.28)}{4}$$

$$= \mathbf{2.34 \times 10^{-5}} \qquad \textbf{Ans.}$$

24.12 MISCELLANEOUS EXAMPLES

EXAMPLE 240. *What is the conjugate acid of* HS^-*?*

SOLUTION. Since conjugate acid and conjugate base pair differ by H^+, so the conjugate acid of HS^- will be H_2S.

EXAMPLE 241. *Aniline,* $C_6H_5NH_2$ *is a weak organic base in aqueous solutions. Suggest a solvent in which this compound would become a strong base.*

SOLUTION. The needed solvent should be such which has appreciably stronger acid properties than water. One such solvent is liquid acetic acid.

EXAMPLE 242. *At 298K, the self-ionisation constant,* $K = [HCOO^-]\,[HCOOH_2^+]$ *is* 10^{-6}*. Calculate the percentage of formic acid molecules in pure formic acid (HCOOH) that can be converted to formate ion,* $HCOO^-$*. (density of formic acid* $= 1.22\ g\ cm^{-3}$*).*

SOLUTION. wt. of formic acid = 1.22 g ;

g. mol. wt. of HCOOH = 1 + 12 + (2 × 16) + 1 = 46 g ; $1L = 10^{-3}\ cm^3$.

$\therefore$ no. of mol L^- of HCOOH

$$= \frac{1.22\ g}{cm^3} \times \frac{10^3\ cm^3}{L} \times \frac{1\ mol\ HCOOH}{46\ g\ HCOOH}$$

$$= 26.5\ mol\ L^-$$

Also $2HCOOH \rightleftharpoons HCOO^- + HCOOH_2^+ ; K = 10^{-6}$

Conc. mol L^- $\qquad x \qquad x$

$$\therefore \quad K = [HCOO^-]\,[HCOOH_2^+] ;$$

$$10^{-6} = x^2 ;$$

$$x = (10^{-6})^{1/2} = 10^{-3}$$

$$\therefore [HCOO^-] = 10^{-3}\ M$$

Hence percent dissociated to formate ion

$$= \frac{10^{-3}}{26.5} \times 100 = \mathbf{0.0038} \qquad \textbf{Ans.}$$

EXAMPLE 243. *At –50°C the ionic product of weakly ionised* NH_3 *is given as* $K = [NH_2^-]\,[NH_4^+] = 10^{-30}$*. Calculate the number of amide ions that are present per* mm^3 *of pure liquid ammonia.*

SOLUTION. $2NH_3 \rightleftharpoons NH_2^- + NH_4^+ ; K = 10^{-30}$

Conc. (mol L^-) $\qquad x \qquad x$

$$\therefore \quad K = [NH_2^-]\,[NH_4^+] ;\ 10^{-30} = x \times x ;$$

$$x = (10^{-30})^{1/2} = 10^{-15}$$

$\therefore$ no. of amide ions (NH_2^-) present per mm^3 of pure liquid ammonia

$$= \frac{10^{-15} mol}{L} \times \frac{1L}{10^6 mm^3} \times \frac{6.02 \times 10^{23}}{mol}$$

$$= 602 \text{ ions per } mm^3.$$

EXAMPLE 244. *Calculate the pH of* 7.0×10^{-8} *M acetic acid. Also calculate the concentration of unionised acetic acid.* $(K_a = 1.8 \times 10^{-5})$*.*

SOLUTION. (*a*) Given concentration of acetic acid indicates that the acid solution is very dilute. So, complete ionisation of acid can be considered but ionisation of water must be considered. Thus, we have :

$H_2O \rightleftharpoons H^+ + OH^- ; CH_3COOH \rightleftharpoons CH_3COO^- + H^+$

Conc. (mol L^-)

$x \qquad x \qquad\qquad 7 \times 10^{-8} \quad 7 \times 10^{-8}$

$$\therefore \quad [H^+] = x + (7 \times 10^{-8}) ; [OH^-] = x.$$

Thus : $\quad K_w = [H^+]\,[OH^-] ;$

$$10^{-14} = [x + (7 \times 10^{-8})] \times x ;$$

$$x^2 + (7 \times 10^{-8})x - 10^{-14} = 0$$

$$\therefore \quad x = \frac{-7 \times 10^{-8} + [(7 \times 10^{-8})^2 - 4(1 \times -10)^{-14}]^{1/2}}{2}$$

$$= \frac{-7 \times 10^{-8} + (49 \times 10^{-16} + 4 \times -10^{-14})^{1/2}}{2}$$

$$x = \frac{-7 \times 10^{-8} + [10^{-16}(49 + 400)^{1/2}}{2}$$

$$= \frac{-7\times10^{-8} + 21.2\times10^{-8}}{2} = 7.1\times10^{-8}$$

∵ for $ax^2 + bx + c = 0$

$$x = \frac{-b\pm\sqrt{b^2-4ac}}{2a}$$

$$\therefore \quad [OH^-] = 7.1\times10^{-8}; [H^+] = x + 7\times10^{-8}$$
$$= 7.1\times10^{-8} + 7\times10^{-8}$$
$$= 14.1\times10^{-8}$$

$$\therefore \quad pH = -\log 14.1\times10^{-8}$$
$$= -(\log 14.1 + \log 10^{-8})$$
$$= -1.15 + 8 = \mathbf{6.85} \qquad \textbf{Ans.}$$

(*b*) From electroneutrality, we have :

$$[CH_3COO^-] + [OH^-] = [H^+]; [CH_3COO^-]$$
$$= [H^+] - [OH^-]$$
$$= 14.1\times10^{-8} - 7.1\times10^{-8}$$
$$= 7\times10^{-8}$$

$$CH_3COOH + H_2O \rightleftharpoons CH_3COO^- + H_3O^+$$

$$K_a = \frac{[CH_3COO^-][H_3O^+]}{[CH_3COOH]};$$

$$1.8\times10^{-5} = \frac{7\times10^{-8}\times14.1\times10^{-8}}{[CH_3COOH]}$$

$$\therefore \quad [CH_3COOH] = \frac{7\times10^{-8}\times14.1\times10^{-8}}{1.8\times10^{-5}}$$
$$= \mathbf{5.5\times10^{-10}\,M} \qquad \textbf{Ans.}$$

EXAMPLE 245. *Calculate the pH of a 1.0L of 0.1M pyridine solution to which 0.12 mol of pyridinium chloride, $C_5H_5NH^+Cl^-$ has been added, assuming no change is volume. (K_b of pyridine = 1.52×10^{-9}).*

SOLUTION. $C_5H_5N + H_2O \rightleftharpoons C_5H_5NH^+ + OH^-$

Conc. at start 0.1

Conc. at equilibrium $0.1 - x$ $\quad x \quad x$

$C_5H_5NH^+Cl^- \rightleftharpoons C_5H_5NH^+ + Cl^-$

Conc. at start 0.12

$$\therefore \quad [C_5H_5NH^+] = x + 0.12 = 0.12;$$
$$[OH^-] = x; [C_5H_5N] = 0.1 - x = 0.1$$

$$\therefore \quad K_b = \frac{[C_5H_5NH^+][OH^-]}{[C_5H_5N]};$$

$$1.52\times10^{-9} = \frac{0.12x}{0.1};$$

$$x = \frac{1.52\times10^{-9}\times0.1}{0.12}$$

Or $\quad x = 1.27\times10^{-9};$
$\quad [OH^-] = 1.27\times10^{-9};$

$$[H^+] = \frac{K_w}{[OH^-]} = \frac{10^{-14}}{1.27\times10^{-9}}$$
$$= 7.8\times10^{-6}$$

$$\therefore \quad pH = -\log 7.8\times10^{-6}$$
$$= -(\log 7.8 + \log 10^{-6})$$
$$= -(0.89 - 6) = \mathbf{5.11} \qquad \textbf{Ans.}$$

EXAMPLE 246. *Calculate the pH and extent of hydrolysis of 0.1M NH_4NO_3 solution. ($K_b = 1.8\times10^{-5}$).*

SOLUTION. $NH_4^+ + H_2O \rightleftharpoons NH_3 + H_3O^+$
$[\because NH_4NO_3 \rightleftharpoons NH_4^+ + NO_3^-]$

Conc. at start 0.1

Conc. at equilibrium $0.1 - x$ $\quad x \quad x$
$\simeq 0.1$

$$\therefore \quad K_h = \frac{[NH_3][H_3O^+]}{[NH_4^+]} = \frac{x\times x}{0.1} \quad ...(1)$$

$$\text{But} \quad K_h = \frac{K_w}{K_b} = \frac{10^{-14}}{1.8\times10^{-5}} \quad ...(2)$$

From (1) and (2), we get :

$$\frac{x^2}{0.1} = \frac{10^{-14}}{1.8\times10^{-5}};$$

$$x = \left(\frac{10^{-14}}{1.8\times10^{-5}}\times0.1\right)^{1/2}$$

$$x = (0.55\times10^{-10})^{1/2}$$
$$= 0.74\times10^{-5} = [H_3O^+]$$

$$\therefore \quad pH = -\log[H_3O^+]$$
$$= -\log 0.74\times10^{-5}$$
$$= -(\log 0.74 + \log 10^{-5})$$
$$pH = -(-0.13 - 5) = \mathbf{5.13} \qquad \textbf{Ans.}$$

$$\%\ \text{hydrolysed} = \frac{\text{Amount hydrolysed}}{\text{Total amount}}\times100$$
$$= \frac{0.74\times10^{-5}}{0.1}\times100$$
$$= 0.0074\%$$

EXAMPLE 247. *A 10^{-2} M solution of $PuO_2(NO_3)_2$ has pH 3.8. Calculate the hydrolysis constant K_h for PuO_2^{2+} and K_b for PuO_2OH^+. ($K_w = 10^{-14}$).*

SOLUTION. $PuO_2^{2+} + H_2O \rightleftharpoons PuO_2(OH)^+ + H_3O^+$

Conc. $\quad 10^{-2} \qquad x$

$$K_h = \frac{[PuO_2(OH)^+][H_3O^+]}{[PuO_2^{2+}]};$$

$$pH = 3.8; -\log[H_3O^+] = 3.8$$

$$\therefore \quad \log[H_3O^+] = -3.8 = -3 - 1 + 1 - 0.8 = \bar{4}.2.$$

Or $\quad [H_3O^+] = \text{antilog}\ \bar{4}.2$

Or $\quad [H_3O^+] = 1.58\times10^{-4} = x = [PuO_2(OH)^+].$

$$\text{Hence} \quad K_h = \frac{1.58\times10^{-4}\times1.58\times10^{-4}}{10^{-2}}$$
$$= \mathbf{2.5\times10^{-6}} \qquad \textbf{Ans.}$$

Also, $K_b = \frac{K_w}{K_h} = \frac{10^{-14}}{2.5 \times 10^{-6}} = \mathbf{4 \times 10^{-9}}$ **Ans.**

Type. Polyprotic acids and bases

Example 248. *Calculate the $[SO_4^{2-}]$ in 0.12M H_2SO_4. K for $(HSO_4^-) = 1.02 \times 10^{-2}$.*

Solution. (*i*) $H_2SO_4 \rightleftharpoons H^+ + HSO_4^-$ (complete ionisation)

(*ii*) $HSO_4^- + H_2O \rightleftharpoons SO_4^{2-} + H_3O^+$ (hydrolysis)

For reaction (*ii*) $K = \frac{[SO_4^{2-}][H_3O^+]}{[HSO_4^-]}$;

$$1.02 \times 10^{-2} = \frac{[SO_4^{2-}][H_3O^+]}{[HSO_4^-]} \qquad ...(1)$$

For reaction (*ii*) at equilibrium,

$$[SO_4^{2-}] = x\ ;\ [H_3O^+] = 0.12 + x$$

$[HSO_4^-] = 0.12 - x$. Hence, from reaction (1), we have :

$$1.02 \times 10^{-2} = \frac{x\,(0.12 + x)}{0.12 - x}\ ;$$

$$0.0102(0.12 - x) = x^2 + 0.12x$$

$$0.0012 - 0.0102x = x^2 + 0.12x\ ;$$

$$x^2 + 0.13x - 0.0012 = 0$$

$\because$ for $a\,x^2 + bx + c = 0$,

$$x = \frac{-b \pm (b^2 - 4ac)^{1/2}}{2a}$$

$$\therefore \quad x = \frac{-\,0.13 + [(0.13)^2 + (4 \times 0.0012)]^{1/2}}{2}$$

$$= \frac{-\,0.13 + 0.147}{2} = 8.5 \times 10^{-3}$$

$\therefore$ $[SO_4^{2-}] = \mathbf{8.5 \times 10^{-3}}$ **Ans.**

Example 249. *Calculate the pH of a solution containing 0.12M HCO_3^- and 0.16M CO_3^{-2}. $(K = (HCO_3^-) = 4.7 \times 10^{-11})$*

Solution. $HCO_3^- \rightleftharpoons H^+ + CO_3^{2-}$

Conc. 0.12M 0.16M

$$\therefore \quad K = \frac{[H^+][CO_3^{2-}]}{[HCO_3^-]}\ ;$$

$$4.7 \times 10^{-11} = \frac{[H^+] \times 0.16}{0.12}$$

$$\therefore \quad [H^+] = \frac{4.7 \times 10^{-11} \times 0.12}{0.16} = 3.50 \times 10^{-11}.$$

Hence : $pH = -\log[H^+] = -\log(3.5 \times 10^{-11})$

$= -(\log 3.5 + \log 10^{-11}) = -(0.54 - 11)$

$pH = \mathbf{10.46}$ **Ans.**

Example 250. *What will be the $[H_3PO_4]$ and $[OH^-]$ of a solution prepared by dissolving 0.12 mol of $[NH_4]_3PO_4$ in sufficient water to make one litre solution? K_1, K_2 and K_3 which refer to the ionisation constants for H_3PO_4 are 7.1×10^{-3}, 6.3×10^{-8} and 4.5×10^{-13} respectively.*

Solution. PO_4^{3-} hydrolyses in three steps.

(*i*) $PO_4^{3-} + H_2O \rightleftharpoons HPO_4^{2-} + OH^-$;

$$K = \frac{K_w}{K_3} = \frac{10^{-14}}{4.5 \times 10^{-13}} = 0.022$$

(*ii*) $HPO_4^{2-} + H_2O \rightleftharpoons H_2PO_4^- + OH^-$;

$$K' = \frac{K_w}{K_2} = \frac{10^{-14}}{6.3 \times 10^{-8}}$$

$$= 1.6 \times 10^{-7}$$

(*iii*) $H_2PO_4^- + H_2O \rightleftharpoons H_3PO_4 + OH^-$;

$$K'' = \frac{K_w}{K_1} = \frac{10^{-14}}{7.1 \times 10^{-3}}$$

$$= 1.4 \times 10^{-12}$$

(*a*) Out of all the above reactions, reaction (*i*) is used to calculate $[OH^-]$ because OH^- ions from this reaction suppress the ionisation of second and third steps due to common ion effect.

$$\therefore \quad K = \frac{[HPO_4^{2-}][OH^-]}{[PO_4^{3-}]}\ ;$$

$$0.022 = \frac{x \times x}{0.12 - x}\ ;\ x^2 = 0.022\,(0.12 - x)$$

$$x^2 + 0.022x - 0.00264 = 0;$$

$$\left[\begin{array}{l}\because \text{for } ax^2 + bx + c = 0 \\ x = \dfrac{-b \pm (b^2 - 4ac)^{1/2}}{2a}\end{array}\right]$$

$$x = \frac{-\,0.022 + [(0.022)^2 - (4 \times 1 \times -\,0.00264)]^{1/2}}{2}$$

$$x = \frac{-\,0.022 + (0.000484 + 0.1056)^{1/2}}{2}$$

$$= \frac{-\,0.022 + 0.105}{2} = 0.0415\ M$$

Or $[OH^-] = 0.0415$ M

(*b*) Concentration of H_3PO_4 is calculated with the help of K' and K''values.

Thus : $K' = \frac{[H_2PO_4^-][OH^-]}{[HPO_4^{2-}]}$;

$$1.6 \times 10^{-12} = \frac{[H_2PO_4^-] \times x}{x}\ ;$$

$$[H_2PO_4^-] = 1.6 \times 10^{-7}$$

$$K'' = \frac{[H_3PO_4][OH^-]}{[H_2PO_4^-]}\ ;$$

$$1.4 \times 10^{-12} = \frac{[H_3PO_4] \times x}{x} ;$$

$$[H_3PO_4] = \mathbf{1.4 \times 10^{-12}\ M} \qquad \textbf{Ans.}$$

Example 251. *Calculate the concentration of sulphide ions in a solution that is 0.045 M H_2S and 0.01M HCl. K_1 and K_2 for H_2S are 10^{-7} and 10^{-14} respectively.*

Solution. HCl is a strong acid and ionises completely. So, it suppresses the ionisation of both H_2S and HS^-. So, in case of HCl, $[H_3O^+] = 0.01M$.

(*i*) $H_2S \rightleftharpoons H^+ + HS^-$;

$$K_1 = \frac{[H^+][HS^-]}{[H_2S]} ;$$

$$10^{-7} = \frac{0.01\,[HS^-]}{0.045}$$

$$\therefore \quad [HS^-] = \frac{10^{-7} \times 0.045}{0.01}$$

$$= \mathbf{4.5 \times 10^{-7}\ M} \qquad \textbf{Ans.}$$

(*ii*) $HS^- \rightleftharpoons H^+ + S^{2-}$;

$$K_2 = \frac{[H^+][S^{2-}]}{[HS^-]} ;$$

$$10^{-14} = \frac{0.01\,[S^{2-}]}{4.5 \times 10^{-7}}$$

$$\therefore \quad [S^{2-}] = \frac{4.5 \times 10^{-7} \times 10^{-14}}{0.01}$$

$$= \mathbf{4.5 \times 10^{-19}\ M} \qquad \textbf{Ans.}$$

Example 252. *Calculate the $[H^+]$ of 0.1M H_2S solution. K_1 and K_2 for H_2S are 10^{-7} and 10^{-14} respectively.*

Solution. (*a*) $H_2S \rightleftharpoons H^+ + HS^-$ (primary ionisation)

	H_2S	H^+	HS^-
Conc.	0.1		
Conc. at equilibrium	$0.1 - x$ $\simeq 0.1$	x	x

$$\therefore \quad K_1 = \frac{[H^+][HS^-]}{[H_2S]} ; 10^{-7} = \frac{x \times x}{0.1} ;$$

$$x = (10^{-7} \times 0.1)^{1/2} = 10^{-4}$$

$$\therefore \quad [H^+] = [HS^-] = 10^{-4}$$

(*b*) $HS^- \rightleftharpoons H^+ + S^{2-}$ (second ionisation)

	HS^-	H^+	S^{2-}
Conc.	10^{-4}		
Conc. at equilibrium	10^{-4}	10^{-4}	

$$K_2 = \frac{[H^+][S^{2-}]}{[HS^-]} ;$$

$$10^{-14} = \frac{10^{-4}\,[S^{2-}]}{10^{-4}} ; [S^{2-}] = 10^{-14}$$

As calculated from first ionisation, the second ionisation is so limited that it does not appreciably lower $[H^+]$ or $[HS^-]$. In general, the [conjugate base] resulting from the second ionisation is numerically equal to K_2 whenever the extent of second ionisation is less than 5%.

Example 253. *Calculate the $[CO_3^{2-}]$ in a 0.001M Na_2CO_3 solution after the hydrolysis reactions have come to equilibrium. $K_2 = 4.7 \times 10^{-11}$.*

Solution. $CO_3^{2-} + H_2O \rightleftharpoons HCO_3^- + OH^-$

Conc. at equilibrium $0.1 - x$ $\quad x \quad x$

Note: First hydrolysis supresses the second

$$\therefore \quad K_h = \frac{[HCO_3^-][OH^-]}{[CO_3^{2-}]} ;$$

$$K_h = \frac{x \times x}{0.001 - x} \qquad ...(1)$$

Also, $$K_h = \frac{K_w}{K_2} = \frac{10^{-14}}{4.7 \times 10^{-11}}$$

$$= 2.1 \times 10^{-4} \qquad ...(2)$$

From (1) and (2) we get :

$$\frac{x^2}{0.001 - x} = 2.1 \times 10^{-4}$$

$$x^2 = 2.1 \times 10^{-4}(0.001 - x) ;$$

$$x^2 + 2.1 \times 10^{-4}x - 2.1 \times 10^{-7} = 0$$

$$\textbf{Or } x = \frac{-2.1 \times 10^{-4} + [(2.1 \times 10^{-4})^2 - (4 \times 1 \times -2.1 \times 10^{-7})]}{2}$$

$$\textbf{Or } x = \frac{-2.1 \times 10^{-4} + [4.41 \times 10^{-8} + 8.4 \times 10^{-7}]^{1/2}}{2}$$

$$= \frac{-2.1 \times 10^{-4} + [10^{-8}(4.41 + 8.4 \times 10)]^{1/2}}{2}$$

$$= \frac{-2.1 \times 10^{-4} + 9.4 \times 10^{-4}}{2}$$

$\because$ for $ax^2 + bx + c = 0$

$$x = \frac{-b \pm (b^2 - 4ac)^{1/2}}{2a}$$

$$x = 3.65 \times 10^{-4} = [OH^-]$$

$$\therefore [CO_3^{2-}] = 0.001 - x = 0.001 - 3.65 \times 10^{-4}$$

$$= \mathbf{0.000635} \qquad \textbf{Ans.}$$

Example 254. *The pH of blood is 7.4. Assuming that the buffer in blood is CO_2, HCO_3^- and CO_3^{2-}, calculate the ratio of conjugate base to acid necessary to maintain blood at its proper pH. Also, write the effect of rapid forced breathing on the blood pH. ($K_1 = 4.5 \times 10^{-7}$).*

Solution. $pH = 7.4 ; -\log[H^+] = 7.4 ; \log[H^+] = -7.4 = -7 - 1 + 1 - 0.4 = \bar{8}.6$

$$\therefore \quad [H^+] = \text{antilog}.\bar{8}.6 = 3.98 \times 10^{-8} = [H_3O^+]$$

$$CO_2 + 2H_2O \rightleftharpoons H_3O^+ + HCO_3^-$$

$$K_1 = \frac{[H_3O^+][HCO_3^-]}{[CO_2]};$$

$$4.5 \times 10^{-7} = \frac{3.98 \times 10^{-8}\,[HCO_3^-]}{[CO_2]}$$

$$\therefore \quad \frac{[HCO_3^-]}{[CO_2]} = \frac{4.5 \times 10^{-7}}{3.98 \times 10^{-8}} = \mathbf{11.3}$$

Rapid breathing would lower $[CO_2]$. It will shift the equilibrium and pH also to some extent. Some dizziness may take place.

EXAMPLE 255. *Calculate the pH of 0.01 M NaHCO$_3$. $K_1 = 4.5 \times 10^{-7}$; $K_2 = 4.7 \times 10^{-11}$.*

SOLUTION. Reaction. (*i*) $HCO_3^- \rightleftharpoons H^+ + CO_3^{2-}$ (Ionisation, acidic solution, $K_2 = 4.7 \times 10^{-11}$)

(*ii*) $HCO_3^- + H_2O \rightleftharpoons H_2CO_3 + OH^-$ (hydrolysis, basic solution, $K_1 = 4.5 \times 10^{-7}$)

$$\text{Hydrolysis constant, } K_h = \frac{K_w}{K_1} = \frac{10^{-14}}{4.5 \times 10^{-7}} = 2.2 \times 10^{-8}$$

It may be noted that K_h for reaction (*ii*) is related to K_1 because both hydrolysis and K_1 equilibrium involve H_2CO_3 and HCO_3^-. Since equilibrium constant for reaction (*ii*) is greater than that of reaction (*i*), the pH is definite to exceed 7. We assume that after self neutralisation, both H^+ and OH^- will be very small. Thus, there will be no appreciable effect on the *ionic charge balance.* Since the cationic charge remains at 0.01M, the $[Na^+]$, regardless of the acid and base equilibria, electrical neutrality can be preserved only by maintaining a fixed total anionic charge among the various carbonate species. In other words, for every negative charge removed by converting HCO_3^- to H_2CO_3, another charge must be created by converting HCO_3^- to CO_3^{2-}. As a result, following conditions are observed.

$$[CO_3^{2-}] = [H_2CO_3] = x;$$

$$[HCO_3^-] = 0.01 - 2x \approx 0.01$$

$$\therefore \quad K_2 = \frac{[H^+][CO_3^{2-}]}{[HCO_3^-]};$$

$$4.7 \times 10^{-11} = \frac{H^+ \times x}{0.01} \qquad ...(iii)$$

$$K_h = \frac{[H_2CO_3][OH^-]}{[HCO_3^-]};$$

$$2.2 \times 10^{-8} = \frac{x \times [OH^-]}{0.01} \qquad ...(iv)$$

Multiply (*iii*) and (*iv*), we get :

$$4.7 \times 10^{-11} \times 2.2 \times 10^{-8} = \frac{[H^+]x \times x[OH^-]}{0.01 \times 0.01}$$

$$= \frac{[H^+][OH^-]x^2}{10^{-4}};$$

$$1.034 \times 10^{-18} = \frac{10^{-14}x^2}{10^{-4}}$$

$$[\because [H^+][OH^-] = K_w = 10^{-14}]$$

$$\therefore \quad x = \left(\frac{1.034 \times 10^{-18} \times 10^{-4}}{10^{-14}}\right)^{1/2}$$

$$= (1.034 \times 10^{-8})^{1/2}$$

$$= 1.02 \times 10^{-4}$$

From equation (*iii*), we have :

$$4.7 \times 10^{-11} = \frac{[H^+]x}{0.01};$$

$$[H^+] = \frac{4.7 \times 10^{-11} \times 0.01}{x}$$

$$= \frac{4.7 \times 10^{-11} \times 0.01}{1.02 \times 10^{-4}}$$

Or $[H^+] = 4.6 \times 10^{-9}$

$$\therefore \quad pH = -\log[H^+] = -\log(4.6 \times 10^{-9})$$

$$= -(\log 4.6 + \log 10^{-9})$$

$$pH = -(0.66 - 9) = \mathbf{8.34} \qquad \textbf{Ans.}$$

EXAMPLE 256. *Calculate the percent hydrolysis in a 10^{-2}M KCN solution. ($K_a = 6.2 \times 10^{-10}$)*

SOLUTION. Reaction. $CN^- + H_2O \rightleftharpoons HCN + OH^-$

Conc. at equilibrium 10^{-2} x x

$= 0.01M$

(hydrolysis ; $KCN \rightleftharpoons K^+ + CN^-$)

$$K_h = \frac{[HCN][OH^-]}{[CN^-]} = \frac{x \times x}{0.01} \qquad ...(1)$$

$$K_h = \frac{K_w}{K_a} = \frac{10^{-14}}{6.2 \times 10^{-10}}$$

$$= 1.6 \times 10^{-5} \qquad ...(2)$$

From (1) and (2), we have :

$$\frac{x^2}{0.01} = 1.6 \times 10^{-5};$$

$$x = (1.6 \times 10^{-5} \times 0.01)^{1/2}$$

Or $x = (16 \times 10^{-8})^{1/2} = 4 \times 10^{-4}$

$$\therefore \quad \%\ \text{Hydrolysis} = \frac{4 \times 10^{-4}}{0.01} \times 100 = \mathbf{4.0\%} \quad \textbf{Ans.}$$

EXAMPLE 257. *Calculate the pH and extent of hydrolysis of 0.01 M CH$_3$COONH$_4$. [K_b(NH$_3$) = 1.8×10^{-5} ; K_a(CH$_3$COOH) = 1.8×10^{-5}].*

SOLUTION. $CH_3COONH_4 \rightleftharpoons NH_4^+ + CH_3COO^-$

In this case NH_4^+ as well as CH_3COO^- hydrolyse. Thus:

$$\text{For } NH_4^+, \quad K_h = \frac{K_w}{K_b\,(NH_3)} = \frac{10^{-14}}{1.8 \times 10^{-5}} = 5.6 \times 10^{-10}$$

$$\text{For } CH_3COO^-, \; K_h = \frac{K_w}{K_a\,(CH_3COOH)}$$

$$= \frac{10^{-14}}{1.8 \times 10^{-5}} = 5.6 \times 10^{-10}$$

Here K_h for cation and anion are identical. Hence $[H^+]$ from NH_4^+ hydrolysis = $[OH^-]$ from CH_3COO^- hydrolysis and solution will be neutral. Thus $[H^+] = [OH^-] = 10^{-7}$; $pH = 7$

$\therefore$ For NH_4^+ hydrolysis : $NH_4^+ \rightleftharpoons H^+ + NH_3$

Conc. at equilibrium $\quad 0.01 - x \quad 10^{-7} \quad x$

$$K_h = \frac{[H^+]\,[NH_3]}{[NH_4^+]};$$

$$5.6 \times 10^{-10} = \frac{10^{-7}x}{0.01 - x}$$

$$5.6 \times 10^{-10}\,(0.01 - x) = 10^{-10}x \,;\, 5.6 \times 10^{-12} - 5.6 \times 10^{-10}\,x = 10^{-7}x$$

Or $10^{-7}x + 5.6 \times 10^{-10}x = 5.6 \times 10^{-12}$;

$$10^{-10}x\,(10^3 + 5.6) = 5.6 \times 10^{-12}$$

Or $$x = \frac{5.6 \times 10^{-12}}{10^{-10} \times 1005.6} = 5.6 \times 10^{-5}$$

$\therefore$ % age of NH_4^+ hydrolysed

$$= \frac{5.6 \times 10^{-5}}{0.01} \times 100 = \mathbf{0.56\%} \quad \textbf{Ans.}$$

EXAMPLE 258. *Calculate the pH in a 0.1M NH_4OCN solution.* $[K_b\,(NH_3) = 1.8 \times 10^{-5}\,;\, K_a\,(HOCN) = 3.0 \times 10^{-4}]$.

SOLUTION. $NH_4OCN \rightleftharpoons NH_4^+ + OCN^-$

Both NH_4^+ and OCN^- hydrolyse. NH_3 is a weaker base than HOCN which is an acid. However, NH_4^+ hydrolyses more than OCN^- and pH is less than 7. In order to preserve electrical neutrality, there can not be appreciable difference between $[NH_3]$ and $[HOCN]$. Thus we assume $[NH_3] = [HOCN] = x$; $[NH_4^+] = [OCN^-] = 0.1 - x$.

(*a*) For NH_4^+; $NH_4^+ \rightleftharpoons H^+ + NH_3$

$$K_h = \frac{[H^+]\,[NH_3]}{[NH_4^+]} \quad ...(1)$$

$$K_h = \frac{K_w}{K_b} = \frac{10^{-14}}{1.8 \times 10^{-5}}$$

$$= 5.6 \times 10^{-10} \quad ...(2)$$

From (1) and (2), we get :

$$\frac{[H^+]\,[NH_3]}{[NH_4^+]} = 5.6 \times 10^{-10}$$

or $$\frac{[H^+] \times x}{0.1 - x} = 5.6 \times 10^{-10} \,;$$

$$[H^+] = \frac{5.6 \times 10^{-10}(0.1 - x)}{x} \quad ...(3)$$

(*b*) For OCN^- ; $H_2O + OCN^- \rightleftharpoons HOCN + OH^-$

$$\therefore \quad K_h = \frac{[HOCN]\,[OH^-]}{[OCN^-]} = \frac{x[OH^-]}{0.1 - x} \quad ...(4)$$

Also $$K_h = \frac{K_w}{K_a} = \frac{10^{-14}}{3.0 \times 10^{-4}}$$

$$= 3.3 \times 10^{-11} \quad ...(5)$$

From (4) and (5), we get,

$$\frac{x[OH^-]}{0.1 - x} = 3.3 \times 10^{-11}$$

$$\therefore \quad [OH^-] = \frac{3.3 \times 10^{-11}(0.1 - x)}{x} \quad ...(6)$$

Dividing (3) and (6), we get,

$$\frac{[H^+]}{[OH^-]} = \frac{5.6 \times 10^{-10}(0.1 - x)}{x} \times \frac{x}{3.3 \times 10^{-11}(0.1 - x)}$$

Or $$\frac{[H^+]}{[OH^-]} = 17 \quad ...(7)$$

But $\quad [H^+]\,[OH^-] = K_w = 10^{-14} \quad ...(8)$

Multiplying (7) and (8), we get

$$\frac{[H^+]\,[H^+]\,[OH^-]}{[OH^-]} = 17 \times 10^{-14} \,;\, [H^+]^2 = 17 \times 10^{-14} \,;$$

$$[H^+] = (17 \times 10^{-14})^{1/2}$$

Or $\quad [H^+] = 4.1 \times 10^{-7}$.

Hence, $\quad pH = -\log\,[H^+] = -\log 4.1 \times 10^{-7}$

$= -(\log 4.1 + \log 10^{-7})$

$= -(0.61 - 7) = 6.39.$

So, $\quad pH = \mathbf{6.39} \quad$ **Ans.**

EXAMPLE 259. *Calculate the* $[OH^-]$ *in a 0.005M solution of* $Na_2C_2O_4$. K_1 *and* K_2 *for oxalic acid,* $H_2C_2O_4$ *are* 5.6×10^{-2} *and* 5.4×10^{-5} *respectively.*

SOLUTION. $Na_2C_2O_4 \rightleftharpoons 2Na^+ + C_2O_4^{2-}$

$C_2O_4^{2-} + H_2O \rightleftharpoons HC_2O_4^- + OH^-$ (hydrolysis)

Conc. at equilibrium

$0.005 - x \quad x \quad x$

≈ 0.005

$$\therefore \quad K_h = \frac{[HC_2O_4^-]\,[OH^-]}{[C_2O_4^{-2}]} = \frac{x \times x}{0.005} \quad ...(1)$$

Also, $$K_h = \frac{K_w}{K_2} = \frac{10^{-14}}{5.4 \times 10^{-5}}$$

$$= 1.85 \times 10^{-10} \quad ...(2)$$

From (1) and (2), we get :

$$\frac{x^2}{0.005} = 1.85 \times 10^{-10} \,;$$

$x = (1.85 \times 10^{-10} \times 0.005)^{1/2}$

Or $x = (92.5 \times 10^{-14})^{1/2} = 9.6 \times 10^{-7}$

Or $[OH^-] = \mathbf{9.6 \times 10^{-7}\,M}$ **Ans.**

EXAMPLE 260. *To a solution buffered at pH 9.0, 5 × 10^{-4} mol of $NaHCO_3$ is added. Calculate the material that would exist in each of the three forms, $H_2CO_3^-$, HCO_3^- and CO_3^{2-}. K_1 and K_2 are 4.5 × 10^{-7} and 4.7 × 10^{-11} respectively.*

SOLUTION. (*a*) $HCO_3^- + H_2O \rightleftharpoons H_2CO_3 + OH^-$ (hydrolysis)

$$K_h = \frac{[H_2CO_3][OH^-]}{[HCO_3^-]} \quad ...(1)$$

$$K_h = \frac{K_w}{K_1} = \frac{10^{-14}}{4.5 \times 10^{-7}} = 2.2 \times 10^{-8} \quad ...(2)$$

From (1) and (2),

$$\frac{[H_2CO_3][OH^-]}{[HCO_3^-]} = 2.2 \times 10^{-8} \quad ...(3)$$

(*b*) $HCO_3^- + H_2O \rightleftharpoons CO_3^{2-} + H_3O^+$ (hydrolysis)

$$K_2 = \frac{[CO_3^{2-}][H_3O^+]}{[HCO_3^-]};$$

$$4.7 \times 10^{-11} = \frac{[CO_3^{2-}][H_3O^+]}{[HCO_3^-]} \quad ...(4)$$

(*c*) $pH = 9; -\log[H^+] = 9;$

$\log[H^+] = -9; [H^+] = 10^{-9}$ M.

$$\therefore \quad [OH^-] = \frac{K_w}{[H^+]} = \frac{10^{-14}}{10^{-9}} = 10^{-5}\text{ M}$$

(*d*) From equation (3)

$$\frac{[H_2CO_3] \times 10^{-5}}{[HCO_3^-]} = 2.2 \times 10^{-8};$$

$$\frac{[H_2CO_3]}{[HCO_3^-]} = \frac{2.2 \times 10^{-8}}{10^{-5}}$$

Or $$\frac{[H_2CO_3]}{[HCO_3^-]} = 2.2 \times 10^{-3} \quad ...(5)$$

$$[H_2CO_3] = 2.2 \times 10^{-3}[HCO_3^-] \quad ...(6)$$

(*e*) Also, from equation (4),

$$4.7 \times 10^{-11} = \frac{[CO_3^{2-}] \times 10^{-9}}{[HCO_3^-]}$$

$$\therefore \quad \frac{[CO_3^{2-}]}{[HCO_3^-]} = \frac{4.7 \times 10^{-11}}{10^{-9}} = 4.7 \times 10^{-2} \quad ...(7)$$

$$[CO_3^{2-}] = 4.7 \times 10^{-2}[HCO_3^-] \quad ...(8)$$

All the species being in the same solution, their concentration ratios are equal to their molar ratio.

But $[NaHCO_3] = 0.0005\text{ M} = 5 \times 10^{-4}$ mol.

(*a*) $n[H_2CO_3] + n[HCO_3^-] + n[CO_3^{2-}] = 5 \times 10^{-4}$ mol.

$n \times 2.2 \times 10^{-3}[HCO_3^-] + n[HCO_3^-] + n \times 4.7 \times 10^{-2}[HCO_3^-] = 5 \times 10^{-4}$ mol.

Or $0.0022\,n[HCO_3^-] + n[HCO_3^-] + 0.047\,n[HCO_3^-] = 0.0005$

$1.05\,n[HCO_3^-] = 0.0005$

hence $n[HCO_3^-] = \frac{0.0005}{1.05} = \mathbf{4.76 \times 10^{-4}\,mol}$ **Ans.**

But $[H_2CO_3] = 2.2 \times 10^{-3}[HCO_3^-]$;

$\therefore$ $[H_2CO_3] = 2.2 \times 10^{-3} \times 4.76 \times 10^{-4}$

Or $[H_2CO_3] = 1.05 \times 10^{6}$ mol **Ans.**

(*c*) $[CO_3^{2-}] = 4.7 \times 10^{-2}[HCO_3^-]$

[from equation (8)]

Hence $[CO_3^{2-}] = 4.7 \times 10^{-2} \times 4.76 \times 10^{-4}$

$= \mathbf{2.2 \times 10^{-5}\,mol}$ **Ans.**

EXAMPLE 261. *Calculate the $[H^+]$, concentrations of monovalent anion, divalent anion and trivalent anion in 0.01M polyprotic citric acid. pK_1, pK_2 and pK_3 of citric acid are 3.13, 4.76 and 6.4 respectively.*

SOLUTION. (*a*) Let citric acid is represented as H_3A.

$\therefore \quad H_3A + H_2O \rightleftharpoons H_2A^- + H_3O^+$;

Conc. $0.01 - x \qquad x \qquad x$

$$K_1 = \frac{[H_2A^-][H_3O^+]}{[H_3A]} \quad ...(1)$$

But $pK_1 = 3.13; -\log K_1 = 3.13;$

$\log K_1 = -3.13$

$= -3 - 1 + 1 - 0.13 = \bar{4}.87$.

Hence $K_1 = \text{antilog } \bar{4}.87 = 7.4 \times 10^{-4}$.

$\therefore$ From (1), we have $7.4 \times 10^{-4} = \frac{x \times x}{0.01 - x}$;

$x^2 = 7.4 \times 10^{-4}(0.01 - x)$

$x^2 + 7.4 \times 10^{-4}x - 7.4 \times 10^{-6} = 0;$

$$\left[\because \text{for } ax^2 + bx + c = 0,\; x = \frac{-b \pm (b^2 - 4ac)^{1/2}}{2a}\right]$$

$$x = \frac{-7.4 \times 10^{-4} + [(7.4 \times 10^{-4})^2 - (4 \times 1 \times -7.4 \times 10^{-6})]^{1/2}}{2}$$

Or $$x = \frac{-7.4 \times 10^{-4} + (54.76 \times 10^{-8} + 29.6 \times 10^{-6})]^{1/2}}{2}$$

$$= \frac{-7.4 \times 10^{-4} + (10^{-8}(54.76 + 29.6 \times 100)]^{1/2}}{2}$$

$$x = \frac{-7.4 \times 10^{-4} + 54.9 \times 10^{-4}}{2} = 0.0024$$

$= \mathbf{[H_3O^+]}$ **Ans.**

(*b*) $H_2A^- + H_2O \rightleftharpoons HA^{2-} + H_3O^+$;

$$K_2 = \frac{[HA^{2-}][H_3O^+]}{[H_2A^-]} \quad ...(2)$$

$pK_2 = 4.76; -\log K_2 = 4.76;$

$\log K_2 = -4.76$

$$= -4 - 1 + 1 - 0.76 = \bar{5}.24$$

$$\therefore \quad K_2 = \text{antilog } \bar{5}.24 = 1.74 \times 10^{-5}$$

∴ From (2), we have,

$$K_2 = \frac{[HA^{2-}] \times x}{x};$$

$$1.74 \times 10^{-5} = \mathbf{[HA^{2-}]} \qquad \textbf{Ans.}$$

(*c*) $HA^{2-} + H_2O \rightleftharpoons A^{3-} + H_3O^+$;

$$K_3 = \frac{[A^{3-}][H_3O^+]}{[HA^{2-}]} \qquad ...(3)$$

$$pK_3 = 6.4 \,;\, -\log K_3 = 6.4 \,;\, \log K_3 = -6.4$$

$$= -6 - 1 + 1 - 0.4 = \bar{7}.6$$

$$\therefore \quad K_3 = \text{antilog } \bar{7}.6 = 3.98 \times 10^{-7}$$

∴ From (3), we have :

$$3.98 \times 10^{-7} = \frac{[A^{3-}] \times 0.0024}{1.74 \times 10^{-5}}$$

$$\therefore \quad [A^{3-}] = \frac{3.98 \times 10^{-7} \times 1.74 \times 10^{-5}}{0.0024}$$

$$= \mathbf{2.9 \times 10^{-9}\ M} \qquad \textbf{Ans.}$$

Example 262. *If 10^{-4} M H_3PO_4 is added to a one litre solution buffered at pH = 7, calculate the relative proportions of the four forms H_3PO_4, $H_2PO_4^-$, HPO_4^{2-} and PO_4^{3-}. K_1, K_2 and K_3 values of respective species are 7.1 × 10^{-3}, 6.3 × 10^{-8} and 4.5 × 10^{-13} respectively.*

Solution. The given solution being well buffered, *p*H value does not change on adding H_3PO_4. So, if $[H^+]$ is fixed, the ratio of the two desired concentrations from each of the ionisation constant equations will be:

(*a*) $H_3PO_4 \rightleftharpoons H^+ + H_2PO_4^-$;

$$K_1 = \frac{[H^+][H_2PO_4^-]}{[H_3PO_4]};\ \frac{[H_3PO_4]}{[H_2PO_4^-]} = \frac{[H^+]}{K_1}$$

$$\text{or} \quad \frac{[H_3PO_4]}{[H_2PO_4^-]} = \frac{10^{-7}}{7.1 \times 10^{-3}} = 1.4 \times 10^{-5} \qquad ...(1)$$

(*b*) $H_2PO_4^- \rightleftharpoons H^+ + HPO_4^{2-}$;

$$K_2 = \frac{[H^+][HPO_4^{2-}]}{[H_2PO_4^-]}$$

$$\text{or} \quad \frac{[H^+]}{K_2} = \frac{[H_2PO_4^-]}{[HPO_4^{2-}]};\ \frac{10^{-7}}{6.3 \times 10^{-8}} = \frac{[H_2PO_4^-]}{[HPO_4^{2-}]};$$

$$\frac{[H_2PO_4^-]}{[HPO_4^{2-}]} = 1.59 \qquad ...(2)$$

(*c*) $HPO_4^{2-} \rightleftharpoons H^+ + PO_4^{3-}$;

$$K_3 = \frac{[H^+][PO_4^{3-}]}{[HPO_4^{2-}]}$$

$$\frac{[HPO_4^{2-}]}{[PO_4^{3-}]} = \frac{[H^+]}{K_3} = \frac{10^{-7}}{4.5 \times 10^{-13}}$$

$$= 2.2 \times 10^{5} \qquad ...(3)$$

Out of these, the ratio $\frac{[H_3PO_4]}{[H_2PO_4^-]}$ is very small but that of $\frac{[HPO_4^{2-}]}{[PO_4^{3-}]}$ is very large. Hence, practically all the material will exist as $H_2PO_4^-$ and HPO_4^{2-}. These sum of amounts of these species will, thus be practically equal to 10^{-4}M or 0.0001 M.

$$\text{Let} \quad [HPO_4^{2-}] = x \,;\, [H_2PO_4^-] = 0.0001 - x.$$

$$\text{But} \quad \frac{[H_2PO_4^-]}{[HPO_4^{2-}]} = 1.59 \,;$$

$$\therefore \quad \frac{0.0001 - x}{x} = 1.59$$

$$\textbf{Or} \quad 1.59x + x = 0.0001 \,;\, 2.59x = 0.0001.$$

$$\text{Hence} \quad x = \frac{0.0001}{2.59} = 3.88 \times 10^{-5} \ \textit{i.e.,}$$

$$[HPO_4^{2-}] = x = \mathbf{3.86 \times 10^{-5}} \qquad \textbf{Ans.}$$

$$[H_2PO_4^-] = 0.0001 - 3.86 \times 10^{-5}$$

$$= \mathbf{6.14 \times 10^{-5}} \qquad \textbf{Ans.}$$

$$\text{Also,} \quad \frac{[H_3PO_4]}{[H_2PO_4^-]} = 1.4 \times 10^{-5} \,;$$

$$[H_3PO_4] = 1.4 \times 10^{-5}\,[H_2PO_4^-]$$

$$\text{Hence} \quad [H_3PO_4] = 1.4 \times 10^{-5} \times 6.14 \times 10^{-5}$$

$$= \mathbf{8.6 \times 10^{-10}} \qquad \textbf{Ans.}$$

Similarly, from (3),

$$[PO_4^{3-}] = \frac{[H_2PO_4^{2-}]}{2.2 \times 10^5} = \frac{3.86 \times 10^{-5}}{2.2 \times 10^5}$$

$$= \mathbf{1.75 \times 10^{-10}} \qquad \textbf{Ans.}$$

Example 263. *Calculate the equilibrium $[CO_3^{2-}]$ after equal volumes of 1.0M HCl and 1.0M Na_2CO_3 are mixed together. K_1 and K_2 are 4.5 × 10^{-7} and 4.7 × 10^{-11} respectively.*

Solution. $Na_2CO_3 + HCl \longrightarrow NaHCO_3 + NaCl$

Since the solution is same as that of $\frac{0.1}{2}$ *i.e.*, 0.5 M $NaHCO_3$ and 0.5M NaCl (when volume becomes double, molarity becomes one half), HCO_3^- reacts with water in the following two ways.

(*i*) $HCO_3^- + H_2O \rightleftharpoons CO_3^{2-} + H_3O^+$;

$$K_a \text{ or } K_2 = 4.7 \times 10^{-11}$$

$$= \frac{[CO_3^{2-}][H_3O^+]}{[HCO_3^-]} \qquad ...(1)$$

(*ii*) $HCO_3^- \rightleftharpoons CO_2 + OH^-$;

$$K_h = \frac{[CO_2][OH^-]}{[HCO_3^-]} \qquad ...(2)$$

The magnitude of both of these constants are small. It is, therefore, supposed that the $[HCO_3^-]$ remains 0.5M within experimental error. Thus $[CO_2] \approx [CO_3^{2-}]$.

Multiplying (1) and (2) we get :

$$K_2K_h = \frac{[CO_3^{2-}][H_3O^+][CO_2][OH^-]}{[HCO_3^-]^2}$$

$$= \frac{[CO_3^{2-}][CO_2] \times K_w}{[HCO_3^-]}$$

But $$K_h = \frac{K_w}{K_1}$$

So, $$K_2 \times \frac{K_w}{K_1} = \frac{[CO_3^{2-}][CO_2] \times K_w}{[HCO_3^-]^2}$$

Or $$\frac{K_2}{K_1} = \frac{[CO_3^{2-}][CO_2]}{[HCO_3^-]^2} = \frac{[CO_3^{2-}][CO_3^{2-}]}{[HCO_3^-]^2}$$

$$[\because [CO_3^{2-}] = [CO_2]]$$

Taking square root of both sides, we get :

$$\therefore \quad \frac{[CO_3^{2-}]}{[HCO_3^-]} = \left(\frac{K_2}{K_1}\right)^{1/2};$$

$$[CO_3^{2-}] = \left(\frac{4.7 \times 10^{-11}}{4.5 \times 10^{-7}}\right)^{1/2} \times [HCO_3^{2-}]$$

$$\therefore \quad [CO_3^{2-}] = (1.04 \times 10^{-4})^{1/2} \times 0.5$$

$$= 1.01 \times 10^{-2} \times 0.5 = \mathbf{5 \times 10^{-3}} \text{ Ans.}$$

EXAMPLE 264. *0.01 mol of $AgNO_3$ is added to one litre of a solution which is 0.1M in Na_2CrO_4 and 0.005M in $NaIO_3$. Calculate the mol of precipitate formed at equilibrium and the concentration of Ag^+, IO_3^- and CrO_4^{2-}. (K_{sp} values of Ag_2CrO_4 and $AgIO_3$ are 10^{-8} and 10^{-13} respectively.)* **(Roorkee 2001)**

SOLUTION. The chemical reactions involved are :

$$\underset{0.1\ \text{mol}}{2AgNO_3 + Na_2CrO_4} \longrightarrow Ag_2CrO_4 + 2NaNO_3$$

$$\underset{0.005\ \text{mol}}{AgNO_3 + NaIO_3} \longrightarrow AgIO_3 + NaNO_3$$

Thus, the molar conc. of $AgNO_3$ that will react with

$NaIO_3$ = 0.005 mol.

∴ Precipitate of $AgIO_3$ formed = 0.005 mol

Number of moles of $AgNO_3$ left

= 0.01 – 0.005 = 0.005 mol.

The whole of $AgNO_3$ left will react completely with Na_2CrO_4.

Na_2CrO_4 reacted = 0.005/2 = 0.0025 mol.

Hence, Na_2CrO_4 left = 0.1 – 0.0025 = 0.0975 mol.

Precipitate of $AgNO_3$ formed = 0.0025 mol.

Thus, $[CrO_4^{2-}]$ = 0.0975 + CrO_4^{2-} (obtained from Ag_2CrO_4 which can be neglected)

= 0.0975 mol = 9.75×10^{-2} M.

$$Ag_2CrO_4 \longrightarrow 2Ag^+ + CrO_4^{2-}$$

$$K_{sp}(Ag_2CrO_4) = [Ag^+]^2 [CrO_4^{2-}]$$

$$10^{-8} = [Ag^+]^2 \times (9.75 \times 10^{-2})$$

$$[Ag^+]^2 = \frac{10^{-8}}{9.75 \times 10^{-2}} = 0.1 \times 10^{-6}$$

or $$[Ag^+] = (0.1 \times 10^{-6})^{1/2} = 0.32 \times 10^{-3}\ M$$

$$= 3.2 \times 10^{-4}.$$

Total precipitate formed = 0.005 + 0.0025 = 0.0075 mol

Clearly, it is the total Ag^+ ion conc. present in the solution which is obtained from Ag_2CrO_4 and $AgIO_3$.

$$AgIO_3 \longrightarrow Ag^+ + IO_3^-$$

$$K_{sp}(AgIO_3) = [Ag^+][IO_3^-];$$

$$10^{-13} = (3.2 \times 10^{-4})[IO_3^-]$$

$$[IO_3^-] = \frac{10^{-13}}{3.2 \times 10^{-4}} = 0.3125 \times 10^{-9}$$

$$= 3.125 \times 10^{-10}\ M$$

EXAMPLE 265. *What $[H_3O^+]$ must be maintained in a saturated H_2S solution to precipitate Pb^{2+} but not Zn^{2+} from a solution in which each ion is present at a concentration of 0.01M?*

(K_{sp} H_2S = 1.1×10^{-22} and K_{sp} ZnS = 1.0×10^{-21})

(Roorkee 2000)

SOLUTION. Given that K_{sp} for ZnS = 1.0×10^{-21}

and $[Zn^{2+}]$ = 0.01 M = 10^{-2} M

But we know that

$$K_{sp}\ ZnS = [Zn^{2+}][S^{2-}] \text{ or } 10^{-21} = (10^{-2})(S^{2-})$$

or $$[S^{2-}] = 10^{-21}/10^{-2} = 10^{-19}\ M.$$

Clearly to prevent precipitation of Zn^{2+} ions, S^{2-} ion conc. must be less than 10^{-19} M.

Again $H_2S + 2H_2O \longrightarrow 2H_3O^+ + S^{2-}$

$$K_{sp}(H_2S) = [H_3O^+]^2[S^{2-}]$$

$$1.1 \times 10^{-22} = [H_3O^+]^2[S^{2-}]$$

or $$1.1 \times 10^{-22} = [H_3O^+]^2 \times 10^{-19}$$

$$\therefore \quad [H_3O^+]^2 = \frac{1.1 \times 10^{-22}}{10^{-19}} = 1.1 \times 10^{-3}$$

or $$[H_3O^+] = (1.1 \times 10^{-3})^{1/2} = 3.32 \times 10^{-2}\ M$$

Thus, the molar conc. of hydronium ion equal to 3.32×10^{-2} M must be maintained.

EXAMPLE 266. *The average concentration of SO_2 in the atmosphere over a city on a certain day is 10 ppm when the average temperature is 298 K. Given that the solubility of SO_2 in water at 298 K is 1.3653 mole lit^{-1} and the pK_a of H_2SO_3 is 1.92. Estimate the pH of rain on that day.* **(IIT 2000 mains)**

SOLUTION. The chemical equation involved is

$$SO_2 + H_2O \longrightarrow H_2SO_3$$

Thus, the molar conc. of SO_2 in the molar conc. of H_2SO_3.

$$[H_2SO_3] = [SO_2] = 1.3653 \text{ mole lit}^{-1}$$

$$H_2SO_3 \rightleftharpoons 2H^+ + SO_3^{2-}$$

Let us suppose that the molar conc. of H^+ ion at equilibrium = x mol L^{-1}

Then, $[H_2SO_3] = (1.3653 - x/2)$ and

$[SO_3^{2-}] = x/2$ mol L^{-1}

Applying the law of chemical equilibrium

$$K_a = \frac{[H^+][SO_3^{2-}]}{[H_2SO_3]} = \frac{x^2 \times x/2}{1.3653 - x/2} \quad ...(i)$$

Given $pK_a = 1.92$ or $-\log K_a = 1.92$

or $\log K_a = -1.92$ or $K_a = 10^{-1.92}$

Equation (i) can be written as $\dfrac{x^3}{2 \times 1.3653} = 10^{-1.92}$

($x/2$ may be neglected compared to 1.3653)

$$\begin{aligned}
\text{or} \quad x^3 &= 2 \times 1.363 \times 10^{-1.92} \\
\text{or} \quad x^3 &= 2.7306 \times 10^{-1.92} \\
\text{Taking logs } \log x^3 &= \log (2.7306 \times 10^{-1.92}) \\
&= 0.4348 - 1.92 \\
3 \log x &= -1.4852 \\
\text{or} \quad -\log x &= \frac{1.4852}{3} = 0.485 \\
\text{or} \quad -\log [H^+] &= pH = \mathbf{0.485}
\end{aligned}$$

EXAMPLE 267. *When 3.06 g of solid NH_4HS is introduced into a two litre evacuated flask at 27°C, 30% of the solid decomposes into gaseous ammonia and hydrogen sulphide. (i) Calculate K_p and K_c for the reaction at 27°C (ii) What would happen to the equilibrium when more solid NH_4HS is introduced into the flask ?* **(IIT 1999)**

SOLUTION. $NH_4HS(s) \rightleftharpoons NH_3(g) + H_2S(g)$

$$\text{Initial moles} = \frac{3.06}{51} = 0.06$$

Moles at equilibrium,

$$\frac{0.06 \times 70}{100} = 0.042 \quad \frac{0.06 \times 30}{100} = 0.018 \quad \frac{0.06 \times 30}{100} = 0.018$$

$$\begin{aligned}
K_c &= [NH_3]\,[H_2S] = \left(\frac{0.018}{2}\right)\left(\frac{0.018}{2}\right) \\
&\qquad\qquad \because \text{Volume} = 2\text{L}] \\
&= (0.009 \times 0.009)\ \text{mole}^2\ \text{litre}^{-2} \\
&= 8.1 \times 10^{-5}\ \text{mol}^2\ \text{litre}^{-2} \\
K_p &= K_c(RT)^{\Delta n}\ ;\ \Delta n = (1 + 1) - 0 = 2 \\
\therefore \quad K_p &= 8.1 \times 10^{-5} \times (0.082 \times 300)^2 = 0.049
\end{aligned}$$

Addition of NH_4HS does not change the position of equilibrium.

EXAMPLE 268. *We have taken a saturated solution of AgBr. K_{sp} of AgBr is 12×10^{-14}. If 10^{-7} mole of $AgNO_3$ are added to 1 litre of this solution, find the conductivity (specific conductance of this solution in terms of 10^{-7} Sm^{-} units. Given $\lambda°_{(Ag+)} = 6 \times 10^{-3}$ Sm^2/mol; $\lambda°_{(Br-)} = 8 \times 10^{-3}$ Sm^2/mol, $\lambda°_{(NO^-{}_3)} = 6 \times 10^{-3}$ Sm^2/mol.)* **(IIT-JEE, 2006)**

SOLUTION. *Reaction* $AgBr \rightleftharpoons Ag^+ + Br^-$

Solubility, mol L^- $\quad S \quad S$

$AgNO_3 \rightleftharpoons Ag^+ + NO_3^-$

Solubility, mol L^- $\quad 10^{-7} \quad 10^{-7}$

$\therefore$ Solubility of $Ag^+ = S + 10^{-7}$

$$K_{sp} = [Ag^+]\,[Br^-] = (S + 10^{-7}) \times S$$

$$\text{or} \quad 12 \times 10^{-14} = S^2 + 10^{-7}S\ ;$$

$$S^2 + 10^{-7}S - 12 \times 10^{-14} = 0$$

$$\therefore S = \frac{-10^{-7} \pm [(-10^{-7})^2 - (4 \times 1 \times -12 \times 10^{-14})]^{1/2}}{2 \times 1}$$

$$\left[\because \text{for } ax^2 + bx + c = 0,\quad x = \frac{-b \pm (b^2 - 4ac)^{1/2}}{2a} \right.$$

$$\begin{aligned}
&= \frac{-10^{-7} \pm [10^{-14} + 48 \times 10^{-14}]^{1/2}}{2 \times 1} \\
&= \frac{-10^{-7} \pm (49 \times 10^{-14})^{1/2}]}{2} \\
&= \frac{-10^{-7} + 7 \times 10^{-7}}{2} = 3 \times 10^{-7}
\end{aligned}$$

$$\begin{aligned}
\therefore \quad [Br^-] &= S = 3 \times 10^{-7} \times 10^3 = 3 \times 10^{-4}\ \text{m}^3; \\
[NO_3^-] &= 10^{-7} \times 10^3 = 10^{-4}\ \text{m}^3\ ; \\
[Ag^+] &= S + 10^{-7} = 3 \times 10^{-7} + 10^{-7} \\
&= 10^{-7}\,(3 + 1) = 4 \times 10^{-7} \\
&= 4 \times 10^{-7} \times 10^3 = 4 \times 10^{-4}\ \text{m}^3
\end{aligned}$$

$$\begin{aligned}
\text{But} \quad {}^\wedge m &= \frac{K \times 1000}{C}; \\
K &= \frac{{}^\wedge m \times C}{1000} = {}^\wedge mC \times 10^{-3} \\
\therefore \quad K_{(Ag+)} &= 6 \times 10^{-3} \times 4 \times 10^{-4} = 24 \times 10^{-7} \\
K_{(Br-)} &= 8 \times 10^{-3} \times 3 \times 10^{-4} = 24 \times 10^{-7} \\
K_{(NO_3^-)} &= 7 \times 10^{-3} \times 10^{-4} = 7 \times 10^{-7} \\
\therefore \quad K_{(total)} &= K_{Ag+} + K_{Br-} + K_{(NO_3^-)} \\
&= 24 \times 10^{-7} + 24 \times 10^{-7} + 7 \times 10^{-7} \\
&= 10^{-7}\,[24 + 24 + 7] = 55 \times 10^{-7}\ Sm^- \\
&= \mathbf{55\,Sm^-}(\text{in terms of } 10^{-7} Sm^-)\ \textbf{Ans.}
\end{aligned}$$

24.13 AIEEE PATTERN EXAMPLES

EXAMPLE 269. *2.5 mL of 2/5 M weak monoacidic base ($K_b = 1 \times 10^{-12}$ at 25°C) is titrated with $^2/_{15}$ M HCl in water at 25°C. The concentration of H^+ at equivalence point is ($K_w = 1 \times 10^{-14}$ at 25°C) is*

(*a*) 3.7×10^{-13} M (*b*) 3.2×10^{-7} M
(*c*) 3.2×10^{-2} M (*d*) 2.7×10^{-2} M

(IIT-JEE, 2008)

SOLUTION. Reaction : $BOH + HCl \rightarrow BCl + H_2O$

Conc. $\quad$ C

$B^+ + H_2O \rightleftharpoons BOH + H^+$

Conc. $\quad C\,(1 - h) \quad ch \quad ch$

We know that : $N_{acid} \times V_{acid} = N_{base} \times V_{base}$

$$2/15 \times V = 2.5 \times 2/5$$

$$\therefore \quad V = \frac{2.5 \times 2 \times 15}{2 \times 5} = 7.5\ \text{mL (acid used)}$$

In the resulting solution, concentration of salt [BCl]

$$= \frac{2/5 \times 2.5}{10} = 0.1$$

But $$\frac{[BOH][H^+]}{[B^+]} = \frac{Ch \times Ch}{C(1-h)} = \frac{Ch^2}{1-h} = Ch^2$$

[∵ h is very small as compared to 1]

$$Ch^2 = \frac{K_w}{K_b}$$

or $$h = \left(\frac{K_w}{K_b \times C}\right)^{1/2}$$

$$= \left(\frac{10^{-14}}{10^{-12} \times 0.1}\right)^{1/2} = \left(\frac{1}{10}\right)^{1/2}$$

But $$(H^+) = Ch = 0.1\ C\left(\frac{1}{10}\right)^{1/2}$$

$$= 0.1 \times 0.316 \simeq 3.2 \times 10^{-2}\ \text{M}$$

So, the correct answer is (*c*).

EXAMPLE 270. *The dissociation constant of an acid, the pH of whose molar solution in 5, is :*

(*a*) 10^{-7} (*b*) 10^{-8}

(*c*) 10^{-9} (*d*) 10^{-10}

SOLUTION. $pH = 5\ ;\ -\log [H^+] = 5\ ;$

$\log [H^+] = -5\ ;\ [H^+] = 10^{-5}$

$HA \rightleftharpoons H^+ + A^-\ ;\ [HA] = 1M$

$$\therefore \quad K_a = \frac{[H^+][A^-]}{[HA]};$$

$$K_a = \frac{[H^+][H^+]}{[HA]} \qquad [\because [H^+] = [A^-]]$$

$$\therefore \quad K_a = \frac{10^{-5} \times 10^{-5}}{1} = 10^{-10}.$$

So, the correct answer is (*d*).

EXAMPLE 271. *The pH of 10^{-2} M $Ca(OH)_2$ is*

(*a*) 12 (*b*) 12.3

(*c*) 11.3 (*d*) 2 **(Orissa JEE, 2011)**

SOLUTION. $Ca(OH)_2 \rightleftharpoons Ca^{2+} + 2OH^-$

10^{-2} M $\qquad 2 \times 10^{-2}$ M

$\therefore$ $(OH^-) = 2 \times 10^{-2}$. But $pOH = -\log [OH^-]$

$\therefore$ $pOH = -\log (2 \times 10^{-2}) = -[\log 2 + \log 10^{-2}]$

$= -[0.3010 - 2] = 1.6990.$

$\therefore$ $pH = 14 - pOH;$

$pH = 14 - 1.6990 = 12.3010.$

So, the correct answer is (*b*).

EXAMPLE 272. *At a certain temperature, the value of K_w is 9.55×10^{-14}. So, the pH value of water will be :*

(*a*) 7 (*b*) 7.9

(*c*) 6.51 (*d*) 8.51

SOLUTION. In $H_2O \rightleftharpoons H^+ + OH^-$, $[H^+] = [OH^-]$

$K_w = 9.55 \times 10^{-14}.$

But $K_w = [H^+][OH^-] = [H^+][H^+] = [H^+]^2$

$\therefore$ $9.55 \times 10^{-14} = [H^+]^2$ **Or** $[H^+] = (9.55 \times 10^{-14})^{1/2}$

$$\therefore \quad pH = -\log [H^+] = -\log (9.55 \times 10^{-14})^{1/2}$$

$$= -\frac{1}{2}[\log 9.55 + \log 10^{-14}]$$

$$= -\frac{1}{2}[0.98 - 14] = 6.51.$$

So, the correct answer is (*c*).

EXAMPLE 273. *The pH of a solution that contains 6.02×10^{11} H^+ ions per mL solution is :*

(*a*) 7 (*b*) 8

(*c*) 9 (*d*) 10

SOLUTION. 1 mL solution contains H^+ ions = 6.02×10^{11}

$\therefore$ 1000 mL (= 1L) solution contains H^+ ions

$= 6.02 \times 10^{11} \times 1000$

$= 6.02 \times 10^{11} \times 1000 = 6.02 \times 10^{14}$

$$\therefore \text{ no. of mol of } H^+ \text{ ions} = \frac{6.02 \times 10^{14}}{6.02 \times 10^{23}}$$

[∵ 1 mol = 6.02×10^{23} particles]

$= 10^{14-23} = 10^{-9}$

Or $[H^+] = 10^{-9}\ ;\ pH = -\log [H^+]$

$= -\log 10^{-9} = (-)(-9) \log 10$

Or **pH** = 9

So, the correct answer is (*c*).

EXAMPLE 274. *For an aqueous solution to be neutral, it must have :*

(*a*) $[H^+] < OH^-$ (*b*) $[H^+] = (Kw)^{1/2}$

(*c*) $pH = 7$ (*d*) $[H^+] = [OH^-]$

SOLUTION. For an aqueous solution to be neutral, $[H^+]$ must always be equal to $[OH^-]$. Hence, (*d*) is correct.

EXAMPLE 275. *Assume that the dissociation constant for ammonia and acetic acid are same. The pOH of an ammonia solution, when that of acetic acid of equal strength is 3.27, would be :*

(*a*) 3.27 (*b*) 10.8

(*c*) 7 (*d*) 1.6635

SOLUTION. pK_a of acetic ccid = 3.2 ; pK_b of ammonia = ?

We know, $pK_a + pK_b = 14$. Substituting the values, we get :

$3.2 + pK_b = 14$

$\therefore$ $pK_b = 14 - 3.2 = 10.8.$

Hence, correct answer is (*b*).

EXAMPLE 276. *The values of K_{p_1} and K_{p_2} for the reactions: $X \rightleftharpoons Y + Z$...... (i) and $A \rightleftharpoons 2B$ .....(ii)*

are in the ratio 9 : 1. If degree of dissociation of X and A be equal, then total pressure at equilibrium (i) and (ii) are in the ratio :

(*a*) 36 : 1 (*b*) 1 : 1

(*c*) 3 : 1 (*d*) 1 : 9

(CBSE–PMT, 2008 Prelims)

Solution. Given : $X \rightleftharpoons Y + Z$ ...(*i*)

Initial mol $1 \quad 0 \quad 0$

mol at equilibrium $1-\alpha \quad \alpha \quad \alpha$

$\therefore$ Total no. of mol at equilibrium

$$= 1-\alpha+\alpha+\alpha = 1+\alpha$$

Also : $A \rightleftharpoons 2B$ ...(*ii*)

Initial mol $1 \quad 0$

Mol at equilibrium $1-\alpha \quad 2\alpha$

$\therefore$ Total no. of mol at equilibrium $= 1-\alpha+2\alpha = 1+\alpha$

Hence
$$k_{p_1} = \frac{p_y \times p_z}{p_x} = \frac{\frac{\alpha}{1+\alpha}\times p_1 \times \frac{\alpha}{1+\alpha}\times p_1}{\frac{1-\alpha}{1+\alpha}\times p_1}$$

$$k_{p_2} = \frac{(P_B)^2}{P_A} = \frac{\left(\frac{2\alpha}{1+\alpha}\times P_2\right)^2}{\frac{1-\alpha}{1+\alpha}\times P_2};$$

$$\frac{K_{p_1}}{K_{p_2}} = \frac{P_1}{4P_2}; \frac{9}{1} = \frac{P_1}{4P_2}$$

i.e., $\frac{P_1}{P_2} = \frac{36}{1}$ *i.e.,* 36 : 1. So, the correct answer is (*a*).

Example 277. *An acidic indicator HIn ionises as,* $HIn \rightleftharpoons H^+ + In^-$. *The maximum pH value at which its solution will have distinct colour characteristic of HIn will be :*

(*a*) pK_{In+1} (*b*) pK_{In-1}

(*c*) 6 (*d*) 5

Solution. For the colour characteristic of acidic indicator, HIn.

$$pH = pK_{In} - \log\frac{[HIn]}{[In^-]} = pK_{In+1}$$

$$[\because HIn \rightleftharpoons H^+ + In^-]$$

So, the correct answer is (*a*).

Example 278. *At 298K, an aqueous solution has thrice as many* OH^- *ions as pure water. Its pOH will be :*

(*a*) 7 (*b*) 6.5229

(*c*) 7.312 (*d*) 4.921

Solution. $[H^+]$ of water $= 10^{-7}$ $\therefore$ $[OH^-] = 3\times10^{-7}$

Taking logs of both sides, we have :

$$\log[OH^-] = \log 3\times10^{-7}$$

Or $$-\log[OH^-] = -\log 3\times10^{-7}$$

$$\therefore \quad pOH = -[\log 3 + \log 10^{-7}]$$
$$= -[0.4771 - 7\log 10]$$
$$= -[0.4771 - (7\times1)]$$
$$= 7 - 0.4771 = 6.5229$$

$\therefore$ The correct answer is (***b***).

Example 279. *The hydrolysis constant* (K_h) *for zinc chloride will be :*

(*a*) $K_h = \frac{K_a}{K_b}$ (*b*) $\frac{K_a}{K_w^2}$

(*c*) $\frac{K_w^2}{K_b}$ (*d*) $\frac{K_b}{K_w^2}$

Where K_b is the effective dissociation constant of the base, $Zn(OH)_2$.

Solution. $ZnCl_2 \rightleftharpoons Zn^{2+} + 2Cl^-$

$Zn^{2+} + 2H_2O \rightleftharpoons Zn(OH)_2 + 2H^+$ (hydrolysis)

$$\therefore \quad K_h = \frac{[Zn(OH)_2][H^+]^2}{[Zn^{2+}]} \quad ...(1)$$

$Zn(OH)_2 \rightleftharpoons Zn^{2+} + 2OH^-$ (ionisation)

Base

$$\therefore \quad K_b = \frac{[Zn^{2+}][OH^-]^2}{[Zn(OH)_2]} \quad ...(2)$$

Also, $K_w = [H^+][OH^-]$

From equations (1) and (2), we have

$$K_h \times K_b = \frac{[Zn(OH)_2][H^+]^2 \times [Zn^{2+}][OH^-]^2}{[Zn^{2+}][Zn(OH)_2]}$$
$$= [H^+]^2[OH^-]^2 = K_w^2$$

$$\therefore \quad K_h = \frac{K_w^2}{K_b}$$

Hence, the correct answer is (*c*).

Example 280. *Solubility of AgCl in water, 0.01M* $BaCl_2$, *0.01M KCl and 0.05M* $AgNO_3$ *are* S_1, S_2, S_3, *and* S_4 *respectively. Then :*

(*a*) $S_4 > S_3 > S_2 > S_1$ (*b*) $S_3 > S_4 > S_1 > S_2$

(*c*) $S_2 > S_3 > S_4 > S_1$ (*d*) $S_1 > S_3 > S_2 > S_4$

Solution. $AgCl \rightleftharpoons Ag^+ + Cl^-$ (in water)

$BaCl_2 \rightleftharpoons Ba^{2+} + 2Cl^-$ (in $BaCl_2$)

$0.01 \quad 0.01 \quad 2\times0.01 = 0.02$

$KCl \rightleftharpoons K^+ + Cl^-$ (in KCl)

$0.01 \quad 0.01 \quad 0.01$

$AgNO_3 \rightleftharpoons Ag^+ + NO_3^-$ (in $AgNO_3$)

$0.05 \quad 0.05 \quad 0.05$

Common ion effect suppresses the degree of ionisation *i.e.,* solubility. This effect is maximum in $AgNO_3$. So, AgCl will be least soluble in $AgNO_3$ and maximum soluble is water. Considering KCl and $BaCl_2$ also, the order of solubility will be, $\longrightarrow S_1 > S_3 > S_2 > S_4$. So, the correct answer is (***d***).

Example 281. 10^{-3} *mol of KOH was added to 10 litre of water. The pH of the solution will change by :*

(*a*) 1 (*b*) 2

(*c*) 3 (*d*) 4

Solution. In the beginning, pH for water = 7

$$[OH^-] = 10^{-3}\times\frac{1}{10} = 10^{-4}.$$

But $[H^+][OH^-] = K_w = 10^{-14}$

$\therefore$ $[H^+]\times10^{-4} = 10^{-14}$

$$\text{Or} \qquad [H^+] = \frac{10^{-14}}{10^{-4}} = 10^{-14+4} = 10^{-10}$$

$$\therefore \qquad pH = -\log 10^{-10}$$

$$\text{or} \quad -(-10)\log 10 = -(-10)\times 1 = +10$$

$\therefore$ pH change $= 10 - 7 = 3$. So, true answer is **(*c*)**.

EXAMPLE 282. *A solution of benzonic acid was titrated with NaOH solution. When half of the solution was neutralised, the pH of the solution was found to be 4.2. The dissociation constant of the acid is :*

(*a*) 6.31×10^{-4} (*b*) 1.585×10^{-4}
(*c*) 6.31×10^{-5} (*d*) 7.23×10^{-6}

SOLUTION. Benzoic acid reacts with NaOH as follows :

$$C_6H_5COOH + NaOH \rightleftharpoons C_6H_5COONa + H_2O.$$

Conc. after neutralisation 0.5 (weak acid) 0.5 Salt

The above solution is a buffer solution of weak acid and its salt. So, we have :

$$pH = pK_a + \log \frac{[\text{salt}]}{[\text{acid}]}$$

$$4.2 = pK_a + 0 \ \text{Or}\ pK_a = -4.2$$

$$\text{or} \qquad -\log K_a = 4.2. \text{ Thus } \log K_a = -4.2$$

$$\therefore \qquad K_a = \text{antilog of } -4.2 = -4 - 1 + 1 - 0.2$$

$$= \bar{5}.8 = 6.31 \times 10^{-5}.$$

Hence the correct answer is **(*c*)**.

EXAMPLE 283. *The pH of a solution having $[H_3O^+]$ equal to 4×10^{-2} g ion L^- is :*

(*a*) -1 (*b*) 2.7
(*c*) 1.398 (*d*) None of these

SOLUTION. $[H_3O^+] = 4 \times 10^{-2}$;

$$pH = -\log [H_3O^+] = -(\log 4 \times 10^{-2})$$

$$\text{Or} \qquad pH = -(\log 4 + \log 10^{-2})$$

$$= -(0.602 - 2) = \mathbf{1.398} \qquad \textbf{Ans.}$$

So, the correct answer is (*c*).

EXAMPLE 284. *H_2S is passed into one dm^3 of a solution containing 0.1 mol of Zn^{2+} and 0.01 mol of Cu^{2+} till the sulphide ion concentration reaches 8.1×10^{-19} moles. Which of the following statement is true?*

(*a*) *Only ZnS precipitates*
(*b*) *both CuS and ZnS precipitate*
(*c*) *Only CuS precipitates*
(*d*) *No precipitation takes place*

[K_{sp} ZnS = 3×10^{-22}; CuS = 8×10^{-36}]

(Karnataka CET, 2011)

SOLUTION. A precipitate is formed when ionic product becomes greater than the solubility product. 1 dm^3 (= 1L) solution contains, 0.1 mol Zn^{2+}, 0.01 mol Cu^{2+} and 8.1×10^{-19} mol of S^{2-} ions. Thus

(*i*) **For ZnS,** ionic product = $(Zn^{2+})\,[S^{2-}] = 0.1 \times 8.1 \times 10^{-19} = 8.1 \times 10^{-20}$ K_{sp} of Zn S = 3×10^{-22}. Since ionic product > K_{sp}, ZnS will be precipitated.

(*ii*) For CuS, ionic product = $[Cu^{2+}]\,[S^{2-}] = 0.01 \times 8.1 \times 10^{-19} = 8.1 \times 10^{-21}$ K_{sp} of CuS = 8×10^{-36}. Since ionic product > K_{sp}, CuS will be precipitated. So, the correct answer is (*b*).

EXAMPLE 285. *The solubility product (K_{sp}) of the following compounds are given at 25° C.*

The most soluble and least soluble compounds are:

Compounds	K_{sp}
AgCl	1.1×10^{-10}
AgI	1.0×10^{-16}
$PbCrO_4$	4.0×10^{-14}
Ag_2CO_3	8.0×10^{-12}

(*a*) *AgCl and $PbCrO_4$* (*b*) *Ag I and Ag_2CO_3*
(*c*) *AgCl and Ag_2CO_3* (*d*) *Ag_2CO_3 and AgI*
(*e*) *Ag_2CO_3 and $PbCrO_4$* **(Kerala, PET, 2011)**

SOLUTION. (*i*) Consider solubility equilibrium of AgCl.

$$AgCl \rightleftharpoons Ag^+ + Cl^-$$

Solubility at equi. S mol S mol S mol

$$\therefore \qquad K_{sp} = [Ag^+][Cl^-];\ 1.1 \times 10^{-10} = S \times S = S^2.$$

$$\text{So,} \qquad S = (1.1 \times 10^{-10})^{1/2} = \mathbf{1.0 \times 10^{-5}}$$

(*ii*) Consider solubility equilibrium of Ag I

$$AgI \rightleftharpoons Ag^+ + I^-$$

Solubility at equi. S mol S mol S mol

$$\therefore K_{sp} = [Ag^+]\,[I^-];$$

$$1.0 \times 10^{-16} = S \times S = S^2;$$

$$S = (1.0 \times 10^{-16})^{1/2} = \mathbf{1.0 \times 10^{-8}}$$

(*iii*) Consider solubility equilibrium of $PbCrO_4$.

$$Pb\,CrO_4 \rightleftharpoons Pb^{2+} + CrO_4^{2-}$$

Solubility at equi. S mol S mol S mol

$$\therefore \qquad K_{sp} = [Pb^{2+}]\,[CrO_4^{2-}] = S \times S = S^2;$$

$$S = (4.0 \times 10^{-14})^{1/2} = \mathbf{2.0 \times 10^{-7}}$$

(*iv*) Consider solubility equilibrium of Ag_2CO_3.

$$Ag_2\,CO_3 \rightleftharpoons 2Ag^+ + CO_3^{2-}$$

Solubility at eqm. S mol 2 S mol S mol

$$\therefore \qquad K_{sp} = [Ag^+]^2\,[CO_3^{2-}] = (2\,S)^2 \times S = 4\,S^3;$$

$$S = \left(\frac{8.0 \times 10^{-12}}{4}\right)^{1/3}$$

$$= (2 \times 10^{-12})^{1/2} = \mathbf{1.26 \times 10^{-4}}$$

From above (*i*), (*ii*), (*iii*) and (*iv*) values, it is clear that Ag_2CO_3 is most soluble and Ag I is least soluble. So, the correct answer is (*d*).

EXAMPLE 286. *Let the solubility of an aqueous solution of $Mg(OH)_2$ be x, then its K_{sp} is :*

(*a*) $9x$ (*b*) $27x^4$
(*c*) $4x^3$ (*d*) $108x^5$

(AIEEE, 2003)

Solution. $Mg(OH)_2$ ionises as :

$$Mg(OH)_2 \rightleftharpoons Mg^{2+} + 2OH^-$$

Solubility $\qquad x \qquad\qquad x \qquad 2x$

But $\qquad K_{sp} = [Mg^{2+}][OH^-]^2.$

Substituting the values, we get :

$$K_{sp} = x \times (2x)^2 = 4x^3$$

So, the correct answer is, (*c*).

Example 287. *The value of equilibrium constant of the reaction, HI(g)* $\rightleftharpoons \frac{1}{2}$ *$H_2(g)$ +* $\frac{1}{2}$ *I_2 (g) is 8.0. The equilibrium constant of the reaction*

$H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$ will be

(*a*) *16* (*b*) *1/8*

(*c*) *1/16* (*d*) *1/64*

(CBSE–PMT, 2008 Prelims)

Solution. For $HI(g) \rightleftharpoons \frac{1}{2} H_2(g) + \frac{1}{2} I_2(g)$

$$K = \frac{(H_2)^{1/2}[I_2]^{1/2}}{[HI]} = 8$$

For $H_2(g) + I_2(g) \rightleftharpoons 2HI$,

$$K' = \frac{[HI]^2}{[H_2][I_2]} = \left(\frac{1}{8}\right)^2 \text{ or } K' = \frac{1}{64}.$$

So, the correct answer is (*d*).

Example 288. *The pH of 10^{-10} molar solution of HCl solution at 25°C is approximately :*

(*a*) *6* (*b*) *5*

(*c*) *11* (*d*) *7*

Solution. $\qquad HCl \rightleftharpoons H^+ + Cl^-; [H^+] = 10^{-10}$

For such solutions in which *p*H > 7, the concentration of H^+ ions of water can not be neglected. Thus :

Total H^+ ion concentration

$$\begin{aligned} &= 10^{-10} \text{ (of HCl)} + 10^{-7} \text{ (of } H_2O) \\ &= 10^{-10}(1 + 10^3) = 10^{-10} + 1001 \\ \therefore \quad pH &= -\log[H^+] = -\log(10^{-10} + 1001) \\ &= (-)[\log 10^{-10} + \log 1001] \\ &= (-)[-10 \log 10 + 3] \\ &= -[-10 \times 1 + 3] = 10 - 3 = 7 \end{aligned}$$

So, the correct answer is, **(*d*)**.

Example 289. *200 mL water is added to 500 mL of 0.2 M solution. What is the molarity of this diluted solution?*

(*a*) *0.501 M* (*b*) *0.2897 M*

(*c*) *0.4005 M* (*d*) *0.1428 M*

(Kerala PET, 2010)

Solution. No. of millimoles = 500 × 0.2 = 100. So, molarity of diluted solution = 100/700 = 0.1428 M. So, correct answer is (*d*).

Example 290. *If a mol L^- is the solubility of $KAl(SO_4)_2$, then K_{sp} is equal to*

(*a*) a^4 (*b*) $2a^4$

(*c*) $3a^4$ (*d*) $4a^4$

Solution. $KAl(SO_4)_2$ ionises as :

$$KAl(SO_4)_2 \rightleftharpoons K^+ + Al^{3+} + 2SO_4^{2-}$$

Solubility $\qquad a \qquad a \qquad 2a$

$$\begin{aligned} \therefore \quad K_{sp} &= [K^+][Al^{3+}][SO_4^{2-}]^2 \\ &= a \times a \times (2a)^2 = a \times a \times 4a^2 = 4a^4. \end{aligned}$$

So, the correct answer is, (*d*).

Example 291. *The pH of a solution is 6. If H^+ ion concentration is reduced by 100, the resulting solution will be :*

(*a*) *more acidic* (*b*) *less acidic*

(*c*) *neutral* (*d*) *can not say*

Solution. $\qquad pH = 6 ; \therefore pH = -\log[H^+],$

Or $\qquad [H^+] = 10^{-6}$

On, diluting 100 times,

$$\begin{aligned} [H^+] &= \frac{10^{-6}}{10^2} = 10^{-8} \\ \therefore \quad pH &= -\log[H^+] = -\log 10^{-8} \\ &= -[-8 \log 10] \\ &= -[-8 \times 1] = 8 \end{aligned}$$

The solution being acidic, *p*H value should be less than 7 but it is more than 7 (= 8).

So, answer is less acidic and correct answer is (*b*).

Example 292. *The % age ionisation of 0.2 M CH_3COOH will be :*

(*a*) *1* (*b*) *0.8*

(*c*) *0.95* (*d*) *6.7*

($K_a = 1.8 \times 10^{-5}$)

Solution. $CH_3COOH \rightleftharpoons CH_3COO^- + H^+$ (ionisation)

Conc. (mol L⁻) $\qquad 0.2$

Conc. at equilibrium $\qquad 0.2 - x \qquad x \qquad x$

$$\therefore \quad K = \frac{[CH_3COO^-][H^+]}{[CH_3COOH]} = \frac{x \times x}{0.2 - x}$$

$$1.8 \times 10^{-5} = \frac{x^2}{0.2 - x} = \frac{x^2}{0.2}$$

$$\therefore \quad x^2 = 0.2 \times 1.8 \times 10^{-5}; x = (3.6 \times 10^{-6})^{1/2}$$

Or $\qquad x = 1.9 \times 10^{-3} = [H^+]$

Let fraction of CH_3COOH (0.2 M) ionised = *y*

$$\therefore \quad 0.2y = 1.9 \times 10^{-3};$$

$$y = \frac{1.9 \times 10^{-3}}{0.2} = 9.5 \times 10^{-3}$$

∴ % age ionisation of $CH_3COOH = 9.5 \times 10^{-3} \times 100$ = 0.95%

So, the correct answer is (*c*).

Example 293. *1.96 g of H_2SO_4 is present in 200 mL of the solution. The pH value of this solution will be :*

(*a*) *1.7* (*b*) *10*

(*c*) *0.699* (*d*) *14*

Solution. wt. of H_2SO_4 = 1.96 g ;

g. mol. wt. of $\quad H_2SO_4 = (2 \times 1) + 32 + (4 \times 16) = 98$ g

Volume of solution in mL = 200 mL.

$$\text{But : Molarity of } H_2SO_4 = \frac{\text{wt. of } H_2SO_4}{\text{g. mol. wt. of } H_2SO_4} \times \frac{1000}{\text{Volume of solution in mL}}$$

$$= \frac{1.96}{98} \times \frac{1000}{200} = 0.1 \text{ M}$$

Also, $H_2SO_4 \rightleftharpoons 2H^+ \text{ (2 mol)} + SO_4^{2-}$

$\therefore$ $[H^+] = 2 \times 0.1 \text{ M} = 0.2 \text{ M}$

$\therefore$ $pH = -\log[H^+] = -\log 0.2$

$= -[-0.699] = 0.699$

So, the correct answer is (*c*).

EXAMPLE 294. *The pH of a solution obtained by mixing equal volumes of N/10 NaOH and N/20 HCl is:*

(*a*) *13.4* (*b*) *12.4*

(*c*) *7.6* (*d*) *1.6*

(AMU, med. 2010)

SOLUTION. Let V = volume of both acid and base; total volume = V + V = 2V, N_1V_1(Base) = N_2V_2 (acid); 1/10 × V –1/20 V = N_R × 2V; N_R = 0.025

$\therefore$ $[H^+]$ = 0.025. Hence pH = –log [0.025] = **1.6.** So, correct answer is (*d*).

EXAMPLE 295. *The pH value of* 10^2*M KOH is :*

(*a*) *14* (*b*) *15*

(*c*) *2* (*d*) *None of these.*

Explain also.

SOLUTION. $KOH \rightleftharpoons K^+ + OH^-$

Conc. at start 10^2M 0 0

Conc. after ionisation 0 10^2M 10^2M

$\therefore$ $[OH^-] = 10^2\text{M}$;

$$\text{But } [H^+] = \frac{K_w}{[OH^-]} = \frac{10^{-14}}{10^2} = 10^{-16}$$

$\therefore$ $pH = -\log [H^+] = -\log 10^{-16}$

$= -(-16) \log 10$

$= 16 \times 1 = 16$

But *p*H value can not be 16 (*i.e.,* more than 14). So, the correct answer is (*d*). The reason is same as shown in above example. So, *p*H of 10^{2} M KOH can not be calculated. It can, thus, be concluded that *p*H of 10^2 M KOH lies near to 14.

EXAMPLE 296. *The hydrogen ion concentration of a solution having a pH value of 4.32 is*

(*a*) *4.79 × 10*$^{-5}$ (*b*) *3.8 × 10*^{2}

(*c*) *2 × 10*$^{-6}$ (*d*) *11 × 10*$^{-9}$

SOLUTION. $pH = -\log [H^+] ; \log [H^+] = -pH = -4.32$

$= -4 - 1 + 1 - 0.32 = \bar{5}.68$.

$\therefore$ $[H^+] = \text{antilog } \bar{5}.68 = 4.79 \times 10^{-5}$.

So, the correct answer is (*a*).

EXAMPLE 297. *Solution of 0.8 M NH*$_4$*Cl and 0.1M Mg*$^{2+}$ *ions when mixed in equal volumes, just gave precipitate. The concentration of NH*$_3$ *in solution will be :*

(*a*) *0.74* (*b*) *0.37*

(*c*) *1.11* (*d*) *2.0*

$(K_b \text{ (NH}_4\text{OH)} = 1.8 \times 10^{-5}$;

$K_{sp} = [Mg(OH)_2] = 1.4 \times 10^{-11})$.

SOLUTION. Let V = volume of each solution of NH_4Cl and Mg^{2+}.

Total volume = $V + V = 2V$

$Mg(OH)_2 \rightleftharpoons Mg^{2+} + 2OH^-$

$$\text{Conc. at start } \left(\frac{N_1V_1}{\text{total vol}}\right) = \frac{0.1 \times V}{2V} = 0.05$$

$\therefore$ $K_{sp} = [Mg^{2+}] [OH^-]^2$;

$1.4 \times 10^{-11} = 0.05 \times [OH^-]^2$

$$\therefore \quad [OH^-] = \left(\frac{1.4 \times 10^{-11}}{0.05}\right)^{1/2} = (2.8 \times 10^{-10})^{1/2}$$

$= 1.67 \times 10^{-5}$ M.

It means when $[OH^-]$ is 1.67×10^{-5} M, $Mg(OH)_2$ will form precipitate on the addition of NH_4Cl and NH_3. For such a buffer solution of NH_4Cl and NH_3,

$$pOH = pK_b + \log \frac{[\text{salt}]}{[\text{base}]} ;$$

$$-\log [OH^-] = -\log K_b + \log \frac{[NH_4Cl]}{[NH_3]}$$

Or $-\log (1.67 \times 10^{-5}) = -\log 1.8 \times 10^{-5} + \log [NH_4Cl] - \log [NH_3]$ ...(1)

$$[NH_4Cl] = \frac{N_1V_1}{\text{Total volume}} = \frac{0.8 \times V}{2V} = 0.4 \text{ M}$$

$$[NH_3] = \frac{N_2V_2}{\text{Total volume}} = \frac{xV}{2V} = 0.5x$$

[$\because x = [NH_3]$ suppose]

Substituting these values in equation (1), we get :

$-\log (1.67 \times 10^{-5}) = -\log 1.8 \times 10^{-5} + \log 0.4 - \log 0.5x$

$-(\log 1.67 + \log 10^{-5}) = -(\log 1.8 + \log 10^{-5} + \log 10^{-5}$

$- 0.398 - \log 0.5x)$

$-(0.223 - 5) = -(0.255 - 5) - 0.398 - \log 0.5x$

$\therefore$ $\log 0.5x = 5 - 0.255 - 0.398 + 0.223 - 5 = -0.43$

$= -0.43 = -1 + 1 - 0.43 = \bar{1}.57$

$\therefore$ $0.5x = \text{antilog } \bar{1}.57 = 3.7 \times 10^{-1}$

Or $[NH_3] = 0.5x = 3.7 \times 10^{-1} = 0.37\text{M}$.

So, the correct answer is **(*b*)**.

EXAMPLE 298. *The value of pH at which the 1.2 × 10*$^{-3}$ *M solution of an indicator having K*$_b$ *value 10*$^{-10}$ *will change colour is :*

(*a*) *2* (*b*) *3*

(*c*) *4* (*d*) *5*

SOLUTION. An indicator changes colour when its conjugate acid and base concentrations are equal. Since K_b is given, indicator is basic in nature. Reactions is :

$$InOH \rightleftharpoons In^+ + OH^-$$

$$\therefore \quad K_b = \frac{[In^+][OH^-]}{[InOH]};\ K_b = [OH^-]$$

$$[\because [In^+] = [InOH] = 1.2 \times 10^{-3}]$$

$$\text{But} \quad [H^+] = \frac{K_w}{[OH^-]} = \frac{10^{-14}}{10^{-10}} = \log 10^{-4}$$

$$\therefore \quad pH = -\log [H^+] = -\log 10^{-4}$$

$$= -(-4 \log 10) = 4 \times 1 = 4$$

So, the correct answer is (*c*).

EXAMPLE 299. *A buffer solution contains 0.1 mol of sodium acetate dissolved in 1000 cm^3 of 0.1 M acetic acid. To the above buffer solution, 0.1 mol of sodium acetate is further added and dissolved. The pH of the resulting buffer is:*

(*a*) pK_a (*b*) $pK_a + 2$

(*c*) $pK_a - \log 2$ (*d*) $pK_a + \log 2$

(Karnataka CET, 2011)

SOLUTION. Moles of acetic acid (CH_3COOH) added = 0.1 M in 1L (= 1000 cm^3). Total no. of mol of sodium acetate, CH_3COONa = 0.1 + 0.1 = 0.2

$$\therefore \quad pH = pK_a + \log \frac{[CH_3COONa]}{[CH_3COOH]}$$

$$= pK_a + \log \frac{0.2}{0.1}$$

$$pH = pK_a + \log 2.$$

So, the correct answer is (*d*)

EXAMPLE 300. *The maximum pH value that could be used so that at least 90% of total Fe(III) in a dilute solution exists as Fe^{3+} is :*

(*a*) 4 (*b*) 6

(*c*) 7 (*d*) 1.23

[K_a for acid ionisation of Fe^{3+} to $[Fe(OH)]^{2+}$ and H_3O^+ is 6.5×10^{-3}]

SOLUTION. Reaction

	$Fe^{3+} + 2H_2O$	$\rightleftharpoons$ $Fe(OH)^{2+}$	+ H_3O^+
Conc. is mol L^-	$\frac{90}{100} = 0.90$	100 – 90 = 10%	x
		$= \frac{10}{100} = 0.1$	

$$\therefore \quad K_a = \frac{[Fe(OH)^{2+}][H_3O^+]}{[Fe^{3+}]};$$

$$6.5 \times 10^{-3} = \frac{0.1 \times x}{0.9}$$

$$\therefore \quad x = \frac{6.5 \times 10^{-3} \times 0.9}{0.1}$$

$$= 0.0585;\ [H_3O^+] = [H^+] = 0.0585$$

$$\therefore \quad pH = -\log [H^+] = -\log 0.585$$

$$= -(-1.23) = 1.23.$$

So, the correct answer is (*d*).

EXAMPLE 301. *The composition [salt] and [acid] of an acid buffer solution of total molarity 0.29 having pH 4.5 is : ($K_a = 1.8 \times 10^{-5}$)*

(*a*) 0.1, 0.19 (*b*) 0.2, 0.09

(*c*) 3, 2 (*d*) None of these

SOLUTION. Let x = [salt] ; [acid] = 0.29 – x.

$$\text{For an acid buffer, } pH = pK_a + \log \frac{[\text{salt}]}{[\text{acid}]}$$

$$4.5 = -\log K_a + \log [\text{salt}] - \log [\text{acid}]$$

$$4.5 = -\log (1.8 \times 10^{-5}) + \log x - \log (0.29 - x)$$

$$= -[\log 1.8 + \log 10^{-5}] + \log x - \log (0.29 - x)$$

$$4.5 = -(0.255 - 5) + \log x - \log (0.29 - x).$$

$$4.5 + 0.255 - 5 = \log \frac{x}{0.29 - x};$$

$$-0.245 = \log \frac{x}{0.29 - x};$$

$$-1 + 1 - 0.245 = \log \frac{x}{0.29 - x};\ \bar{1}.755 = \log \frac{x}{0.29 - x}$$

Taking antilogs we have :

$$\text{Antilog } \bar{1}.755 = \frac{x}{0.29 - x};$$

$$0.57 = \frac{x}{0.29 - x};\ 0.57\,(0.29 - x) = x$$

$$0.16 - 0.57x = x;\ x + 0.57x = 0.16;\ 1.57x = 0.16$$

$$\therefore \quad x = \frac{0.16}{1.57} \simeq 0.1$$

$$\text{Hence} \quad [\text{salt}] = x = 0.1;$$

$$[\text{acid}] = 0.29 - x = 0.29 - 0.1 = 0.19$$

So, the correct answer is (*a*).

EXAMPLE 302. *The pH of a solution, one litre of which contains 0.1 mol CH_3COOH and 0.1 mol HCOOH is :*

(*a*) 4.1 (*b*) 2.36

(*c*) 3.7 (*d*) 1.43

[K_a (HCOOH)] = 1.8×10^{-4} and

K_a for CH_3COOH = 1.8×10^{-5}]

SOLUTION. let mol of CH_3COOH dissociated = x ; mol of HCOOH dissociated = y.

Thus :	CH_3COOH	$\rightleftharpoons$ CH_3COO^-	+ H^+
Conc. at start	0.1	0	0
Conc. after change	0.1 – x = 0.1	x	x

($\because$ x is very small as compared to 0.1, it is neglected)

	HCOOH	$\rightleftharpoons$ $HCOO^-$	+ H^+
Conc. at start	0.1	0	0
Conc. after change	0.1 – y = 0.1	y	y

($\because$ y is very small as compared to 0.1, it is neglected)

$$\therefore \text{ For } CH_3COOH\ ; K_a = \frac{[CH_3COO^-][H^+]}{[CH_3COOH]}$$

$$1.8 \times 10^{-5} = \frac{x(x+y)}{0.1} \qquad ...(1)$$

$[\because [H^+] = x \text{ (of } CH_3COOH) + y \text{ (of HCOOH)}]$

For HCOOH ; $K_a = \dfrac{[HCOO^-][H^+]}{[HCOOH]}$

$$1.8 \times 10^{-4} = \frac{y(x+y)}{0.1} \qquad ...(2)$$

$[\because [H^+] = x \text{ (of } CH_3COOH) + y \text{ (of HCOOH)}]$

(*a*) Dividing (1) and (2), we get :

$$\frac{1.8 \times 10^{-5}}{1.8 \times 10^{-4}} = \frac{x(x+y)}{0.1} \times \frac{0.1}{y(x+y)} = \frac{x}{y}$$

Or $$10^{-1} = \frac{x}{y} ; y = 10x.$$

(*b*) Substituting the value of $y = 10x$ is (1), we get :

$$1.8 \times 10^{-5} = \frac{x(x+10x)}{0.1};$$

$$1.8 \times 10^{-5} \times 0.1 = 11x^2 ;$$

$$x^2 = \frac{1.8 \times 0.1 \times 10^{-5}}{11}$$

Or $$x^2 = 1.6 \times 10^{-7} = 16 \times 10^{-8} ;$$

$$x = (16 \times 10^{-8})^{1/2} = 4 \times 10^{-4}$$

$\therefore$ $$y = 10x = 10 \times 4 \times 10^{-4} = 4 \times 10^{-3}.$$

Hence $$[H^+] = x + y = 4 \times 10^{-4} + 4 \times 10^{-3}$$
$$= 4 \times 10^{-4}(1 + 10) = 44 \times 10^{-4}$$

$\therefore$ $$pH = -\log [H^+] = -\log 44 \times 10^{-4}$$
$$= -(\log 44 + \log 10^{-4})$$
$$pH = -(1.64 - 4) = 2.36.$$

So, the correct answer is (*b*).

EXAMPLE 303. *The pH of a solution obtained by mixing 50 cm^3 of 0.4M NH_3 and 50 cm^3 of 0.3M HCl is :*

(*a*) *8.778*	(*b*) *11*
(*c*) *14*	(*d*) *2.5*

(K_b *for* $NH_4OH = 1.8 \times 10^{-5}$)

SOLUTION. m. mol of $NH_3 = M_1V_1 = 0.4 \times 50 = 20$

m. mol of HCl $= M_2V_2 = 0.3 \times 50 = 15$

$\therefore$ m. mol of NH_3 left unreacted = 20 – 15 = 5

Total volume = 50 + 50 = 100 cm^3

$\therefore$ m. mol of NH_4^+ produced = 15

Hence the solution contains, NH_4^+ ions

$$= \frac{15 \times 1000}{1000 \times 100} = 0.15 \text{ M}$$

The solution contains NH_3 unreacted

$$= \frac{5 \times 1000}{100 \times 1000} = 0.05\text{M}$$

Reaction $NH_3 + HCl \rightleftharpoons NH_4^+ + Cl^-$

Conc. after reaction 0.05 M 0.15M

But $$pOH = pK_b + \log \frac{[\text{salt}]}{[\text{base}]}$$
$$= -\log K_b + \log \frac{[\text{salt}]}{[\text{base}]}$$

Or $$pOH = -\log 1.8 \times 10^{-5} + \log \frac{0.15}{0.05}$$
$$= -(\log 1.8 + \log 10^{-5}) + \log 3$$
$$= -(0.255 - 5) + 0.477$$
$$= 5 - 0.255 + 0.477 = 5.222$$

But $pH + pOH = 14$;

$\therefore$ $pH = 14 - 5.222 = 8.778.$

So, the correct answer is (*a*).

EXAMPLE 304. *The pH of a solution formed by mixing 20 mL of 0.05 M H_2SO_4 with 5.0 mL of 0.45 M NaOH at 298 K is:*

(*a*) *6*	(*b*) *2*
(*c*) *12*	(*d*) *7*

(J and K-CET, 2011)

SOLUTION. Reaction $2NaOH + H_2SO_4 = Na_2SO_4 + 2H_2O$
2 m. mol 1 m. mol

Millimoles of NaOH = 5 × 0.45 = 2.25 m. mol

Millimoles of H_2SO_4 = 20 × 0.05 = 1 m. mol

Total volume of solution = 5 + 20 = 25 mL

For H_2SO_4 containing $2H^+$, millimoles = 2 × 1 = 2 m. mol.

Millimoles of NaOH = 2.25

$\therefore$ millimoles of OH^- ions left behind = 2.25 – 2.0 = 0.25

$\therefore$ Concentration of OH^- ions in solution

$$= \frac{0.25}{25} = 0.01 = 10^{-2} \text{ M}$$

$\therefore$ $$pOH^- = -\log (10^{-2}) = -(-2) \log 10$$
$$= +2 \times 1 = +2$$

$\therefore$ $$pH = 14 - pOH^- = 14 - 2 = 12.$$

So, correct answer is (*c*).

EXAMPLE 305. *The solubility of AgCN in a buffer solution of pH = 3 in mol L$^-$ (mol dm^{-3}) is :*

(*a*) 0.58×10^{-10}	(*b*) 1.58×10^{-5}
(*c*) 2.58×10^{-5}	(*d*) 10^{-7}

[K_{sp} *(AgCN)* $= 1.2 \times 10^{-16}$; K_a *(HCN)* $= 4.8 \times 10^{-10}$]

SOLUTION. (*a*) $AgCN + H^+ \rightleftharpoons Ag^+ + HCN$

Solubility (mol L$^-$) s s

$\therefore$ $[Ag^+] = s, [HCN] = s$

where s = solubility of AgCN in mol L$^-$

(*b*) For HCN, $HCN \rightleftharpoons H^+ + CN^-$

$$K_a = \frac{[H^+][CN^-]}{[HCN]}; [CN^-] = \frac{K_a [HCN]}{[H^+]}$$

Or $$[CN^-] = \frac{(4.8 \times 10^{-10}) \times s}{10^{-3}} = 4.8 \times 10^{-7} s$$

$\{\because pH = 3 ; -\log [H^+] = 3$ **or** $[H^+] = 10^{-3}\}$

(*c*) For $AgCN \rightleftharpoons Ag^+ + CN^- ; K_{sp} = [Ag^+][CN^-]$;

$$1.2 \times 10^{-16} = (s) \times 4.8 \times 10^{-7}s$$

$$\therefore \quad s^2 = \frac{1.2\times10^{-16}}{4.8\times10^{-7}} = 2.5\times10^{-10}\ ;$$

$$s = (2.5\times10^{-10})^{1/2}$$

$$= \mathbf{1.58\times10^{-5}\ mol\ L^{-}\ (mol\ dm^{-3})\ Ans.}$$

So, the correct answer is (*b*).

EXAMPLE 306. *1.0 M Al(NO$_3$)$_3$ solution is found to have a pH value 2.7. The K_a for the reaction*

$$Al^{3+} + HOH \rightleftharpoons [AlOH]^{2+} + H^+ \textit{ will be :}$$

(*a*) 10^{-6} (*b*) 2×10^{-6}

(*c*) 3×10^{-6} (*d*) 4×10^{-6}

SOLUTION. pH = 2.7 ; $-\log[H^+] = 2.7$;

$$\log[H^+] = -2.7$$

$$= -2-1+1-0.7 = \bar{3}.3$$

Or $\log[H^+] = \bar{3}.3$.

Hence $[H^+] = \text{antilog } \bar{3}.3 = 2.0\times10^{-3}$

For the given reaction

	$Al^{3+} + HOH \rightleftharpoons$	$[AlOH]^{2+}$	$+ \quad [H^+]$
Conc. at start	1M		
Conc. at equilibrium	$1-(2\times10^{-3})$ $=1$	2×10^{-3}	2×10^{-3}

($\because$ 2×10^{-3} is very small as compared to 1)

$$\therefore \quad K_a = \frac{[AlOH]^{2+}[H^+]}{[Al^{3+}]}$$

$$= \frac{(2\times10^{-3})\times(2\times10^{-3})}{1} = 4\times10^{-6}$$

So, the correct answer is (*d*).

EXAMPLE 307. *The concentration of S^{2-} ion in an acid solution is 1.7×10^{-21} g/litre. A litre of 0.1 M ZnSO$_4$ solution is added to one litre of above solution. As a result, ZnS :*

(*a*) *gets precipitated*

(*b*) *does not form ppt* (*c*) *gets hydrolysed*

(*K_{sp} of ZnS = 2.5×10^{-22}*)

SOLUTION. Total volume = 1 + 1 = 2L ;

$$\therefore \quad [Zn^{2+}] = \frac{0.1M}{2} = 0.05M$$

$$[S^{2-}] = \frac{1.7\times10^{-21}}{2} = 0.85\times10^{-21}\ g\ L^{-}$$

$$\therefore \quad \text{Ionic product} = [Zn^{2+}][S^{2-}] = 0.05\times0.85\times10^{-21}$$

$$= 4.25\times10^{-23}]$$

Since ionic product is less than K_{sp}, ZnS does not form precipitate. So, the correct answer is **(*b*)**.

EXAMPLE 308. *When one litre of a saturated solution of PbCl$_2$ is evaporated to dryness, the residue is found to weigh 4.5 g. The K_{sp} for PbCl$_2$ will be :*

(*a*) 1.6×10^{-5} (*b*) 2.7×10^{-6}

(*c*) 1.0×10^{-7} (*d*) *None of these.*

(*Mol. wt. of PbCl$_2$ = 278*).

SOLUTION. wt. of PbCl$_2$ = 4.5 g ;

g. mol. wt. of PbCl$_2$ = 278 g.

$$\therefore \quad \text{no. of mol of PbCl}_2 = \frac{4.5}{278} = 0.(016$$

	$PbCl_2 \rightleftharpoons$	Pb^{2+}	$+ \quad 2Cl^-$
Solubility (mol L$^-$)		0.016	$2\times0.016 = 0.032$

$$\therefore \quad K_{sp} = [Pb^{2+}][Cl^-]^2 = 0.016\times(0.032)^2$$

$$= 1.6\times10^{-5}.$$

So, the correct answer is (*a*).

EXAMPLE 309. *At 20°C, 0.016N solution of acetic acid is 4% ionised. The ionisation constant of acetic acid will be :*

(*a*) 2.66×10^{-5} (*b*) 10^{-5}

(*c*) 5.32×10^{-5} (*d*) 10^{-6}

(Modified UP 1984)

SOLUTION. $\alpha = 4\% = \frac{4}{100} = 0.04$;

$C = 0.016$.

$$\text{For a weak acid : } K_a = \frac{C\alpha^2}{1-\alpha} = \frac{0.016\times(0.04)^2}{1-0.04}$$

$$= \frac{0.016\times0.0016}{0.96} = 2.66\times10^{-5}$$

So, the correct answer is (*a*).

EXAMPLE 310. *The degree of dissociation of 0.1M NH$_4$OH solution will be :*

(*a*) *34%* (*b*) *3.4%*

(*c*) *1.34%* (*d*) *1.8%*

$K_b = 1.8\times10^{-5}$

SOLUTION. [NH$_4$OH] = C = 0.1M ; $K_b = 1.8\times10^{-5}$

For a weak base : $K_b = C\alpha^2$; $1.8\times10^{-5} = 0.1\times\alpha^2$

$$\therefore \quad \alpha = \left(\frac{1.8\times10^{-5}}{0.1}\right)^{1/2} = (1.8\times10^{-4})^{1/2}$$

$$= 1.34\times10^{-2}$$

$\therefore$ % age degree of dissociation

$$= 1.34\times10^{-2}\times100 = 1.34\%$$

So, the correct answer is (*c*).

EXAMPLE 311. *The degree of dissociation of NH$_4$OH in a solution which is 0.2 M with respect to NH$_4$Cl and 0.1M with respect to NH$_4$OH is :*

(*a*) $9\times10^{-3}\%$ (*b*) $0.9\times10^{-30}\%$

(*c*) $2\times10^{-3}\%$ (*d*) *None of these*

SOLUTION. $NH_4OH \rightleftharpoons NH_4^+ + OH^-$

Conc. at start C $C\alpha$ $C\alpha$

Conc. at equilibrium $C = (1-\alpha)\ C\alpha$

$$NH_4Cl \rightleftharpoons NH_4^+ + Cl^-$$

Conc. at equilibrium 0.2

$\therefore$ $[NH_4OH] = C(1-\alpha) = C$ (assuming α to be very small).

$$[NH_4^+] = C\alpha + 0.2\ ;\ [OH^-] = C\alpha.$$

$$\therefore \qquad K_b = \frac{[NH_4^+][OH^-]}{[NH_4OH]};$$

$$1.8 \times 10^{-5} = \frac{(C\alpha + 0.2) \times C\alpha}{C}$$

or $\quad 1.8 \times 10^{-5} = 0.2\alpha$

[$\because$ α is very small, $C\alpha + 0.2 = 0.2$]

$$\therefore \qquad \alpha = \frac{1.8 \times 10^{-5}}{0.2} = 9 \times 10^{-5}$$

or $\quad \alpha = 9 \times 10^{-5} \times 100 = 9 \times 10^{-3}\%$

So, the correct answer is (*a*).

Example 312. *0.1M NH_4OH solution is 1.34% dissociated. Its K_b value will be*

(*a*)	1.8×10^{-4}	(*b*)	2.9×10^{-5}
(*c*)	1.8×10^{-5}	(*d*)	1.8×10^{-12}

Solution. $[NH_4OH] = C = 0.1M$;

$$\alpha = 1.34\% = \frac{1.34}{100} = 1.34 \times 10^{-2}$$

We know that for a weak base,

$$K_b = C\alpha^2 = 0.1 \times (1.34 \times 10^{-2})^2$$

Or $\quad K_b = 1.8 \times 10^{-5}$.

So, the correct answer s (*c*).

Example 313. *The equilibrium constant for the reaction $2X(g) + Y(g) \rightleftharpoons 2Z(g)$ is 2.25. The concentration of y at equilibrium with 2 moles of X and 3 moles of Z in one litre vessel is :*

(*a*)	1.0 mol	(*b*)	2.25 mole
(*c*)	2.0 mol	(*d*)	4.0 mole

(SCRA, 2000)

Solution. Reaction $\quad 2X(g) + Y(g) \rightleftharpoons 2Z(g)$

$$\therefore \qquad K = \frac{[Z]^2}{[X]^2\,[Y]}$$

But $\quad [X] = 2$ mole, $[Z] = 3$ mole ; K = 2.25

$$\therefore \qquad 2.25 = \frac{(3)^2}{(2)^2 \times Y};\ Y = \frac{9}{4 \times 2.25};\ Y = 1$$

So, the correct answer is (*a*).

Example 314. *At 50°C, pure water has $[H_3O^+] = 10^{-6}$ mole litre$^-$. The value of K_w at 50°C is :*

(*a*)	10^{-14}	(*b*)	10^{-6}
(*c*)	10^{-8}	(*d*)	10^{-12}

(SCRA, 2000)

Solution. In pure water, $[H_3O^+] = [OH^-]$.

We know that : $K_w = [H_3O^+]\,[OH^-]$.

But $[H_3O^+] = 10^{-6}$ mole litre$^-$

$$\therefore \qquad K_w = 10^{-6} \text{ mole litre}^- \times 10^{-6} \text{ mole litre}^- = 10^{-12} \text{ mol}^2 \text{ L}^{-2}$$

So, the correct answer is (*d*).

Example 315. *The solubility of a sparingly soluble salt AB_3 of molecular weight M, is x gL^- and therefore, its K_{sp} is :*

(*a*) $27x^4$ (*b*) $27(x/M)^4$ (*c*) $(x/M)^4$ (*d*) $9(x/M)^4$

(SCRA, 2000)

Solution. For AB_3 molecule, $\quad AB_3 \rightleftharpoons A^{+3} + 3B^-$

Solubility (gL^-) $\qquad S \qquad S \qquad 3S$

$$\therefore \qquad K_{sp} = [A^{3+}]\,[B^-]^3 ;$$

$$K_{sp} = S \times (3S)^3 = S \times 27S^3 = 27S^4$$

But $\quad S = \dfrac{x}{M}$. Hence $K_{sp} = 27\left(\dfrac{x}{M}\right)^4$.

So, the correct answer is (*b*).

Example 316. *Will the pH of water be same at 4°C and 25°C? Explain.* **(IIT 2003)**

Solution. At 25°C, $K_w = 10^{-14}$. Hence $pK_w = -\log 10^{-14} = -(-14)\log 10$ or $pK_w = 14 \times 1 = 14$. But $pH + pOH = 14$. Pure water is neutral.

Hence, $pH = pOH$. Hence $pH = pOH = 7$.

As the temperature decreases, K_w decreases due to low ionisation of H_2O and ΔH = +ve while pK_w increases. But pH of water = $pK_w/2$. so, pH of water will increase. Hence pH of water at 4°C will be more than that at 25°C but H_2O remains neutral.

Example 317. *The hydroxyl ion concentration in a solution having pH value 3 will be :*

(*a*)	10^{-11}	(*b*)	10^{-7}
(*c*)	10^{-3}	(*d*)	10^{-14} **(BET, 2003)**

Solution. We know,

$$pH + pOH = 14. \text{ Given } pH = 3$$

$$\therefore \qquad pOH = 14 - pH = 14 - 3 = 11$$

i.e., $\quad pOH = 11$

$$\therefore \qquad -\log [OH^-] = 11 ; \log [OH^-] = -11 ;$$

$$[OH^-] = 10^{-11}.$$

So, the correct answer is **(*a*)**.

Example 318. *The K_a of a weak monobasic acid is 1×10^{-5}. The percentage of ionisation in a decimolar acid solution is:*

(*a*)	0.1	(*b*)	10
(*c*)	0.01	(*d*)	0.5
(*e*)	1		**(Kerala PMT, 2010)**

Solution. $K_a = 10^{-5}$, C = 1/10 or 10^{-1} M. So, $\alpha = (K_a/C)^{1/2} = (10^{-5}/10^{-1})^{1/2}$.

$(10^{-4})^{1/2} = 10^{-2}$. % age ionisation $= 10^{-2} \times 100 = 1$. So, correct answer is (*e*).

Example 319. K_{sp} *[AB] = 1×10^{-10}. If $[A^+] = 1 \times 10^{-5}$, which of the following solution of $[B^-]$ can not be precipitated.*

(*a*)	1×10^{-5}	(*b*)	5×10^{-6}
(*c*)	2×10^{-5}	(*d*)	5×10^{-5}

(IMS – BHU 2003)

Solution. $K_{sp}(AB) = 10^{-10}$ *i.e.*, $[A^+]\,[B^-] = 10^{-10}$.

But $\quad [A^+] = 10^{-5}$, so $[B^-] = \dfrac{10^{-10}}{10^{-5}}$

$$= 10^{-10+5} = 10^{-5}.$$

AB can not be precipitated if $[A^+]\,[B^-] < K_{sp}$. It is possible only if $[B^-] < 10^{-5}$ *i.e.*, $[B^-]$ is 10^{-6}, 10^{-7} etc. Out of the answers given, 5×10^{-6} is less than 10^{-5}. So, the correct answer is (*b*).

EXAMPLE 320. *The pK_a of a certain weak acid is 4.0. What should be the [salt] to [acid] ratio if we have to prepare a buffer with pH = 5 using the acid and one of the salts?*

(*a*) 1 : 10	(*b*) 10 : 1
(*c*) 5 : 4	(*d*) 4 : 5

(Karnataka CET, 2000)

SOLUTION.
$$pH = pK_a + \log\frac{[\text{salt}]}{[\text{acid}]}$$
(Hendersons's equation)
$$\therefore \quad 5 = 4 + \log\frac{[\text{salt}]}{[\text{acid}]};$$
$$5 - 4 = \log\frac{[\text{salt}]}{[\text{acid}]};\ 1 = \log\frac{[\text{salt}]}{[\text{acid}]}$$

Taking antilog of both sides, we get :
$$\text{antilog } 1 = \frac{[\text{salt}]}{[\text{acid}]} \quad \textbf{Or} \quad \frac{10}{1} = \frac{[\text{salt}]}{[\text{acid}]}$$

Hence [salt] to [acid] ratio is 10 : 1. So, the correct answer is (*b*).

EXAMPLE 321. *By adding 20 mL of 0.1N HCl to 20mL of 0.001N KOH, the pH of the obtained solution will be :*

(*a*) 1.3	(*b*) 2
(*c*) 7	(*d*) 0

(Karnataka CET, 2000)

SOLUTION. Total volume = 20 mL + 20 mL = 40 mL.

Let N = normality of the resulting solution.

So, milliequivalents of resulting solution = 40 N

(*i*) Milliequivalents of HCl (N_1V_1) = 0.1 × 20 = 2

(*ii*) Milliequivalents of KOH (N_2V_2) = 0.001 × 20 = 0.02

∴ Milliequivalents of HCl left behind = 2 – 0.02 = 1.98
$$\therefore \quad 40\text{N} = 1.98 ;\ \text{N} = \frac{1.98}{40} = 0.0495$$
$$\underset{}{\text{HCl}} \rightleftharpoons \underset{0.0495}{\text{H}^+} + \underset{0.0495}{\text{Cl}^-}$$
$$\therefore \quad pH = -\log[\text{H}^+] = -\log 0.0495$$
$$= -(-1.3054) = +1.3054 \simeq 1.3.$$

So, the correct answer is (*a*).

EXAMPLE 322. *What is the $[H^+]$ in a 0.4 M solution of HOCl, $K_a = 3.5 \times 10^{-8}$?* **(DU met, 2010)**

(*a*) 1.4×10^{-8} M	(*b*) 1.2×10^{-4} M
(*c*) 1.9×10^{-9} M	(*d*) 3.7×10^{-4} M

SOLUTION. V = 1/0.4 L = 2.5 L; $K_a = 3.5 \times 10^{-8}$. So, $\alpha = (K_a\ V)^{1/2} = (3.5 \times 10^{-8} \times 2.5)^{1/2} = 2.95 \times 10^{-4}$; $[H^+] = \alpha/V = 2.95 \times 10^{-4}/2.5 \simeq 1.2 \times 10^{-4}$ M

So, the correct answer is (*b*).

EXAMPLE 323. *In a solution of weak acid having concentration 'c' and dissociation constant K_a, the H^+ ion concentration is almost equal to*

(*a*) $(K_a/C)^{1/2}$	(*b*) $\sqrt{K_a.C}$
(*c*) $\sqrt{C/K_a}$	(*d*) K_a/C

(Kerala CET, 2010)

SOLUTION. Let α = degree of dissociation.

Thus	HA	$\rightleftharpoons$	$H^+ + A^-$
Initial conc.	C		0 0
After dissociation, conc :	$C - C\alpha$		$C\alpha$ $C\alpha$

$$\therefore \quad K_a = \frac{[H^+][A^-]}{[HA]}$$
$$= \frac{C\alpha \times C\alpha}{C - C\alpha \text{ or } C(1-\alpha)} = \frac{C\alpha^2}{1-\alpha}$$

If α is very small,1 – α = 1.
$$\text{Thus :} \quad K_a = C\alpha^2 ;\ \alpha = \left(\frac{K_a}{C}\right)^{1/2}$$
$$\text{Thus} \quad [H^+] = C\alpha = C \times \left(\frac{K_a}{C}\right)^{1/2} = \left(\frac{K_aC^2}{C}\right)^{1/2}$$
$$\text{or} \quad [H^+] = (K_aC)^{1/2}$$

So, the correct answer is **(*b*)**.

EXAMPLE 324. *The dissociation constant of two acids HA_1 and HA_2 are 3.4×10^{-14} and 1.8×10^{-5} respectively. The relative strength of the acids will approximately be :*

(*a*) 1 : 4	(*b*) 4 : 1
(*c*) 1 : 16	(*d*) 16 : 1

(Rajasthan Pre. med. 2000)

SOLUTION.
$$\frac{\text{Strength of } HA_1}{\text{Strength of } HA_2} = \left(\frac{Ka_1}{Ka_2}\right)^{1/2} = \left(\frac{3.4 \times 10^{-4}}{1.8 \times 10^{-5}}\right)^{1/2}$$
$$= (18.88)^{1/2} \simeq \frac{4}{1}$$

So, the correct answer is (*b*).

EXAMPLE 325. *The equilibrium constant for equilibria $SO_2(g) + \frac{1}{2}O_2(g) \rightleftharpoons SO_3(g)$ and $2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g)$ are K_1 and K_2 respectively. Then :*

(*a*) $K_2 = K_1^2$	(*b*) $K_2 = \dfrac{1}{K_1^2}$
(*c*) $K_2 = K_1$	(*d*) $K_2 = \dfrac{1}{K_1}$

(Kerala CET, 2010)

SOLUTION. For $SO_2(g) + \frac{1}{2}O_2(g) \rightleftharpoons SO_3(g)$,
$$K_1 = \frac{[SO_3]}{[SO_2][O_2]^{1/2}} \quad \text{...(1)}$$

For $2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g)$,
$$K_2 = \frac{[SO_3]^2}{[SO_2]^2\,[O_2]} \quad \text{...(2)}$$

Squaring (1), we get :
$$K_1^2 = \frac{[SO_3]^2}{[SO_2]^2\,[O_2]} \quad \text{...(3)}$$

Since $K_2 = K_1^2$, the correct answer is **(*a*)**.

EXAMPLE 326. *If the solubility product K_{sp} of a sparingly soluble salt MX_2 at 25°C is 1.0×10^{-11}, the solubility of salt in mole $litre^{-}$ at this temperature will be :*

(*a*) 2.46×10^{14} (*b*) 1.36×10^{-4}
(*c*) 2.60×10^{-7} (*d*) 1.20×10^{-10}

(Rajasthan Pre-med. 2000)

SOLUTION. $MX_2 \rightleftharpoons M^{2+} + 2X^-$

$$\text{S} \quad \text{2S} \qquad \text{(solubilities)}$$

$$K_{sp} = [M^{2+}]\,[X^-]^2 ;$$

$$1.0 \times 10^{-11} = S \times (2S)^2 = 4S^3$$

$$\therefore \quad S = \left(\frac{10^{-11}}{4}\right)^{1/3} .$$

Taking logs of both sides, we get :

$$\log S = \log\left(\frac{10^{-11}}{4}\right)^{1/3}$$

$$= \frac{1}{3}\,[\log 10^{-11} - \log 4]$$

$$= \frac{1}{3}\,[-11 - 0.602] = -3.8673$$

$$= -3 - 1 + 1 - 0.8673 = \bar{4}.1327 .$$

Taking antilog of both sides, we get :

$$S = 1.36 \times 10^{-4}\ \text{mol L}^{-}.$$

So, the correct answer is (*b*).

EXAMPLE 327. *10^{-6} M NaOH is diluted 100 times. The pH of the diluted base is:*

(*a*) *between 5 and 6* (*b*) *between 6 and 7*
(*c*) *between 10 and 11* (*d*) *between 7 and 8*

(Karnataka CET, 2009)

SOLUTION. $NaOH \rightleftharpoons Na^+ + OH^-$. So, given $[OH^-] = 10^{-6}$. On diluting the solution 100 *i.e.*, 10^2 times,

$$[OH^-] = \frac{10^{-6}}{10^2} = 10^{-6-2} = 10^{-8}$$

Since the base is weak, autoprotolysis of water will also take place. So, the OH^- ions available from water will also be considered.

$\therefore$ Total $[OH^-] = 10^{-8} + [OH^-]$ water. So, the correct answer is (*d*).

EXAMPLE 328. *When 0.1 mol of CH_3NH_2 (ionisation constant $K_b = 5 \times 10^{-4}$) is mixed with 0.08 mol HCl and the volume is made up to 1 lit., the $[H^+]$ of resulting solution is:*

(*a*) 8×10^{-2} (*b*) 2×10^{-11}
(*c*) 1.23×10^{-4} (*d*) 8×10^{-11}

[IIT-JEE (screening), 2005]

SOLUTION. *Reaction.* $CH_3NH_2 + HCl \rightleftharpoons CH_3NH_3^+Cl^-$

Initial conc. (mol)	0.1	0.08	0
After the reaction	0.1 – 0.08	0.08 – 0.08	0.08
	= 0.02	= 0	
	(base)	(acid)	(salt)]

According to Hendersons's equation :

$$pOH = pK_b + \log\frac{[\text{salt}]}{[\text{base}]}$$

$$= -\log 5 \times 10^{-4} + \log\frac{0.08}{0.02}$$

$$= -[\log 5 + \log 10^{-4}] + \log 4$$

$$= -(0.6989 - 4) + 0.602$$

$$pOH = -0.6989 + 4 + 0.602 = 3.903$$

But $pH + pOH = 14$. Hence $pH = 14 - pOH$

$$= 14 - 3.903 = 10.097$$

But $pH = -\log[H^+]$. So, $[H^+] = 10^{-pH} = 10^{-10.097}$

$$\therefore \quad [H^+] = \text{antilog} - 10.097$$

$$= \text{antilog}\,(-10 - 1 + 1 - 0.097 = \overline{11}.903)$$

Or $[H^+] = 8 \times 10^{-11}$.

So, the correct answer is **(*d*)**.

EXAMPLE 329. *For the reaction, $AB(g) \rightleftharpoons A(g) + B(g)$, AB is 33% dissociated at a total pressure of P. Therefore, P is related to K_p by one of the following options.*

(*a*) $P = K_p$ (*b*) $P = 3K_p$
(*c*) $P = 4K_p$ (*d*) $P = 8K_p$

(AMU Med. 2010)

SOLUTION. $AB(g) \rightleftharpoons A(g) + B(g)$

At start (mol)	1	0	0
At eqmb.	1–0.33	0.33	0.33;

Total mol = 1 –0.33 + 0.33 + 0.33 = 1.33.

$\therefore$ $p_A = (0.33/1.33)$ P; $p_B = (0.33/1.33)$ P; $p_{AB} = (0.67/1.33)$ P; $K_p = p_A \times p_B/p_{AB}$

$\therefore$ $K_p = 0.33 \times 0.33 \times P/0.67 \times 1.33$; $P = 8\,K_p$.

So, the correct answer is (*d*).

EXAMPLE 330. *At 25°C, the dissociation constant of a base, BOH, is 1.0×10^{-12}. The concentration of hydroxyl ions in 0.01 M aqueous solution of the base would be :*

(*a*) 1.0×10^{-5} *mol* L^- (*b*) 1.0×10^{-6} *mol* L^-
(*c*) 2.0×10^{-6} *mol* L^- (*d*) 1.0×10^{-7} *mol* L^-

(CBSE - PMT (screening), 2005)

SOLUTION. *Reaction.* $BOH \rightleftharpoons B^+ + OH^-$

Initial conc.	C	0	0
Conc. at equilibrium	C – Cα	Cα	Cα

$\therefore$ $[OH^-] = C\alpha$. Also, $K_b = 1.0 \times 10^{-12}$;

$$C = 0.01 = \frac{1}{100} = 10^{-2}$$

But $[OH^-] = (K_bC)^{1/2} = (1.0 \times 10^{-12} \times 10^{-2})^{1/2}$

$$= (10^{-14})^{1/2}$$

$$= 10^{-7}\ \text{mol L}^-$$

$\therefore$ Correct answer is **(*d*)**.

EXAMPLE 331. *The absolute enthalpy of neutralisation of the reaction :*

$MgO(s) + 2HCl(aq) \longrightarrow MgCl_2(aq) + H_2O(l)$ will be :

(*a*) *– 57.33 kJ* mol^-
(*b*) *greater than – 57.33 kJ* mol^-

(*c*) *less than –57.33 kJ mol⁻*

(*d*) *57.33 kJ mol⁻* **(CBSE.PMT (Prelims), 2005)**

SOLUTION. Since some energy is used up to break MgO(s), enthalpy is less than – 57.33 kJ mol⁻. So, the correct answer is **(*c*)**.

EXAMPLE 332. *On adding 0.1M solution each of* $[Ag^+]$, $[Ba^{2+}]$, $[Ca^{2+}]$ *in a* Na_2SO_4 *solution, species first precipitated is:*

$(K_{sp}\ BaSO_4 = 10^{-11}, K_{sp}\ CaSO_4 = 10^{-6}, K_{sp}\ Ag_2SO_4 = 10^{-5})$

(*a*) Ag_2SO_4	(*b*) $BaSO_4$
(*c*) $CaSO_4$	(*d*) *all of these*

(DCE, 2005)

SOLUTION. (*a*) $Ag_2SO_4 \rightleftharpoons 2Ag^+ + SO_4^{2-};$

$$K_{sp} = [Ag^+]^2\,[SO_4^{2-}]$$

$$\therefore \quad [SO_4^{2-}] = K_{sp}/[Ag^+]^2 = \frac{10^{-5}}{0.1 \times 0.1} = 10^{-3}$$

(*b*)
$$BaSO_4 \rightleftharpoons Ba^{+2} + SO_4^{2-};\ K_{sp} = [Ba^{2+}]\,[SO_4^{2-}]$$

$$[SO_4^{2-}] = K_{sp}/[Ba^{2+}]$$

$$\therefore \quad [SO_4^{2-}] = \frac{10^{-11}}{0.1} = 10^{-10}$$

(*c*)
$$CaSO_4 \rightleftharpoons Ca^{2+} + SO_4^{2-};$$

$$K_{sp} = [Ca^{2+}]\,[SO_4^{2-}];$$

$$[SO_4^{2-}] = K_{sp}/[Ca^{2+}]$$

$$\therefore \quad [SO_4^{2-}] = \frac{10^{-6}}{0.1} = 10^{-5}$$

Since the ionic product of $BaSO_4$ is less, so Ba^{2+} will be precipitated first. So, the correct answer is (*b*).

EXAMPLE 333. *Partial pressure of* O_2 *in the reaction :*

$$2Ag_2O(s) \rightleftharpoons 4Ag(s) + O_2(g) \text{ is :}$$

(*a*) K_p	(*b*) $\sqrt{K_p}$
(*c*) $3\sqrt{K_p}$	(*d*) $2K_p$ **(DCE, 2005)**

SOLUTION. We know that : $[Ag_2O(s)] = [Ag(s)] = 1$.
Hence K_p for the reaction

$$2Ag_2O(s) \rightleftharpoons 4Ag(s) + O_2(g) \text{ is :}$$

$$\frac{(pAg(s))^4 \times pO_2}{(pAg_2O(s))^2} = \frac{1 \times pO_2}{1}$$

$$\therefore \quad K_p = pO_2.$$

So, the correct answer is **(*a*)**.

EXAMPLE 334. $A(g) + 3B(g) \rightleftharpoons 4C(g)$. *Initial concentration of A is equal to that of B. The equilibrium concentrations of A and C are equal.* $K_c =$

(*a*) 0.08	(*b*) 0.8
(*c*) 8	(*d*) 80
(*e*) 1/8	**(Kerala PET, 2005)**

SOLUTION. Given reaction :

	A	+	3B	⇌	4C
Conc. at start :	*a*		*b*		*0*
Conc. at equilibrium	*a – x*		*b – 3x*		*4x*

$$\therefore \quad K_c = \frac{[C]^4}{[A]\,[B]^3} - \frac{(4x)^4}{(a-x)\,(b-3x)^3}$$

But we are given that,

$$a = b\ ;\ a - x = 4x \text{ i.e., } a = 4x + x = 5x$$

$$\therefore \quad a = b = 5x.$$

Substituting the values, we get :

$$K_c = \frac{(4x)^4}{(5x-x)\,(5x-3x)^3} = \frac{(4x)^4}{4x \times (2x)^3}$$

$$= \frac{4x \times 4x \times 4x \times 4x}{4x \times 8x^3} = 8$$

So, the correct answer is **(*c*)**.

EXAMPLE 335. *Two mol of* PCl_5 *are heated in a closed vessel of 2 litre capacity. When the equilibrium is attained, 40% of it has been found to be dissociated. What is the value of* K_c *in mol/dm*^{3}*?*

(*a*) 0.532	(*b*) 0.266
(*c*) 0.133	(*d*) 0.174
(*e*) 0.25	**(Kerala PET, 2005, 2011)**

SOLUTION. Degree of dissociation,

$$\alpha = 40\% = \frac{40}{100} = 0.40$$

$$PCl_5 \rightleftharpoons PCl_3 + Cl_2$$

$$\text{Initial conc.}\ \frac{2\text{mol}}{V = 2L} = 1 \text{ mol L}^- \text{ or } 1 \text{ mol dm}^{-3}$$

According to Ostwald dilution law :

$$K_c = \frac{\alpha^2 C}{1 - \alpha}$$

$$\therefore \quad K_c = \frac{(0.4)^2 \times 1\text{mol dm}^{-3}}{1 - 0.4 = 0.6}$$

$$= 0.266 \text{ mol/dm}^3$$

So, the correct answer is (*b*).

EXAMPLE 336. *For the reaction,* $2NO_2(g) \rightleftharpoons 2NO(g) + O_2(g)$ ($K_c = 1.8 \times 10^{-6}$ *at 184°C, R = 0.0831 kJ/mol K). When* K_p *and* K_c *are compared at 184°C, it is found that*

(*a*) K_p *is greater than* K_c (*b*) K_p *is less than* K_c

(*c*) $K_p = K_c$

(*d*) *Whether* K_p *is greater than, less than or equal to* K_c *depends upon total gas pressure.* **(AIEEE, 2005)**

SOLUTION. We know that

$$K_p = K_c\,(RT)^{\Delta n}.$$

For
$$\underset{2\text{ mol}}{2NO_2(g)} \rightleftharpoons \underset{2\text{ mol}}{2NO(g)} + \underset{1\text{ mol}}{O_2(g)}$$

$$\Delta n = (2 + 1) - 2 = 1.$$

$$T = 184 + 273 = 457 \text{ K}$$

$$\frac{K_p}{K_c} = (0.0831 \text{ kJ mol}^-\text{K}^- \times 457\text{K}) \simeq 38$$

Hence K_p is greater than K_c. So, the correct answer is **(*a*)**.

EXAMPLE 337. *An amount of solid* NH_4HS *is placed in a flask already containing ammonia gas at a certain temperature and 0.50 atm pressure. Ammonium hydrogen sulphide* *decomposes to yield NH_3 and H_2S gases in the flask. When the decomposition reaction reaches equilibrium, the total pressure in the flask rises to 0.84 atm. The equilibrium constant for NH_4HS decomposition at this temperature is :*

(*a*) *0.30* (*b*) *0.18* (*c*) *0.17* (*d*) *0.11*

(AIEEE 2005)

Solution.	$NH_4HS(s) \rightleftharpoons$	$NH_3(g)$ +	$H_2S(g)$
Initial pressure	0	0.5	0
Pressure at equilibrium	0	$0.5 + p$	p

$$\therefore \quad 0.5 + p + p = 0.84 ; 2p = 0.84 - 0.5 = 0.34$$

$$\therefore \quad p = \frac{0.34}{2} = 0.17 \text{ atm.}$$

$$\therefore \quad p_{NH_3} = 0.5 + p = 0.5 + 0.17 = 0.67 \text{ atm}$$

$$\therefore \quad K_p = p_{NH_3} \times p_{H_2S}$$
$$= 0.67 \text{ atm} \times 0.17 \text{ atm} = 0.11 \text{ atm}^2$$

So, the correct answer is (*d*).

Example 338. *Solubility product constants (K_{sp}) of salts of types MX, MX_2 and M_3X at temperature T are 4.0×10^{-8}, 3.2×10^{-14} and 2.7×10^{-15} respectively. Solubility (mol dm^{-3}) of the salts at temperature T are in the order.*

(*a*) $MX > MX_2 > M_3X$

(*b*) $M_3X > MX_2 > MX$

(*c*) $MX_2 > M_3X > MX$

(*d*) $MX > M_3X > MX_2$ **(IIT-JEE, 2008)**

Solution. Let solubility of MX, MX_2 and M_3X are x_1, x_2 and x_3 respectively.

(*i*) $MX \rightleftharpoons \underset{x_1}{M^+} + \underset{x_1}{X^-}; K_{sp} = (M^+)(X^-) = x_1 \times x_1 = x_1^2$

$$\therefore x_1^2 = K_{sp}; x_1 = (K_{sp})^{1/2} = (4 \times 10^{-8})^{1/2} = 2 \times 10^{-4}.$$

(*ii*) $MX_2 \rightleftharpoons \underset{x_2}{M^+} + \underset{2x_2}{2X^-}; K_{sp} = (M^+)(X^-)^2 = x_2 \times (2x_2)^2$

$$\text{or} \quad 4x_2^3 = K_{sp}; x_2 = \left(\frac{K_{sp}}{4}\right)^{1/3} = \left(\frac{3.2 \times 10^{-14}}{4}\right)^{1/3}$$

$$\text{or} \quad x_2 = \mathbf{2 \times 10^{-5}}$$

(*iii*) $M_3 X \rightleftharpoons \underset{3x_3}{3M^+} + \underset{x_3}{X^-}; K_{sp} = (M^+)^3 (X^-) = (3x_3)^3 \times x_3$

$$= 27\, x_3^4 ; x_3 = \left(\frac{K_{sp}}{27}\right)^{1/4}$$

$$= \left[\frac{2.7 \times 10^{-15}}{27} = 10^{-16}\right]^{1/4} = 10^{-4}$$

From the values in (*i*), (*ii*) and (*iii*) above, we see that $x_1 > x_3 > x_2$ *i.e.*, $MX > M_3X > MX_2$.

So, the correct answer is (*d*).

Example 339. *The pH value of which one of the following is not equal to one.*

(*a*) *0.1 M CH_3COOH* (*b*) *0.1 M HNO_3*

(*c*) *0.05 M H_2SO_4*

(*d*) *50 cm^3 0.4 M HCl + 50 cm^3 0.2 M NaOH.*

(BCECE, 2005, Karanataka CET, 2011)

Solution. Out of all the given options, only CH_3COOH is a weak acid which does not dissociate completely. So, pH is not equal to one.

Example 340. *Given pH of a solution is 3 and it is mixed with another solution B having pH 2. If both mixed, the resultant pH of the solution will be :*

(*a*) *3.2* (*b*) *1.96*

(*c*) *3.4* (*d*) *3.5*

(IMS-BHU 2005)

Solution. (*i*)*p*H of solution, *A* = 3.

But $\quad pH = -\log [H^+]$

$\therefore \quad [H^+] = 10^{-pH} = 10^{-3}M$ ...(1)

(*ii*) *p*H of solution, *B* = 2.

But $\quad pH = -\log [H^+]$.

Hence : $\quad [H^+] = 10^{-pH} = 10^{-2}$ M ...(2)

$\therefore$ Total $[H^+]$ from (1) and (2)

$$= 10^{-3}M + 10^{-2}M = 10^{-3}(1 + 10)M$$
$$= 11 \times 10^{-3}M$$

$\therefore$ *p*H of resultant solution

$$= -\log [H^+] = -[\log 11 \times 10^{-3}]$$
$$= -[\log 11 + \log 10^{-3}] = -[1.04 - 3]$$
$$= 3 - 1.04 = 1.96$$

So, the correct answer is (*b*).

Example 341. *$A + B \rightleftharpoons C + D$. If initially the concentration of A and B are both equal but at equilibrium concentration of D will be twice of that of A then what will be the equilibrium constant of reaction ?*

(*a*) *4/9* (*b*) *9/4*

(*c*) *1/9* (*d*) *4*

(IMS – BHU, 2005)

Solution. *Reaction.*	*A*	+ *B* $\rightleftharpoons$	*C* + *D*
Initial conc.	*x* mol	*x* mol	0 0
Conc. at equilibrium			2*x* 2*x*

Applying law of chemical equilibrium, we have :

$$K_c = \frac{[C][D]}{[A][B]}; \; K_c = \frac{2x \times 2x}{x \times x} = 4$$

So, the correct answer is (*d*).

Example 342. *$Ag^+ + NH_3 \rightleftharpoons [Ag(NH_3)^+]$;*

$$K_1 = 6.8 \times 10^{-3}$$

$[Ag(NH_3)^+] + NH_3 \rightleftharpoons [Ag(NH_3)_2]^+$;

$$K_2 = 1.6 \times 10^{-3}$$

Then the formation constant of $[Ag(NH_3)_2]^+$ is :

(*a*) *1.08×10^{-7}* (*b*) *1.08×10^{-5}*

(*c*) *1.08×10^{-9}* (*d*) *none of these*

(IIT-JEE, 2006)

Solution. Since the reaction takes place in two steps :

$$k = k_1 \times k_2 = 6.8 \times 10^{-3} \times 1.6 \times 10^{-3}$$
$$= 1.08 \times 10^{-5}.$$

So, the correct answer is (*b*).

EXAMPLE 343. *If the concentration of OH^- ions in the reaction*

$$Fe(OH)_3(s) \rightleftharpoons Fe^{3+}(aq) + 3OH^-(aq)$$

is decreased by 1/4 times, then equilibrium concentration of Fe^{3+} will increase by :

(*a*) *64 times* (*b*) *4 times* (*c*) *8 times* (*d*) *16 times*

(CBSE-PMT 2008 (Prelims))

SOLUTION. For the reaction :

$$Fe(OH)_3(s) \rightleftharpoons Fe^{3+}(aq) + 3OH^-(aq)$$

$$K = \frac{[Fe^{3+}][OH^-]^3}{[Fe(OH)_3]} = [Fe^{3+}][OH^-]^3$$

[∵ activity of solids is one]

From above relation of K, it is clear that if the concentration of OH^- is decreased by 1/4 times, the equilibrium concentration of Fe^{3+} will be increased by 4^3 *i.e.*, 64 times, in order to keep the value of K as constant.

EXAMPLE 344. *Equal volumes of three acid solutions of pH 3, 4 and 5 are mixed is a vessel. What will be the H^+ ion concentration in the mixture ?*

(*a*) *3.7×10^{-3} M* (*b*) *1.11×10^{-3} M*

(*c*) *1.11×10^{-4} M* (*d*) *3.7×10^{-4} M*

(CBSE-PMT, 2008 Prelims)

SOLUTION. Since pH = $-\log(H^+)$, So, $(H^+) = 10^{-pH}$

(*i*) For solution 1, pH = 3. So, $(H^+) = 10^{-3}$

(*ii*) For solution 2, pH = 4. So, $(H^+) = 10^{-4}$

(*iii*) For solution 3, pH = 5. So, $(H^+) = 10^{-5}$

∴ Total concentration of $(H^+) = 10^{-3} + 10^{-4} + 10^{-5}$

$$= 10^{-3}(1 + 10^{-1} + 10^{-2})$$

$$= 10^{-3}\left(1 + \frac{1}{10} + \frac{1}{100}\right)$$

$$= 10^{-3}\left(\frac{100+10+1}{100} = \frac{111}{100}\right)$$

$$= 1.11 \times 10^{-3}$$

Hence (H^+) is a mixture containing equal volume of these acids solution

$$= \frac{1.11 \times 10^{-3}}{3} = 3.7 \times 10^{-4} M.$$

So, the correct answer is (*d*).

EXAMPLE 345. *30 c.c. of M/3 HCl, 20 c.c. of M/2 HNO_3 and 40 c.c. of M/4 NaOH solutions are mixed and the volume was made up to 1 dm^3. The pH of the resulting solution is:*

(*a*) *2* (*b*) *1*

(*c*) *3* (*d*) *8*

(Karnataka CET, 2009, HP Board, 2007)

SOLUTION. Total milliequivalents of H^+ ions = (Volume of HCl × molarity of HCl) + (Volume of HNO_3 × molarity of HNO_3) $= \left(30 \times \frac{1}{3}\right) + \left(20 \times \frac{1}{2}\right) = 20$

Total milliequivalents of NaOH *i.e.*, OH^- ions = volume of NaOH × molarity of NaOH

$$= 40 \times \frac{1}{4} = 10$$

∴ Milliequivalents of H^+ ions left = 20 – 10 = 10

Total volume of solution = 1 dm^3 = 1000 c.c.

∴ $[H^+] = 10/1000 = 10^{-2}$

∴ $pH = -\log[H^+] = -\log 10^{-2}$

$= (-)(-2)\log 10 = 2 \times 1 = 2.$

So, the correct answer is (*a*).

EXAMPLE 346. *The dissociation constants for acetic acid and HCN at 25°C are 1.5×10^{-5} and 4.5×10^{-10} respectively. The equilibrium constant for the equilibrium*

$CN^- + CH_3COOH \rightleftharpoons HCN + CH_3COO^-$, would be :

(*a*) *3.0×10^{-5}* (*b*) *3.0×10^{-4}* (*c*) *3.0×10^{4}* (*d*) *3.0×10^{5}*

(CBSE-PMT, 2009)

SOLUTION. (*i*) For $CH_3COOH \rightleftharpoons CH_3COO^- + H^+$;

$$K_1 = \frac{[CH_3COO^-][H^+]}{[CH_3COOH]} = 1.5 \times 10^{-5}$$

(*ii*) For $HCN \rightleftharpoons H^+ + CN^-$;

$$K_2 = \frac{[H^+][CN^-]}{[HCN]} = 4.5 \times 10^{-10}$$

Given: $CN^- + CH_3COOH \rightleftharpoons HCN + CH_3COO^-$;

$$K = \frac{[HCN][CH_3COO^-]}{[CN^-][CH_3COOH]}$$

But $K = \frac{K_1}{K_2} = \frac{1.5 \times 10^{-5}}{4.5 \times 10^{-10}} = 0.3 \times 10^5$

or $K = 3.0 \times 10^4$.

So, the correct answer is (*c*).

EXAMPLE 347. *0.023 g of sodium metal is reacted with 100 cm^3 of water. The pH of the resulting solution is:*

(*a*) *10* (*b*) *8* (*c*) *9* (*d*) *12*

(Karnataka, 2011)

SOLUTION. Wt. of Na-metal = 0.023 g; Volume of water = 100 cm^3; At. wt. (or mol. wt.) of Na = 23 g mol^-.

∴ Molarity of solution

$$= \frac{\text{wt.}}{\text{mol. wt}} \times \frac{1000}{\text{Volume in mL}}$$

$$= \frac{0.023}{23} \times \frac{1000}{100} = 0.01\text{ M} = 10^{-2}\text{ M}$$

Reaction. $Na + H_2O = Na^+ + OH^- + \frac{1}{2}H_2$

Here, $[OH^-] = 10^{-2}$ M. we know that:

$pOH = -\log[OH^-] = -\log 10^{-2}$

$= (-)(-2)\log 10 = +2 \times 1 = +2$

∴ pH = 14 – pOH = 14 – 2 = 12.

So, the correct answer is (*d*).

Type: Strong alkali + Strong alkali .

To calculate (H^+) and pH of a mixtrue of alkali solutions (say v_1mL of x M alkali + v_2 mL of y M alkali + ...) Use the relation :

(*i*) $[OH^-]$

$$= \frac{\text{Total no. of milli equivalents of all the alkalies}}{\text{Total volume of solution } (= v_1 + v_2 + ...) \text{ in mL}} \times 1000$$

Where no. of milliequivalents of the alkali.

= volume × molarity × acidicity of base

= volume × normality (if normalities are given).

(*ii*) $(H^+) = Kw/[OH^-] = \{10^{-14}/[OH^-]\} = x$ (say)

(*iii*) $pH = -\log [H^+] = -\log x$.

Type: Strong acid + strong alkali .

To calculate the $[H^+]$ and pH of a mixture of solution of a strong acid (e.g. v_1 mL of $x\,M$ of HCl, HNO_3 or H_2SO_4) and strong alkali (e.g. v_2 mL of $y\,M$ NaOH or KOH), Use the relations:

(*i*) no. of milliequivalents of alkali = $v_1 \times x \times$ acidity of base = p

(*ii*) no. of milliequivalents of acid = $v_2 \times y \times$ basicity of acid = q

(*iii*) If $p > q$, no. of milliequivalents of alkali left behind $= p - q$

(*iv*) If $q > p$, no. of milliequivalents of acid left behind $= q - p$

Then for (*iii*), $[OH^-] = \dfrac{p-q}{v_1+v_2} \times 1000$ m.eq. $L^- = Z$

$\therefore [H^+] = [Kw^2/(OH^-)] = 10^{-14}/Z$; $pH = -\log [H^+]$.

For (iv), $(H^+) = \dfrac{q-p}{v_1+v_2} \times 1000$ m.eq. L^-; $pH - \log [H^+]$.

> **Note.** If normalities of solutions are given, then: no. of milliequivalents = volume × normality of solution.

EXAMPLE 348. *5mL of 0.4 N NaOH is mixed with 20 mL of 0.1N HCl. the pH of the resulting solution will be:*

(*a*) 6 (*b*) 7

(*c*) 8 (*d*) 5

(Karnataka, CET, 2012)

SOLUTION. no. of millieqiuivalents of NaOH = 5 × 0.4 = 2.0

no. of millieqiuivalents of HCl = 20 × 0.1 = 2.0

Since the no. of millieqiuivalents of NaOH and HCl are Equal the solution is mental . So, the pH of the solution = 7. So, the correct answer is (*b*).

EXAMPLE 349. *Which one of the following will decrease the pH of 50 mL of 0.01 M hyrochloric acid?*

(*a*) Addition of 50 mL of 0.01 M HCl

(*b*) Addition of 50 mL of 0.002 M HCl

(*c*) Addition of 150 mL of 0.002 M HCl

(*d*) Addition of 5 mL of 1 M HCl

(*e*) Addition of metallic zinc. **(Kerala PMT, 2012)**

SOLUTION. For 0.01 M HCl or $10^{-2}[H^+]$, $pH = -\log (H^+)$ or $pH = -\log 10^{-2} = -(-2) \log 10 = +2$. For the pH of the mixture of solutions (for total volume, $V_1 + V_2$) We have:

$$N_1V_1 + N_2V_2 = N_3 (V_1 + V_2)$$

$\therefore$ For (*a*), $50 \times 0.01 + 50 \times 0.01 = N_3 \times (50 + 50)$;

$$N_3 = \frac{0.5 + 0.5}{100} = 10^{-2}$$

$pH = -\log 10^{-2} = -(-2) \log 10 = +2 \times 1 = +2$ (same pH)

For (*b*) $50 \times 0.01 + 50 \times 0.002 \times N_3 (50 + 50)$;

$$N_3 = \frac{0.5 + 0.1}{100} = 6 \times 10^{-3}$$

$pH = -\log (6 \times 10^{-3}) = 2.2$ (pH increased)

(*c*) $50 \times 0.01 + 150 \times 0.002 = N_3 (50 + 150)$; $N_3 = \dfrac{0.5 + 0.3}{200}$

$$= 4\ 0 \times 10^{-3}$$

$\therefore pH = -\log 4 \times 10^{-3} = 2.39$ (pH increased)

(*d*) $50 \times 0.01 + 5 \times 1 = N_3 (50 + 5)$; $N_3 = \dfrac{0.5 + 5}{55} = 0.1$

$$= 10^{-1}$$

$pH = -\log 10^{-1} = 1$ (pH decreased)

Type: Strong acid + strong acid:

To calculate $[H^+]$ and pH of a mixture of acid solutions (say v_1 mL of $x\,M$ acid + v_2 mL of $y\,M$ acid), use the relations:

$$(i)\ [H^+] = \frac{\text{Total no. of milliequivalent of all the acids}}{\text{Total valume of solution } (= v_1 + v_2) \text{ in mL}} \times 1000$$

Where no. of milliequivalent of an acid = Volume × molarity × basicity of acid = volume × normality of acid if normalities are given.

e.g. no. of milliequivalents of 100 mL of 0.2M H_2SO_4 = (100 × 0.2 × 2 = 40 ($\because$ H_2SO_4 is dibasic acid).

> **Note:** For HCl and HNO_3, basicity = 1 for each acid

EXAMPLE 350. *The pK_a of an acid HA is 4.77 and pK_b of a base BOH is 4.75. The pH of 0.1 M aqueous solution of the salt is:*

(*a*) 7.02 (*b*) 7.01

(*c*) 6.99 (*d*) 7.00

(*e*) 6.98

(Karnataka, CET, 2012)

SOLUTION. $HA + BOH \longrightarrow AB \text{ (salt)} + H_2O$.

AB is a salt of a weak acid and a weak base. So:

$$pH = 7 + \frac{1}{2}\,pK_a - \frac{1}{2}\,pK_b;\ pK_a = 4.77;\ pK_b = 4.75$$

$$\therefore pH = 7 + \left(\frac{1}{2} \times 4.77\right) - \frac{1}{2}(4.75) = 7 + 2.385 - 2.375$$

= 7.01. So the correct answer is (*b*)

EXAMPLE 351. *The pH of a 0.1 molar solution of the acid, HQ is 3. The value of ionisation constant, Ka of this acid is:*

(*a*) 1×10^{-3} (*b*) 1×10^{-5}
(*c*) 1×10^{-7} (*d*) 3×10^{-1}

(AIEEE, 2012)

SOLUTION. pH = 3. So, $[H^+] = 10^{-pH} = 10^{-3}$

$\{\because pH = -\log [H^+]\}$

Concentration, $C = 0.1\ M$. But:

$[H^+] = (KaC)^{1/2}; 10^{-3} = (KaC)^{1/2}$. Squaring both sides, we get:

$$(10^{-3})^2 = K_a \times 0.1. \text{ So, } K_a = \frac{10^{-6}}{0.1} = 10^{-5}.$$

So, the correct answer is (*b*).

Type. When v_1 mL solution of pH = *x*, is mixed with v_2 mL solution of pH = *y*, then resulting [H⁺] and pH of solution can be found by using the relations:

(*i*) $$[H^+] = \left[\frac{v_1 \times 10^{-x}}{1000} + \frac{v_2 \times 10^{-y}}{1000}\right] \times \frac{1000}{v_1 + v_2} = R(\text{say})$$

(*ii*) $pH = -\log R$

EXAMPLE 352. *The pH of a solution obtained by mixing 100 mL of a solution of pH = 3 with 400 mL of a solution of pH = 4 is:*

(*a*) 3 – log 2.8 (*b*) 7–log 2.8
(*c*) 4 – log 2.8 (*d*) 5 – log 2.5

(Karnataka, CET, 2012)

SOLUTION. Total volume of solution = 100 + 400 = 500 mL.

(*i*) pH = 3. So, $[H^+] = 10^{-3}\ M$

1000 mL solution = $10^{-3}\ M$

$$100 \text{ mL solution} = \frac{10^{-3}}{1000} \times 100 = 10^{-4}\ M$$

(*ii*) pH = 4. So, $[H^+] = 10^{-4}\ M$

1000 mL solution = $10^{-4}\ M$

$$\therefore \quad 400 \text{ mL solution} = \frac{10^{-4}}{1000} \times 400 = 4 \times 10^{-5}\ M$$

Total [H⁺] of mixed solution = $[10^{-4} + 4 \times 10^{-5}]\ M = 10^{-5}[10 + 4]\ M = 14 \times 10^{-5}\ M$

Now 500 mL solution has $[H^+] = 14 \times 10^{-5}\ M$

$$\therefore \quad 1000 \text{ mL solution has } [H^+] = \frac{14 \times 10^{-5}}{500} \times 1000 = 28 \times 10^{-5}\ M = 2.8 \times 10^{-4}\ M$$

$\therefore$ pH = – log [H⁺] = – [log 2.8 ×10⁻⁴] = – [log 2.8 – 4 log 10]

= 4 – log 2.8 $[\because \log 10 = 1]$

So, the correct answer is (*c*).

Second method. $$[H^+] = \frac{v_1 \times 10^{-x} + v_2 \times 10^{-y}}{1000} \times \frac{1000}{v_1 + v_2}$$

$$= \frac{100 \times 10^{-3} + 400 + 10^{-4}}{1000} \times \frac{1000}{500} = 2.8 \times 10^{-4}$$

$\therefore pH = -\log 2.8 \times 10^{-4} = 4 - \log 2.8$

EXAMPLE 353. *If the solubility of pb Br$_2$ is S g-mole per liter, its solubility product,considering it to be 80% ionised is:*

(*a*) 2.048 S² (*b*) 20.48 S²
(*c*) 2.048 S³ (*d*) 2.048 S⁴

(AMU. Engg. 2012)

SOLUTION. $$\text{Pb Br}_2 \rightleftharpoons Pb^{2+} + 2\,Br^-$$

$$\text{Solubility} \quad S \qquad \frac{S \times 80}{100} \qquad \frac{2S \times 80}{100}$$

$[\because$ Pb Br$_2$ gets 80% ionised]

$$\therefore \quad K_{sp} = [Pb^{2+}] \times [Br^-]^2$$

$$= \frac{S \times 80}{100} \times \frac{2S \times 80}{100} \times \frac{2S \times 80}{100} = 2.048\ S^3$$

So, the correct answer is (*c*).

EXAMPLE 354. *A buffer solution is prepared by mixing equal concentration of weak base and its salt with strong acid. For the base, K_b is given as 10^{-9}. The pH of the buffer solution is:*

(*a*) 3 (*b*) 5
(*c*) 8 (*d*) 9

(Odisha, JEE, 2012)

SOLUTION. For a buffer salt:

$$pOH = pKb + \log \frac{[\text{Salt}]}{[\text{Base}]}.$$

Since $K_b = 10^{-9}$, $pK_b = -\log K_b = -\log 10^{-9}$

= (–) (– 9 log 10) = + 9 × 1 = 9

$\therefore$ pOH = 9, pH = 14 – 9 = 5.

So, the correct answer is (*b*).

EXAMPLE 355. *A solution has $[H_3O^+]$ as 10^{-4}. This solution is ;*

(*a*) natural (*b*) basic
(*c*) acidic (*d*) amphoteric

(Odisha. JEE. 2012)

SOLUTION. $[H_3O^+] = 10^{-4}$. So, $pH = -\log [H_3O^+] = -\log 10^{-4}$

= – (– 4)log 10 = 4 × 1 = 4.

Since pH is less tham 7, it is acidic. So, the correct answer is (*c*).

EXAMPLE 356. *The number of moles of Ca(OH)$_2$ that must be dissolved to make 250 mL solution in water of pH 10.65 is:*

(*a*) 5.6×10^{-5} (*b*) 6.5×10^{-5}
(*c*) 4.5×10^{-5} (*d*) 5.4×10^{-5}

(AMS, Engg. 2012)

SOLUTION. We know pH + pOH = 14; 10.65 + pOH = 14; pOH = 14 – 10.65 = 3.35. Since pOH = – log[OH⁻]; $[OH^-] = 10^{-3.35}$

Taking logs of both sides, we get, $\log [OH^-] = \log 10^{-3.35} = -3.35 \log 10 = -3.35$.

Taking antilogs of both sides, [OH⁻] = antilog – 3.35 + 1 – 1 i.e., $\bar{4}.65 = 4.47 \times 10^{-4}$ M.

$$Ca(OH)_2 \rightleftharpoons Ca^{2+} + 2OH^-$$

2 mol

$$\therefore\ [Ca(OH)_2] = \frac{4.47 \times 10^{-4}}{2} M = 2.235 \times 10^{-4} M$$

$$\therefore\ \text{No. of moles in 250 mL} = \frac{2.235 \times 10^{-4} \times 250}{1000} = 5.58$$

$\times\ 10^{-5} \simeq 5.6 \times 10^{-5}$. So, the correct answer is (*a*).

EXAMPLE 357. *20 mL of 0.1N acetic acid is mixed with 10 mL of 0.1N solution of NaOH. The pH of the resulting solution is (pK of acetic acid is 4.74):*

(*a*) 3.74 (*b*) 4.74

(*c*) 5.74 (*d*) 6.74

(WB. JEE. 2012)

SOLUTION. Moles of acetic acid

$$= \frac{\text{Normality} \times \text{volume in mL}}{1000} = \frac{0.1 \times 20}{1000} = 0.002$$

$$\text{Moles of NaOH} = \frac{0.1 \times 10}{1000} = 0.001$$

	CH_3COOH	$+\ NaOH \longrightarrow$	CH_3COONa	$+\ H_2O$
	1mol	1mol	1mol	1mol
Initial mol	0.002	0.001		
Mol after reaction	0.002 − 0.001 = 0.001	0	0.001	0.001

But $\text{pH} = pK_a + \log \frac{[\text{salt}]}{[\text{acid}]}$ (Henderson's equaiton)

$$= 4.74 + \log \frac{(0.001)}{(0.001)}$$

$= 4.74 + \log 1 = 4.74 + 0 = 4.74$

So, the correct answer is (*b*).

EXAMPLE 358. *On adding which of the following, the pH of 20 mL of 0.1 NHCl will not alter?*

(*a*) *1 mL of 1NHCl*

(*b*) *20 mL of distilled water*

(*c*) *1 mL of 0.1NaOH*

(*d*) *500 mL of HCl of pH = 1* **(Karnataka, CET, 2012)**

SOLUTION. For 0.1 NHCl, $[H^+] = 10^{-1}$. So, $\text{pH} = -\log [H^+] = -\log 10^{-1} = (-)(-1) \log 10 = 1 \times 1 = 1$

(*a*) $N_1V_1 + N_2V_2 = N_3 (V_1 + V_2)$

$(20 \times 0.1) + (1 \times 1) = N_3 (20 + 1); N_3 = \frac{3}{21}; [H^+] = 10^{-3/21}$

(*b*) Solution will become dilute and pH will change.

(*c*) $(20 \times 0.1) + (0.1 \times 1) = N_3 (20 + 1); N_3 = 2.1/21 = 10^{-1}; [H^+] = 10^{-1}$

$\therefore\ \text{pH} = -\log [H^+] = -\log 10^{-1} = (-)(-1) \log 10 = 1 \times 1 = 1$. This pH is same as that of given solution. So, correct answer is (*c*).

(*d*) $\text{pH} = 1 ; [H^+] = 10^{-1}$ mol L^- *i.e.*,

1000 mL solution contain $[H^+] = 10^{-1}$

$$\text{500 mL solution contain } [H^+] = \frac{10^{-1}}{1000} \times 500 = 0.5 \times 10^{-1}$$

Since $[H^+]$ is not same as that of given solution, its pH will be different from that of given solution.

EXAMPLE 359. *Which of the following acids is stronger than benzoic acid ($K_a = 6.3 \times 10^{-5}$):*

(*a*) $A\ (K_a = 1.67 \times 10^{-8}$

(*b*) $B\ (pK_a = 6.0)$

(*c*) $C\ (pK_a = 4.0)$

(*d*) $D\ (K_a = 1.0 \times 10^{-5})$

(AMU, Engg. 2012)

SOLUTION. An acid having greater value of K_a than that of benzoic acid will be stronger acid than benzoic acid.

(*a*) K_a value is less than benzoic acid

(*b*) $pK_a = 6.0; -\log K_a = 6.0: K_a = -\text{antilog } 6.0 = 1 \times 10^{-6}$. This value is less than that of benzoic acid

(*c*) $pK_a = 4.0 ; -\log K_a = 4.0 ; K_a = -\text{antilog } 4.0 = 10^{-4}$. This value is more than that of benzoic acid.

(*d*) $K_a = 10^{-5}$. Out of all K_a values, value of K_a of (*c*) is more than that of benzoic acid. So, the correct answer is (*c*).

EXAMPLE 360. *pH of 0.0002 M formic acid (HCOOH, Ka = 2 × 10^{-4}) approximately is :*

(*a*) 1.35 (*b*) 0.5

(*c*) 3.7 (*d*) 1.85

(J&K, CET, 2012)

SOLUTION.	$HCOOH + H_2O \rightleftharpoons$	H_3O^+	$+\ HCOO^-$
Moles at start	0.0002M	0	0
Change by reaction	$-x$	x	x
At equilibrium	$0.0002 - x$	x	x

$$K_c = \frac{[H_3O^+][HCOO^-]}{[HCOOH]}$$

$$2 \times 10^{-4} = \frac{x \times x}{0.0002 - x}$$

x being very small, it can be ignored from denominator.

$\therefore\ 2 \times 10^{-4} \times 0.0002 = x^2 ; x^2 = 4 \times 10^{-8} ; x = [4 \times 10^{-8}]^{1/2} = 2 \times 10^{-4}$

$\therefore\ [H^+] = 2 \times 10^{-4} ; \text{pH} = -\log [H^+]$

or $\text{pH} = -\log 2 \times 10^{-4} = -[\log 2 + \log 10^{-4}] = -(0.3010 - 4)$

$= 3.699 \approx 3.7$. So, the correct answer is (*c*).

EXAMPLE 361. *If 40 mg of NaOH is dissolved in 10 litre of water, what is the resulting pH of of the solution?*

(*a*) 4 (*b*) 13

(*c*) 10 (*d*) 1 **(AFMC,2012)**

SOLUTION. $40 \text{ mg} = \frac{40}{1000} g = 0.04$ g; mol. wt. of NaOH

$= 23 + 16 + 1 = 40 \text{ g mol}^-$; no. of mol of NaOH $= \frac{0.04}{40} = 0.001$.

molarity of solution $= \frac{0.001}{10} = 10^{-4}$. So, $[OH^-] = 10^{-4}$.

$$\therefore \; [H^+] = \frac{K_w}{[OH^-]} = \frac{10^{-14}}{10^{-4}} = 10^{-10}.$$

Hence pH = – log 10^{-10} = (–) (–10) log 10 = 10.

So, the correct answer is (*c*).

Example 362. *The solubility product of a sparingly soluble salt AB is* 1.21×10^{-6}. *Its molar solubility is*:

(*a*) 1.1×10^{-3} *mol* L^-
(*b*) 1.21×10^{-6} *mol* L^-
(*c*) 1.01×10^{-3} *mol* L^-
(*d*) 1.1×10^{-4} *mol* L^-

(AFMC, 2012)

Solution.

Given:	AB	$\rightleftharpoons$	A^+	+	B^-
Solubility	s		s		s

Solubility product = $[A^+]\,[B^+] = s \times s = s^2$

$\therefore \; s^2 = 1.21 \times 10^{-6}; \; s = [1.21 \times 10^{-6}]^{1/2}$

$= 1.1 \times 10^{-3}$ mol L^-

So, the correct answer is (*a*).

Example 363. *At temperature, T, a compound* $AB_2(g)$ *dissociates according to the reaction;* $2AB_2(g) \rightleftharpoons 2AB(g) + B_2(g)$ *with a degree of dissociation, x which is small as compared to unity. The expression for* K_p *in terms of x and the partial pressure, P is:*

(*a*) $\frac{Px^3}{2}$
(*b*) $\frac{Px^2}{3}$
(*c*) $\frac{Px^3}{3}$
(*d*) $\frac{Px^2}{2}$

(AFMC,2012)

Solution.	$2AB_2$	$\rightleftharpoons$	$2AB_{(g)}$	+	$B_{2(g)}$
Initial mol.	1		0		0
At equilibrium	$1-x$		x		$x/2$

Total no. of mol = $1 - x + x + x/2 = (2 + x)/2$

$$\therefore \; K_p = \frac{p^2AB \times pB_2}{p^2AB_2}$$

$$= \frac{\left[\frac{x}{(2+x)/2}\right]^2 \times \frac{x/2}{(2+x)/2}}{\left[\frac{1-x}{(2+x)/2}\right]^2} = \frac{px^3}{(2+x)\,(1-x)^2}$$

Since $x <<< 1$, so $1 - x$ can be neglected and $2 + x \simeq 2$

$$\therefore \; K_p = \frac{Px^3}{2}.$$

So, the correct answer is (*a*).

Example 364. *How many liters of water must be added to 1 litre of an aqueous solution of HCl with a pH of 1 to create an aqueous solution of pH of 2 ?*

(*a*) 0.9L
(*b*) 2.0 L
(*c*) 9.0 L
(*d*) 0.1 L **(JEE Main, 2013)**

Solution. (*i*) pH = – log [H^+] = 1. So, [H^+] = $10^{-1}\,M = M_1$

(*ii*) pH = – log [H^+] = 2. So, [H^+] = $10^{-2}\,M = M_2$

V_1 = Volume of HCl = 1 L, Let volume of water added V_2L.

$\therefore \; M_1V_1 = M_2\,(V_1 + V_2)$

$10^{-1} \times 1 = 10^{-2}\,(1 + V_2)$

$\frac{0.1}{0.01} = 1 + V_2\,;\; V_2 = 10 - 1 = 9$ L.

So the correct answer is (3)

PROBLEMS FOR PRACTICE

1. Calculate the pH of 10^4 M HCl

   [**Ans.** pH = – 4 but it is not possible because pH range is from 0 to 14.]

2. 3.65×10^{-2} g of HCl is dissolved in 100 mL of water. Calculate the pH of the solution. **(UP 1984)**

   [**Hint.** 100 mL solution contain HCl = 3.65×10^{-2} g. Hence 1000 mL solution will contain HCl = 0.365 g. Now this question is same as example, 37.]

   Ans. pH = +2

3. The concentration of H^+ ions in water is 10^{-7} g ion per litre. Even then, it is neutral. Why?

   Ans. [H^+] = [OH^-] = 10^{-7} in water. So, water is neutral.

4. The H^+ ion concentration of a solution is 0.001 M. What will be the OH^- ion concentration of the solution?

   [**Hint.** [H^+] = 0.001 = 10^{-3} ; [OH^-] = K_w/[H^+]
   = $10^{-14}/10^{-3} = 10^{-11}$] **Ans.** 10^{-11}

   (UP 1989)

5. Calculate the H^+ ion concentration of a solution, which has a pH 4.5. **(UP 1985).**

   Ans. 3.16×10^{-5} g ion L^-

6. Find the pH of the solution obtained by dissolving 3.2 g of hydrogen chloride in 1.0 L of water. **(NCERT Text book problem).**

   [**Hint.** g. mol. wt. of HCl = 1 + 35.5 = 36.5 g ;
   [H^+] = 3.2/36.5 = 8.77×10^{-2} ; *p*H = **1.057 Ans.**]

7. When 0.001 mol of a base is added to 250 mL of a buffer solution, the pH of a buffer solution increases by 0.01 units. Calculate the buffer capacity of the system.

   [**Hint.** Buffer capacity = $\left(\frac{0.001 \times 1000}{250}\right) \times \frac{1}{0.01}$
   = 0.4 units. Ans.]

8. Calculate the pH of a buffer solution containing 0.25 mol NH_4Cl and 0.15 mol NH_4OH ($K_b = 1.8 \times 10^{-5}$).

   Ans. 9.034

9. Calculate the hydrolysis constant of a salt containing NO_2^- ions. [K_a (HNO_2) = 4.5×10^{-5}]. **Hint.** $K_h = K_w/K_a$ = $10^{-14}/4.5 \times 10^{-10}$). **Ans. 2.2×10^{-5}**

10. Calculate the solubility of silver chloride in 0.1M KCl. Given K_{sp} for AgCl equal to 2.8×10^{-10} at 25°C.

Ans. 2.8×10^{-9} mol L^{-}

11. The solubility of silver chromate (Ag_2CrO_4) is 2.2×10^{-2} gL^{-}. Determine the solubility product of Ag_2CrO_4. **Ans. 1.1×10^{-12} mol^3 L^{-3}**

12. Determine the solubility of Hg_2I_2 at 298K if K_{sp} (Hg_2I_2) = 4.5×10^{-29}. (**Hint.** $Hg_2I_2 \rightleftharpoons Hg_2^{2+} + 2I^-$)

Ans. $[Hg_2^{2+}] = 2.24 \times 10^{-10}$ M ; $[I^-] = 4.48 \times 10^{-10}$

13. The solubility of $PbSO_4$ in water is 0.038 gL^{-} at 25°C. Calculate its solubility product at the same temperature (mol. wt. of $BaSO_4$ = 303).

Ans. 1.57×10^{-8}

(UP 1981)

[**Hint,** solubility = $\dfrac{0.038}{303}$ mol L^{-}]

14. The equivalent conductivity of a weak acid at dilution of 256000 cm^3 is 23.82 ohm^{-} cm^2 $(equiv)^{-}$ at 298 K. At infinite dilution, it is 364 ohm^{-} cm^2 $(equiv)^{-}$. Calculate the dissociation constant of the acid. (**Hint.** $K = \alpha^2/(1-\alpha)V$ where $V = 256{,}000/1000$ = 256L ; $a = 23.82/364 = 0.0654$). **Ans. 1.788×10^{-7}**

15. 10^{-2} mol of NaOH was added to 10 litre of water. The *p*H of the solution will change by :

(*a*) *4* (*b*) *3*
(*c*) *2* (*d*) *1* **Ans.** (*a*)

16. 0.023 g of sodium metal is reacted with 100 cm^3 of water. The pH of resulting solution is:

(*a*) 10 (*b*) 11
(*c*) 9 (*d*) 12 **Ans.** (*d*)

(Karnataka CET, 2010)

17. A buffer solution contains 0.1 mol of sodium acetate in 100 cm^3 of 0.1 M acetic acid. To the above buffer solution, 0.1 mol of sodium acetate is further added and dissolved. The pH of the resulting buffer is:

(*a*) $pK_a - \log 2$ (*b*) pK_a
(*c*) $pK_a + 2$ (*d*) $pK_a + \log 2$

Ans. (*d*) **(Karnataka CET, 2010)**

18. One dm^3 solution containing 10^{-5} mol each of Cl^- ions and CrO_4^{2-} ions is treated with 10^{-4} mol of silver nitrate. Which one of the following observations is made; K_{sp} $Ag_2CrO_4 = 4 \times 10^{-12}$; K_{sp} (AgCl) = 1×10^{-10}

(*a*) Precipitation does not occur
(*b*) Ag_2CrO_4 is precipitated first
(*c*) AgCl is precipitated first
(*d*) Both Ag_2CrO_4 and AgCl get precipitated simultaneously. **Ans.** (*c*)

(Karnataka CET 2010)

19. The pH value of which of the following is not equal to one?

(*a*) 0.1 M HNO_3 (*b*) 0.05 M H_2SO_4
(*c*) 0.1 M CH_3COOH
(*d*) 50 cm^3 of 0.4 M HCl + 50 cm^3 of 0.2 M NaOH

Ans. (*c*)

(Karnataka CET, 2010)

20. At 25°C, the solubility product of $Mg(OH)_2$ is 1.0×10^{-11}. At which pH, will Mg^{2+} ions start precipitating in the form of $Mg(OH)_2$ from a solution of 0.001 Mg^{2+} ions?

(*a*) 8 (*b*) 9
(*c*) 10 (*d*) 11 **Ans.** (*c*)

(AIEEE, 2010)

21. Solubility product of $Mg(OH)_2$ is 4×10^{-12} mol L^{-}. Solubility of $Mg(OH)_2$ is:

(*a*) 4×10^{-4} mol L^{-} (*b*) 1×10^{-12} mol L^{-}
(*c*) 1×10^{-4} mol lit^{-} (*d*) 2×10^{-6} mol L^{-}

Ans. (*c*) **(Orissa JEE, 2010)**

22. The pH of 10^{-3} M NaOH is

(*a*) 3 (*b*) 11
(*c*) 4 (*d*) 12 **Ans.** (*b*)

(Orissa JEE, 2010)

23. The concentration of $[H^+]$ and $[OH^-]$ of 0.1 M aqueous solution of 2% ionised weak acid is: [K_{sp} (H_2O) = 1×10^{-14}]

(*a*) 2×10^{-3} and 5×10^{-12} M
(*b*) 1×10^{-3} M and 3×10^{-11} M
(*c*) 0.02×10^{-3} M and 5×10^{-11} M
(*d*) 3×10^{-2} M and 4×10^{-13} M **Ans.** (*a*)

(BHU, 2010)

24. If pH of a saturated solution of $Ba(OH)_2$ is 12, the value of its K_{sp} is:

(*a*) 4.0×10^{-6} M^3 (*b*) 4.0×10^{-7} M^3
(*c*) 5.0×10^{-6} M^3 (*d*) 5.0×10^{-7} M^3

Ans. (*d*) **(CBSE, PMT, 2010)**

25. In a buffer solution containing equal concentration of B^- and HB, the K_b for B^- is 10^{-10}. The pH of buffer solution is:

(*a*) 10 (*b*) 7
(*c*) 6 (*d*) 4 **Ans.** (*d*)

(CBSE, PMT, 2010)

25

CHAPTER

Estimation of Elements in Organic Compounds

25.1 ESTIMATION OF CARBON AND HYDROGEN BY LIEBIG'S METHOD

A known weight of an organic compound is burnt in excess of oxygen. Carbon and hydrogen present in it get oxidised to CO_2 and H_2O respectively.

$$C_xH_y + \left(x + \frac{y}{4}\right)O_2 \rightarrow xCO_2 + \frac{y}{2}H_2O$$

The weights of CO_2 and water are determined from the increase in the weights of potash bulbs and $CaCl_2$ u-tube respectively. From the weights of CO_2 and H_2O formed, the percentage of carbon and hydrogen are then calculated.

EXAMPLE 1. *In a Liebig's method, an organic compound weighing 0.198 g produced 0.524 g CO_2 and 0.132 g H_2O. Calculate the percentage of carbon and hydrogen in the given compound.*

SOLUTION. Wt. of compound = 0.198 g;

wt. of CO_2 = 0.524 g;

wt. of H_2O = 0.132 g.

(*i*) *To find % age of carbon.* $\underset{12+(2\times16)=44g}{CO_2} \equiv \underset{12g}{C}$

44 g CO_2 contain carbon

= 12g

0.524 g CO_2 contain carbon

$$= \frac{12}{44} \times 0.524 \text{ g}$$

∴ % age of carbon

$$= \frac{\text{wt. of C}}{\text{wt. of substance}} \times 100$$

$$= \frac{12 \times 0.524}{44} \times \frac{100}{0.198}$$

= **72.18%** **Ans.**

(*ii*) *To find % age of hydrogen.* $\underset{(2\times1)+16=18\,g}{H_2O} \equiv \underset{2\,g}{2H}$

18g H_2O contain hydrogen

= 2 g

0.132g H_2O contain hydrogen

$$= \frac{2}{18} \times 0.132 \text{ g}$$

∴ % age of hydrogen

$$= \frac{\text{wt. of H}}{\text{wt. of substance}} \times 100$$

$$= \frac{2 \times 0.132}{18} \times \frac{100}{0.198} = \mathbf{7.4\%}$$ **Ans.**

EXAMPLE 2. *An organic compound contains carbon, hydrogen and oxygen. In a Liebig's method, 0.2475 g of it was analysed. The increase in the weight of U-tube and the potash bulb at the end of operation was found to be 0.2025 g and 0.4950 g respectively. Calculate the percentage composition of the compound.*

SOLUTION. Wt. of compound = 0.2475 g;

wt. of CO_2 = increase in the wt. of potash bulb

= 0.4950 g;

wt. of H_2O = increase in the wt. of U-tube (containing $CaCl_2$) = 0.2025 g.

(*i*) *To find % age of carbon.* $\underset{12+(2\times16)=44g}{CO_2} \equiv \underset{12g}{C}$

44 g CO_2 contain carbon = 12 g

0.495 g CO_2 contain carbon $= \frac{12}{44} \times 0.495$ g

$$\%\text{ age of C} = \frac{\text{wt. of C}}{\text{wt. of substance}} \times 100$$

$$= \frac{12 \times 0.495}{44} \times \frac{100}{0.2475}$$

= **54.54%** **Ans.**

(*ii*) *To find percentage of hydrogen.* $\underset{(2\times1)+16=18\,g}{H_2O} \equiv \underset{2\times1=2\,g}{2H}$

18 g H_2O contain hydrogen = 2 g

0.2025 g H_2O contain hydrogen $= \frac{2}{18} \times 0.2025$ g

$$\therefore \quad \%\text{ age of hydrogen} = \frac{\text{wt. of hydrogen}}{\text{wt. of substance}} \times 100$$

$$= \frac{2\times 0.2025}{18}\times\frac{100}{0.2475} = 9.09\%$$

∴ % age of oxygen $= 100 - (54.54 + 9.09)$

$= \mathbf{36.37\%}$ **Ans.**

Example 3. *An organic compound contains 52.18% carbon and 13.04% hydrogen, the rest being oxygen. Calculate the masses of CO_2 and H_2O produced when 0.2346 g of this compound is subjected to complete combustion.*

Solution. We know that :

(*i*) % age of carbon

$$= \frac{12}{44}\times\frac{\text{mass of } CO_2 \text{ formed}}{\text{mass of organic compound}}\times 100$$

$$\left[\because \underset{12+(2\times 16)=44\,g}{CO_2} \equiv \underset{12\,g}{C}\right]$$

$$\therefore \quad 52.18 = \frac{12}{44}\times\frac{\text{mass of } CO_2 \text{ formed}}{0.2346}\times 100$$

$$\therefore \quad \text{Mass of } CO_2 \text{ formed} = \frac{52.18\times 44\times 0.2346}{12\times 100}$$

$= \mathbf{0.4488\ g}$ **Ans.**

(*ii*) % age of hydrogen

$$= \frac{2}{18}\times\frac{\text{mass of } H_2O \text{ formed}}{\text{mass of organic compound}}\times 100$$

$$\left[\because \underset{(2\times 1)+16=18\,g}{H_2O} \equiv \underset{2\times 1=2\,g}{2H}\right]$$

$$13.04 = \frac{2}{18}\times\frac{\text{mass of } H_2O \text{ formed}}{0.2346}\times 100$$

$$\therefore \text{Mass of } H_2O \text{ formed} = \frac{13.04\times 18\times 0.2346}{2\times 100} = \mathbf{0.2753\ g.}$$

25.2 ESTIMATION OF NITROGEN BY DUMA'S METHOD

A known weight of organic compound is mixed with CuO and heated in an atmosphere of CO_2. Volume of N_2 gas set free is collected over 40% KOH to absorb CO_2 and H_2O formed. This N_2 gas is now converted to N.T.P.

$$C_xH_yN_z + \left(2x+\frac{y}{2}\right)CuO \rightarrow xCO_2 +$$

$$\frac{y}{2}H_2O + \frac{z}{2}N_2 + \left(2x+\frac{y}{2}\right)\text{Cu compound}$$

Example 4. *0.2 g of an organic compound on combustion with CuO, gave 30.1 cm^3 of moist nitrogen at 15°C and 730.7 mm pressure. Calculate the percentage of nitrogen in the compound. (Aqueous tension at 15°C = 12.7 mm).*

Solution. Wt. of organic compound = 0.2 g.

$P_1 = 730.7 - 12.7 = 718$ mm, $V_1 = 30.1$ cm^3, $T_1 = 15 + 273 = 288$ K; at NTP, $P_2 = 760$ mm, $V_2 = ?$, $T_2 = 273$ K.

$$\text{We know, } \frac{P_1V_1}{T_1} = \frac{P_2V_2}{T_2} \text{ (Gas equation)}$$

$$\therefore \quad V_2 = \frac{P_1V_1T_2}{T_1\times P_2} = \frac{718\,\text{mm}\times 30.1\,\text{cm}^3\times 273\text{ K}}{288\text{ K}\times 760\,\text{mm}}$$

$= 26.96$ mL

But, 22400 mL of

N_2 weighs = g. mol. wt. of N_2 = 28 g

26.96 mL of

$$N_2 \text{ weighs} = \frac{28}{22400}\times 26.96 \text{ g}$$

$$\therefore \quad \%\text{ age of } N_2 = \frac{28\times 26.96}{22400}\times\frac{100}{0.2} = \mathbf{16.85\%} \quad \textbf{Ans.}$$

Example 5. *An organic compound having molecular formula C_4H_9N was analysed by Duma's method for the estimation of nitrogen in this compound. Calculate the volume of nitrogen liberated at N.T.P. from 2.1 g of the substance (at. wt., C = 12, H = 1, N = 14).*

Solution. Mol. wt. of

$C_4H_9N = (4 \times 12) + (9 \times 1) + 14 = 71$

Reaction :

$$\underset{1\,\text{mol}=71\,g}{C_4H_9N} \xrightarrow[\Delta]{CuO} 4CO_2 + \frac{9}{2}H_2O + \underset{\frac{1}{2}\text{mol}=\frac{1}{2}\times 22400=11200\text{ mL at NTP}}{\frac{1}{2}N_2}$$

71 g of C_4H_9N produce

N_2 at NTP = 11200 mL

∴ 2.1 g of C_4H_9N would produce

$$N_2 \text{ at NTP} = \frac{11200}{71}\times 2.1 = \mathbf{331.3\ mL}$$

Volume of

N_2 at N.T.P. = **331.3 mL** **Ans.**

Example 6. *An organic compound containing carbon, hydrogen, oxygen and nitrogen gave the following results on analysis. 0.27 g of the compound gave 0.396 g of CO_2 and 0.216 g water. 0.36 g of the same compound gave 48.88 mL of N_2 at 17°C and 740 mm pressure by Duma's method. Calculate the percentage composition of the compound.*

Solution. (*i*) Wt. of compound = 0.27 g

(*a*) *To find % age of C.* $\underset{12+(2\times 16)=44\,g}{CO_2} \equiv \underset{12\,g}{C}$

44 g CO_2 contain carbon = 12 g

$$0.396 \text{ g } CO_2 \text{ contain carbon} = \frac{12}{44}\times 0.396 \text{ g}$$

$$\therefore \quad \%\text{ age of C} = \frac{12\times 0.396}{44}\times\frac{100}{0.27}$$

$= \mathbf{40\%}$ **Ans.**

(*b*) *To find % age of hydrogen.* $\underset{(2\times 1)+16=18\,g}{H_2O} \equiv \underset{2\times 1=2\,g}{2H}$

18 g H_2O contain H = 2 g

$$0.216 \text{ g } H_2O \text{ contain H} = \frac{2}{18} \times 0.216 \text{ g}$$

$$\therefore \text{ \% age of H} = \frac{2 \times 0.216}{18} \times \frac{100}{0.27} = \mathbf{8.89\%}$$

(*c*) *To find % age of nitrogen.*

Wt. of substance = 0.36 g; $P_1 = 740$ mm, $V_1 = 48.88$ mL, $T_1 = 17 + 273 = 290$ K; at N.T.P., $P_2 = 760$ mm, $V_2 = ?$, $T_2 = 273$ K. We know,

$$\frac{P_1V_1}{T_1} = \frac{P_2V_2}{T_2} \text{ (gas equation);}$$

$$V_2 = \frac{P_1V_1}{T_1} \times \frac{T_2}{P_2}$$

$$\therefore \quad V_2 = \frac{740 \text{ mm} \times 48.88 \text{ mL} \times 273 \text{ K}}{290 \text{ K} \times 760 \text{ mm}}$$

$$= 44.8 \text{ mL}$$

22400 mL of N_2 at N.T.P. weighs

$$= \text{g. mol. wt. of } N_2 = 2 \times 14 = 28 \text{ g}$$

44.8 mL of N_2 at N.T.P. weighs

$$= \frac{28}{22400} \times 44.8 \text{ g}$$

$$\therefore \text{ \% age of nitrogen} = \frac{28 \times 44.8}{22400} \times \frac{100}{0.36} = \mathbf{15.56\%}$$

Ans.

$$\therefore \text{ \% age of oxygen} = 100 - (40 + 8.89 + 15.56)$$

$$= \mathbf{35.55\%}$$ **Ans.**

25.3 ESTIMATION OF NITROGEN BY KJELDAHL'S METHOD

A known weight of organic compound is digested with conc. H_2SO_4 to convert nitrogen present in the compound to $(NH_4)_2SO_4$. The latter is heated with alkali to get ammonia gas which is passed through excess of standard acid. The volume of unreacted acid is determined with standard alkali. From the amount of NH_3 evolved, the percentage of nitrogen is calculated.

Example 7. *0.45 g of an organic compound on Kjeldahl's analysis gave enough ammonia to just neutralise 20 mL of 0.1 M H_2SO_4. Calculate the percentage of nitrogen in the compound.*

SOLUTION. Wt. of organic compound = 0.45 g.

Volume of 0.1 M H_2SO_4 required to neutralise NH_3 = 20 mL.

$$\underset{\substack{2\text{mol}\\2\text{vol}}}{2NH_3} + \underset{\substack{1\text{mol}\\1\text{vol}}}{H_2SO_4} \rightarrow (NH_4)_2SO_4$$

20 mL of 0.1 M H_2SO_4 = 2 × 20 mL of 0.1 M NH_3 = 40 mL of 0.1 M NH_3

$$= \frac{40 \times 0.1 \text{M}}{1 \text{M}}$$

$$= 4 \text{ mL of 1 M } NH_3$$

But 1000 mL of 1 M NH_3 = 14 g N

$$\therefore \quad 4 \text{ mL of 1 M } NH_3 = \frac{14}{1000} \times 4 \text{ gN}$$

$$\therefore \quad \text{\% age of nitrogen} = \frac{14 \times 4}{1000} \times \frac{100}{0.45} = \mathbf{12.4\%} \quad \textbf{Ans.}$$

or 1000 mL of 1 M NH_3 = 14 g N

$$40 \text{ mL of 0.1 M } NH_3 = \frac{14}{1000} \times 40 \times 0.1 = 0.056 \text{ g of N.}$$

$$\therefore \quad \text{\%age of nitrogen} = \frac{0.056}{0.45} \times 100 = \mathbf{12.4\%} \quad \textbf{Ans.}$$

Example 8. *An organic compound weighing 0.354 g on analysis by Kjeldahl's method gave ammonia which was absorbed in 70 mL of M/10 H_2SO_4. The excess of the acid required 40 mL of M/5 NaOH for complete neutralisation. (i) The percentage of nitrogen in the compound and (ii) amount of NH_3 formed is:*

(*a*) 25, 0.4
(*b*) 27, 0.5
(*c*) 23.73, 0.102
(*d*) 18.1, 0.9
(*e*) 11.11, 0.8

(Kerala, PMT, 2012)

Solution. (*i*) Volume of H_2SO_4 of molarity M/10 taken = 70 mL.

$$\frac{(M_1V_1) \text{ Residual } H_2SO_4}{(M_2V_2) \text{NaOH}} = \frac{1}{2}$$

$$\left(\because \ \underset{2\text{mol}}{2\text{NaOH}} + \underset{1\text{mol}}{H_2SO_4} \rightarrow Na_2SO_4 + 2H_2O \right)$$

$$\frac{\frac{1}{10} \times V_1}{40 \times \frac{1}{5}} = \frac{1}{2}; \ V_1 = 40 \times \frac{1}{5} \times \frac{10}{2} = 40 \text{ mL}$$

$\therefore$ Volume of M/10 acid left unused = 40 mL

Volume of M/10 H_2SO_4 used by NH_3

$$= 70 - 40 = 30 \text{ mL}$$

$$\therefore \quad 30 \text{ mL of } \frac{M}{10} H_2SO_4 \equiv 2 \times 30 \text{ mL of } \frac{M}{10} NH_3$$

$$= 60 \text{ mL of } \frac{M}{10} NH_3$$

$$(\because 2NH_3 + H_2SO_4 \rightarrow (NH_4)_2SO_4)$$

But, 1000 mL of
1 M NH_3 contain nitrogen = 14 g

$$60 \text{ mL of } \frac{M}{10} H_2SO_4 \text{ contain nitrogen} = \frac{14}{1000} \times 60 \times \frac{1}{10} \text{g}$$

$$\therefore \quad \text{\% age of nitrogen} = \frac{14 \times 60}{1000} \times \frac{1}{10} \times \frac{100}{0.354}$$

$$= \mathbf{23.73\%}$$ **Ans.**

(*ii*) *To find weight of NH_3 formed*

1000 mL of 1 M NH_3 contain NH_3

$$= \text{g. mol. wt. of } NH_3 = 14 + (3 \times 1) = 17 \text{ g}$$

∴ 60 mL of $\frac{M}{10}$ NH_3 contain NH_3

$$= \frac{17}{1000} \times 60 \times \frac{1}{10} = \mathbf{0.102\ g}$$

∴ **Wt. of NH_3 formed = 0.102g** **Ans.**

So, the correct answer is (*c*).

EXAMPLE 9. *An organic compound weighing 0.4 g was Kjeldahlised and ammonia gas produced was absorbed in 50 mL of M/4 H_2SO_4. The residual acid solution was diluted with distilled water and the volume was made up to 150 mL. The 20 mL of this diluted solution required 31mL of 0.05 M NaOH for complete neutralisation. Calculate the percentage of nitrogen in the compound.*

SOLUTION.

Wt. of compound = 0.4 g.

Volume of $\frac{M}{4}$ H_2SO_4 required to absorb ammonia

= 50 mL

(*i*) $\underset{2\,\text{mol}}{2NaOH} + \underset{1\,\text{mol}}{H_2SO_4} \rightarrow Na_2SO_4 + 2H_2O$

$$\frac{M_1V_1 \text{ (diluted acid)}}{M_2V_2 \text{ (NaOH)}} = \frac{1\,\text{mol}}{2\,\text{mol}}; M_1 \times 20 = \frac{0.05 \times 31}{2};$$

$$M_1 \text{ (dil. acid)} = \frac{0.05 \times 31}{2 \times 20}$$

(*ii*) To find volume of $\frac{M}{4}$ original H_2SO_4 left used

$$M_3V_3 \text{ (dil. acid)} = M_4V_4 \text{ (original acid)}$$

$$\frac{0.05 \times 31}{2 \times 20} \times 150 = \frac{1}{4} \times V_4;$$

$$V_4 = \frac{0.05 \times 31 \times 150 \times 4}{2 \times 20} = 23.25 \text{ mL}$$

∴ Volume of $\frac{M}{4}$ H_2SO_4 used = 50 – 23.25 = 26.75 mL

Now, 26.75 mL of $\frac{M}{4}$ H_2SO_4 = 2 × 26.75 mL of $\frac{M}{4}$ NH_3

$$\left(\because \underset{2\,\text{mol}}{2NH_3} + \underset{1\,\text{mol}}{H_2SO_4} \rightarrow (NH_4)_2SO_4 \right)$$

But, 1000 mL of 1M NH_3 contain nitrogen

= g. at. wt. of N = 14 g

∴ 2 × 26.75 mL of $\frac{1}{4}$ M NH_3 contain nitrogen

$$= \frac{14}{1000} \times 2 \times 26.75 \times \frac{1}{4} \text{g}$$

$$\therefore \quad \text{\% age of nitrogen} = \frac{14 \times 2 \times 26.75}{1000 \times 4} \times \frac{100}{0.4}$$

= **46.81%** **Ans.**

Type. To find % age of N_2 when normality of H_2SO_4 is given.

EXAMPLE 10. *Ammonia gas evolved in Kjeldahl estimation from 1.61 g of organic compound, was passed through 250 mL of seminormal H_2SO_4. The residual acid was diluted to one litre with distilled water. 25 mL of the diluted acid required 25.5 mL of decinormal NaOH for complete neutralisation. Calculate the percentage of nitrogen in the organic compound and also the amount of ammonia produced.*

SOLUTION. Wt. of organic compound = 1.61 g

Volume of original $\frac{N}{2}$ H_2SO_4 taken = 250 mL

(*i*) *To find normality of diluted H_2SO_4.*

Diluted acid NaOH solution

$$N_1V_1 = N_2V_2$$

$$N_1 \times 25 = \frac{1}{10} \times 25.5;$$

$$N_1 = \frac{25.5}{10 \times 25} = 0.102$$

(*ii*) *To find volume of used $\frac{N}{2}$ H_2SO_4 by NH_3*

Diluted acid Original acid

$$N_3V_3 = N_4V_4$$

$$0.102 \times 1000 = \frac{1}{2} \times V_4;$$

$$V_4 = 2 \times 0.102 \times 1000 = 204 \text{ mL}$$

Volume of unused $\frac{N}{2}$ H_2SO_4 = 204 mL

∴ Volume of used $\frac{N}{2}$ H_2SO_4 = 250 – 204 = 46 mL

∴ 46 mL of $\frac{N}{2}$ H_2SO_4 ≡ 46 mL of $\frac{N}{2}$ NH_3.

(*iii*) *To find % age of nitrogen.*

1000 mL of 1N NH_3 contain nitrogen

= g. at. wt. of N = 14 g

∴46 mL of $\frac{N}{2}$ NH_3 contain nitrogen

$$= \frac{14}{1000} \times 46 \times \frac{1}{2} \text{g}$$

$$\therefore \quad \text{\% age of nitrogen} = \frac{14 \times 46 \times 1}{1000 \times 2} \times \frac{100}{1.61} = \mathbf{20\%} \quad \textbf{Ans.}$$

(*iv*) *To find amount of ammonia NH_3.*

[mol. wt. = 14 + (3 × 1) = 17g]

1000 mL of 1N NH_3 ≡ g. eq. wt. of NH_3 = 17g

$$\therefore \quad 46 \text{ mL of } \frac{N}{2} NH_3 \equiv \frac{17}{1000} \times 46 \times \frac{1}{2} = \mathbf{0.391\ g}$$

Ans.

EXAMPLE 11. *0.236 g of an organic compound on distillation with caustic soda solution yielded ammonia which required 40 mL of decinormal sulphuric acid for complete neutralisation. Calculate the percentage of nitrogen in the compound.*

Solution.

Wt. of substance = 0.236 g

$$40 \text{ mL of } \frac{N}{10} H_2SO_4 \equiv 40 \text{ mL of } \frac{N}{10} NH_3$$

But, 1000 mL of 1 N NH_3 contain nitrogen

= g. at. wt. of nitrogen = 14 g

∴ 40 mL of $\frac{N}{10}$ NH_3 contain nitrogen

$$= \frac{14}{1000} \times 40 \times \frac{1}{10} = 0.056 \text{ g}$$

$$\therefore \quad \% \text{ age nitrogen} = \frac{\text{wt. of nitrogen}}{\text{wt. of substance}} \times 100$$

$$= 0.056 \times \frac{100}{0.236} = \mathbf{23.73\%} \textbf{ Ans.}$$

Example 12. *0.26 g of an organic compound was Kjeldahlised and NH_3 gas evolved was absorbed in 45 mL of decinormal hydrochloric acid which further required 18.0 mL of decinormal NaOH for complete neutralisation. Calculate the percentage of nitrogen in the compound.*

Solution. Wt. of organic compound = 0.26 g

(*i*) *To find volume of HCl used by NH_3.*

$$\begin{aligned} &\text{HCl} \quad \text{NaOH} \\ N_1V_1 &= N_2V_2 \text{ (normality equation)} \\ \frac{1}{10} \times V_1 &= \frac{1}{10} \times 18\,; \\ V_1 &= \frac{1}{10} \times 18 \times 10 = 18 \text{ mL} \end{aligned}$$

∴ Volume of unused

HCl = 18 mL

Hence, volume of used

HCl by NH_3 = 45 – 18 = 27 mL

$$27 \text{ mL of } \frac{N}{10} \text{ HCl} = 27 \text{ mL of } \frac{N}{10} NH_3$$

But, 1000 mL of 1N NH_3 contain nitrogen

= g. at. wt. of nitrogen = 14 g

∴ 27 mL of $\frac{N}{10}$ NH_3 contain nitrogen

$$= \frac{14}{1000} \times 27 \times \frac{1}{10} \text{g}$$

$$\% \text{ age of nitrogen} = \frac{14 \times 27}{1000 \times 10} \times \frac{100}{0.26}$$

$$= \mathbf{14.54\%} \qquad \textbf{Ans.}$$

25.4 ESTIMATION OF HALOGENS (Cl, Br AND I) BY CARIUS METHOD

A known weight of organic compound is heated with fuming nitric acid and solid $AgNO_3$ in a sealed tube called carius tube. The halogens (Cl, Br or I) present in the organic compound changes into silver halide (AgCl, AgBr or AgI) precipitate. The latter is separated, washed, dried and weighed. From the weight of silver halide, the percentage of halogen in the compound is calculated.

Example 13. *In a carius method, 0.24 g of an organic substance was heated with fuming nitric acid and solid $AgNO_3$. As a result, 0.31 g of dry silver chloride was obtained. Calculate the percentage of Cl in the given substance. (at. wt., Ag = 108, Cl = 35.5).*

Solution. Wt. of organic substance= 0.24 g.

Wt. of AgCl ppt = 0.31 g.

$$\text{We know,} \quad \underset{108+35.5=143.5\text{g}}{\text{AgCl}} \equiv \underset{35.5\text{g}}{\text{Cl}}$$

143.5 g AgCl contain Cl= 35.5 g

$$0.31 \text{ g AgCl contain Cl} = \frac{35.5}{143.5} \times 0.31\text{g}$$

$$\% \text{ age of Cl} = \frac{\text{wt. of Cl}}{\text{wt. of substance}} \times 100$$

$$= \frac{35.5 \times 0.31}{143.5} \times \frac{100}{0.24}$$

$$= \mathbf{31.95\%} \qquad \textbf{Ans.}$$

Example 14. *In a carius method, 0.31 g of an organic compound yielded 0.296 g of silver bromide. Calculate the percentage of bromine in the organic compound. (At. wt. Ag = 108, Br = 80).*

Solution. Wt. of

organic substance = 0.31 g.

Wt. of AgBr ppt = 0.296 g

$$\text{We know :} \quad \underset{108+80=188\text{g}}{\text{AgBr}} \equiv \underset{80\text{g}}{\text{Br}}$$

188 g AgBr contain Br = 80 g;

$$0.296 \text{ g AgBr contain Br} = \frac{80}{188} \times 0.296\text{g}$$

$$\% \text{ age of Br} = \frac{\text{wt. of Br}}{\text{wt. of substance}} \times 100$$

$$= \frac{80 \times 0.296}{188} \times \frac{100}{0.31}$$

$$= \mathbf{40.63\%} \qquad \textbf{Ans.}$$

Example 15. *An organic compound weighing 0.197 g was heated with fuming nitric acid and solid $AgNO_3$ in a carius tube. As a result, 0.3525 g of dry silver iodide was obtained. Calculate the percentage of iodine in the given compound.*

(At. wt. Ag = 108, I = 127).

Solution. Wt. of

organic compound = 0.197 g;

Wt. of Ag I ppt = 0.3525 g

$$\text{We know :} \quad \underset{108+127=235\text{g}}{\text{Ag I}} \equiv \underset{127\text{g}}{\text{I}}$$

235 g Ag I contain I = 127 g

$$0.3525 \text{ g Ag I contain I} = \frac{127}{235} \times 0.3525\text{g}$$

$$\therefore \quad \%\text{ age of I} = \frac{\text{wt. of I}}{\text{wt. of substance}} \times 100$$

$$= \frac{127 \times 0.3525}{235 \times 0.197} \times 100$$

$$= \mathbf{96.7\%}$$ **Ans.**

25.5 ESTIMATION OF SULPHUR BY CARIUS METHOD

A known weight of organic compound is heated with fuming nitric acid in a carius tube. Sulphur present in the organic substance is oxidised to sulphuric acid. The resulting solution is treated with excess of barium chloride solution to get barium sulphate precipitate. From the weight of dry $BaSO_4$ ppt, the percentage of sulphur can be calculated.

Example 16. *An organic compound weighing 0.3198 g was heated with fuming nitric acid in a carius tube. The resulting solution was treated with excess of* $BaCl_2$ *solution to get 0.2330 g dry* $BaSO_4$*. Calculate the percentage of sulphur in the organic compound (at. wt., Ba = 137, S = 32, O = 16).*

Solution. Wt. of organic substance = 0.3198 g;
Wt. of $BaSO_4$ = 0.233 g

$$\underset{\substack{137+32+(4\times16)\\=233\text{ g}}}{BaSO_4} \equiv \underset{32\text{g}}{S}$$

233 g $BaSO_4$ contain sulphur = 32 g

$$0.233 \text{ g } BaSO_4 \text{ contain sulphur} = \frac{32}{233} \times 0.233 \text{ g}$$

$$\%\text{ age of sulphur} = \frac{\text{wt. of S}}{\text{wt. of substance}} \times 100$$

$$= \frac{32 \times 0.233}{233} \times \frac{100}{0.3198}$$

$$= \mathbf{10.0\%}$$ **Ans.**

Example 17. *An organic compound contains C, H, O and sulphur. Its analysis was done as under :*

(i) 0.167 g of it on combustion gave 0.456 g CO_2 *and 0.0666 g* H_2O.

(ii) 0.125 g of the substance on being heated with nitric acid and barium chloride gave 0.13 g barium sulphate. Calculate the percentage of C, H, O and sulphur in the given compound.

Solution. (*i*) Wt. of organic substance = 0.167 g;
Wt. of CO_2 = 0.456 g

$$\underset{12+(2\times16)=44\text{ g}}{CO_2} \equiv \underset{12\text{g}}{C}$$

44 g CO_2 contain carbon = 12 g

$$0.456 \text{ g } CO_2 \text{ contain carbon} = \frac{12}{44} \times 0.456 \text{ g}$$

$$\%\text{ age of carbon} = \frac{\text{wt. of C}}{\text{wt. of substance}} \times 100$$

$$= \frac{12 \times 0.456}{44} \times \frac{100}{0.167} = \mathbf{74.47\%}$$

(*ii*) Wt. of substance = 0.167 g;
Wt. of H_2O = 0.0666 g

$$\underset{(2\times1)+16=18\text{g}}{H_2O} \equiv \underset{2\times1=2\text{g}}{2H}$$

18 g water contain H = 2 g

0.0666 g water contains

$$H = \frac{2}{18} \times 0.0666 \text{g}$$

$$\therefore \quad \%\text{ age of hydrogen} = \frac{\text{wt. of H}}{\text{wt. of substance}} \times 100$$

$$= \frac{2 \times 0.0666}{18} \times \frac{100}{0.167} = 4.43\%$$

(*iii*) Wt. of substance = 0.125 g;
Wt. of $BaSO_4$ = 0.13 g

$$\underset{\substack{137+32+(4\times16)\\=233\text{ g}}}{BaSO_4} \equiv \underset{32\text{g}}{S}$$

233 g $BaSO_4$ contain sulphur = 32 g;

$$0.13 \text{ g } BaSO_4 \text{ contain sulphur} = \frac{32}{233} \times 0.13 \text{g}$$

$$\therefore \quad \%\text{ age of sulphur} = \frac{\text{wt. of S}}{\text{wt. of substance}} \times 100$$

$$= \frac{32 \times 0.13}{233} \times \frac{100}{0.125} = 14.28\%$$

(*iv*) $\therefore$ % age of oxygen = 100 – (74.47 + 4.43 + 14.28)
= **6.82%** **Ans.**

25.6 ESTIMATION OF PHOSPHORUS BY CARIUS METHOD

A known weight of organic compound is heated with fuming nitric acid in a carius tube to get phosphoric acid. The latter is treated with magnesia mixture ($MgCl_2$ + NH_4Cl + NH_4OH) to get precipitate of magnesium ammonium phosphate, $MgNH_4PO_4$. The latter precipitate is heated to get magnesium pyrophosphate $Mg_2P_2O_7$ from which the percentage of phosphorus can be calculated.

Example 18. *0.298 g of an organic compound containing phosphorus gave 0.5314 g* $Mg_2P_2O_7$*, in a carius estimation. Calculate the percentage of phosphorus in this compound. (At. wt., Mg = 24, P = 31, O = 16).*

Solution. Wt. of organic substance = 0.298 g;
Wt. of $Mg_2 P_2O_7$ = 0.5314 g

$$\underset{\substack{(2\times24)+(2\times31)+(7\times16)\\=222\text{g}}}{Mg_2P_2O_7} \equiv \underset{2\times31=62\text{g}}{2P}$$

222 g $Mg_2P_2O_7$ contain phosphorus = 62 g

$$0.5314 \text{ g } Mg_2P_2O_7 \text{ contain phosphorus} = \frac{62}{222} \times 0.5314 \text{ g}$$

$$\therefore \text{ \% age of phosphorus} = \frac{\text{Wt. of P}}{\text{Wt. of substance}} \times 100$$

$$= \frac{62 \times 0.5314 \times 100}{222 \times 0.298}$$

$$= \mathbf{49.8\%} \qquad \textbf{Ans.}$$

Note: Oxygen element can be estimated as:

$$\text{\% age of oxygen} = 100 - \left[\begin{array}{l}\text{sum total of \% ages of all the other} \\ \text{elements in the given organic compound.}\end{array}\right]$$

25.7 AIEEE PATTERN EXAMPLES

Example 19. *In a Liebig's method to estimate carbon in an organic compound, 0.2 g of the latter produced 0.532g CO_2. The percentage of carbon in this compound is :*

(1) 36.27 *(2) 72.54*

(3) 90 *(4) 45*

Solution. Wt. of organic substance = 0.2 g;

Wt. of CO_2 = 0.532g

$$\underset{\substack{12+(2\times16)\\=44\,g}}{CO_2} \equiv \underset{12g}{C}$$

44 g CO_2 contain carbon = 12 g

0.532 g CO_2 contain carbon

$$= \frac{12}{44} \times 0.532 \text{ g}$$

$$\therefore \quad \text{\% age of carbon} = \frac{\text{wt. of C}}{\text{wt. of substance}} \times 100$$

$$= \frac{12 \times 0.532}{44 \times 0.2} \times 100 = \mathbf{72.54\%}$$

So, the correct answer is (2)

Example 20. *0.316 g of an organic compound containing hydrogen and carbon produced 0.272 g water. The % age of hydrogen in the compound is*

(1) 9.56 *(2) 4.78*

(3) 2.39 *(4) 19.12*

Solution. Wt. of organic substance = 0.316 g

Wt. of H_2O = 0.272 g

$$\underset{(2\times1)+(1\times16)=18\,g}{H_2O} \equiv \underset{2\times1=2g}{2H}$$

18 g H_2O contain H = 2 g

$$0.272 \text{ g } H_2O \text{ contains H} = \frac{2}{18} \times 0.272 \text{ g}$$

$$\text{\% age of H} = \frac{\text{wt. of H}}{\text{wt. of substance}} \times 100$$

$$= \frac{2 \times 0.272}{18} \times \frac{100}{0.316} = \mathbf{9.56\%}$$

So, the correct answer is (1).

Example 21. *0.246 g of an organic compound yielded 31.2 mL of N_2 gas at N.T.P. by Duma's method. The percentage of N_2 in the organic compound is*

(1) 31.70 *(2) 3.17*

(3) 15.85 *(4) 1.6*

Solution.

Wt. of substance = 0.246 g;

Volume of N_2 gas at N.T.P. = 31.2 mL.

22400 mL of N_2 weighs = g. mol. wt. of N_2 = 2 × 14 = 28 g

$$31.2 \text{ mL of } N_2 \text{ weighs} = \frac{28}{22400} \times 31.2\text{g}$$

$$\therefore \quad \text{\% age of } N_2 = \frac{\text{wt. of } N_2}{\text{wt. of substance}} \times 100$$

$$= \frac{28 \times 31.2}{22400} \times \frac{100}{0.246} = \mathbf{15.85\%}$$

So, the correct answer is (3).

Example 22. *1.2 g of organic compound on Kjeldahlization liberates ammonia which consumes 30 cm^3 of 1 M HCl. The percentage of nitrogen in the compound is :*

(a) 30 *(b) 35*

(c) 46.67 *(d) 20.8* **(Karnataka CET, 2011)**

Solution.

Wt. of organic compound = 1.2 g;

normality of acid = 1,

volume consumed for NH_3 = 30 cm^3.

% age of nitrogen = 1.4 × normality of acid × volume of acid used for NH_3

$$= \frac{1.4 \times 1 \times 30}{1.2} = 35.$$

So, the correct answer is (*b*).

Example 23. *0.5 g of an organic compound on Kjeldahl's analysis gave enough ammonia to just neutralise 25 mL of 0.08 M H_2SO_4. The % age of nitrogen in the compound is :*

(1) 1.9 *(2) 1.8*

(3) 10.7 *(4) 11.2*

Solution. Wt. of organic substance = 0.5 g

Volume of 0.08 M H_2SO_4 required to neutralise NH_3 = 25 mL.

$$\underset{2\,mol}{2NH_3} + \underset{1\,mol}{H_2SO_4} \rightarrow (NH_4)_2SO_4$$

25 mL of 0.08 M H_2SO_4 = 2 × 25 mL of 0.08 M NH_3 = 50 mL of 0.08 M NH_3

But 1000 mL of 1 M NH_3 = 14 g N

$$50 \text{ mL of 0.08 M } NH_3 = \frac{14}{1000} \times 50 \times 0.08 \text{ g nitrogen}$$

$$\therefore \quad \text{\% age of nitrogen} = \frac{\text{wt. of nitrogen}}{\text{wt. of substance}} \times 100$$

$$= \frac{14 \times 50 \times 0.08 \times 100}{1000 \times 0.5} = \mathbf{11.2\%}$$

So, the correct answer is (4).

Example 24. *An organic compound weighing 0.2562 g gave 0.2998 g of silver bromide. The percentage of bromine in this compound is :*

(1) 36.36 (2) 18.18

(3) 40.34 (4) 49.79

Solution. Wt. of organic compound = 0.2562 g;

Wt. of silver bromide = 0.2998 g

$$\underset{108+80=188\text{ g}}{\text{AgBr}} \equiv \underset{80\text{g}}{\text{Br}}$$

188 g AgBr contain Br = 80 g; 0.2998 g AgBr contains

$$\text{Br} = \frac{80}{188} \times 0.2998 \text{ g}$$

$$\% \text{ age of bromine} = \frac{\text{wt. of Br}}{\text{wt. of substance}} \times 100$$

$$= \frac{80 \times 0.2998}{188} \times \frac{100}{0.2562} = \mathbf{49.79\%}$$

So, the correct answer is (4).

Example 25. *In Kjeldahl method, ammonia from 5.0 g of food neutralises 30 cm^3 of 0.1 N acid. The % age of nitrogen in the food is :*

(*a*) 0.84 (*b*) 8.4

(*c*) 16.8 (*d*) 1.68 **(Karnataka CET, 2010)**

Solution. % age of N = 1.4 × N_1 × V/w = 1.4 × 0.1 × 30/5 = **0.84%**. So, the correct answer is (*a*)

Example 26. *In a carius determination of sulphur, 0.16g of an organic compound gave 0.4908g of barium sulphate. The % age of sulphur in the compound is :*

(1) 42.13 (2) 84.26

(3) 60.1 (4) 17.98

(AFMC, 2012)

Solution.

Wt. of substance = 0.16g;

Wt. of $BaSO_4$ = 0.4908 g

$$\underset{\substack{137+32+(4\times16)\\=233\text{g}}}{BaSO_4} \equiv \underset{32\text{g}}{S}\ ; \quad 233 \text{ g } BaSO_4 \text{ contain sulphur} = 32 \text{ g}$$

0.4908 g $BaSO_4$ contains sulphur

$$= \frac{32}{233} \times 0.4908 \text{ g}$$

$$\therefore \quad \% \text{ age of sulphur} = \frac{32 \times 0.4908}{233} \times \frac{100}{0.16} = \mathbf{42.13\%}$$

So, the correct answer is (1).

Example 27. *0.155 g of an organic compound containing phosphorus gave 0.275 g of $Mg_2P_2O_7$ in a carius estimation. The percentage of phosphorus in the compound is :*

(1) 98.1 (2) 24.75

(3) 49.55 (4) 73.75

Solution. Wt. of

organic substance = 0.155 g;

Wt. of $Mg_2P_2O_7$ = 0.275 g

$$\underset{\substack{(2\times24)+(2\times31)+(7\times16)\\=222\text{ g}}}{Mg_2P_2O_7} \equiv \underset{2\times31=62\text{ g}}{2P}$$

222 g $Mg_2P_2O_7$ contain phosphorus

= 62 g

0.275 g $Mg_2P_2O_7$ contains phosphorus

$$= \frac{62}{222} \times 0.275 \text{ g}$$

$$\% \text{ age of phosphorus} = \frac{62 \times 0.275}{222} \times \frac{100}{0.155} = \mathbf{49.55\%}$$

So, the correct answer is (3).

PROBLEMS FOR PRACTICE

1. An organic compound weighing 0.354 g containing C, H, N and oxygen gave on combustion by Liebig's method, 0.528 g CO_2 and 0.27 g water. Calculate the percentage of carbon and hydrogen in this compound. (**Ans.** C = 40.68%, H = 8.48%)

Hint. Consult example, 1.

2. An organic compound weighing 0.25 g contains carbon, hydrogen and oxygen. On analysis by Liebig's method, an increase in weights of calcium chloride U-tube and potash bulbs were found to be 0.15 g and 0.1837 g respectively. Calculate the percentage composition of the compound.

(**Ans.** % C = 20.04; % H = 6.66%; O = 73.3)

Hint. Consult example, 2.

3. An organic nitrogenous compound has molecular formula C_3H_7N. It was analysed by Duma's method. Calculate the volume of N_2 gas at NTP produced from 1.5 g of this compound. (**Ans.** 294.74 mL)

Hint. Consult example, 5.

4. In a Duma's method for the estimation of nitrogen, 0.3 g of an organic compound gave 50 mL of nitrogen collected at 300 K temperature and 715 mm pressure. (Aqueous tension at 300 K = 15 mm). Calculate the percentage of nitrogen in the compound.

(**Ans.** 17.46%)

Hint. Consult example, 4.

5. During the estimation of nitrogen by Kjeldahl's method, the NH_3 gas evolved from 0.5 g of the compound neutralised 10 mL of 1M H_2SO_4. Calculate the percentage of nitrogen in the compound.

(**Ans.** 56%)

Hint. Consult example, 7.

6. An organic compound weighing 0.35 g was Kjeldahlised and NH_3 gas evolved was absorbed in 100 mL of 0.1 M H_2SO_4. The residual acid required

154 mL of M/40 NaOH for complete neutralisation. Calculate the % age of nitrogen in the compound. **(Ans.** 18.4%**)**

Hint. Consult example, 8.

7. An organic compound weighing 0.5 g was Kjeldahlised and ammonia gas produced was absorbed in 45 mL of M/4 H_2SO_4. The residual solution was diluted to 100 mL. The 20 mL of this diluted solution required 35 mL of M/20 NaOH for complete neutralisation. Calculate the percentage of nitrogen in the compound. **(Ans.** 38.5%**)**
8. An organic compound weighing 0.246 g gave 0.248 g dry silver chloride. Calculate the percentage of chlorine in the compound. (At. wt., Ag = 108, Cl = 35.5). **(Ans.** 24.94% Cl**)**

   Hint. Consult example, 13.
9. In a carius determination of halogens, 0.18 g of an organic compound gave 0.145 g of silver bromide. Calculate the percentage of bromine in the compound. (At. wt., Ag = 108, Br = 80). **(Ans.** 34.28% Br**)**

   Hint. Consult example, 14.
10. 0.229 g of an organic compound when heated with excess of strong HNO_3 and solid $AgNO_3$ yielded 0.41 g of silver iodide. Calculate the percentage of iodine in the organic compound. (At. wt., Ag = 108, I = 127). **(Ans.** 96.76%**)**

    Hint. Consult example, 15.
11. In a carius method, 0.2746 g of an organic compound gave 0.37 g of barium sulphate. Calculate the percentage of sulphur in the compound. **(Ans.** 18.5%**)**

    Hint. Consult example, 16.
12. An organic compound weighing 0.375 g and containing phosphorus was heated with conc. HNO_3 in the carius tube. The phosphoric acid thus formed was precipitated with magnesia mixture as $MgNH_4PO_4$. The latter when ignited after washing and drying left a residue of 0.6273 g of $Mg_2P_2O_7$. Calculate the % age of phosphorus in the given compound (At. wt. Mg = 24, P = 31, O = 16) **(Ans.** 46.72%**)**

    Hint. Consult example, 18.

Note. For more problems and their solution, see appendix (*i*).

26

CHAPTER

Empirical and Molecular Formulae

26.1 PERCENTAGE COMPOSITION

The percentage composition of a compound is a relative weight of each of its constituent elements in 100 parts of it. Mathematically :

% age composition of each component in the compound

$$= \frac{\text{wt. of each component}}{\text{mol. wt.}} \times 100$$

Type. To find mol. wt.

Example 1. *Calculate the molecular weight of the following compounds (i) Green vitriol or ferrous sulphate crystals ($FeSO_4$. 7 H_2O). (At. wt. S = 32, O = 16, Fe = 56, H = 1).*

Solution. (*i*) ***$FeSO_4 . 7H_2O$.***

1 atom of Fe = 1 × 56 = 56 a.m.u. or 56 u
1 atom of S = 1 × 32 = 32 a.m.u.
11 atoms of O = 11 × 16 = 176 a.m.u.
14 atoms of H = 14 × 1 = 14 a.m.u.

∴ Mol. wt. of $FeSO_4 . 7H_2O$

= 56 + 32 + 176 + 14

= **278 a.m.u.** Ans.

Example 2. *Blood contains red coloured compound haemoglobin. The latter contains 0.355% of iron (at. wt. 56). Calculate the mol. wt. of haemoglobin if four atoms of iron are present in one molecule of it.*

Solution. ***Haemoglobin.*** 4 atoms of

Fe = 4 × 56 = 224 a.m.u.

0.355 parts of Fe correspond to haemoglobin

= 100 parts

∴ 224 parts of Fe correspond to haemoglobin

$$= \frac{100}{0.355} \times 224 = 63098$$

∴ Mol. wt. of haemoglobin

= **63098 a.m.u.** Ans.

Type. % age composition of a compound

$$= \frac{\text{wt. of each component}}{\text{mol. wt.}} \times 100$$

Example 3. *Calculate the percentage composition of $BaCl_2 . 2H_2O$. Also find the weight of barium and water of crystallisation in 20 g of the crystals. (At. wt., Ba = 137.5, Cl = 35.5, H = 1, O = 16).*

Solution. Mol. wt. of $BaCl_2 . 2H_2O$ = 137.5 + (2 × 35.5) + 2 [(2 × 1) + 16)] = 137.5 + 71 + 36 = 244.5 a.m.u.

$$\therefore \quad \text{\% age of Ba} = \frac{137.5 \times 100}{244.5} = 56.24\,;$$

$$\text{\% age of Cl} = \frac{71 \times 100}{244.5} = 29.04$$

$$\text{\% age of H} = \frac{4 \times 100}{244.5} = 1.64\,;$$

$$\text{\% age of O} = \frac{32 \times 100}{244.5} = 13.08;$$

$$\text{\% age of } H_2O = \frac{36}{244.5} \times 100 = 14.72$$

Wt. of Ba in 20 g of $BaCl_2 . 2\,H_2O$

$$= \frac{137.5 \times 20}{244.5} = 11.25 \text{ g}$$

$$\left[\because \underset{244.5}{BaCl_2.2H_2O} \equiv \underset{137.5}{Ba}\right]$$

Wt. of H_2O in 20 g of $BaCl_2 . 2H_2O$

$$= \frac{36 \times 20}{244.5} = 2.94 \text{ g}$$

$$\left[\because \underset{244.5}{BaCl_2.2H_2O} \equiv \underset{36}{2H_2O}\right]$$

Example 4. *Calculate the percentage composition of microcosmic salt (sodium ammonium hydrogen phosphate tetrahydrate) $NaNH_4HPO_4$; 4 H_2O; Cr = 52, P = 31, Na = 23, N = 14, O = 16].*

Solution.

Mol. wt. of $NaNH_4\,HPO_4 . 4\,H_2O$ = 23 + 14 + 4 × 1 + 1 + 31 + 4 × 16 + 4 (2 + 16) = 209

$$\begin{aligned}
\text{1 atom of Na} &= 23 \times 1 = 23 \text{ a.m.u.}\\
\text{\% age of Na} &= \frac{23}{209} \times 100 = 11\\
\text{1 atom of N} &= 14 \times 1 = 14 \text{ a.m.u.}\\
\text{\% age of N} &= \frac{14}{209} \times 100 = 6.7\\
\text{5 atom of H} &= 5 \times 1 = 5 \text{ a.m.u.}\\
\text{\% age of H} &= \frac{5 \times 100}{209} = 2.39\\
\text{1 atom of P} &= 31 \times 1 = 31 \text{ a.m.u.}\\
\text{\% age of P} &= \frac{31 \times 100}{209} = 14.83\\
\text{4 atoms of O} &= 16 \times 4 = 64\\
\text{\% age of O} &= \frac{64 \times 100}{209} = 30.62\\
\text{4 molecules of } H_2O &= 18 \times 4 = 72 \text{ a.m.u.}\\
\text{\% age of } H_2O &= \frac{72 \times 100}{209} = 34.45
\end{aligned}$$

26.2 EMPIRICAL FORMULA (E.F.)

It is the simplest formula that represents the relative whole number ratio of atoms of different elements present in one molecule of the substance *e.g.*, the E.F. of glucose ($C_6H_{12}O_6$) = CH_2O (after dividing by common factor, 6); E.F. of ethene (C_2H_4) is CH_2 (after dividing by common factor, 2).

26.3 MOLECULAR FORMULA (M.F.)

The molecular formula of a compound is the formula that represents the actual number of atoms of different elements present in one molecule of the compound. *For example,* M.F. of glucose is $C_6H_{12}O_6$, that of ethene is C_2H_4 and that of benzene is C_6H_6.

26.4 RELATION BETWEEN EMPIRICAL FORMULA AND MOLECULAR FORMULA

Molecular formula (M.F.) = $n \times$ Empirical formula (E.F).

$$\text{where} \qquad n = \frac{\text{Mol. wt.}}{\text{Empirical formula weight (E.F.wt)}}$$

In order to find the E.F., use the following table.

Element	% age	at. wt.	Relative number of atoms = $\frac{\%\text{ age}}{\text{at. wt}}$ or $\frac{\text{wt.}}{\text{At. wt.}}$	Simple ratio	Whole number ratio.

(*i*) Simple ratio is obtained by dividing relative number of atoms by least value of relative number of atoms.

(*i*) If simple (or least) ratio is in 0.5, 1.5, 2.5, etc., multiply all ratios by 2 to get nearest whole number ratio.

(*ii*) If simple (or least) ratio is in 0.33, 0.66, 1.33, 1.66, etc., multiply all ratios by 3 to get nearest whole number ratio.

(*iii*) If simple (or least) ratio is in 0.14, 1.14, etc., multiply all ratios by 7 to get nearest whole number.

EXAMPLE 5. *Assuming the at. wt. of a metal M to be 56, find the E.F. of its oxide containing 30% of oxygen.*

SOLUTION. % age of M = 100 – 30 = 70; %age of O = 30.

To find E.F.

Element	*%age*	*At.wt.*	*Relative number of atoms = % age/At. wt.*	*Least ratio*	*Whole no. ratio*
Metal, M	70	56	$\frac{70}{56} = 1.25$	$\frac{1.25}{1.25} = 1$	1 × 2 = 2
O	30	16	$\frac{30}{16} = 1.875$	$\frac{1.875}{1.25} = 1.5$	1.5 × 2 = 3

$\therefore$ E.F. = M_2O_3.

EXAMPLE 6. *An organic compound contains C, H and O. 1.80 g of the substance on combustion gave 2.64 g of CO_2 and 1.08 g of water. Calculate the E.F. of the compound.*

SOLUTION. (*i*) To find %age of C

$$\underset{12+2\times16=44\,g\,CO_2}{CO_2} \equiv \underset{12\,g\,C}{C} \qquad \text{Wt. of substance} = 1.8 \text{ g}$$

$$\begin{aligned}
\therefore \quad 44 \text{ g } CO_2 &\equiv 12 \text{ gC}\\
2.64 \text{ g } CO_2 &= \frac{12}{44} \times 2.64 = 0.72 \text{ g}\\
\text{\% age of C} &= \frac{0.72}{1.8} \times 100 = 40
\end{aligned}$$

(*ii*) To find %age of H

$$\underset{2\times1+16=18}{H_2O} \equiv \underset{2\times1=2\,g}{2H}$$

$$\begin{aligned}
18 \text{ g } H_2O &\equiv 2 \text{ gH}\\
1.08 \text{ g } H_2O &\equiv \frac{2}{18} \times 1.08 = 0.12 \text{ g}\\
\text{\% age of H} &= \frac{0.12}{1.8} \times 100 = 6.66\%
\end{aligned}$$

(*iii*) % age of O = 100 – (%age of C + %age of H)

= 100 – (40 + 6.66) = 53.34.

(*iv*) **To find E.F.**

Element	*%age*	*At.wt.*	*Relative number of atoms = % age/At. wt.*	*Least ratio*	*Whole no. ratio*
C	40	12	$\frac{40}{12} = 3.33$	$\frac{3.33}{3.33} = 1$	1

Element	*%age*	*At.wt.*	*Relative number of atoms = % age/At. wt.*	*Least ratio*	*Whole no. ratio*
H	6.66	1	$\frac{6.66}{1} = 6.66$	$\frac{6.66}{3.33} = 2$	2
O	53.34	16	$\frac{53.34}{16} = 3.33$	$\frac{3.33}{3.33} = 1$	1

$\therefore$ E.F. = CH_2O.

Example 7. *100 g of a hydrated salt contains 25.45 g of copper, 12.82 g of sulphur, 25.65 g of oxygen and 36.07 g of water of crystallisation. Calculate the E.F. of the salt. (At. wt., Cu = 63.5, S = 32, O = 16, H = 1).*

Solution. Calculation of E.F.

Element or compound	*Weight*	*At. wt. (or mol. wt.*	*Relative no. of atoms = wt./At. wt or wt./mol. wt.*	*Simple ratio*	*Whole no. ratio*
Cu	25.45	63.5	$\frac{25.45}{63.5} = 0.4$	$\frac{0.4}{0.4} = 1$	1
S	12.82	32	$\frac{12.82}{32} = 0.4$	$\frac{0.4}{0.4} = 1$	1
O	25.65	16	$\frac{25.65}{16} = 1.6$	$\frac{1.6}{0.4} = 4$	4
H_2O	36.07	18	$\frac{36.07}{18} = 2.0$	$\frac{2.0}{0.4} = 5$	5

$\therefore$ E.F. of salt = $Cu_1S_1O_4 . 5H_2O$ *Or* $\mathbf{CuSO_4 . 5\,H_2O}$ **Ans.**

Example 8. *A carbohydrate containing C, H and O has atomic ratio of H and O as 2 : 1. When heated in absence of air, 155 g of it gave 62 g of carbon. Calculate its empirical and molecular formula if 0.167 mol of it contain 2.0 g hydrogen. (At. wt. C = 12, H = 1, O = 16).*

Solution. (*i*) To calculate E.F.,

wt. of H_2O = 155 – 62 = 93 g.

Element or compound	*Weight*	*At. wt. (or mol. wt.*	*Relative no. of atoms = wt./at. wt or wt./mol. wt.*	*Simple ratio*	*Whole no. ratio*
C	62	12	$\frac{62}{12} = 5.17$	$\frac{5.17}{5.17} = 1$	1
H_2O	93	18	$\frac{93}{18} = 5.17$	$\frac{5.17}{5.17} = 1$	1

$\therefore$ E.F. of carbohydrate

$$= C_1(H_2O)_1 = CH_2O.$$

(*ii*) **To calculate M.F.**

0.167g mol of carbohydrate contain hydrogen

= 2g or 2 mol atoms.

1 mol of carbohydrate contain hydrogen

$$= \frac{2}{0.167} \simeq 12 \text{ mol atoms}$$

or 1 molecule of carbohydrate contain H-atoms = 12.

In order to get 12-atoms of hydrogen, the E.F. CH_2O should be multiplied by $\frac{12}{2}$ *i.e.*, 6 to get M.F. Hence, M.F.

= 6 × CH_2O = $\mathbf{C_6H_{12}O_6}$ **Ans.**

Example 9. *An inorganic compound mixed with sand has the following % age composition. K = 26.57%, Cr = 35.36%, O = 38.07%. Calculate the molecular formula of the compound if its molecular mass is 294 (K = 39, Cr = 52, O = 16).*

Solution. To find E.F.

Element	*% age*	*At.wt*	*Relative number of atoms = % age/At. wt.*	*Simple ratio*	*Whole no. ratio*
K	26.57	39	$\frac{26.57}{39} = 0.68$	$\frac{0.68}{0.68} = 1$	1 × 2 = 2
Cr	35.36	52	$\frac{35.36}{52} = 0.68$	$\frac{0.68}{0.68} = 1$	1 × 2 = 2
O	38.07	16	$\frac{38.07}{16} = 2.379$	$\frac{2.379}{0.68} = 3.5$	3.5 × 2 = 7

$\therefore$ E.F. = $K_2Cr_2O_7$.

E.F. wt. = 2 × 39 + 2 × 52 + 7 × 16 = 294

$$\text{M.F.} = \frac{\text{mol. wt.}}{\text{E.F. wt.}} \times \text{E.F.}$$

$$= \frac{294}{294} \times K_2Cr_2O_7 = \mathbf{K_2Cr_2O_7}$$ Ans.

Note. The impurity (sand) does not affect the relative ratio of atoms.

Example 10. *A crystalline salt on being rendered anhydrous loses 45.6% of its weight. The percentage composition of the anhydrous salt is Al = 10.5%, K = 15.1%, S = 24.96% and O = 49.92%. Find the simplest formula of anhydrous and crystalline salt (K = 39, Al = 27, S = 32, O = 16).*

Solution. (*i*) To find E.F. of anhydrous salt.

Element	*% age*	*At.wt*	*Relative number of atoms = % age/At. wt.*	*Simple ratio*	*Whole no. ratio*
K	15.1	39	$\frac{15.1}{39} = 0.39$	$\frac{0.39}{0.39} = 1$	1
Al	10.5	27	$\frac{10.5}{27} = 0.39$	$\frac{0.39}{0.39} = 1$	1
S	24.96	32	$\frac{24.96}{32} = 0.78$	$\frac{0.78}{0.39} = 2$	2

Element	*% age*	*At.wt*	*Relative number of atoms = % age/At. wt.*	*Simple ratio*	*Whole no. ratio*
O	49.92	16	$\frac{49.92}{16}=3.12$	$\frac{3.12}{0.39}=8$	8

$\therefore$ E.F of anhydrous salt = K Al S_2O_8.

(*ii*) To find E.F. of hydrated salt.

E.F. wt. of anhydrous salt,

$$KAlS_2O_8 = 39 + 27 + 2 \times 32 + 8 \times 16 = 258 \text{ a.m.u.}$$

Let wt. of hydrated salt = 100 g

wt. of water lost = 45.6 g

wt. of anhydrous salt = 100 – 45.6 = 54.4 g

E.F. mass of hydrated salt

$$= \frac{\text{wt. of hydrated salt}}{\text{wt. of anhydrous salt}} \times \begin{array}{c}\text{E.F. wt of}\\ \text{anhydrous salt}\end{array}$$

$$= \frac{100 \times 258}{54.4} = 474.3 \text{ g}$$

E.F. mass of anhydrous salt = 258 g

$\therefore$ wt. of water lost = 474.3 – 258 = 216.3 g

Mol. wt. of H_2O molecule = 2 × 1 + 16 = 18 g

$\therefore$ no. of water molecules in the hydrated salt

$$= \frac{216.3}{18} \simeq 12$$

$\therefore$ E.F. of hydrated salt = $KAlS_2O_8 \cdot 12\,H_2O$.

EXAMPLE 11. *A compound on analysis gave the following % age composition. Na = 14.31%; S = 9.97%; H = 6.22% and O = 69.5%. Calculate the molecular formula of the compound on the assumption that all the hydrogens in the compound are present in combination with oxygen as water of crystallisation. The molecular mass of the compound is 322. [At. mass Na = 23, S = 32, H = 1, O = 16].*

SOLUTION. (*i*) To find empirical formula of the compound.

Element	*% age*	*At.wt*	*Relative number of atoms = % age/At. wt.*	*Simple ratio*	*Whole no. ratio*
Na	14.31	23	$\frac{14.31}{23}=0.62$	$\frac{0.62}{0.31}=2$	2
S	9.97	32	$\frac{9.97}{32}=0.31$	$\frac{0.31}{0.31}=1$	1
H	6.22	1	$\frac{6.22}{1}=6.22$	$\frac{6.22}{0.31}=20$	20
O	69.5	16	$\frac{69.5}{16}=4.34$	$\frac{4.34}{0.31}=14$	14

$\therefore$ E.F. of compound = $Na_2S\,H_{20}\,O_{14}$.

E.F. of compound containing water molecules

$$= Na_2SO_4 \cdot 10\,H_2O$$

$$\text{E.F. wt.} = 2 \times 23 + 32 + 4 \times 16 + 10\,(18) = 322$$

$$\text{Mol. formula} = \frac{\text{mol. wt.}}{\text{E.F. wt.}} \times \text{E.F.}$$

$$= \frac{322}{322} \times Na_2SO_4.10H_2O$$

$$= Na_2SO_4.10H_2O$$

EXAMPLE 12. *A compound on analysis gave the following percentage composition by weight. H = 9.09%; O = 36.36% and C = 54.55%. Its V.D. is 44. Find the molecular formula of the compound. (At. wt. H = 1, O = 16, C = 12).*

SOLUTION. (*i*) **To find E.F.**

Element	*% age*	*At.wt*	*Relative number of atoms = % age/At. wt.*	*Simple ratio*	*Whole no. ratio*
H	9.09	1	$\frac{9.09}{1}=9.09$	$\frac{9.09}{2.27}=4$	4
O	36.36	16	$\frac{36.36}{16}=2.27$	$\frac{2.27}{2.27}=1$	1
C	54.55	12	$\frac{54.55}{12}=4.55$	$\frac{4.55}{2.27}=2$	2

$\therefore$ E.F. = C_2H_4O.

E.F. wt. = 2 × 12 + 4 × 1 + 16 = 44.

(*ii*) To find M.F.

Mol. wt. = 2 × V.D. = 2 × 44 = 88

$$\text{M.F.} = \frac{\text{Mol. wt.}}{\text{E.F. wt}} \times \text{E.F.} = \frac{\cancel{88}^{\,2}}{\cancel{44}} \times C_2H_4O$$

$$= \mathbf{C_4H_8O_2}$$ **Ans.**

EXAMPLE 13. *An inorganic substance has the following %age composition. N = 35%, H = 5%, O = 60%. On being heated, it yielded a gaseous compound containing N = 63.63% and O = 36.37%. Suggest formula for each substance and write equation for the chemical change.*

SOLUTION. (*i*) To find E.F.

Element	*% age*	*At.wt*	*Relative number of atoms = % age/At. wt.*	*Simple ratio*	*Whole no. ratio*
N	35	14	$\frac{35}{14}=2.5$	$\frac{2.5}{2.5}=1$	1 × 2 = 2
H	5	1	$\frac{5}{1}=5$	$\frac{5}{2.5}=2$	2 × 2 = 4

Element	*% age*	*At.wt*	*Relative number of atoms = % age/At. wt.*	*Simple ratio*	*Whole no. ratio*
O	60	16	$\frac{60}{16} = 3.75$	$\frac{3.75}{2.5} = 1.5$	$1.5 \times 2 = 3$

$\therefore$ E.F. = $N_2H_4O_3$.

(*ii*) To find E.F. of gaseous compound.

Element	*% age*	*At.wt*	*Relative number of atoms = % age/At. wt.*	*Simple ratio*	*Whole no. ratio*
N	63.63	14	$\frac{63.63}{14} = 4.55$	$\frac{4.55}{2.27} = 2$	2
O	36.37	16	$\frac{36.37}{16} = 2.27$	$\frac{2.27}{2.27} = 1$	1

$\therefore$ E.F. = N_2O (nitrous oxide).

Since the compound formed is N_2O, the original compound is expected as NH_4NO_3.

(*ii*) *Reaction* : $NH_4NO_3 \xrightarrow{\Delta} N_2O + 2\,H_2O$.

Example 14. *A compound of carbon, hydrogen and nitrogen contains three elements in the respective ratio 9 : 1 : 3.5. Calculate its empirical formula. If the mol. wt. is 108, what is its molecular formula ?* **(I.I.T., 1973)**

Solution. (*i*) To find E.F.

Element	*Ratio by wt.*	*At.wt*	*Relative number of atoms = Ratio by wt./At. wt.*	*Simple ratio*	*Whole no. ratio*
C	9	12	$\frac{9}{12} = 0.75$	$\frac{0.75}{0.25} = 3$	3
H	1	1	$\frac{1}{1} = 1$	$\frac{1}{0.25} = 4$	4
N	3.5	14	$\frac{3.5}{14} = 0.25$	$\frac{0.25}{0.25} = 1$	1

$\therefore$ E.F. = C_3H_4N.

E.F. wt. = $3 \times 12 + 4 \times 1 + 14 = 54$.

(*ii*) To find M.F.

$$\text{M.F.} = \frac{\text{Mol. wt.}}{\text{E.F. wt.}} \times \text{E.F.}$$

$$= \frac{\cancel{108}}{\cancel{54}} \times C_3H_4N = 2 \times C_3H_4N$$

$$= C_6H_8N_2$$

Example 15. *A certain compound contains 23.7% sulphur, 23.7% oxygen and rest chlorine. 0.182 g of its vapours occupy 36 mL at 27°C and 700 mm pressure. Calculate the molecular formula of the compound. Also, name the compound.*

Solution. $P_1 = 700$ mm, $V_1 = 36$ mL, $T_1 = 27 + 273 = 300$ K; At. N.T.P., $P_2 = 760$ mm, $V_2 = ?$, $T_2 = 273$ K. Using gas equation :

$$\frac{P_1V_1}{T_1} = \frac{P_2V_2}{T_2};$$

$$V_2 = \frac{P_1V_1T_2}{T_1P_2} = \frac{700\,\text{mm} \times 36\,\text{mL} \times 273\,\text{K}}{300\,\text{K} \times 760\,\text{mm}}$$

or V_2 (at N.T.P.) = 30.2 mL. We know :

$$\text{Mol. wt.} = \frac{\text{Wt.}}{V_{\text{NTP}}} \times 22400;$$

$$\text{Mol. wt.} = \frac{0.182\,\text{g}}{30.2\,\text{mL}} \times 22400\,\text{mL} = 135\,\text{g}$$

(*i*) To find E.F. % age of Cl

= 100 – (23.7 + 23.7) = 52.6.

Element	*% age*	*At.wt*	*Relative number of atoms = % age/At. wt.*	*Simple ratio*	*Whole no. ratio*
S	23.7	32	$\frac{23.7}{32} = 0.74$	$\frac{0.74}{0.74} = 1$	1
O	23.7	16	$\frac{23.7}{16} = 1.48$	$\frac{1.48}{0.74} = 2$	2
Cl	52.6	35.5	$\frac{52.6}{35.5} = 1.48$	$\frac{1.48}{0.74} = 2$	2

$\therefore$ E.F. of compound = SO_2Cl_2.

E.F. wt. of SO_2Cl_2

= 32 + (2 × 16) + (2 × 35.5) = 135.

$$\therefore \quad \text{M.F.} = \text{E.F.} \times \frac{\text{Mol. wt.}}{\text{E.F. wt.}} = SO_2Cl_2 \times \frac{135}{135}$$

= $\mathbf{SO_2Cl_2}$ **Ans.**

Name of the compound is sulphuryl chloride.

Example 16. *Determine the molecular formula of the compound which contains H = 2.1%, C = 12.8%, Br = 85.1%. One gram of it occupies 119 cc at N.T.P. = (C = 12, H = 1, Br = 80).*

Solution. (*i*) To find E.F.

Element	*% age*	*At.wt*	*Relative number of atoms = % age/At. wt.*	*Simple ratio*	*Whole no. ratio*
H	2.1	1	$\frac{2.1}{1} = 2.1$	$\frac{2.1}{1.06} = 2$	2

Element	*% age*	*At.wt*	*Relative number of atoms = % age/At. wt.*	*Simple ratio*	*Whole no. ratio*
C	12.8	12	$\frac{12.8}{12} = 1.07$	$\frac{1.07}{1.06} = 1$	1
Br	85.1	80	$\frac{85.1}{80} = 1.06$	$\frac{1.06}{1.06} = 1$	1

$\therefore$ E.F. = CH_2Br

E.F. wt. = $12 + 2 \times 1 + 80 = 94$.

(*ii*) To find M.F.

$\therefore$ g. mol. wt. of gas

$$= \frac{\text{wt}}{V_{NTP}} \times 22400 = \frac{1 \times 22400}{119} = 188.2\text{ g}$$

$$\text{M.F.} = \frac{\text{Mol. wt.}}{\text{E.F. wt.}} \times \text{E.F.} = \frac{\cancel{188.2}^{2}}{\cancel{94}} \times CH_2Br$$

$\therefore$ M.F. = $C_2H_4Br_2$

Example 17. *Calculate the formula of kaolin, the composition of which is as follows. Al_2O_3 = 39.5%; SiO_2 = 46.6% and H_2O = 13.9% (At. wt. Al = 27, Si = 28, O = 16, H = 1).*

Solution. To find E.F. of kaolin.

Element	*% age*	*Mol. wt.*	*Relative number of molecules = % age/mol. wt.*	*Simple ratio*	*Whole no. ratio*
Al_2O_3	39.5	2 × 27 + 3 × 16 = 102	$\frac{39.5}{102} = 0.387$	$\frac{0.387}{0.387} = 1$	1
SiO_2	46.6	28 + 2 × 16 = 60	$\frac{46.6}{60} = 0.777$	$\frac{0.777}{0.387} = 2$	2
H_2O	13.9	2 × 1 + 16 = 18	$\frac{13.9}{18} = 0.772$	$\frac{0.772}{0.387} = 2$	2

$\therefore$ E.F. = $Al_2O_3 . 2\,SiO_2 . 2\,H_2O$.

Example 18. *2.5 g of a sample of a metal was heated in air. The resulting oxide weighed 2.95g. Determine the empirical formula of the oxide (At. wt. of metal is 238).*

Solution. Wt. of metal = 2.5 g

wt. of metal oxide = 2.95 g

$\therefore$ wt. of oxygen = 2.95 – 2.5 = 0.45 g

To find E.F.

Element	*Weight*	*At.wt*	*Relative number of atoms = % age/At. wt.*	*Simple ratio*	*Whole no. ratio*
M	2.5	238	$\frac{2.5}{238} = 0.0105$	$\frac{0.0105}{0.0105} = 1$	1 × 3 = 3
O	0.45	16	$\frac{0.45}{16} = 0.028$	$\frac{0.028}{0.0105}$ = 2.66	2.66 × 3 = 7.98 ≃ 8

$\therefore$ E.F. = M_3O_8.

Example 19. *9.7g of a hydrate of $CuSO_4$ loses 3.5 g of water on heating. What is the empirical formula of the hydrate ? (Cu = 63.5, S = 32, O = 16).*

SOLUTION. E.F. wt. of $CuSO_4$ anhydrous = 63.5 + 32 + 4 × 16 = 159.5 g

Wt. of hydrated compound = 9.7 g

Wt. of water = 3.5 g

Wt. of anhydrous compound = 9.7 – 3.5 = 6.2 g

$\therefore$ E.F. wt. of hydrated $CuSO_4$

$$= \frac{\text{wt. of hydrated salt}}{\text{wt. of anhydrous compound}} \times \begin{array}{c}\text{E.F. Wt. of}\\ \text{anhydrous compound}\end{array}$$

$$= \frac{9.7}{6.2} \times 159.5 = 249.5\text{ g}$$

E.F. wt. of anhydrous $CuSO_4$ = 159.5 g

$\therefore$ Wt. of water = 249.5 – 159.5 = 90

$\therefore$ No. of water molecules = $\frac{90}{18} = 5$

$\therefore$ Formula of hydrated copper sulphate

= $CuSO_4 . 5H_2O$

Example 20. *1g of hydrated compound of iron contains 0.2014 g of Fe, 0.1153g of S, 0.231g of O and 0.4532g of water of crystallisation. Find the E.F. of the compound (Fe = 56, S = 32, O = 16, H = 1).*

Solution. To find E.F.

Element or compound	*Weight*	*At.wt or mol. wt.*	*Relative number of atoms = % age/At. wt. or mol. wt.*	*Simple ratio*	*Whole no. ratio*
Fe	0.2014	56	$\frac{0.2014}{56} = 0.0035$	$\frac{0.0035}{0.0035} = 1$	1
S	0.1153	32	$\frac{0.1153}{32} = 0.0036$	$\frac{0.0036}{0.0036} = 1$	1
O	0.231	16	$\frac{0.231}{16} = 0.0144$	$\frac{0.0144}{0.0035} = 4$	4
H_2O	0.4532	18	$\frac{0.4532}{18} = 0.0251$	$\frac{0.0251}{0.0035} = 7$	7

$\therefore$ E.F. = $FeSO_4 . 7H_2O$.

Example 21. *A dibasic acid containing C, H and O was found to contain C = 26.7% and hydrogen 2.2%. The vapour density of diethyl ester was found to be 73. What is the molecular formula of the acid ? (At. wt. C = 12, O = 16,. H = 1).*

(P.U.C.E.T. 1989)

Solution. To find E.F.; % age of O

= 100 – (26.7 + 2.2 = 28.9) = 71.1%.

Element	*% age*	*At.wt*	*Relative number of atoms = % age/At. wt.*	*Simple ratio*	*Whole no. ratio*
C	26.7	12	$\frac{26.7}{12}=2.2$	$\frac{2.2}{2.2}=1$	1
H	2.2	1	$\frac{2.2}{1}=2.2$	$\frac{2.2}{2.2}=1$	1
O	71.1	16	$\frac{71.1}{16}=4.4$	$\frac{4.4}{2.2}=2$	2

∴ E.F. = CHO_2.

E.F. wt. = 12 + 1 + 2 × 16 = 45.

Mol. mass of acid

= Mol. mass – mol. mass of two + at. mass of two
of ester ethyl (C_2H_5)groups H-atoms

= 2 × (V.D) – mass of two + mass of two
C_2H_5 groups H-atoms

= (2 × 73) – 2 (2 × 12 + 5 × 1) + (2 × 1)

= 146 – 58 + 2 = 90.

$$\text{M.F.} = \frac{\text{Mol. wt.}}{\text{E.F. wt.}} \times \text{E.F.} = \frac{\cancel{90}^{2}}{\cancel{45}} \times CHO_2$$

$= C_2H_2O_4$ **Ans.**

Type. Determination of M.F. of monobasic acid when V.D. of its ethylester is given.

Example 22. *The empirical formula of monobasic acid is CH_2O. The vapour density of its* ***ethyl ester*** *is found to be 44. Calculate the molecular formula of the acid.*
(C = 12, H = 1, O = 16).

Solution. E.F. = CH_2O.

E.F. wt. of

CH_2O = 12 + 2 × 1 + 16 = 30.

Mol. mass of

acid = Mol. mass of – Mol. wt. of + at. mass of
ethyl ester one ethyl one H-atom
(C_2H_5)

= (2 × (V.D) – (2 × 12 + 5 × 1) + 1

i.e., 2 × 44 = 88

= 88 – 29 + 1 = 60

$$\text{M.F.} = \frac{\text{Mol. wt.}}{\text{E.F. wt.}} \times \text{E.F.} = \frac{\cancel{60}^{2}}{\cancel{30}} \times CH_2O$$

$= C_2H_4O_2$ **Ans.**

Example 23. *In case of a hydrocarbon, it was found from analysis that the hydrogen content is $\frac{1}{12}$ of that of carbon by weight. What is the empirical formula of the compound ? (C = 12, H = 17).*

Solution. To find E.F.

Element	*Wt.*	*At.wt*	*Relative number of atoms = Wt./ At. wt*	*Simple ratio*	*Whole no. ratio*
C	12	12	$\frac{12}{12}=1$	$\frac{1}{1}=1$	C
H	1	1	$\frac{1}{1}=1$	$\frac{1}{1}=1$	H

∴ E.F. = CH.

Example 24. *The empirical formula of a compound is $FeSH_{14}O_{11}$, write its formula if all the hydrogen atoms are present in it as water of crystallisation.*

Solution. E.F. = $FeS\,H_{14}O_{11} = FeSO_4 . 7H_2O$

$[\because 7H_2O = H_{14}O_7 \ \therefore\ H_{14}O_7 + 4O = H_{14}O_{11}]$

Example 25. *An organic acid contain C, H and O. A 4.24 mg of the sample is burnt completely. It gives 8.45 mg CO_2 and 3.46 mg H_2O. What is the mass percentage of each ? Calcualte the empirical formula of the compound (C = 12, O = 16, H = 1).*

Solution. (*i*) To find % age of C.

$$\text{\% age of C} = \frac{\text{Wt. of C}}{\text{Wt. of compound}} \times 100$$

$$= \frac{2.304}{4.24} \times 100 = 54.34$$

(*ii*) To find % age of H

$$\text{\% age of H} = \frac{\text{Wt. of H}}{\text{Wt. of compound}} \times 100$$

$$= \frac{0.384}{4.24} \times 100 = 9.06$$

% age of O = 100 – (54.34 + 9.06)

= 36.60.

$CO_2 \equiv C$

12 + 2 × 16 = 44 mg ≡ 12 mg

44 mg CO_2 ≡ 12 mg C

$$8.45 \text{ mg } CO_2 \equiv \frac{12}{44} \times 8.45 = 2.304 \text{ mg}$$

$H_2O \equiv 2H$

2 × 1 + 16 = 18 mg 2 × 1 = 2 mg

18 mg H_2O ≡ 2 mgH

$$3.46 \text{ mg } H_2O \equiv \frac{2}{18} \times 3.46 = 0.384 \text{ mg}$$

(*iii*) To find E.F.

Element	*% age*	*At.wt*	*Relative number of atoms = % age/At. wt.*	*Simple ratio*	*Whole no. ratio*
C	54.34	12	$\frac{54.34}{12} = 4.52$	$\frac{4.52}{2.26} = 2$	2
H	9.06	1	$\frac{9.06}{1} = 9.06$	$\frac{9.06}{2.26} = 4$	4
O	36.60	16	$\frac{36.60}{16} = 2.26$	$\frac{2.26}{2.26} = 1$	1

∴ E.F. = C_2H_4O.

Example 26. *A hydrocarbon contains 10.5 g of carbon per gram of hydrogen. One litre of the vapour of the hydrocarbon at 127°C and 1 atm pressure weighs 2.8 g. Find the molecular formula.* **(I.I.T. 1980)**

Solution. (*i*) To find E.F.

Element	*Wt.*	*At.wt*	*Relative number of atoms = wt./At. wt.*	*Simple ratio*	*Whole no. ratio*
C	10.5 g	12	$\frac{10.5}{12} = 0.875$	$\frac{0.875}{0.875} = 1$	1 × 7 = 7
H	1 g	1	$\frac{1}{1} = 1$	$\frac{1}{0.875}$ = 1.143	1.143 × 7 ≃ 8

∴ E.F. of hydrocarbon = C_7H_8

∴ E.F. wt. = (7 × 12) + (8 × 1) = 92.

(*ii*) To find molecular weight. We know :

$$PV = nRT; \; PV = \frac{\text{Wt.}}{\text{mol. wt.}} \times RT;$$

$$\text{Mol.wt.} = \frac{\text{wt.} \times RT}{PV}$$

But P = 1 atm, V = 1L, wt. = 2.8g,

R = 0.0821L atm K^{-} mol^{-};

T = 127 + 273 = 400K.

Substituing the values, we get :

$$\text{Mol. wt.} = \frac{2.8\text{g} \times 0.0821\text{L atm K}^{-}\text{mol}^{-} \times 400\text{K}}{1\text{atm} \times 1\text{L}}$$

$$\simeq 92 \text{ g mol}^{-}$$

(*iii*) To find M.F.

$$\text{M.F.} = \text{E.F.} \times \frac{\text{mol. wt.}}{\text{E.F. wt.}} = C_7H_8 \times \frac{92}{92} = C_7H_8$$

∴ M.F. of hydrocarbon = $\mathbf{C_7H_8}$ **Ans.**

Example 27. *A certain compound containing only carbon and oxygen has an approximate molecular weight of 290. On analysis, it is found to contain exactly 50 per cent by weight of each element. What is the molecular formula of the compound ?* **(I.I.T. 1970)**

Solution. (*i*) To find E.F.

Element	*% age*	*At.wt*	*Relative number of atoms = % age/At. wt.*	*Simple ratio*	*Whole no. ratio*
C	50	12	$\frac{50}{12} = 4.16$	$\frac{4.16}{3.125} = 1.33$	1.33 × 3 ≃ 4
O	50	16	$\frac{50}{16} = 3.125$	$\frac{3.125}{3.125} = 1$	1 × 3 = 3

∴ E.F. of compound = C_4O_3.

E.F. wt. = (4 × 12) + (3 × 16) = 96.

But
$$\text{M.F.} = \text{E.F.} \times \frac{\text{mol. wt.}}{\text{E.F. wt.}} = \text{E.F.} \times \frac{290}{96}$$

$$= C_4O_3 \times 3$$

$$= \mathbf{C_{12}O_9}$$ **Ans.**

Example 28. *A compound 'X' contains 36.5% Na, 25.4% S and rest oxygen. Calculate the molecular formula of X if its mol. wt. is 126. 'X' is also easily oxidised to give a compound 'Y'. Calculate the percentage composition of 'Y'.*

(At. wt. Na = 23, S = 32, O = 16).

Solution. % age of oxygen = 100 – (36.5 + 25.4) = 38.1%

(*i*) To find E.F.

Element	*% age*	*At.wt*	*Relative number of atoms = % age/At. wt.*	*Simple ratio*	*Whole no. ratio*
Na	36.5	23	$\frac{36.5}{23} = 1.587$	$\frac{1.587}{0.793} = 2.001$	2
S	25.4	32	$\frac{25.4}{32} = 0.793$	$\frac{0.793}{0.793} = 1$	1
O	38.1	16	$\frac{38.1}{16} = 2.381$	$\frac{2.381}{0.793} = 3.001$	3

∴ E.F. of compound = Na_2SO_3.

On oxidation, Na_2SO_3 forms Na_2SO_4. So, compound 'Y' is Na_2SO_4. Mol. wt. of Na_2SO_4 = (2 × 23) + 32 + (4 × 16) = 142 because in Na_2SO_4; 2 atoms of Na = 2 × 23 = 46 a.m.u., 1 atom of S = 32 a.m.u. and 4 atoms of oxygen = 4 × 16 = 64 a.m.u. Hence :

$$\text{\% age of Na} = \frac{46 \times 100}{142} = \mathbf{32.39}$$ **Ans.**

$$\text{\% age of S} = \frac{32 \times 100}{142} = \mathbf{22.54}$$ **Ans.**

$$\text{\% age of O} = \frac{64 \times 100}{142} = \mathbf{45.07}$$ **Ans.**

Example 29. *18.488g of Epsom salt lost 9.459 g water of crystallisation on heating and left behind $MgSO_4$. Find the formula of Epsom salt. (At. wt., Mg = 24, S = 32, O = 16, H = 1).*

SOLUTION. Wt. of water, H_2O = 9.459g; g. mol. wt. of $H_2O = (2 \times 1) + 16 = 18$g;

Wt. of $MgSO_4 = 18.488 - 9.459 = 9.029$ g.

To find E.F.; mol. wt. of

$$MgSO_4 = 24 + 32 + (4 \times 16) = 120.$$

Compound	*Wt.*	*Mol. wt.*	*Relative number of molecules = Wt./Mol. wt.*	*Simple ratio*	*Whole no. ratio*
$MgSO_4$	9.029	120	$\frac{9.029}{120} = 0.075$	$\frac{0.075}{0.075} = 1$	1
H_2O	9.459	18	$\frac{9.459}{18} = 0.526$	$\frac{0.526}{0.075} = 7$	7

∴ E.F. of Epsom salt = $MgSO_4 . 7H_2O$ **Ans.**

EXAMPLE 30. *An organic compound on qualitative analysis was found to contain C, H and N. One gram of it on oxidation with CuO and oxygen gave 1.239 g of CO_2 and 0.1269g of H_2O. 2.0g of the sample was digested with conc. H_2SO_4 and the residue was distilled after the addition of excess solution of sodium hydroxide. The ammonia gas evolved was absorbed in 50 mL of 1.0N sulphuric acid. The resulting solution was diluted to 500 mL in a measuring flask. 25 mL of this solution required 21.8 mL of 0.05N NaOH for complete neutralisation. Calculate the empirical formula of the compound.* **(I.I.T., 1971)**

SOLUTION. Wt. of compound = 1.0 g;

Wt. of CO_2 = 1.239g; wt. of H_2O = 0.1269g.

(*a*) $CO_2 \equiv C$

$$12 + (2 \times 16) = 44\text{g} \quad 12\text{g}$$

$$44 \text{ g } CO_2 \equiv 12\text{g C}$$

$$1.239\text{g } CO_2 \equiv \frac{12}{44} \times 1.239 \text{ g C}$$

$$\therefore \quad \%\text{ age of C} = \frac{12 \times 1.239}{44} \times \frac{100}{1} = \mathbf{33.79\%}$$

(*b*) $H_2O \equiv 2H$

$$(2 \times 1) + 16 = 18\text{g} \quad 2 \times 1 = 2\text{g}$$

$$18\text{g } H_2O \equiv 2 \text{ g H}$$

$$0.1269 \text{ g } H_2O \equiv \frac{2}{18} \times 0.1269\text{g H}$$

$$\therefore \quad \%\text{ age of } H_2 = \frac{2}{18} \times \frac{0.1269 \times 100}{1} = \mathbf{1.41\%}$$

(*c*) To find %age of nitrogen.

(*i*) To find normality of dil H_2SO_4

Dil. H_2SO_4 NaOH solution

$$N_1V_1 = N_2V_2;$$

$$N_1 \times 25 = 21.8 \times 0.05;$$

$$N_1 = 0.0436$$

(*ii*) To find volume of original acid unused

Dil. H_2SO_4 Original H_2SO_4

$$N_3V_3 = N_4V_4;$$

$$0.0436 \times 500 = 1 \times V_4;$$

$$V_4 = 21.8 \text{ mL}$$

(*iii*) To find volume of original acid used by ammonia = 50 – 21.8 = 28.2 mL.

(*iv*) To find weight and % age of nitrogen.

28.2 mL of 1N H_2SO_4 ≡ 28.2 mL of 1N NH_3

Now

1000 mL of 1N NH_3 ≡ 14 g N

$$\therefore \quad 28.2 \text{ mL of 1N } NH_3 \equiv \frac{14}{1000} \times 28.2 \times 1 = 0.3948 \text{ g}$$

$$\therefore \quad \%\text{ age of nitrogen} = \frac{0.3948}{2.0} \times 100 = 19.74$$

$$\%\text{ age of oxygen} = 100 - (33.79 + 1.41 + 19.74) = 45.06\%$$

(*v*) To find E.F.

Element	*% age*	*At.wt*	*Relative number of atoms = % age/At. wt.*	*Simple ratio*	*Whole no. ratio*
C	33.79	12	$\frac{33.79}{12} = 2.816$	$\frac{2.816}{1.41} = 2$	2
H	1.41	1	$\frac{1.41}{1} = 1.41$	$\frac{1.41}{1.41} = 1$	1
N	19.74	14	$\frac{19.74}{14} = 1.41$	$\frac{1.41}{1.41} = 1$	1
O	45.06	16	$\frac{45.06}{16} = 2.816$	$\frac{2.816}{1.41} \simeq 2$	2

∴ E.F. of the compound = C_2HNO_2 **Ans.**

EXAMPLE 31. (*i*) *An organic mono-acid base contains 78.6% C and 8.4% hydrogen. (ii) 1.070 g of the base needed 25.0 mL of N/2.5 H_2SO_4 for complete neutralisation. (iii) 0.6g of the base gave 65.4 mL N_2 at 15°C and one atmospheric pressure. Calculate the molecular formula of the base.*

SOLUTION. (*i*) To find % age of nitrogen. P_1 = 1 atm = 760 mm, V_1 = 65.4 mL, T_1 = 15 + 273 = 288 K. At. N.T.P., P_2 = 760 mm, V_2 = ?, T_2 = 273 K.

Using gas equation, we have

$$\frac{P_1V_1}{T_1} = \frac{P_2V_2}{T_2} \textbf{ Or } V_2 = \frac{P_1V_1T_2}{T_1P_2}$$

$$\therefore \quad V_2 = \frac{760 \times 65.4 \times 273}{288 \times 760} = 62 \text{ mL}$$

22400 mL of N_2 weighs = g. mol. wt. of N_2
= 2 × 14 = 28 g

$$62 \text{ mL of } N_2 \text{ weighs} = \frac{28}{22400} \times 62\text{g}$$

$$\therefore \quad \%\text{ age of } N_2 = \frac{28 \times 62}{22400} \times \frac{100}{0.6} = 12.92\%$$

(*ii*) To find E.F.

Element	*% age*	*At.wt*	*Relative number of atoms = % age/At. wt.*	*Simple ratio*	*Whole no. ratio*
C	78.6	12	$\frac{78.6}{12} = 6.55$	$\frac{6.55}{0.92} = 7$	7
H	8.4	1	$\frac{8.4}{1} = 8.4$	$\frac{8.4}{0.92} \simeq 9$	9
N	12.92	14	$\frac{12.92}{14} = 0.92$	$\frac{0.92}{0.92} = 1$	1

$\therefore$ E.F. of base = C_7H_9N **Ans.**

E.F. wt. of base = (7 × 12) + (9 × 1) + 14 = 107.

(*iii*) To find mol. wt. of base

25.0 mL of $\frac{N}{2.5}$ H_2SO_4 neutralised base

$$= 1.07 \text{ g}$$

1000 mL of 1N H_2SO_4 neutralised base

$$= \frac{1.07}{25} \times 1000 \times 2.5 = 107\text{g}$$

$\therefore$ Eq. wt. of base = 107;

Mol. wt. = Eq. wt. × acidity

= 107 × 1 = 107.

$$\therefore \quad \text{M.F.} = \text{E.F.} \times \frac{\text{Mol. wt.}}{\text{E.F. wt.}}$$

$$= C_7H_9N \times \frac{107}{107} = \mathbf{C_7H_9N}$$

Ans.

EXAMPLE 32. *(i) 0.203 g of an organic liquid in a victor meyer apparatus displaced 55.92 mL of dry air measured at 15°C and 750 mm pressure. (ii) In a Kjeldahl's apparatus, the ammonia gas obtained from 2.02 g of the compound was neutralised by 23.2 mL of 1N H_2SO_4. (iii) In a carius estimation of sulphur, 0.4132 g of the substance resulted in the precipitation of 1.1088 g of $BaSO_4$. The compound also contains 41.37% C and 5.75% hydrogen. Calculate the molecular formula of the organic liquid. (At. wt., Ba = 137, S = 32, O = 16).*

SOLUTION. (*i*) Wt. of substance = 0.203 g; P_1 = 750 mm; V_1 = 55.92 mL, T_1 = 15 + 273 = 288 K; at N.T.P, P_2 = 760 mm, V_2 = ?, T_2 = 273 K.

Using gas equation :

$$\frac{P_1V_1}{T_1} = \frac{P_2V_2}{T_2};$$

$$V_2 = \frac{P_1V_1T_2}{T_1P_2} = \frac{750 \times 55.92 \times 273}{288 \times 760}$$

or $\quad V_2 = 52.31$ mL

$$\therefore \quad \text{Mol. wt.} = \frac{W}{V_2} \times 22400 = \frac{0.203}{52.31} \times 22400$$

$$= 86.93 \text{ g mol}^{-}$$

(*i*) To find % age of nitrogen.

23.2 mL of 1N H_2SO_4 ≡ 23.2 mL of 1N NH_3

1000 mL of 1N NH_3 contain nitrogen

= At. wt. of nitrogen = 14 g

23.2 mL of 1N NH_3 contain nitrogen

$$= \frac{14}{1000} \times 23.2 \text{ g}$$

$$\therefore \quad \text{\% age of nitrogen} = \frac{14 \times 23.2 \times 100}{1000 \times 2.02} = 16.08\%$$

(*ii*) To find % age of sulphur.

$BaSO_4$ ≡ S

137 + 32 + (4 × 16) = 233 g 32 g

233 g $BaSO_4$ contain S = 32 g

1.1088 g $BaSO_4$ contains S

$$= \frac{32}{233} \times 1.1088 \text{ g}$$

$$\therefore \quad \text{\% age of S} = \frac{32 \times 1.1088 \times 100}{233 \times 0.4132} = 36.85$$

(*iii*) To find E.F.

Element	*% age*	*at.wt*	*Relative number of atoms = % age/At. wt.*	*Simple ratio*	*Whole no. ratio*
C	41.37	12	$\frac{41.37}{12} = 3.45$	$\frac{3.45}{1.15} = 3$	3
H	5.75	1	$\frac{5.75}{1} = 5.75$	$\frac{5.75}{1.15} = 5$	5
N	16.08	14	$\frac{16.08}{14} = 1.15$	$\frac{1.15}{1.15} = 1$	1
S	36.85	32	$\frac{36.85}{32} = 1.15$	$\frac{1.15}{1.15} = 1$	1

$\therefore$ E.F. of compound = C_3H_5NS

E.F. wt. of compound = (3 × 12) + (5 × 1) + 14 + 32

= 87

$$\therefore \quad \text{M.F.} = \text{E.F.} \times \frac{\text{Mol. wt.}}{\text{E.F. wt.}}$$

$$= C_3H_5NS \times \frac{86.93}{87}$$

$$\simeq C_3H_5NS \times 1$$

M.F. = $\mathbf{C_3H_5NS}$ **Ans.**

EXAMPLE 33. *(a) A solution of a 1.25g of the non-volatile substance in 25g of water boiled at 100.26°C. The value of 'K', the molecular elevation for 100 g of water is 5.2 °C. (b) 2g of the substance when Kjeldahlised produced 0.34g of NH_3. If the percentage of carbon and hydrogen in the compound are 48% and 5% respectively, what would be the molecular formula of the compound.*

SOLUTION. (*a*) Elevation in b.pt, ΔT = 100.26 – 100 = 0.26 °C = 0.26 K, Mol. wt. of solute, M_2 = ?,

W = wt. of substance = 1.25 g;

$$W = \text{wt. of solvent} = 25\text{ g} \times \frac{1\text{kg}}{1000\text{ g}} = 0.025\text{ kg};$$

K = 5.2 °C kg mol^{-}/100 g = 0.52 °C or 0.52K kg mol^{-}.

$$\text{Mol. wt., } M_2 \text{ of substance} = \frac{K \times w}{W \times \Delta T}$$

$$= \frac{0.52\text{K kg mol}^{-} \times 1.25\text{g}}{0.025\text{kg} \times 0.26\text{ K}} = 100\text{g mol}^{-}\cdot$$

(*b*) To find % age of nitrogen.

Mol. wt. of NH_3 = 14 + (3 × 1) = 17

17g NH_3 contain N = 14 g (∵ at. wt. of N = 14)

$$0.34\text{g } NH_3 \text{ contain N} = \frac{14}{17} \times 0.34\text{ g}$$

$$\therefore \quad \% \text{ age of N} = \frac{14 \times 0.34}{17} \times \frac{100}{2} = \mathbf{14\%}$$

(*c*) To find E.F., C = 48%, H = 5%,

N = 14%,

O = 100 – (48 + 5 + 14) = 33 %.

Element	*% age*	*at.wt*	*Relative number of atoms = % age/At. wt.*	*Simple ratio*	*Whole no. ratio*
C	48	12	$\frac{48}{12} = 4$	$\frac{4}{1} = 4$	4
H	5	1	$\frac{5}{1} = 5$	$\frac{5}{1} = 5$	5
N	14	14	$\frac{14}{14} = 1$	$\frac{1}{1} = 1$	1
O	33	16	$\frac{33}{16} = 2$	$\frac{2}{1} = 2$	2

∴ E.F. of substance = $C_4H_5NO_2$

E.F. wt. of substance = (4 × 12) + (5 × 1) + 14 + (2 × 16) = 99

$$\therefore \quad \text{M.F.} = \text{E.F.} \times \frac{\text{Mol. wt.}}{\text{E.F. wt.}}$$

$$= C_4H_5NO_2 \times \frac{100}{99}$$

$$= C_4H_5NO_2 \times 1$$

$$= \mathbf{C_4H_5NO_2}$$ **Ans.**

EXAMPLE 34. *A sample of an organic substance weighing 1.0g having the empirical formula CH_2O was vaporised at 220°C and 760 mm pressure. Its vapours occupied 560 mL volume. The same volume was occupied by 0.5g of C_2H_6 (ethane) gas under similar conditions of temperature and pressure. Calculate the molecular formula of the substance.*

SOLUTION. The given organic substance as well as C_2H_6 occupy the same volume (560 mL) under similar conditions of temperature and pressure. So, according to ***Avogadro's law***, equal volume of both gases would contain equal number of molecules. So, the ratio of their weights (of equal volume) would give the ratio of the weights of single molecules or mol. wt. *i.e.,*

	Sample	C_2H_6
wt.	1.0	0.5
Ratio of wts.	$\frac{1.0}{0.5} = 2$	$\frac{0.5}{0.5} = 1$

Mol. wt. of C_2H_6 = (2 × 12) + (6 × 1) = 30

∴ Mol. wt. of sample = 2 × 30 = 60

E.F. of sample = CH_2O;

E.F. wt. of sample = 12 + (2 × 1) + 16 = 30

$$\therefore \quad \text{M.F. of sample} = \text{E.F.} \times \frac{\text{Mol. wt.}}{\text{E.F. wt.}}$$

(= 2)

$$= CH_2O \times \frac{60}{30}$$

$$= \mathbf{C_2H_4O_2}$$ **Ans.**

EXAMPLE 35. *The element composition of an unknown compound of molecular mass 86 is found to be carbon 69.75%, hydrogen 11.65% and the balance oxygen. What is the molecular formula of the compound ? Also specify the group to which it belongs.* **(P.b. C.E.T. 1998)**

SOLUTION. Percentage of oxygen = 100 – (% of C + % of H) = 100 – (69.75 + 11.65) = 18.6%.

Element	*% age*	*At.wt*	*Relative number of atoms = % age/At. wt.*	*Simple ratio*	*Whole no. ratio*
C	69.75	12	$\frac{69.75}{12} = 5.8125$	$\frac{5.8125}{1.1625} = 5$	5
H	11.65	1	$\frac{11.65}{1} = 11.65$	$\frac{11.65}{1.1625} = 10.02$	10
O	18.6	16	$\frac{18.6}{16} = 1.1625$	$\frac{1.1625}{1.1625} = 1$	1

Empirical formula = $C_5H_{10}O$

Empirical formula mass

= 12 × 5 + 1 × 10 + 16 × 1 = 86

Molecular mass = 86

$$n = \frac{\text{Molecular mass}}{\text{Empirical formula mass}}$$

$$= \frac{86}{86} = 1.$$

Molecular formula = *n* × Emp. formula

= 1 × $C_5H_{10}O$ =$C_5H_{10}O$

The molecular formula indicates that the given compound can be aldehyde or ketone. Therefore, the functional group present is >C = O.

EXAMPLE 36. *An aromatic compound contains 69.4% carbon and 5.8% hydrogen. A sample of 0.303 g of this compound was analysed for nitrogen by Kjeldahl's method. The ammonia evolved was absorbed in 50 mL of 0.05 M sulphuric acid. The excess acid required 25 mL of 0.1 M sodium hydroxide for neutralisation. Determine the molecular formula of the compound if its molecular weight is 121. Draw two possible structures for this compound.* **(I.I.T. 1982)**

SOLUTION. (*i*) *Calculation of the percentage of nitrogen.*

Since, eq. wt. of H_2SO_4 is half its mol. wt., therefore, molarity of H_2SO_4 is half its normality.

$\therefore$ 50 mL of 0.05 M sulphuric acid = 50 mL of 2 × 0.05 (= 0.1 N) sulphuric acid.

Excess acid requires 25 mL of 0.1 M or 0.1N NaOH (normality of NaOH = molarity of NaOH) for neutralisation.

$\therefore$ 0.1N H_2SO_4 neutralised by 25 mL of 0.1 N NaOH = 25 mL.

Acid used up for the neutralisation of ammonia evolved is :

$$= 50 \text{ mL of } 0.1\text{N } H_2SO_4 - 25 \text{ mL of } 0.1\text{N } H_2SO_4$$

$$= 25 \text{ mL of } 0.1\text{N } H_2SO_4$$

$$25 \text{ mL of } 0.1\text{N } H_2SO_4 \equiv 25 \text{ mL } 0.1 \text{ N } NH_3$$

$$\equiv 2.5 \text{ mL } (= 25 \times 0.1 = 2.5) \text{ of } 1 \text{ N } NH_3$$

$$1000 \text{ mL } 1\text{N } NH_3 \equiv 17 \text{ g } NH_3 = 14 \text{ g nitrogen}$$

$$\therefore \quad 2.5 \text{ mL } 1\text{N } NH_3 = \frac{14}{1000} \times 2.5 = \frac{7}{200} \text{ g nitrogen}$$

Thus, 0.303 g of aromatic compound contains $\frac{7}{200}$ g of nitrogen.

Hence,percentage of nitrogen

$$= \frac{7 \times 100}{200 \times 0.303} = 11.55$$

(*ii*) *Calculation of empirical formula*

Percentage of carbon = 69.40

Percentage of hydrogen = 5.80

Percentage of nitrogen = 11.55

Percentage of oxygen = 100 – (69.4 + 5.8 + 11.55) = 13.25

$$\therefore \quad C : H : N : O = \frac{69.40}{12} : \frac{5.80}{1} : \frac{11.55}{14} : \frac{13.25}{16}$$

$$= 5.8 : 5.80 : 0.825 : 0.828$$

$$= 7 : 7 : 1 : 1$$

(by dividing each with 0.825)

$\therefore$ The empirical formula of the aromatic compound is C_7H_7NO.

(*iii*) *Calculation of molecular formula*

The empirical formula weight of the aromatic compound, C_7H_7NO, is 7 × 12 + 7 × 1 + 14 + 16 = 121.

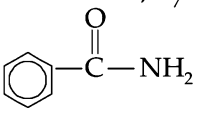
$$n = \frac{\text{Molecular weight}}{\text{Empirical formula weight}} = \frac{121}{121} = 1$$

Hence, molecular formula of the compound is the same as the empirical formula *i.e.*, C_7H_7NO. ($\because$ M.F. = *n* × E.F. = 1 × C_7H_7NO = C_7H_7NO)

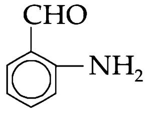
(*iv*) *Structure of the compound.*

Since, the aromatic compound must contain a benzene ring, the two possible structures for the compound with molecular formula, C_7H_7NO are :

(*i*)



(*ii*)



26.5 AIEEE PATTERN EXAMPLES

EXAMPLE 37. *The empirical formula of a non-electrolyte is CH_2O. A solution containing 3 g of the compound exerts the same osmotic pressure as that of 0.05 M glucose solution. The molecular formula of the compound is :*

(*a*) CH_2O (*b*) $C_2H_4O_2$

(*c*) $C_4H_8O_4$ (*d*) $C_3H_6O_3$

(Karnatka CET, 2011)

SOLUTION.

Empirical formula = CH_2O. So, E.F. mass = 12 + (2 × 1) + 16 = 30

wt. of glucose = 3 g.

1 M of glucose, $C_6H_{12}O_6$ = (6 × 12) + (12 × 1) + (6 × 16) = 180 g mol$^-$

$\therefore$ 0.05 M glucose, 180 × 0.05 = 9 g

$$\text{For isotonic solution, } \frac{W_a}{M_a} = \frac{W_{C_6H_{12}O_6}}{M_{C_6H_{12}O_6}};$$

$$\frac{3}{M_a} = \frac{9}{180}$$

$$\therefore \quad M_a = 3 \times 180/9 = 60$$

But Molecular formula = *n* × Empirical formula

where *n* = M.wt./E.F. wt = 60/30 = 2.

$\therefore$ Molecular formula = 2 × CH_2O = $C_2H_4O_2$.

So, the correct formula is (*b*).

EXAMPLE 38. *An organic compound having molecular mass 60 is found to contain C = 20%, H = 6.67% and N = 46.67% while rest is oxygen. On heating, it gives NH_3 along with a solid residue. The solid residue gives violet colour with alkaline copper sulphate solution. The compound is :*

(1) CH_3NCO (2) CH_3CONH_2

(3) $(NH_2)_2CO$ (4) $CH_3CH_2CONH_2$

(AIEEE, 2005)

SOLUTION. C = 20%, H = 6.67%,

N = 46.67%,

$$O = 100 - (20 + 6.67 + 46.67)$$
$$= 26.66.$$

Element	*% age*	*At.wt*	*Relative number of atoms = % age/At. wt.*	*Simple ratio*	*Whole no. ratio*
C	20	12	$\frac{20}{12} = 1.67$	$\frac{1.67}{1.67} = 1$	1
H	6.67	1	$\frac{6.67}{1} = 6.67$	$\frac{6.67}{1.67} = 4$	4
N	46.67	14	$\frac{46.67}{14} = 3.33$	$\frac{3.33}{1.67} = 2$	2
O	26.66	16	$\frac{26.66}{16} = 1.67$	$\frac{1.67}{1.67} = 1$	1

$\therefore$ E.F. of compound = $C_1H_4N_2O_1 = CH_4N_2O$.

Since the compound gives out NH_3 on heating and it gives violet colour with alkaline copper sulphate (Biuret test), it appears to be urea, NH_2CONH_2.

$$2NH_2CONH_2 \xrightarrow{\Delta} NH_2CONHCONH_2 + NH_3 \uparrow$$

So, the correct answer is (3).

EXAMPLE 39. *A solution containing 1.8 g of a compound (empirical formula CH_2O) in 40 g water is observed to freeze at –0.465°C. The molecular formula of the compound is : (K_f for water = 1.86 kg K mol⁻) :*

(*a*) $C_2H_4O_2$ (*b*) $C_3H_6O_3$ (*c*) $C_4H_8O_4$

(*d*) $C_5H_{10}O_5$ (*e*) $C_6H_{12}O_6$ **(Kerala PET, 2011)**

SOLUTION. Let M = molar mass of compound ;

E.F. = CH_2O ;

$$\text{Molality, } m = \frac{\text{wt.}}{\text{Mol. wt}} \times \frac{1000}{\text{wt. of solvent}}$$

$$= \frac{1.8 \text{ g}}{\text{M}} \times \frac{1000}{40 \text{ g}} = \frac{45}{\text{M}} \text{ mol kg}^{-}$$

$$\Delta T_f = 0.465°\text{C or } 0.465 \text{ K}.$$

We know that

$$\Delta T_f = K_f \times m \text{ ;}$$

$$0.465 \text{ K} = 1.86 \text{ kg K mol}^{-} \times \frac{45}{\text{M}} \text{ mol kg}^{-}$$

$$\therefore \qquad \text{M} = \frac{1.86 \text{ kg K mol}^{-} \times 45 \text{ mol kg}^{-}}{0.465 \text{ K}}$$

$= 180$ [E.F. wt. of CH_2O = 12 + (2 × 1) + 16 = 30]

Molecular formula = n × empirical formula

$$\text{where} \qquad n = \frac{\text{Molecular mass (wt.)}}{\text{E.F. weight}}$$

$$= \frac{180}{30} = 6$$

$\therefore$ Molecular formula = 6 × CH_2O = $C_6H_{12}O_6$.

Hence the correct answer is (*e*).

EXAMPLE 40. *A hydrocarbon contains 80% carbon. What is the empirical formula of the compound ?*

(*a*) CH_4 (*b*) CH_3 (*c*) CH_4

(*d*) CH (*e*) C_2H_3 **(Kerala PMT, 2011)**

SOLUTION. % age of C = 80 ; % age of H = 100 – 80 = 20

To find empirical formula (E.F.), we use the following table.

Element	*% age*	*At.wt*	*Relative no. of atoms = % age/At. wt.*	*Simple ratio*	*Whole no. ratio*
Carbon, C	80	12	80/12 = 6.67	$\frac{6.67}{6.67} = 1$	1
Hydrogen, H	20	1	20/1 = 20	$\frac{20}{6.67} = 2.99$	3

$\therefore$ E.F. of hydrocarbon = C_1H_3 or CH_3.

So, the correct answer is (*b*).

EXAMPLE 41. *In the estimation of sulphur by carius method, 0.480 g of an organic compound gives 0.699 g of barium sulphate. The percentage of sulphur in this compound is (atomic mass, Ba = 137, S = 32, O = 16):*

(*a*) 20 % (*b*) 15 % (*c*) 35 %

(*d*) 30 % (*e*) 40 % **(Kerala PET, 2012)**

SOLUTION. $BaSO_4 \equiv S$

137 + 32 + (4 × 16)

= 233 g 32g

233 g $BaSO_4$ contain S = 32 g

$$0.699 \text{ g BaSO}_4 \text{ contain S} = \frac{32}{233} \times 0.699 \text{ g}$$

$$\therefore \text{ \% age of S} = \frac{\text{wt. of S}}{\text{wt. of substance}} \times 100$$

$$= \frac{32}{233} \times \frac{0.699}{0.48} \times 100 = 20.$$

So, the correct answer is (*a*).

EXAMPLE 42. *A gaseous hydrocarbon gives upon combustion 0.72 g of water and 3.08 g of CO_2. The empirical formula of hydrocarbon is:*

(1) C_3H_4 (2) C_6H_5

(3) C_7H_8 (4) C_2H_4 **(JEE Main, 2013)**

SOLUTION. Mol wt. of H_2O $(2 \times 1) + 16 = 18$g mol^{-}; mol. wt. of $CO_2 = 12 + (2 \times 16) = 44$ g mol^{-}.

$$\text{No. of mol of } H_2O \text{ produced} = \frac{\text{wt}}{\text{mol . wt}} = \frac{0.72}{18} = 0.04$$

$$\text{No. of mol of } CO_2 \text{ produced} = \frac{\text{wt}}{\text{mol. wt.}} = \frac{3.08}{44} = 0.07$$

Equation to show combustion of hydrocarbon C_xH_y is:

$$C_xH_y + \left(x + \frac{y}{4}\right)O_2 \longrightarrow xCO_2 + \frac{y}{2}\, H_2O \text{ ....(1)}$$

From equation (1), $x = 0.07$ and $\frac{y}{2} = 0.04$ i.e.,

$y = 2 \times 0.04 = 0.08$

$\therefore \ \frac{x}{y} = \frac{0.07}{0.08} = \frac{7}{8}$. Hence the empirical formula of hydrocarbon is C_7H_8.

So, the correct answer is (3).

PROBLEMS FOR PRACTICE

1. Calculate the empirical formula of the following molecular formulae.

   (*i*) C_6H_6 (*ii*) N_2O_4

   (*iii*) H_2O (*iv*) Na_2CO_3

   [**Ans** (*i*) CH (*ii*) NO_2 (*iii*) H_2O (*iv*) Na_2CO_3]

2. Calculate the % age of Na in Na_2CO_3. **Ans.** 43.4%

3. A hydrocarbon is composed of 75 % carbon. The empirical formula of the compound is :

   (*a*) CH_2 (*b*) CH_3 (*c*) C_2H_5

   (*d*) C_2H_7 (*e*) CH_4 **(Kerala PMT, 2010)**

   Ans. (*e*)

4. In an experiment, 4 g of M_2O_x oxide was reduced to 2.8 g of the metal. If the atomic mass of the metal is 56 g mol^{-}, the number of O-atoms in the oxide is :

   (*a*) 1 (*b*) 2

   (*c*) 3 (*d*) 4

   (AFMC, 2010)

   Ans. (*c*).

5. 1.0 g of a hydrated compound of iron contains 0.2014 g of Fe, 0.1153 g of S, 0.231 g O and 0.4532 g of water of crystallisation. Find the empirical formula of the compound. (**Ans.** $FeSO_4 \cdot 7H_2O$)

6. When anhydrous salt of zinc weighing 1.615 g. was placed in moist air, it got fully hydrated and weighed 2.875 g. Calculate the molecular formula of the hydrated compound, if it contains Zn = 40.6%, O = 39.6% and S = 19.8%. (At. wt. Zn = 65, S = 32, O = 16, H = 1)

   (**Ans.** $ZnSO_4.7H_2O$).

7. The chloride of a platinum contains 42.1 % chlorine. Calculate its empirical formula (At. wt. Pt = 195, Cl = 35.5)

   (**Ans.** Pt Cl_4)

8. Calculate he molecular formula of an organic compound having mol. wt. 30 g mol^{-} and percentage of C and H as 80% and 20% respectively. (At. wt. C = 12, H = 1)

   (**Ans.** C_2H_6).

9. Copper chloride weighing 4.0 g on analysis was found to contain 2.11 g chlorine (Cl) and 1.89 g copper (Cu). Calculate the empirical formula of the compound.

   (At. wt. Cu = 63.5, Cl = 35.5)

   (**Ans.** Cu Cl_2)

10. The molecular weight of an organic compound is 78 g mol^{-} and its percentage composition is 92.3% C and 7.69% H. Find its molecular formula.

    (**Ans.** C_6 H_6)

27

CHAPTER

Structure and Reaction Based Problems

27.1 SOME BASIC CONCEPTS

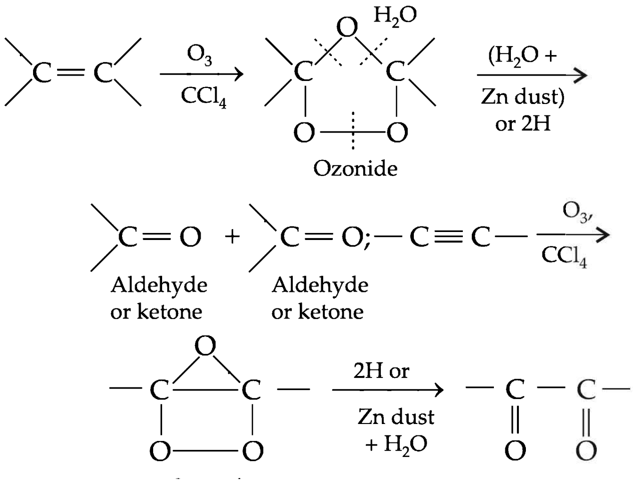
In order to elucidate structure of organic compounds based on certain given reactions, some specific reactions of organic compounds are given for the help of students. The students are advised to go through these reactions before attempting the concerned problem.

1. **Saturated hydrocarbons** (C_nH_{2n+2}). These usually undergo **substitution** reactions. e.g.,

$$CH_4 + Cl_2 \xrightarrow{h\nu} CH_3Cl + HCl$$

2. Unsaturated hydrocarbons [C_nH_{2n} *i.e.*, $C=C$ **double bond** ; C_nH_{2n-2} *i.e.*, $C\equiv C$ **triple bond**]. These undergo **addition reactions.** For example :

(*a*) Ozonolysis reactions.



The process helps to decide nature of unsaturation in the compound. It also helps to locate the position of unsaturation in a compound. For example; the **terminal alkynes** give the following reactions.

(*i*) Reaction with ammoniacal Cu_2Cl_2 to give red precipitate of Cu(I) acetylide

$$\underset{\text{Terminal Carbon}}{2[-C\equiv CH]} + Cu_2Cl_2 \longrightarrow \underset{\text{Red ppt.}}{[-C\equiv C.Cu]} + 2HCl$$

(*ii*) Reaction with Na to give H_2 gas

$$-C\equiv CH \xrightarrow[NH_3]{\text{Na in}} -C\equiv C.\,Na + \frac{1}{2}H_2$$

(*iii*) Reaction with ammoniacal silver nitrate to give white ppt. of silver alkylide.

$$-C\equiv CH + Ag_2O \longrightarrow \underset{\text{Silver alkylide (white ppt.)}}{-C\equiv C.\,Ag} + H_2O$$

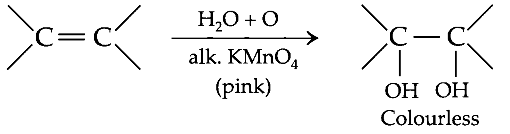
Note. **Ozonolysis of** (*i*) **Symmetrical alkenes** (e.g., $CH_2=CH_2$, $CH_3CH=CHCH_3$ etc) give two mole of same carbonyl compound ($>C=O$).

(*ii*) **Alkynes** give one product having two carbonylic groups.

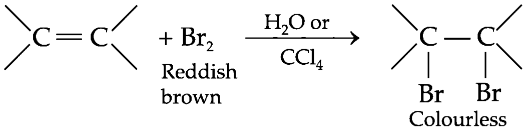
(*iii*) **Cycloalkenes** give one product having two carbonyl groups.

(*b*) **Halogenation of alkenes.** These follow anti-addition. Br_2 adds to cis-2-butene to give a racemic mixture of 2,3-dibromobutane. Br_2 adds to trans-2-butene to give a meso-derivative of 2, 3-dibromobutane.

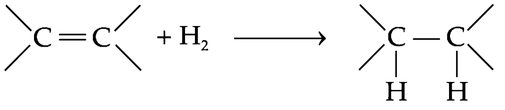
(*c*) **Decolorises Baeyer's reagent** (1% cold alkaline $KMnO_4$ solution).



(*d*) Decolorises bromine water or Br_2 solution in CCl_4.

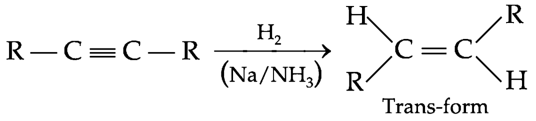


(*e*) **Addition of H_2** to form saturated hydrocarbon.

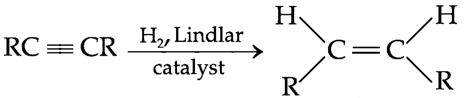


(*f*) **Hydrogenation of alkynes**

(*i*) With Na/NH_3, trans-form is formed.



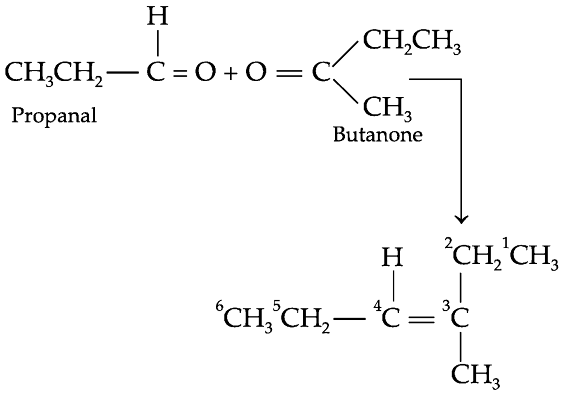
(*ii*) With H_2 in presence of **Lindlar catalyst,** cis form is obtained.



$$RC \equiv CR \xrightarrow[\text{catalyst}]{H_2,\text{ Lindlar}} \text{(H)(R)C} = \text{C(H)(R)}$$

Cis-form

Location of C ═ C in alkenes : The structure of alkene can be obtained by removing the oxygen atoms of the two carbonyl carbons of products and making a double bond between the carbonyl carbon atoms. *e.g.,* if an alkene on ozonolysis followed by action with Zn-dust and water gives propanal and butanone, the structure of alkene will be:



3-Methyl-hex-3-ene

3. Halides

(*i*) **Monohalides.** (a) with KOH(aq), these give **alcohols**

$$RX + KOH(aq) \longrightarrow ROH + KX$$

(*b*) **With KOH (alcoholic),** these give **alkene**

$$RCH_2 - CH_2X + KOH\ (alc) \longrightarrow RCH = CH_2 + KX + H_2O$$

(*ii*) **Dihalides.** (a) with KOH (aq), **vicinal** dihalides (*i.e.,* halogens on different carbon atoms), give diol.

$$CH_2X - CH_2X \xrightarrow{KOH\,(aq)} CH_2OH - CH_2OH\ (diol)$$

(*b*) **With KOH(aq), gem** dihalides (*i.e.,* halogens on the same carbon atom) with **terminal** position to halogens, give **aldehydes.**

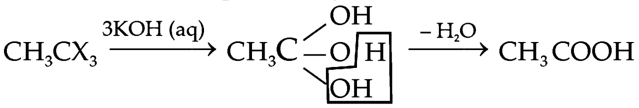
$$CH_3CH_2CHX_2 \xrightarrow{KOH\,(aq)} CH_3CH_2CHO \quad \text{(Propanal)}$$

(*c*) **With KOH(aq),** gem dihalides with **non-terminal position** to halogens give **ketones**

$$CH_3.CX_2.CH_3 \xrightarrow{KOH\,(aq)} CH_3COCH_3\ \text{(Acetone)}$$

(*iii*) **Trihalides.** When all the three halogens are on terminal carbon atoms then :

(*a*) With KOH (aq), **carboxylic acid** is formed,



$$CH_3CX_3 \xrightarrow{3KOH\,(aq)} CH_3C(OH)_3 \xrightarrow{-H_2O} CH_3COOH$$

Unstable Acetic acid

(*b*) With primary amine and alc. KOH, these give **carbylamine reaction.** As a result, unpleasant odour is produced.

$$CHCl_3 + RNH_2 + 3KOH\,(alc) \longrightarrow RN \equiv C + 3KCl + 3H_2O$$

Chloroform Carbylamine (unpleasant smell)

4. Alcohols.

(*i*) These give esters (having fruity odour) when warmed with carboxylic acids.

$$ROH + RCOOH \xrightarrow{\text{Warm}} RCOOR + H_2O.$$

(*ii*) These give red colour with ceric ammonium nitrate

(*iii*) These evolve H_2 gas with effervescence when treated with Na or K metal.

$$2ROH + 2Na \longrightarrow 2RONa + H_2\,(g).$$

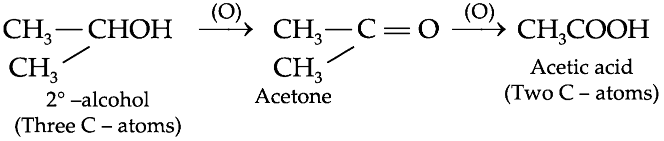
Distinction among primary (1°), secondary (2°) and tertiary (3°) alcohols.

Oxidation test (*a*) 1°- alcohols on oxidation give firstly aldehyde and finally carboxylic acid having same number of carbon atoms as that of 1°-alcohol

$$RCH_2OH \xrightarrow{[O]} RCHO \xrightarrow{[O]} RCOOH$$

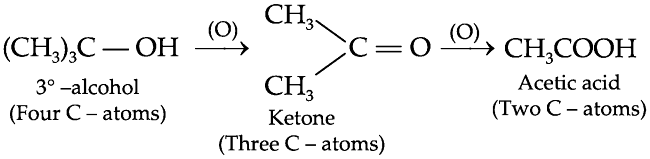
1°-alcohol Aldehyde Carboxylic acid.

(*b*) 2°–alcohols (on oxidation) give first of all ketones (with same number of carbon atoms as of 2°–alcohol) and finally carboxylic acid (having one carbon atom less than the parent 2°–alcohol)



$$(CH_3)_2CHOH \xrightarrow{(O)} (CH_3)_2C = O \xrightarrow{(O)} CH_3COOH$$

(*c*) **3°-alcohols** (on drastic oxidation) give first of all ketones (with one C-atom less than the parent 3°-alcohol) and finally carboxylic acid (with two C-atoms less than the parent 3°-alcohol)



$$(CH_3)_3C - OH \xrightarrow{(O)} (CH_3)_2C = O \xrightarrow{(O)} CH_3COOH$$

(B) **Lucas Test.** Lucas reagent is 'anhydrous $ZnCl_2$ + Conc. HCl'.

(*i*) Primary alcohols donot give white ppt. or cloudiness with Lucas reagent within 15 minutes but give separate layer of alkyl chloride on heating.

$$CH_3CH_2OH \xrightarrow[\text{conc,HCl, }\Delta]{\text{anhy. }ZnCl_2,} CH_3CH_2Cl$$

(*ii*) **Secondary alcohols** give ppt. or cloudiness in 5-10 minutes with Lucas reagent.

$$(CH_3)_2CHOH \xrightarrow[\text{conc,HCl}]{\text{Anhy. }ZnCl_2,} (CH_3)_2\,CHCl$$

(Isopropyl chloride)

(*iii*) **Tertiary alcohols** give ppt. or cloudiness immediately.

$$(CH_3)_3COH \xrightarrow[\text{conc,HCl}]{\text{Anhyd. }ZnCl_2,} (CH_3)_3CCl$$

(tert. butyl chloride)

(C) Victor Meyer's method

(*i*) Primary, secondary and tertiary alcohols on treatment with P + I_2, $AgNO_2$ and alkali, give blood red colour, blue colour and no colour respectively.

(D) Action of dehydration reagent. At low temperature, these give ether.

$$2ROH \xrightarrow[\text{temp.}]{\text{low}} R\text{–}OR(\text{ether}) + H_2O$$

At higher temperature, alkene is formed. The order of reaction is : tert. alcohol > sec. alcohol > primary alcohol.

$$CH_3CH_2OH \longrightarrow CH_2 = CH_2 + H_2O.$$

(E) Action with Cu at 200–300°C. 1°, 2° and 3° alcohols give aldehyde, ketone and alkene respectively.

5. Ethers.

(*i*) These donot change the colour of litmus.

(*ii*) **Action with conc.** HI.

(*a*) **In cold,** alkyl iodide is formed.

$$ROR + HI \longrightarrow RI + ROH$$

(*b*) **In hot,** two mol of alkyl iodide are formed

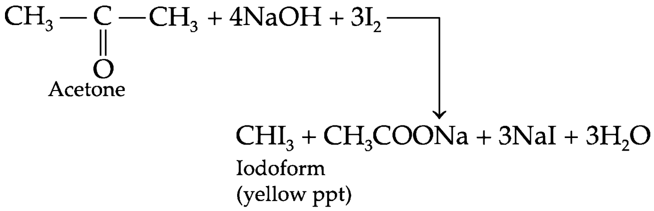
$$ROR' + 2HI \longrightarrow RI + R'I + H_2O$$

(*c*) With mixed ethers, the iodide gets attached to alkyl group having less number of carbon atoms.

$$CH_3OC_2H_5 + HI \longrightarrow CH_3I + C_2H_5OH$$

6. Carbonyl ($>C=O$) compounds (aldehydes and ketones)

(*i*) **Iodoform test.** Acetaldehyde and all methyl ketones *i.e.*, organic compounds containing  $CH_3-\underset{\underset{O}{\|}}{C}-$ unit bonded to H or carbon give yellow *ppt.* with NaOH + I_2 solution.



$$\underset{\text{Acetone}}{CH_3-\underset{\underset{O}{\|}}{C}-CH_3} + 4NaOH + 3I_2 \longrightarrow \underset{\substack{\text{Iodoform}\\ \text{(yellow ppt)}}}{CHI_3} + CH_3COONa + 3NaI + 3H_2O$$

(*ii*) Action with DNP *i.e.*, 2, 4-dinitrophenyl hydrazine. Both aldehyde and ketone give orange-yellow solid with DNP.

(*iii*) **Aldehydes.** (*a*) Reduce Schiff's reagent to give pink colour.

(*b*) Reduce Benedict reagent to give red ppt. of Cu_2O.

(*c*) Reduce Fehling solution to give red ppt. of Cu_2O

$$R\,CHO + 2CuO \longrightarrow R\,COOH + Cu_2O\downarrow \text{(red ppt.)}.$$

Benzaldehyde does not give this test.

(*d*) Reduce Tollen's reagent (ammoniacal silver nitrate solution) to give silver mirror test.

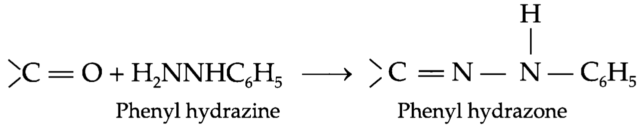
$$RCHO + Ag_2O \longrightarrow RCOOH + 2Ag\downarrow \text{(silver mirror)}$$

(*e*) Give primary alcohols on reduction.

(*f*) **Addition reactions.** All aldehydes (and only methyl ketones) give white ppt. with sodium bisulphite.

(*g*) Carbonyl compounds give oxime with hydroxylamine and hydrazone with phenylhydrazine.

$$>C=O + \underset{\text{Hydroxylamine}}{H_2NOH} \longrightarrow \underset{\text{Oxime}}{>C=NOH} + H_2O$$



$$>C=O + \underset{\text{Phenyl hydrazine}}{H_2NNHC_6H_5} \longrightarrow \underset{\text{Phenyl hydrazone}}{>C=N-\overset{\overset{H}{|}}{N}-C_6H_5}$$

Note 1. Like aldehydes, ketones form addition products with $NaHSO_3$, 2, 4-dinitrophenyl hydrazine, HCN, NH_3. Ketones donot reduce Fehling solution, Benedict solution, donot give pink colour with Schiff's reagent, give secondary alcohol on reduction, on oxidation give carboxylic acid with one carbon atom less than the parent ketone.

2. An aldehyde when warmed with dilute alkali undergoes aldol condensation. Such an aldehyde must contain an α-hydrogen.

7. Carboxylic acids.

(*i*) These turn blue litmus red.

(*ii*) These give effervescence with $NaHCO_3$ solution.

$$RCOOH + NaHCO_3 \longrightarrow RCOONa + CO_2\uparrow + H_2O$$

(*iii*) When heated with soda-lime (NaOH + CaO), CO_2 gas is evolved along with alkane.

$$RCOOH \xrightarrow[\Delta]{CaO + NaOH} RH + CO_2.$$

(*iv*) **With NH_3.** When heated with NH_3, amide is formed which on further heating with P_2O_5 form cyanide.

$$RCOOH + NH_3 \longrightarrow RCOONH_4 \xrightarrow{-H_2O}$$

$$\underset{\text{Amide}}{RCONH_2} \xrightarrow[-H_2O]{P_2O_5} \underset{\text{Cyanide}}{RCN}$$

(*v*) With alcohol and conc. H_2SO_4, acids give esters having fruity odour.

$$RCOOH + R'OH \xrightarrow[H_2SO_4]{\text{Conc.}} \underset{\text{ester}}{RCOOR'} + H_2O.$$

(*vi*) **On dry distillation** (*a*) Calcium formate gives formaldehyde.

$$Ca(HCOO)_2 \longrightarrow CaCO_3 + HCHO \text{ (formaldehyde)}$$

(*b*) Calcium acetate gives acetaldehyde.

$$Ca(CH_3COO)_2 \longrightarrow CaCO_3 + CH_3CHO \text{ (acetaldehyde)}$$

(*c*) A mixture of $Ca(HCOO)_2$ and $Ca(CH_3COO)_2$ give acetaldehyde.

$$Ca(HCOO)_2 + Ca(CH_3COO)_2 \longrightarrow 2CaCO_3 + 2CH_3CHO.$$

(*d*) If a mixture contains $Ca(HCOO)_2$, only aldehydes are formed. See reaction (*c*) above

(*e*) Mixed calcium salts of acids give all possible products.

8. Acid derivatives

(*i*) **Acid anhydrides.** (*a*) These form carboxylic acid on hydrolysis.

$$RCO.O.COR + H_2O \longrightarrow 2RCOOH$$

(*b*) These form ester and carboxylic acid with alcohol.

$$\text{RCO.O.COR} + \text{R'OH} \longrightarrow \text{RCOOH} + \underset{\text{(ester)}}{\text{R COOR'}}$$

(*ii*) **Acid amides.** (*a*) Form ammonia, when boiled with alkali, NH_3 gives brown ppt. with Nessler's reagent.

$$\text{RCONH}_2 + \text{NaOH} \longrightarrow \text{RCOONa} + \text{NH}_3$$

(*b*) **Hofmann's bromamide reaction.** These give primary amine when heated with KOH (aq) and Br_2.

$$\text{RCONH}_2 + 4\text{KOH} + \text{Br}_2 \longrightarrow \underset{\text{Primary amine}}{\text{RNH}_2} + \text{K}_2\text{CO}_3 + 2\text{KBr} + 2\text{H}_2\text{O}$$

(*c*) Form **nitrogen gas,** when heated with nitrous acid (HNO_2)

$$\text{RCONH}_2 + \text{HONO} \longrightarrow \text{RCOOH} + \text{N}_2\uparrow + \text{H}_2\text{O}$$

(*d*) Form cyanides *i.e.*, nitriles when heated with dehydrating agents like P_2O_5, $KHSO_4$ etc.

$$\text{RCONH}_2 \xrightarrow[\Delta]{\text{P}_2\text{O}_5} \text{RCN} + \text{H}_2\text{O}$$

(*iii*) **Esters.** (*a*) These possess fruity smell.

(*b*) Decolorise pink colour of phenolphthalein when boiled with aqueous alkali.

(*c*) On **reduction,** form two molecules of alcohol.

$$\text{RCOOR'} \xrightarrow{\text{Reduction}} \text{RCH}_2\text{OH} + \text{R'OH}$$

(*d*) On **hydrolysis,** form an alcohol and carboxylic acid.

$$\text{RCOOR'} + \text{HOH} \longrightarrow \text{R'OH} + \text{RCOOH}$$

(*iv*) **Acid chlorides.** (*a*) These fume in moist air due to their hydrolysis into HCl(g) and corresponding acid.

$$\text{RCOCl} + \text{HOH} \longrightarrow \text{HCl(g)}\uparrow + \text{RCOOH}$$

(*b*) On Rosenmund's reduction, these form aldehydes.

$$\text{RCOCl} + \text{H}_2 \xrightarrow[\text{S}]{\text{Pd, BaSO}_4} \text{RCHO} + \text{HCl}$$

9. Amines

(*i*) **Primary amines.** (*a*) Aliphatic as well as aromatic amines (*e.g.,*) aniline, $C_6H_5NH_2$, give carbylamine reaction (see serial no. 3, halides)

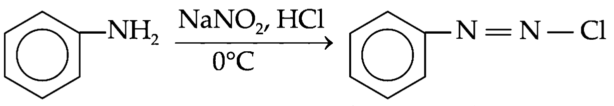
(*b*) **Action with HNO_2**($NaNO_2$ + HCl, 0°C). These give N_2 gas with HNO_2.

$$\text{RNH}_2 + \text{HONO} \longrightarrow \text{ROH} + \text{N}_2\uparrow + \text{H}_2\text{O}$$

(*c*) **Action with Hinsberg's reagent,** $C_6H_5SO_2Cl$. These give sulphonamide with $C_6H_5SO_2Cl$ which is soluble in an alkali

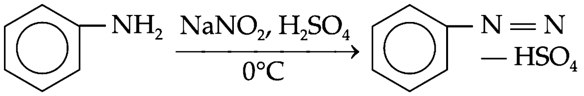
$$\text{RNH}_2 + \text{C}_6\text{H}_5\text{SO}_2\text{Cl} \longrightarrow \text{RNHSO}_2\text{C}_6\text{H}_5 \xrightarrow{\text{NaOH}} \text{RN NaSO}_2\text{C}_6\text{H}_5 \text{ (Solution)}$$

(*d*) **Diazotization.** Aromatic amines having $-NH_2$ group undergo diazotization with HNO_2 *i.e.*, $NaNO_2$ + HCl at 0°C (or $NaNO_2$ + H_2SO_4 at 0°C) to form diazonium salt

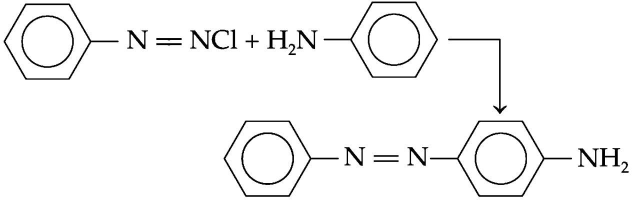


Aniline Benzene diazonium chloride

or



These diazonium salts undergo coupling reaction to form dye



p-Aminoazobenzene (yellow dye)

(*ii*) **Secondary amines.** (*a*) These react with nitrous acid HNO_2 ($NaNO_2$ + HCl) to give yellow oily substance, called nitrosamine.

$$\text{R}_2\text{NH} \xrightarrow{\text{HNO}_2} \underset{\text{(Yellow oily substance)}}{\text{R}_2\text{N}-\text{N}=\text{O}}$$

(*b*) **With Hinsberg's reagent,** $C_6H_5SO_2Cl$. These give sulphonamide with $C_6H_5SO_2Cl$ which is insoluble in an alkali.

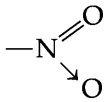
$$\text{R}_2\text{NH} + \text{C}_6\text{H}_5\text{SO}_2\text{Cl} \longrightarrow \text{R}_2\text{NSO}_2\text{C}_6\text{H}_5 \xrightarrow{\text{alkali}} \text{no action.}$$

(*iii*) **Tertiary amines.** (*a*) These react with HNO_2 ($NaNO_2$ + HCl) to give following products.

$$\text{R}_3\text{N} \xrightarrow{\text{HONO}} \text{R}_3\text{N.HNO}_2 \xrightarrow{\Delta} \text{R}_2\text{N.NO} + \underset{\text{(alcohol)}}{\text{ROH}}$$

(*b*) With Hinsberg's reagent $C_6H_5SO_2Cl$, these amines donot react.

10. Nitro compounds



(*i*) These form yellow coloured substance with NaOH solution.

(*ii*) Reduction with Sn + HCl. These form primary amine on reduction with Sn and HCl.

$$\text{RNO}_2 \xrightarrow[\text{(Sn + HCl)}]{6\text{H}} \text{RNH}_2 + 2\text{H}_2\text{O}$$

(*iii*) These give acids and hydroxylamine on hydrolysis.

11. Alkyl nitrite (R — O — N = O)

(*i*) On **hydrolysis,** these give corresponding alcohols giving nitrous acid.

(*ii*) On **reduction, these** form corresponding alcohols, liberating ammonia.

12. Cyanids.

(*i*) On **reduction,** these form primary amines.

$$\text{RCN} + 2\text{H}_2 \xrightarrow{\text{Pt}} \text{RCH}_2\text{NH}_2$$

(*ii*) On **hydrolysis** by an acid or alkali, acids are formed,

$$RCN + H_2O \xrightarrow{H^+} RCONH_2 \xrightarrow{H_2O, H^+} RCOOH + NH_4^+$$

13. **Isocyanides.**

(*i*) On **reduction**, these form secondary amines.

$$RNC + 2H_2 \longrightarrow RNHCH_3$$

(*ii*) On **hydrolysis**, these give primary amines.

$$RNC + 2HOH \longrightarrow HCOOH + RNH_2$$

14. **Aromatic compounds.**

(*a*) Such compounds obey $(4n + 2)\ \pi$ electron rule (*i.e.*, **Huckel's rule**) in planar ring system. Here, *n* is any integer, 0, 1, 2 etc.

(*b*) Groups such as $-OH$, $-NH_2$, $-OR$, $-NHCOCH_3$, $-SH$, $-CH_3$, $-X$, NH_3^+, $-NC$ etc, already present in the nucleus, are **ortho and para dircting** groups.

(*c*) Groups such as $-NO_2$(nitro), $-CN$, $-CHO$, $-COOH$, $-SO_3H$, $-CCl_3$ etc are **meta–directing** groups

15. **Carbohydrates.**

(*i*) **Molish's test.** 2 mL carbohydrate (aq) is firstly mixed with 1 or 2 drops of alcoholic solution of α – naphthol. Now 1mL of conc. H_2SO_4 is added along the sides of the tube. Violet ring at the junction confirms carbohydrate.

(*ii*) **Osazone formation.** When glucose or fructose ($C_6H_{12}O_6$) is heated with phenylhydrazine in presence of acetic acid, a yellow crystalline compound called osazone (m.p. 205°C) is formed.

16. **Phenols**

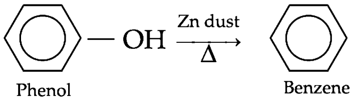
(*i*) These turn moist blue litmus red

(*ii*) These donot give effervescence with $NaHCO_3$

(*iii*) These are soluble in alkali

(*iv*) These give characteristic colour with aqueous $FeCl_3$ solution.

(*v*) Phenol when heated with zinc dust forms benzene.



17. **Ammonium salts of acids.**

(*i*) When ammonium salts of monocarboxylic acid are heated, acid amides are formed. For test of amides, see acid amides on previous pages.

(*ii*) When ammonium salts of dicarboxylic acids (having — COOH groups on adjacent C–atoms) of aliphatic and aromatic compounds are heated, amides are formed which further lose ammonia molecule to give imides.

27.2 SOME TYPICAL FACTS

1. A compound which undergoes haloform reaction, must contain CH_3CO- group.
2. A compound which does not answer iodoform test, does not contain CH_3CO- group.
3. A compound which forms mono-ozonide contains a $C=C$ double bond. A mono-ozonide of the type shown in Fig. 1 undergoes hydrolysis in presence of zinc dust to give RCHO (aldehyde) and $\begin{matrix}R\\R'\end{matrix}\!\!>C=O$ (a ketone) where R′ = alkyl group and not H; if R′ = H, then aldehyde is obtained.

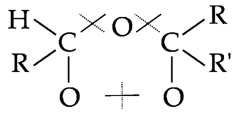


Fig. 1.

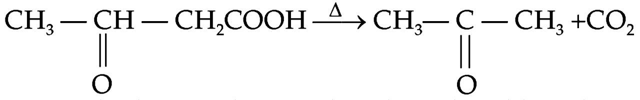
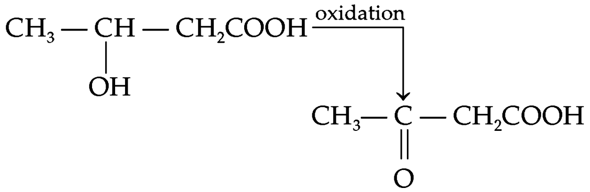
4. To assign position to keto group in carbon chain, keto acids on careful oxidation undergo C — C bond fission at a place where $>C=O$ is situated.

   Further keto-group is also converted into–COOH and remains with acid having smaller number of C-atoms
5. Only β – hydroxy acids (and not α – hydroxy acids) lose H_2O on heating
6. Compounds like $CH_3CH_2CHOHCOOH$ or $CH_3CHOHCH_2COOH$ lose optical activity on strong heating because of the formation of alkene.
7. β - keto-substituted acids when heated give out CO_2 gas, *e.g.*,



$$CH_3-\underset{\underset{O}{\|}}{C}H-CH_2COOH \xrightarrow{\Delta} CH_3-\underset{\underset{O}{\|}}{C}-CH_3 + CO_2$$

8. β - hydroxy substituted acids with mild oxidants will give β-keto-acids. *e.g.*,



$$CH_3-\underset{\underset{OH}{|}}{CH}-CH_2COOH \xrightarrow{\text{oxidation}} CH_3-\underset{\underset{O}{\|}}{C}-CH_2COOH$$

9. Hydrolysis of tertiary alkyl halides is independent of nucleophilic concentration.
10. Phenols give Libermann as well as Reimer-Tiemann ($CHCl_3/KOH$ or CCl_4/KOH) reaction to introduce —CHO or COOH groups in the ring at ortho and para positions.
11. An organic compound which on heating with NaOH or KOH gives NH_3 (giving white fumes with a rod dipped in HCl) will contain—$CONH_2$ group or — CN group.

    Compounds which give red colour with ceric ammonium nitrate contain an alcoholic group, — OH
12. An optically active compound contains asymmetric C–atom. Geometrical isomers contain $C=C-$ β or δ.
13. Tollen's reagent converts compounds like $CH_3CH=CHCHO$ to $CH_3CH=CHCOOH$
14. Carbylamine test is only performed for primary amines with $CHCl_3$ + KOH, to get obnoxious smelling isocyanide.

15. Symmetrical aromatic hydrocarbons like CH_3 —  — CH_3 give only one monosubstituted (*e.g.*, mononitro) derivative.
16. An organic compound that has an asymmetric (or chiral) carbon atom as well as a C $=$ C, will show optical as well as geometrical isomerisms. e.g., $CH_3CH = CH — CH^*(Br)\ CH_3$. Here C* is the chiral carbon. A chiral C–atom is that which is bonded to four different atoms or groups.
17. Compounds which do not reduce Fehling solution but form oxime are ketones; give Beilstein test, are usually alkyl halides; give ppt. with ammonical Cu_2Cl_2, will have $C \equiv CH$ at the corner; aldol condensation takes place in aldehydes and ketones having α-hydrogen; give silver mirror test and reduce Fehling solution, are aldehydes.
18. Degree of unsaturation = [No. of C– atoms] – [No. of H–atoms] + 1.

27.3. OPTICAL ISOMERS

Type. To calculate number of optical isomers.

1. For molecules having no symmetry.

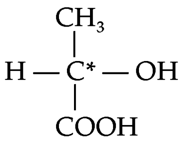
(*a*) no. of *d* and *l* forms, $a = 2^n$ where n = no. of asymmetric carbon atoms.

(*b*) no. of meso *l*-forms, $m = 0$

$\therefore$ Total no. of optical isomers $= a + m = 2^n + 0 = 2^n$

EXAMPLE 1. *Calculate the total number of optical isomers of lactic acid.*

SOLUTION. Lactic acid is :



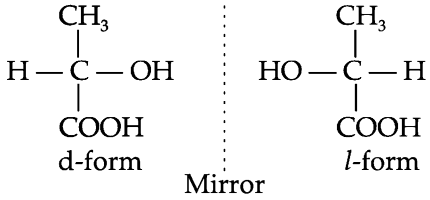
$$H — \overset{\displaystyle CH_3}{\underset{\displaystyle COOH}{C^*}} — OH$$

no plane of symmetry

no. of asymmetric C–atoms = 1

$\therefore$ *d* and *l* forms, $a = 2^n = 2^1 = 2$

Meso forms, $m = 0$ $\therefore$ Total number of optical isomers $= a + m = 2 + 0 = 2$



$$H — \overset{\displaystyle CH_3}{\underset{\displaystyle COOH}{C}} — OH \qquad HO — \overset{\displaystyle CH_3}{\underset{\displaystyle COOH}{C}} — H$$

d-form Mirror *l*-form

Mirror images are also called enantiomers.

Type. For molecules having symmetry.

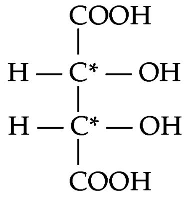
(*a*) no. of *d* and *l* forms, $a = 2^{n-1}$ where n is the number of asymmetric C–atoms.

(*b*) no. of meso *l*-forms, $m = 2^{\frac{n}{2}-1}$; Total no. of optical isomers $= a + m = 2^{n-1} + 2^{\frac{n}{2}-1}$

(*c*) No. of racemic forms $= a/2$.

EXAMPLE 2. *Calculate the total number of optical isomers of tartaric acid.*

SOLUTION. Tartaric acid is :



$$\begin{array}{c} COOH \\ | \\ H — C^* — OH \\ | \\ H — C^* — OH \\ | \\ COOH \end{array}$$

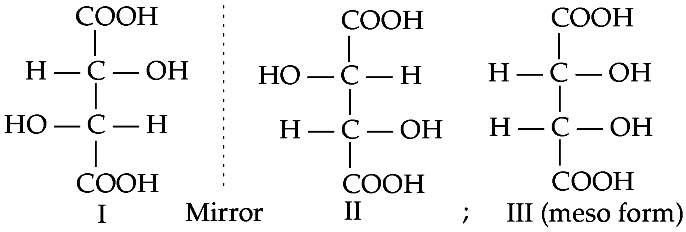
Plane of symmetry
$n = 2$

no. of asymmetric C-atoms = 2 ; *d* and *l* forms,

$$a = 2^{n-1} = 2^{2-1} = 2$$

Meso forms, $m = 2^{\frac{n}{2}-1} = 2^{\frac{2}{2}-1} = 2^{1-1} = 2^0 = 1$

$\therefore$ Total no. of optical isomers $= a + m = 2 + 1 = 3$



$$\begin{array}{c} COOH \\ | \\ H — C — OH \\ | \\ HO — C — H \\ | \\ COOH \end{array} \qquad \begin{array}{c} COOH \\ | \\ HO — C — H \\ | \\ H — C — OH \\ | \\ COOH \end{array} \qquad \begin{array}{c} COOH \\ | \\ H — C — OH \\ | \\ H — C — OH \\ | \\ COOH \end{array}$$

I Mirror II ; III (meso form)

Structures I and III or II and III which are not mirror images of each other, are called **diastereoisomers**.

Type. Specific rotation $[\alpha]_{\lambda}^{T} = \dfrac{\alpha}{l \times C}$

Where, l = length of tube in decimeters (dm)

C = concentration in g cm^{-3}, for a solution, density is in g cm^{-3} for a pure liquid,

λ = wave length of light used.

EXAMPLE 3. *The specific rotation of R–(–)–2–bromooctane was found to be–36°. Calculate the percentage composition of a mixture of enantiomers of 2 – bromooctane where rotation is + 18°.*

SOLUTION. Let mole fraction of $R = x$

$$\begin{aligned} \therefore \quad \text{mole fraction of } S &= 1 - x \\ \therefore \quad x(-36°) + (1 - x)\,36° &= 18° \\ \therefore \quad -36°x + 36° - 36°x &= 18°; \\ -72°x &= 18 - 36 = -18° \\ \therefore \quad x &= \frac{-18°}{-72°} = \frac{1}{4} \\ \therefore \quad \%\text{ age of } R &= \frac{1}{(1+4)} \times 100 = 25\%; \\ \%\text{ age of } S &= 100 - 25 = 75\% \end{aligned}$$

27.4 MISCELLANEOUS PROBLEMS

EXAMPLE 4. *A compound (X) containing only C, H and O is unreactive to-wards sodium. It does not add bromine. It also does not react with Schiff's reagent. On refluxing with an excess of hydriodic acid, (X) yields only one organic product (Y). On hydrolysis, (Y) yields a new compound (Z) which can be converted to (Y) by reaction with red phosphorus and iodine. The compound (Z) on oxidation with potassium permanganate gives carboxylic acid. The equivalent weight of this acid is 60. What are the compounds (X), (Y) and (Z) ? Write chemical equations leading to the conversion of (X) to (Y).* **(IIT, 1981)**

Solution. (*X*) does not react with Schiff's base. So, it is not an aldehyde. (*Z*) on oxidation gives carboxylic acid, so it should be an alcohol. (*X*) reacts with HI to give iodide. Also, (*Z*) gives (*Y*) with P_4 and I_2. So, (*X*) is expected to be an ether. Thus :

$$\underset{\text{Diethyl ether } (= X)}{CH_3CH_2OCH_2CH_3} \xrightarrow{HI} \underset{(Y)}{CH_3CH_2I} + \underset{(Z)}{CH_3CH_2OH}$$

$$\underset{(Z)}{CH_3CH_2OH} \xrightarrow[\text{Red P, } I_2]{HI,} \underset{(Y)}{CH_3CH_2I} + H_2O$$

$$\underset{Z}{CH_3CH_2OH} \xrightarrow{2[O]} \underset{\text{Carboxylic acid (acetic acid)}}{CH_3COOH + H_2}$$

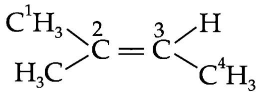
∴ (*X*) = Diethyl ether ;

(*Y*) = Ethyl iodide ; (*Z*) = Ethyl alcohol.

Example 5. *One mole of a hydrocarbon (A) reacts with one mole of bromine giving a dibromo compound $C_5H_{10}Br_2$. Substance (A) on treatment with cold, dilute alkaline potassium permanganate solution forms a compound $C_5H_{10}O_2$. On ozonolysis, (A) gives equimolar quantities of propanone and ethanal. Deduce the structural formula of (A).* **(IIT, 1981)**

Solution. Since (*A*) reacts with Br_2 and alkaline $KMnO_4$, (A) must contain a C = C double bond. The products of (*A*) on ozonolysis are $(CH_3)_2\,C = O$ and  $CH_3\underset{\underset{H}{|}}{C} = O$. So, the compound (*A*) can be the compound as shown below:

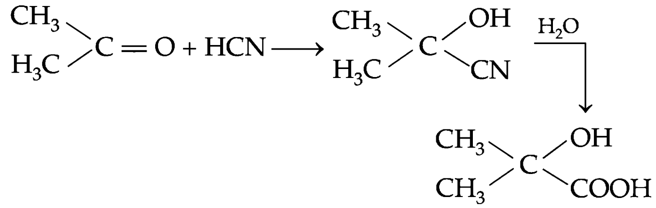
$$(CH_3)_2C = \underset{\text{remove}}{\boxed{O+O}} = C\,(H)\,(CH_3) \text{ i.e.,}$$



or 2 - Methyl but-2-ene.

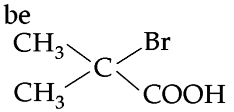
Example 6. *An alkene (A) on ozonolysis yields acetone and an aldehyde. The aldehyde is easily oxidised to an acid (B). When (B) is treated with bromine in the presence of phosphorus, it yields a compound (C) which an hydrolysis gives a hydroxy acid (D). This acid can also be obtained from acetone by the reaction with hydrogen cyanide followed by hydrolysis. Identify the compounds A, B, C and D.* **(IIT, 1982)**

Solution. (*i*) (*D*) is obtained by the action of acetone on HCN followed by hydrolysis. So, we have :



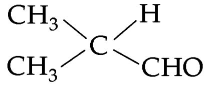
(D)

(*ii*) Since (*D*) is also obtained by the hydrolysis of (*C*), so (*C*) will be

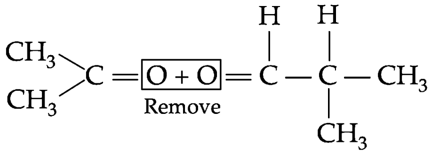


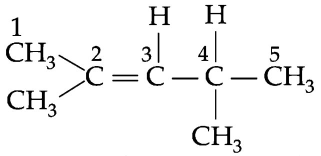
(C)

(*iii*) (*C*) is obtained by treating (*B*) with Br_2 and P. So, (*B*) must contain α – hydrogen. Hence, (*B*) is  . The aldehyde from (***B***) will be



(*iv*) Alkene (*A*) on ozonolysis gives acetone (CH_3COCH_3) and the aldehyde (B). So, the alkene will be:





2, 4-Dimethyl pent -2-ene. (**A**)

Example 7. *An alcohol (A) when heated with conc. H_2SO_4 gives an alkene (B). When (B) is bubbled through bromine water and the product obtained is dehydrohalogenated with excess of sodalime, a new compound (C) is obtained. The compound (C) gives (D) when treated with warm dil. H_2SO_4, in presence of $HgSO_4$. (D) can also be obtained by either oxidising A with $KMnO_4$ or from acetic acid through its calcium salt. Identify A, B, C and D.* **(IIT, 1983)**

Solution. (A) is an alcohol. (D) is obtained from oxidation of A or from CH_3COOH through its calcium salt. So, (*A*) will contain two carbon atoms. Thus :

(*i*) (*A*) is C_2H_5OH (ethyl alcohol).

(*ii*) $C_2H_5OH + H_2SO_4 \xrightarrow{170°C} \underset{\text{Ethene } (B)}{CH_2 = CH_2} + H_2O$

(*iii*) $CH_2 = CH_2 \xrightarrow{Br_2} CH_2Br - CH_2Br$

$$\xrightarrow[\substack{\text{with sodalime} \\ (-\ 2HBr)}]{\text{Dehydrohalogenated}} \underset{\substack{\text{Ethyne} \\ (C)}}{CH \equiv CH}$$

(*iv*) $CH \equiv CH \xrightarrow[HgSO_4]{\text{dil. } H_2SO_4} \underset{(D)}{CH_3CHO}$. Also ,

$$C_2H_5OH \xrightarrow[KMnO_4]{[O]} \underset{(D)}{CH_3CHO} + H_2O$$

Example 8. *A certain hydrocarbon (A) was found to contain 85.7 % carbon and 14.3 percent hydrogen. This compound consumes 1 molar equivalent of hydrogen to give a saturated hydrocarbon (B). 1.0 g of hydrocarbon (A) just decolorised 38.05 g of a 5 percent solution (by weight) of Br_2, in CCl_4. Compound (A) on oxidation with concentrated $KMnO_4$, gave compound (C) (molecular formula C_4H_8O) and acetic acid. Compound (C) could easily be prepared by the action of acidic aqueous mercuric sulphate on 2– butyne. Determine the molecular formula of (A) and deduce the structures of A, B and C.* **(IIT, 1984)**

Solution. At. wt. of $C = 12 ; H = 1 ; Br = 80$

Given : $C = 85.7\ \% ; H = 14.3\% ;$

wt. of $(A) = 1.0$ g ;

Wt. of Br_2 decolorised = 38.05 g of 5% Br_2.

(*i*) Number of carbon atoms $= \frac{85.7}{12} = 7.14$

(*ii*) Number of *H*–atoms $= \frac{14.3}{1} = 14.3$

$\therefore$ Atomic ratio of C : H is 7 . 14 : : 14.3

or $\frac{7.14}{7.14} : \frac{14.3}{7.14}$ or **1 : 2**

$\therefore$ Empirical formula $= C_1H_2$ Or $\mathbf{CH_2}$.

(*A*) consumes 1 molar equivalent of H_2. So, (*A*) will have only one $C = C$. Thus :

1 g of (*A*) consumes $Br_2 = \frac{38.05}{100} \times 5 = 1.9025$ g ;

Mol. wt. of $Br_2 = 2 \times 80 = 160$

$\therefore$ 1.9025 g of Br_2 is consumed by $A = 1.0$ g

160 g of Br_2 is consumed by

$$A = \frac{1}{1.9025} \times 160 = 84.1\text{g} \approx 84\text{ g}$$

No. of C–atoms in 84 g

$$A = \frac{\text{Wt}}{\text{Mol. wt. of } CH_2}$$

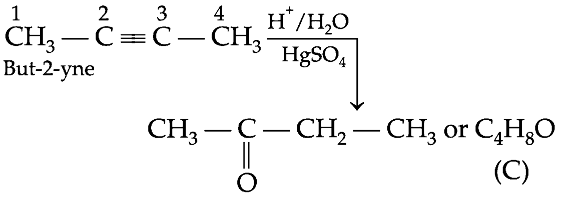
$$= \frac{84}{[12 + (2 \times 1)] = 14} = 6$$

$\therefore$ No. of H–atoms in $A = 84 - (12 \times 6) = 12$

$\therefore$ Molecular formula of $A = \mathbf{C_6H_{12}}$

(*iii*) (*A*) on oxidation with $KMnO_4$ gives (*C*) and acetic acid, CH_3COOH. (*C*) has molecular formula C_4H_8O. Thus :

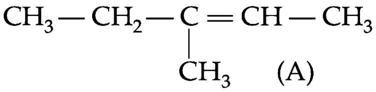
$(A) \xrightarrow{KMnO_4} (C) + CH_3COOH$. Also, (*C*) is formed from the reaction.



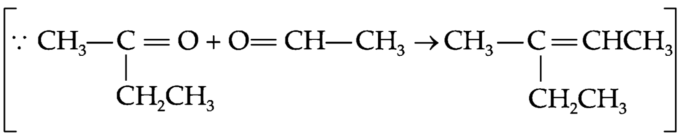
$$\overset{1}{C}H_3 - \overset{2}{C} \equiv \overset{3}{C} - \overset{4}{C}H_3 \xrightarrow[HgSO_4]{H^+/H_2O} CH_3 - \underset{\underset{O}{\|}}{C} - CH_2 - CH_3 \text{ or } C_4H_8O$$

But-2-yne (C)

(*iv*) The molecular formula of (*A*) will thus be :



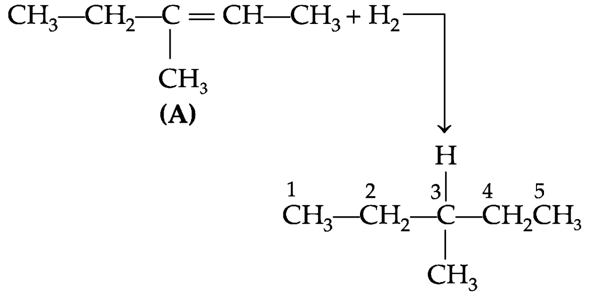
$$CH_3 - CH_2 - \underset{\underset{CH_3}{|}}{C} = CH - CH_3 \quad (A)$$



$$\left[\because CH_3 - \underset{\underset{CH_2CH_3}{|}}{C} = O + O = CH - CH_3 \rightarrow CH_3 - \underset{\underset{CH_2CH_3}{|}}{C} = CHCH_3 \right]$$

; CH_3CHO gives CH_3COOH on oxidation.

But $A + H_2 \longrightarrow B$. So, (*B*) will be :



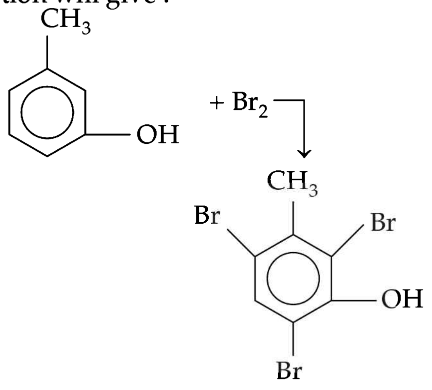
$$CH_3-CH_2-\underset{\underset{CH_3}{|}}{C} = CH-CH_3 + H_2 \longrightarrow \overset{1}{C}H_3-\overset{2}{C}H_2-\overset{\overset{H}{|}}{\overset{3}{C}}-\overset{4}{C}H_2\overset{5}{C}H_3 \text{ with } CH_3 \text{ on } C_3$$

(A)

3-Methyl pentane (**B**).

Example 9. *A compound of molecular formula C_7H_8O is insoluble in water and dilute sodium bicarbonate but dissolves in aqueous sodium hydroxide. On treatment with bromine water, it readily gives a precipitate of $C_7H_5OBr_3$. Write down the structure of the compound.* **(IIT, 1985)**

Solution. The compound is insoluble in water and $NaHCO_3$ but soluble in NaOH (aq). So, the compound is expected to be a phenol. The formula of this compound will be . This compound on bromination will give :



or $C_7H_5OBr_3$ **Ans.**

1-Methyl-2, 4, 6,-tribromophenol.

Example 10. *A white precipitate was formed slowly when silver nitrate was added to compound (A) with molecular formula $C_6H_{13}Cl$. Compound (A) on treatment with hot alcoholic KOH gave a mixture of two isomeric alkenes (B) and (C) having formula C_6H_{12}. The mixture of (B) and (C) on ozonolysis furnishes four compounds :*

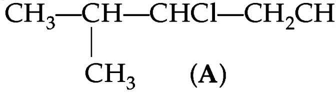
(*i*) CH_3CHO (*ii*) C_2H_5CHO

(*iii*) CH_3COCH_3 *and*

(*iv*) 
$$CH_3-\underset{\underset{CH_3}{|}}{CH}-CHO.$$

Write the structures of A, B and C. **(IIT, 1986)**

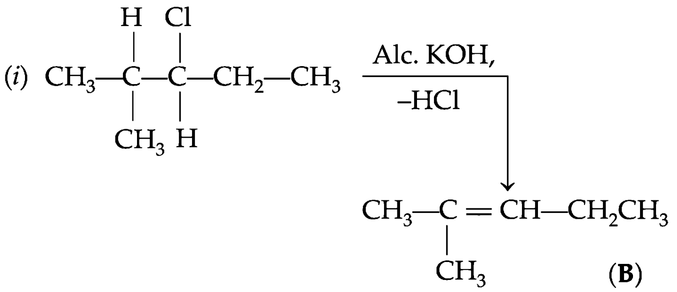
Solution. (*a*) The structure of (*A*) having molecular formula $C_6H_{13}Cl$ will be



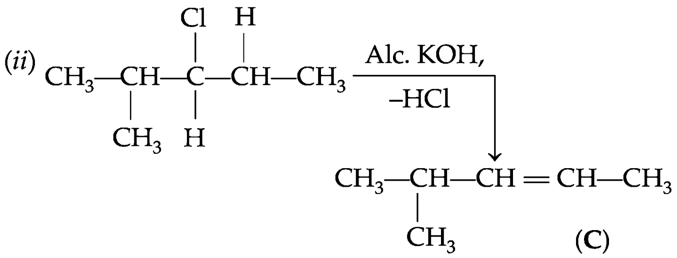
$$CH_3-\underset{\underset{CH_3}{|}}{CH}-CHCl-CH_2CH_3 \quad (A)$$

because it gives white precipitate of AgCl with $AgNO_3$.

(*b*) (*A*) gives following two isomers when treated with alcoholic KOH because alcoholic KOH removes HCl.

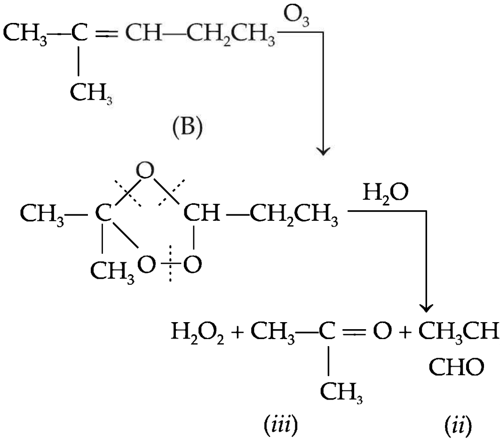


(*i*) $CH_3-\underset{CH_3}{\overset{H}{C}}-\underset{H}{\overset{Cl}{C}}-CH_2-CH_3 \xrightarrow[-HCl]{Alc.\ KOH,} CH_3-\underset{CH_3}{C}=CH-CH_2CH_3$ (**B**)



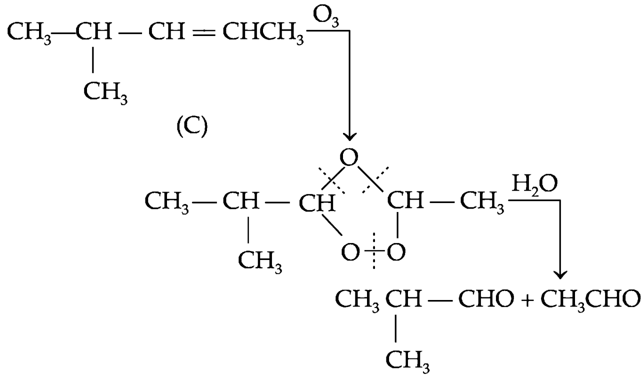
(*ii*) $CH_3-\underset{CH_3}{\overset{Cl}{CH}}-\underset{H}{\overset{H}{C}}-CH-CH_3 \xrightarrow[-HCl]{Alc.\ KOH,} CH_3-\underset{CH_3}{CH}-CH=CH-CH_3$ (**C**)

(*c*) (*B*) and (*C*) on ozonolysis followed by hydrolysis gives the following compounds as required in question.



$CH_3-\underset{CH_3}{C}=CH-CH_2CH_3 \xrightarrow{O_3}$ (B) ozonide $\xrightarrow{H_2O} H_2O_2 + CH_3-\underset{CH_3}{C}=O + CH_3CH_2CHO$

(*iii*) (*ii*)

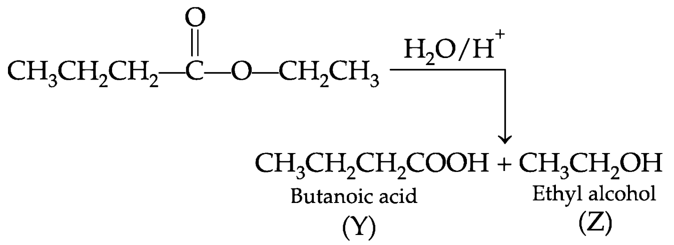


$CH_3-\underset{CH_3}{CH}-CH=CHCH_3 \xrightarrow{O_3}$ (C) ozonide $\xrightarrow{H_2O} CH_3\underset{CH_3}{CH}-CHO + CH_3CHO$

(*iv*) (*i*)

Example 11. *A liquid (X) having a molecular formula $C_6H_{12}O_2$ is hydrolysed with water in the presence of an acid to give a carboxylic acid (Y) and an alcohol (Z). Oxidation of (Z) with chromic acid gives (Y). What are the structures of X, Y and Z ?* **(IIT, 1986)**

Solution. (*X*) gives a carboxylic acid (*Y*) and an alcohol (*Z*), so (*X*) will be an ester. So, $C_6H_{12}O_2$ will be an ester. (*X*), $CH_3CH_2CH_2-COO-CH_2CH_3$ *i.e.*, ethyl propyl ester. Oxidation of (*X*) gives the following compounds.



$CH_3CH_2CH_2-\overset{O}{\overset{\|}{C}}-O-CH_2CH_3 \xrightarrow{H_2O/H^+} \underset{\text{Butanoic acid (Y)}}{CH_3CH_2CH_2COOH} + \underset{\text{Ethyl alcohol (Z)}}{CH_3CH_2OH}$

Example 12. *An unknown compound of carbon, hydrogen and oxygen contain 69.77 % carbon and 11.63% hydrogen and has a molecular weight of 86. It does not reduce Fehling solution but forms a bisulphite addition compound and gives a positive iodoform test. What are the possible structures ?* **(IIT, 1987)**

Solution. At. wt. of C = 12 ; H = 1 ; O = 16 ; C = 69.77%, H = 11.63%, O = 100 –(69.77 + 11.63 = 81.40) = 18.6%.

∴ No. of C–atoms = 69.77/12 = 5.81 ;

No. of H–atoms = 11.63/1 = 11.63

No. of O–atoms = 18.6/16 = 1.16. The ratio of atoms of C : H : O is :

$$5.81 : 11.63 : 1.16 \quad \text{or} \quad \frac{5.81}{1.16} : \frac{11.63}{1.16} : \frac{1.16}{1.16}$$

or 5 : 10 : 1. Hence:

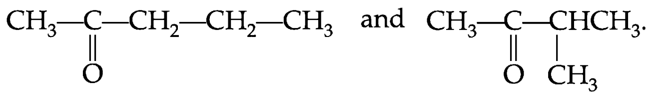
Empirical formula (E.F.) of unknown compound $= C_5H_{10}O$

E.F. wt. of $C_5H_{10}O = (5 \times 12) + (10 \times 1) + (1 \times 16)$
$= 60 + 10 + 16 = 86$

Given mol. wt. = 86.

Hence, molecular formula = E.F. *i.e.*, $\mathbf{C_5H_{10}O}$.

The compound does not reduce Fehling solution. So, it is not an aldehyde *i.e.*, —CHO group is absent. The compound forms a bisulphite. So, it should be a ketone. Since the ketone gives iodoform test, $CH_3-\underset{O}{\underset{\|}{C}}-$ group is a must. So, the possible structures of the keto compounds will be :



$CH_3-\underset{O}{\underset{\|}{C}}-CH_2-CH_2-CH_3$ and $CH_3-\underset{O}{\underset{\|}{C}}-\underset{CH_3}{CH}CH_3$.

Example 13. *An organic compound (A) on treatment with acetic acid in the presence of sulphuric acid produces an ester (B). (A) on mild oxidation gives (C). (C) with 50% potassium hydroxide followed by acidification with hydrochloric acid generates (A) and (D). (D) with phosphorus pentachloride followed by reaction with ammonia gives (E). (E) on dehydration produces hydrocyanic acid. Identify the compounds A, B, C, D and E.* **(IIT, 1987)**

Solution. The sequence of reactions given in the question is :

(*a*) $A + CH_3COOH \xrightarrow{H_2SO_4} B$ (ester)

(*b*) $A \xrightarrow[\text{Oxidation}]{\text{Mild}} (C) \xrightarrow[\text{(ii) HCl}]{\text{(i) 50\% KOH}} (A) + (D)$

(*c*) $(D) \xrightarrow[\text{(ii) } NH_3]{\text{(i) } PCl_5} (E) \xrightarrow[(-H_2O)]{\text{Dehydration}} HCN$

Since (E) on dehydration gives HCN, it suggests that (E) will be an amide with one C–atom only. So, (E) is $HCONH_2$ (formamide). Also, (A gives the ester (B) with CH_3COOH, so (A) will be an alcohol with one C–atom *i.e.*, CH_3OH. So, the reactions will be as follows :

$$\underset{(A)}{CH_3OH} + CH_3COOH \xrightarrow[-H_2O]{H_2SO_4} \underset{\text{Dimethyl ester }(\mathbf{B})}{CH_3COOCH_3}$$

$$CH_3OH \xrightarrow[\text{oxidation}]{\text{Mild}} \underset{\text{Formaldehyde }(\mathbf{C})}{HCHO}$$

$$\underset{(C)}{2HCHO} \xrightarrow[\text{(ii) Dil. HCl}]{\text{(i) 50\% KOH}} \underset{(\mathbf{A})}{CH_3OH} + \underset{\text{Formic acid }(\mathbf{D})}{HCOOH}$$

$$\underset{(\mathbf{D})}{HCOOH} \xrightarrow[\text{(ii) } NH_3]{\text{(i) } PCl_5} \underset{\text{Formamide }(\mathbf{E})}{HCONH_2} \qquad \underset{(\mathbf{E})}{HCONH_2} \xrightarrow{-H_2O} HCN$$

EXAMPLE 14. *An organic compound (A) containing C,H,N and O, on analysis gives 49.32% carbon, 9.59% hydrogen and 19.18% nitrogen. (A) on boiling with NaOH gives off* NH_3 *and a salt which on acidification gives a monobasic nitrogen free acid (B). The silver salt of (B) contains 59.67% silver. Deduce the structures of (A) and (B).* **(IIT, 1988)**

SOLUTION. To calculate empirical formula (E.F.) of (A).
% age of O = 100 – (% age of C, H, N) = 100 – (49.32 + 9.59 + 19.18) = 21.91

Element	*At. wt.*	*% age*	*Relative no. of atoms = % age/ At.wt.*	*Simple ratio*	*Whole no. ratio*
C	12	49.32	49.32/12 = 4.11	4.11/1.37 = 3	3
H	1	9.59	9.59/1 = 9.59	9.59/1.37 = 7	7
N	14	19.18	19.18/14 = 1.37	1.37/1.37 = 1	1
O	16	21.91	21.19/16 = 1.37	1.37/1.37 = 1	1

∴ E.F. of (A) = C_3H_7NO.

(A) when boiled with NaOH gives off NH_3. So, (A) will be an amide. But % age of Ag in silver salt, (B) = 59.67

$$\text{But Eq. wt. of acid} = \left[\frac{\text{Eq. wt. of Ag}}{\text{wt. of Ag}} \times 100\right] - 107$$

$$= \left[\frac{108 \times 100}{59.67}\right] - 107$$

$$= 181 - 107 = 74$$

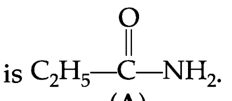
Mol. wt. of monobasic acid

$$= \text{Eq. wt. of acid} \times \text{basicity}$$

$$= 74 \times 1 = 74$$

∴ Mol. wt. of acid = $C_3H_6O_2$ (mol. wt. = 74)

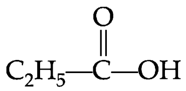
So, **structure of amide,** C_3H_7NO is



$C_2H_5-\overset{\overset{\large O}{\|}}{C}-NH_2$.

(A)

Structure of acid is



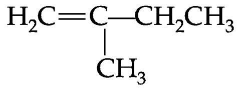
$C_2H_5-\overset{\overset{\large O}{\|}}{C}-OH$

(B)

EXAMPLE 15. *A hydrocarbon (molecular formula* C_5H_{10}*) yields 2-methyl butane on catalytic hydrogenation. (A) adds HBr (in accordance with Markownikoff's rule) to form a compound (B) which on reaction with silver hydroxide forms an alcohol (C),* $C_5H_{12}O$*. Alcohol (C) on oxidation gives a ketone (D). Deduce the structures of A, B, C and D and show the reactions involved.* **(IIT, 1988)**

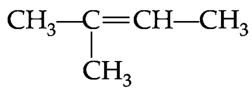
SOLUTION. C_5H_{10} is an alkene (A) because it gives an alkane (2–methyl butane) on catalytic hydrogenation. So, (A) must have a C = C double bond. The alkene will, thus, have the following possible structures.

(*i*)



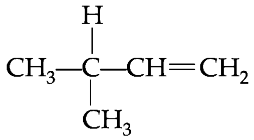
$H_2C{=}\underset{\underset{\large CH_3}{|}}{C}-CH_2CH_3$

(*ii*)



$CH_3-\underset{\underset{\large CH_3}{|}}{C}{=}CH-CH_3$

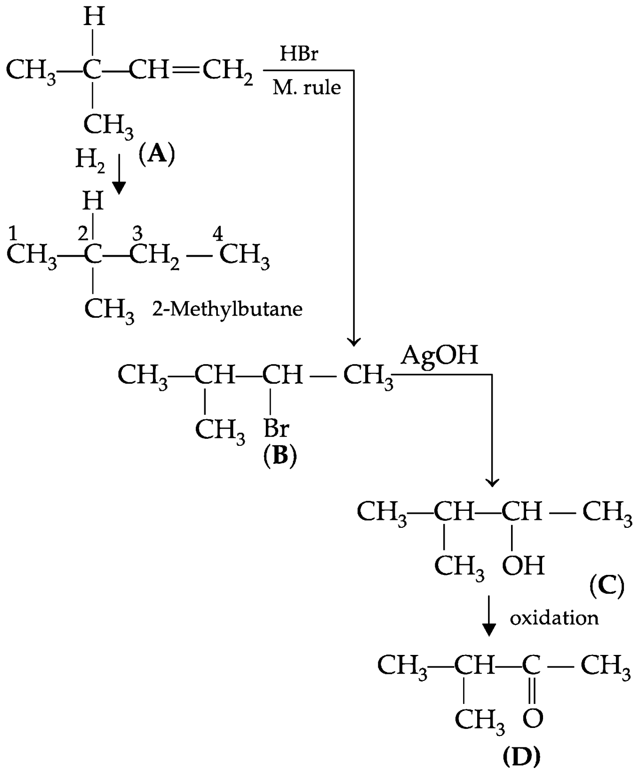
(*iii*)



$CH_3-\overset{\overset{\large H}{|}}{\underset{\underset{\large CH_3}{|}}{C}}-CH{=}CH_2$

(*C*) gives a ketone on oxidation. So, (C) must be a secondary alcohol. The corresponding bromide (B) should also be a secondary bromide. But secondary bromide is fomed by the addition of HBr to alkene by Markownikoff's rule. So, the alkene (A) will have the structure, (*iii*).

Thus :



EXAMPLE 16. *An organic compound (X) on analysis gives 24.24 percent carbon and 4.04 percent hydrogen. Further, sodium extract 1.0 g of X gives 2.90 g of silver chloride with acidified silver nitrate solution. The compound (X) may be represented by two isomeric structures (Y) and (Z). (Y) on treatment with aqueous potassium hydroxide solution gives dihydroxy com-*

pound while (Z) gives ethanal. Find out the molecular formula of (X) and give the structures of (Y) and (Z). **(IIT, 1989)**

Solution. Given : C = 24.24% ; H = 4.04%. At. wt. of C = 12, H = 1, Cl = 35.5, Ag = 108, molar mass of AgCl = 108 + 35.5 = 143.5. We know that :

Mass percent of chlorine

$$= \frac{\text{at. mass of Cl}}{\text{mol. mass of AgCl}} \times \frac{\text{Mass of AgCl obtained}}{\text{Mass of compound taken}} \times 100$$

$$= \frac{35.5}{143.5} \times \frac{2.9}{1.0} \times 100 = \mathbf{71.74\%}$$

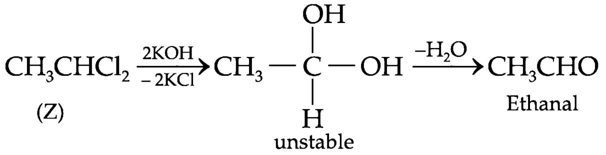
Calculation of empirical formula (E.F.)

Element	At. wt.	% age	Relative no. of atoms = % age/At. wt.	Simple ratio	Whole no. ratio
C	12	24.24	24.24/12 = 2.02	2.02/2.02 = 1	1
H	1	4.04	4.04/1 = 4.04	4.04/2.02 = 2	2
Cl	35.5	71.74	71.74/35.5 = 2.02	2.02/2.02 =1	1

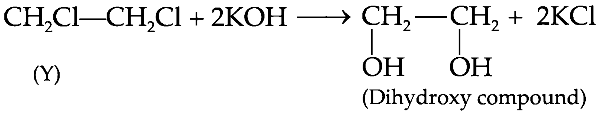
∴ E.F. of compound (X) = $\mathbf{CH_2Cl}$.

(Y) on treatment with KOH (aq) gives dihydroxy compound. So, (X) must have two Cl atoms. So, (X) will be $(CH_2Cl)_2$, or $C_2H_4Cl_2$. *i.e.*, **[X] =** $\mathbf{C_2H_4Cl_2}$

Two isomers of $C_2H_4Cl_2$ will be, CH_3CHCl_2 and $CH_2Cl—CH_2Cl$. These react with KOH as follows.



$$\underset{(Z)}{CH_3CHCl_2} \xrightarrow[-2KCl]{2KOH} \underset{\text{unstable}}{CH_3—\overset{OH}{\overset{|}{C}}(H)—OH} \xrightarrow{-H_2O} \underset{\text{Ethanal}}{CH_3CHO}$$



$$\underset{(Y)}{CH_2Cl—CH_2Cl} + 2KOH \longrightarrow \underset{\text{(Dihydroxy compound)}}{\underset{OH}{CH_2}—\underset{OH}{CH_2}} + 2KCl$$

Example 17. *n-Butane is produced by the monobromination of ethene followed by the Wurtz reaction. Calculate the volume of ethane at NTP required to produce 55 g n-butane, if the bromination takes place with 90% yield and the Wurtz reaction with 85% yield.* **(IIT 1989)**

Solution. $\underset{\text{Ethene (1 mol)}}{CH_2 = CH_2} \xrightarrow[\text{HBr}]{\text{Monobromination}} \underset{\text{(1 mol)}}{CH_3CH_2Br}$ ...(1)

$\underset{\text{1 mol}}{CH_3CH_2Br} + Zn + \underset{\text{1 mol}}{BrCH_2CH_3} \xrightarrow[\text{reaction}]{\text{Wurtz}} \underset{n\text{-Butane}}{CH_3CH_2CH_2CH_3} + ZnBr_2$ ...(2)

Volume of ethane = ? ; Mass of *n*-butane = 55 g.

∴ no. of moles of *n*-butane to be prepared

$$= \frac{\text{Wt.}}{\text{mol. wt}} = \frac{55\text{ g}}{58\text{ g mol}^-}$$

= 0.948 mol

From reaction (2), 1 mol *n*-butane ≡ 1 + 1 *i.e.*, 2 mol C_2H_5Br

$$\left[\begin{array}{l} \because \text{Mol. wt of } C_4H_{10} \\ = (4 \times 12) + (10 \times 1) \\ = 58\text{ g mol}^- \end{array}\right.$$

0.948 mol *n*-butane ≡ 2 × 0.948 mol = 1.896 mol

Since the conversion is only 85%

∴ Amount of C_2H_5Br required

$$= 1.896 \times \frac{100}{85} = 2.23\text{ mol}$$

Also, $\underset{\text{Ethane (1 mol)}}{C_2H_6} + Br_2 \longrightarrow \underset{\text{1 mol}}{C_2H_5Br} + HBr$ ...(3)

From reaction (3), we see that 1 mol ethane ≡ 1 mol C_2H_5Br. But %age conversion of C_2H_6 to C_2H_5Br is 90. So :

Amount of C_2H_6 required

$$= 2.23 \times \frac{100}{90} = 2.478\text{ mol}$$

1 mol C_2H_6 at NTP requires volume = 22.4 L

∴ 2.478 mol C_2H_6 at NTP requires volume

≡ 22.4 L × 2.478 = **55.51 L.**

Example 18. *The sodium salt of a carboxylic acid, (A) was produced by passing a gas, (B) into an aqueous solution of caustic alkali at an elevated temperature and pressure. (A) on heating in presence of sodium hydroxide followed by treatment with sulphuric acid gave a dibasic acid, (C). A sample of 0.4 g of acid (C) on combustion gave 0.08 g of water and 0.39 g of carbon dioxide. The silver salt of the acid weighing 1.0 g on ignition yielded 0.71 g of silver as residue. Identify A, B, and C.* **(IIT, 1990)**

Solution. At. wt. of Ag = 108, C = 12, H = 1, O = 16. Since the given acid is dibasic, so:

$$\text{1 mol dicarboxylic acid} \xrightarrow{\Delta} \text{2 mol of Ag (= 2 × 108 = 216 g).}$$

0.71 g silver is obtained from silver salt = 1.0 g

216 g silver is obtained from silver salt

$$= \frac{1}{0.71} \times 216 = 304.2$$

But Mol. wt. of acid = Mol. wt. of silver salt–2 (at. wt. of Ag) + 2(at. wt. of H)

= 304.2 – (2 × 108) + 2(1)

= 304.2 – 216 + 2 = 90.2 g

So, th dicarboxylic acid (Mol. wt. 90.2) is HOOC—COOH (**C**).

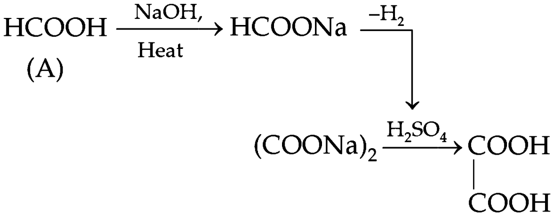
This acid is obtained as given below :

$$A \xrightarrow[\text{Heat}]{\text{NaOH,}} \text{Intermediate compound}$$

$$\xrightarrow{H_2SO_4} HOOC—COOH$$

To find empirical formula (E.F.) of compound (try yourself). Use the method shown in example 21. %age of C = 2.22, H = 26.6, O = 100 – (2.22 + 26.6) = 71.18. So, E.F. = HCO_2 or HCOOH.

The compound (A) should be formic acid because HOOC—COOH is obtained from it as follows.



$$\underset{(A)}{HCOOH} \xrightarrow[\text{Heat}]{\text{NaOH,}} HCOONa \xrightarrow{-H_2} (COONa)_2 \xrightarrow{H_2SO_4} \underset{COOH}{\overset{|}{COOH}}$$

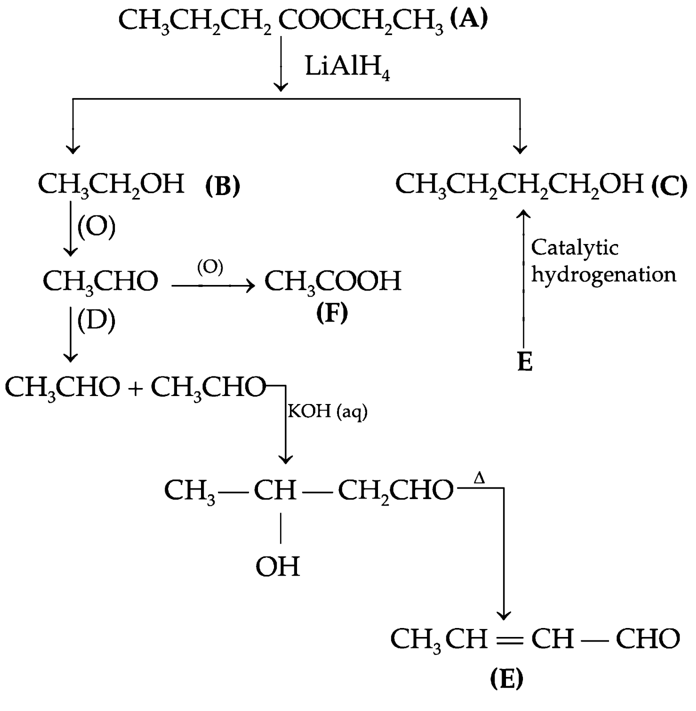
(A) *i.e.*, HCOOH (formic acid) is prepared as follows :

$$NaOH + \underset{(B)}{CO} \xrightarrow[\text{and pressure}]{\text{High temp.}} HCOONa$$

Hence, A = HCOOH ; B = CO gas ; C is COOH—COOH

Example 19. *Compound (A) ($C_6H_{12}O_2$) on reduction with Li AlH_4 yielded two compounds (B) and (C). The compound (B) on oxidation gave (D), which on treatment with aqueous alkali and subsequent heating furnished (E). The latter on catalytic hydrogenation gave (C). The compound (D) was oxidised further to give (E) which was found to be monobasic acid (molecular formula weight = 90.0). Deduce the structures of A, B, C, D, E and F.* **(IIT, 1990)**

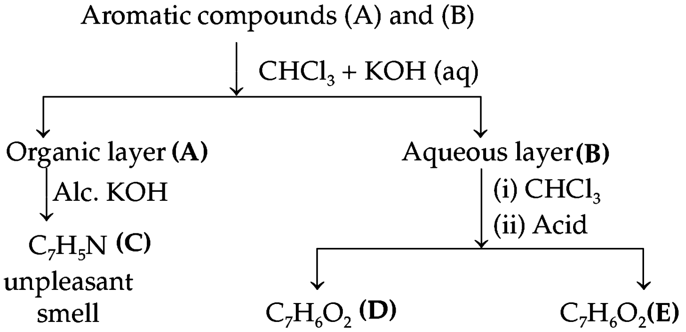
Solution. The compound (A) *i.e.*, $C_6H_{12}O_2$ contains two oxygen atoms. So, it should be an **ester**, $CH_3CH_2CH_2COOCH_2CH_3$. It is propyl ethyl ester. It gives two different alcohols on reduction. The overall reactions are given below.



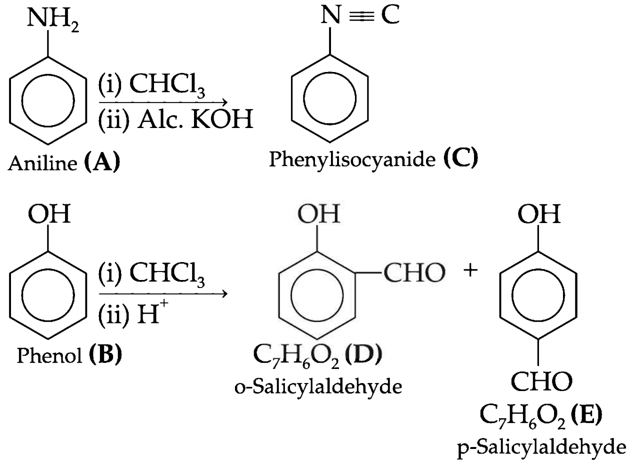
So, A, B, C, D, E and F compounds are those as shown above.

Example 20. *A mixture of two aromatic compounds (A) and (B) was separated by dissolving in chloroform followed by extraction with aqueous KOH solution. The organic layer containing compound (A), when heated with alcoholic solution of KOH produced a compound (C), (C_7H_5N) associated with an unpleasant odour. The alkaline aqueous layer on the other hand, when heated with chloroform and then acidified gave a mixture of two isomeric compounds (D) and (E) of molecular formula $C_7H_6O_2$. Identify the compounds A, B, C, D, E and write their structures.* **(IIT, 1990)**

Solution. The flow sheet of the given data is :



We know that aromatic compounds which have unpleasant smell are isocyanides. These isocyanides are obtained from the action of aromatic compounds containing NH_2 group, on $CHCl_3$ and alcoholic KOH. So, the compound (A) should be aniline. The other aromatic compound (B) should be a phenol because phenol reacts with $CHCl_3$ followed by acidification, gives a mixture of ortho and para salicylaldehydes. Thus :



Example 21. *An organic compound containing C, H and O exists in two isomeric forms (A) and (B). An amount of 0.108 g of one of the isomers gives on combustion 0.308 g of CO_2 and 0.072 g of H_2O. (A) is insoluble in NaOH and $NaHCO_3$ while (B) is soluble in NaOH. (A) reacts with Conc. HI to give compounds (C) and (D). (C) can be separated from (D) by the ethanolic $AgNO_3$ solution and (D) is soluble in NaOH. (B) reacts readily with bromine water to give compound (E) of molecular formula $C_7H_5OBr_3$. Identify A, B, C, D, and E with justification and give their structures.* **(IIT, 1991)**

Solution. To find percentage of C, H and O in the compound.

(*i*) $$\underset{\substack{12 + (2 \times 16)\\ = 44\text{ g}}}{CO_2} \equiv \underset{12\text{ g}}{C}$$

44 g CO_2 contain C ≡ 12g;

$$0.308 \text{ g } CO_2 \text{ contain } C \equiv \frac{12}{44} \times 0.308\text{g}$$

$$\therefore \quad \%\text{ age of C} = \frac{\text{Wt. of } C}{\text{Wt. of substance}} \times 100$$

$$= \frac{12}{44} \times \frac{0.308 \times 100}{0.108} = 77.78$$

(*ii*) $H_2O \equiv 2H$

$(2 \times 1) + 16 = 18$ g $\quad (2 \times 1) = 2$ g

18 g H_2O contain H = 2 g; 0.072 g

$$H_2O \text{ contain H} = \frac{2}{18} \times 0.072\text{g}$$

$$\therefore \quad \% \text{ age of H} = \frac{\text{Wt. of } H}{\text{Wt. of substance}} \times 100$$

$$= \frac{2}{18} \times \frac{0.072}{0.108} \times 100 = 7.41$$

(*iii*) $\% \text{ age of O} = 100 - (\% \text{ age of C} + \% \text{ age of H})$

$= 100 - (77.78 + 7.41)$

$= 100 - 85.19 = 14.81$

(*b*) To find empirical formula (E.F.) of the compound.

Element	At. wt.	% age	Relative no. of atoms = % age/at. wt.	Simple ratio	Whole no. ratio
C	12	77.78	77.78/12 = 6.48	6.48/0.926 = 6.99	7
H	1	7.41	7.41/1 = 7.41	7.41/0.926 = 8	8
O	16	14.81	14.81/16 = 0.926	0.926/0.926 = 1	1

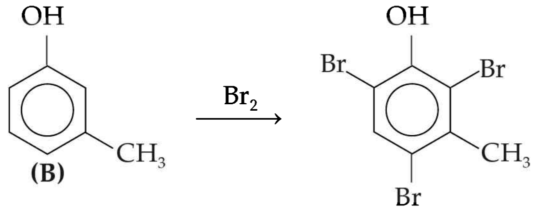
$\therefore$ E. F. of the compound = C_7H_8O.

The carbon content in this compound is very high. So, it will be an aromatic compound. (B) reacts readily with bromine water to give compound (E) of molecular formula $C_7H_5OBr_3$. It indicates that (A) and (B) have same molecular formula.

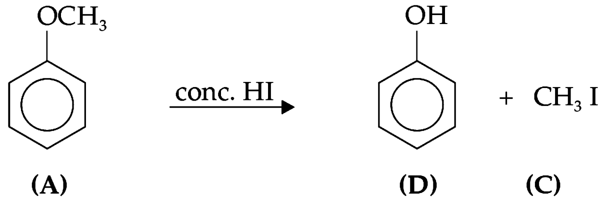
Compound (B) is soluble in NaOH, so, it appears to be a phenol of the formula  (**B**)

The compound (A) is insoluble in NaOH and $NaHCO_3$. So, the other isomer (A) will not be a phenol. So, (**A**) is .

Since (E) is $C_7H_5O\ Br_3$ and contains three Br– atoms, OH and CH_3 groups must be at meta positions in (B). Thus:



Action of (A) with HI will be:



Since (C) can be separated from (D) by ethanolic $AgNO_3$ solution, (C) will be soluble in it, while (D) is insoluble. (D) is soluble in NaOH. The compounds A, B, C, D and E will be :

(A) 
Anisol

(B) 
m-cresol

(C) CH_3I

Methyl iodide

(D) 
Phenol

(E) 
m-Methyl 2, 4, 6 - tribromophenol

Example 22. *Compound (X) containing chlorine, on treatment with strong ammonia gives a solid (Y) which is free from chlorine. (Y) analysed as : C = 49.31%, H = 9.59% and N = 19.18 % and reacts with* Br_2 *and caustic soda to give a basic compound (Z). (Z) reacts with* HNO_2 *to give ethanol. Suggest structures of (X), (Y) and (Z).* **(IIT, 1992)**

Solution. C = 49.31%, H = 9.59%, N = 19.18%, O = 100 – (49.31 + 9.59 + 19.18) = 100 – 78.08 = 21.92 (*a*) To calculate empirical formula (E.F.) of (Y).

Element	At. wt.	% age	Relative no. of atoms = % age/At. wt.	Simple ratio	Whole no. ratio
C	12	49.31	49.31/12 = 4.11	4.11/1.37 = 3.2	3
H	1	9.59	9.59/1 = 9.59	9.59/1.37 = 7	7
N	14	19.18	19.18/14 = 1.37	1.37/1.37 = 1	1
O	16	21.92	21.92/16 = 1.37	1.37/1.37 = 1	1

$\therefore$ E.F. of (*Y*) = C_3H_7NO.

Since (Z) reacts with HNO_2 to give ethanol, CH_3CH_2OH, (Z) will be $CH_3CH_2NH_2$ (ethylamine). So, the sequence of reaction is $(X) \xrightarrow{NH_3} Y \xrightarrow{Br_2/KOH} Z \xrightarrow{HNO_2} C_2H_5OH$

Since *Z* is obtained from (*Y*) and Br_2/KOH, *Y* will be an amide, $C_2H_5CONH_2$. Since (*X*) contains Cl, (*X*) will be C_2H_5COCl. So ; (X) = C_2H_5COCl ; (Y) = $C_2H_5CONH_2$; (Z) = $C_2H_5NH_2$.

Example 23. *An organic compound (A) on treatment with ethyl alcohol gives a carboxylic acid (B) and compound (C). Hydrolysis of (C) under acidic conditions gives (B) and (D). Oxidation of (D) with* $KMnO_4$ *also gives (B). (B) on heating with* $Ca(OH)_2$ *gives (E) (molecular formula* C_3H_6O*). (E) does not give Tollen's test and does not reduce Fehling solution but forms a 2, 4–dinitrophenyl hydrazone. Identify A, B, C, D and E.* **(IIT, 1992)**

Solution. (E) does not give Tollen's test and does not reduce Fehling solution and forms 2, 4-dinitrophenyl hydrazone. So, (E) is not an aldehyde but a ketone. The ketone having given formula C_3H_6O will be CH_3COCH_3 *i.e.*, acetone.

(B) on heating with $Ca(OH)_2$ gives (E) *i.e.*, acetone. So, (B) must be acetic acid, CH_3COOH as $Ca\ (CH_3COO)_2$ on heating gives acetone. (D) will be ethyl alcohol because it gives acetic acid on oxidation.

(C) on hydrolysis under acidic conditions gives (B) *i.e.*, CH_3COOH and (D) *i.e.*, C_2H_5OH. So, (C) will be an ester *i.e.*, $CH_3COOC_2H_5$. (A) reacts with ethyl alcohol (D) to give carboxylic acid (B) and an ester. So, (A) will be acetic anhydride, $CH_3CO.O.COCH_3$.

$$\underset{(A)}{CH_3CO.O.COCH_3} + \underset{(D)}{C_2H_5OH} \rightarrow \underset{(B)}{CH_3COOH} + \underset{(C)}{CH_3COOC_2H_5}$$

Example 24. *Compound (X) (molecular formula, C_5H_8O) does not react appeciably with Lucas reagent at room temperature but gives a precipitate with ammoniacal silver nitrate. With excess of Me Mg Br, 0.42 g of (X) gives 224 mL of CH_4 at S.T.P. Treatment of (X) with H_2 in presence of Pt catalyst followed by boiling with excess HI, gives n-pentane. Suggest, structure for (X) and write the equations involved.* **(IIT, 1992)**

Solution. The compound (*X*) [C_5H_8O, mol. wt. = $(5 \times 12) + (8 \times 1) + 16 = 84$] does not react with Lucas reagent appreciably. So, (*X*) will be a primary alcohol.

(*i*) No. of moles of

$$(X) = \frac{\text{Wt. of } (X)}{\text{Mol. wt. of } (X)}$$

$$= \frac{0.42}{84} = 5 \times 10^{-3} = 0.005 \text{ mol.}$$

(*ii*) No. of moles of CH_4

$$= \frac{\text{Volume of } CH_4 \text{ (mL)}}{22400 \text{ mL}}$$

$$= \frac{224}{22400} = 0.01 \text{ mol}$$

Thus : 0.01 mol of CH_4 contain H–atoms = 4

∴ 0.005 mol of CH_4 obtained from (*X*) will contain

$$\text{active H–atoms} = \frac{4}{0.01} \times 0.005 = 2$$

Out of these two active H-atoms, one must be of —OH group. Since (*X*) gives a precipitate with $AgNO_3$, the other active H-atom will be from — C ≡ CH. Also, (*X*) reacts with H_2/Pt followed by boiling with HI gives *n*-pentane. So, (*X*) will contain a straight chain. So, structure of (*X*) will be

$$\overset{5}{HC} \equiv \overset{4}{C}—\overset{3}{CH_2}—\overset{2}{CH_2}—\overset{1}{CH_2OH}$$

Pent-4-yn-1-ol.

Reactions involved are :

(*i*) $HC \equiv C — CH_2CH_2CH_2OH \xrightarrow{AgNO_3}$ $Ag\,C \equiv C — CH_2CH_2CH_2OH$

(*ii*) $HC \equiv C — CH_2CH_2CH_2OH \xrightarrow{MeMgBr}$ BrMg $C \equiv CCH_2CH_2CH_2O\,MgBr + 2CH_4$

(*iii*) $HC \equiv C — CH_2CH_2CH_2OH \xrightarrow{H_2/Pt}$ $CH_3CH_2CH_2CH_2CH_2OH \xrightarrow[\text{Boil}]{HI,}$ $CH_3CH_2CH_2CH_2CH_3$

Example 25. *A basic, volatile nitrogen compound gave a foul smelling gas when treated with chloroform and alcoholic potash. A 0.295 g sample of the substance, dissolved in aq. HCl and treated with $NaNO_2$ solution at 0°C, liberated a colourless, odourless gas whose volume corresponded to 112 mL at S.T.P. After the evolution of the gas was complete, the aqueous solution was distilled to give an organic liquid which did not contain nitrogen and which on warming with alkali and iodine gave a yellow precipitate. Identify the original substance. Assume that it contains one N–atom per molecule.* **(IIT, 1993)**

Solution. Since the compound is basic and gives a foul smelling gas with chloroform and alc. KOH, it must be a primary amine, $R\,NH_2$ because it contains one N-atom. Its reaction with $NaNO_2$ and HCl at 0°C will be:

$$\underset{\text{Mol. wt.} = M}{R\,NH_2} + NaNO_2 + HCl \longrightarrow ROH + NaCl + \underset{22.4 \text{ L or } 22400 \text{ mL}}{N_2\uparrow} + H_2O.$$

Wt. of substance = 0.295 g

112 mL gas is obtained from substance = 0.295 g

22400 mL gas is obtained from substance

$$= \frac{0.295}{112} \times 22400 = 59 \text{ g}$$

∴ Mol. wt. of substance = 59 g mol^{-}.

But, $R = C_n\,H_{2n+1}$.

So, $R\,NH_2 = C_n\,H_{2n+1}.\,NH_2$

Or $(12 \times n) + 1(2n + 1) + 14 + (2 \times 1) = 59$

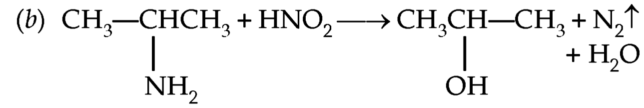
$12n + 2n + 1 + 14 + 2 = 59$ **Or** $14n = 59 - 17 = 42$

Or $n = 42/14 = 3$

∴ The given compound = $\mathbf{C_3H_7NH_2}$. The possible amines can be :

(I) $CH_3CH_2CH_2NH_2$ (II) $CH_3CH(NH_2)CH_3$.

(*a*) $CH_3CH_2CH_2NH_2 + HNO_2 \longrightarrow CH_3CH_2CH_2OH + N_2\uparrow + H_2O$

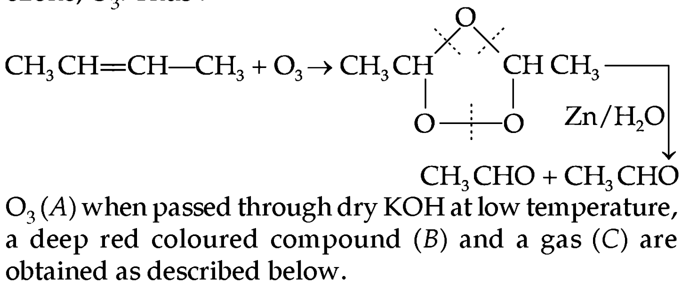


(*b*) $CH_3—\underset{NH_2}{CH}CH_3 + HNO_2 \longrightarrow CH_3\underset{OH}{CH}—CH_3 + N_2\uparrow + H_2O$

The product from (II) is $CH_3CH\ (OH)\ CH_3$ which yields yellow precipitate, with alkali and I_2. Hence the unknown compound is $\mathbf{CH_3CH\ (NH_2)\ CH_3}$.

Example 26. *When gas (A) is passed through dry KOH at low temperature, a deep red–coloured compound, (B) and a gas (C) are obtained. The gas (A), on reaction with but–2–ene, followed by treatment with Zn/H_2O yields acetaldehyde. Identify A, B and C.* **(IIT, 1994)**

Solution. (*A*) reacts with but–2–ene followed by action with Zn/H_2O gives acetaldehyde. So, (*A*) is expected to be ozone, O_3. Thus :



O_3 (*A*) when passed through dry KOH at low temperature, a deep red coloured compound (*B*) and a gas (*C*) are obtained as described below.

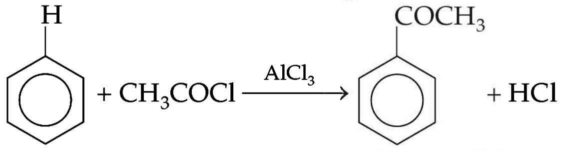
$$3\,KOH + 2O_3 \longrightarrow \underset{\underset{(B)}{\text{Potassium ozide (red)}}}{2KO_3\,(s)} + KOH.\,H_2O(s) + \underset{(C)}{½\,O_2(g)}$$

Example 27. *An organic compound (A), C_8H_6 on treatment with dilute sulphuric acid containing mercuric sulphate gives a compound (B) which can also be obtained from a reaction of benzene with an acid chloride in the presence of anhydrous aluminium chloride. The compound (B), when treated with iodine in aqueous KOH, yields (C) and a yellow compound, (D). Identify A, B, C and D with justification. Show how (B) is formed from (A).* **(IIT, 1994)**

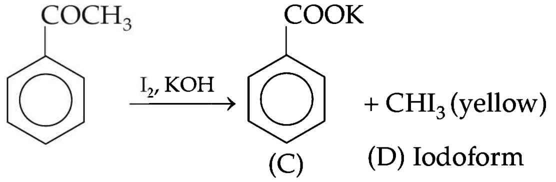
Solution. The sequence of various reactions required in the question is :

$$\begin{tikzcd} C_8H_6 \arrow[r, "\text{Dil. } H_2SO_4", "HgSO_4"'] & B \arrow[r, "I_2\text{, KOH (aq)}"] & C + D \text{ (yellow compound)} \\ & C_6H_6 \text{ (Benzene)} \arrow[u, "CH_3COCl/AlCl_3"'] & \end{tikzcd}$$

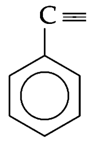
The reaction of C_6H_6 with CH_3COCl and $AlCl_3$ is :



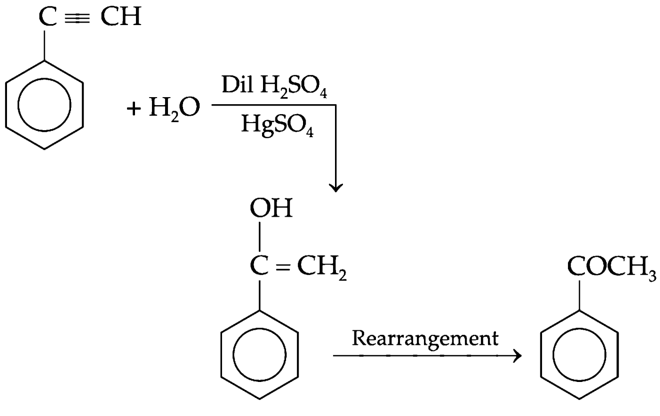
Acetophenone (**B**)



Since (A) reacts with dil. H_2SO_4 and $HgSO_4$, there must be $-C \equiv CH$ bond in (A). C_8H_6 formula indicates a benzene ring. So, (A) will be



Hence :



∴ (A) $= C_6H_5C\equiv CH$ (B) $C_6H_5COCH_3$

(C) C_6H_5COOK (D) CHI_3

Example 28. *An alkanone (A) that undergoes a haloform reaction, gives a compound (B) on reduction. When (B) is heated with H_2SO_4, forms the compound (C) which gives mono-ozonide (D). (D) on hydrolysis in presence of zinc dust forms only ethanal. Identify A, B, C and D. Also, write the reactions involved.* **(IIT, 1989)**

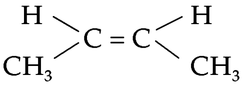
Solution. The given general reactions are :

$$A \xrightarrow{\text{Reduction}} B \xrightarrow[\text{(dehydration)}]{H_2SO_4,\Delta} C\,;$$

(C) forms mono-azonide (D) and

$$D \xrightarrow{Zn/H_2O} CH_3CHO$$

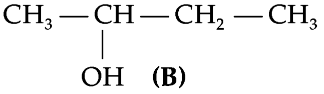
(A) undergoes, haloform reaction. So, it will contain CH_3CO group. (C) forms mono-ozonide (D), so (C) contains a C = C double bond. (D) on hydrolysis in presence of Zn dust gives only CH_3CHO. So, structure of (C) will be :



(But-2-ene)

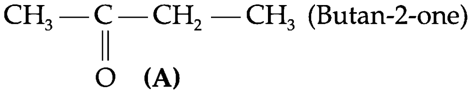
(C)

(C) is obtained by the action of H_2SO_4 *i.e.*, by dehydration of (B), so (B) will be a secondary alcohol.



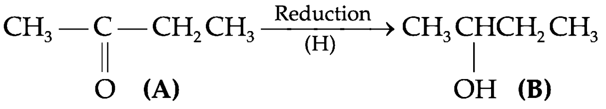
$$CH_3-\underset{\underset{OH}{|}}{CH}-CH_2-CH_3 \quad \textbf{(B)}$$

But (B) is obtained by the reduction of (A). So (A) should have the structure



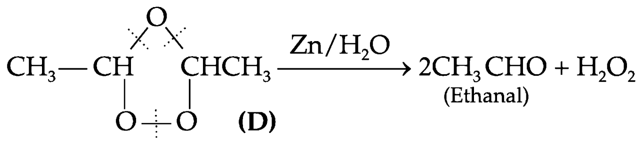
$$CH_3-\underset{\underset{O}{\|}}{C}-CH_2-CH_3 \text{ (Butan-2-one)} \quad \textbf{(A)}$$

Hence the reactions involved are :



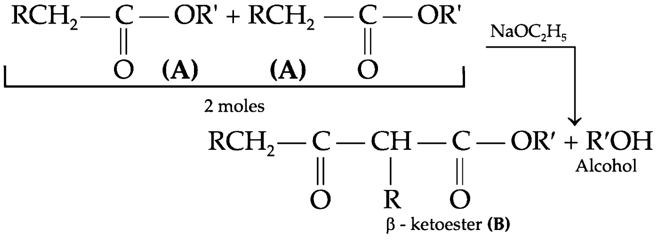
$$\underset{\textbf{(A)}}{CH_3-\underset{\underset{O}{\|}}{C}-CH_2CH_3} \xrightarrow[\text{(H)}]{\text{Reduction}} \underset{\textbf{(B)}}{CH_3\underset{\underset{OH}{|}}{CH}CH_2CH_3}$$

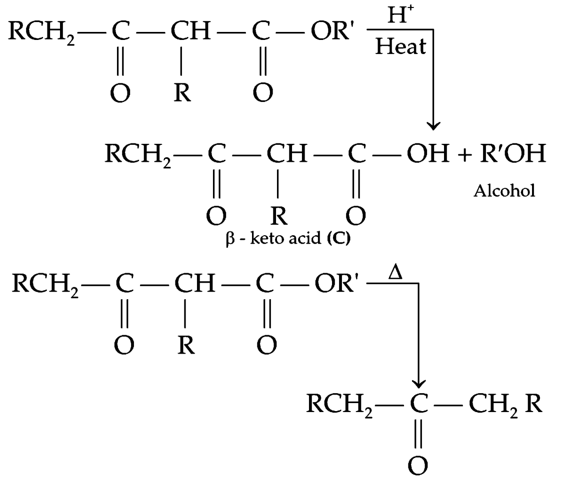
$$\xrightarrow[(-H_2O)]{H_2SO_4} CH_3-CH=CHCH_3 \xrightarrow{O_3}$$



Example 29. *An alkyl alkanoate (2 moles) when condensed in presence of sodium ethoxide gave ethanol and a β-keto ester (B). (B) on heating in acidic medium, gave ethanol and a β–keto acid (C). On decarboxylation, (C) formed pentan–3–one. Identify A, B and C with appropriate reasoning.* **(Roorkee, 1992)**

Solution. Alkyl alkanoate is called an ester. The action of an ester with sodium ethoxide to give an alcohol and β-keto ester is called Claisen condensation reaction. So, the reaction is ;

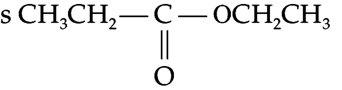




In order to get the required product,

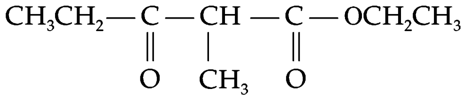
$R = -CH_3\ ;\ R' = -CH_2CH_3$

∴ (A) is



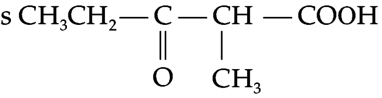
$CH_3CH_2-\underset{\underset{O}{\|}}{C}-OCH_2CH_3$

(B) is



$CH_3CH_2-\underset{\underset{O}{\|}}{C}-\underset{\underset{CH_3}{|}}{CH}-\underset{\underset{O}{\|}}{C}-OCH_2CH_3$

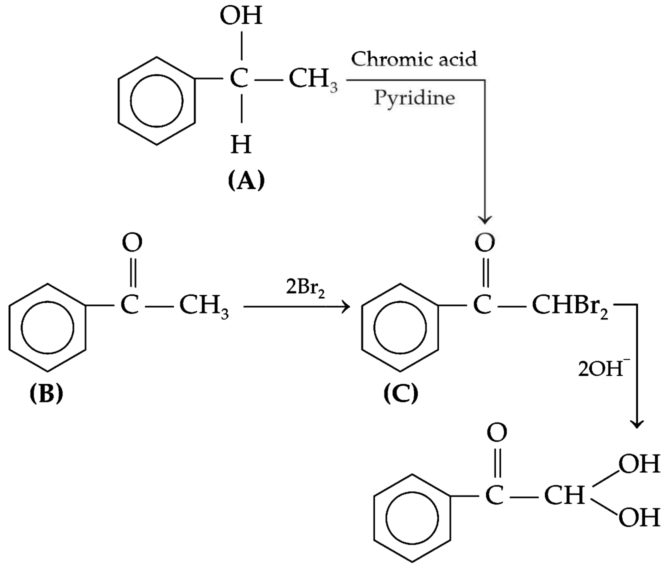
(B) is

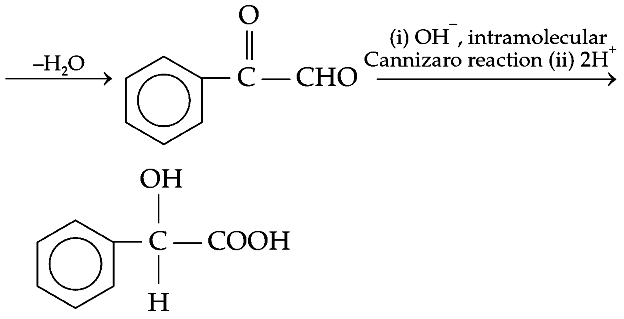


$CH_3CH_2-\underset{\underset{O}{\|}}{C}-\underset{\underset{CH_3}{|}}{CH}-COOH$

EXAMPLE 30. *A compound (A) $C_8H_{10}O$ when treated with chromic acid, pyridine give a compound (B) C_8H_8O. When (B) is treated with two equivalents of Br_2 gives (C) $C_8H_6O\ Br_2$ which on treatment with NaOH followed by acidification forms compound (D) $C_8H_8O_3$. (D) when treated with $NaHCO_3$ liberate CO_2 and is resolvable. Identify A, B, C and D.*

SOLUTION. Since (B) C_8H_8O is formed from (A) $C_8H_{10}O$, (B) must have been formed by the reduction of a secondary alcohol. Number of 8 carbon atoms indicate an aromatic ring. So, we have :



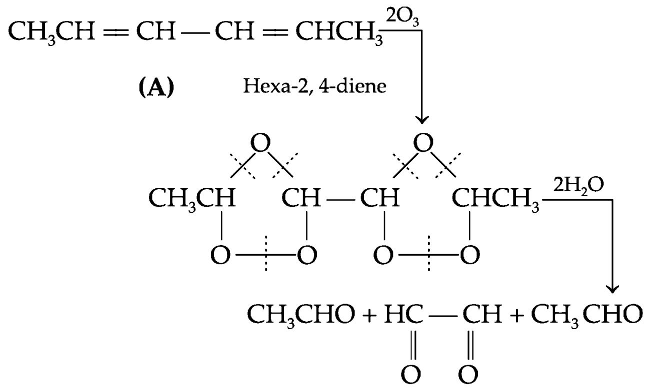


(D)

EXAMPLE 31. *When an organic compound (A) C_6H_{10} was reduced, first of all it forms B (C_6H_{12}) and finally (C) (C_6H_{14}). On ozonolysis, and followed by hydrolysis, (A) gives two aldehydes, D (C_2H_4O) and E ($C_2H_2O_2$). When (B) was oxidised with acidified $KMnO_4$, F ($C_4H_8O_2$) which is an acid was formed. Determine the structures of A, B,C, D, E and F along with reasons.*

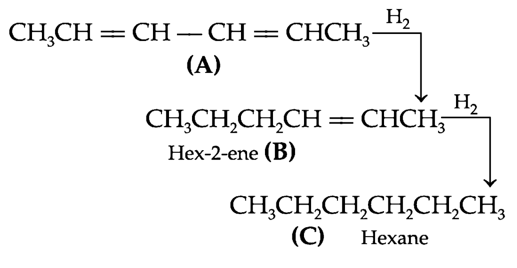
(Roorkee1993)

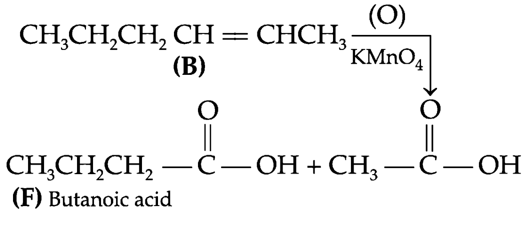
SOLUTION. (A) on reduction gives two compounds (B) and (C). Also, (A) on ozonolysis followed by hydrolysis forms two aldehydes. So, (A) must have two C = C double bonds. It means there will be two molecules of D (CH_3CHO) and one molecule of E (OHC – CHO). The above reactions can be represented as :



(D) (E) (D)

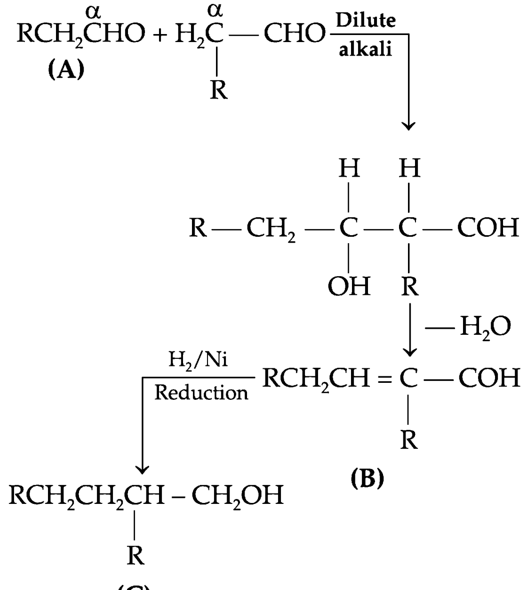
Elucidation of structures of (B) and (C) is explained below.





Example 32. *An organic compound (A) gives positive silver mirror test and reduces Fehling's solution. On warming with dilute alkali, followed by dehydration, it gives the product (B), which also responds to both the above tests. In addition, it decolorises the colour of bromine water. On treatment with hydrogen in the presence of nickel under pressure, the compound (B) is converted to (C) which does not give anyone of the above three tests. Molecular weight of (C) is 74 g mol⁻. Identify A and B, give reactions involved and draw their structures.*

Solution. (A) gives silver mirror test and reduces Fehling's solution. So, (A) must be an aldehyde. Warming (A) with dilute alkali indicates that (A) undergoes aldol condensation to give (B). So, it must have an α–hydrogen. (B) decolorises bromine water. So, (B) will contain unsaturation *i.e.*, C = C double bond. So, (A) will have the structure, RCH_2CHO. The reaction can be :



(C)

The mol. wt. of (C) is 74 g mol⁻. Thus :

R + 12 + (2 × 1) + 12 + (2 × 1) + 12 + 1 + R + 12 + (2 × 1) + 16 + 1 = 74

2R + 72 = 74 Or 2R = 74 – 72 = 2 *i.e.*,

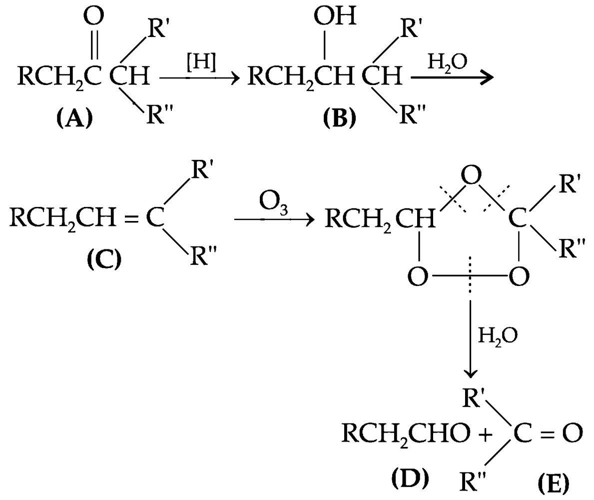
R = 2/2 = 1. Hence,

R is H. Substituting R = H in (A), (B) and (C), the structures of (A), (B) and (C) will be :

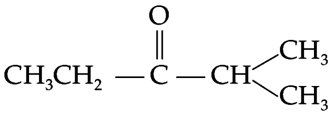
(A) is CH_3CHO ; (B) is $CH_3CH = CHCHO$ (C) is $CH_3CH_2CH_2CH_2OH$.

Example 33. *An organic compound (A) $C_6H_{12}O$ does not reduce Tollen's reagent but forms an oxime. On reduction with Na/Hg, (A) forms an alcohol (B) which on dehydration forms mainly a single alkene (C). The ozonolysis of (C) produces (D) and (E). The compound (D) reduces Tollen's reagent but does not give iodoform test. Explain the reactions involved and write the structures of A, B, C, D, and E compounds.*

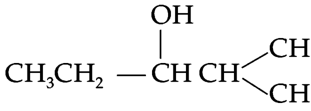
Solution. (A) does not reduce Tollen's reagent. So, it is not an aldehyde. It forms an oxime, so, it must be a ketone. (D) does not give iodoform test. So, it does not contain CH_3CO-group. So, (D) will be an aldehyde while (E) will be a ketone. Suppose (D) is RCH_2CHO and (E) is RCOR′ where R, R′ and R″ are alkyl groups. The sequence of reactions will be as follows.



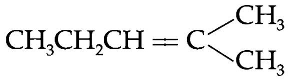
Since the compound (A) contains six carbon atoms, R, R′ and R″ must be CH_3. So, the structures of A, B, C, D and E will be :

(A):


$CH_3CH_2—\overset{O}{\overset{\|}{C}}—CH(CH_3)_2$

(B): is


$CH_3CH_2—\overset{OH}{\overset{|}{C}H}\,CH(CH_3)_2$

(C): is


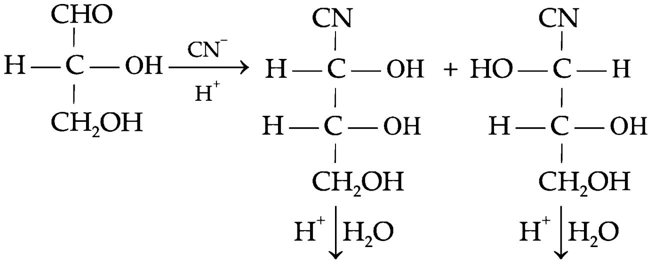
$CH_3CH_2CH = C(CH_3)_2$

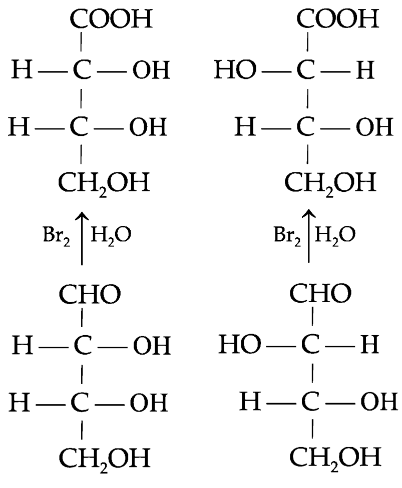
(D): is CH_3CH_2CHO and

(E): is CH_3COCH_3

Example 34. *When $CH_2OHCH(OH)CHO$ (R glyceraldehyde) is treated with cyanide and the resulting product is hydrolysed, two monocarboxylic acids are formed. These acids are identical with the acids obtained by the oxidation of (–) erythrose and (–) threose. Assign single structure to (–) threose and (–) erythrose.*

Solution. We know that a threose isomer is convertible to a racemic modification, while a erythrose isomer is convertible (in principle at least) into a meso structure. The names of these compounds are the basis to designate erythro and threo acids to specify certain configurations of compounds containing two chiral carbons. The various reactions involved are as follows :

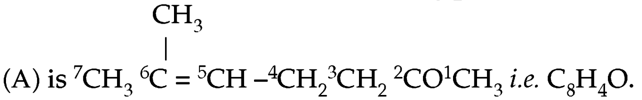




(–) Erythrose (–) Threose

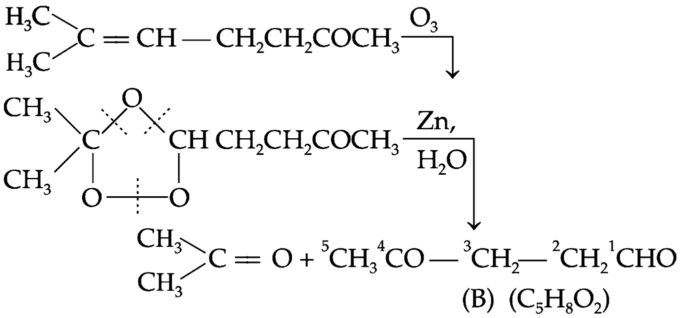
EXAMPLE 35. *An organic compound (A) $C_8H_{14}O$ gives a positive haloform reaction and forms an oxime. (A) on ozonolysis forms a compound (B) and acetone. (B) $C_5H_8O_2$ forms a dioxime and on subjecting to haloform reaction forms an acid (C), $C_4H_6O_4$. On treatment with excess of ammonia and strong heating, (C) gives a neutral compound (D) $C_4H_5O_2N$. When (D) was distilled with Zn-dust, pyrrole was formed. Suggest the sructures and give IUPAC names of A, B, C and D compounds.*

SOLUTION. A compound which gives a positive haloform reaction and forms an oxime, must contain CH_3CO–group. Also, it undergoes ozonolysis to give acetone and a compound (B). Since one of the products is acetone, so C = C double bond must be present as $(CH_3)_2$ C =. Hence :



(A) is $^7CH_3\,{}^6\overset{\overset{CH_3}{|}}{C} = {}^5CH - {}^4CH_2{}^3CH_2\,{}^2CO{}^1CH_3$ *i.e.* C_8H_4O.

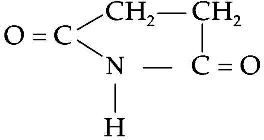
Its IUPAC name is 6– Methyl hept-5-en-2-one.



I.U.P.A.C. Name is 4-oxopentanal

Since (B) forms a dioxime and on subjecting to haloform reaction, forms an acid (C) $C_4H_6O_4$, so (C) will be HOOC. $CH_2.CH_2$.COOH. Its IUPAC name is butan –1, 4–dioic acid.

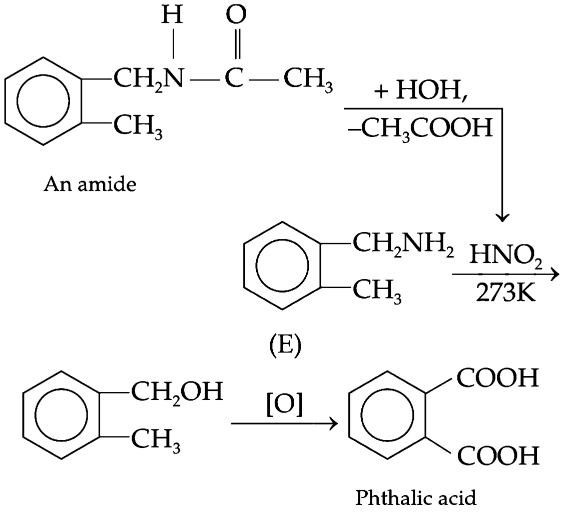
(C) reacts with excess NH_3 and on strong heating gives a neutral compound (D) $C_4H_5O_2N$ which forms pyrrole on distillation with Zn. So, (D) is



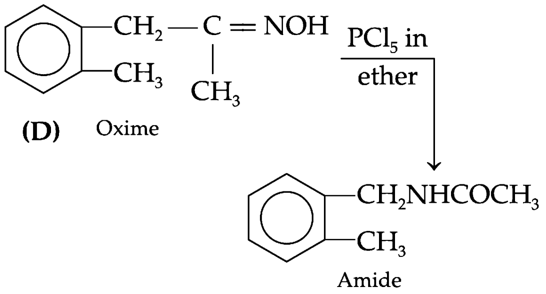
Its IUPAC name is succinimide.

EXAMPLE 36. *An organic compound (A) $C_{18}H_{20}O$ gives (B) $C_{10}H_{12}O$ and (C) $C_8H_8O_2$ on ozonolysis. (B) gives iodoform reaction and gives oxime (C) $C_{10}H_{13}ON$ with NH_2OH. The oxime undergoes rearrangement to form an amide when treated with PCl_5 in dry ether. This amide on hydrolysis gives a compound (E) $C_8H_{11}N$ and acetic acid. (E) with nitrous acid at 273 K gives an aromatic alcohol $C_8H_{10}O$, oxidation of which gives phthalic acid. (C) gives a carboxylic acid $C_8H_8O_2$ which is degraded by HI to CH_3I and p-hydroxybenzoic acid. Describe various reactions involved and identify A, B, C, D and E.* **(Roorkee, 1998)**

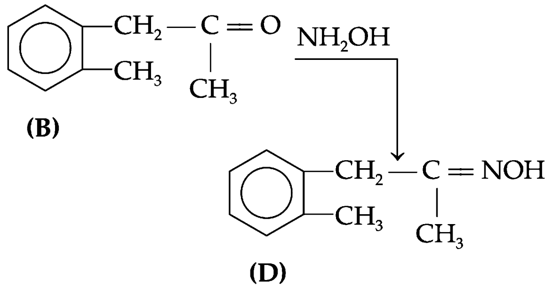
SOLUTION. (B) gives iodoform test and forms an oxime. So, it must contain CH_3CO–group. (E) obtained after hydrolysis of amide must contain aliphatic amine, $-NH_2$ group as it gives an alcohol at 273 K with HNO_2. The oxidation of above alcohol gives phthalic acid. So, the alcoholic substituent must be at the ortho position to the another substituent. Keeping the above facts in view, we proceed as follows :



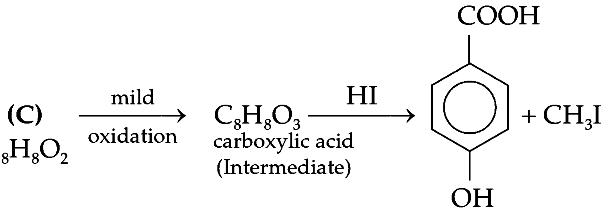
Above amide is formed by the rearrangement of oxime (D) as shown below.



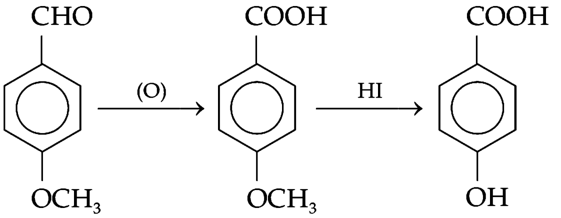
The structure of (B) would be :



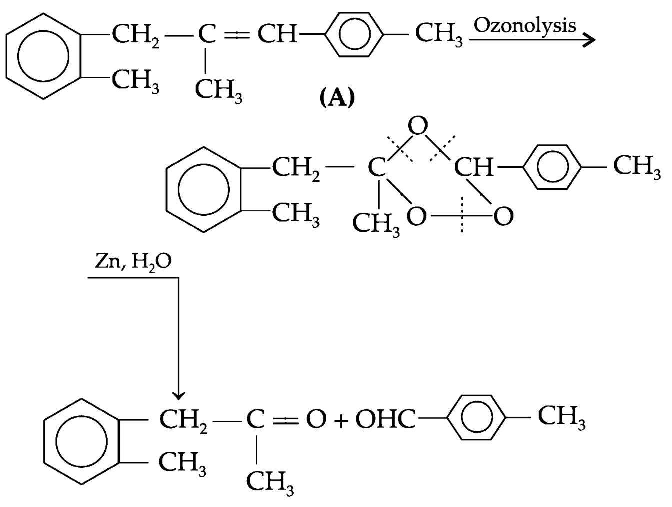
From the given data, reactions on (C) would be



The above intermediate must be an ether. Also, (C) must be containing $>C = O$ keto group because it is the ozonolysis product of (A). Keeping in view the above facts, the reactions can be given as :

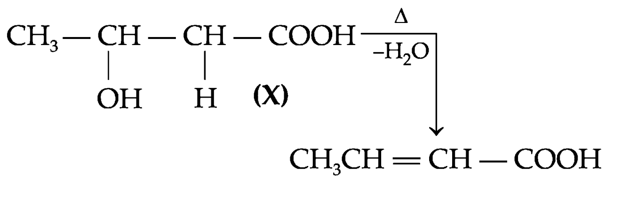


The structure of (A) can finally be written as :



EXAMPLE 37. *An organic compound (X) ($C_4H_8O_3$), acidic in reaction is oxidised with mild oxidants to give (A) (unstable), syrupy compound. It easily forms (B) C_3H_6O and CO_2 gas. (X) alone gives (C), $C_4H_6O_2$ having an acid neutralisation equivalent of 104 on simply heating. Write the structural formulae of X, A, B and C.*

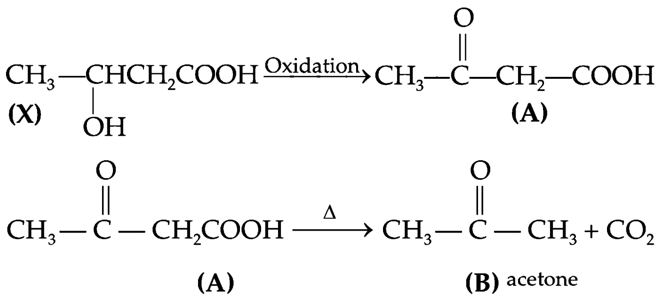
SOLUTION. Since (X) is acidic in reaction, $C_4H_8O_3$ must contain —COOH group. So, $C_4H_8O_3$ can be written as C_3H_7O—COOH. Here, C_3H_7O contains one O-atom. The product (C) C_3H_5COOH is an unsaturated acid that is obtained by heating X.



$$\underset{\text{OH}}{\underset{|}{CH_3-CH}}-\underset{\text{H}}{\underset{|}{CH}}-COOH\ (X)\ \xrightarrow[-H_2O]{\Delta}\ CH_3CH=CH-COOH$$

(C) $C_4H_6O_2$ Buten-2-oic acid

We know β-hydroxy substituted acids form substituted acids on heating. Thus, (X) should be β-hydroxy substituted acid. *i.e.*, $CH_3-\underset{\text{OH}}{\underset{|}{{}^{\beta}CH}}\,{}^{\alpha}CH_2-COOH$ (X). (X) on oxidation with mild oxidant give the following compound.

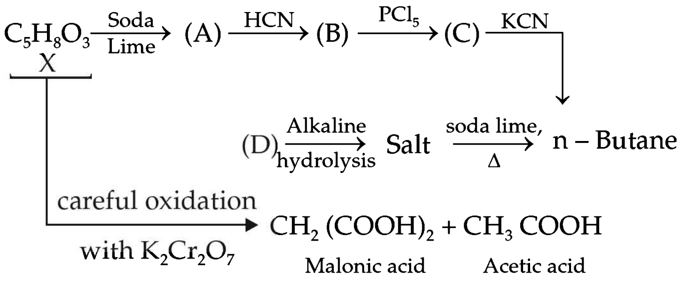


$$\underset{(X)}{CH_3-\underset{\text{OH}}{\underset{|}{CH}}CH_2COOH}\xrightarrow{\text{Oxidation}}\underset{(A)}{CH_3-\overset{\text{O}}{\overset{\|}{C}}-CH_2-COOH}$$

$$\underset{(A)}{CH_3-\overset{\text{O}}{\overset{\|}{C}}-CH_2COOH}\xrightarrow{\Delta}\underset{(B)\ \text{acetone}}{CH_3-\overset{\text{O}}{\overset{\|}{C}}-CH_3}+CO_2$$

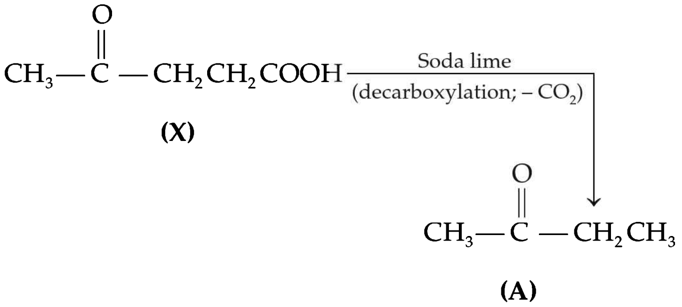
EXAMPLE 38. *An organic compound (X) $C_5H_8O_3$ gives a compound (A) on heating with soda-lime. (A) reacts wih HCN to form (B). (B) gives (C) on treating with PCl_5. (C) reacts with KCN to form (D). D gives a salt on alkaline hydrolysis. This salt is isolated and gives n-butane when heated with soda-lime. (X) when oxidised carefully with potassium dichromate, formed malonic acid and CH_3COOH. What are X, A, B, C, and D. Write their structural formula.* **(Roorkee, 1999)**

SOLUTION. The flow sheet of reactions as required in the given data are:

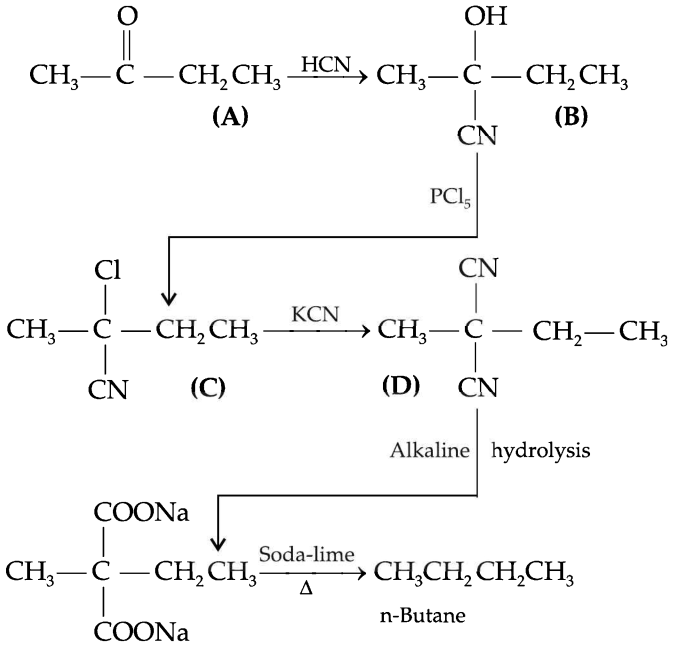


(X) on careful oxidation gives CH_3COOH and $CH_2(COOH)_2$ *i.e.*, three COOH groups. We know that on oxidaton, only two —COOH groups can be introduced *i.e.*, one to each carbon undergoing C—C fission. It confirms that (X) initially contains one —COOH group. So, $C_5H_8O_3$—COOH *i.e.*, C_4H_7O will be the remaining group of (X). This group will have a keto substituted alkyl group, $C_3H_7-\underset{|}{C}=O$. Hence, (X) is keto substituted acid.

In order to assign $>C = O$ keto group in carbon chain, we know that keto acids on careful oxidation undergo C—C bond fission at a place where $>C = O$ is situated. Keto group is also converted to —COOH group and remains with acid having small number of carbon atoms. It means CH_3COOH must have formed from $CH_3{>}C = O$ arrangement. So, $C_3H_7\overset{|}{C} = O$ will have the structure $CH_3-\overset{O}{\overset{\|}{C}}-CH_2CH_2-$ and compound (X) will be $\underset{(X)}{CH_3-\overset{O}{\overset{\|}{C}}-CH_2CH_2COOH}$



$$\underset{\textbf{(X)}}{CH_3-\overset{O}{\overset{\|}{C}}-CH_2CH_2COOH} \xrightarrow[\text{(decarboxylation; }-CO_2)]{\text{Soda lime}} \underset{\textbf{(A)}}{CH_3-\overset{O}{\overset{\|}{C}}-CH_2CH_3}$$



$$\underset{\textbf{(A)}}{CH_3-\overset{O}{\overset{\|}{C}}-CH_2CH_3} \xrightarrow{HCN} \underset{\textbf{(B)}}{CH_3-\overset{OH}{\overset{|}{\underset{CN}{\underset{|}{C}}}}-CH_2CH_3}$$

$$\xrightarrow{PCl_5} \underset{\textbf{(C)}}{CH_3-\overset{Cl}{\overset{|}{\underset{CN}{\underset{|}{C}}}}-CH_2CH_3} \xrightarrow{KCN} \underset{\textbf{(D)}}{CH_3-\overset{CN}{\overset{|}{\underset{CN}{\underset{|}{C}}}}-CH_2-CH_3}$$

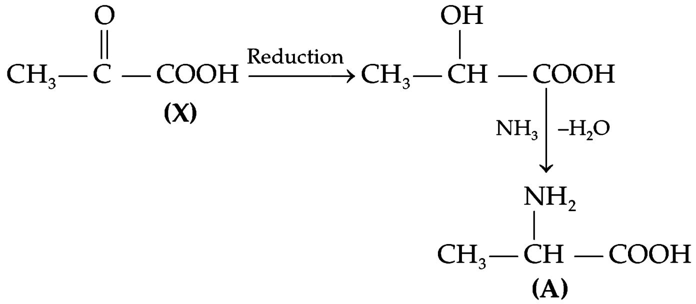
$$\xrightarrow{\text{Alkaline hydrolysis}} CH_3-\overset{COONa}{\overset{|}{\underset{COONa}{\underset{|}{C}}}}-CH_2CH_3 \xrightarrow[\Delta]{\text{Soda-lime}} \underset{\text{n-Butane}}{CH_3CH_2CH_2CH_3}$$

EXAMPLE 39. *An organic acid (X) $C_3H_4O_3$ gives the product (A) when catalytically reduced in presence of ammonia. (A) $C_3H_7NO_2$ reacts with acetyl chloride, HCl and alcohols. When treated with HNO_2, it gives another compound (B) $C_3H_6O_3$ along with N_2 gas. Citing reasons, identify (X), A and B compounds.*

SOLUTION. (X) is an acid. So, it contains one COOH group. The remaining part of (X) will be C_2H_3O or $CH_3-C{\overset{\nearrow O}{\searrow}}$. The structural formula of (X) will be:

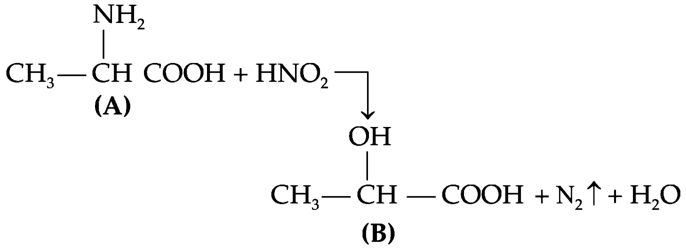
$CH_3-\overset{O}{\overset{\|}{C}}-COOH$ **(X)**.

(*i*) Catalytic reduction of keto group gives secondary alcohol which gives amino acid with ammonia. Thus:



$$\underset{\textbf{(X)}}{CH_3-\overset{O}{\overset{\|}{C}}-COOH} \xrightarrow{\text{Reduction}} CH_3-\overset{OH}{\overset{|}{CH}}-COOH \xrightarrow{NH_3,\ -H_2O} \underset{\textbf{(A)}}{CH_3-\overset{NH_2}{\overset{|}{CH}}-COOH}$$

(A) reacts with HNO_2 to give (B) and N_2 gas.

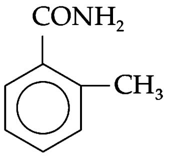


$$\underset{\textbf{(A)}}{CH_3-\overset{NH_2}{\overset{|}{CH}}\ COOH} + HNO_2 \longrightarrow \underset{\textbf{(B)}}{CH_3-\overset{OH}{\overset{|}{CH}}-COOH} + N_2\uparrow + H_2O$$

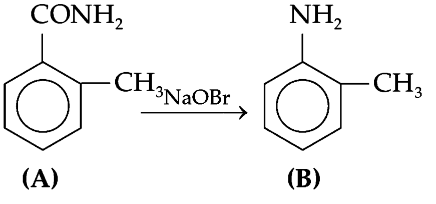
EXAMPLE 40. *An organic neutral compound (A) C_8H_9ON when treated with NaOBr forms an acid soluble substance C_7H_9N (B). (B) reacts with $NaNO_2$ and dil HCl at 0 to –5°C to give an ionic compound (C) $C_7H_7N_2Cl$. (C) reacts with alkaline β-naphthol solution to give red dye. When treated wih potassium cuprocyanide, (C) yields a neutral substance (D) C_8H_7N. (D) gives (E) $C_8H_8O_2$ on hydrolysis. (E) reacts with $NaHCO_3$ to produce CO_2 gas. Also, (E) on oxidation with permanganate gives (F). When (F) was nitrated, two isomeric mononitroderivatives (G) and (H) having molecular formula $C_8H_5NO_6$ were formed. Write various reactions involved and identify A, B, C, D, E, F, G and H.*

SOLUTION. Since (A) reacts with NaO Br, to form a base C_7H_9N (B), so, A should be an aromatic amide and (B) should be an amine. Thus :

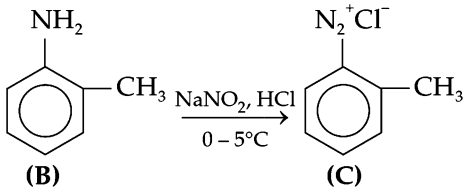
(*i*) A is

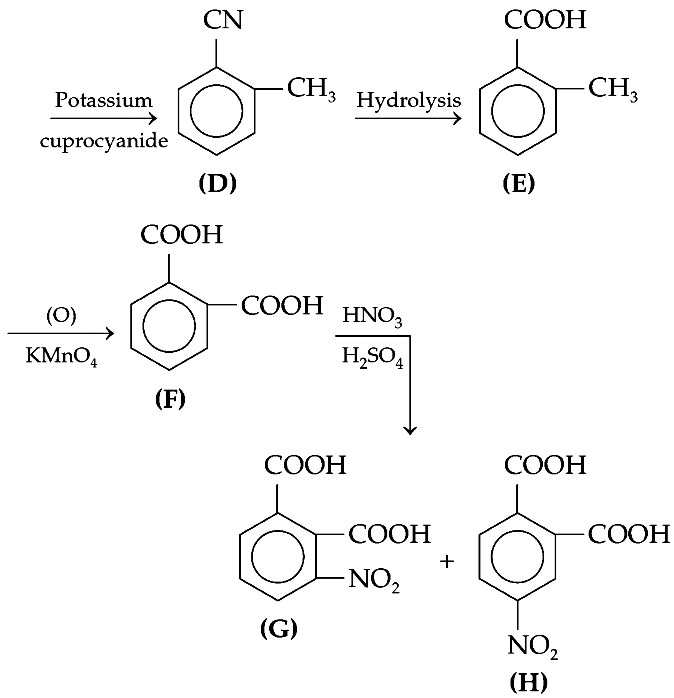


(*ii*)



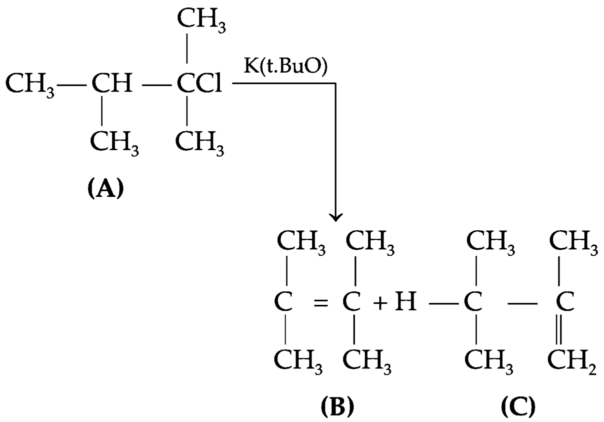
(*iii*)



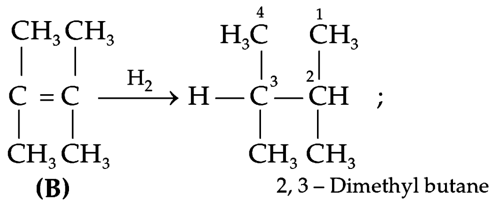


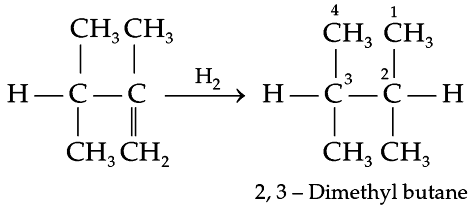
EXAMPLE 41. *An alkylhalide (A) having molecular formula $C_6H_{13}Cl$ when treated with potassium tertiary butoxide gave two isomeric alkenes (B) and (C) (C_6H_{12}). Both alkenes on hydrogenation gives 2, 3-dimethyl butane. Assign structures to A, B and C compounds.* **(IIT, 1996)**

SOLUTION. The given alkyl halide (A) $C_6H_{13}Cl$ gives two isomeric alkenes. It shows that the 'Cl' should not be bonded to the C-atom of terminal alkyl group. So, the reactions can be shown as follows :



(B) and (C) on hydrogenation give 2, 3–dimethyl butane as shown below:





EXAMPLE 42. *An alcohol ROH having mass 0.37 g was added to CH_3MgI and a gas evolved measured 112 mL at N.T.P. Calculate the molecular mass of ROH. This alcohol on dehydration forms an alkene which on ozonolysis gave acetone as one of the products. Also, this alcohol on oxidation easily gives an acid containing same number of carbon atoms. Assign structures to the acid as well as the alcohol with reasons.* **(Roorkee, 1994)**

SOLUTION. Wt (W) of ROH = 0.37 g ;

$$\text{Volume (V)} = 112\text{ mL} = 112/1000 = 0.112\text{ L}$$

$$T = 273\text{K} ;\ \text{Mol. wt. (M)} = ? ;$$

$$R = 0.0821\text{ L atm. K}^{-}\text{ mol}^{-};\ P = 1\text{ atm.}$$

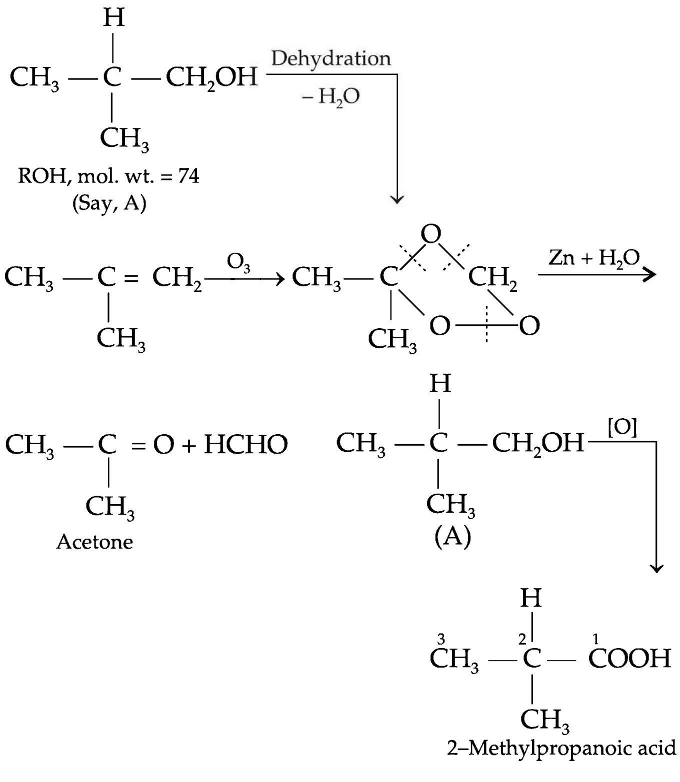
We know, $PV = nRT$ or $PV = \frac{W}{M}RT$

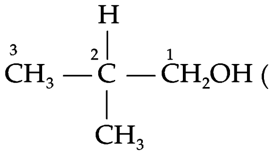
Or $M = \frac{WRT}{PV}$

$$= \frac{0.37\text{g} \times 0.0821\text{ L atm mol}^{-}\text{ K}^{-} \times 273\text{ K}}{1\text{ atm} \times 0.112\text{ L}} = 74\text{ g mol}^{-}$$

∴ Mol. wt. of ROH = **74 g mol⁻.** **Ans.**

ROH on dehydration gives alkene, which on ozonolysis gives acetone, CH_3COCH_3. Thus the reactions will be :

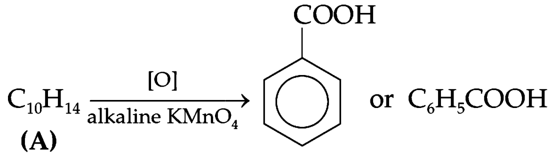




and alcohol is $\overset{3}{C}H_3-\overset{2}{C}(H)(CH_3)-\overset{1}{C}H_2OH$ (2 – methyl propanol)

Example 43. *An organic chiral compound (A) $C_{10}H_{14}$ gives C_6H_5COOH when oxidised with alkaline $KMnO_4$. But the achiral compound (B) $C_{10}H_{14}$ is inert to oxidation under the same conditions. Assign structures to (A) and (B).*

Solution. From the given data, we have :

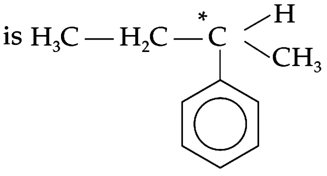


(*i*) $\underset{(A)}{C_{10}H_{14}} \xrightarrow[\text{alkaline KMnO}_4]{[O]}$ or C_6H_5COOH

(*ii*) $\underset{(B)}{C_{10}H_{14}} \xrightarrow[\text{alkaline KMnO}_4]{[O]}$ no action *i.e.*, inert to oxidation.

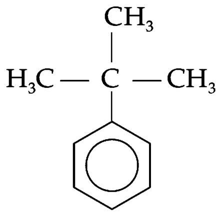
From (i), it is clear that C_6H_5COOH is the only product. So, (A) should be monosubstituted compound *i.e.*, $C_{10}H_{14} - C_6H_5$ or C_4H_9 group should be present in the monosubstituted benzene. Thus :

(A) is



Chiral and prone to oxidation

(B)



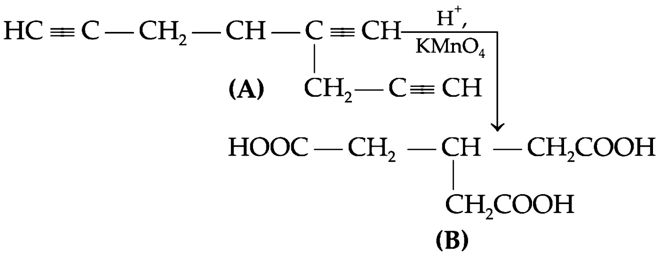
Achiral and inert to oxidation

Example 44. An organic compound (A) $C_{10}H_{10}$ gives only one organic compound $HOOC.\,CH_2.\,\underset{\displaystyle CH_2COOH}{CH}\,CH_2COOH$ (B) on oxidative cleavage. Deduce the structural formula of $C_{10}H_{10}$ compound.

Solution. (A) on oxidative cleavage gives only one compound containing COOH groups. So, the degree of unsaturation in the compound can be calculated by the relation :

$$\text{Degree of unsaturation} = (\text{No. of C-atoms}) - \frac{\text{No. of H - atoms}}{2} + 1 = 10 - \frac{10}{2} + 1 = 10 - 5 + 1 = 6$$

So, the compound (A) contains 6 bonds. Since on oxidative cleavage, (A) gives only one compound, so, all the multiple bonds should be on the terminal atom. Hence, we have :



Example 45. *An organic compound (A) containing chlorine showed the following properties.*

(*i*) *when vaporised, 1.49g of (A) produced 448 mL of vapour at N.T.P.*

(*ii*) *gives a precipitate with ammonical cuprous chloride*

(*iii*) *decolorises bromine in CCl_4 liquid.*

(*iv*) *absorbs H_2 in the presence of a catalyst.*

Identify (A).

Solution. At N.T.P., $P = 1$ atm ; $T = 273$ K., $V = 448$ mL $= 448/1000 = 0.448$ L ; $R = 0.0821$ L atm. K^- mol^-; Mol. wt. (M) = ? ; $W = 1.49$ g.

$$\text{We know } PV = n\,RT = \frac{W\,RT}{M}$$

$$\textbf{Or } M = \frac{W\,RT}{PV}.$$

Substituting the values, we get :

$$M = \frac{1.49\text{g} \times 0.0821 \text{ L atm. } K^-.\text{mol}^-. \times 273 \text{ K}}{1 \text{ atm} \times 0.448 \text{ L}}$$

$$= \mathbf{74.54\ g\ mol^-}$$

(A) gives a ppt. with ammonical cuprous chloride, decolorises bromine water and absorbs H_2 in presence of a catalyst. So, (A) must have terminal $C \equiv C$.

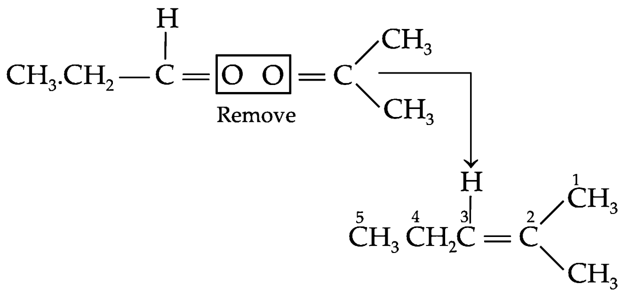
Mol. wt. of (A) *i.e.*, R. Cl = 74.45

$\therefore$ Mol. wt. of R = 74.45 – at. wt. of Cl (= 35.5) = 38.95 ≃ 39.

R contains C and H atoms. The number of C–atoms are obtained by dividing the mol. wt. by at. wt. of C (= 12) and the remainder represents number of H–atoms. So, 39/12 = 3 with remainder 3 which represents H–atoms. So, the formula of R is C_3H_3. Thus, the molecular formula of RCl is C_3H_3Cl *i.e.*, $CH_2Cl—C \equiv CH$.

Example 46. *On ozonolysis, an alkene C_6H_{12} gives two products. One of the products gave a positive iodoform test while a negative Tollen's test. The other product gave a positive Tollen's test but a negative iodoform test. Identify the alkene and give its I.U.P.A.C name.*

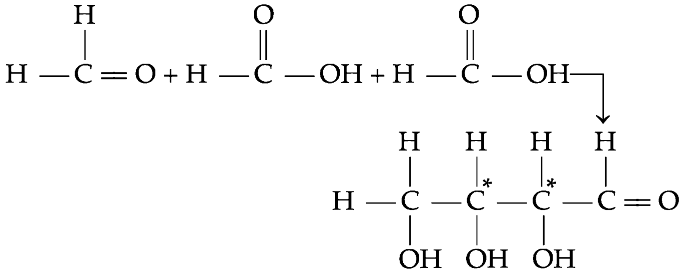
Solution. One product gives positive iodoform test but negative Tollen's test. So, it will contain CH_3CO – group or it will be methyl ketone. The other product gives a positive Tollen's test and a negative iodoform test. So, it will be an aldehyde and will not contain methyl group. Hence the products will on ozonolysis be $CH_3CO\,CH_3$ and CH_3CH_2CHO. The alkene can be obtained by removing O–atoms from $C = O$ groups of aldehyde and ketone and joining them by $C = C$.



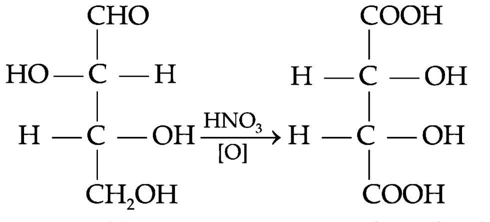
2 – Methyl pent-2-ene (IUPAC name)

EXAMPLE 47. *An organic compound, (–) erythrose* $C_4H_8O_4$ *gives tests with Benedict's solution and Tollen's reagent. It is also oxidised to an optically active acid,* $C_4H_8O_5$*. Treatment with ethanoic anhydride yields* $C_{10}H_{14}O_7$*. It consumes 3 moles of periodic acid and yields one mole of methanal and 3 moles of methanoic acid. Oxidation of erythrose by* HNO_3 *gives an optically inactive compound* $C_4H_8O_5$*. (–) threose, an isomer of erythrose, shows similar chemical behaviour except that* HNO_3 *oxidation yields an optically active compound* $C_4H_8O_6$*. On the basis of these evidences what structure or structures are possible for (–) threose and for (–) erythrose.*

SOLUTION. We know that erythrose is an aldehyde and contains three –OH groups. Cleavage by 3 moles of HIO_3 show that it has the following structure containing two chiral carbon* atoms.

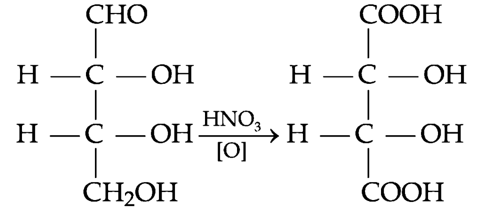


When (–) erythrose is oxidised, a dicarboxylic acid, HOOC – *CH– (OH) CH (OH) COOH is formed. This acid being optically inactive, it must have meso configuration, showing that (–) erythrose has either structure I or II as shown below :



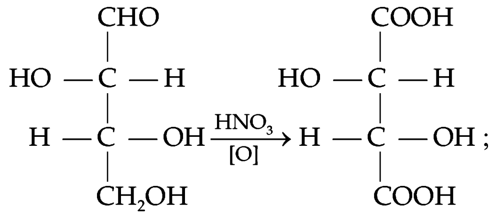
(I) Meso form of acid

or

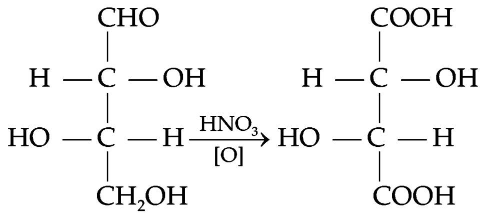


(II) Same meso form of acid

Also, (–) threose must be a diasteroisomer of erythrose, having either structure (III) or (IV) as shown below :



(III) Active acid



(IV) Active acid

EXAMPLE 48. *A compound having molecular formula* C_2HCl_3O *forms an addition product with sodium bisulphite and yields chloroform when warmed wih caustic soda solution. Derive the structural formula of the compound.*

SOLUTION. Molecular formula is C_2HCl_3O.

Structural formula. Since the compound forms an addition product with $NaHSO_3$, it must be a carbonyl compound containing either aldehyde (–CHO) or keto group (>C = O). First member of a ketone is CH_3COCH_3 that contains 3 carbon atoms. So, the given compound containing 2 carbon atoms cannot be a ketone. It will be an aldehyde. So, the compound will be CCl_3 – CHO *i.e.,* **trichloroacetaldehyde** or chloral.

It forms chloroform when heated with NaOH solution.

$$CCl_3.CHO + NaOH \longrightarrow \underset{\text{Chloroform}}{CHCl_3} + HCOONa$$

It gives addition compound with sodium bisulphite.

EXAMPLE 49. *An organic compound A having molecular formula* C_7H_8O *when oxidised on controlled condition, firstly gave an aldehyde (B) and then an acid (C). Sodium salt of the (C) gave benzene on distillation with soda-lime. Determine the structural formula of the compound A.*

SOLUTION. Since A on oxidation firstly gives an aldehyde B and then an acid (C) whose sodium salt on distillation with soda-lime gives benzene, A may be an alcohol *i.e.,* $C_6H_5CH_2OH$. A on oxidation gives aldehyde C_6H_5CHO (B) which on oxidation gives C_6H_5COOH (C).

EXAMPLE 50. *An organic compound gave the following results on analysis. (a) C = 26.08%, H = 4.34% (b) vapour density = 23. The compound gave brisk effervescence with sodium bicarbonate and reduced* $HgCl_2$ *solution. Write a suitable structure for the compound giving reasons.* **(KU 1978)**

SOLUTION. C = 26.08%, H = 4.34%,

O = 100 – (26.08 + 4.34) = 69.58%

(*i*) To find E.F.

Element	% age	At. wt.	Relative no. of atoms = % age/at. wt.	Simple ratio	Whole no. ratio
C	26.08	12	$\frac{26.08}{12} = 2.17$	$\frac{2.17}{2.17} = 1$	1
H	4.34	1	$\frac{4.34}{1} = 4.34$	$\frac{4.34}{2.17} = 2$	2
O	69.58	16	$\frac{69.58}{16} = 4.35$	$\frac{4.35}{2.17} = 2$	2

$\therefore$ E. F. of compound = CH_2O_2 ;

E.F. wt. = 12 + (2 × 1) + (2 × 16) = 46

(*ii*) **To find M.F.** Mol. wt.

= 2 × V.D. = 2 × 23 = 46

$$\therefore \quad M.F. = E.F. \times \frac{\text{Mol. wt.}}{\text{E.F. wt.}}$$

$$= CH_2O_2 \times \frac{46}{46} = CH_2O_2$$

(*iii*) To find structural formula. Since the compound gives brisk effervescence with $NaHCO_3$, it may be a carboxylic acid with one C – atom *i.e.*, HCOOH (formic acid). It reduces $HgCl_2$ to Hg_2Cl_2 and itself gets oxidised to CO_2.

$$2HgCl_2 + HCOOH \longrightarrow Hg_2Cl_2 + CO_2 + 2\,HCl.$$

So, the structural formula of acid is HCOOH

or 
$H-\overset{\overset{O}{\|}}{C}-OH$

EXAMPLE 51. *A monobasic organic acid on analysis gave the following results.*

(*a*) *0.315 g required 33.33 mL of N/10 NaOH for complete neutralisation*

(*b*) *0.2079 g of carious determination gave 0.3157 g silver chloride*

(*c*) *0.189g gave 0.1761 g CO_2 and 0.054g H_2O on analysis. Derive the molecular as well as structural formula of the compound.*

SOLUTION. (*i*) **To find mol. wt. of acid.** 33.33mL of N/10 NaOH ≡ 0.315g acid

$$1000\text{mL of 1N NaOH} \equiv \frac{0.315}{33.33} \times \frac{10}{1} \times 1000$$

= 94.51g acid.

$\therefore$ Eq. wt. of acid = 94.51

$\therefore$ Mol. wt. of acid = Basicity × Eq. wt.

= 1 × 94.51 = 94.51

[$\because$ acid given is monobasic]

(*ii*) To calculate E.F.

(*a*) Wt. of AgCl = 0.3157g.

AgCl ≡ Cl

108 + 35.5 35.5g

= 143.5g

143.5g AgCl ≡ 35.5g Cl

$$0.3175\text{g AgCl} \equiv \frac{35.5}{143.5} \times 0.3175 = 0.0781\text{g of Cl}$$

$$\therefore \quad \%\text{ age of Cl} = \frac{0.0781}{0.2079} \times 100 = \mathbf{37.57\%}$$

(*b*) $CO_2 \equiv C$;

12 + (2 × 16) 12g

= 44g

44g CO_2 ≡ 12g C

$$0.1761\text{g } CO_2 \equiv \frac{12}{44} \times 0.1761 = 0.048\text{g};$$

$$\therefore \%\text{ age of C} = \frac{0.048}{0.189} \times 100 = \mathbf{25.4\%}$$

(*c*) $H_2O \equiv 2H$

(2 × 1) + 16 2 × 1 = 2g

= 18 g

18g H_2O ≡ 2g H

$$0.054\text{g } H_2O \equiv \frac{2}{18} \times 0.054 = 6 \times 10^{-3}$$

$$\therefore \quad \%\text{ age of H} = \frac{6 \times 10^{-3}}{0.189} \times 100 = 3.17\%;$$

$$\%\text{ age of O} = 100 - (37.57 + 25.4 + 3.17) = 33.86\%$$

Element	% age	At. Wt.	Relative no. of atoms = % age/at. wt.	Simple ratio	Whole no. ratio
C	25.4	12	$\frac{25.4}{12} = 2.1$	$\frac{2.1}{1.058} = 2$	2
H	3.17	1	$\frac{3.17}{1} = 3.17$	$\frac{3.17}{1.058} = 3$	3
Cl	37.57	35.5	$\frac{37.57}{35.5} = 1.058$	$\frac{1.058}{1.058} = 1$	1
O	33.86	16	$\frac{33.86}{16} = 2.1$	$\frac{2.1}{1.058} = 2$	2

$\therefore$ E. F. of compound = $C_2H_3ClO_2$

E.F. wt. of $C_2H_3ClO_2$ = (2 × 12) + (3 × 1) + 35.5 + (2 × 16) = 94.5

$$\therefore \quad M.F. = E.F. \times \frac{\text{Mol. wt}}{\text{E.F. wt}}$$

$$= C_2H_3ClO_2 \times \frac{94.51}{94.5} = C_2H_3ClO_2$$

(*iii*) **Structural formula.** The given compound is monobasic acid. So, it contains one —COOH group. So, $C_2H_3ClO_2$ can be written as ; CH_2Cl COOH *i.e.*, monochloroacetic acid.

EXAMPLE 52. *An organic compound (A) containing C, H and O with boiling point 78°C and possessing a rather pleasant odour, on heating with conc. H_2SO_4 gives a gaseous product (B) with the empirical formula CH_2. 'B' decolorises bromine water as well as alkaline $KMnO_4$ solution and takes up one mol of H_2 (per mol of 'B') in the presence of finely-divided nickel at high temperature. Identify the substances A and B.* **(IIT 1979)**

SOLUTION. The empirical formula CH_2 indicates that its general formula will be $(CH_2)_n$ or C_nH_{2n} *i.e.*, alkene. Alkenes also decolorise Br_2 water as well as alkaline $KMnO_4$ and also adds up H_2 at high temperature. So, B is alkene. Compound A contains C, H and O. It is pleasant smelling with b.p. 78°C. So, it will be ethyl alcohol (C_2H_5OH). It gives ethene (C_2H_4) when heated with conc. H_2SO_4. So, A is C_2H_5OH ; B is C_2H_4

Reactions. $C_2H_5OH \xrightarrow[\Delta]{\text{Conc. } H_2SO_4} CH_2 = CH_2$

$\xrightarrow[\text{water}]{Br_2} CH_2Br\text{–}CH_2Br ; CH_2 = CH_2 \xrightarrow[\substack{KMnO_4(H_2O + O) \\ \text{Pink}}]{\text{Alkaline}}$

$\underset{\text{glycol (colourless)}}{CH_2OH - CH_2OH} ; CH_2 = CH_2 \xrightarrow[\text{Catalyst}]{H_2, \Delta} \underset{\text{Ethane}}{CH_3 - CH_3}$

Example 53. *An organic compound having molecular formula $C_4H_8O_2$ on treatment with sodium hydroxide gave ethyl alcohol and sodium salt of an acid. When heated with sodalime, the sodium salt gave methane. Derive the structural formula of the compound.*

Solution. The given compound gives C_2H_5OH and sodium salt of acid. So, the compound may be an ester. The sodium salt of the acid gave methane (CH_4) with soda lime. So, the acid produced by the hydrolysis of ester should be CH_3COOH and ester should be $CH_3COOC_2H_5$.

Reactions :

(*i*) $CH_3COOC_2H_5 + NaOH \longrightarrow \underset{\text{Sodium acetate}}{CH_3COONa} + \underset{\text{Ethyl alcohol}}{C_2H_5OH}$

(*ii*) $CH_3COONa + NaOH \xrightarrow{CaO} CH_4 + Na_2CO_3$.

Example 54. *An organic compound A (V.D., 46.25) gave a positive Beilstein test. When A was treated with alcoholic KOH, another compound B was formed which did not give Beilstein test. B on oxidation with acidic $KMnO_4$ yielded an acid C (V.D., 37). Derive the structural formula of A and name it.*

Solution. (*i*) Mol. wt. of A = 2 × V.D. = 2 × 46.25 = 92.50. Since it gives a positive Beilstein test, it must be alkyl chloride (not bromide and iodide because their mol. wt. will be much higher than 92.5). So, the expected alkyl chloride is C_4H_9Cl (mol. wt. = 4 × 12 + 9 × 1 + 35.5 = 92.5).

(*ii*) C_4H_9Cl when treated with alc. KOH gives an olefin (C_4H_8).

$$\underset{\text{(A)}}{C_4H_9Cl} \xrightarrow[-\,HCl]{\text{alc. KOH}} \underset{\text{(B)}}{C_4H_8}$$

(*iii*) The olefin on oxidation with acidic $KMnO_4$ gets oxidised at C = C to give following two monocarboxylic acids.

$$CH_3CH_2CH = CH_2 \xrightarrow{O} \underset{\text{(C) Propanoic acid}}{CH_3CH_2COOH} + HCOOH$$

Mol. wt. of compound C = 2 × V.D. = 2 × 37 = 74.

Also, mol. wt. of CH_3CH_2COOH = 12 + (3 × 1) + 12 + (2 × 1) + 12 + (2 × 16) + 1 =74. So, C is CH_3CH_2COOH

(*iv*) If C_4H_8 is taken as $CH_3CH = CHCH_3$, then on oxidation, we get CH_3COOH which has mol. wt. (= 60 ; 12 + (3 × 1) + 12 + (2 × 16) + 1 = 60). So, this structure is rule out. Hence the structure of A is $CH_3CH_2CH_2CH_2Cl$ *i.e.*, **1–chlorobutane.**

Example 55. *An organic liquid A (C_2H_6O) on oxidation gives an acid B having empirical formula CH_2O. Both A and B form a sweet smelling liquid C (Mol. wt. 88), when treated with conc–H_2SO_4. Calculate the structural formula of A, B and C.*

Solution. Organic liquid A is C_2H_6O. It can be either CH_3OCH_3 (dimethyl ether) or C_2H_5OH (ethyl alcohol).

(*i*) If CH_3OCH_3 is oxidised, HCOOH (E.F. = CH_2O_2) is formed which does not correspond to given E.F. (CH_2O). So, it is not CH_3OCH_3.

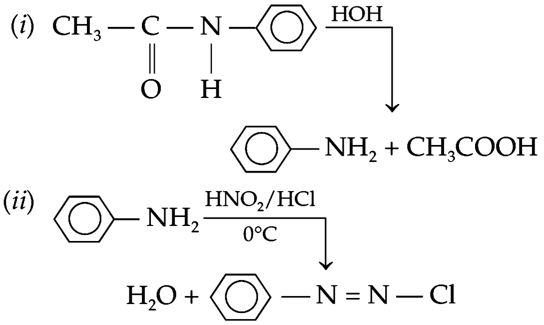
If C_2H_5OH is oxidised, CH_3COOH (B) (E.F. = CH_2O) is formed which has the same E.F. as required. So, A is ethyl alcohol.

B *i.e.*, CH_3COOH reacts with A (C_2H_5OH) in presence of conc. H_2SO_4 to give a sweet smelling substance (C), ethyl acetate [$CH_3COOC_2H_5$, mol. wt. = 12 + (3 × 1) + 12 + (2 × 16) + (2 × 12) + (5 × 1) = 88] whose mol. wt. is same as given in the question. So, C is **ethyl acetate,** $CH_3COOC_2H_5$.

Example 56. *An organic compound having molecular formula C_8H_9NO on hydrolysis yields acetic acid and a primary amine. If the amine is diazotisable, name the compound and assign structural formula to it.*

Solution. The compound C_8H_9NO gives acetic acid (CH_3COOH) and an amine on hydrolysis. But amine is diazotisable. So, the compound may be the derivative of acetic acid and aromatic amine (aniline). So, the expected compound is $CH_3CO.NH.C_6H_5$ (acetanilide)

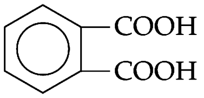
Reactions.



(Benzene diazonium chloride)

Example 57. *An organic acid (mol. formula $C_8H_6O_4$) when heated with its sodium salt formed benzene. It also formed two series of salts and two series of esters. It also forms an anhydride on simple heating. Derive the structural formula from the above data.*

Solution. Since $C_8H_6O_4$ compound gives two series of salts and two series of esters, the given acid will be a dibasic acid. When heated with sodalime, it gives benzene. So, it is a benzene derivative and may be benzene dicarboxylic acid, $C_6H_4(COOH)_2$. Also, it forms an anhydride on simple heating. So, it may be **ortho-phthalic acid,**



Example 58. *An organic compound $C_6H_5NO_2$ when heated with Sn and HCl gave a compound B (C_6H_7N). B on treatment with $NaNO_2$ and HCl followed by treatment with KCN gave a compound C which on hydrolysis yielded benzoic acid. Name the compounds B and C.*

Solution. (*i*) $C_6H_5NO_2$ on reduction with Sn/HCl gives amine.

$$C_6H_5NO_2 \xrightarrow[H]{Sn/HCl} \underset{\text{B (aniline)}}{C_6H_5NH_2}$$

So, compound B is aniline, $C_6H_5NH_2$ *i.e.*, C_6H_7N.

(*ii*) $C_6H_5NH_2$ on treatment with $NaNO_2$ and HCl gives benzene diazonium chloride, $C_6H_5N_2Cl$. The latter reacts

$$C_6H_5NH_2 \xrightarrow[0°C]{NaNO_2/HCl} C_6H_5N_2Cl$$

with KCN to give phenyl cyanide, C_6H_5CN (compound, C)

$$C_6H_5N_2Cl + KCN \longrightarrow C_6H_5CN + N_2 + KCl.$$

C_6H_5CN on hydrolysis gives benzoic acid, C_6H_5COOH

$$\underset{(C)}{C_6H_5CN} \xrightarrow{HOH} C_6H_5COOH + NH_3$$

Example 59. *A compound X reduces Fehling solution but does not react with sodium bicarbonate. On the otherhand, a compound Y does not reduce Fehling solution but reacts with sodium bicarbonate. Derive the structures of X and Y if their empirical formulae are same but their vapour densities are 15 and 30 respectively. Give reactions also.*

Solution. (*i*) The E.F. of X = CH_2O. Since X compound reduces Fehling solution but does not react with $NaHCO_3$, it will be an aldehyde with E.F. CH_2O. But mol. wt. of aldehyde is 2 × V.D. = 2 × 15 = 30. So, **X = HCHO** (mol. wt. = 30) *i.e.*, formaldehyde.

$$HCHO + \underset{\text{(From Fehling solution)}}{2CuO} \longrightarrow \underset{\text{Red ppt}}{Cu_2O\downarrow} + HCOOH$$

$$HCHO + NaHCO_3 \longrightarrow \text{No action.}$$

(*ii*) The E.F. of Y = CH_2O. Y compound does not reduce Fehling solution but reacts with $NaHCO_3$. So, it will be an acid and not an aldehyde. The acid may be acetic acid, CH_3COOH ($C_2H_4O_2$) having E.F., CH_2O. So **Y is CH_3COOH.**

$$CH_3COOH + \underset{\text{From Fehling solution}}{CuO} \longrightarrow \text{No action}$$

$$CH_3COOH + NaHCO_3 \longrightarrow CH_3COO\,Na + CO_2 + H_2O.$$

Example 60. *An organic substance A (mol. wt., 135) contains 71.13% carbon, 10.35% nitrogen and 6.67% hydrogen. 'A' on hydrolysis forms a monobasic acid B and an amine. The acid B contains 40% carbon and 6.6% hydrogen. 0.167g of its silver salt on ignition left behind 0.108g silver. Calculate the molecular formula of the compounds and write the various reactions involved.*

Solution. C = 71.13% , N = 10.35%, H = 6.67% and O = 100 – (71.13 + 10.35 + 6.67) = 11.85.

(*i*) **To find E.F.**

Element	% age	At. wt.	Relative no. of atoms = % age/at. wt.	Simple ratio	Whole no. ratio
C	71.13	12	$\frac{71.13}{12} = 5.928$	$\frac{5.928}{0.739} = 8$	8
H	6.67	1	$\frac{6.67}{1} = 6.67$	$\frac{6.67}{0.739} = 9$	9
N	10.35	14	$\frac{10.35}{14} = 0.739$	$\frac{0.739}{0.739} = 1$	1
O	11.85	16	$\frac{11.85}{16} = 0.740$	$\frac{0.740}{0.739} = 1$	1

∴ E.F. of compound = C_8H_9NO

$$\text{E.F. wt.} = (8 \times 12) + (9 \times 1) + 14 + 16 = 135$$

$$\therefore \quad \text{M.F.} = \text{E.F.} \times \frac{\text{Mol. wt.}}{\text{E.F. wt.}} = C_8H_9NO \times \frac{135}{135}$$

$$= \mathbf{C_8H_9NO}$$

(*ii*) Eq. wt. by silver salt method

$$= \frac{\text{wt. of Ag-salt}}{\text{wt. of Ag}} \times 108 - 107$$

$$= \frac{0.167 \times 108}{0.108} - 107 = 60$$

$$\therefore \quad \text{Mol. wt.} = \text{Eq. wt.} \times \text{basicity} = 60 \times 1 = 60.$$

To find E.F., C = 40%, H = 6.6%,

O = 100 – (40 + 6.6) = 53.4%

Element	% age	At. wt.	Relative no. of atoms = % age/at. wt.	Simple ratio	Whole no. ratio
C	40	12	$\frac{40}{12} = 3.33$	$\frac{3.33}{3.33} = 1$	1
H	6.6	1	$\frac{6.6}{1} = 6.66$	$\frac{6.66}{3.33} = 2$	2
O	53.4	16	$\frac{53.4}{16} = 3.33$	$\frac{3.33}{3.33} = 1$	1

$$\therefore \quad \text{E.F.} = CH_2O;$$

$$\text{E.F. wt.} = 12 + (2 \times 1) + 16 = 30.$$

$$\therefore \quad \text{M.F.} = \text{E.F.} \times \frac{\text{Mol. wt.}}{\text{E.F. wt.}}$$

$$= CH_2O \times \frac{60}{30} = C_2H_4O_2.$$

The substance A on hydrolysis gives acid B with molecular formula $C_2H_4O_2$ or CH_3COOH (acetic acid) because carboxylic acid group is –COOH. It also gives amine. So, A is an acetyl derivative of an amine with the formula, $C_6H_5NH_2$ (aniline).

Hence A = acetanilide, $C_6H_5NHCOCH_3$

Reaction :

$$C_6H_5NHCOCH_3 + H_2O \longrightarrow \underset{\text{Acetic acid}}{CH_3COOH} + \underset{\text{Aniline}}{C_6H_5NH_2}$$

EXAMPLE 61. *Two compounds A and B, both having same molecular weight (= 58) contain C = 62% , H = 10.4% and oxygen = 27.6%. A on oxidation gives a mixture of two acids containing one and two atoms of carbon per molecule respectively while B compound gives a monobasic acid containing three carbon atoms in the molecule. What are the compounds A and B? Give their reaction with (i) ammonical silver nitrate (ii) ammonia and (iii) sodium bisulphite.*

SOLUTION. (*i*) **To find E.F.**

Element	% age	At. wt.	Relative no. of atoms = % age/at. wt.	Simple ratio	Whole no. ratio
C	62	12	$\frac{62}{12} = 5.17$	$\frac{5.17}{1.725} = 3$	3
H	10.4	1	$\frac{10.4}{1} = 10.4$	$\frac{10.4}{1.725} = 6$	6
O	27.6	16	$\frac{27.6}{16} = 1.725$	$\frac{1.725}{1.725} = 1$	1

$\therefore$ E.F. of compound $= C_3H_6O$.

$$\text{E.F. wt.} = (3 \times 12) + (6 \times 1) + 16 = 58$$

$$\therefore \quad \text{M.F.} = \text{E.F.} \times \frac{\text{Mol. wt.}}{\text{E.F. wt.}}$$

$$= C_3H_6O \times \frac{58}{58} = C_3H_6O$$

(*ii*) 'A' compound on oxidaton gives a mixture of acids (– COOH) with one (HCOOH) and two (CH_3COOH) carbon atoms per molecule respectively. So, A must be a ketone having formula **CH_3COCH_3 (acetone or propanone)**
Compound 'B' on oxidation gives an acid with 3 carbon atoms and it can be CH_3CH_2COOH which has same number of C–atoms as B has. So, **B** may be an aldehyde with formula CH_3CH_2CHO *i.e.*, **propanal** or propionaldehyde

Reactions

(*i*) $CH_3COCH_3 + Ag_2O \longrightarrow$ no action

$CH_3CH_2CHO + Ag_2O \longrightarrow CH_3CH_2COOH + 2Ag$

(*ii*) $2CH_3COCH_3 + NH_3 \longrightarrow \underset{\text{(Diacetone amine)}}{(CH_3)_2C(NH_2)CH_2COCH_3}$

$CH_3CH_2CHO + NH_3 \longrightarrow \underset{\text{Propionaldehyde ammonia}}{CH_3CH_2CH(OH)NH_2}$

(*iii*) $CH_3COCH_3 + NaHSO_3 \longrightarrow \underset{\text{Acetone bisulphite compound}}{(CH_3)_2C(OH)SO_3Na}$

$CH_3CH_2CHO + NaHSO_3 \longrightarrow \underset{\text{Propionaldehyde bisulphite compound.}}{CH_3CH_2CH(OH)\ SO_3Na}$

EXAMPLE 62. *An organic liquid 'X' having molecular formula C_2HCl_3O (i) undergoes oxidaton to give a monobasic acid Y (containing C = 14.68%, H = 0.612% and Cl = 65.13%) and also reduces Fehling solution. Y gives a sweet smelling liquid (Z) containing 89.12% chlorine, when distilled with sodalime. (Z) can also be obtained by heating 'X' with alkali. Derive the structural formulae of X, Y and Z, using various reactions involved.*

SOLUTION. (*i*) Molecular formula of X = C_2HCl_3O.

To find E.F. of Y. C = 14.68%, H = 0.612%, Cl = 65.13%, O = 100–(14.68 + 0.612 + 65.13) = 19.578%

Element	% age	At. wt.	Relative no. of atoms = % age/at. wt.	Simple ratio	Whole no. ratio
C	14.68	12	$\frac{14.68}{12} = 1.223$	$\frac{1.223}{0.612} \simeq 2$	2
H	0.612	1	$\frac{0.612}{1} = 0.612$	$\frac{0.612}{0.612} = 1$	1
Cl	65.13	35.5	$\frac{65.13}{35.5} = 1.835$	$\frac{1.835}{0.612} \simeq 3$	3
O	19.578	16	$\frac{19.578}{16} = 1.223$	$\frac{1.223}{0.612} \simeq 2$	2

$\therefore$ E.F. of $Y = C_2HCl_3O_2$

'**X**' compound reduces Fehling solution and on oxidation gives monobasic acid '*Y*'. So, ***X* will be** an aldehyde *i.e.*, **CCl_3CHO** (trichloroacetaldehyde) while ***Y* will be $CCl_3.COOH$** (trichloroacetic acid)

Reactions. $CCl_3CHO \xrightarrow{O} CCl_3COOH$

$\underset{\text{(from Fehling solution)}}{CCl_3CHO + 2CuO} \longrightarrow CCl_3COOH + \underset{\text{Reddish brown ppt}}{Cu_2O\downarrow}$

(*ii*) '*Y*' gives sweet smelling liquid '*Z*' as shown below.

$$CCl_3COONa + NaOH \xrightarrow{CaO} \underset{\text{Z (Chloroform)}}{CHCl_3} + Na_2CO_3$$

Mol. wt. of $CHCl_3 = 12 + 1 + (35.5 \times 3) = 119.5$

$\therefore$ % age of Cl in $CHCl_3$

$$= \frac{(3 \times 35.5)}{119.5} \times 100 = 89.12\%$$

This value is in agreement with given percentage of chlorine.

Also, compound 'X' gives $CHCl_3$ on heating with alkali, NaOH.

$$CCl_3CHO + NaOH \longrightarrow CHCl_3 + \underset{\text{(Sodium formate)}}{HCOONa}$$

EXAMPLE 63. *An organic compound 'X' (chemical formula CH_2O) reduces Fehling solution as well as forms phenyl hydrazone. When 2 molecules of X react in presence of conc. NaOH solution, one molecule of a neutral compound 'Y' and a sodium salt of monobasic acid 'Z' are formed. Derive the structures of A, B and C and also, the various reactions involved in these.*

SOLUTION. (*i*) Compound 'X' reduces Fehling solution and forms phenyl hydrazone. So 'X' may be an aldehyde.

The formula CH_2O corresponds to the **formaldehyde, HCHO.** So, X = HCHO. Reactions are :

$$HCHO + 2CuO \longrightarrow HCOOH + Cu_2O \text{ (red ppt).}$$

(from Fehling solution)

$$HCHO + C_6H_5NHNH_2 \longrightarrow HCH = NNHC_6H_5$$

(phenyl hydrazone)

(*ii*) HCHO undergoes Cannizaro's reaction to form a neutral compound (CH_3OH = Y) and sodium salt of monobasic acid (HCOONa, sodium formate) *i.e.*, Z compound.

$$\underset{(X)}{2HCHO} + NaOH \longrightarrow \underset{(Y)}{CH_3OH} + \underset{(Z)}{HCOONa}$$

EXAMPLE 64. *An organic compound (CH_2O) gave two compounds A and B when treated with conc. NaOH. 'A' on oxidation gives original compound CH_2O while 'B' compound reduces ammoniacal silver nitrate. Name the compounds CH_2O, A and B and write the various reactions involved in it.*

SOLUTON. CH_2O reacts with conc. NaOH to give A which on oxidation gives CH_2O. It also gives B which reduces ammoniacal silver nitrate. So, CH_2O will be an aldehyde which gives Cannizaro's reaction. So, CH_2O is aldehyde *i.e.*, **formaldehyde (HCHO).** The reactions are :

(*i*) $2HCHO + NaOH \longrightarrow \underset{(A)}{CH_3OH} + \underset{(B)}{HCOONa}$

(*ii*) $CH_3OH \xrightarrow{O} HCHO + H_2O$

(*iii*) $HCOONa + Ag_2O$ (from ammoniacal silver nitrate solution) $\longrightarrow 2Ag\downarrow + CO_2 + NaOH.$

EXAMPLE 65. *A dibasic organic acid contains 26.59% C, 2.22% hydrogen and rest oxygen. 2.40g of a silver salt on ignition gave 1.704 g silver as residue. Calculate the molecular formula of the acid and write its structural formula.*

SOLUTION. Wt. of Ag–salt = 2.40g ;

wt. of silver = 1.704g. we know that :

$$\text{Eq. wt. of acid} = \left[\frac{\text{Wt. of Ag-salt}}{\text{Wt. of Ag}} \times 108\right] - 107$$

$$= \frac{2.4 \times 108}{1.704} - 107$$

$$= 152.1 - 107 = 45.1$$

$\therefore$ Mol. wt. of acid = Eq. wt. × basicity = 45.1 × 2 = 90.2

To find E.F. C = 26.59%, H = 2.22%, O = 100 – (26.59 + 2.22) = 71.19%

Element	% age	At. wt.	Relative no. of atoms = % age/At. wt.	Simple ratio	Whole no. ratio
C	26.59	12	$\frac{26.59}{12} = 2.2$	$\frac{2.2}{2.22} = 1$	1
H	2.22	1	$\frac{2.22}{1} = 2.22$	$\frac{2.22}{2.22} = 1$	1
O	71.19	16	$\frac{71.19}{16} = 4.44$	$\frac{4.44}{2.22} = 2$	2

$\therefore$ E.F. of organic acid = CHO_2 ;

$$\text{E.F. wt.} = 12 + 1 + (2 \times 16) = 45$$

$$\therefore \quad \text{M.F.} = \text{E.F.} \times \frac{\text{Mol. wt.}}{\text{E.F. wt}}$$

$$= CHO_2 \times \frac{90.2}{45} = C_2H_2O_4.$$

The given acid is a dibasic acid, so, it wll contain two COOH groups. Hence the structure of the organic acid is

$$\begin{array}{l} O = C\text{—}OH \\ \quad\ | \\ O = C\text{—}OH \end{array}$$

i. e., **oxalic acid**

EXAMPLE 66. *An organic compound (0.6g) on combustion gave 1.32g CO_2 and 0.72g H_2O. Calculate its molecular formula if its vapour density is 30. Write the structure of three compounds having this formula.*

SOLUTION. (*i*) $CO_2 \equiv C$

$44g\ CO_2 \equiv 12g\ C$

$12 + (2 \times 16) \quad 12g$

$= 44$ g

$$1.32g\ CO_2 \equiv \frac{12}{44} \times 1.32 = 0.36g$$

$$\therefore \quad \%\text{ age of C} = \frac{0.36}{0.6} \times 100 = 60\%$$

(*ii*) $H_2O \equiv 2H$

$18g\ H_2O \equiv 2g\ H$

$(2 \times 1) + 16 \quad 2 \times 1$

$= 18g \quad = 2g$

$$0.72g\ H_2O \equiv \frac{2}{18} \times 0.72 = 0.08g$$

$$\therefore \quad \%\text{ age of H} = \frac{0.08 \times 100}{0.6} = 13.33\%$$

$$\%\text{ age of O} = 100 - (60 + 13.33) = 26.67$$

To Find E.F.

Element	% age	At. wt.	Relative no. of atoms = % age/at. wt.	Simple ratio	Whole no. ratio
C	60	12	$\frac{60}{12} = 5$	$\frac{5}{1.67} \simeq 3$	3
H	13.33	1	$\frac{13.33}{1} = 13.33$	$\frac{13.33}{1.67} \simeq 8$	8
O	26.67	16	$\frac{26.67}{16} = 1.67$	$\frac{1.67}{1.67} = 1$	1

$\therefore$ E.F. of compound = C_3H_8O *i.e.,* $C_nH_{2n+2}O$.

E.F. wt. = (3 × 12) + (8 × 1) + 16 = 60 ;

Mol. wt. = 2 × V.D. = 2 × 30 = 60.

$$\therefore \quad \text{M.F.} = \text{E.F.} \times \frac{\text{Mol. wt.}}{\text{E. F. wt.}}$$

$$= C_3H_8O \times \frac{60}{60} = C_3H_8O$$

C_3H_8O may be an ether or an alcohol. Among alcohols, it cannot be tertiary alcohol because the latter contains

4 carbon atoms. Keeping in view valencies of C (= 4), O (= 2) and H (= 1), following structures can be suggested for C_3H_8O.

(*i*) $CH_3OC_2H_5$ (ethyl methyl ether)

(*ii*) $CH_3CH_2CH_2OH$ (*n* – propyl alcohol *i.e.*, 1° or primary alcohol.

(*iii*) $\begin{matrix}H_3C\\H_3C\end{matrix}\!>CHOH$ Isopropyl alcohol or propan – 2 – ol.

Example 67. *An organic compound on analysis was found to contain 64% oxygen, 4% hydrogen and rest being carbon. Calculate the molecular formula if 6 oxygen atoms per molecule of the compound are present.*

Solution. O = 64%, H = 4%, C = 100 – (64 + 4) = 32%

To find E.F.

Element	% age	At. wt.	Relative no. of atoms = % age/At. wt.	Simple ratio	Whole no. ratio
C	32	12	$\frac{32}{12} = 2.67$	$\frac{2.67}{2.67} = 1$	1 × 2 = 2
H	4	1	$\frac{4}{1} = 4$	$\frac{4}{2.67} = 1.5$	1.5 × 2 = 3
O	64	16	$\frac{64}{16} = 4$	$\frac{4}{2.67} = 1.5$	1.5 × 2 = 3

∴ E.F. of the compound = $C_2H_3O_3$.

To find M.F. Since each molecule of compound contains six atoms of oxygen, M.F. = 2 × $C_2H_3O_3$ = $\mathbf{C_4H_6O_6}$ **Ans.**

Example 68. *A nitrogen containing organic compound gave the following results on analysis. 0.93g of it on combustion gave 2.64g CO_2 and 0.630g water. 0.465g of the substance liberated 55.6 cm^3 of nitrogen at N.T.P. (1 cm^3 of N_2 weighs 0.00126g). Calculate the empirical formula of the substance. write its structure if it gives tests of diazotisation.*

Solution. (*i*) wt. of compound = 0.93g; wt. of CO_2 = 2.64g and wt. of H_2O = 0.63 g.

(*a*)
$$\begin{array}{rl} CO_2 & \equiv C \\ 44g\ CO_2 & \equiv 12g\ C \\ 12 + (2 \times 16) & \ \ 12g \\ = 44g & \\ 2.64g\ CO_2 & \equiv \frac{12}{44} \times 2.64 = 0.72 \end{array}$$

$$\therefore \ \% \text{ age of C} = \frac{0.72}{0.93} \times 100 = 77.42$$

(*b*)
$$\begin{array}{rl} H_2O & = 2H \\ 18g\ H_2O & \equiv 2g\ H \\ (2 \times 1) + 16 & \ \ 2 \times 1 \\ = 18\ g & \ \ = 2g \\ 0.63g\ H_2O & \equiv \frac{2}{18} \times 0.63 = 0.07g \end{array}$$

$$\therefore \ \% \text{ age of H} = \frac{0.07}{0.93} \times 100 = \mathbf{7.53\%}$$

(*c*) 1 cm^3 of N_2 weighs = 0.00126g

55.6 cm^3 of N_2 weighs = 0.00126 × 55.6g

$$\therefore \ \% \text{ age of nitrogen} = \frac{0.00126 \times 55.6}{0.465} \times 100 = 15.07\%$$

To find E.F.

Element	% age	At. wt.	Relative no. of atoms = % age/At. wt.	Simple ratio	Whole no. ratio
C	77.42	12	$\frac{77.42}{12} = 6.45$	$\frac{6.45}{1.08} = 6$	6
H	7.53	1	$\frac{7.53}{1} = 7.53$	$\frac{7.53}{1.08} = 7$	7
N	15.07	14	$\frac{15.07}{14} = 1.08$	$\frac{1.08}{1.08} = 1$	1

∴ E.F. = C_6H_7N

The compound gives diazotisation test. So, it contains NH_2 group. The compound will thus be aniline, $C_6H_5NH_2$.

Example 69. *0.5g of the chloroplatinate of organic mono-acid base on ignition left 0.195g of platinum residue. (b). 0.36g of the base in Kjeldahl's experiment liberated 0.136g of NH_3 Derive the molecular formula as well as structural formula of the base if it contains 53.33% C and 15.56% hydrogen. (at. wt., Pt = 195). Also, give action of base on nitrous acid.*

Solution. (*i*) **To find mol. wt. of base (B).** We know that :

$$\frac{\text{Wt. of chloroplatinate}}{\text{Wt. of Pt residue}} = \frac{\text{Mol. wt. of chloroplatinate } (B_2H_2\ Pt\,Cl_6)}{\text{At. wt. of Pt } (= 195)}$$

$$\frac{0.5}{0.195} = \frac{\text{Mol. wt. of } B_2H_2\ Pt\,Cl_6}{195}$$

$$\therefore \text{Mol. wt. of } B_2H_2\ Pt\,Cl_6 = \frac{0.5 \times 195}{0.195} = 500$$

∴ Eq. wt. of base (B)

$$= \frac{\text{Mol. wt. of } B_2H_2\ Pt\,Cl_6 - \text{mol. wt. of } H_2\ Pt\,Cl_6}{2}$$

$$= \frac{500 - 410}{2} = 45$$

$$\left[\because \text{mol. wt. of } H_2PtCl_6 = (2 \times 1) + 195 + (6 \times 35.5) = 410\right]$$

∴ Mol. wt. = Eq. wt. × basicity = 45 × 1 = 45

(*ii*) **To find % age of nitrogen.** g. mol. wt. of

$$NH_3 = 14 + (3 \times 1) = 17g$$

17g NH_3 contain nitrogen = 14g

[∵ at. wt. of N = 14]

∴ 0.136g NH_3 contain nitrogen

$$= \frac{14}{17} \times 0.136g$$

$$\therefore \text{ \% age of nitrogen } = \frac{14 \times 0.136}{17} \times \frac{100}{0.36} = 31.11$$

(*iii*) **To find E.F.**, C = 53.33%, H = 15.56%, N = 31.11%

Element	% age	At. wt.	Relative no. of atoms = % age/At. wt.	Simple ratio	Whole no. ratio
C	53.33	12	$\frac{53.33}{12} = 4.44$	$\frac{4.44}{2.22} = 2$	2
H	15.56	1	$\frac{15.56}{1} = 15.56$	$\frac{15.56}{2.22} = 7$	7
N	31.11	14	$\frac{31.11}{14} = 2.22$	$\frac{2.22}{2.22} = 1$	1

$\therefore$ E.F. of the base = C_2H_7N

E.F. wt. of C_2H_7N = (2 × 12) + (7 × 1) + 14 = 45

$$\therefore \quad \text{M.F.} = \text{E.F.} \times \frac{\text{Mol. wt.}}{\text{E. F. wt.}}$$

$$= C_2H_7N \times \frac{45}{45} = C_2H_7N.$$

The structural formula of compound can be anyone of the following compounds.

(*i*) $C_2H_5NH_2$ (ethyl amine, 1° – amine)

(*ii*) $(CH_3)_2$ NH (dimethyl amine, 2°–amine)

Reactions.

(*i*) $C_2H_5NH_2 + HONO \longrightarrow C_2H_5OH + N_2 + H_2O$

(*ii*) $(CH_3)_2\,NH + HONO \longrightarrow (CH_3)_2\,N.\,NO + H_2O$

Dimethyl nitrosoamine

EXAMPLE 70. *An organic compound A on heating with PCl_5 gives B which gives C when heated with NH_3. 'C' gives 'D' when distilled wih P_2O_5. The substance D containing 0.205g of 'D' gave 65mL of N_2 gas at N.T.P. The substance 'D' gives 'A' on complete hydrolysis. Calculate the molecular formula and structural formula of the compound. Also, identify A, B, C and D compounds if the percentage of C and H in 'D' are 58.54 and 7.32 respectively.*

SOLUTION. To find the % age of nitrogen ; g. mol. wt. of N_2 = 2 × 14 = 28g.

22400mL of N_2 weighs = 28g

$$56\text{mL of } N_2 \text{ weighs} = \frac{28}{22400} \times 56 = 0.07\text{g}$$

$$\therefore \text{ \% age of nitrogen} = \frac{0.07}{0.205} \times 100 = 34.14\%$$

To find E.F. of the compound.

Element	% age	At. wt.	Relative no. of atoms = % age/At. wt.	Simple ratio	Whole no. ratio
C	58.54	12	$\frac{58.54}{12} = 4.88$	$\frac{4.88}{2.44} = 2$	2
H	7.32	1	$\frac{7.32}{1} = 7.32$	$\frac{7.32}{2.44} = 3$	3
N	34.14	14	$\frac{34.14}{14} = 2.44$	$\frac{2.44}{2.44} = 1$	1

$\therefore$ E.F. of the compound = C_2H_3N

The structural formula may be represented as

$CH_3—C \equiv N$ or $CH_3—N \rightleftarrows C$.

CH_3CN = Methyl cyanide or acetonitrile ;

$CH_3—N \rightleftarrows C$ is Methyl isocyanide.

(*i*) $CH_3CN + 2H_2O \xrightarrow{\text{Hydrolysis}} CH_3COOH + NH_3$

(*ii*) $CH_3NC + 2H_2O \longrightarrow HCOOH + CH_3NH_2$

(*a*) CH_3CN = D ; CH_3COOH = A

Reactions :

(*i*) $\underset{(A)}{CH_3COOH} + PCl_5 \longrightarrow \underset{(B)}{CH_3COCl} + POCl_3 + HCl$

$\underset{(B)}{CH_3COCl} + NH_3 \longrightarrow \underset{(C)}{CH_3CONH_2} + HCl$

$\underset{(C)}{CH_3CONH_2} \xrightarrow[-H_2O]{P_2O_5} \underset{(D)}{CH_3CN}$

$\underset{(D)}{CH_3CN} + 2H_2O \longrightarrow \underset{(A)}{CH_3COOH} + NH_3$

EXAMPLE 71. *A hydrocarbon A, adds one mole of hydrogen in presence of platinum catalyst to form n-hexane. When A is oxidised vigorously with $KMnO_4$, a single carboxylic acid containing three carbon atoms is isolated. Give the structure of A and explain.* **(IIT 1997)**

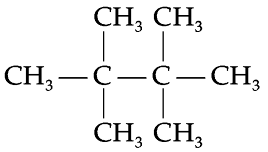
SOLUTION. Since hydrocarbon A adds a single molecule of hydrogen, it must be an alkene *i.e.*, hexene.

On vigorous oxidation with $KMnO_4$, it forms only one acid containing three carbon atoms. Clearly, it must be a symmetrical hexene *i.e.*, 3-hexene. The reaction is shown below :

$$\underset{\text{3-Hexene}}{CH_3—CH_2—CH=CH—CH_2—CH_3} \xrightarrow[\text{(O)}]{\text{alk. KMnO}_4} \underset{\text{Propanoic acid}}{2CH_3CH_2COOH}$$

EXAMPLE 72. *An organic compound C_8H_{18} on monochlorination gives a single monochloride. Write the structure of the hydrocarbon.* **(Roorkee 1999)**

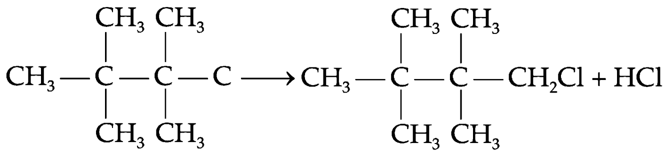
SOLUTION. As C_8H_{18} forms one and only one monochloride, it is clear that all the hydrogen atoms in C_8H_{18} are all alike. Such hydrogens are all primary H-atoms and the probable structure of alkane is given below :



$$CH_3—\underset{CH_3}{\overset{CH_3}{C}}—\underset{CH_3}{\overset{CH_3}{C}}—CH_3$$

2, 2, 3, 3-tetra methyl butane

Since all hydrogen atoms are equivalent, Cl_2 reacts with it to form the following monochloroproduct.



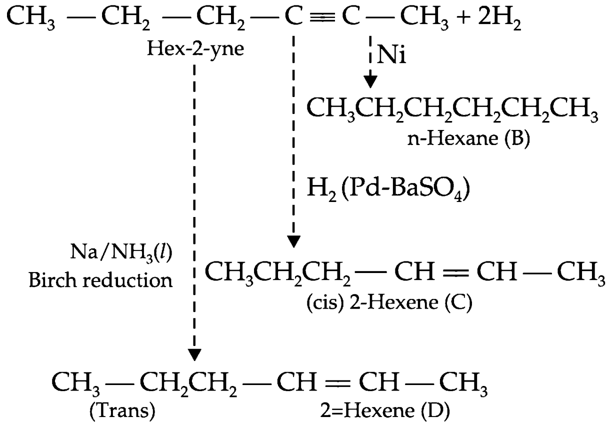
$$CH_3—\underset{CH_3}{\overset{CH_3}{C}}—\underset{CH_3}{\overset{CH_3}{C}}—C \longrightarrow CH_3—\underset{CH_3}{\overset{CH_3}{C}}—\underset{CH_3}{\overset{CH_3}{C}}—CH_2Cl + HCl$$

1 – chloro – 2, 2, 3,
3 – tetra methyl butane

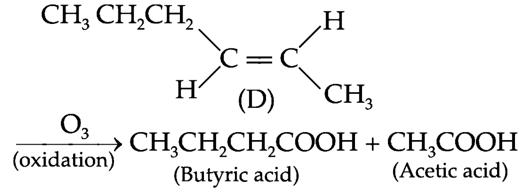
Example 73. *Hydrocarbon (A) C_6H_{10} on treatment with H_2/ Ni, H_2/Lindlar's catalyst and Na/NH_3 (l) forms three different products (B), (C) and (D) respectively. (A) forms salt (E) on heating with $NaNH_2$ in inert solvent but it does not form salt with ammonical $AgNO_3$ solution. Compound (E) further reacts with CH_3I to form (F). Compound (D) on oxidation ozonolysis gave butyric acid along with other products.*

Give the structures from (A) to (F) with proper reasoning. **(Roorkee 1998)**

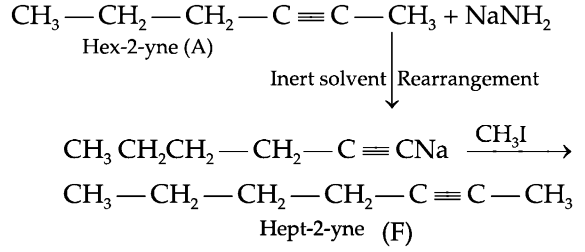
Solution. The hydrocarbon (A) C_6H_{10} appears to be hex-2-yne. Its reduction under different conditions is shown below :



(D) On oxidative ozonolysis gives butyric acid



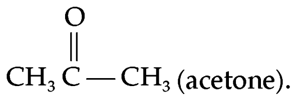
When hex-2-yne is heated wth $NaNH_2$ in inert solvent, then hex-2-yne rearranges to hex-1-yne which further reacts with $NaNH_2$ to form sodium salt. It then reacts with CH_3I to form hept-2-yne.



Example 74. *Ozonolysis of an alkene 'X' followed by decomposition with zinc and water gave two isomeric compounds of the formula C_3H_6O. Give the structure of the alkene and write the IUPAC name of this compound.*

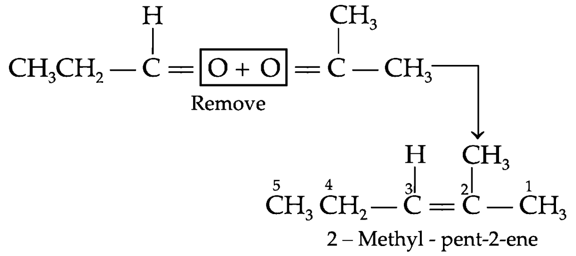
Solution. Since ozonolysis of an alkene gives an aldehyde or ketone or a mixture of aldehyde and ketone, so the isomers of C_3H_6O will be :

(*i*) CH_3CH_2CHO (propanal) and



(*ii*) $CH_3\overset{\overset{\displaystyle O}{\|}}{C}-CH_3$ (acetone).

The structure of alkene can be obtained by removing the oxygen atoms of the two carbonyl carbons of propanal and butanone and making a double bond between the carbonyl carbon atoms. Thus, we have :



Example 75. $A(C_6H_{12}) \xrightarrow{HCl} B + C$

$C_6H_{13}Cl$

$B \xrightarrow{Alc.\,KOH}$ *D (isomer of A)*

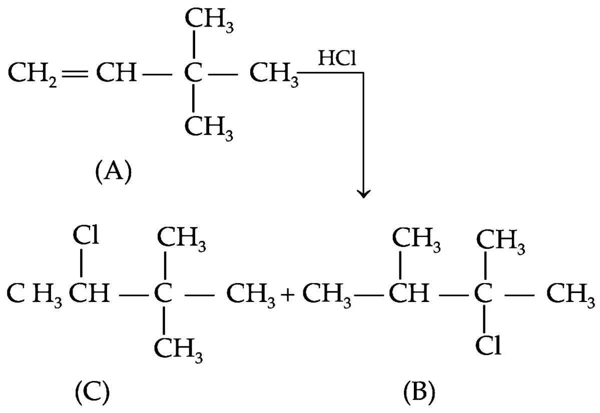
$D \xrightarrow{ozonolysis}$ *E (it gives negative test with Fehling solution but responds to iodoform test)*

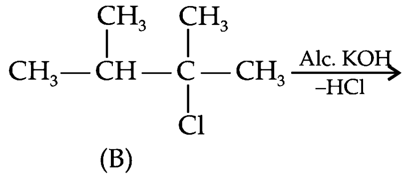
$A \xrightarrow{ozonolysis}$ *F + G (both give positive Tollen's test but donot give iodoform test)*

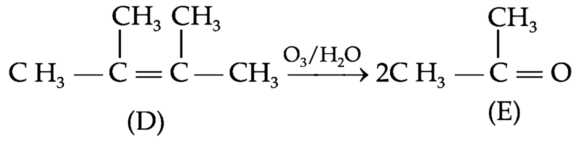
$F + G \xrightarrow{Conc.\,NaOH}$ *HCOONa + a primary alcohol).*

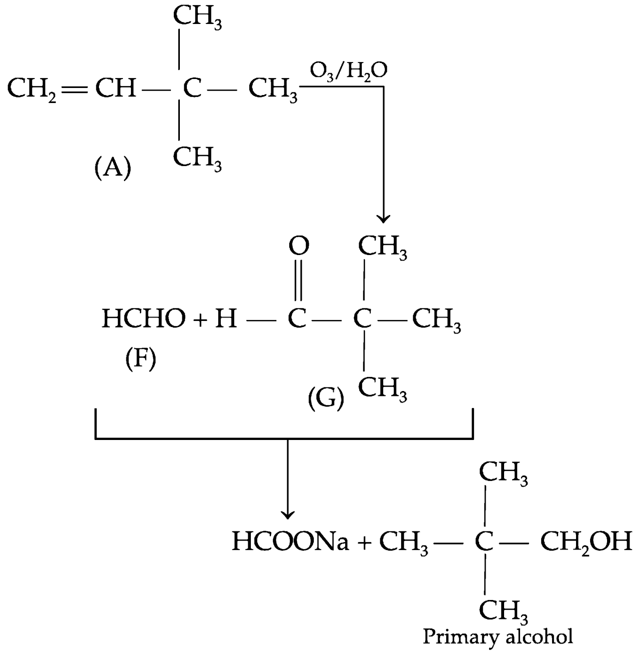
Identify A to G. **(IIT, 2003)**

Solution. Formation of $C_6H_{13}Cl$ from C_6H_{12} indicates one C = C bond, at which HCl is added. So, we have :





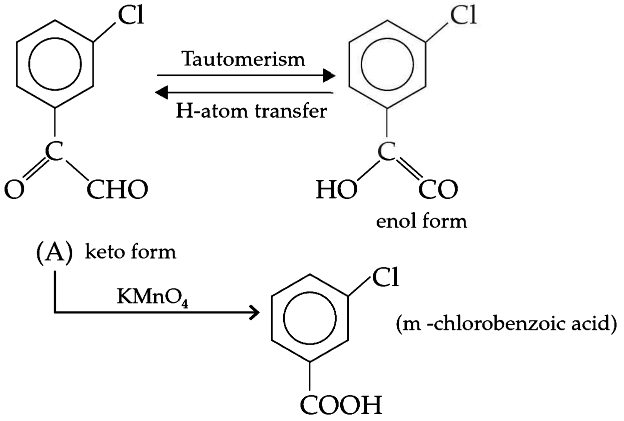




F and G donot give iodoform test because these donot contain $CH_3\overset{|}{C}=O$ group.

EXAMPLE 76. *A compound A of molecular formula $C_9H_7O_2Cl$ exists in ketoform and predominantly in enolic form 'B'. On oxidation with $KMnO_4$, A gives m-chlorobenzoic acid. Identify A and B.* **(IIT, 2003)**

SOLUTION. Keto form contains >C = O group, while enol form contains –OH group. So, the tautomeric forms of $C_9H_7O_2Cl$ can be written as :



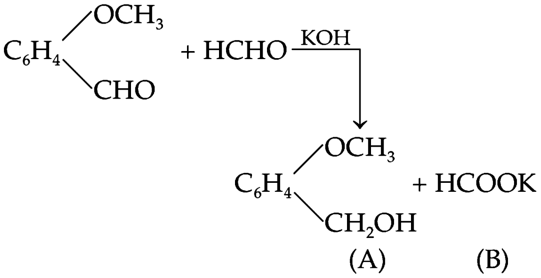
EXAMPLE 77. *Complete the following*

(*a*) 
$C_6H_4\left\langle\begin{matrix}OCH_3\\CHO\end{matrix}\right. + HCHO \xrightarrow{KOH} A + B$

(*b*) $C_6H_5\,CONH_2 \xrightarrow{P_2O_5} A \xrightarrow{H^+, H_2O, \Delta} B$

(*c*)  $+ (CH_3)_2CHCH_2Cl \xrightarrow{AlCl_3} A$ **(IIT, 1992)**

SOLUTION. (*a*)



(b) $C_6H_5CONH_2 \xrightarrow[-H_2O]{P_2O_5} C_6H_5CN \xrightarrow[\text{Hydrolysis}]{H^+, H_2O, \Delta}$

$C_6H_5COOH + NH_3$

(c) 
EXAMPLE 78. *Complete the following*

(*a*) 
(*b*) 
$B \xrightarrow[HCl,\ 0-5°C]{NaNO_2} C \xrightarrow{Cu_2Cl_2} D$

(*c*) $CH_3CH_2CH_2OH \xrightarrow{P + Br_2} A \xrightarrow{KOH(alc.)}$

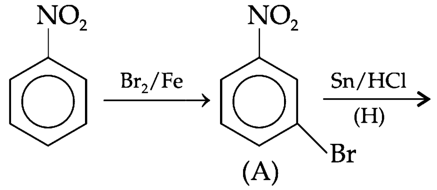
$B \xrightarrow{HBr} C \xrightarrow[\Delta]{NH_3(g)} D$

(*d*) $C_6H_5COOC_6H_5 \xrightarrow{\text{mononitration}} A$ **(IIT, 1993)**

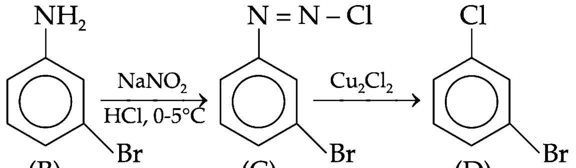
SOLUTION.

(*a*) 
So A = CH_3Cl, B =  ,

(C) = KCN, D = 
(*b*) NO_2, group is meta- directing. So,



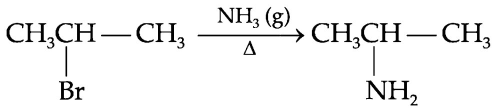
(A)



(B) (C) (D)

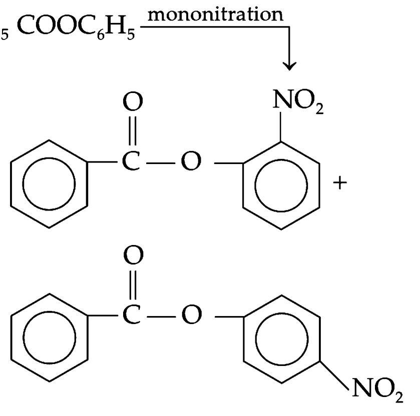
(*c*) $CH_3CH_2CH_2OH \xrightarrow{P + Br_2}$

$$\underset{(A)}{CH_3CH_2CH_2Br} \xrightarrow[-HBr]{Alc.\ KOH} \underset{(B)}{CH_3CH = CH_2} \xrightarrow[M.\ rule]{HBr}$$



$$\underset{(C)}{CH_3\underset{\underset{Br}{|}}{CH}—CH_3} \xrightarrow[\Delta]{NH_3\ (g)} \underset{(D)}{CH_3\underset{\underset{NH_2}{|}}{CH}—CH_3}$$

(*d*) $C_6H_5\ COOC_6H_5 \xrightarrow{mononitration}$



EXAMPLE 79. *Predict the major product in the following reactions.*

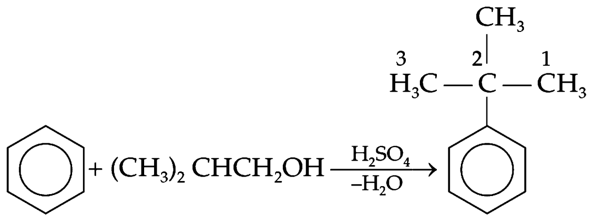
(*a*) $C_6H_6 + (CH_3)_2\ CHCH_2OH \xrightarrow{H_2SO_4}$

(*b*) $C_6H_5CH_2COOCH_3 \xrightarrow[2.\ 2H^+]{1.\ CH_3Mg\ Br\ (excess)}$

(*c*) $C_6H_5C_2H_5 \xrightarrow[2.\ NaCN]{1.\ Br_2,\ heat,\ light}$ **(ITT, 1994)**

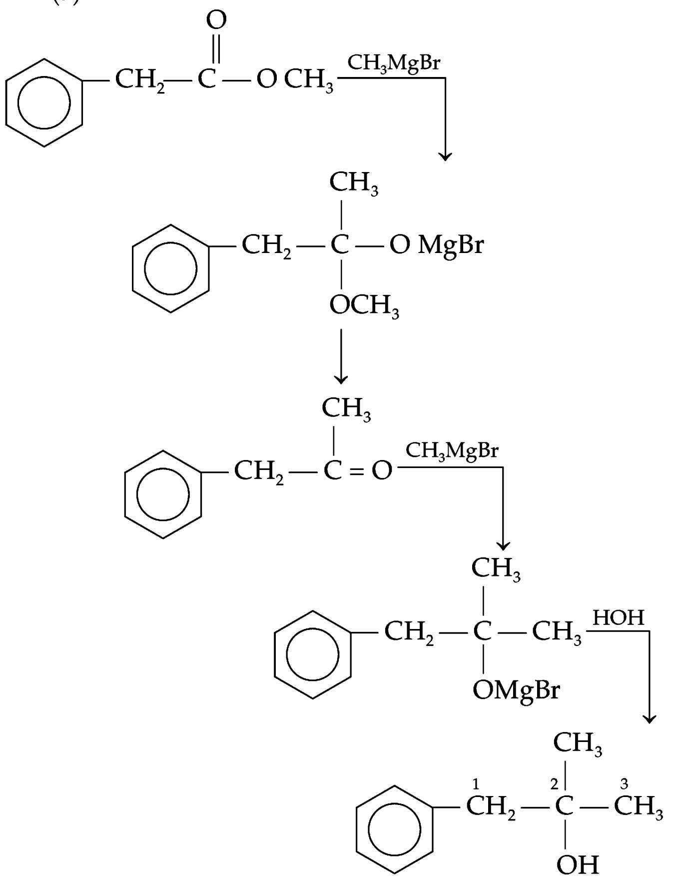
SOLUTION.

(*a*)



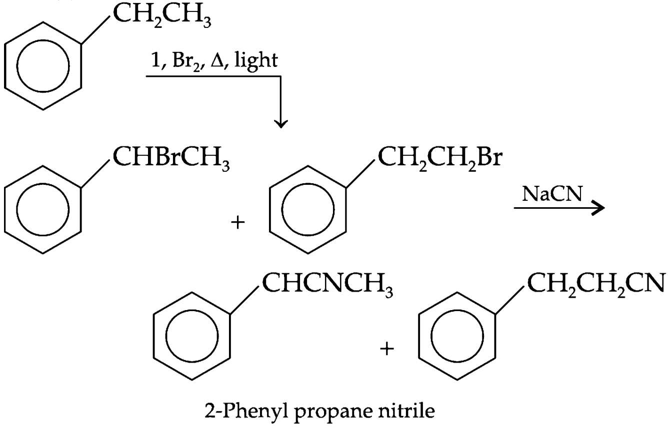
2 - Methyl-2-phenylpropane

(*b*)



(2-Methyl -1-phenyl - propan-2-ol.)

(*c*)



2-Phenyl propane nitrile

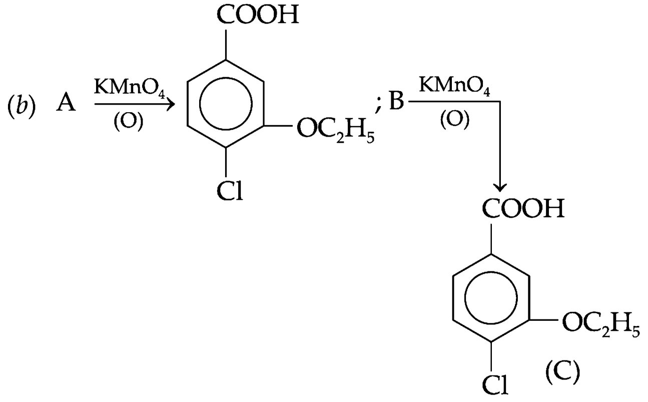
(Major) (Minor)

EXAMPLE 80. *Two isomeric compounds A and B have the same formula $C_{11}H_{13}OCl$. Both are unsaturated, yield the same compound (C) on catalytic hydrogenation and produce 4-chloro-*

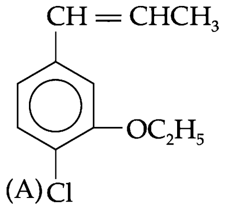
3-ethoxybenzoic acid on vigorous oxidation. (A) exists in geometrical isomers, (D) and (E) but not (B). Give structures of (A) to (E) with proper reasoning. **(Roorkee, 1994)**

SOLUTION. Both isomers A and B have the formula $C_{11}H_{13}OCl$ and are unsaturated. Hence :

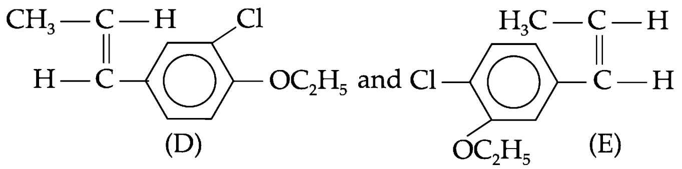
(*a*) $A \xrightarrow[\text{hydrogenation}]{\text{Catalytic}} C \; ; \quad B \xrightarrow[\text{hydrogenation}]{\text{Catalytic}} C$



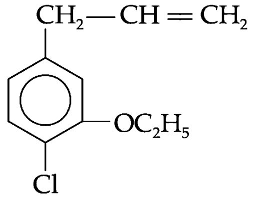
Since the side chain at carbon no. 1 is oxidised to —COOH, the compound (A) will be



which has following two isomers.



So, (B) will be simply



EXAMPLE 81. *Complete the following.*

$$CH_3CH_2COOH \xrightarrow{P + Br_2} A. \xrightarrow[2.\ H^+]{1.\ Alc.\ KOH\ (excess)} B$$

(IIT, 1995)

SOLUTION.

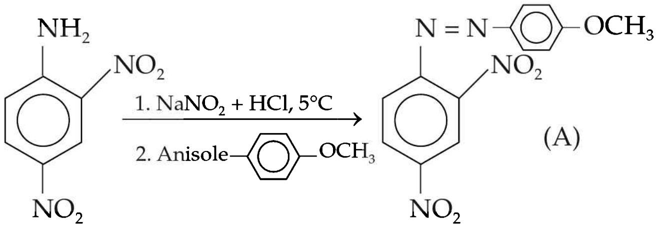
$$CH_3CH_2COOH \xrightarrow{P + Br_2} \underset{(A)}{CH_3CHBrCOBr} \xrightarrow[2.\ H^+]{1.\ KOH\ (alc)} \underset{(B)}{CH_2 = CH.COOH} + HBr$$

EXAMPLE 82. *Complete the following.*

$$2,\ 4\text{-}Dinitroaniline \xrightarrow[\text{at } 5°\ C,\ anisole]{NaNO_2 \text{ and } HCl} A$$

(IIT, 1995)

SOLUTION.



EXAMPLE 83. *Complete the following.*

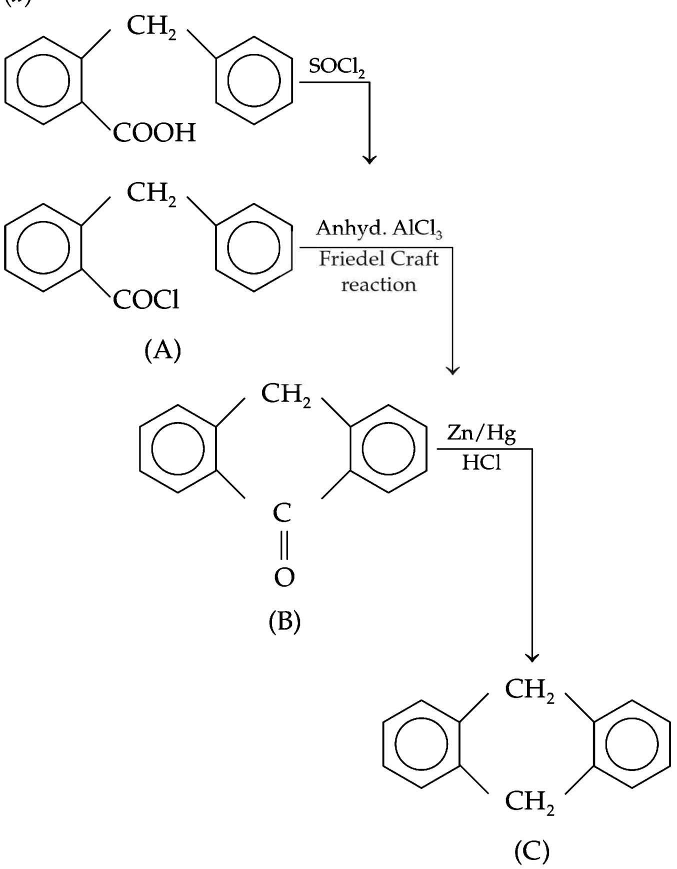
(*a*) $o - HOOC - C_6H_4 - CH_2 - C_6H_5 \xrightarrow{SOCl_2} A \xrightarrow{Anhyd.\ AlCl_3} B \xrightarrow[HCl]{Zn/Hg} C$

(*b*) $C_6H_5CHO + CH_3COOC_2H_5 \xrightarrow[C_2H_5OH \text{ and heat}]{NaOC_2H_5 \text{ in absolute}} A$

(ITT, 1995)

SOLUTION.

(*a*)

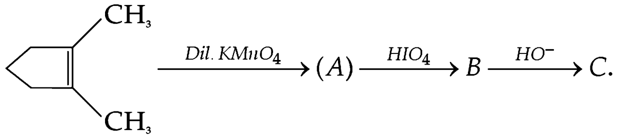


(*b*) $C_6H_5CHO + CH_3COOC_2H_5 \xrightarrow[C_2H_5OH \text{ and heat}]{NaOC_2H_5 \text{ in absolute}}$

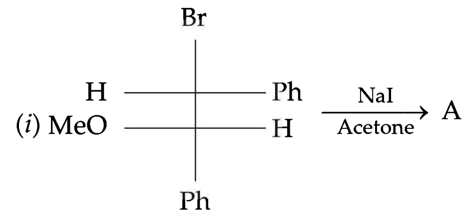
(Claisen condensation)

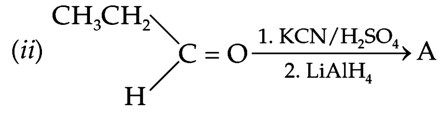
$$\underset{(A)}{C_6H_5CH = CHCOOC_2H_5}$$

EXAMPLE 84. (*a*) Suggest appropriate structures of the missing compounds. The number of carbon atoms remain same throughout the reactions



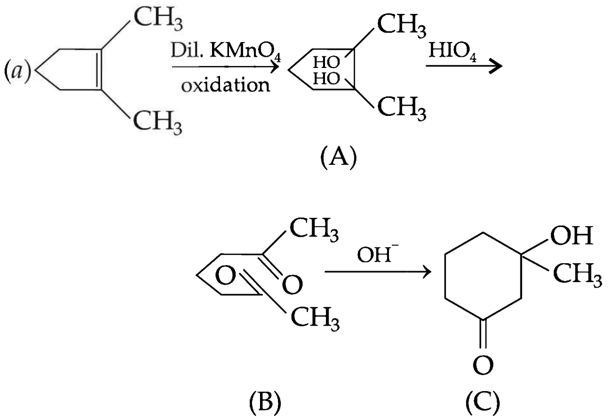
(*b*) Predict the structure of the product in the following reactions



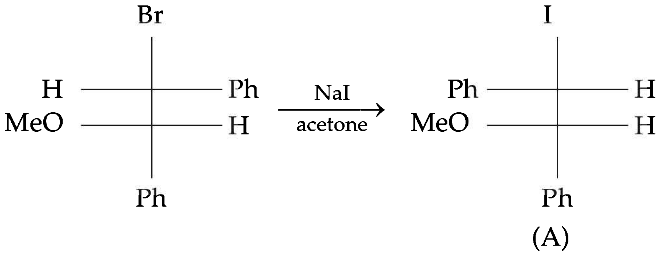


(ITT, 1996)

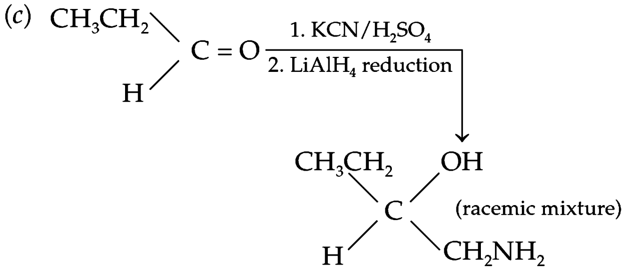
SOLUTION.



(*b*)



The product (A) is formed because enantiomer of original compound is formed involving SN^2 mechanism.

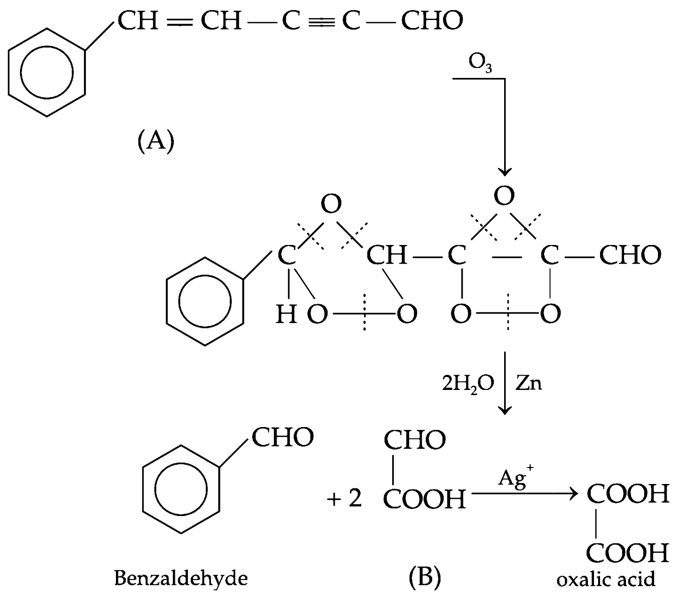


(A)

EXAMPLE 85. *An aldehyde (A) ($C_{11}H_8O$) which does not undergo self aldol condensation, gives benzaldehyde and two mol of (B) on ozonolysis. Compound (B), on oxidation with silver ion, gives oxalic acid. Identify the compounds A and B.*

(IIT, 1998)

SOLUTION. Since the compound does not undergo self aldol condensation, the compound will be $CH=CH—C\equiv C—CHO$ because it gives benzaldehyde on ozonolysis.

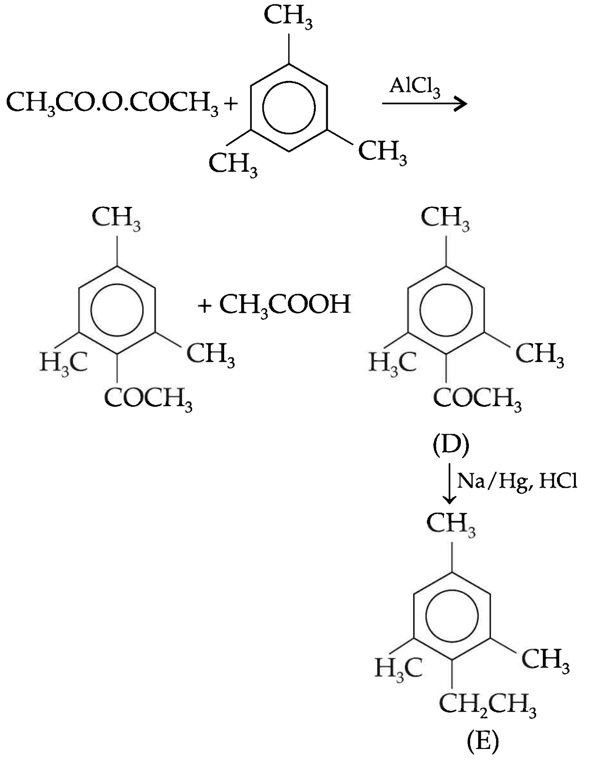


EXAMPLE 86. *An organic acid (A) on heating with $AlPO_4$ at 700°C forms (B). Compound (B) also reacts with (A) to give (C). Compound (C) on reaction with 1, 3, 5- trimethyl benzene in presence of $AlCl_3$ gives a ketone (D) and CH_3COOH. (D) on treatment with Na/Hg/HCl gives an aromatic hydrocarbon (E). Give structures of (A) to (E) with proper reasoning.*

(Roorkee, 1998)

SOLUTION. When an organic acid is heated with $AlPO_4$, a ketene is formed. Ketene reacts with organic acid to give a ketone. So, A is expected to be acetic acid.

$$\underset{(A)}{CH_3COOH} \xrightarrow{AlPO_4,\,700°C} \underset{\substack{(B)\\ \text{Ketene}}}{CH_2=C=O} \xrightarrow{CH_3COOH} \underset{(C)}{CH_3CO.O.COCH_3}$$

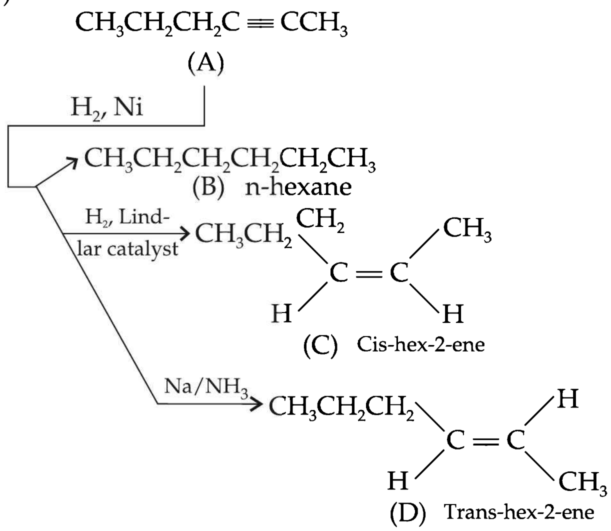


EXAMPLE 87. *Hydrocarbon (A), C_6H_{10} on treatment with H_2/Ni, H_2/Lindlar's catalyst and Na/liquid ammonia forms three different reduction products (B), (C) and (D) respectively. (A) does not form any salt with ammoniacal $AgNO_3$ solution but forms a salt (E) on heating with $NaNH_2$ in an inert solvent. Compound E reacts with CH_3I to give (F). Compound (D) on oxidative ozonolysis gives n-butanoic acid along with other product. Give structures of (A) to (F) with proper reasoning.*

(Roorkee, 1998)

SOLUTION. The formula C_6H_{10} corresponds to the general formula of an alkyne. Also, (A) does not form salt with ammoniacal $AgNO_3$. So, ≡ C does not contain ≡ CH. So, alkyne (A) is, $CH_3CH_2CH_2C \equiv CCH_3$. Its reactions will be:

(*i*)



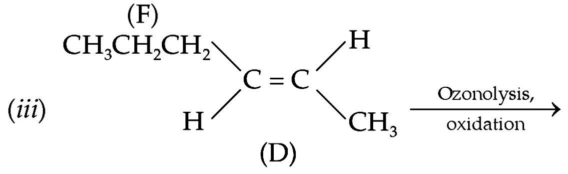
(*ii*) (A) gives (E) with $NaNH_2$ which *i.e.*, E reacts with CH_3I to form F. Thus :

$$CH_3CH_2CH_2C \equiv CCH_3 \xrightarrow[\Delta]{NaNH_2,}$$

$$CH_3CH_2CH_2CH_2C \equiv CNa \xrightarrow{CH_3I}$$

$$\underset{(F)}{CH_3CH_2CH_2CH_2C \equiv CCH_3}$$

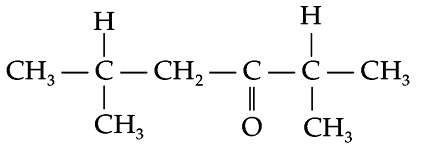
(*iii*)



$$\underset{n\text{-Butanoic acid}}{CH_3CH_2CH_2COOH} \quad + \quad \underset{\text{Ethanoic acid}}{CH_3COOH}$$

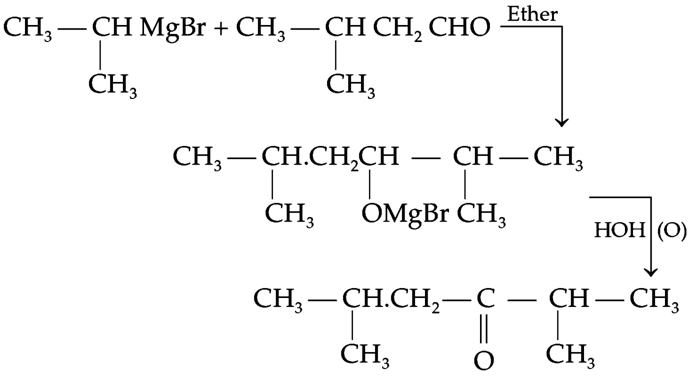
EXAMPLE 88. *Compounds (A) and (B) on reaction in ether medium and subsequent acidification and oxidation gave 2, 5-dimethyl-3-hexanone. What are (A) and (B).* **(Roorkee, 1998)**

SOLUTION. 2, 5-dimethyl-3-hexanone is



$$CH_3-\overset{H}{\underset{CH_3}{C}}-CH_2-\underset{O}{\overset{\|}{C}}-\overset{H}{\underset{CH_3}{C}}-CH_3$$

Since this compound is obtained from (A) and (B) compounds in ether medium and subsequent acidification and oxidation, (A) or (B) can be as follows :



2, 5 - Dimethyl -3-hexanone.

EXAMPLE 89. *A chlorocompound (A) showed the following properties.*

(*i*) *Decolorised bromine in CCl_4*
(*ii*) *Absorbed hydrogen catalytically*
(*iii*) *Gave a precipitate with ammoniacal cuprous chloride*
(*iv*) *When vaporised 1.49g of (A) gave 448 mL of vapours at STP. Identify (A) and write down the equations of reactions.* **(Roorkee, 1991)**

SOLUTION. (*i*) Mol. wt. of (A)

$$= \frac{\text{wt.}}{\text{volume at STP}} \times 22400$$

$$= \frac{1.49}{448} \times 22400 = \mathbf{74.5}$$

(*ii*) Since the compound decolorises Br_2 in CCl_4 and absorbs H_2 catalytically, it will be an unsaturated compound having double or triple bond.
Also, it gives a ppt. with ammoniacal Cu_2Cl_2. So, it will have a triple bond at the corner.

(*iii*) Since the compound has a ≡ CH at the corner, a Cl– atom, and mol. wt. 74.5, so, we have :

$$RCl\,C \equiv CH = 74.5$$

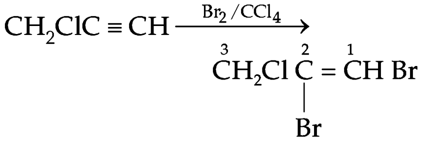
$$R + 35.5 + 12 + 12 + 1 = 74.5\,;$$

$$R + 60.5 = 74.5\,;\ R = 14 \text{ or R is } CH_2$$

∴ Compound is $\mathbf{CH_2Cl.\ C \equiv CH.}$

Reactions :

(*i*)



$$CH_2ClC \equiv CH \xrightarrow{Br_2/CCl_4} \overset{3}{C}H_2Cl\,\underset{Br}{\overset{2}{C}} = \overset{1}{C}H\,Br$$

1, 2 Dibromo-3-chloroprop-1-ene

(*ii*) $$CH_2ClC \equiv CH \xrightarrow{H_2} \overset{1}{C}H_2Cl\overset{2}{C}H_2 - \overset{3}{C}H_3$$

1-chloropropane

(*iii*) $$2CH_2ClC \equiv CH \xrightarrow[Cu_2Cl_2\ i.e.,\ Cu_2O]{\text{Ammoniacal}} 2CH_2ClC \equiv CCu + H_2O$$

Red ppt.

EXAMPLE 90. *A hydrocarbon (A) [C = 90.56%, vapour density = 53] was subjected to vigorous oxidation to give a dibasic acid (B). 0.10g of (B) required 24.1mL of 0.05 N NaOH for complete neutralisation. When (B) was heated strongly with sodalime, it gave benzene. Nitration of benzene gave a single* *mono nitroderivative. Identify (A) and (B) with proper reasoning and also give their structure.* **(Roorkee, 1991)**

SOLUTION. (*i*) To find empirical formula.

Element	At. wt.	% age	Relative no. of atoms = % age/at. wt.	Simple ratio	Whole no. ratio
C	12	90.56	$\frac{90.56}{12} = 7.55$	$\frac{7.55}{7.55} = 1$	1 × 4 = 4
H	1	100 – 90.56 = 9.44	$\frac{9.44}{1} = 9.44$	$\frac{9.44}{7.55} = 1.25$	1.25 × 4 = 5

$\therefore$ E.F. $= C_4H_5$;

E.F. wt. = (4 × 12) + (5 × 1) = 53

Given mol. wt. = 2 × V.D. = 2 × 53 = 106

$$\therefore \text{Molecular formula} = \frac{\text{Mol. wt.}}{\text{E.F. wt.}} \times \text{E.F.}$$

$$= \frac{106}{53} \times C_4H_5 = C_8H_{10}$$

(*ii*) 24.1mL of 0.05 N dibasic acid = 0.1 g

1000mL of 1N dibasic acid

$$= \frac{0.1}{24.1 \times 0.05} \times 1000 = 82.98 \simeq 83$$

$\therefore$ Eq. wt. of dibasic acid,

$R(COOH)_2 = 83$ Or Mol. wt. of

$R(COOH)_2 = 2 \times 83 = 166.$

$\therefore$ Mol. wt. of $R = 166 - 2(12 + 16 + 16 + 1) = 76$

Also, mol. wt. of $C_6H_4 = (6 \times 12) + (4 \times 1) = 76$

$\therefore R(COOH)_2 = C_6H_4\begin{smallmatrix}\diagup COOH\\ \diagdown COOH\end{smallmatrix}$ and hance

$(B) = C_6H_4\begin{smallmatrix}\diagup COOH\\ \diagdown COOH.\end{smallmatrix}$

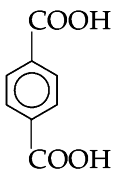
(*iii*) 
$$C_6H_4\begin{smallmatrix}\diagup COOH\\ \diagdown COOH.\end{smallmatrix} \xrightarrow{\text{Sodalime}} \underset{\text{Benzene}}{C_6H_6}$$

(B)

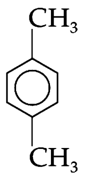
(*iv*) 
$$C_6H_4\begin{smallmatrix}\diagup CH_3\\ \diagdown CH_3\end{smallmatrix} \xrightarrow{(O)} C_6H_6\begin{smallmatrix}\diagup COOH\\ \diagdown COOH\end{smallmatrix}$$

(A) (B)

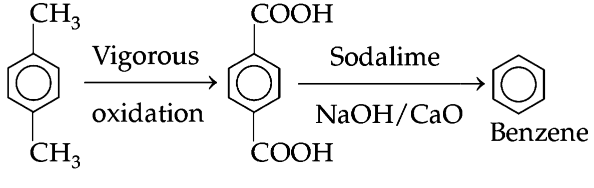
Since (B) shows mononitroderivative, so, (B) is



while (A) is



Reactions. (*v*)



(A) p-xylene **(B)** Terephthalic acid

(*v*) 
(B)

EXAMPLE 91. *An ester has molecular weight 102. On aqueous hydrolysis, it produces a monobasic acid and an alcohol. If 0.185g of the acid produced, completely neutralises 25mL of 0.1N NaOH, find out the structural formula of the produced alcohol, acid and the ester with proper reasoning.* **(Roorkee, 1990)**

SOLUTION. Mol. wt. of ester RCOOR′ = 102

Thus $R + 12 + 16 + 16 + R' = 102$;

$R + R' = 102 - 44 = 58$

$RCOOR' + HOH \longrightarrow R\,COOH + R'\,OH$

25mL of 0.1N or 0.1M NaOH neutralise acid

RCOOH = 0.185g

1000mL of 1M NaOH neutralise

$$RCOOH = \frac{0.185}{25 \times 0.1} \times 1000 = 74$$

$\therefore$ Mol. wt. of R in

$RCOOH = R + 12 + 16 + 16 + 1$;

$74 = R + 45$;

$\therefore R = 74 - 45 = 29$

But $R + R' = 58$; $29 + R' = 58$;

$R' = 58 - 29 = 29$

$\therefore R = R'$; $C_n H_{2n+1} = R = R' = 29$;

$12n + 1(2n + 1) = 29$;

$14n = 29 - 1 = 28$; $n = 2.$

Hence $R = R' = C_nH_{2n+1} = \mathbf{C_2H_5}$

$\therefore$ Ester $= C_2H_5COOC_2H_5$

Reaction :

$$C_2H_5COOC_2H_5 + HOH \longrightarrow \underset{\text{Propanoic acid}}{C_2H_5COOH} + \underset{\text{Ethanol}}{C_2H_5OH}$$

EXAMPLE 92. *An organic compound (A) of mol. wt. 140.5 has 68.32% C and 6.4% H and 25.26% Cl. Hydrolysis of (A) with dilute acid gives compound (B), $C_8H_{10}O$. Compound (B) can be oxidised under mild conditions to compound (C), C_8H_8O. Compound (C) forms a phenyl hydrazone (D) with $PhNHNH_2$ and gives positive iodoform test. Deduce the structures of (A) to (D) with proper reasoning.* **(Roorkee, 1990)**

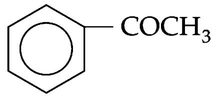
SOLUTION. (*i*) To Find empirical formula of (A)

Element	At. wt.	% age	Relative no. of atoms = % age/at. wt.	Simple ratio	Whole no. ratio
C	12	68.32	$\frac{68.32}{12} = 5.59$	$\frac{5.59}{0.71} \simeq 8$	8
H	1	6.4	$\frac{6.4}{1} = 6.4$	$\frac{6.4}{0.71} \simeq 9$	9
Cl	35.5	25.26	$\frac{25.26}{35.5} = 0.71$	$\frac{0.71}{0.71} = 1$	1

$$\begin{aligned}\therefore \quad \text{E.F.} &= C_8H_9Cl,\ \text{E.F. wt.}\\ &= (8 \times 12) + (9 \times 1) + (35.5 \times 1)\\ &= 140.5\\ \text{Given mol. wt.} &= 140.5\\ \therefore \text{Molecular formula} &= \frac{\text{Mol. wt.}}{\text{E.F. wt.}} \times \text{E.F.}\\ &= \frac{140.5}{140.5} \times C_8H_9Cl = C_8H_9Cl.\end{aligned}$$

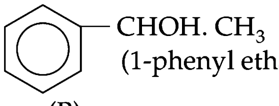
(*ii*) $\underset{\textbf{(A)}}{C_8H_9Cl} \xrightarrow{HOH} \underset{\textbf{(B)}}{C_8H_9OH} \xrightarrow{\text{Oxidation}} \underset{\textbf{(C)}}{C_8H_8O}$

Since (C) reacts with phenyl hydrazine, it will be a carbonyl compound. Since (C) gives a positive iodoform test, it will have $-CH_3CO$ group. Hence (C) is



(C) Acetophenone

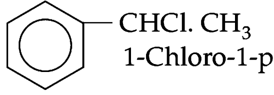
(*iii*) Since secondary alcohol >CHOH group on oxidation gives ketone >C = O, so (B) will be



(1-phenyl ethanol)

(B)

(*iv*) Since (B) is obtained by the hydrolysis of (A), so (A) will be

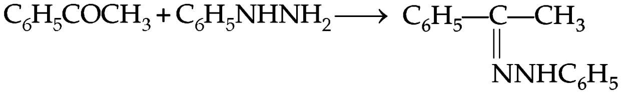


1-Chloro-1-phenyl ethanol.

(A)

Possible reactions.

$$\underset{(A)}{C_6H_5CHClCH_3} \xrightarrow[H^+]{H_2O,} \underset{(B)}{C_6H_5CHOH.CH_3} \xrightarrow{(O)} \underset{(C)}{C_6H_5COCH_3}$$



$$C_6H_5COCH_3 + C_6H_5NHNH_2 \longrightarrow C_6H_5-\underset{\underset{NNHC_6H_5}{\|}}{C}-CH_3$$

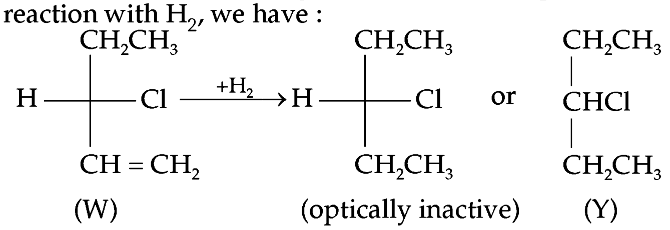
(Phenyl hydrazone)

$$C_6H_5COCH_3 + 4NaOH + 3I_2 \longrightarrow CHI_3 + C_6H_5COONa + 3NaI + 3H_2O$$

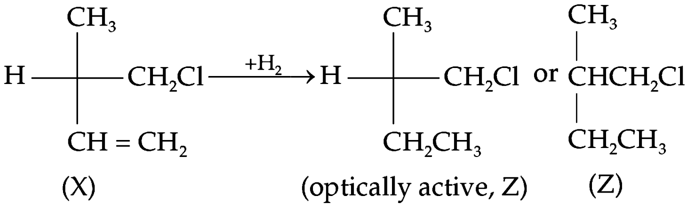
Iodoform (Yellow ppt.)

EXAMPLE 93. *(W) and (X) are optically active isomers of C_5H_9Cl. (W) on treatment with one mol of H_2 is converted to an optically inactive compound (Y), but (X) gives an optically active compound (Z) under the same conditions. Give structure of (Y) and configurations of (W), (X) and Z in Fischer projections.* **(Roorkee, 2000)**

SOLUTION. Under the given conditions in question for reaction with H_2, we have :



$$\underset{(W)}{H-\overset{\overset{CH_2CH_3}{|}}{\underset{\underset{CH=CH_2}{|}}{C}}-Cl} \xrightarrow{+H_2} \underset{\text{(optically inactive)}}{H-\overset{\overset{CH_2CH_3}{|}}{\underset{\underset{CH_2CH_3}{|}}{C}}-Cl} \text{ or } \underset{(Y)}{\overset{\overset{CH_2CH_3}{|}}{\underset{\underset{CH_2CH_3}{|}}{CHCl}}}$$



$$\underset{(X)}{H-\overset{\overset{CH_3}{|}}{\underset{\underset{CH=CH_2}{|}}{C}}-CH_2Cl} \xrightarrow{+H_2} \underset{\text{(optically active, Z)}}{H-\overset{\overset{CH_3}{|}}{\underset{\underset{CH_2CH_3}{|}}{C}}-CH_2Cl} \text{ or } \underset{(Z)}{\overset{\overset{CH_3}{|}}{\underset{\underset{CH_2CH_3}{|}}{CHCH_2Cl}}}$$

EXAMPLE 94. $(A) \xrightarrow[250°C]{Al_2O_3} B \xrightarrow[(ii)\ AgOH]{(i)\ HI} (C) \xrightarrow[150°C]{Al_2O_3,} (B) \xrightarrow[(ii)\ H_2O_2,\ OH^-]{(i)\ B_2H_6,} (A).$

In the above reactions, compounds (A) and (C) are isomers. (B) has a formula of C_5H_{10}, which can also be obtained from the product of the reactions of CH_3CH_2MgBr and $(CH_3)_2CO$. Give structures of (A), (B) and (C). **(Roorkee, 2000)**

SOLUTION. (B) is C_5H_{10}. So, the data suggests :

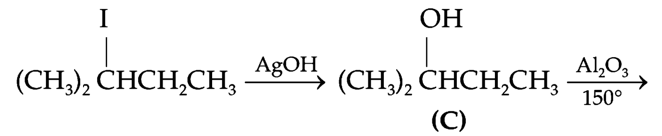
$$\underset{(A)}{C_5H_{11}OH} \xrightarrow[250°]{Al_2O_3} \underset{(B)}{\underset{(-H_2O)}{}\ C_5H_{10}} \xrightarrow[AgOH]{HI} \underset{(C)}{C_5H_{11}OH}$$

$$\xrightarrow[150°]{Al_2O_3,} \underset{(B)}{C_5H_{10}} \xrightarrow[H_2O_2,\ OH^-]{B_2H_6,} \underset{(A)}{C_5H_{11}OH}$$

$-H_2O$

The above reactions are possible if (A) is $(CH_3)_2 CH.CHOH.CH_3$. Thus :

(*i*) $(CH_3)_2\,CH.CHOH\,CH_3 \xrightarrow[250°]{Al_2O_3} \underset{\textbf{(B)}}{(CH_3)_2\,CH = CHCH_3} \xrightarrow{HI}$

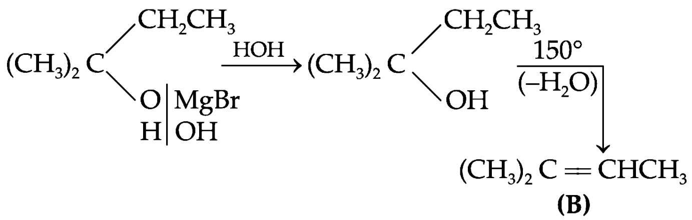


$$(CH_3)_2\overset{\overset{I}{|}}{C}HCH_2CH_3 \xrightarrow{AgOH} \underset{\textbf{(C)}}{(CH_3)_2\overset{\overset{OH}{|}}{C}HCH_2CH_3} \xrightarrow[150°]{Al_2O_3}$$

$$\underset{\textbf{(B)}}{(CH_3)_2\,CH = CHCH_3} \xrightarrow[OH]{B_2H_6,\ H_2O_2} \underset{\textbf{(A)}}{(CH_3)_2\,CHCHOHCH_3}$$

(*ii*)

$$(CH_3)_2\,C = O + CH_3CH_2MgBr \longrightarrow$$



EXAMPLE 95. *Give structures of (W). (X), (Y) and (Z) in the following reactions.*

$$H_2C = CH—CH_2OH \xrightarrow[(CH_2Cl_2)]{CrO_3.2C_5H_5N} (W)$$

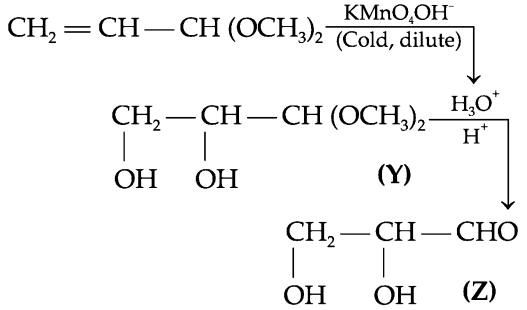
$$\xrightarrow{CH_3OH,\ H^+} (X)\ C_5H_{10}O_2 \xrightarrow[\text{Cold, dilute}]{KMnO_4,\ OH^-} (Y)\ C_5H_{12}O_4$$

$$\xrightarrow[H_2O]{H_3O^+,} (Z)\ C_3H_6O_3.$$

(Roorkee, 2000)

SOLUTION. $CH_2 = CH—CH_2OH \xrightarrow[(CH_2Cl_2)]{CrO_3.\ 2C_5H_5N}$

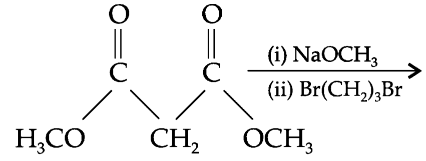
$$\underset{\textbf{(W)}}{CH_2 = CH\ CHO} \xrightarrow{CH_3OH,\ H^+}$$



$$CH_2{=}CH{-}CH(OCH_3)_2 \xrightarrow[\text{(Cold, dilute)}]{KMnO_4, OH^-} \underset{OH\quad OH}{CH_2{-}CH{-}CH(OCH_3)_2}\ (Y) \xrightarrow[H^+]{H_3O^+} \underset{OH\quad OH}{CH_2{-}CH{-}CHO}\ (Z)$$

EXAMPLE 96. What are (A) to (L) in the scheme of reactions given below ?

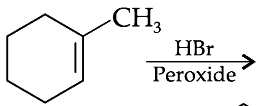
(*a*)



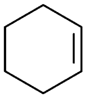
$(A) \xrightarrow{NaOCH_3} (B) \xrightarrow[\text{(ii) } H_3O^+]{\text{(i) NaOH}} (C) \xrightarrow{-CO_2}$

(D) (cycloalkane carboxylic acid)

(*b*)



(E); (c)



$\xrightarrow[(CH_2Cl_2)]{Br_2} (F) \xrightarrow[\text{Acetic acid}]{Zn}$

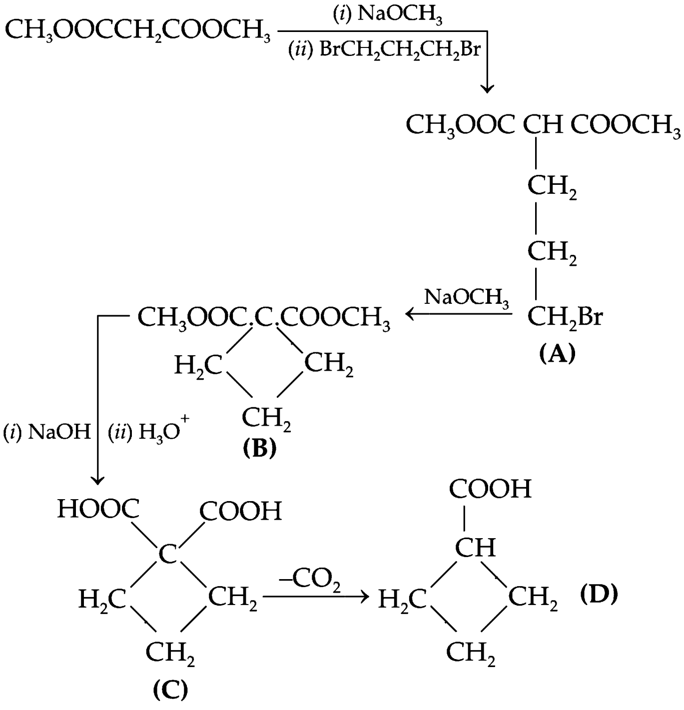
$(G)C_6H_{10} \xrightarrow[(ii)\ H_2O_2;OH^-]{(i)\ (Br_3)_2} (H)$

(*d*) $(J) \xleftarrow[H_2O]{HCrO_4} (I) \xrightarrow[\text{(Pyridine)}]{CrO_3} CH_3CHO$

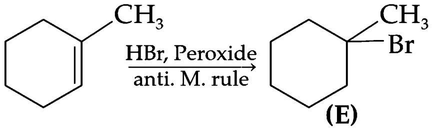
(*e*) Acetone (2 mol) $\xrightarrow{OH^-} (K) \xrightarrow[\textit{Heat}]{NaHSO_4} (L)$

(Roorkee, 2000)

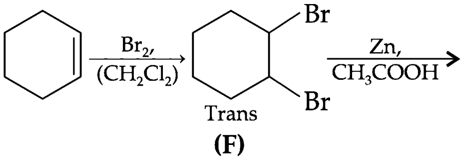
SOLUTION. (*a*)

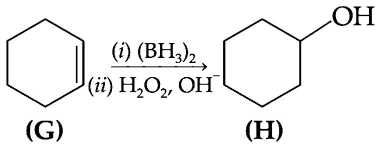


(*b*)



(*c*)





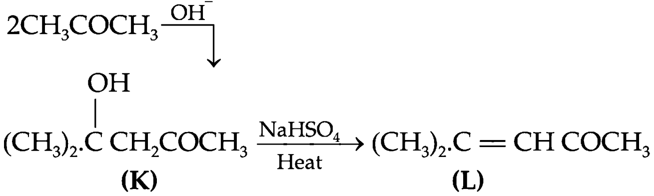
(*d*) $CH_3CH_2OH \xrightarrow[H_2O]{HCrO_4} CH_3COOH$

(I) (J)

$\downarrow CrO_3$, pyridine

CH_3CHO

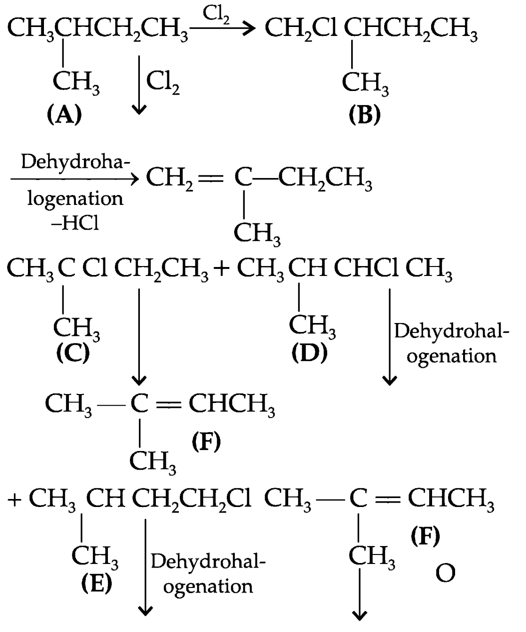
(*e*)



$$2CH_3COCH_3 \xrightarrow{OH^-} (CH_3)_2.\overset{OH}{C}\,CH_2COCH_3\ (K) \xrightarrow[\text{Heat}]{NaHSO_4} (CH_3)_2.C = CH\,COCH_3\ (L)$$

EXAMPLE 97. *An alkane (A), C_5H_{12} on chlorination at 300°C gives a mixture of four different monochlorinated derivatives, (B), (C), (D) and (E). Two of these derivatives give the same stable alkene (F) on dehydrohalogenation. On oxidation with hot alkaline $KMnO_4$, followed by acidification, (F) gives two products (G) and (H). Give the structures of (A) to (H) with proper reasoning.* **(Roorkee, 1995)**

SOLUTION. Alkane C_5H_{12} gives four different monochloroderivatives. So, alkane will be a branched chain alkane. So, it will be isopentane,



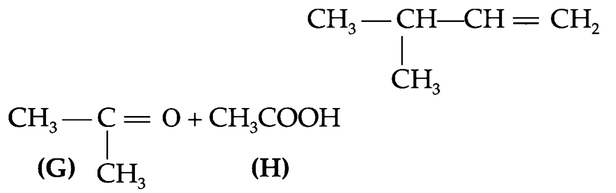
$$\underset{CH_3}{CH_3CHCH_2CH_3}\ (A) \xrightarrow{Cl_2} \underset{CH_3}{CH_2Cl\,CHCH_2CH_3}\ (B) \xrightarrow[\text{logenation } -HCl]{\text{Dehydroha-}} \underset{CH_3}{CH_2{=}C{-}CH_2CH_3}$$

$$\downarrow Cl_2$$

$$\underset{CH_3}{CH_3C\,Cl\,CH_2CH_3}\ (C) + \underset{CH_3}{CH_3CH\,CHCl\,CH_3}\ (D) \xrightarrow{\text{Dehydrohalogenation}}$$

$$\underset{CH_3}{CH_3{-}C{=}CHCH_3}\ (F)$$

$$+ \underset{CH_3}{CH_3\,CH\,CH_2CH_2Cl}\ (E) \xrightarrow{\text{Dehydrohalogenation}} \quad \underset{CH_3}{CH_3{-}C{=}CHCH_3}\ (F) \quad O$$



$CH_3—CH—CH = CH_2$ (CH_3 on CH)

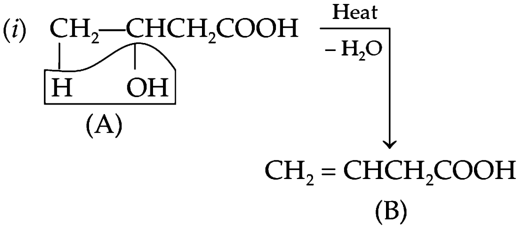
$CH_3—C = O + CH_3COOH$ (CH_3 on C)

(G) **(H)**

Example 98. *An acidic compound (A),$C_4H_8O_3$ loses its optical activity on strong heating yielding (B), $C_4H_6O_2$ which reacts readily with $KMnO_4$. (B) forms a derivative (C) with $SOCl_2$ which on reaction with $(CH_3)_2$ NH gives (D). The compound (A) on oxidation with dilute chromic acid gives an unstable compound (E) which decarboxylates readily to give (F), C_3H_6O. The compound (F) gives a hydrocarbon (G) on treatment with amalgamated Zn and HCl. Give structures of (A) to (G) with proper reasoning.* **(Roorkee, 1995)**

Solution. Since (A) *i.e.*, $C_4H_8O_3$ loses its optical activity on strong heating to give B *i.e.*, $C_4H_6O_2$, (A) is expected to be $CH_3CHOHCH_2COOH$ or $CH_3CH_2CHOHCOOH$. Also, since (B) is $C_4H_6O_2$ (formed) by loss of H_2O, (A) is β-hydroxy acid *i.e.*, $CH_3CHOH\ CH_2COOH$. It cannot be α-hydroxy acid because only β-hydroxy acid loses water on strong heating. Thus :

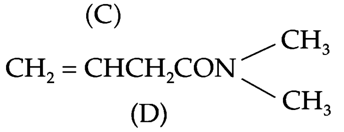
(*i*)



(*ii*) $CH_2 = CHCH_2COOH \xrightarrow{SOCl_2}$

$CH_2 = CHCH_2COCl \xrightarrow{(CH_3)_2NH}$

(C)



$CH_2 = CHCH_2CON(CH_3)_2$

(D)

(*iii*) $CH_3CHOHCH_2COOH \xrightarrow{[O]}$

(A)

$CH_3COCH_2COOH \xrightarrow[(-\ CO_2)]{\text{Decarboxylation}} CH_3COCH_3$

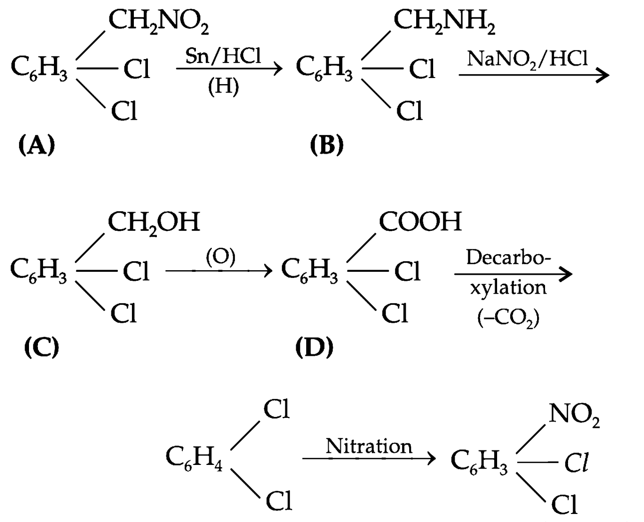
(E) **(F)**

$\xrightarrow[\text{Reduction}]{Zn/HCl} CH_3CH_2CH_3$

n-Propane, **(G)**

Example 99. *An aromatic compound (A), $C_7H_5NO_2Cl_2$ on reduction with Sn/HCl gives (B) which on reaction with $NaNO_2$/HCl gives (C). Compound (B) does not form a dye with β-naphthol. However, (C) gives red colour with ceric ammonium nitrate and on oxidation gives an acid (D) of equivalent weight 191. Decarboxylation of (D) gives (E) which forms a single mononitroderivative, (F) on nitration. Give structures of (A) to (F) with proper reasoning.* **(Roorkee, 1995)**

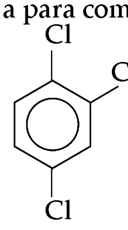
Solution. (A) contains NO_2 group which on reduction gives NH_2 group. The latter changes to OH with $NaNO_2$/ HCl. Thus, the data suggests :



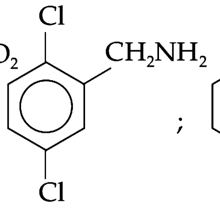
i.e., One product only.

(E) **(F)**

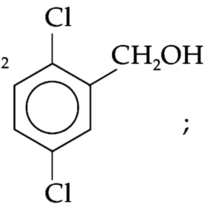
Since the compound (F) is only one product, so (E) will be a para compound. Hence :



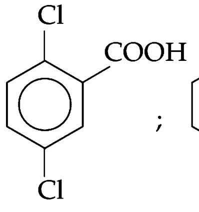
(A)



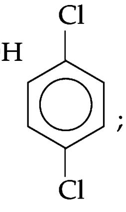
(B)



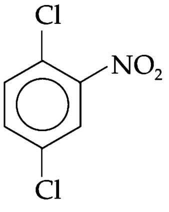
(C)



(D)



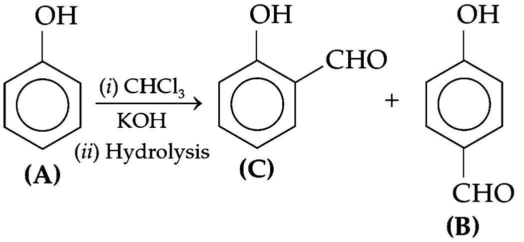
(E)



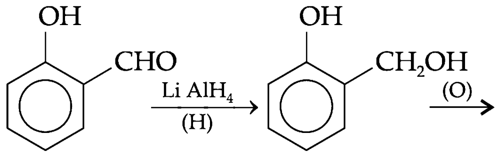
(F)

Example 100. *An organic compound (A) gives positive Libermann reaction and on treatment with $CHCl_3$/KOH followed by hydrolysis gives (B) and (C). Compound (B) gives colour with Schiff's reagent but not (C) which is steam volatile. (C) on treatment with $LiAlH_4$ gives (D) $C_7H_8O_2$ which on oxidation gives (E). Compound (E) reacts with $(CH_3CO)_2O/CH_3COOH$ to give a pain reliever (F). Give structures of (A) to (F) with proper reasoning.* **(Roorkee, 1995)**

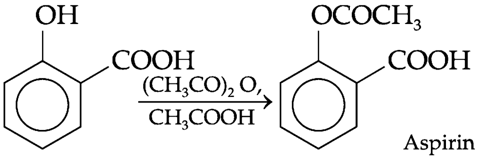
Solution. (*i*) Since (A) gives Libermann as well as Riemer-Tiemann reaction ($CHCl_3$/KOH), it can be a phenol. So:



(*ii*) (C) is steam volatile and does not reduce Schiff's reagent due to intramolecular hydrogen bonding. The reactions of (C) as given in data are:



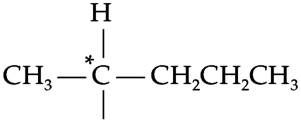
(C) **(D)**



(E) **(F)** Aspirin (a pain reliever)

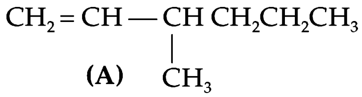
EXAMPLE 101. *There are six different alkenes (A), (B), (C), (D), (E) and (F). Each on addition of one mol of hydrogen gives (G) which is the lowest molecular weight hydrocarbon containing only one asymmetric carbon atom. None of the alkenes give acetone as a product on ozonolysis. Give structures of (A) to (F). Identify the alkene which is likely to give a ketone containing more than five carbon atoms on-treatment with a warm concentrated solution of alkaline $KMnO_4$. Show various configurations of (G) in Fischer projections.* **(Roorkee, 1992)**

SOLUTION. (*i*) An alkene on the addition of one mol of H_2 gives (G) which has lowest mol. wt. and contains one asymmetric carbon atom. So, it should be 3-methyl hexane which has one asymmetric C*-atom



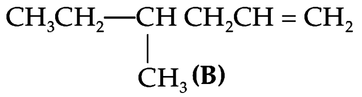
$$CH_3-\underset{\underset{\displaystyle CH_2CH_3}{|}}{\overset{\overset{\displaystyle H}{|}}{\overset{*}{C}}}-CH_2CH_2CH_3$$

(G). Six different alkenes from this compound will be the following which donot give acetone on ozonolysis.



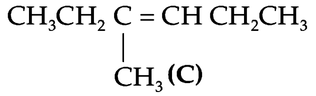
$$CH_2=CH-\underset{\underset{\displaystyle CH_3}{|}}{CH}\,CH_2CH_2CH_3$$

(A) 3-Methyl hex-1-ene



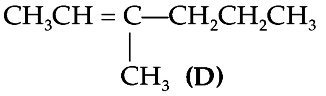
$$CH_3CH_2-\underset{\underset{\displaystyle CH_3}{|}}{CH}\,CH_2CH=CH_2$$

(B) 4-Methyl hex-1-ene



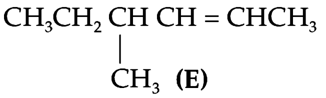
$$CH_3CH_2\,\underset{\underset{\displaystyle CH_3}{|}}{C}=CH\,CH_2CH_3$$

(C) 3-Methyl hex-3-ene



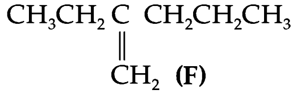
$$CH_3CH=\underset{\underset{\displaystyle CH_3}{|}}{C}-CH_2CH_2CH_3$$

(D) 3-Methyl hex-2-ene



$$CH_3CH_2\,\underset{\underset{\displaystyle CH_3}{|}}{CH}\,CH=CHCH_3$$

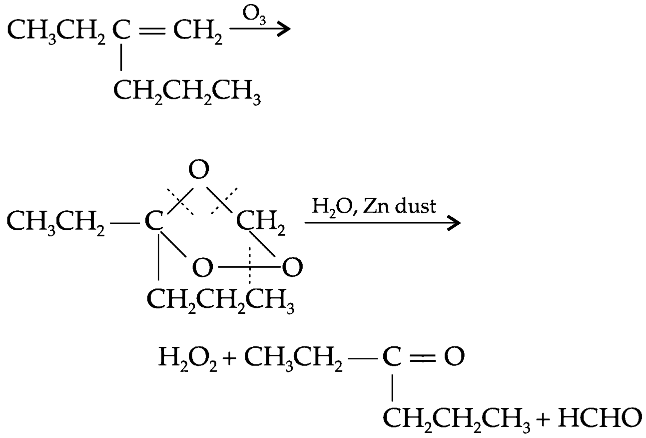
(E) 4-Methyl hex-2-ene



$$CH_3CH_2\,\underset{\underset{\displaystyle CH_2}{\|}}{C}\,CH_2CH_2CH_3$$

(F) 2-Ethyl pent-1-ene

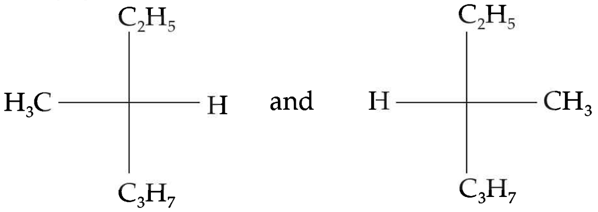
(*ii*) Alkene (F) on ozonolysis gives ketone with more than five C-atoms as shown below:



$$CH_3CH_2\,\underset{\underset{\displaystyle CH_2CH_2CH_3}{|}}{C}=CH_2\xrightarrow{O_3}$$

$$H_2O_2+CH_3CH_2-\underset{\underset{\displaystyle CH_2CH_2CH_3}{|}}{C}=O+HCHO$$

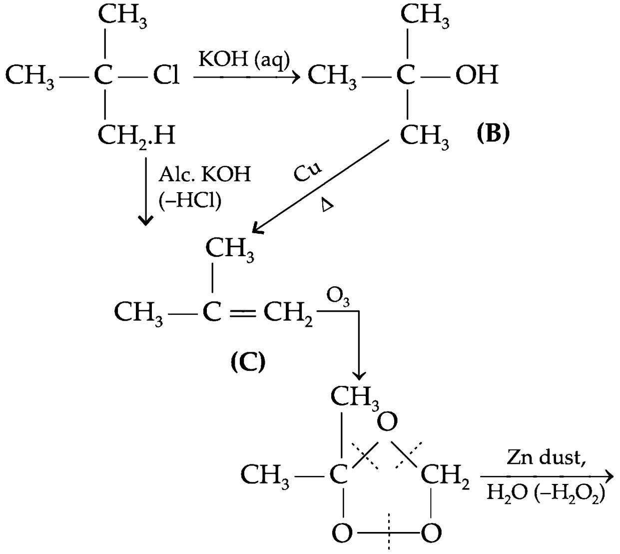
Various configurations of (G) in Fischer projections are :

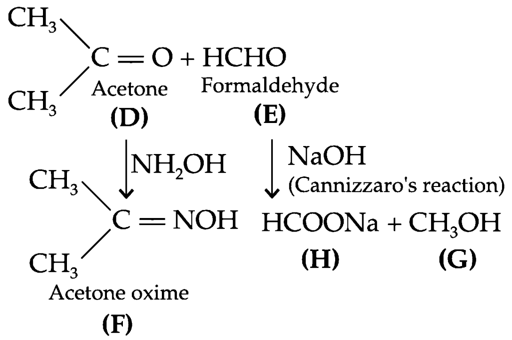


EXAMPLE 102. *An organic compound (A), C_4H_9Cl on reacting with aqueous KOH gives (B) and on reaction with alcoholic KOH gives (C) which is also formed on passing the vapours of (B) over heated copper. The compound (C) readily decolorises bromine water. Ozonolysis of (C) gives two compounds (D) and (E). Compound (D) reacts with NH_2OH to give (F) and the compound (E) reacts with NaOH to give an alcohol (G) and sodium salt (H) of an acid. (D) can also be prepared from propyne on treatment with water in presence of Hg^{2+} and H_2SO_4. Identify (A) to (H) with proper reasoning.* **(Roorkee, 1996)**

SOLUTION. Aqueous KOH forms an alcohol while alc. KOH on dehydrohalogenation forms an alkene. Such an alkene is also formed on passing vapours over heated copper. So, C_4H_9Cl is $(CH_3)_3CCl$.

Thus ; (**A**) = $(CH_3)_3$ CCl,





Note: Since (E) undergoes Cannizzaro's reaction, so (D) and (E) are formed from ozonolysis.

Formation of (D) from propyne:

$$CH_3{-}C\equiv CH \xrightarrow[H_2O]{Hg^{2+},\, H_2SO_4,} \underset{(D)}{CH_3COCH_3}$$

Example 103. *An aliphatic hydrocarbon A on treatment with sulphuric acid in the presence of $HgSO_4$ yields a liquid B with molecular formula C_2H_4O. B on oxidation with acidified potassium dichronate yields C which gives effervescence with sodium bicarbonate. C when treated with $SOCl_2$ gives D. WHen D reacts with ethanol, it gives a sweet smelling liquid E. E is also formed when C reacts with ethanol in presence of Conc. H_2SO_4. Identify A, B, C, D and E.* **(ISC, 2012)**

Solution. (*a*) C_2H_4O appears to be CH_3CHO (acetaldehyde) which is a liquid. It is formed from acetylene, $HC\equiv CH$:

$$HC{\equiv}CH + H_2O \xrightarrow[H_2SO_4]{HgSO_4} CH_2 = CHOH \xrightarrow[\text{ment}]{\text{Rearrange-}} CH_3CHO$$

So, A is acetylene and B is acetaldehyde.

(*b*) Since C gives effervescence with $NaHCO_3$, it appears to be an acid. So:

$$\underset{(B)}{CH_3CHO} \xrightarrow[K_2Cr_2O_7,\, H^+]{[O]} \underset{(C)}{CH_3COOH}$$

So, C is acetic acid.

(*c*) $$\underset{(C)}{CH_3COOH} + SOCl_2 \longrightarrow \underset{(D)}{CH_3COCl} + SO_2 + HCl$$

$$CH_3COCl + C_2H_5OH \longrightarrow \underset{\text{Ethyl acetate (ester) (E)}}{CH_3COOC_2H_5} + HCl$$

D will be CH_3COCl (acetyl chloride) because it gives an ester E which is a sweet smelling liquid.

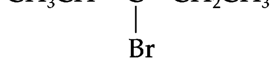
(*d*) $$\underset{(C)}{CH_3COOH} + C_2H_5OH \longrightarrow \underset{(E)}{CH_3COOC_2H_5} + H_2O$$

So, A = Acetylene; B = Acetaldahyde; C = Acetic acid; D = Acetyl Chloride; E = Ethyl acetate.

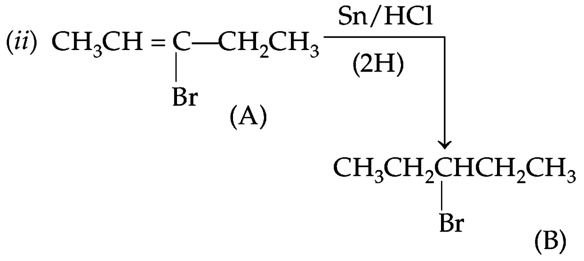
Example 104. *An organic compound (A), C_5H_9Br which readily decolorises bromine water and $KMnO_4$ solution, gives (B), $C_5H_{11}Br$ on treatment with Sn/HCl. The reaction of (A) with $NaNH_2$ produces (C), with evolution of ammonia. (C) neither reacts with sodium nor forms any metal acetylide but reacts with Lindlar's catalysts to give (D) and on reaction with Na/NH_3(liq.) produces (E). Both the compounds (D) and (E) are isomeric. Give structures of (A) to (E) with proper reasoning.*

(Roorkee, 1997)

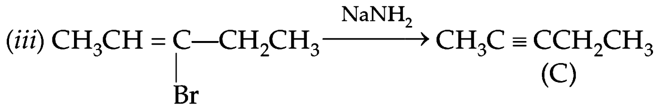
Solution. (*i*) Decolorisation of Br_2 water and $KMnO_4$ indicates unsaturation in C_5H_9Br. So, (A) can be



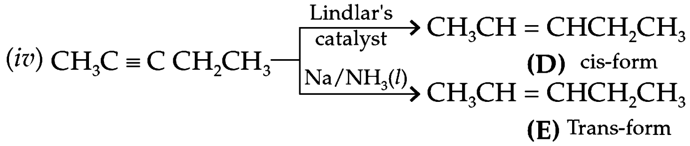
$$CH_3CH = \underset{Br}{\underset{|}{C}}{-}CH_2CH_3$$



(*ii*) $$\underset{(A)}{CH_3CH = \underset{Br}{\underset{|}{C}}{-}CH_2CH_3} \xrightarrow[(2H)]{Sn/HCl} \underset{(B)}{CH_3CH_2\underset{Br}{\underset{|}{C}}HCH_2CH_3}$$



(*iii*) $$CH_3CH = \underset{Br}{\underset{|}{C}}{-}CH_2CH_3 \xrightarrow{NaNH_2} \underset{(C)}{CH_3C\equiv CCH_2CH_3}$$



(*iv*) $$CH_3C\equiv C\,CH_2CH_3 \begin{cases} \xrightarrow{\text{Lindlar's catalyst}} \underset{\text{(D) cis-form}}{CH_3CH = CHCH_2CH_3} \\ \xrightarrow{Na/NH_3(l)} \underset{\text{(E) Trans-form}}{CH_3CH = CHCH_2CH_3} \end{cases}$$

(D) and (E) are geometrical isomers

The compound (C) is not a terminal alkyne. So, it will neither react with Na nor it will form metal acetylide.

Example 105. *Dehydrobromination of compounds (A) and (B) yield the same alkene (C). Alkene (C) can regenerate (A) and (B) by the addition of HBr in the presence and absence of peroxide respectively. Hydrolysis of (A) and (B) give isomeric products, (D) and (E) respectively. 1,1-diphenyl ethane is obtained on reaction of (C) with benzene in presence of H^+. Give structures of (A) to (E) with reasons.* **(Roorkee, 1997)**

Solution. (*i*) Dehydrobromination suggests that (*A*) and (*B*) should be bromoderivatives of an alkane which on reaction with alc. KOH undergo dehydrobromination. So, expected compounds having a phenyl group will be (*A*) = $C_6H_5CH_2CH_2$ Br and (B) = $C_6H_5CHBrCH_3$, Thus :

(*ii*) $$\underset{(A)}{C_6H_5CH_2Br} \xrightarrow[-HBr]{\text{Alc. KOH}}$$

$$\underset{(C)}{C_6H_5CH = CH_2} \xrightarrow[\substack{\text{Peroxide} \\ \text{(anti M.Rule)}}]{+\,HBr}$$

$$\underset{(A)}{C_6H_5CH_2CH_2Br} \xrightarrow{HOH} \underset{(D)}{C_6H_5CH_2CH_2OH}$$

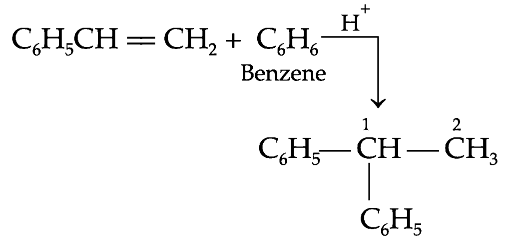
(*iii*) $C_6H_5CHBrCH_3 \xrightarrow[-HBr]{\text{Alc. KOH}}$

$\underset{(C)}{C_6H_5CH = CH_2} \xrightarrow[\text{M. Rule}]{HBr}$

$\underset{(B)}{C_6H_5CHBrCH_3} \xrightarrow{HOH} \underset{(E)}{C_6H_5CH(OH)CH_3}$

From above, we see that (*D*) and (*E*) are isomeric alcohols

(*iv*)



$C_6H_5CH = CH_2 + \underset{\text{Benzene}}{C_6H_6} \xrightarrow{H^+} C_6H_5-\overset{1}{C}H(C_6H_5)-\overset{2}{C}H_3$

1, 1- Diphenyl ethane

EXAMPLE 106. *An organic acid (A), $C_5H_{10}O_2$ reacts with Br_2 in the presence of phosphorus to give (B). Compound (B) contains an asymmetric carbon atom and yields (C) on dehydrobromination. Compound (C) does not show geometrical isomerism and on decarboxylation gives an alkene (D) which on ozonolysis gives (E) and (F). Compound (E) gives a positive Schiff's test but F does not. Give structures of (A) to (F) with reasons.*

(Roorkee, 1997)

SOLUTION. Since (*A*) reacts with $Br_2 + P_4$ *i.e.*, it gives Hell Volhard Zelinsky reaction, so acid (*A*) will be *R* CH_2COOH.

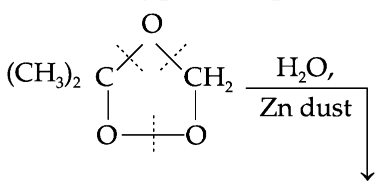
(*i*) $\underset{(\mathbf{A})}{R\,CH_2COOH} \xrightarrow{Br_2 + P_4} \underset{(\mathbf{B})}{R\,\overset{*}{C}HBr\,COOH}$ where $R = C_3H_7$ and C^* is asymmetric *C*– atom.

(*ii*) $\underset{(C)}{R\,CHBr\,COOH} \xrightarrow{-HBr} (C).$

Since (C) has not geometrical isomers, so (C) can be $\underset{(C)}{(CH_3)_2C = CHCOOH}$.

(*iii*) $(CH_3)_2C = CHCOOH \xrightarrow[\text{boxylation}(-CO_2)]{\text{Decar-}} \underset{\mathbf{(D)}}{(CH_3)_2C = CH_2}$

(*iv*) $(CH_3)_2C = CH_2 \xrightarrow{\text{Ozonolysis}}$



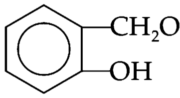
$(CH_3)_2CO \quad + \quad HCHO$

Acetone, (F) negative test with Schiff's reagent	(E) positive test with Schiff's reagent.

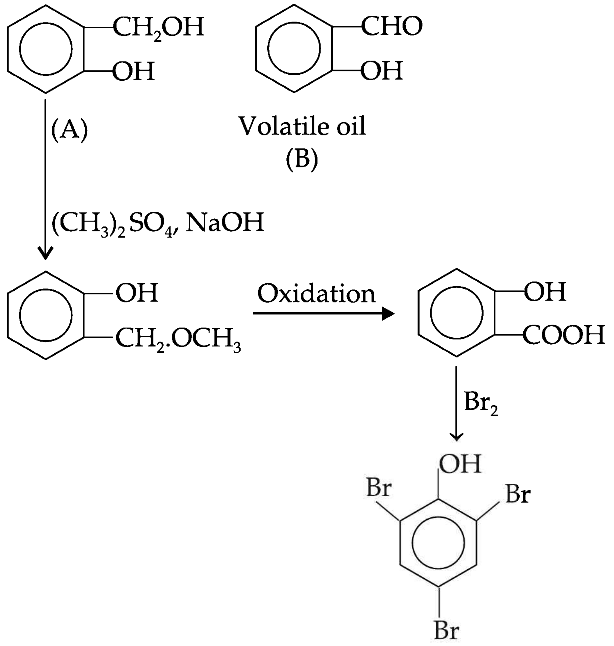
Thus, (C) is $(CH_3)_2C = CH.COOH$.

EXAMPLE 107. *A phenolic compound (A), $C_7H_8O_2$ on mild oxidation gives a highly volatile oil (B). (A) forms (C) on reaction with dimethylsulphate in alkali. Oxidation of (C) with hot $KMnO_4$ gives (D) which then reacts with bromine water to give (E) containing about 72% bromine. Give structures of (A) to (E) with proper reasoning.* **(Roorkee, 1997)**

SOLUTION. Compound (A), $C_7H_8O_2$ with phenolic group –OH is



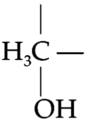
. Writing reactions as required in question, we have :

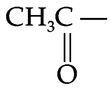


72% bromine in this (E) compound

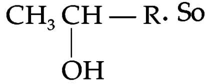
EXAMPLE 108. *Compound (A) $C_{12}H_{12}O$ gives off hydrogen on treatment with sodium metal and also decolorises Br_2 in CCl_4 to give (B), $C_{10}H_{12}OBr_2$. (A) on treatment with I_2 in NaOH gives iodoform and acid (C) after acidification. Give structures of (A) to (C) and also of all the geometrical and optical isomers of (A).*

(Roorkee, 1997)

SOLUTION. (*a*) We know iodoform test is given by compounds having


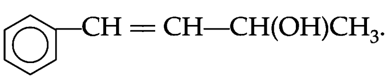
$CH_3\underset{OH}{C}-$ group,


$CH_3\underset{O}{\overset{\|}{C}}-$ etc groups.

So (A) should have the structure,


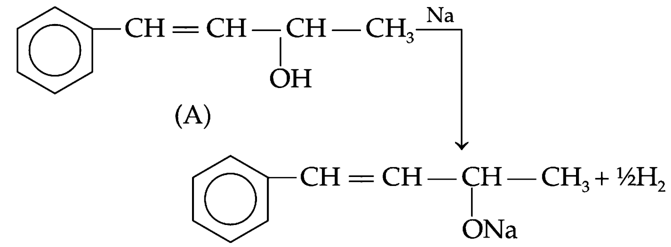
$CH_3\underset{OH}{CH}-R$. So, (A)

$C_{12}H_{12}O$ is expected to be :

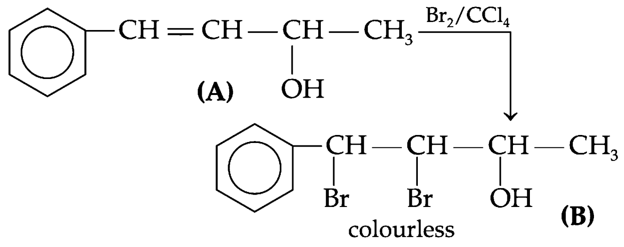


The double bonds indicate the decoloration of Br_2/CCl_4 solution because of unsaturation. – OH group indicates evolution of H_2 with Na-metal. So, reactions involved will be :

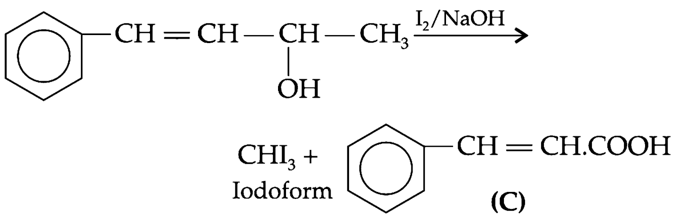
(*i*)



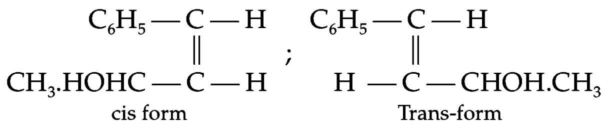
(*ii*)



(*iii*)

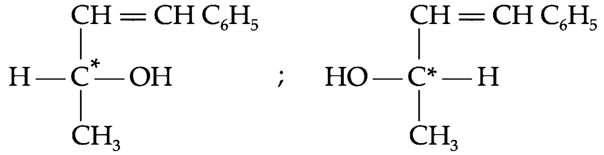


(*b*) **Geometrical isomers** of (A) are cis and trans as shown below.



$$\begin{array}{c} C_6H_5—C—H \\ \| \\ CH_3.HOHC—C—H \\ \text{cis form} \end{array} \quad ; \quad \begin{array}{c} C_6H_5—C—H \\ \| \\ H—C—CHOH.CH_3 \\ \text{Trans-form} \end{array}$$

(*c*) Optical isomers of (A) are :



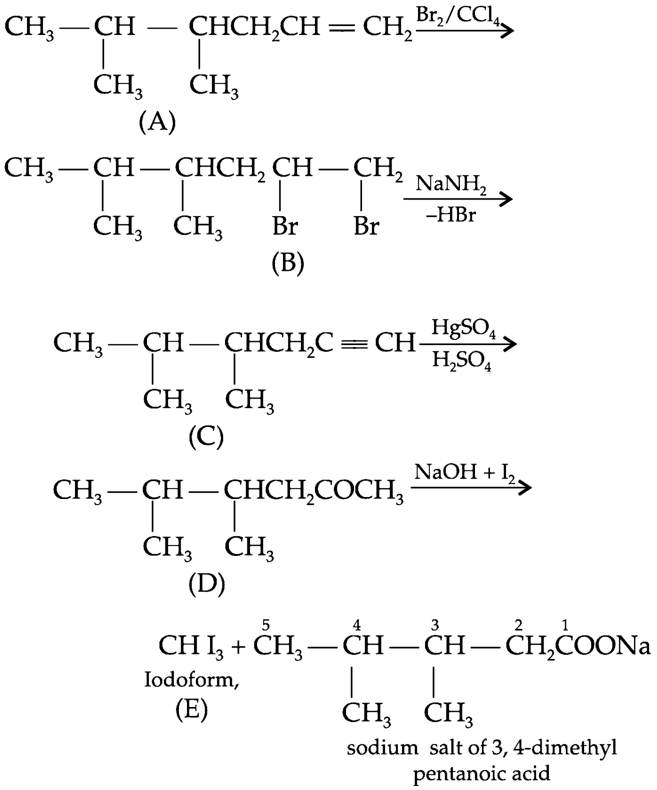
$$\begin{array}{c} CH=CH\,C_6H_5 \\ | \\ H—C^*—OH \\ | \\ CH_3 \end{array} \quad ; \quad \begin{array}{c} CH=CH\,C_6H_5 \\ | \\ HO—C^*—H \\ | \\ CH_3 \end{array}$$

C* indicate asymmetric carbon atom.

EXAMPLE 109. *An alkene (A) on passing through Br_2/CCl_4 gives a compound (B), which on dehydrobromination in presence of $NaNH_2$ gives a hydrocarbon (C). Compound (C) yields (D) when warmed with dilute H_2SO_4 in the presence of $HgSO_4$. (D) gives a yellow ppt. of (E) on treatment with I_2 and NaOH and also forms sodium salt of 3, 4–dimethyl pentanoic acid. Give structures of (A) to (E) with reasons.* **(Roorkee, 2001)**

SOLUTION. Action of alkene (A) with Br_2/CCl_4 indicates unsaturation in (A). Dehydrobromination in presence of $NaNH_2$ indicates terminal $C\equiv CH$ etc. The last compound has seven C-atoms and iodoform CHI_3. So, the data suggests that :

(A) is



$$\underset{(A)}{CH_3—\underset{CH_3}{\underset{|}{CH}}—\underset{CH_3}{\underset{|}{C}}HCH_2CH=CH_2} \xrightarrow{Br_2/CCl_4}$$

$$\underset{(B)}{CH_3—\underset{CH_3}{\underset{|}{CH}}—\underset{CH_3}{\underset{|}{C}}HCH_2\,\underset{Br}{\underset{|}{CH}}—\underset{Br}{\underset{|}{CH_2}}} \xrightarrow[-HBr]{NaNH_2}$$

$$\underset{(C)}{CH_3—\underset{CH_3}{\underset{|}{CH}}—\underset{CH_3}{\underset{|}{C}}HCH_2C\equiv CH} \xrightarrow[H_2SO_4]{HgSO_4}$$

$$\underset{(D)}{CH_3—\underset{CH_3}{\underset{|}{CH}}—\underset{CH_3}{\underset{|}{C}}HCH_2COCH_3} \xrightarrow{NaOH + I_2}$$

$$\underset{\text{Iodoform, (E)}}{CH\,I_3} + \overset{5}{C}H_3—\underset{CH_3}{\underset{|}{\overset{4}{C}H}}—\underset{CH_3}{\underset{|}{\overset{3}{C}H}}—\overset{2}{C}H_2\overset{1}{C}OONa$$

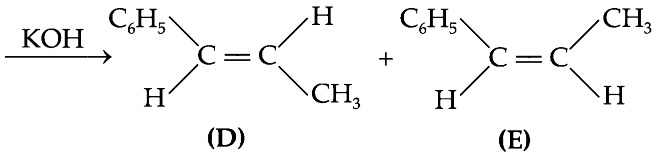
sodium salt of 3, 4-dimethyl pentanoic acid

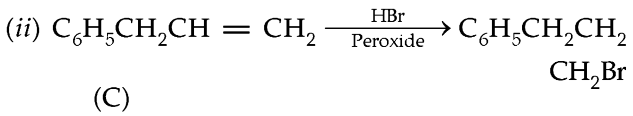
EXAMPLE 110. *A Grignard reagent (A) and a haloalkene (B) react to give (C). Compound (C) on heating with KOH yields a mixture of two geometrical isomers, (D) and (E), of which (D) predominates. (D) and (E) have the same molecular formula and (C) gives I-bromo-3-phenylpropane on reaction with HBr in the presence of peroxide. Give structures of (A), (B) and (C) and configurations of (D) and (E) with reasons.* **(Roorkee, 2001)**

SOLUTION. Since (C) gives 1-bromo-3-phenyl propane when treated with HBr in presence of peroxide (anti Markownikoff's rule), so (C) will be an alkene. This suggests the following.

(*i*)

$$\underset{\textbf{(A)}}{C_6H_5MgX} + \underset{\textbf{(B)}}{CH_2=CHCH_2X} \longrightarrow \underset{\textbf{(C)}}{C_6H_5CH_2CH=CH_2}$$

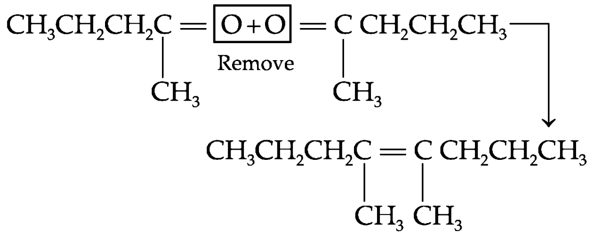




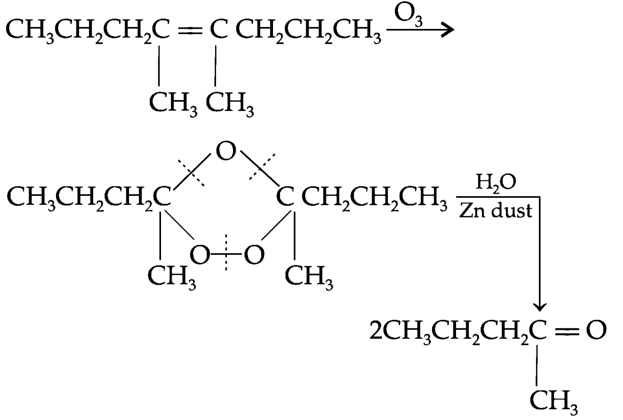
$$(ii)\ \underset{(C)}{C_6H_5CH_2CH=CH_2} \xrightarrow[\text{Peroxide}]{HBr} \underset{CH_2Br}{C_6H_5CH_2CH_2}$$

EXAMPLE 111. *Write the structure and give IUPAC name of the alkene which gives only pentan-2-one on ozonolysis.* **(Roorkee, 1985)**

SOLUTION. Product is $CH_3CH_2CH_2\overset{\overset{\displaystyle O}{\|}}{C}—CH_3$ on ozonolysis. So, the alkene should be :



It is confirmed from the following reactions.



(Pentan-2-one).

EXAMPLE 112. *Compound (A) contains only carbon and hydrogen. It decolorises Br_2 in CCl_4 solution and reacts slowly with Conc. H_2SO_4. Compound (A) reacts with HBr to form (B). (B) reacts with NaOH to form (C). On oxidation, (C) gives hexanone-3. write the structures of (A), (B) and (C) and give reactions.* **(Roorkee, 1986)**

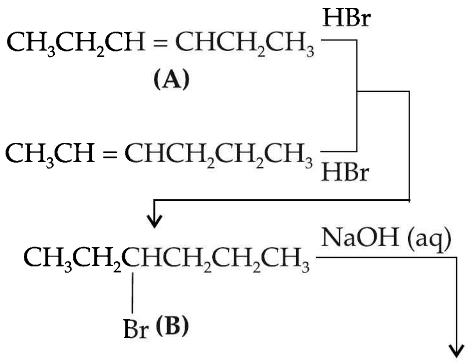
SOLUTION. Since (A) decolorises Br_2 in CCl_4, (*A*) is unsaturated hydrocarbon. Also, (*C*) on oxidation gives a ketone *i.e.*, hexanone-3, so, (*C*) should be a secondary alcohol. Also, position of keto group $>C = O$ should be 3. Thus, (C) is ;

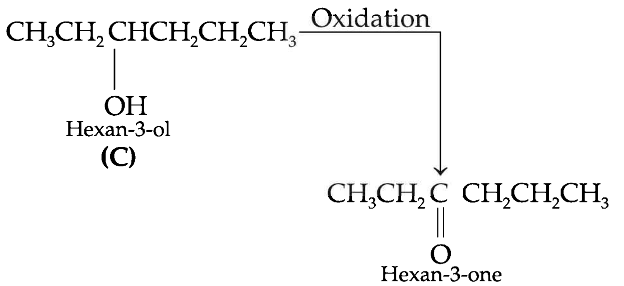
$$CH_3CH_2\underset{\underset{OH}{|}}{C}H\,CH_2CH_2CH_3.$$

Since (C) is formed from (B) on hydrolysis with NaOH, so (B) is $CH_3CH_2\underset{\underset{Br}{|}}{C}H\,CH_2CH_2CH_3$. Also , (A) reacts with HBr to form (B), so (A) should be

$CH_3CH{=}CHCH_2CH_2CH_3$ or $CH_3CH_2CH{=}CHCH_2CH_3$
(A) Hex-2-ene Hex-3-ene (A)

Reactions are :





EXAMPLE 113. *It required 0.7g of a hydrocarbon (A) to react completely with Br_2(2.0g). On treatment of (A) with HBr, it yielded monobromoalkane (B). The same compound (B) was obtained when (A) was treated with HBr in presence of peroxide. Write down the structural formula of (A) and (B) and explain the reactions involved.* **(Roorkee, 1987)**

SOLUTION. Since (A) reacts completely with Br_2, (A) should be an alkene.

Mol. wt. of $Br_2 = 2 \times 80 = 160.$

2.0g of Br_2 react with

(A) = 0.7g

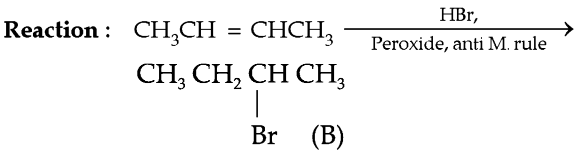
160.0g of Br_2 react with (A)

$$= \frac{0.7}{2.0} \times 160 = 56.0\text{g (A)}$$

$\therefore$ Mol. wt. of alkene,

$$C_nH_{2n} = 56\ ;\ 12n + 2n(1) = 56\ ;\ n = 4.$$

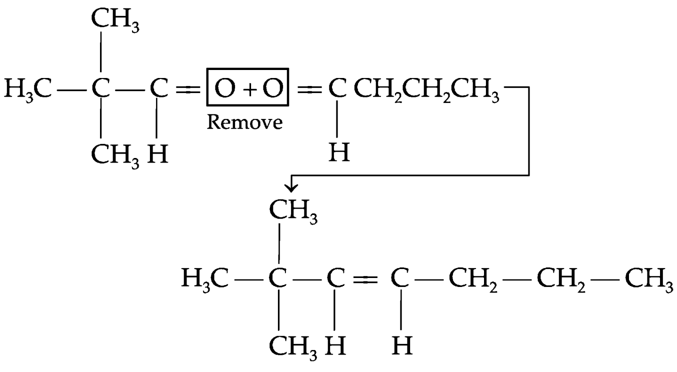
$\therefore$ Alkene = C_4H_8 or $CH_3CH = CHCH_3$
But - 2 - ene, (A)



Reaction : $CH_3CH = CHCH_3 \xrightarrow[\text{Peroxide, anti M. rule}]{\text{HBr,}} CH_3\,CH_2\,\underset{\underset{Br}{|}}{C}H\,CH_3$ (B)

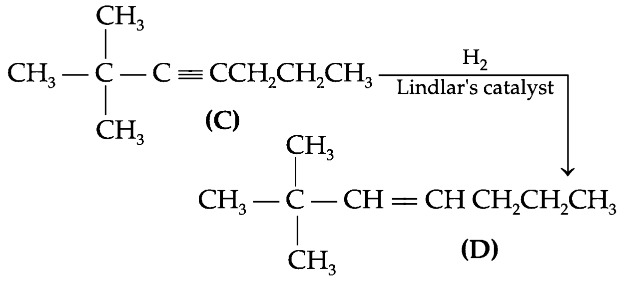
EXAMPLE 114. *An unsaturated hydrocarbon (A), C_6H_{10} readily gives (B) on treatment with $NaNH_2$ in liquid NH_3. When (B) is allowed to react with 1-chloropropane, a compound (C) is obtained. On partial hydrogenation in the presence of Lindlar's catalyst, (C) gives (D), C_9H_{18}. On ozonolysis, (D) gives 2, 2-dimethyl propanal and 1-butanal. Give structures of (A), (B), (C) and (D) with proper reasoning.* **(Roorkee, 1992)**

SOLUTION. (*i*) (D) is an alkene which on ozonolysis gives 2,2-dimethyl propanal and 1-butanal. So, (D) is :



(D)

(*ii*) Since (D) is formed by the partial hydrogenaton of (C) in presence of Lindlar's catalyst, so (C) will be:



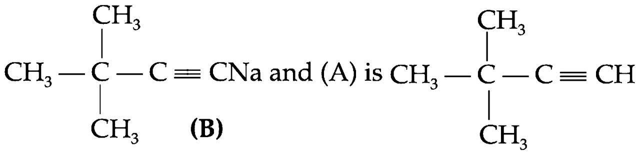
$$\underset{\textbf{(C)}}{CH_3-\overset{\overset{CH_3}{|}}{\underset{\underset{CH_3}{|}}{C}}-C\equiv CCH_2CH_2CH_3} \xrightarrow[\text{Lindlar's catalyst}]{H_2} \underset{\textbf{(D)}}{CH_3-\overset{\overset{CH_3}{|}}{\underset{\underset{CH_3}{|}}{C}}-CH=CH\,CH_2CH_2CH_3}$$

(*iii*) Since (B) reacts with 1-chloropropane to form (C), so (B) will be :

$$\underset{(B)}{CH_3CH_2CH_2CH_2C\equiv CNa} + ClCH_2CH_2CH_3 \longrightarrow$$

$$\underset{(C)}{CH_3CH_2CH_2CH_2C\equiv C-CH_2CH_2CH_3}$$

But the actual structure of (C) is as shown in (ii) above. So, the comparison of two structures of (C) suggests that (B) should be :



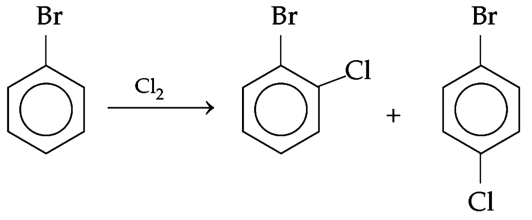
$$\underset{\textbf{(B)}}{CH_3-\overset{\overset{CH_3}{|}}{\underset{\underset{CH_3}{|}}{C}}-C\equiv CNa} \text{ and (A) is } CH_3-\overset{\overset{CH_3}{|}}{\underset{\underset{CH_3}{|}}{C}}-C\equiv CH$$

3, 3 – Dimethyl but – 1 – yne, **(A)**

EXAMPLE 115. *When bromobenzene is monochlorinated, two isomeric compounds (A) and (B) are obtained. Monobromination of (A) gives several isomeric products of formula* $C_6H_3ClBr_2$ *while monobromination of (B) yields only two isomers (C) and (D). Compound (C) is identical with one of the compounds obtained from the bromination of (A), however, (D) is totally different from any of the isomeric compounds obtained from the bromination of (A). Give structures of (A), (B), (C) and (D) and also suggest structures of four isomeric monobrominated products of (A). Support your answer with reasoning.*

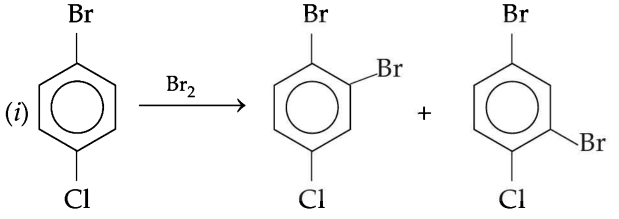
(Roorkee, 1992)

SOLUTION. –Br group in bromobenzene is ortho and para directing group. So, we have :



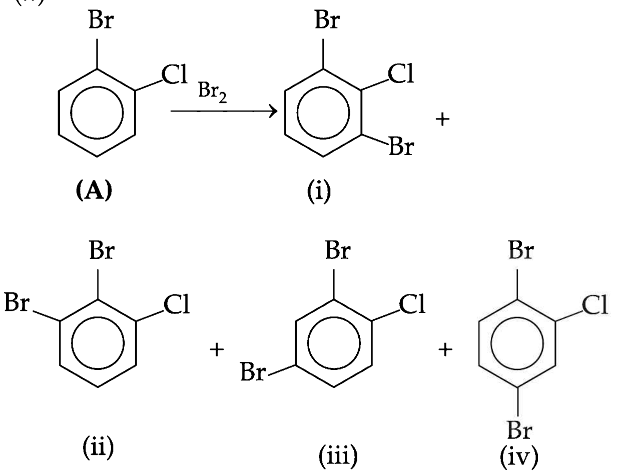
(A) **(B)**

Since (B) gives only two isomers while (A) gives several products on monobromination, so, we have :



(B) **(D)** **(C)**

(*ii*)



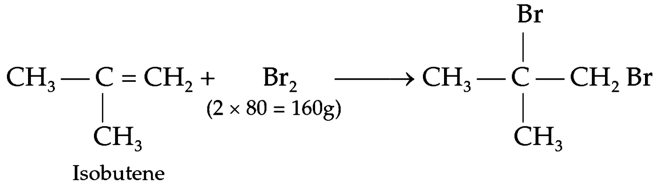
Structure (C) is identical to structure (*iii*) but structure (D) is different from the structures (*i*), (*ii*) and (*iv*)

EXAMPLE 116. *A 10g mixture of isobutane and isobutene requires 20g of* Br_2 *(in* CCl_4*) for complete addition. If 10g of the mixture is catalytically hydrogenated and the entire alkane is monobrominated in the presence of light at 127°C, which is the exclusive product and how much of it would be formed ? (atomic weight of bromine = 80).* **(Roorkee, 1998)**

SOLUTION. (*i*) Wt. of isobutane + isobutene = 10g.

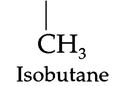
Let wt. of isobutene $= x$ g ; wt. of isobutane = 10 – x g.

Reactions :



$$\underset{\text{Isobutene}}{CH_3-\underset{\underset{CH_3}{|}}{C}=CH_2} + \underset{(2\times 80\,=\,160g)}{Br_2} \longrightarrow CH_3-\overset{\overset{Br}{|}}{\underset{\underset{CH_3}{|}}{C}}-CH_2\,Br$$

(Mol. wt. = 12 + 3 + 12 + 12 + 3 + 12 + 2 = 56g)



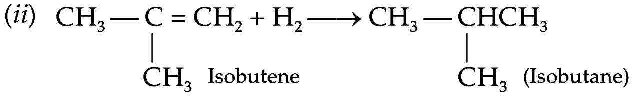
$$\underset{\text{Isobutane}}{CH_3-\underset{\underset{CH_3}{|}}{C}HCH_3} \xrightarrow{Br_2} \text{no action}$$

160g Br_2 is needed for isobutene = 56g

∴ 20g Br_2 is needed for isobutene $= \frac{56}{160} \times 20 = 7g$

∴ Wt. of isobutene = 7g

Wt. of isobutane = 10 – 7 = 3g

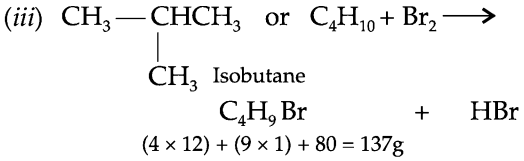


(*ii*) $$\underset{\text{Isobutene}}{CH_3-\underset{\underset{CH_3}{|}}{C}=CH_2} + H_2 \longrightarrow \underset{\text{(Isobutane)}}{CH_3-\underset{\underset{CH_3}{|}}{C}HCH_3}$$

Mol. wt. = 56 Mol. wt. = 58

56g isobutene forms isobutane = 58g

7g isobutene forms isobutane $= \frac{58}{56} \times 7 = 7.25g$



(*iii*) $$\underset{\text{Isobutane}}{CH_3-\underset{\underset{CH_3}{|}}{C}HCH_3} \text{ or } C_4H_{10} + Br_2 \longrightarrow$$

$$\underset{(4\times 12)+(9\times 1)+80\,=\,137g}{C_4H_9Br} + HBr$$

mol. wt. = 58g

58g isobutane forms C_4H_9Br = 137g

$\therefore$ 7.25 + 3 *i.e.*, 10.25g C_4H_{10} forms product

$$= \frac{137}{58} \times 10.25 = \mathbf{24.21g\ C_4H_9Br.}$$

EXAMPLE 117. *An organic compound $C_3H_6O_2$ has two isomers, (A) and (B). (B) gives effervescence with $NaHCO_3$ while (A) does not do so. (B) gives out H_2 when treated with metallic zinc but (A) has no reaction with it. (A) on treatment with excess of NaOH yields two compounds (C) and (D). Compound (C) when treated with dil. H_2SO_4 gives (E) which reduces Tollen's reagent. (D), however, can form iodoform with I_2 and alkali. Identify (A) to (E).*

SOLUTION. (*i*) Since (*B*) gives effervescence with $NaHCO_3$, it will be an acid. Since (*A*) and (*B*) are isomers, (*A*) may be an ester. Thus, $C_3H_6O_2$ may be an acid or ester. (*A*) is $HCOOC_2H_5$ or $H_3CCOOCH_3$; (*B*) is CH_3CH_2COOH (*ii*) (*A*) reacts with NaOH to form (*C*) and (*D*). Since (*D*) gives iodoform test, the ester is $HCOOC_2H_5$

$$HCOOC_2H_5 \xrightarrow{NaOH} HCOONa + C_2H_5OH\,(Ethanol)$$

(*A*), Ethyl formate — (*C*) Sodium formate — (D), gives iodoform test.

$$(ii)\ HCOONa \xrightarrow[H_2SO_4]{H_2O,} HCOOH\ (formic\ acid) + NaOH$$

(*C*) — (*F*), reduces Tollen's reagent

EXAMPLE 118. *An organic compound (A), $C_6H_{12}O_3$ on treatment with conc. H_2SO_4 gives CO_2, H_2O and (B). Compound (B) can be prepared by passing vapours of pentanol–1 over heated copper at 570K. Compound (A) on heating gives (C), $C_{12}H_{20}O_4$. Give structures of (A) to (C) with proper reasoning.*

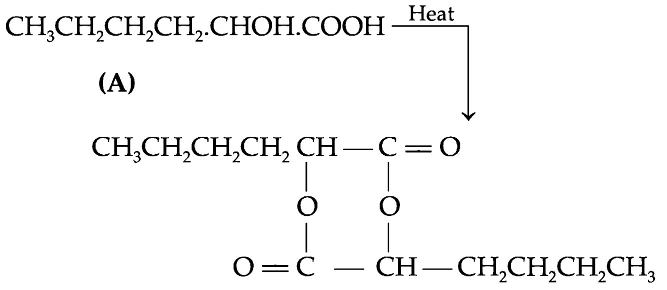
(Roorkee, 1998)

SOLUTION. (*i*) Since primary alcohols on heating with Cu at 570K give aldehyde, so, (B) will be aldehyde as it is obtained from pentanol–1.

$$\underset{\text{Pentanol–1}}{CH_3CH_2CH_2CH_2CH_2OH} \xrightarrow[570K]{Cu,} \underset{\text{(B), Pentanal – 1}}{CH_3CH_2CH_2CH_2CHO}$$

Since on treating (A) with conc. H_2SO_4, we get CO_2, H_2O and (B), so (A) will be $CH_3CH_2CH_2CH_2CHOHCOOH$

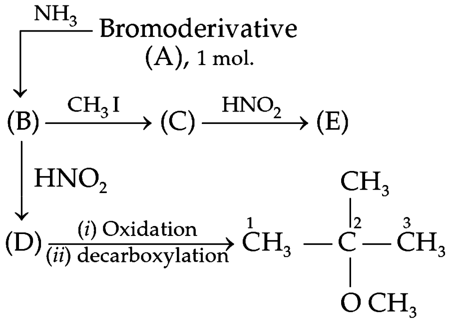
(*ii*) $CH_3CH_2CH_2CH_2CHOHCOOH \xrightarrow{Conc.\ H_2SO_4} CH_3CH_2CH_2CH_2CHO + CO_2 + H_2O$. Also (A) gives (C) on heating. Thus



(C) Lactide

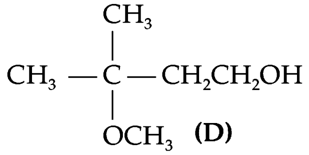
EXAMPLE 119. *One mole of each bromoderivative (A) and NH_3 react to give one mole of an organic compound (B). (B) reacts with CH_3I to give (C). Both (B) and (C) react with HNO_2 to give compounds (D) and (E) respectively. (D) on oxidation and subsequent decarboxylation gives 2-methoxy-2-methyl propane. Give structures of (A) to (E) with proper reasoning.* **Roorkee, 1994)**

SOLUTION.



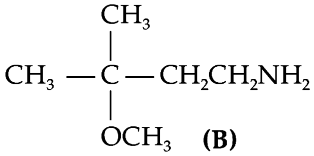
2-Methoxy-2-methyl propane

(*i*) Since 1°-alcohols on oxidation give carboxylic acid and the latter on decarboxylation results in the loss of one carbon atom, so (D) will be



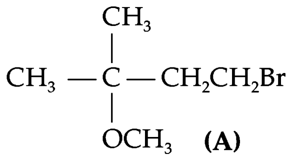
$$CH_3-\underset{OCH_3}{\overset{CH_3}{\underset{|}{\overset{|}{C}}}}-CH_2CH_2OH\quad \mathbf{(D)}$$

(*ii*) Since alcohol is formed by the action of HNO_2 on $-NH_2$ group, so, (B) will be



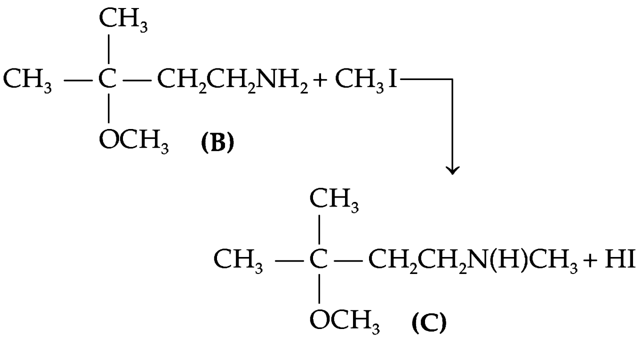
$$CH_3-\underset{OCH_3}{\overset{CH_3}{\underset{|}{\overset{|}{C}}}}-CH_2CH_2NH_2\quad \mathbf{(B)}$$

(*iii*) Since (B) is formed by the action of NH_3 on (A) which is a bromoderivative, so (A) will be :



$$CH_3-\underset{OCH_3}{\overset{CH_3}{\underset{|}{\overset{|}{C}}}}-CH_2CH_2Br\quad \mathbf{(A)}$$

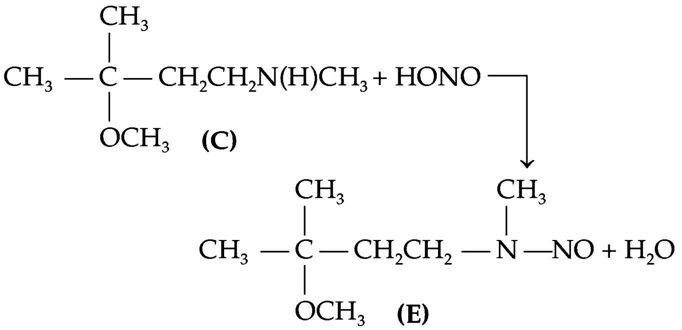
(*iv*) Since (D) is formed by the action of (B) on CH_3I, so, we have.



$$CH_3-\underset{OCH_3}{\overset{CH_3}{\underset{|}{\overset{|}{C}}}}-CH_2CH_2NH_2 + CH_3I \longrightarrow CH_3-\underset{OCH_3}{\overset{CH_3}{\underset{|}{\overset{|}{C}}}}-CH_2CH_2N(H)CH_3 + HI$$

(B) — **(C)**

(*v*) Action of (C) on HNO_2 gives (E). Thus :



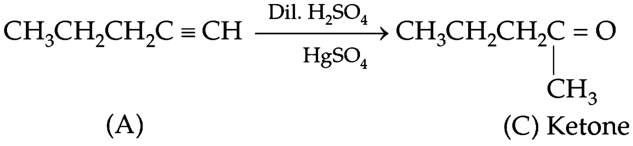
$$\underset{\text{(C)}}{CH_3-\underset{\underset{OCH_3}{|}}{\overset{\overset{CH_3}{|}}{C}}-CH_2CH_2N(H)CH_3} + HONO \longrightarrow \underset{\text{(E)}}{CH_3-\underset{\underset{OCH_3}{|}}{\overset{\overset{CH_3}{|}}{C}}-CH_2CH_2-\overset{\overset{CH_3}{|}}{N}-NO} + H_2O$$

EXAMPLE 120. *An organic compound (A) of molecular formula C_5H_8 when treated with Na in liquid ammonia followed by reaction with n-propyl iodide yields (B), C_8H_{14}. (A) gives a ketone (C), $C_5H_{10}O$ when treated with dil. H_2SO_4 and $HgSO_4$. (B) on oxidation with alkaline $KMnO_4$ gives two isomeric acids (D) and (E), $C_4H_8O_2$. Give structures of compounds (A) to (E) with proper reasoning.* **(Roorkee, 1994)**

SOLUTION. The formula C_5H_8 is of alkyne C_nH_{2n-2}. Since (A) reacts with Na/NH_3, it will be terminated alkyne, $CH_3CH_2CH_2C\equiv CH$. (**A**)

(*i*) $CH_3CH_2CH_2C\equiv CH \xrightarrow{Na} CH_3CH_2CH_2C\equiv CNa \xrightarrow{CH_3CH_2CH_2I} \underset{(B)}{CH_3CH_2CH_2C\equiv C-CH_2-CH_2-CH_3}$.

(*ii*)

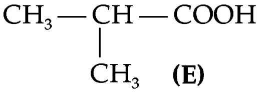


$$\underset{(A)}{CH_3CH_2CH_2C\equiv CH} \xrightarrow[HgSO_4]{Dil.\ H_2SO_4} \underset{\text{(C) Ketone}}{CH_3CH_2CH_2\underset{\underset{CH_3}{|}}{C}=O}$$

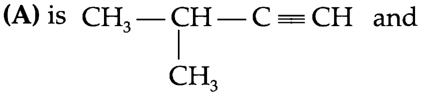
(*iii*) $CH_3CH_2CH_2C\equiv CCH_2CH_2CH_3 \xrightarrow[[O]]{KMnO_4,}$

$\underset{(D)}{CH_3CH_2CH_2COOH} + \underset{(E)}{CH_3CH_2CH_2COOH}$

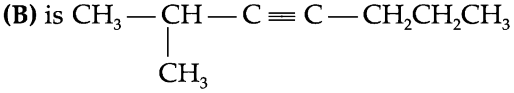
But (D) and (E) are isomeric. So, (E) can be



$$\underset{(E)}{CH_3-\underset{\underset{CH_3}{|}}{CH}-COOH}$$



(A) is $CH_3-\underset{\underset{CH_3}{|}}{CH}-C\equiv CH$ and



(B) is $CH_3-\underset{\underset{CH_3}{|}}{CH}-C\equiv C-CH_2CH_2CH_3$

EXAMPLE 121. *Hydrocarbon (X), C_7H_{12} on reaction with boron hydride followed by treatment with CH_3COOH yields (A). On reduction ozonolysis, (A) yields a mixture of two aldehydes, (B) and (C). Of these, only (B) can undergo Cannizzaro's reaction. (A) exists in two geometrical isomers (A – I) and (A – 2) of which (A–2) is more stable. Give structures of (X), (A), (B), (C), (A – I) and (A – 2) with proper reasoning.* **(Roorkee, 2000)**

SOLUTION. (*i*) $A \xrightarrow[(ii)\ H_2O,\ Zn\ dust]{(i)\ O_3} \underset{(B)}{R\ CHO} + \underset{(C)}{R'\ CHO}$

(*ii*) If (*B*) is HCHO, it will give Cannizzaro's reaction because of the presence of α–H atom in it. But, then (*A*) must have $R'\ C=CH_2$ structure which is not possible because it will not give geometrical isomers.

(*iii*) $\underset{(X)}{C_7H_{12}}$ is an alkyne of formula C_nH_{2n-2}. Its reaction is :

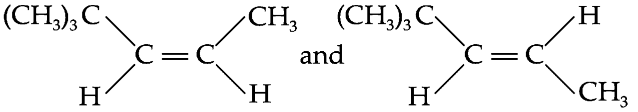
$$\underset{(X)}{C_7H_{12}} \xrightarrow[CH_3COOH]{B_2H_6,} \underset{\text{Alkene}}{C_7H_{14}}$$

But reaction of an alkyne to form alkene takes place through vinylic boranes as intermediate and cis-alkene is the main product. Hence, we have :

$$\underset{(A)}{(CH_3)_3CCH=CHCH_3} \xrightarrow[(ii)\ H_2O,\ Zn\ dust]{(i)\ O_3} \underset{(B)}{(CH_3)_3\ C.CHO} + \underset{(C)}{CH_3CHO}$$

(B) does not have α–H atom but gives Cannizzaro's reaction

(*iv*) Two geometrical isomers of (A) are



cis, (A-1) Trans, (A-2)

EXAMPLE 122. *An organic compound (A) reacts with ethanol to give (B) and (C). On acid hydrolysis, (C) yields (B) and (D). Oxidation of (D) gives (B). (B) is an acid and forms a salt with $Ca(OH)_2$ which on dry distillation gives (E), C_3H_6O. Give structures of (A) to (E) with proper reasoning.* **(Roorkee, 2000)**

SOLUTION. (*i*) (B) is an acid and forms a salt with $Ca(OH)_2$ which on dry distillation gives (E), C_3H_6O *i.e.*, acetone. So, (B) is acetic acid, CH_3COOH.

Reactions.

$2CH_3COOH + Ca(OH)_2 \longrightarrow Ca(CH_3COO)_2 + 2H_2O$

$Ca(CH_3COO)_2 \xrightarrow{\text{Dry distillation}} CaCO_3 + CH_3COCH_3$ *i.e.*, C_3H_6O.

(*ii*) Since (A) reacts with C_2H_5OH to give (B) and (C), so (A) will be acetic anhydride.

$$\underset{\text{Acetic anhydride}}{CH_3CO.O.COCH_3} + \underset{\text{Ethanol}}{C_2H_5OH} \longrightarrow \underset{(B)}{CH_3COOH} + \underset{(C)}{CH_3COOC_2H_5}$$

(*iii*) (C) on acid hydrolysis gives (B) *i.e.*, CH_3COOH and (D) and (D) on oxidation gives (B). So, we have :

$$CH_3COOC_2H_5 + HOH \longrightarrow \underset{(B)}{CH_3COOH} + \underset{(D)}{C_2H_5OH}$$

$$C_2H_5OH \xrightarrow{[O]} \underset{(B)}{CH_3COOH} + H_2O.$$

EXAMPLE 123. *Compound (A), $C_5H_{11}NO$ is not soluble in cold dilute alkaline or acidic solutions. When (A) is refluxed in*

NaOH solution, a gas (B) is evolved and a salt (C) is formed. Acetyl chloride reacts with (B) to give (D), C_4H_9NO. (B) reacts with HNO_2 to give a yellow oil (E). Give structures of (A) to (E) with reactions. **(Roorkee, 2000)**

SOLUTION. Since (B) reacts with HNO_2 to give a yellow oil (E), so, (B) is expected to be secondary amine. Also (A) gives a salt (C) when refluxed with NaOH. So, (C) is sodium salt of an acid. Thus, the given data suggest that, (A) is $(CH_3)_2N.\ COCH_2CH_3$.

(*i*) $\underset{\textbf{(A)}}{(CH_3)_2N.COCH_2CH_3} + NaOH \xrightarrow{\text{Reflux}} \underset{\textbf{(B)}}{(CH_3)_2NH} + \underset{\textbf{(C)}}{CH_3CH_2COONa}$

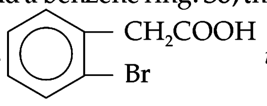
(*ii*) $\underset{\textbf{(B)}}{(CH_3)_2NH} + HONO \longrightarrow \underset{\text{Yellow oil }\textbf{(E)}}{(CH_3)_2N.\ NO}$

(*iii*) $\underset{\textbf{(B)}}{(CH_3)_2NH} + \underset{\text{Acetyl chloride}}{CH_3COCl} \longrightarrow \underset{\textbf{(D)}}{(CH_3)_2N.\ COCH_3}$

EXAMPLE 124. *An acid (A) $C_8H_7O_2$ Br on bromination with $FeBr_3$ gives two isomers (B) and (C) of formula $C_8H_6O_2Br_2$. Vigorous oxidation of (A), (B) and (C) gives acids (D), (E) and (F) respectively. (D) $C_7H_5O_2$ Br is the strongest acid among all of its isomers, whereas (E) and (F) each has a molecular formula of $C_7H_4O_2Br_2$. Give structures of (A) to (F) with justification.*

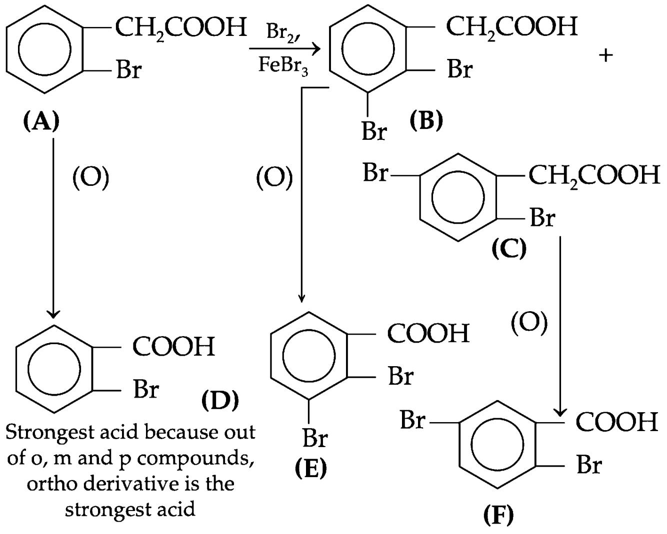
(Roorkee, 2000)

SOLUTION. The formula $C_8H_7O_2Br$ of acid (A) suggests a–COOH group and a benzene ring. So, the given reactions suggest that **(A)** is



i.e. $C_8H_7O_2$ Br.

Hence:



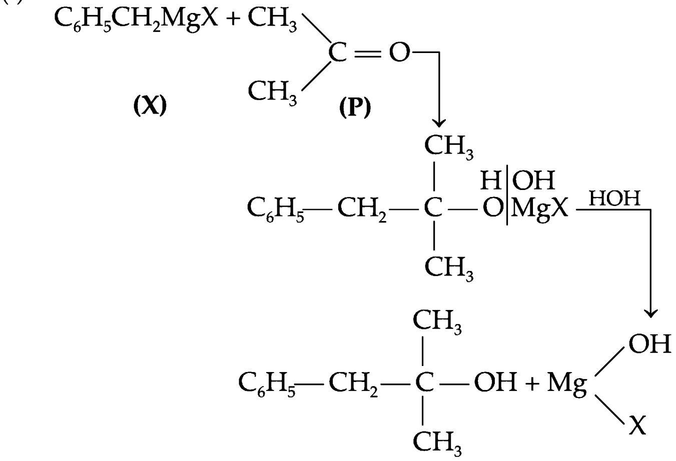
Strongest acid because out of o, m and p compounds, ortho derivative is the strongest acid

EXAMPLE 125. *Two different Grignard reagents, (X) and (Y) produce $C_6H_5CH_2C(CH_3)_2$ OH on reaction with (P) and (Q) respectively. Give structures of (X), (Y), (P) and (Q).*

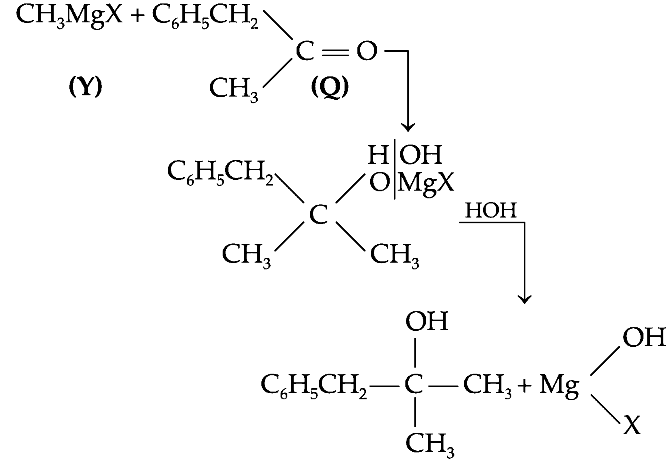
(Roorkee, 2000)

SOLUTION. The product $C_6H_5CH_2C(CH_3)_2OH$ indicates that (X) should be $C_6H_5CH_2MgX$ and (Y) should be CH_3MgX. Since Grignard reagents react with ketones followed by hydrolysis give alcohols, so keeping in view the groups present in the product, we have :

(*i*)

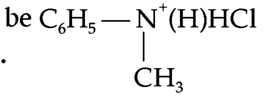


(*ii*)



EXAMPLE 126. *The aqueous solution of a nitrogen and chlorine containing organic compound (A) is acidic to litmus. (A) on treatment with aqueous NaOH gives a compound (B) containing nitrogen, but not chlorine. Compound (B), on treatment with $C_6H_5SO_2Cl$ in the presence of NaOH gives an insoluble product $C_{13}H_{13}NO_2S$. Give structures of (A) and (B).* **(Roorkee, 2000)**

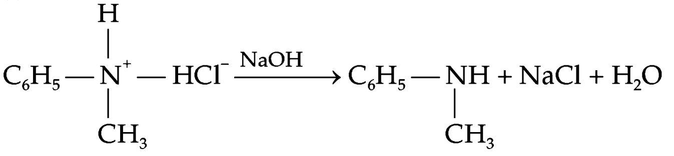
SOLUTION. Since (A) contains N and Cl and is acidic to litmus, it can be



$C_6H_5 - \underset{\underset{\displaystyle CH_3}{|}}{N^+}(H)HCl$

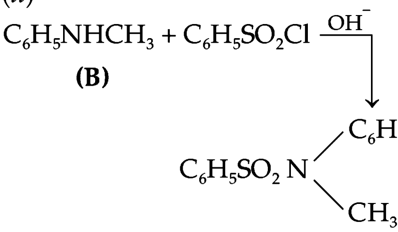
Reaction.

(*i*)



$C_6H_5 - \overset{\overset{\displaystyle H}{|}}{\underset{\underset{\displaystyle CH_3}{|}}{N^+}} - HCl^- \xrightarrow{NaOH} C_6H_5 - \underset{\underset{\displaystyle CH_3}{|}}{NH} + NaCl + H_2O$

(*ii*)



(Insoluble in NaOH as there is no H-atom with N-atom)

EXAMPLE 127. *Compound (A) gives positive Lucas test in 5 minutes. When 6.0g of (A) is treated with sodium metal, 1120mL of hydrogen is evolved at S.T.P. Assuming (A) to contain one atom of oxygen per molecule, write structural formula of (A). Compound (A) when treated with PBr_3 gives (B) which when treated with benzene in presence of anhydrous aluminium chloride gives (C). What are (B) and (C) ?* **(Roorkee, 1990)**

SOLUTION. (*i*) 1120 mL of H_2 is produced from (A) = 6.0 g

11200 mL of H_2 is produced from (A) = $\frac{6}{1120} \times 11200 = 60$ g

Since (A) gives Lucas test within 5 minutes, it will be a secondary alcohol, $>CHOH$. Also, (A) contains one O-atom. So, there will be only one – OH group in (A).

(*ii*) Since one mol of alcohol having one OH group gives 11200 mL H_2 at S.T.P., mol. wt. of (A) = 60.

$$\left[\because\ -OH + Na \rightarrow -ONa + \frac{1}{2}H_2\ (i.e., \frac{1}{2} \times 22400 = 11200\ mL\ H_2)\right]$$

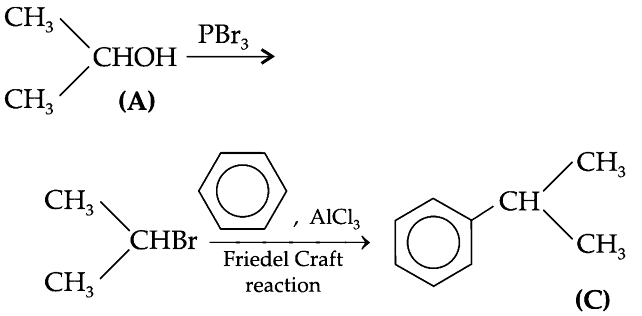
∴ Mol. wt. of

$$C_nH_{2n+1}OH = 60;\ 12n + (2n + 1) \times 1 + 16 + 1 = 60;$$

$$14n = 42;\ n = 3.$$

So. alcohol is C_3H_7OH *i.e.*, $\begin{matrix}CH_3\\CH_3\end{matrix}\!\!>CHOH$ (Isopropyl alcohol)

Reactions.



(A)

(B)
2-Bromopropane

(C)
2-Phenyl propane

EXAMPLE 128. *When 0.0088g of a compound (A) was dissolved in 0.5g of camphor, the melting point of camphor was lowered by 8°C. Analysis of (A) gave 68.18% C and 13.16% H. Compound (A) showed the following reactions.*

(*i*) *It reacted with acid chloride and evolved hydrogen with Na.*

(*ii*) *When reacted with HCl + $ZnCl_2$, a dense oily layer separated out immediately.*

Compound (A) was passed over Al_2O_3 at 350°C to give compound (B). (B) on ozonolysis followed by hydrolysis gave two neutral compounds (C) and (D), which gave positive test with carbonyl reagents but only (C) gave a positive test with Fehling solution and resinous substance with NaOH. Identify (A), (B), (C) and (D) with proper reasoning. K_f for camphor = 40K mol⁻ kg **(Roorkee, 1990)**

SOLUTION. (*i*) To find empirical formula, E.F.,

Element	At. wt.	% age	Relative no. of atoms = % age/at. wt.	Simple ratio	Whole no. ratio
C	12	68.18	$\frac{68.18}{12} = 5.68$	$\frac{5.68}{1.17} = 4.8$	5
H	1	13.16	$\frac{13.16}{1} = 13.16$	$\frac{13.16}{1.17} = 11.2$	11
O	16	100 – (68.18 + 13.16) = 18.66	$\frac{18.66}{16} = 1.17$	$\frac{1.17}{1.17} = 1$	1

∴ E.F. = $C_5H_{11}O$;

E.F. wt. = (5 ×12) + (11 × 1) + 16 = 87

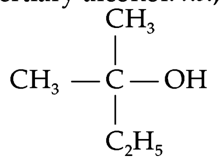
(*ii*) Mol. wt. of (*A*) = $\frac{1000 \times K_f \times \text{wt. of } (A)}{\Delta T \times \text{wt. of camphor solvent}}$

$$= \frac{1000 \times 40K\ mol^{-}\ Kg \times 0.0088g}{8K \times 0.5g} = 88Kg\ mol^{-}$$

∴ Molecular formula = E.F. × $\frac{\text{Mol. wt.}}{\text{E.F. wt.}}$

$$= C_5H_{11}O \times \frac{88}{77} \approx C_5H_{11}O$$

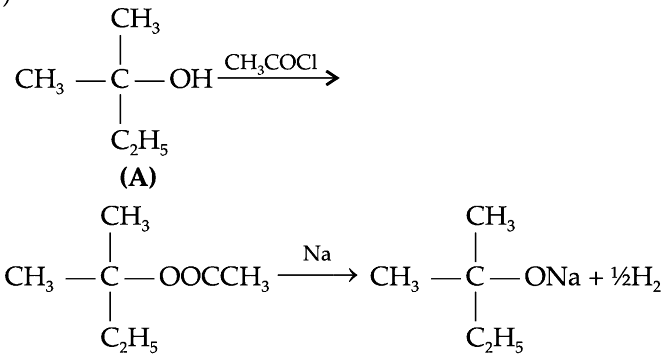
(*iii*) Since (A) reacts with acetyl chloride and liberates H_2 with Na, so (A) is an alcohol. But (A) reacts with Lucas reagent ($ZnCl_2$ + HCl) to give an oily layer, so (A) is a tertiary alcohol. *i.e.*,



$$CH_3-\overset{\overset{CH_3}{|}}{\underset{\underset{C_2H_5}{|}}{C}}-OH$$

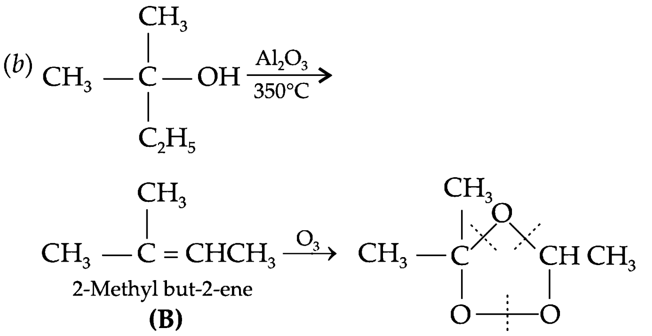
Reactions.

(*a*)



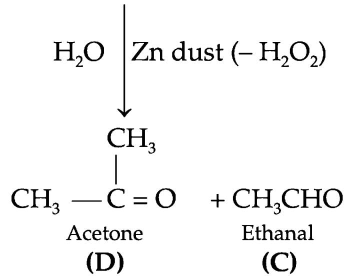
(A)

Methyl 2, 2-dimethyl butanoate



(*b*)

2-Methyl but-2-ene
(B)



$$\xrightarrow[H_2O]{\text{Zn dust } (-H_2O_2)} \underset{\substack{\text{Acetone}\\ \textbf{(D)}}}{CH_3-\overset{\displaystyle CH_3}{\overset{|}{C}}=O} + \underset{\substack{\text{Ethanal}\\ \textbf{(C)}}}{CH_3CHO}$$

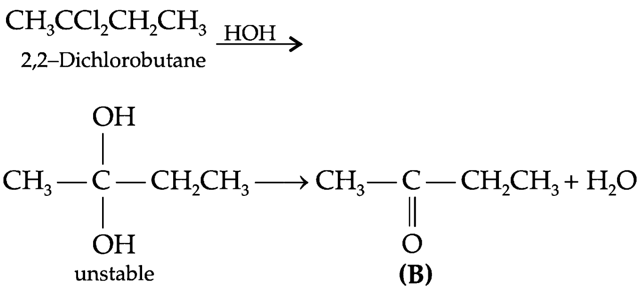
Out of (C) and (D), only (C) gives Fehling solution test. Thus (C) is an aldehyde while (D) will be a ketone because both(C) and (D) give test with carbonyl reagents like $NaHSO_3$, NH_2OH etc.

Example 129. *The compound $C_4H_8Cl_2$ (A) on hydrolysis gives a compound C_4H_8O, (B). The compound (B) reacts with hydroxylamine and gives a negative test with Tollen's reagent. What are (A) and (B)? Support your answer by proper reasoning and give the equations of reactions.* **(Roorkee,1985)**

Solution. (*i*) Since (B) reacts with NH_2OH, it is expected to be a carbonyl compound having aldehyde (–CHO) or keto (>C = O) group. Since (B) gives a negative test with Tollen's reagent, (B) is expected to be a ketone.

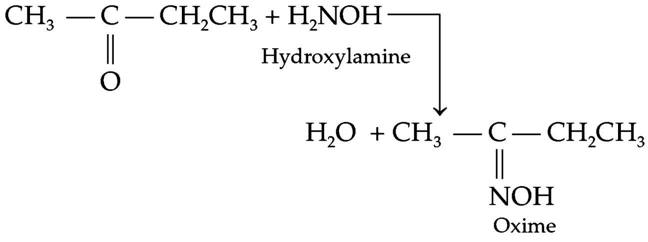
(*ii*) Since (B) is obtained by the hydrolysis of (A), so, both Cl-atoms will be of a gem-dihalide *i.e.*, Cl-atoms are bonded to the same C- atom which is not a corner C-atom. So, (A) is, $CH_3CCl_2CH_2CH_3$.

Reaction :

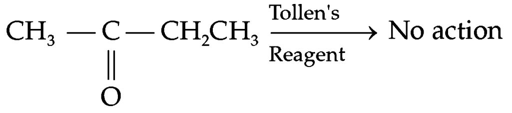


$$\underset{\text{2,2–Dichlorobutane}}{CH_3CCl_2CH_2CH_3} \xrightarrow{HOH}$$

$$\underset{\text{unstable}}{CH_3-\overset{\overset{\displaystyle OH}{|}}{\underset{\underset{\displaystyle OH}{|}}{C}}-CH_2CH_3} \longrightarrow \underset{\textbf{(B)}}{CH_3-\underset{\underset{\displaystyle O}{\|}}{C}-CH_2CH_3} + H_2O$$



$$CH_3-\underset{\underset{\displaystyle O}{\|}}{C}-CH_2CH_3 + \underset{\text{Hydroxylamine}}{H_2NOH} \longrightarrow H_2O + \underset{\text{Oxime}}{CH_3-\underset{\underset{\displaystyle NOH}{\|}}{C}-CH_2CH_3}$$



$$CH_3-\underset{\underset{\displaystyle O}{\|}}{C}-CH_2CH_3 \xrightarrow[\text{Reagent}]{\text{Tollen's}} \text{No action}$$

Example 130. *A mixture of an anhydride (A) and a monobasic acid (B) on heating produces another monobasic acid (C) of equivalent weight 74 and an anhydride (D). The acids and anhydrides remain in equilibrium. The anhydride (D) contains two identical fluoroalkyl groups. The acid (B) contains a trifluoromethyl group and has an equivalent weight of 128. Give structures of (A) to (D) with proper reasoning. (at. wt. of fluorine = 19).* **(Roorkee, 1998)**

Solution. Monobasic acid (B) having equivalent weight, 74 = CH_3CH_2COOH. The acid (B) containing trifluoromethyl group having equivalent weight, 128 = CF_3CH_2COOH ($\because$ at. wt. C = 12, H = 1, F = 19, O = 16). This data suggests that the required reaction is ;

$$\underset{(A)}{(CH_3CH_2CO)_2O} + \underset{(B)}{2CF_3CH_2COOH} \longrightarrow \underset{(C)}{2CH_3CH_2COOH} + \underset{(D)}{(CF_3CH_2CO)_2O}$$

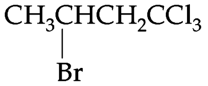
Example 131. *Write the products of the following reactions.*

(*i*) $CH_3CH = CH_2 + Br\,CCl_3 \xrightarrow{\text{Peroxide}}$

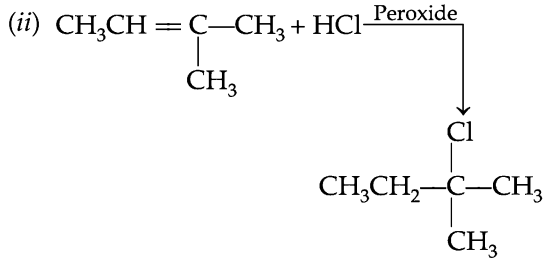
(*ii*) $CH_3CH = C(CH_3)_2 + HCl \xrightarrow{\text{Peroxide}}$

(Roorkee, 1998)

Solution. (*i*) $CH_3CH = CH_2 + Br\,CCl_3 \xrightarrow{\text{Peroxide}}$

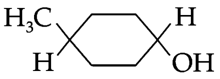


$$CH_3\underset{\underset{\displaystyle Br}{|}}{C}HCH_2CCl_3$$



$$(ii)\ CH_3CH=\underset{\underset{\displaystyle CH_3}{|}}{C}-CH_3 + HCl \xrightarrow{\text{Peroxide}} CH_3CH_2-\overset{\overset{\displaystyle Cl}{|}}{\underset{\underset{\displaystyle CH_3}{|}}{C}}-CH_3$$

Example 132. (*a*) *Dehydration of*



gives a compound which exists in two isomeric forms. Give the structure of both the isomers.

(*b*) *Explain in not more than 2, 3 lines.*

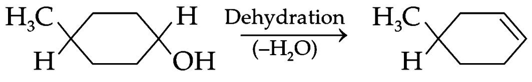
(*i*) Aniline does not undergo Friedel–Crafts reaction

(*ii*) Mineral acid is added in excess in diazotisation of arylamines.

(*c*) *Complete the reaction,* $(CH_3)_2\,C = CH_2$ + *isobutane* $\xrightarrow[273K]{HF}$ **(Roorkee, 1999)**

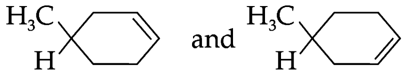
Solution.

(*a*)



(I)

The above compound (I) has following two optically active forms.



(*b*) (*i*) The question is wrong because aniline does undergo Friedel Crafts reaction although the yield is poor. Aniline (base) reacts with Lewis acid ($AlCl_3$) to form $C_6H_5NH_2 . AlCl_3$, and thus resists the attack of carbocation. The formation of carbocation is also hindered because aniline reacts with $AlCl_3$.

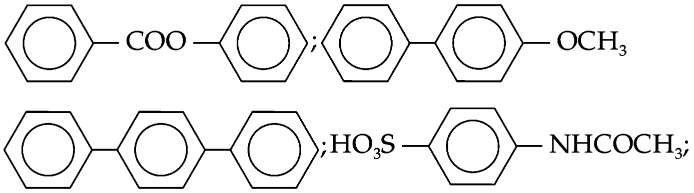
(*ii*) $C_6H_5NH_2 \xrightarrow{NaNO_2\,+\,2HCl\,(\text{excess})} C_6H_5N = NCl$

Excess of HCl is required because reaction needs

HNO_2 and HCl. So, HCl is needed more to get complete reaction. Also, excess of HCl does not allow the coupling of diazonium salt with aniline. The excess of HCl also prevents the hydrolysis of salt formed.

$$NaNO_2 + HCl \longrightarrow NaCl + HNO_2.$$

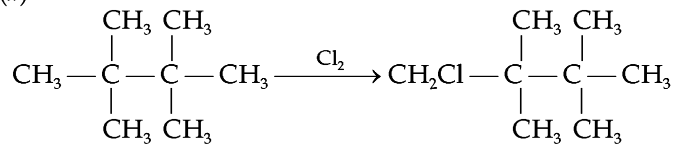
EXAMPLE 133. *(a) An organic compound C_8H_{18} on monochlorination gives a single monochloride. Write the structure of the hydrocarbon. (b) Write the structures of the possible major monosubstituted products formed when Br^+ attacks the following molecules.*



(Roorkee, 1999)

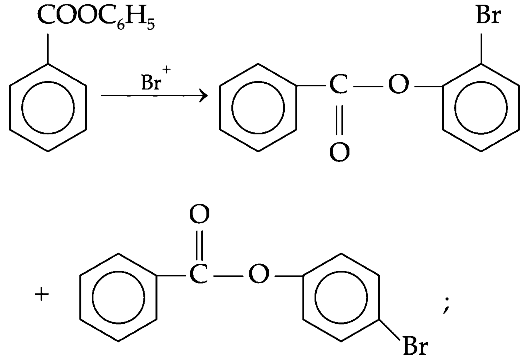
SOLUTION. C_8H_{18} indicates alkane ($C_n H_{2n+2}$). Since, it gives only one monochloride on subsitution, so, there will be all CH_3 groups bonded to C–atoms. Thus.

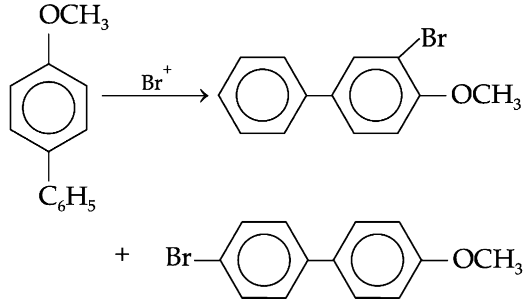
(*a*)

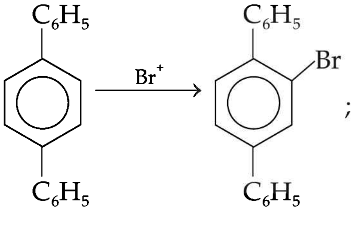


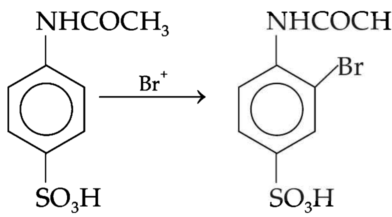
$$CH_3-\underset{CH_3}{\overset{CH_3}{C}}-\underset{CH_3}{\overset{CH_3}{C}}-CH_3 \xrightarrow{Cl_2} CH_2Cl-\underset{CH_3}{\overset{CH_3}{C}}-\underset{CH_3}{\overset{CH_3}{C}}-CH_3$$

(*b*)







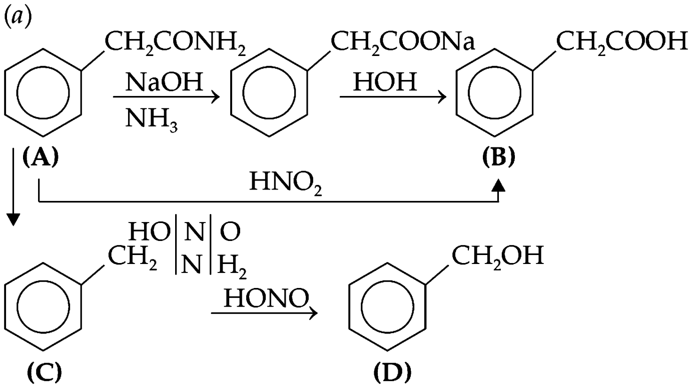


EXAMPLE 134. *An organic compound (A) of molecular weight 135, on boiling with NaOH evolves a gas which gives white dense fumes on bringing a rod dipped in HCl near it. The alkaline solution thus obtained on acidification gives the precipitate of a compound (B) having mol. wt. 136. Treatment of (A) with HNO_2 also yields (B), whereas its treatment with Br_2/KOH gives red colour with ceric ammonium nitrate. On the other hand, (E) an isomer of (A) on boiling with dil. HCl gives an acid (F), having mol. wt. 136. On oxidation followed by heating, (F) gives an anhydride (G) which condenses with benzene in presenece of $AlCl_3$ to give anthraquinone. Give structures of (A) to (G) with proper reasoning.* **(Roorkee, 1996)**

SOLUTION. The organic compound which gives NH_3 on heating with NaOH will contain —$CONH_2$ group. So, (A) compound having mol. wt. 135, should be $C_6H_5CH_2CONH_2$.

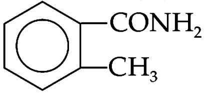
So, reactions are :

(*a*)



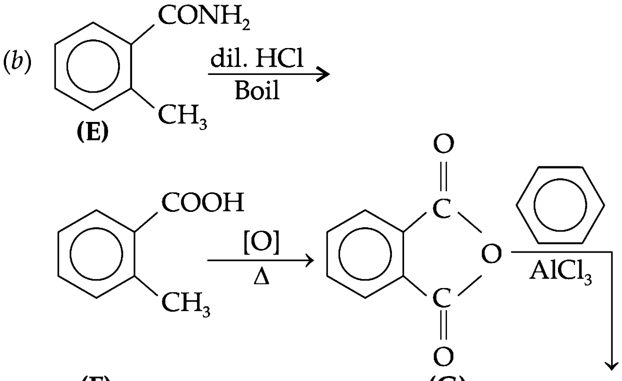
(contains alcoholic group. So, it gives red colour with ceric ammonium nitrate)

Since (E) is an isomer of (A), so (E) will be

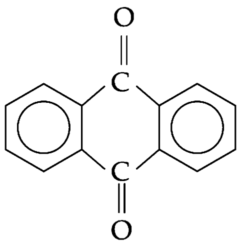


(E)

(*b*)



(F) **(G)**



Anthraquinone

EXAMPLE 135. *Give the structures/configurations of the products (T) to (Z) of the following reactions.*

(*a*) 
$$H_3C-\overset{C_2H_5}{\underset{CH=CH_2}{C}}-H + D_2 \xrightarrow{Pd} (T) + (U)$$

(*b*) 
$$R\overset{O}{\overset{\|}{C}}Cl \xrightarrow[(ii)\ H_2O]{(i)\ N_3H,\ heat} (V)$$

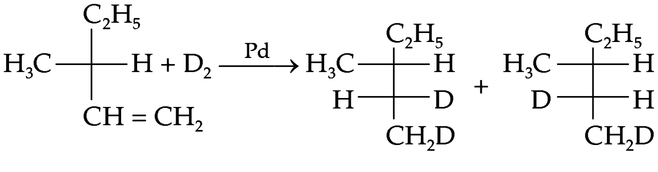
(*c*) 
$$I^- + CH_3CH_2CH_2-\overset{D}{\underset{H}{C}}-I \longrightarrow (W)$$

(*d*) 
(*e*) 
$$H_2C=\underset{CH_3}{C}-COOH \xrightarrow[(ii)\ H_2O_2,\ OH^-]{(i)\ BH_3,\ THF} (Y)$$

(*f*) $2HC \equiv CH \xrightarrow[O_2]{Cu^{2+}} (Z)$

SOLUTION.

(*a*)



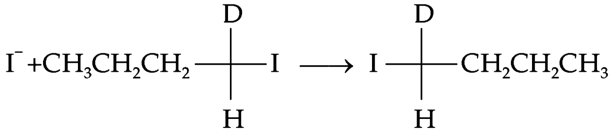
$$H_3C-\overset{C_2H_5}{\underset{CH=CH_2}{C}}-H + D_2 \xrightarrow{Pd} H_3C-\begin{array}{c}C_2H_5\\ C \\ C \\ CH_2D\end{array}\begin{array}{l}\\ -H\\ -D\\ \\\end{array} + H_3C-\begin{array}{c}C_2H_5\\ C \\ C \\ CH_2D\end{array}\begin{array}{l}\\ -H\\ -H\\ \\\end{array}$$

(T) **(U)**

(*b*) $RCOCl \xrightarrow[(ii)\ H_2O]{(i)\ N_3H,\ \Delta} RNH_2$

(V)

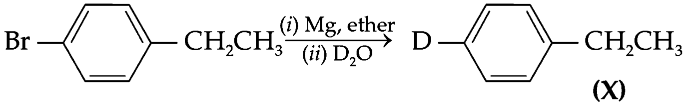
(*c*)



$$I^- + CH_3CH_2CH_2-\overset{D}{\underset{H}{C}}-I \longrightarrow I-\overset{D}{\underset{H}{C}}-CH_2CH_2CH_3$$

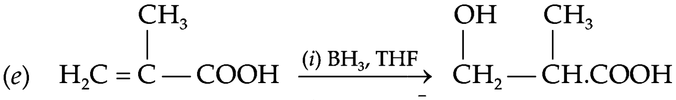
(W)

(*d*)



(X)

(*e*)



$$H_2C=\overset{CH_3}{C}-COOH \xrightarrow[(ii)\ H_2O_2,\ OH^-]{(i)\ BH_3,\ THF} \overset{OH}{CH_2}-\overset{CH_3}{CH}.COOH$$

(Y)

(*f*) $2CH \equiv CH \xrightarrow[O_2]{Cu^{2+}} HC \equiv C-C \equiv CH$

(Z)

EXAMPLE 136. *Compound (A) C_7H_8O is insoluble in aqueous sodium bicarbonate but dissolves in equeous sodium hydroxide and gives a characteristic colour with aqueous ferric chloride. When treated with bromine, (A) forms a compound (B) $C_7H_5OBr_3$*

(*i*) *Give structural formula of (A) and (B)*

(*ii*) *What would be the structure of (A) if it neither dissolves in aqueous sodium hydroxide nor gives a characteristic colour with $FeCl_3$.* **(Roorkee, 1993)**

SOLUTION. Since (A) is insoluble in $NaHCO_3$ but dissolves in NaOH; also gives characteristic colour with $FeCl_3$ (aq), so, (A) has a phenolic group, –OH. Also, (A) forms $C_7H_5OBr_3$ with Br_2. Considering molecular formula of (A), (A) appears to have CH_3 group. So, we have; $C_6H_4(CH_3)$ (OH) *i.e.*, cresol. Considering bromination, (A) can be  because meta position can form tribromoderivative as shown below.

(*i*) 
no reaction as NaHCO$_3$ is a weak base.

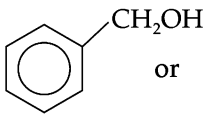
m-cresol

(A)

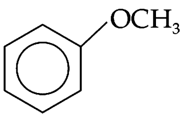
(*ii*) 
(A)

(*iii*) 
(B)

(*iii*) If (A) neither dissolves in NaOH (aq) nor gives characteristic colour with $FeCl_3$, it will be a neutral compound. So, (A) can be



or



Benzyl alcohol Methoxy benzene or anisol

EXAMPLE 137. *(A), (B), (C), (D), (E), (F), and (G) are amines, each of which forms a hydrochloride containing 32.42% chlorine. (A), (B), (C) and (D) evolve N_2 on reaction with HNO_2 but (E), (F) and (G) donot. Give structures of (A) to (G) with reasons.* **(Roorkee, 2001)**

SOLUTION. Amines hydrochloride = C_nH_{2n+3}. N. HCl

Also, since all amines have fixed Cl = 32.42%, so :

For 32.42 Cl, amine = (100 – (32.42 + 1) = 66.58

[∵ HCl = 1 + 32.42 (given)]

$$\text{For 35.5 Cl, amine} = \frac{66.58 \times 35.5}{32.42} = 72.9$$

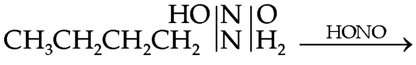
∴ In C_nH_{2n+3} N ; 12n + 1(2n + 3) + 14

= 72.9 ; 14n = 55.9 ≃ 56 ; *n* = 4

∴ Amine = $C_4H_{11}N$.

The expected isomers will be on the basis that some amines evolve N_2 with HNO_2 *i.e.*, some are primary amines which will have NH_2 group. Thus :

(*i*)

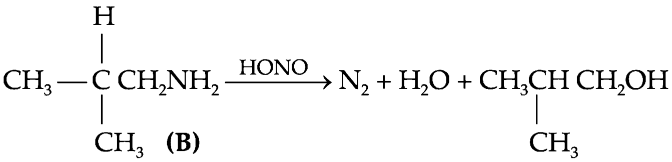


$$CH_3CH_2CH_2CH_2\,\overset{HO}{N}\overset{N}{N}\overset{O}{H_2} \xrightarrow{HONO}$$

(A)

$N_2 + H_2O + CH_3CH_2CH_2CH_2OH$

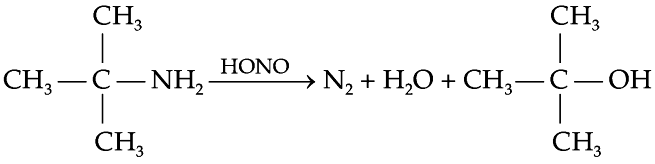
(*ii*)



$$CH_3-\underset{CH_3}{\overset{H}{C}}CH_2NH_2 \xrightarrow{HONO} N_2 + H_2O + CH_3\underset{CH_3}{CH}\,CH_2OH$$

(B)

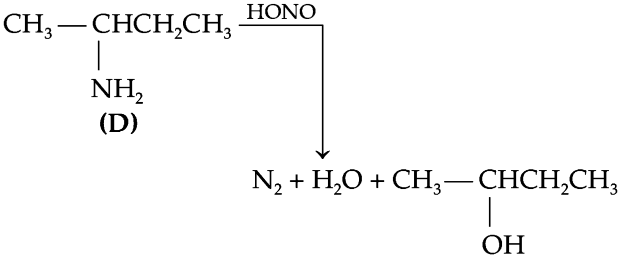
(*iii*)



$$CH_3-\underset{CH_3}{\overset{CH_3}{C}}-NH_2 \xrightarrow{HONO} N_2 + H_2O + CH_3-\underset{CH_3}{\overset{CH_3}{C}}-OH$$

(C)

(*iv*)

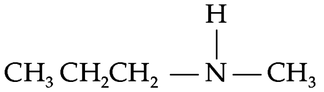


$$CH_3-\underset{NH_2}{CH}CH_2CH_3 \xrightarrow{HONO} N_2 + H_2O + CH_3-\underset{OH}{CH}CH_2CH_3$$

(D)

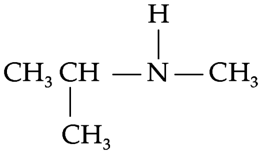
Other amines which donot give N_2 with HNO_2 will be 2° and 3° amines. Thus, we have.

(*v*)



$$CH_3CH_2CH_2-\overset{H}{N}-CH_3$$

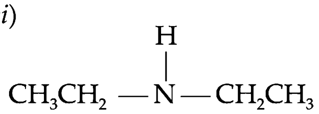
or



$$CH_3\underset{CH_3}{CH}-\overset{H}{N}-CH_3$$

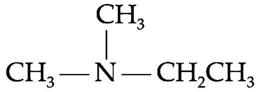
(E) **(E)**

(*vi*)



$$CH_3CH_2-\overset{H}{N}-CH_2CH_3$$

or



$$CH_3-\overset{CH_3}{N}-CH_2CH_3$$

(F)

EXAMPLE 138. *The percentage of carbon, hydrogen and nitrogen in a disubstituted aromatic compound (A) is 71.11, 6.67 and 10.37 respectively. Its molecule contains a single atom of nitrogen. Compound (A) evolves NH_3 when heated with NaOH to form salt (B), from which an acid (C) is obtained on acidification. If an electrophilic substitution is carried on (C), an entering electrophile can occupy either of the two identical positions available in the ring. Acid (C) on heating with PCl_5, gives (D) which reacts with (B) to give an organic product (E). Give structures of (A) to (E) with proper reasoning.*

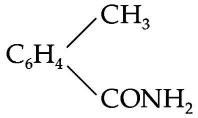
(Roorkee, 1996)

SOLUTION. (*i*) To find empirical formula of (A)

Element	% age	At. wt.	Relative no. of atoms = % age/at. wt.	Simple ratio	Whole no. ratio
C	71.11	12	$\frac{71.11}{12} = 5.92$	$\frac{5.92}{0.74} = 8$	8
H	6.67	1	$\frac{6.67}{1} = 6.67$	$\frac{6.67}{0.74} = 9$	9
N	10.37	14	$\frac{10.37}{14} = 0.74$	$\frac{0.74}{0.74} = 1$	1
O	100 – (71.11 + 6.67 + 10.37) = 11.85	16	$\frac{11.85}{16} = 0.74$	$\frac{0.74}{0.74} = 1$	1

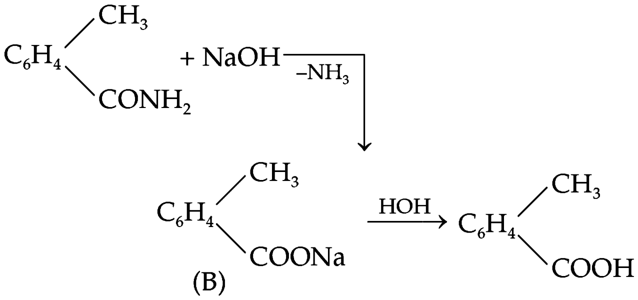
∴ E.F. = C_8H_9NO

(*ii*) Since (A) gives NH_3 when heated with NaOH, it will contain $-CONH_2$ group. Hence (A) is expected to be



$$C_6H_4\begin{matrix} CH_3 \\ CONH_2 \end{matrix}$$

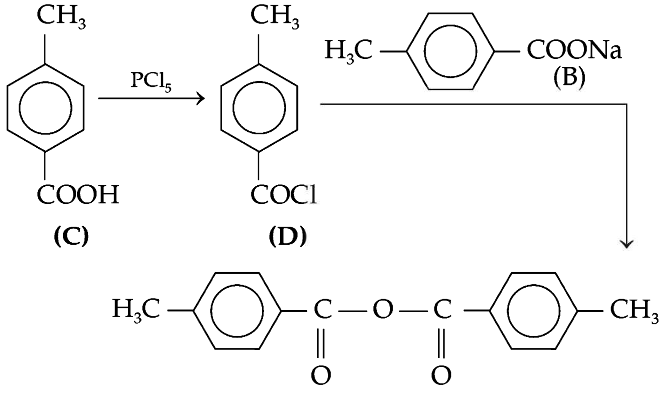
Reaction.



$$C_6H_4\begin{matrix} CH_3 \\ CONH_2 \end{matrix} + NaOH \xrightarrow{-NH_3} C_6H_4\begin{matrix} CH_3 \\ COONa \end{matrix} \xrightarrow{HOH} C_6H_4\begin{matrix} CH_3 \\ COOH \end{matrix}$$

(B)

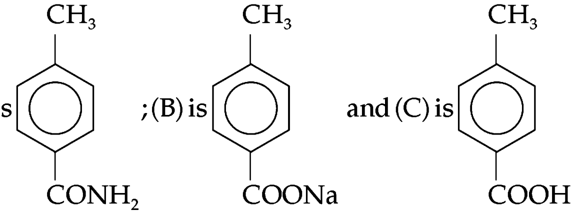
(*iii*) Since (C) on electrophilic substitution gives one product only, (C) will be para derivative. So, we have :



(C) **(D)**

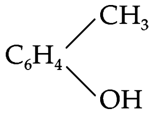
(E)

∴ (A) is ;(B) is and (C) is

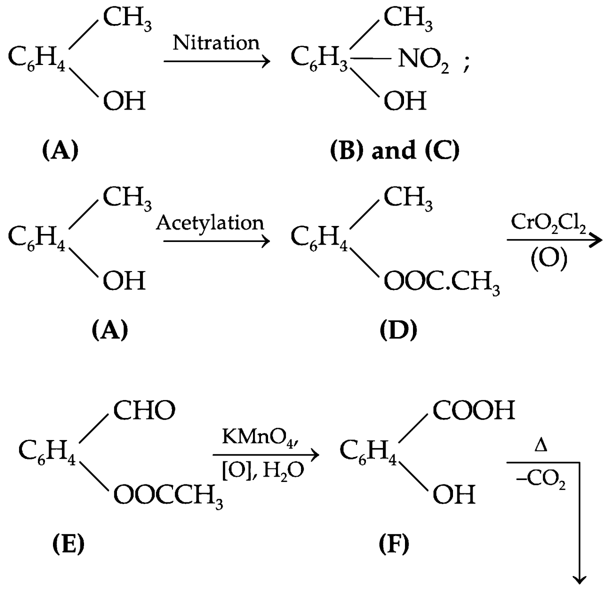


Example 139. *Two isomeric mononitroderivatives (B) and (C) are obtained by the nitration of an organic compound (A), C_7H_8O. Treatment of (A) with acetyl chloride produces (D), which on reaction with CrO_2Cl_2 gives (E) whose oxidation with neutral $KMnO_4$ followed by acdificaton gives, (F). The compound (F) on heating gives phenol. (A) on treatment with alkaline $C_6H_5SO_2Cl$ produces (G) which on oxidation with $KMnO_4$ gives (H). Hydrolysis of (H) also gives (F). Give structures of (A) to (H) with proper reasoning.* **(Roorkee, 1996)**

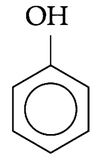
Solution. The reactions given in question suggest that C_7H_8O should contain a C_6H_4 group *i.e.*, (A) can be



$C_6H_4(CH_3)(OH)$ Thus :

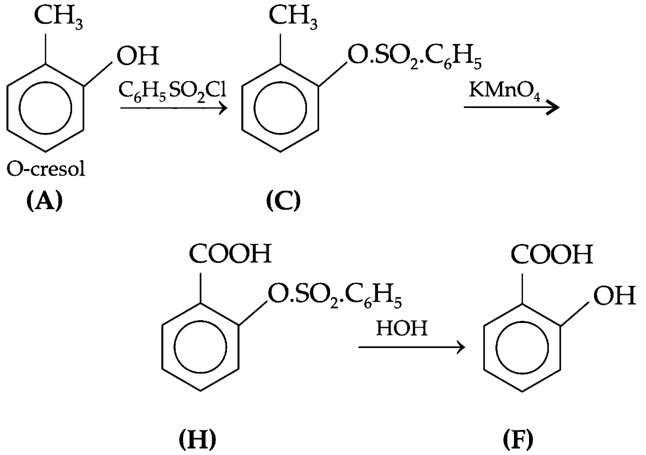


C_6H_5OH or

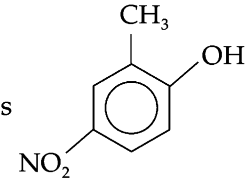


Phenol

It is given that (F) on heating gives phenol. So, (F) is orthoderivative and it is salicylic acid. Hence, (A), (D) and (E) are orthoderivatives, as shown below

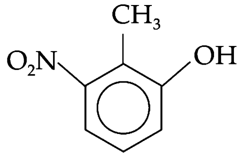


Similarly, **(B)** is



;

(C) is



Example 140. *An organic compound (A), $C_9H_{12}O$ was subjected to a series of tests in the laboratory. It was found that this compound*

(*i*) *rotates the plane of polarised light*

(*ii*) *evolves H_2 with sodium*

(*iii*) *reacts with I_2 and NaOH to produce a pale yellow solid compound*

(*iv*) *does not react with Br_2/CCl_4*

(*v*) *reacts wth hot $KMnO_4$ to form compound (B) $C_7H_6O_2$ which can also be synthesised by the reaction of benzene and carbonyl chloride followed by hydrolysis*

(*vi*) *loses optical activity as a result of formation of compound (C) on being heated with HI and P*

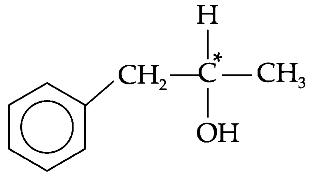
(*vii*) *reacts with Luca's reagent in about 5 minutes.*

Give structures of (A) to (C) with proper reasoning and draw Fischer projections for (A). Give reactions for steps, wherever, necessary. **(Roorkee, 1999)**

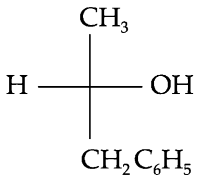
Solution. (*i*) Since the compound (A), $C_9H_{12}O$ rotates the plane of polarised light, it will have an asymmetric C*–atom. It forms iodoform (yellow ppt.) with NaOH and

I_2, it will have  $CH_3—\underset{OH}{\overset{H}{C}}—$ group. which also gives H_2 with Na(due to – OH group).

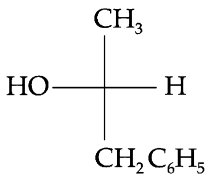
So, (A) can be



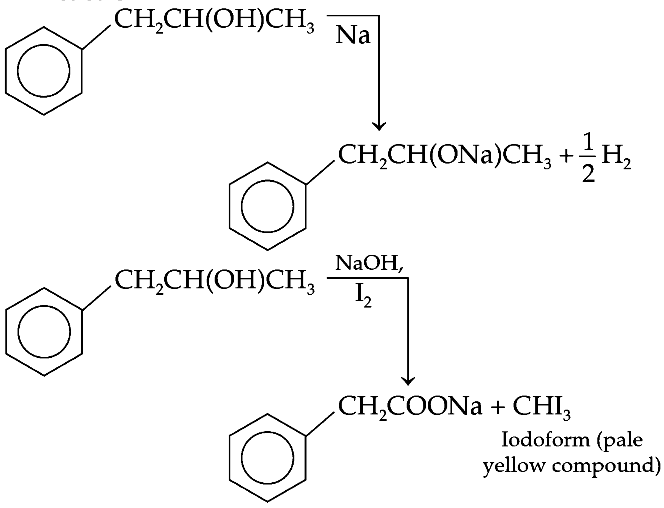
or



and

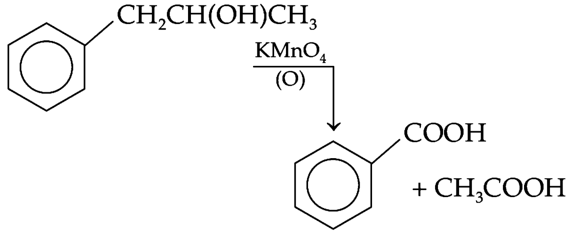


Reaction.

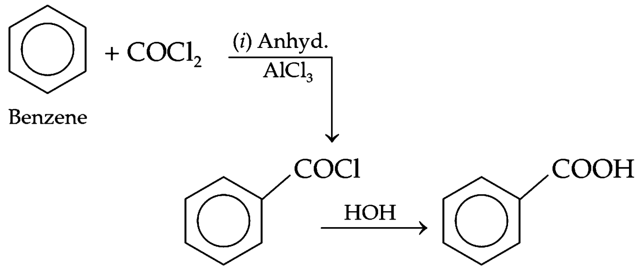


(*ii*) It does not react with Br_2/CCl_4

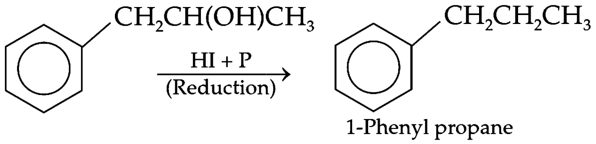
(*iii*)



Also,



(*iv*)



1-Phenyl propane (optically inactive)

(*v*) Since (A) reacts with Lucas reagent in about 5 minutes, it will contain secondary alcoholic group, – CHOH

EXAMPLE 141. *An organic compound (A) containing C = 81.6%, H = 4.8%, N = 13.6% has vapour density 51.5. It gives off ammonia upon heating with KOH. Reaction of (A) with Na and ethanol gives a basic compound (B) which gives off N_2 and forms an alcohol (C) when reacted with HNO_2. The alcohol (C) can be oxidised to benzoic acid. Identify (A). (B) and (C) and explain the reactions.* **(UPSEAT, 1994)**

SOLUTION. (*i*) To find empirical formula of (A) compound.

Element	% age	At. wt.	Relative no. of atoms = % age/ at. wt.	Simple ratio	Whole no. ratio
C	81.6	12	$\frac{81.6}{12}=6.8$	$\frac{6.8}{0.97}=7$	7
H	4.8	1	$\frac{4.8}{1}=4.8$	$\frac{4.8}{0.97}=5$	5
N	13.6	14	$\frac{13.6}{14}=0.97$	$\frac{0.97}{0.97}=1$	1

$\therefore$ E.F. = C_7H_5N ;

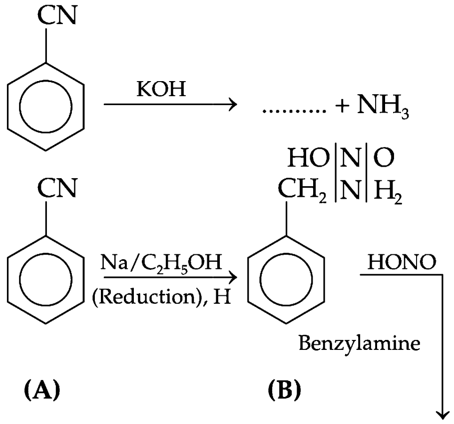
$$\text{E.F. wt.} = (7 \times 12) + (5 \times 1) + (1 \times 14) = 103$$

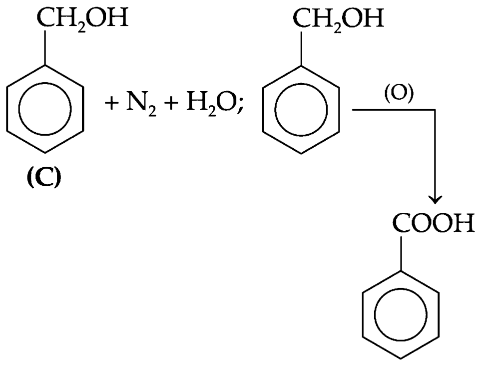
$$\text{M.F.} = \frac{\text{Mol. wt.}}{\text{E.F. wt}} \times \text{E.F.} = \frac{2 \times \text{V.D}}{\text{E.F. wt.}} \times \text{E.F.}$$

$$= \frac{2 \times 51.5}{103} \times C_7H_5N = C_7H_5N$$

$\therefore$ (A) can be 
Since (A) gives off NH_3 on heating with KOH, it can have —CN group.

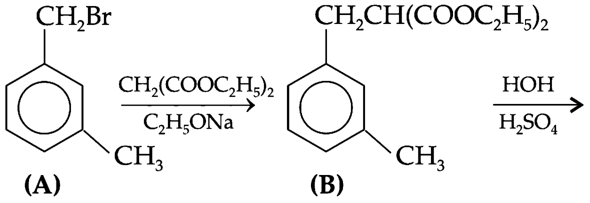
(*ii*) The reactions can be :

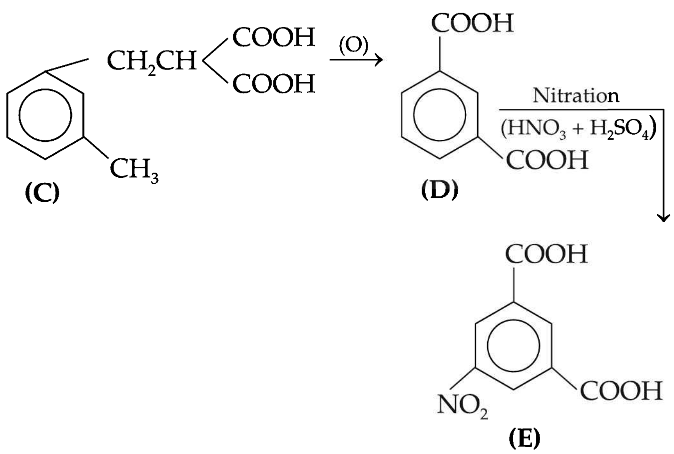




EXAMPLE 142. *An aromatic compound (A), C_8H_9Br reacts with $H_2C\ (COOC_2H_5)_2$ in the presence of C_2H_5ONa to give (B). Compound (B) on refluxing with dil. H_2SO_4 gives (C) which on vigorous oxidation gives (D). The compound (D) is a dibasic acid but on heating does not give an anhydride. It forms a mononitro-derivative (E), in which all the substituents are at equidistant from one another. Give structures of (A) to (E) with proper reasoning.* **(Roorkee, 1998)**

SOLUTION. The molecular formula of (A), C_8H_9Br indicates that the substituents are bonded to the benzene ring. Since it reacts with a bulky group $CH_2(COOC_2H_5)_2$ and other given data, the substituents are expected at meta position. Thus :



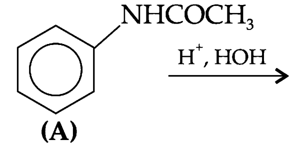


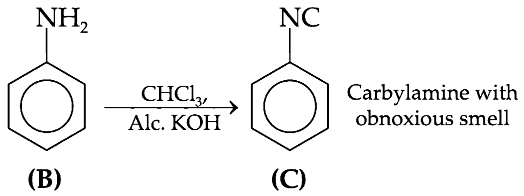
Since (E) is mono-nitroderivative in which all the substituents are at equidistant from each other, it will be a symmetrical trisubstituted (1, 3, 5) product indicating that the two substituents in compounds (A) to (D) are at the meta position.

EXAMPLE 143. *A colourless substance (A) is sparingly soluble in water and gives (B) on heating with mineral acids. Compound (B) on reaction with $CHCl_3$ and alcoholic potash produces an obnoxious smell of carbylamine due to the formation of (C). Compound (A), on reaction with chlorosulphonic acid gives (D) which on treatment with ammonia gives (E). Compound (E) on acid hydrolysis gives sulphanilamide, a well known drug. Give structures of (A) to (E) with proper reasoning.* **(Roorkee, 1998)**

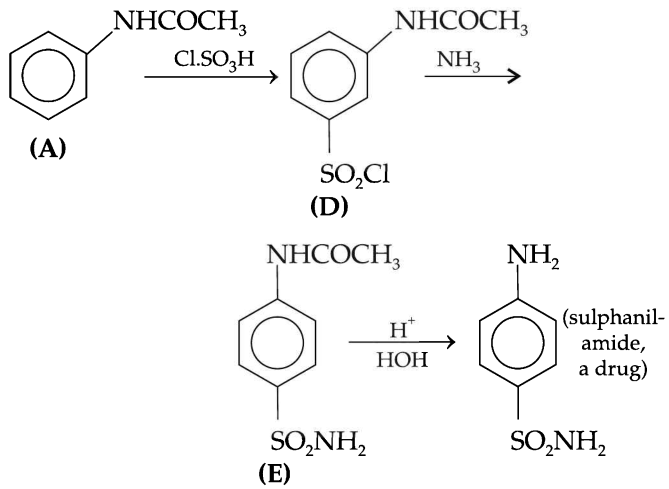
SOLUTION. Since the compound (C) having unpleasant smell is formed by the action of (A) on $CHCl_3$/alc. KOH, (A) should have NH_2 group (1°–amine). Since (A) gives a mineral acid on heating and (A) is also, insoluble in water, it is expected to be acetanilide. So, we have :

(*i*)





(*ii*)



EXAMPLE 144. *Structures of some reactants and products are given in columns I and II respectively. Firstly match the appropriate reactant product pair from columns I and II and then suggest another suitable reagent for each pair.*

Column I		**Column II**	
(*a*)	$R—CH=CH_2$	(*i*)	(*b*)		(*ii*)	(*c*)		(*iii*)	
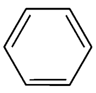
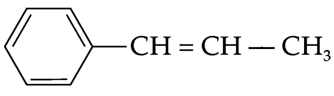
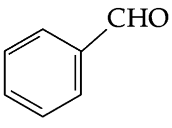
(d)



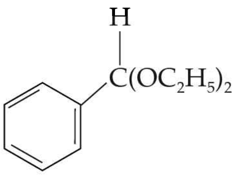
(iv)



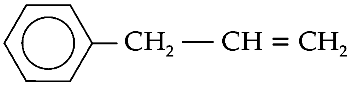
(e)



(v)



(f)



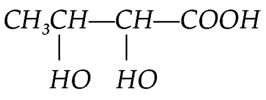
(vi) R — $CHClCH_2CCl_3$ **(Roorkee, 2003)**

SOLUTION.

Column I	Column II	Other Reagent
(*a*) R—CH = CH_2	(*vi*)  $\underset{\displaystyle Cl}{RCH}\,CH_2CCl_3$	CCl_4/ Peroxide
(*b*) 	(*i*) 	HCOOH or Baeyer's reagent or OsO_4 (aq) + $NaHSO_3$
(*c*) 	(*iii*) 	KOH(aq)
(*d*) 	(*ii*) 	ICl or I_2 + HNO_3
(*e*) 	(*v*) 	C_2H_5OH + dry HCl
(*f*) 	(*iv*) 	KOH + heat

EXAMPLE 145. *Read the statements given below and write 'true' against correct statements. If any of the statements is wrong, rectify the mistake/mistakes and give a correct statement in its place*

(*a*) *Tollen's reagent converts* $CH_3CH = CH—CHO$ *to*



$$\underset{\displaystyle HO}{CH_3CH}—\underset{\displaystyle HO}{CH}—COOH$$

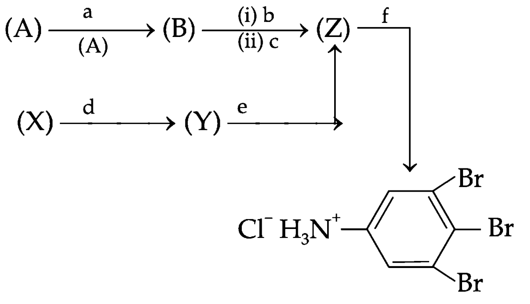
(*b*) *Total number of optical isomers of 3, 4 –dichlorohexane is 3.*

(*c*) *When heated with dil.* H_2SO_4, $C_6H_5\,SO_3H$ *undergoes further sulphonation to give* $C_6H_4\,(SO_3H)_2$.

(*d*) *Addition of HI to 3, 3 – dimethyl - 1- butene not only gives 1-iodo-3, 3-dimethyl butane but also 2-iodo-2, 3-dimethyl butane.* **(Roorkee, 2001)**

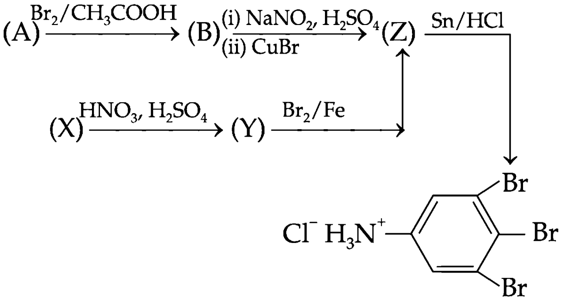
SOLUTION. (*a*) It is not true because Tollen's reagent converts $CH_3CH = CH—CHO$ to $CH_3CH = CH\,COOH$. (*b*) It is true (*c*) It is not correct because desulphonation takes place to form benzene. (*d*) It is not correct because it not only gives 3-iodo-2, 2-dimethyl butane but also 2-iodo-2, 3-dimethyl butane or 3-iodo-2, 3-dimethyl butane.

EXAMPLE 146.



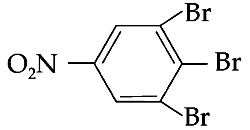
Give structures of (A), (B), (X), (Y) and (Z) in the above scheme of reactions. If reagents a, b, c, d, e and f are Br_2/ CH_3COOH, $NaNO_2/H_2SO_4$ + CuBr, HNO_3/H_2SO_4, Br_2/Fe *and Sn/HCl respectively.* **(Roorkee, 2001)**

SOLUTION.



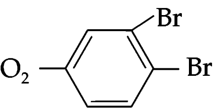
(*i*) Since last compound obtained by the reduction of (Z) with Sn/HCl,(Z) should contain $–NO_2$ group in place of $Cl^-–H_3N^+$. So :

(Z) is



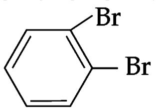
(*ii*) Since (Z) is obtained by the action of (Y) on Br_2/ Fe, (Y) should have one Br-atom less than (Z). So :

(Y) is



(*iii*) Since (Y) is obtained by the nitration of (X), so (X) should have no $–NO_2$ group. hence:

(X) is



(*iv*) Since (Z) is obtained by the action of (*i*) $NaNO_2$ + H_2SO_4 and (*ii*) Cu Br, (B) should also contain $-NH_2$ group. So :

(B) is 
(*v*) Since (B) is obtained by the bromination of (A), so (A) should not have any Br group. So :

(A) is 
EXAMPLE 147. *A hydrocarbon (A) of molecular weight 54 reacts with an excess of Br_2 in CCl_4 to give a compound (B) whose molecular weight is 593% more than that of (A). However, on catalytic hydrogenation, with excess of hydrogen, (A) forms (C) whose molecular weight is only 7.4% more than that of (A). (A) reacts with CH_3CH_2Br in the presence of $NaNH_2$ to give another hydrocarbon (D) which on ozonolysis yields diketone (E). (E) on oxidation gives propionic acid. Give structures of (A) to (E) with reasons.* **(Roorkee, 1997)**

SOLUTION. Step1. Calculation of molcular mass of (B) and (C)

The mol. wt. of compound A = 54

Mol. wt. of compound (B) formed by treatment of A

$$\text{with } Br_2 \text{ in } CCl_4 = \frac{(100+593)}{100} \times 54 = 374.22$$

Thus the increase in weight due to addition of Br atoms

$$= 374.22 - 54.0 = 320.22$$

Therefore, the number of bromine atoms added

$$= \frac{320.22}{80} = 4 \quad [\because \text{ At. wt. of Br} = 80]$$

Hence, the hydrocarbon must be an alkyne.

Mol. wt. of compound (C) formed by hydrogenation of A

$$= \left(\frac{100+7.4}{100}\right) \times 54 = 57.994$$

$$= 58 \text{ (approx)}$$

Thus, the increase in weight due to addition of H atoms

$$= 58 - 54 = 4$$

$$\text{Number of H-atoms added} = \frac{4}{1} = 4$$

This also suggests that hydrocarbon A must be an alkyne.

Step 2. *Structures of (A), (B), (C) and (D)*

Molecular formula of an alkyne having molecular mass

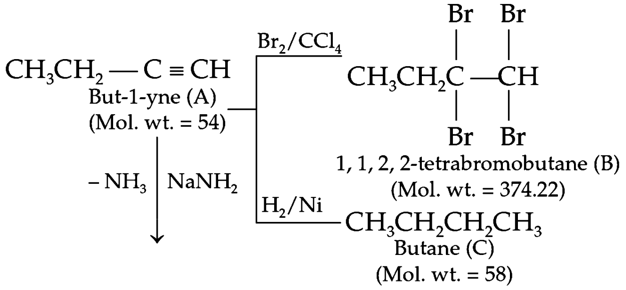
$$54 = C_4H_6$$

Two possible structures for an alkyne are :

$$\underset{\text{But-1-yne}}{CH_3CH_2C\equiv CH} \qquad \underset{\text{But-2-yne}}{CH_3\text{—}C\equiv C\text{—}CH_3}$$

Since (A) reacts with CH_3CH_2Br in presence of Na NH_2 to give another hydrocarbon (D), therefore (A) must be But-1-yne which is a terminal alkyne.

Considering (A) as But-1-yne, the structures of (B), (C) and (D) can be derived as follows:

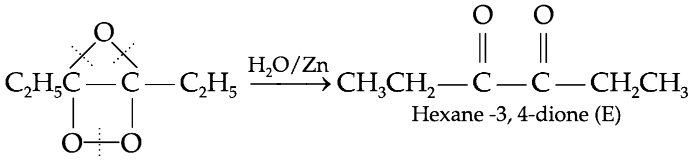


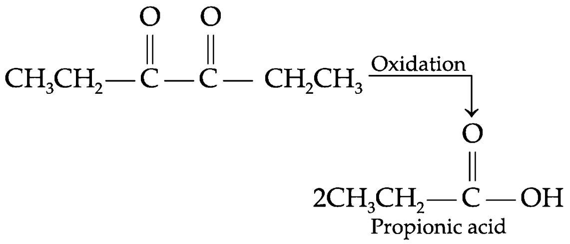
$$CH_3CH_2—C\equiv C^- Na^+ \xrightarrow[-\text{Na Br}]{CH_3CH_2Br} \underset{\text{Hex-3-yne (D)}}{CH_3CH_2C\equiv C.\,CH_2CH_3}$$

Step 3. *Structure of diketone E*

Since the hydrocarbon (D) *i.e.*, Hex-3-yne on ozonolysis gives a diketone (E), which on further oxidation gives propionic acid, therefore, E must be hexane-3, 4-dione as explained below :

$$CH_3CH_2C\equiv C.\,CH_2CH_3 \xrightarrow{O_3}$$





Thus A = but-1-yne, B = 1, 1, 2, 2-tetrabromobutane, C = Butane, D = Hex-3-yne, E = Hexane-3, 4-dione.

EXAMPLE 148. *Compound (A) with molecular weight 108 contained 88.89% C and 11.11% H. It gave a white precipitate with ammoniacal silver nitrate. Complete hydrogenation of (A) gave another compound (B) with molecular weight 112. Oxidation of (A) gave an acid with equivalent weight 128. Decarboxylation of acid gave cyclohexane. Give structures of (A) and (B) and write the equations of the reactions involved.* **(Roorkee, 1988)**

SOLUTION. Calculation of empirical formula

Element	% age	Atomic mass	Relative no. of atoms = % age/at. mass	Simplest ratio	Simple Whole no. ratio
C	88.89	12	$\frac{88.89}{12} = 7.4$	$\frac{7.4}{7.4} = 1$	1 × 2 = 2
H	11.11	1	$\frac{11.11}{1} = 11.11$	$\frac{11.11}{7.4} = 1.5$	1.5 × 2 = 3

∴ Empirical formula = C_2H_3

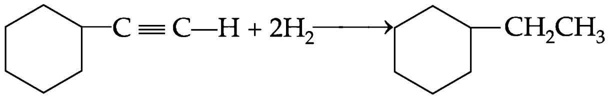
Empirical formula wt. = $2 \times 12 + 1 \times 3 = 27$

Molecular wt. = 108

$n = 108/27 = 4$

∴ Molecular formula = $n \times \text{E.F.} = 4 \times C_2H_3 = C_8H_{12}$(A)

As the hydrocarbon (A) gives white ppt. with $AgNO_3$, it should be an alkyne which on hydrogenation should give C_8H_{16} (B) having molecular weight 112. Oxidation of (A) gave an acid having equivalent weight 128 which on decarboxylation gave cyclohexane. Hence (A) is hydrocarbon having six membered ring and an unsaturated side chain. The structures of A and B and the reactions involved are :



EXAMPLE 149. *448mL of hydrocarbon (A) having C, 87.80% ; H, 12.19% weigh 1.64g at STP. On hydrogenation it gives 2-methylpentane. Treatment of (A) with acidic $HgSO_4$ gives a new compound (B) having molecular formula $C_6H_{12}O$. Compound (A) does not react with ammoniacal $AgNO_3$. Find out the structure of (A) and explain the reactions involved.*

(Roorkee, 1989)

SOLUTION. 448mL of (A) at STP weighs 1.64g.

$$22400\text{mL of A at STP weigh} = \frac{1.64}{448} \times 22400 = 82\text{g}$$

∴ Molecular weight of A = 82

Calculation of empirical formula

Element	% age	Atomic mass	Relative no. of atoms = % age/at. mass	Simple ratio	Whole no. ratio
C	87.8	12	87.8/12 = 7.31	7.31/7.31 = 1	1 × 3 = 3
H	12.19	1	12.19/1 = 12.19	12.19/7.31 = 1.66	1.66 × 3 = 4.98 ≃ 5

Empirical formula = C_3H_5

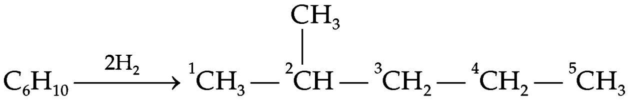
Empirical formula mass = $12 \times 3 + 1 \times 5 = 41$

$$n = \frac{\text{Mol. mass}}{\text{Emp. formula mass}} = \frac{82}{41} = 2$$

∴ Molecular formula of

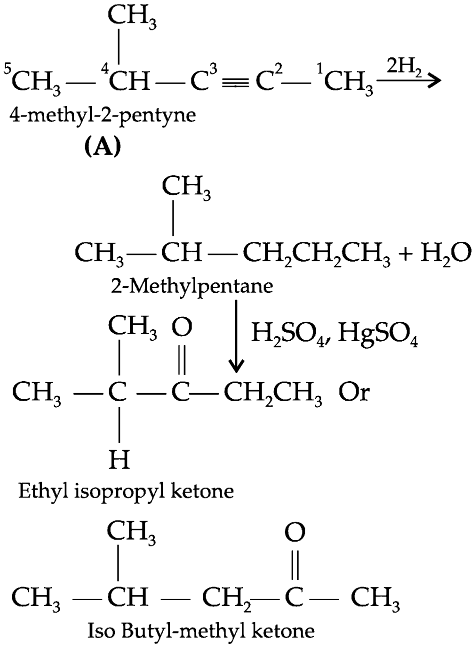
$$A = n \times \text{E.F.} = 2 \times C_3H_5 = C_6H_{10}$$

Treatment of (A) with acidic $HgSO_4$ gives (B) having molecular formula $C_6H_{10}O$. Conversion of (A) to (B) involves the addition of a water molecule and is a characteristic reaction of alkyne. Hence (A) is an alkyne. Further (A) does not react with ammonical $AgNO_3$ indicating the absence of a terminal carbon-carbon triple bond. The exact position of the triple bond in (A) is established by the fact that (A) on hydrogenation gives 2-methylpentane.



$$C_6H_{10} \xrightarrow{2H_2} {}^{1}CH_3-{}^{2}\underset{}{\overset{CH_3}{\overset{|}{C}H}}-{}^{3}CH_2-{}^{4}CH_2-{}^{5}CH_3$$

Since triple bond is not possible between C_2 and C_3 and hence it must be between C_3 and C_4. Thus the compound (A) is 4-methyl-2-pentyne which explains all the given reactions.



27.5 AIEEE PATTERN EXAMPLES

EXAMPLE 150. *Bottles containing C_6H_5I and $C_6H_5CH_2I$ lost their original labels. They were labelled as A and B for testing. A and B were separately taken in test tubes and boiled with NaOH solution. The end solution in each tube was made acidic with dil. HNO_3 and then some $AgNO_3$ solution was added. Substance B gave a yellow precipitate. Which one of the following statements is true for this statement ?*

(*i*) *Addition of HNO_3 was unnecessary*

(*ii*) *A was C_6H_5I*

(*iii*) *A was $C_6H_5CH_2I$*

(*iv*) *B was C_6H_5I* **(AIEEE, 2003)**

SOLUTION. According to the given data, we have :

(*i*) $C_6H_5I \xrightarrow{NaOH} C_6H_5ONa \xrightarrow{HNO_3} C_6H_5OH \xrightarrow{AgNO_3}$ No yellow ppt.

(*ii*) $C_6H_5CH_2I \xrightarrow{NaOH} C_6H_5CH_2ONa$

So, A is C_6H_5I and B is $C_6H_5CH_2I$.

EXAMPLE 151. *An aromatic compound 'Y' having molecular formula C_7H_7NO produces ammonia on heating with alkali. When Y is treated with bromine and alkali, the product will be :*

(*a*) *Aniline* (*b*) *Benzonitrile*

(*c*) *Benzoic acid* (*d*) *Benzamide.*

Solution. The compound produces ammonia on heating with alkali. So, C_7H_7NO must be an amide *i.e.*, benzamide. Since amide is treated with Br_2 and alkali, it must be Hofmann bromamide reaction to form aniline.

$$\underset{\text{Benzamide}}{C_6H_5CONH_2} + NaOH \xrightarrow{\text{Boil}} C_6H_5COONa + NH_3$$

$$C_6H_5CONH_2 \xrightarrow{Br_2/NaOH} C_6H_5NH_2 \text{ (aniline)}$$

Example 152. *An alkene with molecular formula C_8H_{16} on oxidation with hot $KMnO_4$ gives acetone and 3-pentanone. The structure of the alkene is :*

(*a*) $(CH_3)_2C = C(C_2H_5)_2$
(*b*) $(CH_3)(C_2H_5)C = C(CH_3)(C_2H_5)$
(*c*) $CH_3CH_2CH_2CH = C(C_2H_5)_2$
(*d*) $(CH_3)_2C = CH(CH_2)_3CH_3$

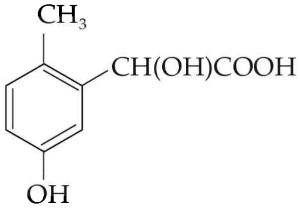
Solution. Since the given compound is alkene and it gives a mixture of ketones, the alkene must have undergone ozonolysis followed by action with H_2O. For such an ozonide reaction, the O–atoms of both keto groups facing each other are removed to get the unknown alkene. So, we have

$$\underset{\text{Acetone}}{(CH_3)_2C =}\boxed{O + O}\underset{\text{Pentanone}}{= C(C_2H_5)_2} \longrightarrow (CH_3)_2C = C(C_2H_5)_2$$

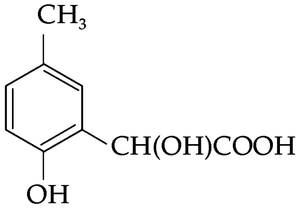
So, the correct answer is, (*a*).

Example 153. *p-cresol reacts with chloroform in alkaline medium to give the compound A which adds hydrogen cyanide to form the compound B. The latter on acidic hydrolysis gives chiral carboxylic acid. The structure of the carboxylic acid is :*

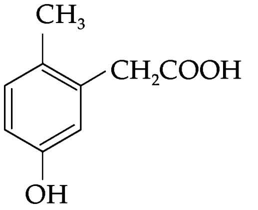
(*a*)



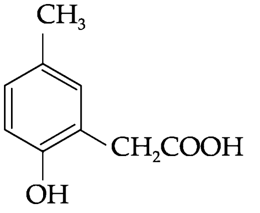
(*b*)



(*c*)

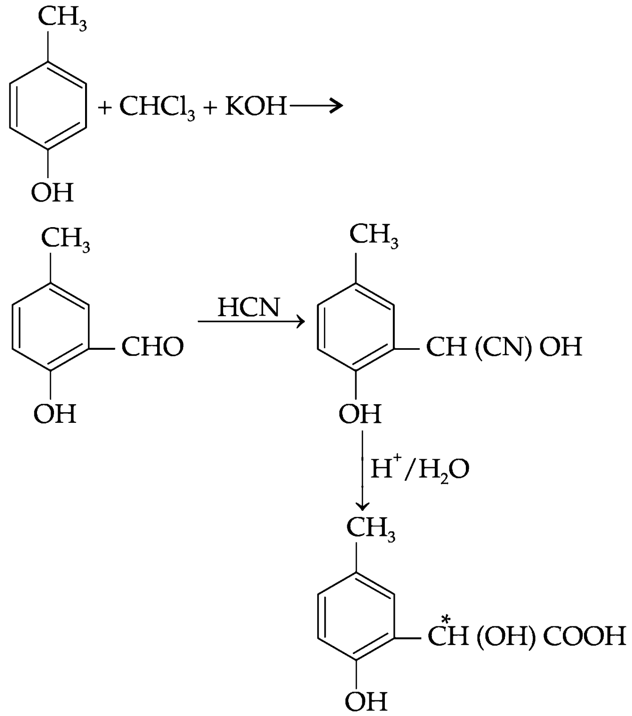


(*d*)



(AIEEE, 2005)

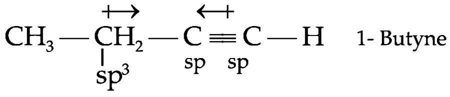
Solution.



So, the correct answer is (*b*)

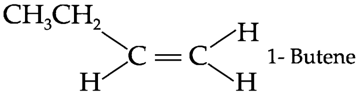
Example 154. *Which of the following has larger dipolemoment? Explain; 1-Butyne or 1-Butene.* **(Roorkee, 1999)**

Solution. Dipolemoment is a vector quantity. The direction of dipolemoment of individual bonds in 1-Butyne and 1-Butene are shown below :



$$CH_3 — \underset{sp^3}{\overset{+\!\!\rightarrow}{CH_2}} — \underset{sp}{\overset{\leftarrow\!\!+}{C}} \equiv \underset{sp}{C} — H$$

1- Butyne



1- Butene

In case of 1-Butyne, the resultant or net dipolemoment is due to the dipolemoments of C—H and CH_3CH_2—C bonds. These oppose each other. Since *sp* hybridised carbon atom is more electronegative than sp^2 carbon, we say that CH_3—CH_2—C (*sp*) is more polar than that of $CH_3—\underset{sp^3}{CH_2}—C(sp^2)$ in 1-Butene. Hence, 1-Butyne has more dipolemoment than that of 1-Butene.

Example 155. *When 32.25g of ethyl chloride is subjected to dehydrohalogenation reaction, the yield of the alkene formed is 50%. The mass of product formed is (atomic mass of chlorine is 35.5):*

(*a*) *14g* (*b*) *28g*
(*c*) *64.5g* (*d*) *56g*
(*e*) *7g*.

(Kerala PET, 2005)

Solution. Reaction

$$C_2H_5Cl \xrightarrow{-HCl} C_2H_4$$

$$(2 \times 12) + (5 \times 1) + 35.5 \qquad (2 \times 12) + (4 \times 1)$$

$$= 64.5g \qquad = 28g$$

Alkene C_2H_4 formed = 50%

Wt. of ethyl chloride = 32.25g

64.5g C_2H_5Cl form C_2H_4 = 28g

$$32.25\text{g } C_2H_5Cl \text{ form } C_2H_4 = \frac{28}{64.5} \times 32.25 = 14\text{g}$$

Since the yield is 50%, so mass of alkene (C_2H_4) formed

$$= 14 \times \frac{50}{100} = 7\text{g}$$

So, the correct answer is (*e*)

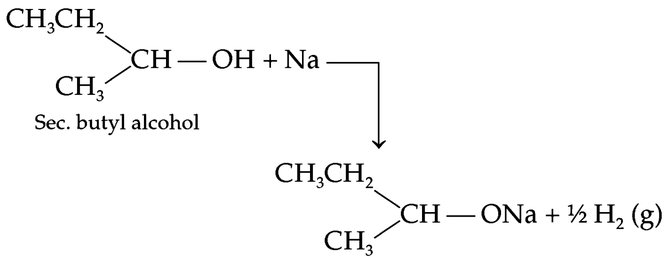
EXAMPLE 156. *A compound of the formula $C_4H_{10}O$ reacts with sodium and undergoes oxidation to give a carbonyl compound which does not reduce Tollen's reagent. The original compound is :*

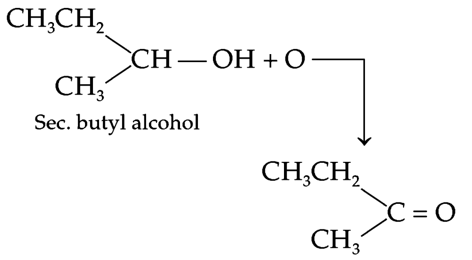
(*a*) *Diethyl ether* (*b*) *n-Butyl alcohol*

(*c*) *Isobutyl alcohol* (*d*) *Sec. butyl alcohol*

(JIPMER-Pondicherry, 2000)

SOLUTION. The given compound $C_4H_{10}O$ is an alcohol because an alcohol reacts with Na to form alkoxide and H_2 gas. Its oxidation product should be a ketone because ketones donot reduce Tollen's reagent.





Butan-2-one (ketone), a carbonyl compound

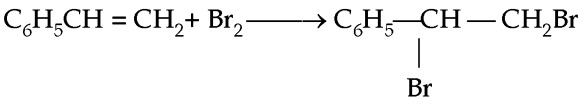
So, the correct answer is (*d*).

EXAMPLE 157. *Complete the following :*

$$C_6H_5CH = CH_2 \xrightarrow{Br_2} [A] \xrightarrow[(ii)\,CH_3I]{(i)\,NaNH_2\,(3.0\,eq)} [B]$$

(Styrene)

SOLUTION. Styrene adds a molecule of Br_2 to form 1, 2-dibromo product.

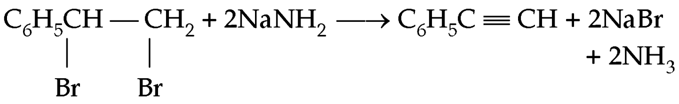


$$C_6H_5CH = CH_2 + Br_2 \longrightarrow C_6H_5\text{—}\underset{\substack{|\\ Br}}{CH}\text{—}CH_2Br$$

Phenyl-1, 2-dibromoethane

(A)

Like other dihalocompounds, (A) also reacts with $NaNH_2$ to form an alkyne.



$$C_6H_5\underset{\substack{|\\ Br}}{CH}\text{—}\underset{\substack{|\\ Br}}{CH_2} + 2NaNH_2 \longrightarrow C_6H_5C \equiv CH + 2NaBr + 2NH_3$$

$$C_6H_5C \equiv CH + NaNH_2 \longrightarrow C_6H_5C \equiv C.Na + NH_3$$

$$C_6H_5C \equiv C.Na + CH_3I \longrightarrow C_6H_5C \equiv C\text{—}CH_3 + NaI$$

1-Phenyl prop-1-yne

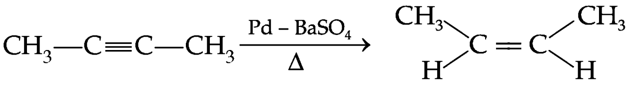
EXAMPLE 158. *When 2-butyne is treated with Pd-BaSO$_4$, the product formed will be :*

(*a*) *Cis-2-butene* (*b*) *trans-2-butene*

(*c*) *1-butene* (*d*) *2-hydroxy butane*

(DCE, 2005)

SOLUTION.



cis-2-butene

The product is cis-form because the reduction from $C \equiv C$ to $C == C$ bond is a syn type

So, the correct answer is (*a*).

EXAMPLE 159. *Which of the following gives iodoform test ?*

(*a*) *$CH_3CH_2(OH)$* (*b*) *C_2H_5CHO*

(*c*) *$(CH_2OH)_2$* (*d*) *none of these.*

(DCE, 2005)

SOLUTION. We know that compounds containing CH_3CO— group or compounds (like CH_3CH_2OH) which on oxidation with halogen and alkali gives CH_3CO— group, give haloform reaction *i.e.*, iodoform test.

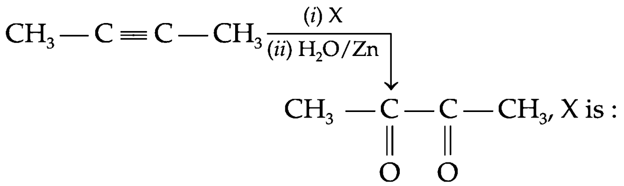
$$CH_3CH_2OH + 4I_2 + 6NaOH \xrightarrow{\Delta} CHI_3 + 5NaI + 5H_2O$$

Iodoform + HCOONa

Sodium formate

So, the correct answer is (*a*).

EXAMPLE 160. *In the reaction,*



$$CH_3\text{—}C \equiv C\text{—}CH_3 \xrightarrow[(ii)\,H_2O/Zn]{(i)\,X} CH_3\text{—}\underset{\substack{\|\\ O}}{C}\text{—}\underset{\substack{\|\\ O}}{C}\text{—}CH_3, \text{ X is :}$$

(*a*) *HNO_3* (*b*) *O_2*

(*c*) *O_3* (*d*) *$KMnO_4$*

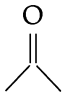
(DCE, 2005)

SOLUTION. Since ozonolysis of $\text{—}C \equiv C\text{—}$ followed by H_2O/Zn action gives $\text{—}\underset{\substack{\|\\ O}}{C}\text{—}\underset{\substack{\|\\ O}}{C}\text{—}$, *X* will be ozone, O_3.

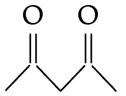
So, the correct answer is (*c*).

EXAMPLE 161. *Maximum enol content is in :*

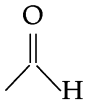
(*a*)



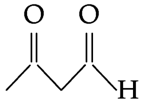
(*b*)



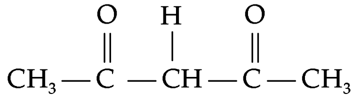
(*c*)



(*d*)

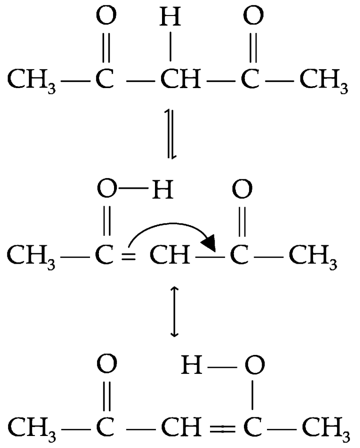


SOLUTION. The compound (*b*) is



$$CH_3-\overset{\overset{O}{\|}}{C}-\overset{\overset{H}{|}}{CH}-\overset{\overset{O}{\|}}{C}-CH_3$$

which can be represented by the following structures.



It may be noted that the enol content further increases if the enol form gets stabilised by H–bonding as well as by conjugation *i.e.*, enolic double bond is in conjugation with a multiple bond or a benzene ring. So, the correct answer is (*b*).

EXAMPLE 162. *Which of the following is most reactive towards nucleophilic substitution reaction ?*

(*a*) $CH_2 = CH—Cl$

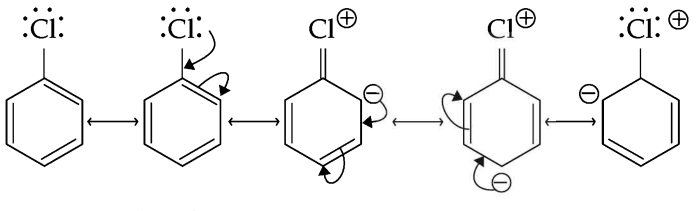
(*b*) C_6H_5Cl

(*c*) $ClCH_2—CH = CH_2$

SOLUTION. The compound (c) is the most reactive out of all the given compounds because in allyl chloride

$$\overset{3}{C}H_2 = \overset{2}{C}H\overset{1}{C}H_2Cl,$$

the π-electrons of carbon-carbon double bond increase the electron density at $\overset{1}{C}$ and help in breaking the carbon-halogen bond. In (*a*) *i.e.*, vinyl chloride ($CH_2 = CH—Cl$), each C–atom is sp^2 hybridised. There is also a partial double bond character between carbon and chlorine due to resonance. So, it is less reactive than (*d*). In (*b*) *i.e.*, C_6H_5Cl, there is a delocalisation of electron cloud and C—Cl bond is difficult to break.



So, order of reactivity is (*c*) > (*a*) > (*b*)

So, the correct answer is (*c*).

EXAMPLE 163. $[A] \xleftarrow[\textit{Catalyst}]{\textit{Lindlar's}} CH_3-C\equiv CH \xrightarrow[liq.\,NH_3]{\textit{Na in}} [B]$

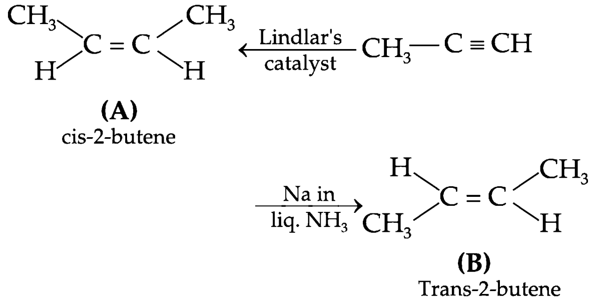
[A] and [B] are respectively

(*a*) *cis, trans-2-butene* (*b*) *both trans-2-butene*

(*c*) *trans-cis-2-butene* (*d*) *both cis - 2- butene.*

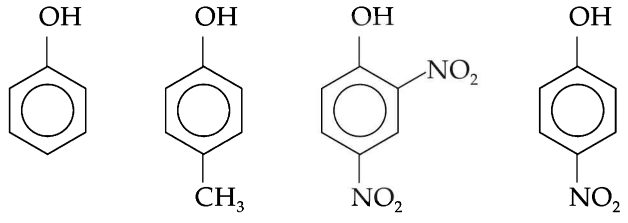
(DCE, 2005)

SOLUTION. Using Lindlar's catalyst (Pd deposited on $BaSO_4$ or $CaCO_3$, and partially poisoned by sulphur, Pb $(CH_3COO)_2$ or quinoline) or nickel boride (called P-2 catalyst), cis-alkenes are formed but with Na in liquid ammonia at 200K (Birch reduction), trans alkenes are formed.



So, the correct answer is (*a*).

EXAMPLE 164. *Strength of acidity is in order*



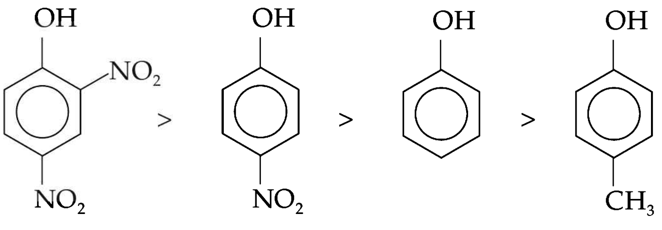
I II III IV

(*a*) *II > I > III > IV* (*b*) *III > IV > I > II*

(*c*) *I > IV > III > II* (*d*) *IV > III > I > II*

(DCE, 2005)

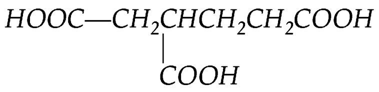
SOLUTION. —NO_2 is electron withdrawing group. Greater the number of electron withdrawing groups, greater the ease with which a proton is released. Hence greater the acidity. —CH_3 is electron releasing group. It increases the electron density on O—H bond. As a result, H^+ ions are not easily released. This causes reduced acidity. So, the strength of acidity is in the following order :



III IV I II

So, the correct answer is (*b*).

EXAMPLE 165. *The IUPAC name of the compound is :*



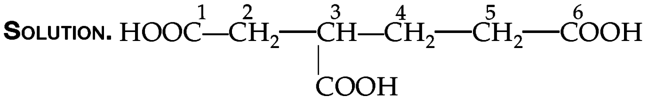
$$HOOC-CH_2\underset{\underset{COOH}{|}}{CH}CH_2CH_2COOH$$

(*a*) *2(carboxymethyl)-pentane 1, 5-dioic acid*

(*b*) *3-carboxyhexane-1, 6-dioic acid*

(*c*) *butane-1, 2, 4-tricarboxylic acid*
(*d*) *4-carboxy hexane-1, 6-dioic acid*
(*e*) *1, 2-dicarboxy pentanoic acid.* **(Kerala PET, 2005)**

SOLUTION.



$$\overset{1}{\text{HOOC}}-\overset{2}{\text{CH}_2}-\underset{\text{COOH}}{\overset{3}{\text{CH}}}-\overset{4}{\text{CH}_2}-\overset{5}{\text{CH}_2}-\overset{6}{\text{COOH}}$$

3–Carboxy hexane–1, 6–dioic acid,

So, the correct answer is (*b*).

EXAMPLE 166. *Propyne and propene can be distinguished by :*

(*a*) Conc. H_2SO_4		(*b*) Br_2 in CCl_4	
(*c*) alk. $KMnO_4$		(*d*) $AgNO_3$ in NH_3	

(DCE, 2005)

SOLUTION.

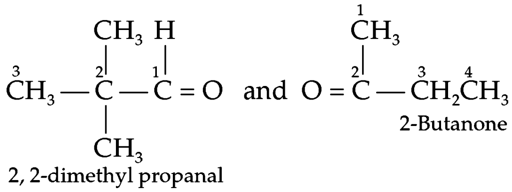
Action of	Propyne	Propene
(*a*) Conc. H_2SO_4	Addition	addition
(*b*) Br_2 in CCl_4	Colour discharges	Colour discharges
(*c*) alk. $KMnO_4$	Colour discharges	Colour is discharged
(*d*) $AgNO_3$ in NH_3	White ppt is formed $2CH_3.C \equiv CH + AgNO_3 + 2\,NH_4OH \longrightarrow 2CH_3C{\equiv}C\,Ag\downarrow + 2H_2O + 2NH_4NO_3$	No action

So, the correct answer is (*d*).

EXAMPLE 167. *An alkene having the molecular formula C_9H_{18} on ozonolysis gives 2, 2-dimethyl propanal and 2-butanone. The alkene is :*

(*a*) *2, 2, 4–trimethyl –3–hexene*
(*b*) *2, 2, 6–trimethyl–3–hexane*
(*c*) *2, 3, 4–trimethyl –2–hexene*
(*d*) *2, 2, 4– trimethyl –2–hexene*
(*e*) *2, 2–dimethyl –3–heptene.* **(Kerala PET, 2005)**

SOLUTION. The compounds formed on ozonolysis are :

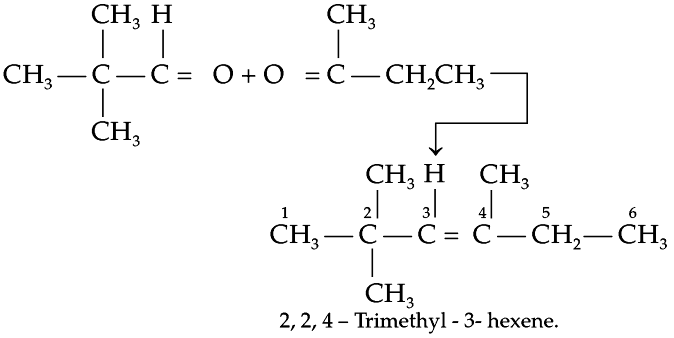


$$\overset{3}{\text{CH}_3}-\underset{\text{CH}_3}{\overset{\text{CH}_3}{\overset{2}{\text{C}}}}-\overset{\text{H}}{\overset{1}{\text{C}}}=\text{O} \quad \text{and} \quad \text{O}=\overset{\overset{1}{\text{CH}_3}}{\overset{2}{\text{C}}}-\overset{3}{\text{CH}_2}\overset{4}{\text{CH}_3}$$

2, 2-dimethyl propanal

2-Butanone

The structure of alkene can be obtained by removing the oxygen atoms of the two carbonyl carbons of products and making a double bond between the carbonyl carbon atoms. So, the alkene will be :



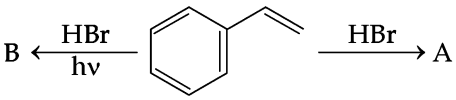
$$\text{CH}_3-\underset{\text{CH}_3}{\overset{\text{CH}_3}{\text{C}}}-\overset{\text{H}}{\text{C}}=\ \text{O}+\text{O}\ =\overset{\text{CH}_3}{\text{C}}-\text{CH}_2\text{CH}_3$$

$$\overset{1}{\text{CH}_3}-\underset{\text{CH}_3}{\overset{\text{CH}_3}{\overset{2}{\text{C}}}}-\overset{\text{H}}{\overset{3}{\text{C}}}=\overset{\text{CH}_3}{\overset{4}{\text{C}}}-\overset{5}{\text{CH}_2}-\overset{6}{\text{CH}_3}$$

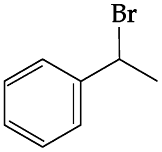
2, 2, 4 – Trimethyl - 3- hexene.

So, the correct answer is (*a*).

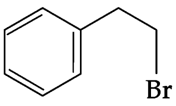
EXAMPLE 168. *Observe the following reactions and predict the nature of A and B*



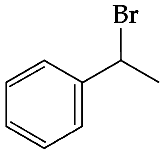
(*a*) *A and B both are*



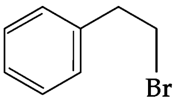
(*b*) *A and B both are*



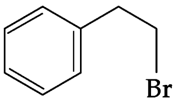
(*c*) *A is*



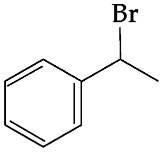
and B is



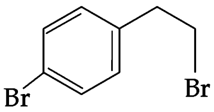
(*d*) A is



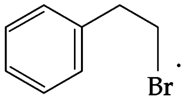
and B is



(*e*) *A is*



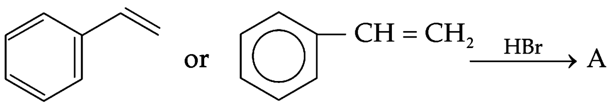
and B is



.

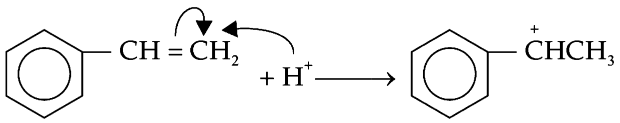
(Kerala PET, 2005)

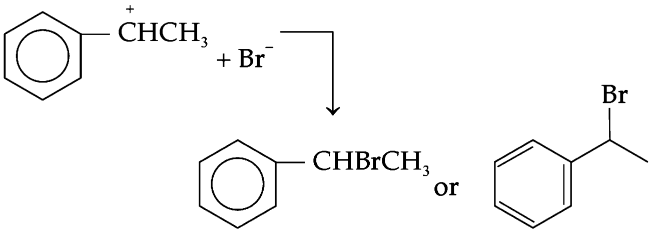
SOLUTION.



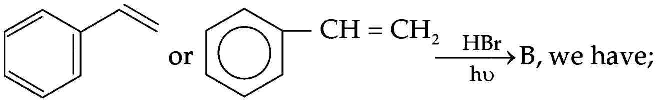
(*i*) HBr ⟶ $H^+ + Br^-$

(*ii*)

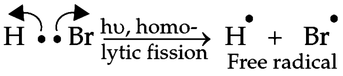




For



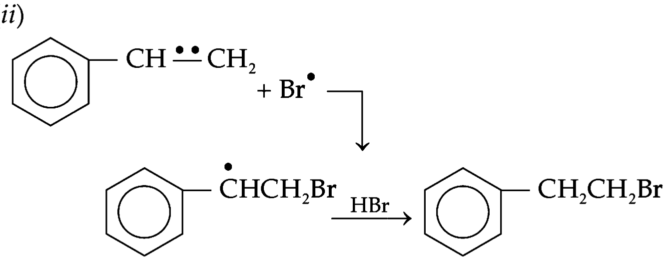
(*i*)



$$\text{H}\,{:}\,\text{Br} \xrightarrow[\text{lytic fission}]{\text{hυ, homo-}} \overset{\bullet}{\text{H}} + \overset{\bullet}{\text{Br}}$$

Free radical

(*ii*)



or  . So, the correct answer is (C).

Example 169. *Nitration of aniline in strongly acidic medium, results in the formaton of m–nitroaniline also. This is because :*

(*a*) *amino group is meta orienting during electrophilic substitution reaction*

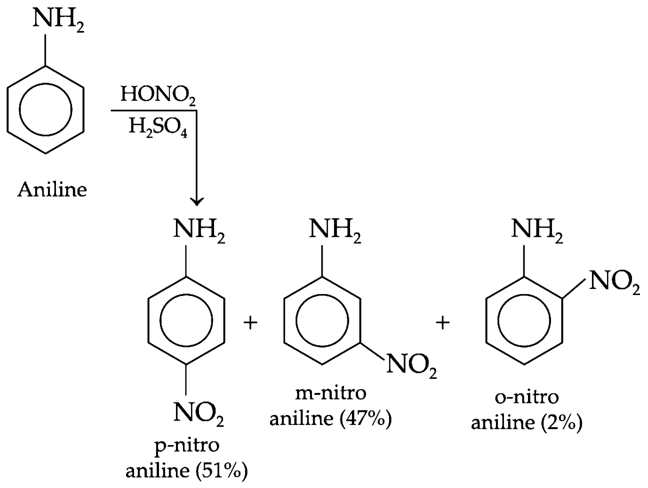
(*b*) *nitrogroup goes always to the meta position irrespective of the substituents.*

(*c*) *nitration of aniline is a nucleophilic substitution reaction in strongly acidic medium*

(*d*) *in strongly acidic solutions, aniline is present in anilinium ion.*

(*e*) *strong acids generate nitrite ion which can only attack the meta position.* **(Kerala PET, 2005)**

Solution.



In strongly acidic medium, the protonation of $-NH_2$ group results in the formation of anilinium cation  which is deactivating and m-directing. So, the correct answer is (*d*).

Example 170. *How many sigma and pi bonds are present in toluene ?*

(*a*) $3\pi + 15\sigma$
(*b*) $3\pi + 6\sigma$
(*c*) $3\pi + 10\sigma$
(*d*) $6\pi + 3\sigma$
(*e*) $6\pi + 6\sigma$

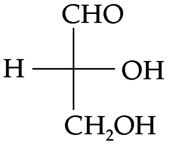
Solution.

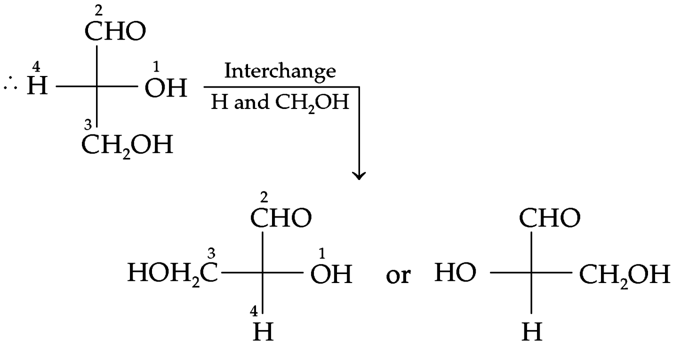
Toluene is 
So, there are 3π and 15σ bonds. So, the correct answer is (*a*).

Example 171. *Which of the following Fischer's projection formula is identical to D-glyceraldehyde?*

(*a*) 
(*b*) 
(*c*) 
(*d*) 
(*e*) 
(Kerala, PET, 2005)

Solution. In a D-glyceraldehyde configuration, –CHO group lies at the top, $-CH_2OH$ group lies at the bottom, H–atom to-wards the left while OH group lies to-wards the right of the Fischer projection. Thus, the D-glyceraldehyde configuration would be





So, the correct answer is (*c*)

Example 172. *The name of compound*  *is :*

(*a*) *(2Z, 4Z) –2, 4–hexadiene*

(*b*) *(2Z, 4E) –2, 4–hexadiene*

(*c*) *(2E, 4Z) –2, 4–hexadiene*

(*d*) *(4E, 4Z) –2, 4–hexadiene*

(*e*) *(2E, 4E) –2, 4–hexadiene* **(Kerala PET, 2005)**

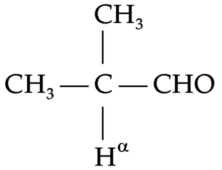
Solution. The rules to assign configuration are if the atoms or groups of higher priority on each carbon atom of double bond are (*i*) on the opposite side of the double bond, the configuration is designated as E and (*ii*) if these are on the same side, the configuration is designated as Z. So, the configuration in the present case is (2E, 4E) –2, 4–hexadiene. Hence the correct answer is (*e*).

Example 173. *Which of the following does not undergo Cannizzaro's reaction ?*

(*a*) *benzaldehyde*
(*b*) *2– methyl propanal*
(*c*) *p– methoxybenzaldehyde*
(*d*) *2, 2–dimethyl propanal*
(*e*) *formaldehyde.* **(Kerala PET, 2005)**

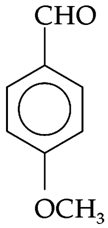
Solution. Aldehydes which donot have α-hydrogen, undergo self oxidation and reduction in presence of concentrated aqueous or alcoholic solution of alkali. (KOH)

(*a*) C_6H_5CHO
no α - H atom

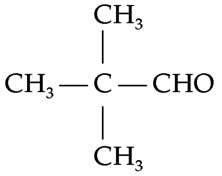
(*b*)


$CH_3-\underset{H^{\alpha}}{\overset{CH_3}{C}}-CHO$

Has α - H atom

(*c*)


no α - H atom

(*d*)


$CH_3-\underset{CH_3}{\overset{CH_3}{C}}-CHO$

no α - H atom

(*e*) HCHO
no α - H atom

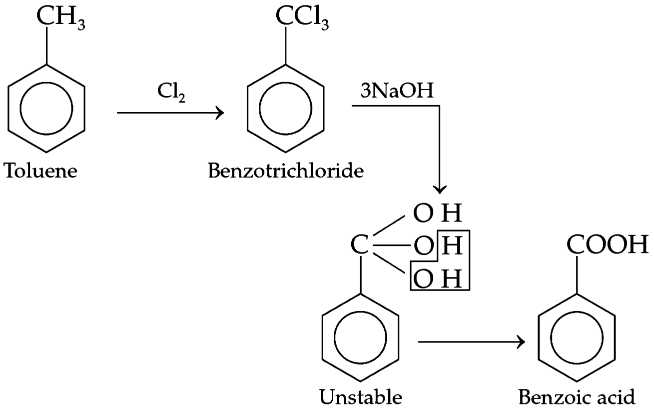
So, the correct answer is (*b*).

Example 174. *Chlorination of toluene in presence of light and heat followed by treatment with aqueous NaOH gives :*

(*a*) *o–cresol*	(*b*) *p–cresol*
(*c*) *mixture of o–cresol and p–cresol*	
(*d*) *benzoic acid*	(*e*) *1, 3, 5– trihydroxy toluene.*

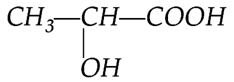
(Kerala PET, 2005)

Solution.



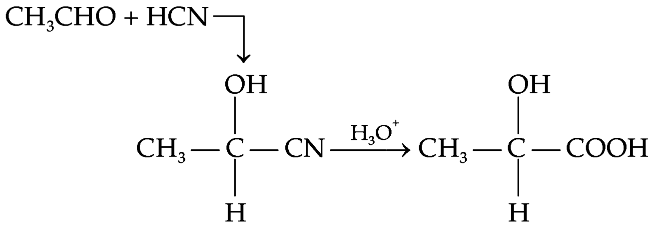
So, the correct answer is (*d*).

Example 175. *CH_3—CHO + HCN ⟶ A. Compound A on hydrolysis gives :*

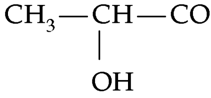
(*a*) *CH_3CH_2COOH*
(*b*) *$CH_3CH_2CH_2NH_2$*
(*c*) *$CH_3CO.\ COOH$*
(*d*) *$CH_3COCH = NOH$*
(*e*)


$CH_3-\underset{OH}{CH}-COOH$ **(Kerala PET, 2005)**

Solution.



$$CH_3CHO + HCN \longrightarrow CH_3-\underset{H}{\overset{OH}{C}}-CN \xrightarrow{H_3O^+} CH_3-\underset{H}{\overset{OH}{C}}-COOH$$



i.e., $CH_3-\underset{OH}{CH}-COOH$. So, the correct answer is (e)

Example 176. *Among the amines :*

(*i*) *$C_6H_5NH_2$*	(*ii*) *CH_3NH_2*
(*iii*) *$(CH_3)_2NH$*	(*iv*) *$(CH_3)_3N$*

the order of basicity is :

(*a*) *(i) < (iv) < (ii) < (iii)*
(*b*) *(iv) < (iii) < (ii) < (i)*
(*c*) *(i) < (ii) < (iii) < (iv)*
(*d*) *(ii) < (iii) < (iv) < (i)*
(*e*) *(iv) < (iii) < (ii) < (i)* **[Kerala PET, 2005]**

Solution. From the combined effects of steric effect, inductive effect, and solvation of ions, secondary amines are the strongest bases while tertiary amines are the least basic. So, actual basic strength of 1°, 2° and 3° amines is ;

Secondary amine (*iii*) > Primary amine, (*ii*) > Tertiary amine, (*iv*)

In case of aniline $C_6H_5NH_2$ *i.e.*, compound (*i*), the phenyl group (– C_6H_5) exerts – I (inductive) effect. *i.e.*, it withdraws electrons. As a result, the lone pair of electron on N–atom is not easily available for protonation. So, it is least basic. So, the correct answer is

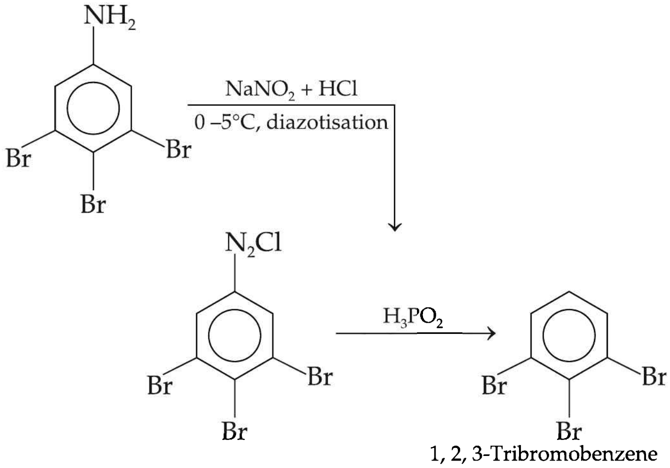
(*i*) < (*iv*) < (*ii*) < (*iii*) *i.e.*, (*a*).

Example 177. *Identify the product in the following equation.*

$$\text{3, 4, 5–tribromoaniline} \xrightarrow[(ii)\,H_3PO_2]{(i)\,diazotisation} ?$$

(*a*) *3, 4, 5–tribromobenzene*
(*b*) *1, 2, 3–tribromobenzene*
(*c*) *2, 4, 6–tribromobenzene*
(*d*) *3, 4, 5– tribromonitrobenzene*
(*e*) *3, 4, 5–tribromophenol.* **(Kerala PET, 2005)**

SOLUTION.



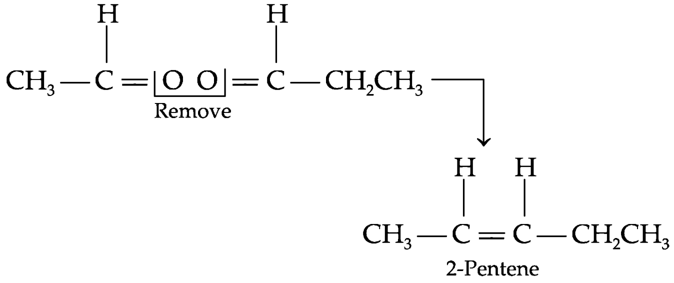
So, the correct answer is (*b*).

EXAMPLE 178. *The olefin which on ozonolysis gives* CH_3CHO *and* CH_3CH_2CHO *is :*

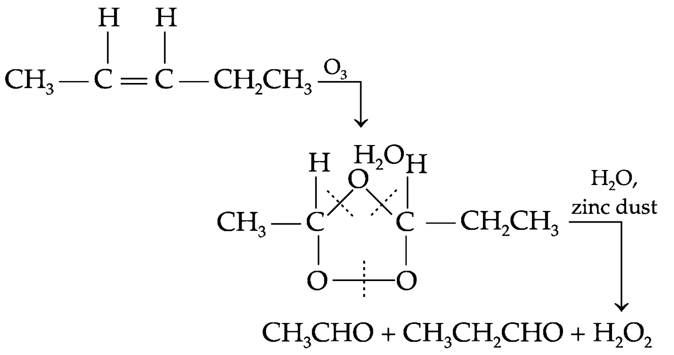
(*a*) *1–Butene* (*b*) *2–Butene*
(*c*) *1–Pentene* (*d*) *2–Pentene*

(Rajasthan Pre-Med. 2000)

SOLUTION. The required alkene can be obtained as :



Confirmation.



So, the correct answer is (*d*).

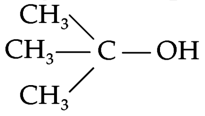
EXAMPLE 179. *Which of the following reagents is used to distinguish between aldehyde and ketone ?*

(*a*) *Ammonical* $AgNO_3$ (*b*) *Phenyl hydrazine*
(*c*) *Hydroxylamine* (*d*) *Semicarbazide*

SOLUTION. Since aldehydes give silver mirror test and Ketones do not, so the correct answer is (*a*)

$$\underset{\text{Aldehyde}}{RCHO} + \underset{\substack{\text{(From ammonical}\\\text{silver nitrate)}}}{Ag_2O} \longrightarrow RCOOH + \underset{\text{Silver mirror}}{2Ag\downarrow}$$

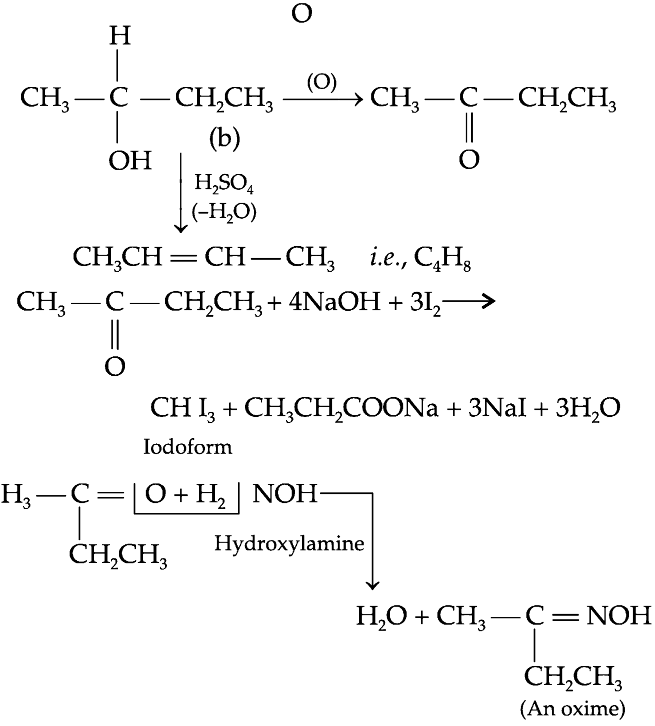
EXAMPLE 180. *A substance* $C_4H_{10}O$ *yields on oxidation a compound,* C_4H_8O*, which gives an oxime and a positive iodoform test. The original substance on treatment with Conc.* H_2SO_4 *gives* C_4H_8*. The structure of the compound is :*

(*a*) $CH_3CH_2CH_2CH_2OH$
(*b*) $CH_3CHOHCH_2CH_3$
(*c*)


$CH_3-\overset{CH_3}{\underset{CH_3}{C}}-OH$
(*d*) $CH_3CH_2OCH_2CH_3$ **(SCRA, 2000)**

SOLUTION. The compound which gives positive iodoform test should contain $CH_3-\underset{\overset{\|}{O}}{C}-$ group which also contains keto group $\rangle C=O$ (that reacts with an oxime).

Considering compound (*b*), we find that this compound on oxidation gives $CH_3-\underset{\overset{\|}{O}}{C}$ group. So, we have:

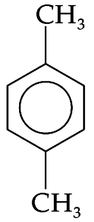


So, the correct answer is (*b*).

EXAMPLE 181. *An aromatic hydrocarbon of molecular formula* C_8H_{10} *forms only one mononitroderivative. The hydrocarbon is :*

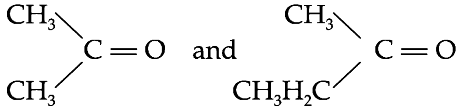
(*a*) *1, 4–dimethyl benzene*
(*b*) *1, 2–dimethyl benzene*
(*c*) *1, 3–dimethyl benzene*
(*d*) *ethyl benzene* **(SCRA, 2000)**

SOLUTION. Since the aromatic compound C_8H_{10} forms only one mononitro derivative, the compound should be symmetrical in structure *i.e.*,



because in this sructure, each position is ortho with respect to the methyl group, —CH_3. So, the correct answer is (*a*) *i.e.*, 1, 4–dimethyl benzene.

Example 182. *An alkene having molecular formula* C_7H_{14} *was subjected to ozonolysis in the presence of zinc dust. An equimolar amount of following two compounds was obtained.*



The IUPAC name of the compound is :

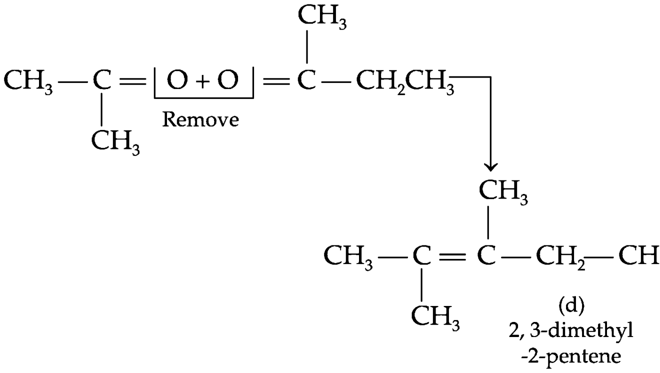
(*a*) *3, 4–dimethyl –3–pentene*

(*b*) *3, 4 – dimethyl –2–pentene*

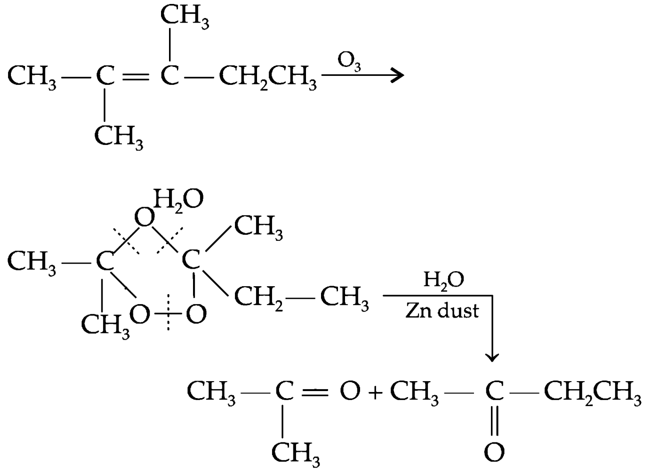
(*c*) *2, 3–dimethyl –3–pentene*

(*d*) *2, 3–dimethyl –2–pentene.* **(SCRA, 2000)**

Solution. The alkene is obtained by removing O–atoms from both compounds. So, we have :



Confirmation of above compound, (*d*) is :



Example 183. *Which one of the following will show optical as well as geometrical isomerism?*

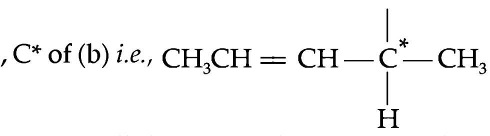
(*a*) *$CH_3(CH_2)_2CH_2OH$*

(*b*) 
$CH_3CH=CHCH(Br)CH_3$

(*c*) 
$CH_3CH_2=CH(Br)CH_2CH_3$

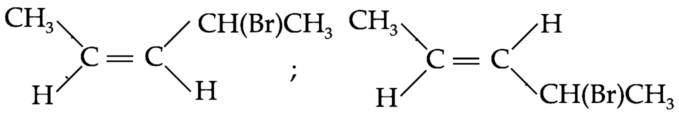
(*d*) 
(CSRA, 2000)

Solution. An organic compound which has atleast one chiral carbon atom as well as a C = C will show optical as well as geometrical isomerism. Out of the above given compounds, C* of (b) *i.e.*,



$CH_3CH=CH-C^*H(Br)-CH_3$

is a chiral carbon. So, it will show optical isomerism. The presence of C = C indicates that it will show following geometrical isomers.



cis-form ; Trans-form

Example 184. *Equal quantities of an alkyl halide,* C_4H_9Cl *were treated with equal volume of 0.1 molar and 0.2 molar solutions of caustic soda respectively at the same temperature in two separate experiments. In both these experiments, the times taken for the reactions of exactly fifty percent of the alkyl halide were the same. The most likely structure of halide is :*

(*a*) *$CH_3CH(Cl)CH_2CH_3$* (*b*) *$(CH_3)_3CCl$*

(*c*) *$(CH_3)_2CHCH_2Cl$* (*d*) *$CH_3(CH_2)_3Cl$.*

Solution. The alkyl halide is treated with equal volumes of different concentrations (0.1 M and 0.2 M) of NaOH. But the times taken for the reactions are of exactly 50% of alkyl halide. So, the hydrolysis of alkyl halide is independent of nucleophilic concentration. It means the alkyl halide will be tertiary alkyl halide because hydrolysis of tertiary alkyl halide is independent of nucleophilic concentration. Thus, the true answer is (*b*).

Type. If *n* = number of asymmetric carbon atoms and molecule has **no symmetry** (*i.e.*, molecule cannot be divided into two equal parts); *a* = number of optically active isomers, then:

(*i*) Number of meso forms (optically inactive), *m* = zero

(*ii*) Number of optically active isomers, $a = 2^n$

(*iii*) Total number of racemic forms, $r = \frac{a}{2}$

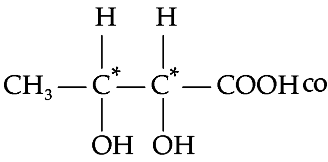
(*iv*) Total number of optical isomers = *a* + *m*.

Asymmetric carbon atom is that which is bonded to four different atoms or groups. For example, C* in lactic acid C*(H) (OH) (CH_3) (COOH) is an asymmetric carbon atom.

EXAMPLE 185. *The total number of optical isomers in CH_3. CHOH. CHOH. COOH are :*

(*a*) 1 (*b*) 2

(*c*) 3 (*d*) 4



$CH_3-\overset{H}{\underset{OH}{C^*}}-\overset{H}{\underset{OH}{C^*}}-COOH$

SOLUTION. $CH_3—C^*—C^*—COOH$ contains two asymmetric C* – atoms. So, $n = 2$ and no. of meso forms, $m = 0$

no. of optically active isomers, $a = 2^n = 2^2 = 4$

So, the correct answer is (*d*).

Type. If n = Even number of asymmetric carbon atoms and molecule **has symmetry** (*i.e.*, the molecule can be divided into two equal halves) then:

(*i*) no. of meso forms,

$$m = 2^{\frac{n}{2}-1}$$

(*ii*) no. of optically active isomers, $a = 2^{n-1}$

(*iii*) no. of racemic forms, $r = \dfrac{a}{2}$

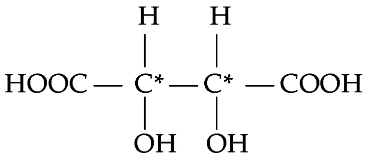
(*iv*) Total number of optical isomers = $a + m$.

EXAMPLE 186. *The total number of optical isomers in CO_2H. CHOH.CHOH, CO_2H are*

(*a*) 1 (*b*) 4

(*c*) 3 (*d*) 2

SOLUTION.



$HOOC-\overset{H}{\underset{OH}{C^*}}-\overset{H}{\underset{OH}{C^*}}-COOH$

The compound $HOOC—C^*—C^*—COOH$ contains two asymmetric C* – atoms.

So, $n = 2$. Hence

(*i*) no. of meso forms, $m = 2^{\frac{n}{2}-1} = 2^{1-1} = 2^\circ = 1$

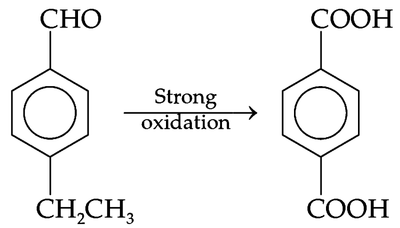
(*ii*) no. of optically active isomers, $a = 2^{n-1} = 2^{2-1} = 2^1 = 2$

$\therefore$ Total number of optical isomers = $a + m = 2 + 1 = 3$.

So, the correct answer is (*c*).

EXAMPLE 187. *An organic compound with molecular formula $C_9H_{10}O$ forms 2, 4 – DNP derivative, reduces Tollen's reagent and undergoes Cannizaro's reaction. On vigorous oxidation, it gives a dicarboxylic acid which is used in the preparation of terylene. Identify the organic compound.* **(WB-JEE, 2011)**

SOLUTION. The data shows that the organic compound gives positive Brady's test which shows carbonyl compound. Tollen's test and Cannizzaro's test shows the presence of aldehyde group without α-hydrogen. The end product being terylene, the organic compound should be



p-ethyl benzaldehyde Terephthalic acid

EXAMPLE 188. *A compound A treated with $NaNH_2$ followed by CH_3CH_2 Br gave compound B. Partial hydrogenation of compound B produced compound C, which on ozonolysis gave carbonyl compound D, C_3H_6O. Compound D did not respond to iodoform test with I_2/KI and NaOH. Find out the structures of A, B, C and D.* **(WB-JEE, 2011)**

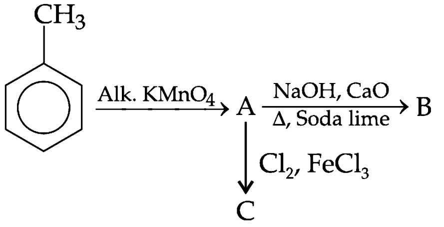
SOLUTION.

$$\underset{(A)}{CH_3CH_2C{\equiv}CH} \xrightarrow[(ii)\,CH_3CH_2\,Br]{(i)\,NaNH_2} \underset{(B)}{CH_3CH_2C{\equiv}C{-}CH_2CH_3}$$

$$\xrightarrow{\text{Partial hydrogenation}} \underset{(C)}{CH_3CH_2CH = CHCH_2CH_3} \xrightarrow[(ii)\,Zn + H_2O]{(i)\,O_3\text{ (ozonolysis)}} \underset{(D)}{2CH_3CH_2CHO}$$

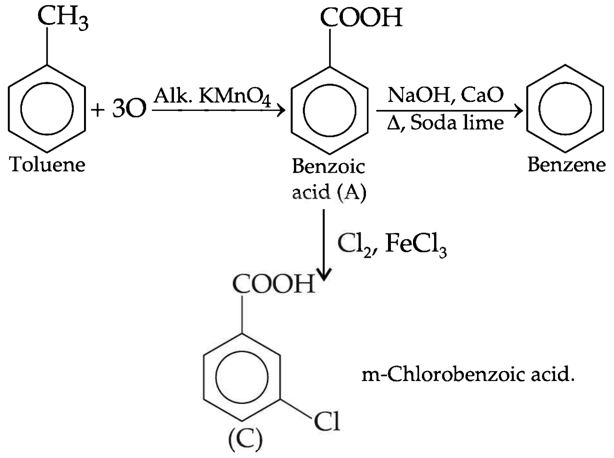
$\xrightarrow[(ii)\,NaOH]{(i)\,I_2/KI}$ no iodoform test because CH_3CH_2CHO does not have CH_3CO – group.

EXAMPLE 189. *Identify the products A, B and C.*



(ISC, 2012)

SOLUTION.



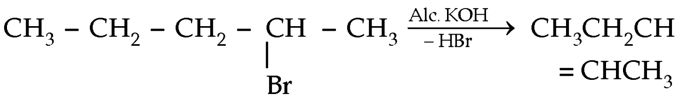
EXAMPLE 190. *2-Bromopentane is treated with alcoholic KOH solution. The major product formed in this reaction and the type of reaction, respectively are:*

(a) pent-2-ene (β-elimination)

(b) pent-1-ene (β-elimination)
(c) 2-pentanol (nucleophilic substitution)
(d) pent-1-ene (nucleophilic substitution)
(e) pent-2-ene (nucleophilic substitution)

(Kerala, PMT, 2012)

SOLUTION.



$$CH_3-CH_2-CH_2-\underset{\displaystyle Br}{\underset{|}{CH}}-CH_3 \xrightarrow[-\,HBr]{Alc.\ KOH} CH_3CH_2CH=CHCH_3$$

2-Bromopentane 2-Pentene

It is a β-elimination reaction.

PROBLEMS FOR PRACTICE

1. In the following reaction,

$$CH_3-C(CH_3)_2\,CH=CH_2 \xrightarrow{H_2O/H^+} \underset{\text{Major Product}}{A} + \underset{\text{Minor Product}}{B}$$

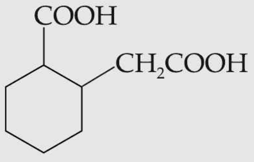
the major product is:

(*a*) $C(CH_3)_2\,(OH)-CH\,(CH_3)_2$
(*b*) $CH_2OH\,C(CH_3)_2\,CH_2\,CH_3$
(*c*) $C(CH_3)_3\,CH(OH)\,CH_3$
(*d*) $C(CH_3)_3\,CH_2CH_2OH$ **Ans.** (*a*)

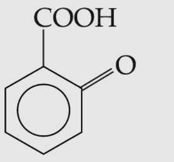
(AIPMT, Prelim, 2012)

2. The compound that undergoes decarboxylation most readily under mild conditions is:

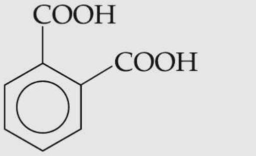
(*a*)



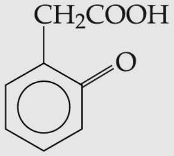
(*b*)



(*c*)



(*d*)



Ans. (*c*)

(IIT, JEE, 2012)

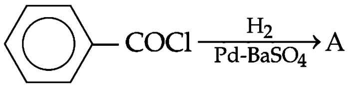
3. An organic compound (C_3H_9N) (A), When treated with nitrous acid, gave an alcohol and N_2 gas was evolved. (A) on warming with $CHCl_3$ and caustic potash gave (C) which on reduction gave isopropylmethylamine. Predict the structure of (A)

(*a*) $(CH_3)_2CHNH_2$ (*b*) $CH_3CH_2NHCH_3$
(*c*) $CH_3N(CH_3)_2$ (*d*) $CH_3CH_2CH_2NH_2$

Ans. (*a*)

(AIPMT (mains), 2012)

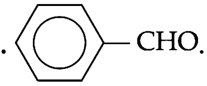
4. Consider the following reaction:



The product (A) is:

(*a*) C_6H_5CHO (*b*) C_6H_5OH
(*c*) $C_6H_5COCH_3$ (*d*) C_6H_5Cl

(**Ans.**



CHO. It is Rosenmund reaction)

5. One mole of propanone and one mole of formaldehyde are the products of ozonolysis of one mole of alkene. The alkene may be:

(*a*) 2-methylpropene (*b*) 2, 2-dimethyl-1-butene
(*c*) propene (*d*) 2-butene
(*e*) 1-butene **Ans.** (*a*)

(Kerala, PMT, 2012)

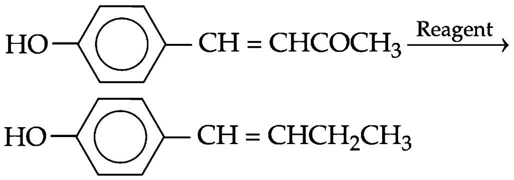
6. How many chiral compounds are possible on monochlorination of 2-methylbutane?

(*a*) 2 (*b*) 4 (*c*) 6 (*d*) 8

Ans. (*a*), **(AIEEE, 2012)**

Hint. Out of 4 compounds, $C_2H_5\,C^*(CH_3)\,CH_2Cl$ and $CH_3C^*(H)(Cl)\,CH(CH_3)_2$ have chiral C* atoms.

7. In the given transformation, which of the following is the most appropriate reagent?



(*a*) Zn–Hg/HCl (*b*) Na,liq. NH_3
(*c*) $NaBH_4$ (*d*) NH_2-NH_2, OH^-

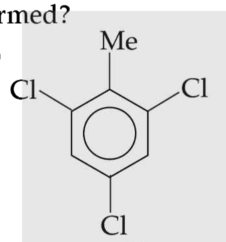
Ans. (*d*)

(AIEEE, 2012)

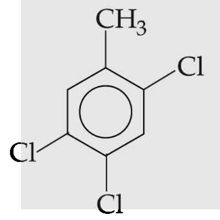
Hint. – OH group and alkene are acid sensitive groups. So, Clemmensen reduction cannot be used and $NaBH_4$ reduces $\rangle C=O$ to – CHOH only.

8. By passing excess Cl_2(g) in boiling toluence, which one of the following compounds is exclusively formed?

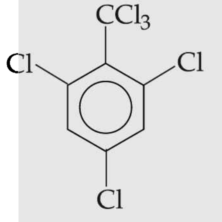
(*a*)



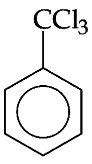
(*b*)



(*c*)



(*d*)



Ans. (*d*)

(W.Bengal JEE, 2012)

9. Iodoform reaction is shown by:
   (*a*) $CH_3CH_2CH_2CH(OH)CH_3$
   (*b*) $C_2H_5OC_2H_5$
   (*c*) $CH_3CH_2CH_2CH_2OH$
   (*d*) (CH_3) COH

[**Ans.** (*a*), **(Odisha JEE, 2012)**]

Hint. All alcohols containing  $>CH-OH$ with CH_3 segment respond to iodoform reaction

10. Ethanoic acid on heating with ammonia forms compound (A) which on treatment with bromine and sodium hydroxide gives compound B. Compound (B) on treatment with $NaNO_2$/dil. HCl gives compound (C). The compounds (A), (B) and (C) respectively are:
   (*a*) ethanamide, methanamine, methanol
   (*b*) Propanamide, ethanamine, ethanol
   (*c*) N-ethylpropanamide, methane isonitrile, methanamine
   (*d*) ethanamine, bromoethane, ethanediazonium chloride
   (*e*) methanamine, ethanamide, methanol

[**Ans.** (*a*), **(Kerala PET, 2012)**]

28

CHAPTER

Water and Hydrogen Peroxide

28.1 HARD WATER

The water sample that contains mainly chlorides and sulphates of calcium and magnesium is called hard water. Such a water gives curdy white precipitate with soap solution in alcohol.

28.2 SOFT WATER

The water sample that contains mainly bicarbonates of calcium and magnesium is called soft water. Such a water gives lather with soap solution in alcohol.

28.3 HARDNESS OF WATER

It is always calculated in terms of calcium carbonate although $CaCO_3$ is not all responsible for causing hardness of water. It is because $CaCO_3$ is insoluble in water. The reason why $CaCO_3$ is chosen for calculating hardness of water is that its molar mass is exact 100 g mol⁻. Following relations are used to calculate amounts of various hardness causing substances in terms of $CaCO_3$.

1. 1 g mol or 162 g of $Ca(HCO_3)_2$ = 1 g mol or 100 g $CaCO_3$
   [∵ Mol. wt. of $Ca(HCO_3)_2$ = 162 g mol⁻]
2. 1 g mol or 146 g of $Mg(HCO_3)_2$ = 1 g mol or 100 g $CaCO_3$
   [∵ Mol. wt. of $Mg(HCO_3)_2$ = 146 g mol⁻]
3. 1 g mol or 111g of $CaCl_2$ = 1 g mol or 100 g $CaCO_3$
   [∵ Mol. wt. of $CaCl_2$ = 111g mol⁻]
4. 1 g mol or 95 g of $MgCl_2$ = 1 g mol or 100 g $CaCO_3$
   [∵ Mol. wt. of $MgCl_2$ = 95 g mol⁻]
5. 1 g mol or 136 g of $CaSO_4$ = 1 g mol or 100 g $CaCO_3$
   [∵ Mol. wt. of $CaSO_4$ = 136 g mol⁻]
6. 1 g mol or 120 g of $MgSO_4$ = 1 g mol or 100 g $CaCO_3$
   [∵ Mol. wt. of $MgSO_4$ = 120 g mol⁻]

Temporary and permanent hardness of water can be calculated as follows :

1. ***Temporary hardness***. Hardness due to $Ca(HCO_3)_2$ + Hardness due to $Mg(HCO_3)_2$.
2. ***Permanent hardness.*** Hardness due to $CaCl_2$ + hardness due to $MgCl_2$ + Hardness due to $CaSO_4$ + Hardness due to $MgSO_4$.

28.4 DEGREE OF HARDNESS

It is expressed in ppm (parts per million) and is defined as the number of parts by weight of $CaCO_3$ (equivalent to Ca and Mg-salts) present in a million (10^6) parts by weight of water. Thus : 1 ppm = 1 part of $CaCO_3$ in 10^6 parts of water.

Also, **1 ppm = 1 mg L⁻**

Equations to be used to determine hardness of water.

1. $\underset{\substack{1\,\text{g mol}\\=111\text{g}}}{CaCl_2} \equiv \underset{\substack{1\,\text{g mol}\\=100\text{g}}}{CaCO_3}$
2. $\underset{\substack{1\,\text{g mol}\\=95\text{g}}}{MgCl_2} \equiv \underset{\substack{1\,\text{g mol}\\=100\text{g}}}{CaCO_3}$
3. $\underset{\substack{1\,\text{g mol}\\=136\text{g}}}{CaSO_4} \equiv \underset{\substack{1\,\text{g mol}\\=100\text{g}}}{CaCO_3}$
4. $\underset{\substack{1\,\text{g mol}\\=120\text{g}}}{MgSO_4} \equiv \underset{\substack{1\,\text{g mol}\\=100\text{g}}}{CaCO_3}$

EXAMPLE 1. *A sample of water contains 25 ppm of $CaCl_2$. Find the degree of hardness of this water.*

SOLUTION. We know that :

$$\underset{\substack{1\,\text{g mol}\\=111\text{g}\\=111\,\text{ppm}}}{CaCl_2} \equiv \underset{\substack{1\,\text{g mol}\\=100\text{g}\\=100\,\text{ppm}}}{CaCO_3}$$

[Mol. wt. of $CaCl_2$ = 40 + (2 × 35.5) = 111g mol⁻
Mol. wt. of $CaCO_3$ = 40 + 12 + (3 × 16) = 100 g mol⁻]

$$111 \text{ ppm } CaCl_2 \equiv 100 \text{ ppm } CaCO_3$$

$$\therefore \quad 25 \text{ ppm } CaCl_2 \equiv \frac{100}{111} \times 25 = 22.52 \text{ ppm } CaCO_3$$

Ans.

EXAMPLE 2. *One litre sample of hard water contains 1 mg $CaCl_2$ and 1 mg $MgCl_2$. Calculate total hardness in terms of $CaCO_3$ per 10^6 parts water by weight.* **(IIT, 1980)**

SOLUTION. Density of water = 1g (mL)⁻;

Volume of water = 1 L = 1000 mL

∴ Wt. of water = Volume × density

= 1000 mL × 1g (mL)⁻ = 1000g

(*i*) Mol. wt. of $CaCl_2$ = 40 + (2 × 35.5) = 111 g mol⁻

$$\text{Wt. of } CaCl_2 = 1\text{mg} \times \frac{1\text{g}}{1000\,\text{mg}} = 0.001\text{g}$$

$$\text{No. of mol. of } CaCl_2 = \frac{\text{wt.}}{\text{mol. wt}} = \frac{0.001\text{g}}{111\text{g mol}^{-}}$$

$$= \frac{0.001}{111}\text{mol}$$

$$1\text{g mol. } CaCl_2 = 1 \text{ g mol } CaCO_3 = 100 \text{ g } CaCO_3$$

$$[\because \text{Mol. wt. of } CaCO_3 = 40 + (3 \times 16) = 100 \text{ g mol}^{-}]$$

$$\therefore \frac{0.001}{111}\text{mol}\, CaCl_2 = \frac{0.001}{111} \times 100\text{g}\, CaCO_3$$

Thus, 1000g H_2O contain $CaCl_2$

$$= \frac{0.001}{111} \times 100 \text{ g } CaCO_3$$

10^6 g H_2O contain $CaCl_2$

$$= \frac{0.001}{111} \times \frac{100}{1000} \times 10^6\text{g}\, CaCO_3$$

$$= 0.9 \text{ g } CaCO_3$$

∴ Hardness of water = 0.9 ppm.

(*ii*) Mol. wt. of $MgCl_2 = 24 + (2 \times 35.5) = 95$ g mol^{-}

$$\text{Wt. of } MgCl_2 = 1\text{mg} \times \frac{1\text{g}}{1000\,\text{mg}} = 0.001\text{g}$$

No. of mol. of $MgCl_2$

$$= \frac{\text{Wt.}}{\text{Mol. wt.}} = \frac{0.001\text{g}}{95\text{g mol}^{-}} = \frac{0.001}{95}\text{mol}$$

$$1\text{g mol } MgCl_2 = 1\text{g mol } CaCO_3 = 100 \text{ g } CaCO_3$$

$$\text{Thus : 1000 g } H_2O \text{ contain } MgCl_2 = \frac{0.001}{95} \times 100\text{g}\, CaCO_3$$

10^6 g H_2O contain $MgCl_2$

$$= \frac{0.001}{95} \times \frac{100}{1000} \times 10^6\text{g}\, CaCO_3$$

$$= 1.05 \text{ g } CaCO_3$$

∴ Hardness of water = 1.05 ppm

∴ Total hardness of water

= 0.9 ppm + 1.05 ppm = **1.95 ppm**

or 1.95 g per 10^6 part water by weight **Ans.**

Example 3. *A sample of water contains 8 mg of calcium sulphate per kilogram of water. Calculate the degree of hardness of this hard water.*

Solution. Mol. wt. of

$$CaSO_4 = 40 + 32 + (4 \times 16) = 136 \text{ g mol}^{-}$$

$$\text{Wt. of } CaSO_4 = 8\,\text{mg} \times \frac{1\text{g}}{1000\,\text{mg}} = 0.008\text{g}$$

∴ no. of mol. of $CaSO_4$

$$= \frac{\text{Wt.}}{\text{Mol. wt.}} = \frac{0.008\text{g}}{136\text{g mol}^{-}}$$

$$= 5.88 \times 10^{-5} \text{ mol.}$$

But 1 g mol $CaSO_4 \equiv$ 1 g mol $CaCO_3 \equiv$ 100 g $CaCO_3$.

∴ 5.88×10^{-5} mol $CaSO_4$

$$= 5.88 \times 10^{-5} \times 100 \text{ g}$$

$$CaCO_3 = 5.88 \times 10^{-3}\text{g}\, CaCO_3$$

Wt. of hard water = 1 kg = 1000 g

∴ 1000 g water contains $CaSO_4$ equivalent to

$$CaCO_3 = 5.88 \times 10^{-3} \text{ g.}$$

∴ 10^6g (*i.e.*, one million) water contains $CaSO_4$ equivalent to $CaCO_3$

$$= \frac{5.88 \times 10^{-3}\text{g}}{1000\text{g}} \times 10^6 \text{ g}$$

$$= 5.88\text{g}\, CaCO_3$$

∴ Hardness of water = 5.88 ppm

Example 4. *A certain sample of water was found to contain 12 ppm of $MgSO_4$ and 42 ppm of $CaCl_2$. Calculate the total hardness in the given sample of water.*

Solution. Mol. wt. of

$$MgSO_4 = 24 + 32 + (4 \times 16) = 120 \text{ g mol}^{-}$$

$$\text{Mol. wt. of } CaCl_2 = 40 + (2 \times 35.5) = 111 \text{ g mol}^{-};$$

$$\text{Mol. wt. of } CaCO_3 = 40 + 12 + (3 \times 16) = 100 \text{ g mol}^{-}$$

We know that hardness of water is expressed in terms of $CaCO_3$. Hence :

(*i*) 1 g mol $MgSO_4 \equiv$ 1 g mol $CaCO_3$

120 g   100 g

120 g $MgSO_4 \equiv$ 100 g $CaCO_3$

or 120 ppm $MgSO_4 \equiv$ 100 ppm $CaCO_3$

$$12 \text{ ppm } MgSO_4 \equiv \frac{100}{120} \times 12 = 10\,\text{ppm}$$

(*ii*) 1 g mol $CaCl_2 \equiv$ 1 g mol $CaCO_3$

111 g   100 g

111 ppm   100 ppm

or 111 ppm $CaCl_2 \equiv$ 100 ppm $CaCO_3$

$$42 \text{ ppm } CaCl_2 = \frac{100}{111} \times 42 = 37.84\,\text{ppm}$$

∴ Total hardness = Hardness due to $MgSO_4$ + Hardness due to $CaCl_2$

= 10 ppm + 37.84 ppm

= **47.84 ppm** **Ans.**

Example 5. *0.45 dm^3 of a sample of hard water contains 0.5 mg of $MgCl_2$ and 0.55 mg of $CaCl_2$. Calculate the total hardness of water in terms of $CaCO_3$ per 10^6 parts of water by mass (at. wt. Ca = 40, Mg = 24, Cl = 35.5).*

Solution. Mol. mass of $CaCl_2$

$$= 40 + (2 \times 35.5) = 111$$

Molar mass of $MgCl_2$

$$= 24 + (2 \times 35.5) = 95 \text{ g mol}^{-}$$

Molar mass of $CaCO_3$

$$= 40 + 12 + (3 \times 16) = 100 \text{ g mol}^{-}$$

(*a*) We know that $CaCl_2 \equiv CaCO_3$

111 parts   100 parts

111 parts $CaCl_2 \equiv$ 100 parts $CaCO_3$

$$0.55 \text{ mg } CaCl_2 \equiv \frac{100}{111} \times 0.55\,\text{mg} = 0.4955\,\text{mg}$$

(*b*) $MgCl_2 \equiv CaCO_3$

95 parts   100 parts

95 parts $MgCl_2 \equiv$ 100 parts $CaCO_3$

$$0.5 \text{ mg } MgCl_2 \equiv \frac{100}{95} \times 0.5\,\text{mg} = 0.5263\,\text{mg}$$

0.45 dm^3 of hard water contain

$$CaCO_3 = 0.4955 + 0.5263 = 1.0218 \text{ mg}$$

∴ 1 dm^3 of hard water contain

$$CaCO_3 = \frac{1.0218}{0.45} = 2.27 \text{ mg}$$

But 1 dm^3 (*i.e.,*, 1L) of water weighs

$$= 1000 \text{ g} \times \frac{1000 \text{ mg}}{1\text{g}} = 10^6 \text{ mg}$$

[∵ density of water = 1g (mL)$^{-}$]

∴ Degree of hardness in water

= 2.27 mg per 10^6 parts of water by mass.

Example 6. *What will be the weight of CaO needed to remove hardness of 10^6 litre of water containing 0.81 g of calcium bicarbonate per litre ?*

Solution. Reaction. $Ca(HCO_3)_2 + CaO \rightarrow 2\ CaCO_3 + H_2O$.

$$\underset{\substack{40+2[1+12+(3\times16)]\\=162=\text{mol. wt.}}}{Ca(HCO_3)_2} \rightleftharpoons \underset{\substack{(i)\,\text{mol}=1\\(ii)\,\text{oxidation state of } Ca^{2+}=2}}{Ca^{2+}} + 2HCO_3^-$$

∴ Eq. wt. of Ca $(HCO_3)_2$

$$= \frac{\text{Mol. wt.}}{\substack{\text{no. of mol. of } Ca^{2+} \text{in}\\ \text{one mol of Ca } (HCO_3)_2} \times \substack{\text{oxidation state}\\ \text{of } Ca^{2+}}} = \frac{162}{1\times2} = 81$$

$$\underset{40+16=56}{CaO} \rightleftharpoons \underset{\substack{(i)\,\text{mol}=1\\(ii)\,\text{oxidation state of } Ca^{2+}=2}}{Ca^{2+}} + O^{2-}$$

∴ Eq. wt. of CaO

$$= \frac{\text{Mol. wt.}}{\substack{\text{no. of mol. of } Ca^{2+} \text{in}\\ \text{one mol of CaO}} \times \substack{\text{oxidation state}\\ \text{of } Ca^{2+}}} = \frac{56}{1\times2} = 28$$

No. of equivalents (eq.) of $Ca(HCO_3)_2$ in 1L hard water

$$= \frac{\text{Wt.}}{\text{Eq. wt.}}$$

$$= \frac{0.81}{81} = 0.01 \qquad \left[\because \text{Eq.} = \frac{\text{Wt.}}{\text{Eq.wt.}}\right]$$

∴ no. of equivalents of CaO needed to remove $Ca(HCO_3)_2$ in 1 L = 0.01

[∵ eq. CaO ≡ eq. $Ca(HCO_3)_2$]

∴ no. of equivalents of CaO needed to remove $Ca(HCO_3)_2$ in 10^6L water = 0.01 × 10^6

Hence, wt. of CaO needed

= no. of equivalents × Eq. wt.

= 0.01 × 10^6 × 28 = **2.8 × 10^5g** **Ans.**

Example 7. *A precipitate of 0.19 g of calcium oxalate ($CaC_2O_4 . H_2O$) was obtained from 300 cm^3 of hard water. Calculate the calcium content in it in ppm (at. wt., Ca = 40, C = 12, O = 16)*

Solution. $CaC_2O_4 . H_2O$ ≡ Ca

40 + (2 × 12) + (4 × 16) + (2 × 1) + 16 40 g

= 146 g

Wt. of $CaC_2O_4 . H_2O$ ppt = 0.19 g

146 g $CaC_2O_4 . H_2O$ ≡ 40 g Ca

$$0.19 \text{ g Ca } C_2O_4 . H_2O \equiv \frac{40}{146} \times 0.19 \text{g}$$

Wt. of 300 cm^3 water = Volume × density

= 300 cm^3 × 1g cm^{-3} = 300 g

$$\therefore \text{ Ca content in ppm} = \frac{\text{Wt. of component, Ca}}{\text{Total wt. of water}} \times 10^6$$

$$= \frac{40}{146} \times \frac{0.19 \times 10^6}{300} = 173.5 \qquad \textbf{Ans.}$$

Type. For softening hard water :

Lime, *i.e.,* $Ca(OH)_2$ required

$$= \frac{\text{Mol. wt. of } Ca(OH)_2}{100} \times \begin{bmatrix} \text{Temporary hardness} \\ + \text{Permanent Mg hardness} \end{bmatrix}$$

Soda *i.e.,* Na_2CO_3 required

$$= \frac{\text{Mol. wt. of } Na_2CO_3}{100} \times [\text{Permanent hardness}]$$

Example 8. *How much soda and lime would be needed to soften 12,000 L of hard water analysed as, permanent hardness = 15 ppm, permanent magnesium hardness = 12 ppm and temporary hardness = 18 ppm ?*

Solution. (*i*) Soda requirement

$$= \frac{\text{Mol. wt. of } Na_2CO_3}{100} \times [\text{Permanent hardness}]$$

$$= \frac{(2\times23)+12+(3\times16)}{100} \times 15$$

$$= \frac{106}{100} \times 15 = 15.9 \text{ ppm} = 15.9 \text{ mgL}^{-}$$

∴ Amount of soda required for 12,000 L water

$$= 15.9 \times 12{,}000 \text{ mg} = \frac{15.9 \times 12{,}000}{1000} \text{g}$$

= **190.8 g** **Ans.**

(*ii*) Lime *i.e.,* $Ca(OH)_2$ required

$$= \frac{\text{Mol. wt. of } Ca(OH)_2}{100} \times \begin{bmatrix} \text{Temporary hardness +} \\ \text{permanent Mg hardness} \end{bmatrix}$$

$$= \frac{40 + 2(16+1)}{100} \times [18 + 12] = \frac{74}{100} \times 30$$

= 22.2 ppm = 22.2 mg L^{-}

∴ Amount of lime required for 12,000 L water

$$= 22.2 \times 12{,}000 \text{mg} = \frac{22.2 \times 22{,}000}{1000} \text{g}$$

= **266.4 g** **Ans.**

Type. For softening hard water :
Lime *i.e.*, $Ca(OH)_2$ required

$$= \frac{\text{Mol. wt. of Ca(OH)}_2}{100} \times \left[\begin{array}{c}\text{CaCO}_3 \text{ equivalent of CO}_2,\\ \text{HCO}_3^- , \text{Mg}^{2+} \text{ and FeSO}_4.7\text{H}_2\text{O}\\ \text{(as coagulent)}\end{array}\right]$$

Soda *i.e.*, Na_2CO_3 required

$$= \frac{\text{Mol. wt. of Na}_2\text{CO}_3}{100} \times \left[\begin{array}{c}\text{Chemical equivalent of}\\ \text{Ca}^{2+} + \text{Mg}^{2+} + \text{FeSO}_4.7\text{H}_2\text{O}\\ -\text{HCO}_3^-\end{array}\right]$$

> **Note** 1. SiO_2, NaCl, KCl etc., do not contribute to hardness.
>
> 2. $CaCO_3$ equivalent = no. of ppm of constituent × $\dfrac{100}{\text{at. wt. or mol. wt. of constituent}}$

Example 9. *A sample of hard water from a lake on analysis gave the following results:* Ca^{2+} *= 45 ppm,* Mg^{2+} *= 50 ppm, 2* HCO^-_3 *= 400 ppm and* CO_2 *= 20 ppm. If 145 ppm of* $FeSO_4 . 7H_2O$ *is used as a coagulant, find the amount of soda and lime used to soften above hard water (at. wt., Ca = 40, Mg = 24, C = 12, H = 1, O = 16, Fe = 56, S = 32).*

Solution. Mol. Wt. of $CO_2 = 12 + (2 \times 16) = 44$; $Ca^{2+} = 40$, $Mg^{2+} = 24$, $2\,HCO^-_3 = 2\,[1 + 12 + (3 \times 16)] = 122$, $FeSO_4 . 7\,H_2O = 56 + 32 + (4 \times 16) + 7\,(2 \times 1 + 16) = 278$. To calculate $CaCO_3$ equivalent :

Constituent	Mol. wt./At. wt.	Amount	$CaCO_3$ equivalent
Ca^{2+}	40	45 ppm	$\frac{(45 \times 100)}{40} = 112.5$
Mg^{2+}	24	50 ppm	$\frac{(50 \times 100)}{24} = 208.3$
$2\,HCO_3^-$	122	400 ppm	$\frac{(400 \times 100)}{122} = 327.9$
CO_2	44	20 ppm	$\frac{(20 \times 100)}{44} = 45.45$
$FeSO_4 . 7H_2O$	278	145 ppm	$\frac{(145 \times 100)}{278} = 52.16$

1. Soda requirement

$$= \frac{\text{Mol. wt. of Na}_2\text{CO}_3}{100} \times \left[\begin{array}{c}\text{CaCO}_3 \text{ equivalent of Ca}^{2+} + \text{Mg}^{2+}\\ + \text{FeSO}_4.7\text{H}_2\text{O} - 2\text{HCO}_3^-\end{array}\right]$$

$$= \frac{106}{100} \times [112.5 + 208.3 + 52.16 - 327.9]$$

$$= \frac{106}{100} \times 45.06 = \mathbf{47.76\ ppm} \qquad \textbf{Ans.}$$

2. Lime requirement

$$= \frac{\text{Mol. wt. of Ca(OH)}_2}{100} \times \left[\begin{array}{c}\text{CaCO}_3 \text{ equivalent of Mg}^{2+}\\ + \text{CO}_2 + 2\text{HCO}_3^- + \text{FeSO}_4.7\text{H}_2\text{O}\end{array}\right]$$

$$= \frac{74}{100} \times [208.3 + 45.45 + 327.9 + 52.16]$$

$$= \frac{74}{100} \times 633.81 = \mathbf{469\ ppm} \qquad \textbf{Ans.}$$

Example 10. *How much soda and lime would be required to soften 900L of hard water from the following data.* Ca^{2+} *= 40 ppm,* Mg^{2+} *= 10 ppm,* CO_2 *= 45 ppm, 2* HCO^-_3 *= 160 ppm ? (at. wt. Ca = 40, Mg = 24, C = 12, O = 16).*

Solution. At. wt. of Ca = 40, Mg = 24, Mol. wt. of $CO_2 = 12 + (2 \times 16) = 44$, $2HCO^-_3 = 2\,[1 + 12 + (3 \times 16)] = 122$.

To calculate $CaCO_3$ equivalent.

Constituent	Mol. wt./At. wt.	Amount	$CaCO_3$ equivalent
Ca^{2+}	40	40 ppm	$\frac{(40 \times 100)}{40} = 100$
Mg^{2+}	24	10 ppm	$\frac{(10 \times 100)}{24} = 41.67$
CO_2	44	45 ppm	$\frac{(45 \times 100)}{44} = 102.27$
$2\,HCO^-_3$	122	160 ppm	$\frac{(160 \times 100)}{122} = 131.14$

1. Soda requirement

$$= \frac{\text{Mol. wt. of Na}_2\text{CO}_3}{100} \times \left[\begin{array}{c}\text{CaCO}_3 \text{ equivalents of Ca}^{2+} + \text{Mg}^{2+}\\ - 2\text{HCO}_3^-\end{array}\right]$$

$$= \frac{106}{100} \times [100 + 41.67 - 131.14]$$

$$= \frac{106 \times 10.53}{100}$$

$$= \mathbf{11.16\ ppm\ or\ mg\ L^-} \qquad \textbf{Ans.}$$

∴ Amount of soda required for 900 L water

$$= 11.16 \times 900 \text{ mg}$$

$$= \frac{11.16 \times 900}{1000} \text{ g} \simeq \mathbf{10g} \qquad \textbf{Ans.}$$

2. Lime *i.e.*, $Ca(OH)_2$ requirement

$$= \frac{\text{Mol. wt. of Ca(OH)}_2}{100} \times \left[\begin{array}{c}\text{CaCO}_3 \text{ equivalent of Mg}^{2+}\\ + \text{CO}_2 + 2\text{HCO}_3^-\end{array}\right]$$

$$= \frac{74}{100} \times [41.67 + 102.27 + 131.14]$$

$$= 203.56 \text{ ppm or mg L}^-$$

∴ Amount of lime required for 900 L water = 203.56 × 900 mg

$$= \frac{203.56 \times 900}{1000} \text{g} = \mathbf{183.204\ g\ \ Ans.}$$

EXAMPLE 11. *A sample of hard water contains Ca^{2+} ions as the only cations, 183 ppm of HCO^-_3 and 96 ppm of SO_4^{2-}. (one ppm means one part of the substance in one million part of water, mass/mass). Calculate the number of moles of CaO needed to remove HCO^-_3 from one thousand kilogram of this water. If 1000 kg of this water is treated with the amount of CaO calculated above, what will be the concentration (in ppm) of residual Ca^{2+} ions ? If the Ca^{2+} ions in one litre of the treated water are completely exchanged with H^+ ions, what will be its pH ? (Assume that $CaCO_3$ is completely insoluble in water).*

SOLUTION. (*a*) Molecular mass of

$$HCO_3^- = 1 + 12 + (3 \times 16) = 61\text{g}.$$

Mass of HCO_3^- in 1000 kg of H_2O = 183 kg

$$\therefore \text{ Mass of } HCO_3^- = \frac{183}{61} = 3\,\text{mol}.$$

(*b*) Molecular mass of SO_4^{2-} = 32 + (4 × 16) = 96 g

Mass of SO_4^{2-} in 1000 g of H_2O = 96 g

$$\therefore \text{ Moles of } SO_4^{2-} = \frac{96}{96} = 1\,\text{mol}.$$

Action of Ca^{2+} ions with HCO_3^- and SO_4^{2-} ions is given below :

$$\underset{\substack{1\,\text{mol}\\ \frac{1}{2}\text{mol}}}{CaO} + \underset{\substack{2\,\text{mol}\\ 1\,\text{mol}}}{2HCO_3^-} \rightarrow Ca(HCO_3)_2 + H_2O \qquad ...(1)$$

$$\underset{1\,\text{mol}}{Ca^{2+}} + \underset{1\,\text{mol}}{SO_4^{2-}} \rightarrow CaSO_4 \qquad ...(2)$$

(*c*) Moles of HCO_3^- = 3 mol

From reaction (1), moles of CaO required to remove all $HCO_3^- = \frac{1}{2} \times 3 = 1.5$ moles

∴ Moles of SO_4^{2-} ions + moles of Ca^{2+} ions

= 1 + 1.5 = 2.5 moles

Reaction of CaO with $Ca(HCO_3)_2$ is : $CaO + Ca(HCO_3)_2 \rightarrow 2CaCO_3 + H_2O$.

(*d*) Moles of Ca^{2+} ions required to remove all

SO_4^{2-} ions = 1 mol

∴ Moles of Ca^{2+} ions left in solution = 2.5 – 1.5 = 1 mol.

∴ Mass of Ca^{2+} ions = 1 mol × mol. mass of Ca^{2+}

= 1 × 40 = 40 g

[At. mass or mol. mass of Ca^{2+} = 40]

(*e*) Moles of Ca^{2+} ions in one litre (= 1000 mL) water

$$= \frac{1}{1000} = 10^{-3}$$

∴ Moles of H^+ ions that will be exchanged with

Ca^{2+} ions $= 10^{-3} \times 2$ [∵ $Ca^{2+} \equiv H_2O$]

Or $[H^+] = 2 \times 10^{-3}$. Hence, $2H^+$

$pH = -\log(H^+)$.

Or $pH = -\log[2 \times 10^{-3}]$

$= -[\log 2 + \log 10^{-3}]$

$= -[0.3010 - 3] = 3 - 0.3010$

pH = 2.699 **Ans.**

28.5 VOLUME STRENGTH OF HYDROGEN PEROXIDE, H_2O_2

Type. Volume strength of H_2O_2 = 5.6 × normality.

x volume H_2O_2 means that one litre (or 1 mL) of *x* volume H_2O_2 liberates oxygen on decomposition = *x* litre (or *x* mL). Thus 20 volume H_2O_2 means that 1 mL of 20 volume H_2O_2 liberates oxygen = 20 mL. Thus :

$$\underset{\substack{2[(2\times1)+(2\times16)\\ =68\,g}}{2H_2O_2} \rightarrow 2H_2O + \underset{22.4\,L\,at\,N.T.P.}{O_2} \qquad ...(1)$$

Calculation of x volume strength of H_2O_2.

From equation (1), it is clear that :

22.4 L O_2 is liberated from H_2O_2 = 68 g

∴ *x* volume O_2 is liberated from

$$H_2O_2 = \frac{68}{22.4} \times x = \frac{17x}{5.6}\text{g}$$

Hence, ***x volume strength of*** $\mathbf{H_2O_2} = \boldsymbol{\frac{17x}{5.6}\,g}$

But *x* volume strength of H_2O_2 = Normality × Eq. wt.

$$\therefore \quad \text{Normality} = \frac{\text{Strength of } x \text{ volume } H_2O_2}{\text{Eq. wt. of } H_2O_2}$$

$$\left[\text{Eq. wt. of } H_2O_2 = \frac{\text{Mol. wt.}}{2} = \frac{(2\times1)+(2\times16)}{2} = 17\right]$$

$$\textbf{Or} \quad \textbf{Normality} = \frac{17x}{5.6 \times 17} = \frac{x}{\mathbf{5.6}}$$

$$\text{Or} \quad \text{normality} = \frac{\text{Volume strength}}{5.6} = \frac{x}{5.6}$$

But molarity × mol. wt. = Normality × Eq. wt.

$$\therefore \quad \text{Molarity} \times 34 = \frac{x}{5.6} \times 17$$

[∵ Mol. wt. of H_2O_2 = (2 × 1) + (2 × 16) = 34]

$$\therefore \textbf{ Molarity of } \mathbf{H_2O_2} = \frac{x}{5.6} \times \frac{17}{34} = \frac{x}{\mathbf{11.2}}.$$

EXAMPLE 12. *20 mL of H_2O_2 solution were added to excess of acidified potassium iodide solution. The liberated iodine required 18.0 mL of 0.1N $Na_2S_2O_3$ solution for titration. Calculate the strength of H_2O_2 in terms of normality and volume.*

SOLUTION. We know :

Meq. of H_2O_2 = Meq. of I_2 = Meq. of $Na_2S_2O_3$

Meq. of H_2O_2 = Volume of H_2O_2 × normality of H_2O_2 (= N say)

Meq. of H_2O_2 = 20 × N ...(1)

Meq. of $Na_2S_2O_3$ = Vol. of $Na_2S_2O_3$ × normality of $Na_2S_2O_3$

Meq. of $Na_2S_2O_3$ = 18 × 0.1 = 1.8 ...(2)

Equating equations (1) and (2), we have :

$$20\ N = 1.8 \text{ Or } \mathbf{N} = \frac{1.8}{20} = \frac{18}{200} = \frac{9}{100} = \mathbf{0.09}$$

Volume strength of H_2O_2 $\underset{\substack{2[(2\times1)+(2\times16)]\\=68\,g}}{2H_2O_2} \rightarrow 2H_2O + \underset{22.4L}{O_2}$

Or 22.4 L O_2 is liberated from H_2O_2 = 68 g

xL O_2 is liberated from

$$H_2O_2 = \frac{68}{22.4} \times x$$

∴ x volume strength of

$$H_2O_2 = \frac{68x}{22.4}$$

But x volume strength of H_2O_2 = Normality × Eq. wt.

$$\therefore \quad \frac{68x}{22.4} = 0.09 \times 17$$

$$\left[\because \text{ Eq. wt. of } H_2O_2 = \frac{\text{Mol. wt.}}{2} = \frac{(2\times1)+(2\times16)}{2} = 17\right]$$

$$\therefore \quad x = \frac{0.09 \times 17 \times 22.4}{68} = 0.504$$

∴Volume strength of H_2O_2 = **0.504 volume.**

EXAMPLE 13. *A bottle containing 20 volume H_2O_2 was left open. As a result, some of the H_2O_2 decomposed. In order to get new volume strength of H_2O_2, 10 mL of the solution was taken and diluted to 100 mL. 10 mL of this diluted solution consumed 25 mL of 0.025 M $KMnO_4$ solution in acidic medium. Calculate the volume strength of H_2O_2 solution.*

SOLUTION. Let normality of H_2O_2 = N

∴ 1 L (= 1000 mL) solution of H_2O_2 contains

H_2O_2 = N equivalents.

∴ 1 mL solution of H_2O_2 contains

$$H_2O_2 = \frac{N}{1000}\text{equivalents}$$

$$\text{Moles of } H_2O_2 \text{ in 1 mL} = \frac{1}{2} \times \frac{N}{1000}$$

$$\left[\because \text{ Eq. wt. of } H_2O_2 = \frac{\text{Mol. wt.}}{2}\right]$$

Moles of O_2 that H_2O_2 gives

$$= \frac{1}{2} \times \frac{1}{2} \times \frac{N}{1000}$$

$$\left[\begin{array}{l}\because\ H_2O_2 \rightarrow H_2O + \frac{1}{2}O_2 \\ \textbf{Or}\ \ \frac{1}{2}O_2^{2-} \rightarrow \frac{1}{2}O_2 + 1\bar{e}\end{array}\right]$$

At N.T.P., volume of O_2 in mL

$$= 22400 \times \frac{1}{2} \times \frac{1}{2} \times \frac{N}{1000} = 5.6 \times \text{Normality}$$

[∵ 1 mol of O_2 occupy volume = 22400 mL at N.T.P.]

Or Volume strength = 5.6 × normality ...(1)

From titration of 10 mL H_2O_2, 25 mL of 0.025 M $KMnO_4$ is used.

Equivalents of H_2O_2 = Vol × normality

= 10 × normality. ...(2)

Equivalents of $KMnO_4$ = Vol. × molarity × n

= 25 × 0.025 × 5 ...(3)

$$\left[MnO_4^- + 8H^+ + \underset{n=5}{5e^-} \rightarrow Mn^{2+} + 4H_2O\right]$$

Equating (2) and (3), we get :

10 × normality of H_2O_2= 25 × 0.025 × 5

$$\therefore \text{ Normality of } H_2O_2 = \frac{25 \times 0.025 \times 5}{10} = 0.3125$$

Or Normality of 100 mL H_2O_2 diluted solution = 0.3125

∴ Normality of original 10 mL H_2O_2 solution

$$= 0.3125 \times \frac{100}{10} = 3.125$$

Substituting this normality value in equation (1), we get :

Volume strength = 5.6 × 3.125 = **17.5** **Ans.**

Type. % age strength of H_2O_2 in a sample marked

$$\textbf{'}x\textbf{ volume'} = \frac{68x}{22400} \times 100$$

EXAMPLE 14. *Find the percentage strength of H_2O_2 in a sample marked "10 volume".* **(Roorkee, 1989)**

SOLUTION. 10 volume H_2O_2 means that 1 mL of 10 volume H_2O_2 at N.T.P. liberates oxygen = 10 mL at N.T.P.

Reaction : $\underset{2[(2\times1)+(2\times16)]=68g}{2H_2O_2} \rightarrow 2H_2O + \underset{22400\,mL}{O_2}$

22400 mL O_2 is liberated from H_2O_2 = 68 g

∴ 10 mL O_2 is liberated

$$\text{from } H_2O_2 = \frac{68g}{22400\,mL} \times 10\,mL = \frac{68}{2240}g$$

$$\text{Thus : 1 mL } H_2O_2 \text{ contains } H_2O_2 = \frac{68}{2240}g$$

100 mL H_2O_2 contains

$$H_2O_2 = \frac{68}{2240} \times 100 = \mathbf{3.03\%}$$ **Ans.**

EXAMPLE 15. *Calculate the volume strength of 12% solution of H_2O_2.*

SOLUTION. 12% H_2O_2 means that :

100 mL H_2O_2 contains H_2O_2 = 12 g

∴ 1L (= 1000 mL) H_2O_2 contains

$$H_2O_2 = \frac{12}{100} \times 1000 = 120\,g$$

Reaction: $\underset{2[(2\times1)+(2\times16)]=68g}{2H_2O_2} \rightarrow 2H_2O + \underset{22400\,mL\,at\,N.T.P=22.4L}{O_2}$

68g H_2O_2 produce O_2 = 22.4 L

120 g H_2O_2 produce $O_2 = \frac{22.4\,L}{68} \times 120$

$\therefore$ 1 L solution gives O_2 at NTP

$$= \frac{22.4 \times 120}{68} L = 39.53\,L$$

Hence volume strength of 12% solution of H_2O_2 = 39.53.

Type. Normality of H_2O_2 solution

$$= \frac{\text{strength (of } x \text{ volume } H_2O_2) \text{ in } gL^-}{\text{Eq. wt. of } H_2O_2 (=17)}$$

Or Volume strength = 5.6 × Normality

EXAMPLE 16. *Calculate the normality of 20 volume H_2O_2.*

(AMU, medical, 2012)

SOLUTION. *Reaction* :

$$\underset{2[(2\times1)+(2\times16)]=68g}{2H_2O_2} \rightarrow 2H_2O + \underset{22.4\text{ L or }22400\text{ mL at N.T.P.}}{O_2} \quad ...(1)$$

20 volume H_2O_2 means that 1 L H_2O_2 produces O_2 = 20 L.

Thus, from equation (1), we see that :

22.4 L O_2 is produced from H_2O_2 = 68 g

$\therefore$ 20 L O_2 is produced from

$$H_2O_2 = \frac{68\,g}{22.4\,L} \times 20\,L = 60.71\,g$$

$\therefore$ Strength of H_2O_2 = 60.71 gL^-

$$\text{But, Eq. wt. of } H_2O_2 = \frac{\text{Mol. wt.}}{2} = \frac{(2\times1)+(2\times16)}{2} = 17$$

$$\text{Strength} = \text{Normality} \times \text{Eq. wt.}$$

$$\text{Normality} = \frac{\text{Strength}}{\text{Eq. wt.}} = \frac{60.71}{17} = 3.57\,N$$

$$\textbf{Or} \quad \textbf{Normality} = \frac{\text{Volume strength of } H_2O_2}{5.6}$$

$$= \frac{20}{5.6} = 3.57\,N \qquad \textbf{Ans.}$$

Type. To find molarity of H_2O_2 solution, proceed, as follows :

(*i*) $\text{Normality} = \frac{\text{Strength of } x \text{ volume } H_2O_2 \text{ in } gL^-}{\text{Eq. wt. of } H_2O_2}$

Or $\text{Normality} = \frac{\text{Volume strength}}{5.6}$

(*ii*) Molarity of

$$H_2O_2 = \frac{\text{Normality} \times \text{Eq. wt. of } H_2O_2}{\text{Mol. wt. of } H_2O_2}$$

EXAMPLE 17. *Calculate the molarity of 5 volume H_2O_2.*

SOLUTION. *Reaction* :

$$\underset{2[(2\times1)+(2\times16)]=68g}{2H_2O_2} \rightarrow 2H_2O + \underset{22.4\,L\,at\,N.T.P}{O_2} \quad ...(1)$$

5 volume H_2O_2 means that 1 L H_2O_2 produces O_2 = 5L

Thus, from equation (1), we see that :

22.4 L O_2 is produced from H_2O_2 = 68 g

5 L O_2 is produced from

$$H_2O_2 = \frac{68g}{22.4\,L} \times 5L = 15.18\ gL^-$$

$\therefore$ Strength of 5 vol = 15.18 gL^-

$$\text{Eq. wt. of } H_2O_2 = \frac{\text{Mol. wt.}}{2} = \frac{(2\times1)+(2\times16)}{2}$$

$$= \frac{34}{2} = 17$$

Mol. wt. of H_2O_2 = 34 g mol^-

$$\text{Normality} = \frac{\text{Strength}}{\text{Eq. wt.}} = \frac{15.18}{17}$$

But, Molarity × mol. wt. = Normality × Eq. wt.

$$\therefore \quad \text{Molarity} = \frac{\text{normality} \times \text{Eq. wt.}}{\text{Mol. wt.}}$$

$$= \frac{15.18}{17} \times \frac{17}{34} = \mathbf{0.446\ M} \qquad \textbf{Ans.}$$

EXAMPLE 18. *What volume of 25 volume H_2O_2 should be decomposed to get 400 mL of O_2 at S.T.P. ?*

SOLUTION. 25 volume H_2O_2 means that :

1 mL of 25 volume H_2O_2 produces oxygen = 25 mL

$\therefore$ 25 mL of O_2 is produced from 25 volume

H_2O_2 = 1 mL

$\therefore$ 400 mL of O_2 is produced from 25 volume

$$H_2O_2 = \frac{1mL}{25mL} \times 400\text{ mL} = \mathbf{16\ mL} \quad \textbf{Ans.}$$

Type. To calculate strength of H_2O_2 solution.

EXAMPLE 19. *Calculate the strength of 10 cm^3 of a 20 volume solution of hydrogen peroxide in g per litre.*

SOLUTION. Volume of H_2O_2 = 10 cm^3; label of H_2O_2 = 20 volume. 20 volume H_2O_2 means that :

1 cm^3 H_2O_2 produce O_2 = 20 cm^3

10 cm^3 H_2O_2 produce O_2 = 20 × 10 = 200 cm^3

$$\text{But,} \quad \underset{\substack{2[(2\times1)+(2\times16)]\\=68g}}{2H_2O_2} \rightarrow 2H_2O + \underset{22400cm^3}{O_2}$$

22400 cm^3 O_2 is produced from H_2O_2 = 68 g

200 cm^3 O_2 is produced from

$$H_2O_2 = \frac{68}{22400} \times 200 = 0.607\,g$$

Thus, 10 cm^3 H_2O_2 contain H_2O_2 = 0.607 g

1000 cm^3 H_2O_2 contain

$$H_2O_2 = \frac{0.607}{10} \times 1000 = 60.7g$$

$\therefore$ Concentration of H_2O_2 = **60.7 g L^-** **Ans.**

Type. To calculate volume strength of H_2O_2.

EXAMPLE 20. *Calculate the strength in volumes of a solution containing 60.7 g L^- of hydrogen peroxide.*

SOLUTION. *Reaction* : $\underset{\substack{2[(2\times1)+(2\times16)]\\=68g}}{2H_2O_2} \rightarrow 2H_2O + \underset{22.4\,L\,at\,N.T.P.}{O_2}$

68 g H_2O_2 produce O_2 = 22.4 L

60.7 g H_2O_2 produce $O_2 = \frac{22.4}{68} \times 60.7 \simeq 20L$

We know that : 1 L O_2 is produced from

H_2O_2 = 1 volume

∴ 20 L O_2 is produced from H_2O_2 = **20 volume** **Ans.**

Example 21. *A 5.0 cm^3 of H_2O_2 liberates 0.508 g of iodine from an acidified KI solution. Calculate the strength of H_2O_2 solution in terms of volume strength at S.T.P.* **(IIT, 1995)**

Solution. Volume of H_2O_2 = 5.0 cm^3; Wt. of I_2 = 0.508 g. Strength of H_2O_2 solution in terms of volume = ?

Reaction :

$$2KI + H_2SO_4 + \underset{(2\times1)+(2\times16)=34g}{H_2O_2} \rightarrow K_2SO_4 + 2H_2O + \underset{2\times127=254g}{I_2}$$

254 g I_2 is formed from H_2O_2 = 34 g

0.508 g I_2 is formed from

$$H_2O_2 = \frac{34}{254} \times 0.508 = 0.068 \text{ g}$$

It means : 5 cm^3 H_2O_2 solution contain

H_2O_2 = 0.068 g

∴ 1 cm^3 H_2O_2 solution contain

$$H_2O_2 = \frac{0.068}{5} = 0.0136g$$

But, $\underset{\substack{2[(2\times1)+(2\times16)]\\=68g}}{2H_2O_2} \rightarrow 2H_2O + \underset{22400cm^3}{O_2}$

68 g H_2O_2 produce O_2 = 22400 cm^3

0.0136 g H_2O_2 produce O_2

$$= \frac{22400}{68} \times 0.0136 = 4.48 \text{ cm}^3 \text{ at S.T.P.}$$

Since 1 cm^3 H_2O_2 produce O_2 = 4.48 cm^3

∴ Strength of H_2O_2 solution = **4.48 volume** **Ans.**

Type. To calculate percentage, normality and molarity of H_2O_2 solution.

Example 22. *The label on a bottle of hydrogen peroxide solution reads as 30 volume. Calculate the concentration of hydrogen peroxide in percentage. Also, calculate the molarity and normality of this solution.* **(Roorkee, 1989)**

Solution. (*a*) 30 volume H_2O_2 means that :

1 L H_2O_2 liberates O_2 = 30 L

But, $\underset{\substack{2[(2\times1)+(2\times16)]\\=68g}}{2H_2O_2} \rightarrow 2H_2O + \underset{22.4L\,at\,N.T.P.}{O_2}$

Thus, 22.4 L O_2 is produced from H_2O_2 = 68 g

30 L O_2 is produced from

$$H_2O_2 = \frac{68g}{22.4L} \times 30L = 91.07gL^{-}$$

∴ Concentration of H_2O_2 = 91.07 g L^{-}.

Thus : 1000 mL H_2O_2 solution contain

H_2O_2 = 91.07 g

∴ 100 mL H_2O_2 solution contain

$$H_2O_2 = \frac{91.07}{1000} \times 100 = 9.107 \text{ g}$$

∴ Conc. of H_2O_2 in percentage = 9.107%

(*b*) To calculate normality of H_2O_2 :

$$\text{Eq. wt. of } H_2O_2 = \frac{\text{Mol. wt.}}{2} = \frac{(2\times1)+(2\times16)}{2} = 17$$

$$\therefore \quad \text{Normality} = \frac{\text{Wt. of } H_2O_2}{\text{g. eq. wt. of } H_2O_2} \times \frac{1000}{\text{Vol. of solution in mL}}$$

$$= \frac{91.07g}{17g} \times \frac{1000}{1000} = \mathbf{5.36} \qquad \textbf{Ans.}$$

(*c*) To calculate molarity of H_2O_2.

g. mol. wt. of H_2O_2 = (2 × 1) + (2 × 16) = 34 g. We know :

Molarity × Mol. wt. = normality × Eq. wt.

$$\therefore \quad \text{Molarity} = \frac{\text{normality} \times \text{Eq. wt.}}{\text{Mol. wt.}}$$

$$= \frac{5.36 \times 17}{34} = \mathbf{2.68\ M} \qquad \textbf{Ans.}$$

Example 23. *Calculate the mass of hydrogen peroxide present in 0.5 litre of a 2.5 M solution. Also, find the volume of oxygen at N.T.P. liberated upon the complete decomposition of 60 cm^3 of the above solution.*

Solution. (*a*) Volume = 0.5 L = 0.5 × 1000 = 500 cm^3; wt. of H_2O_2 = ? Volume of O_2 at N.T.P. = ?, molarity of H_2O_2 = 2.5 M; g. mol. wt. of H_2O_2 = (2 × 1) + (2 × 16) = 34 g.

$$\text{Molarity} = \frac{\text{wt.}}{\text{g. mol. wt.}} \times \frac{1000}{\text{Vol. of solution in cm}^3}$$

Or Wt. of H_2O_2

$$= \frac{\text{molarity} \times \text{g. mol. wt.} \times \text{vol. of solution in cm}^3}{1000}$$

$$= \frac{2.5 \times 34 \times 500}{1000} = \mathbf{42.5\ gL^{-}} \qquad \textbf{Ans.}$$

(*b*) $\underset{\substack{2[(2\times1)+(2\times16)]\\=68g}}{2H_2O_2} \rightarrow 2H_2O + \underset{22400cm^3 at N.T.P.}{O_2}$ ...(1)

1000 cm^3 H_2O_2 contain H_2O_2 = 42.5 g

60 cm^3 H_2O_2 contain $H_2O_2 = \frac{42.5}{1000} \times 60 = 2.55g$

From equation (1), we have :

68 g H_2O_2 liberate O_2 = 22400 cm^3

2.55 g H_2O_2 liberate O_2

$$= \frac{22400}{68} \times 2.55 = \mathbf{840\ cm^3} \qquad \textbf{Ans.}$$

Example 24. *To a 25 mL H_2O_2 solution, excess of acidified solution of potassium iodide was added. The iodine liberated required 20 mL of 0.3 N sodium thisulphate solution. Calculate the volume strength of H_2O_2 solution.* **(IIT, 1997)**

Solution. (*i*) Let N_1 = normality of H_2O_2 solution. Thus:

$$\begin{array}{ll} H_2O_2 \text{ solution} & Na_2S_2O_3 \text{ solution} \end{array}$$

$$N_1V_1 = N_2V_2\,;\; N_1 \times 25 = 0.3 \times 20$$

$$\therefore \quad N_1 = \frac{0.3 \times 20}{25} = 0.24$$

(*ii*) To find amount of H_2O_2 in 25 mL H_2O_2 solution.

$$\text{Eq. wt. of } H_2O_2 = \frac{\text{Mol. wt.}}{2} = \frac{(2\times 1)+(16\times 2)}{2} = 17$$

We know that : 1000 mL 1N

$$H_2O_2 \equiv \text{g. eq. wt. of } H_2O_2 = 17\text{g}$$

$\therefore$ 25 mL of 0.24 N H_2O_2

$$\equiv \frac{17}{1000} \times 25 \times 0.24 = \mathbf{0.102\ g.}$$

(*iii*) To find volume strength of H_2O_2

$$\underset{\substack{2[(2\times1)+(2\times16)]\\=68\,\text{g}}}{2H_2O_2} \rightarrow 2H_2O + \underset{22400\,\text{mL}}{O_2}$$

68g H_2O_2 liberate O_2 = 22400 mL

0.102 g H_2O_2 liberate

$$O_2 = \frac{22400}{68} \times 0.102 = 33.6\,\text{mL at N.T.P.}$$

25 mL H_2O_2 liberate O_2 = 33.6 mL

1 mL H_2O_2 liberate O_2

$$= \frac{33.6}{25} = 1.344\,\text{mL}$$

$\therefore$ Volume strength of H_2O_2 = **1.344** **Ans.**

Example 25. *Hydrogen peroxide solution (20 mL) reacts quantitatively with the solution of $KMnO_4$ (20 mL) acidified with dilute sulphuric acid. The same volume of the $KMnO_4$ solution is just decolorised by 10 mL of $MnSO_4$ in neutral medium simultaneously forming a dark brown precipitate of hydrated MnO_2. The brown precipitate is dissolved in 10 mL of 0.2 M sodium oxalate under boiling conditions in presence of dilute sulphuric acid. Write the balanced equations involved in the reaction and calculate the molarity of H_2O_2.* **(IIT, 2001)**

Solution. The balanced equations are :

(*i*) In acidic medium :

$$MnO_4^- + 8H^+ + 5e^- \rightarrow Mn^{2+} + 4H_2O] \times 2$$

$$H_2O_2 \rightarrow O_2 + 2H^+ + 2e^-] \times 5$$

$$\text{Adding: } 2MnO_4^- + 5H_2O_2 + 6H^+ \rightarrow 2Mn^{2+} + 8H_2O + 5O_2$$

(*ii*) In neutral medium :

$$MnO_4^- + 2H_2O + 3e^- + \rightarrow MnO_2 + 4OH^-] \times 2$$

$$Mn^{2+} + 4OH^- \rightarrow MnO_2 + 2H_2O + 2e^-] \times 3$$

$$\text{Adding : } 2MnO_4^- + 3Mn^{2+} + 4OH^- \rightarrow \underset{\text{Brown ppt}}{5MnO_2} + 2H_2O$$

(*iii*) To dissolve MnO_2ppt in sodium oxalate ($Na_2C_2O_4$) and dil. H_2SO_4.

$$MnO_2 + 4H^+ + 2e^- \rightarrow Mn^{2+} + 2H_2O$$

$$C_2O_4^{2-} \rightarrow 2CO_2 + 2e^-$$

$$\text{Adding : } MnO_2 + C_2O_4^{2-}\ 4H^+ \rightarrow Mn^{2+} + 2CO_2 + 2H_2O$$

We know that 20 mL H_2O_2 reacts quantitatively with 20 mL $KMnO_4$. Also from equation (*iii*) we find that :

x equivalents sodium oxalate $\equiv x$ eqivalents of MnO_2 $\equiv x$ equivalents of H_2O_2 ...(*iv*)

$$C_2O_4^{2-} \rightarrow 2CO_2 + 2e^-$$

$$\therefore \text{ Eq. wt. of } Na_2C_2O_4 = \frac{\text{Mol. wt.}}{2}$$

$\therefore$ Normality of

$$\begin{aligned} Na_2C_2O_4 &= \text{Molarity} \times \text{no. of electrons} \\ \text{involved} &= 0.2 \times 2 = 0.4 \end{aligned}$$

$\therefore$ Milliequivalent of $Na_2C_2O_4$

$$\begin{aligned} &= \text{Normality} \times \text{volume in mL} \\ &= 0.4 \times 10 = 4 \end{aligned}$$

Hence using relation (*iv*), no. of milliequivalents of H_2O_2 in 20 mL = 4.

Or *no. of milliequivalents of H_2O_2 in 1 mL*

$$= \frac{4}{20} = \mathbf{0.2.}$$

Or No. of millimol of

$$H_2O_2 \text{ in 1 mL} = \text{no. of milliequivalents} \times \frac{\text{Eq. wt. of } H_2O_2}{\text{Mol. wt. of } H_2O_2}$$

$$= \frac{0.2 \times 17}{34} = \mathbf{0.1}$$

[$\because$ Mol. wt. of H_2O_2 = (2 × 1) + (2 × 16) = 34; eq. wt. of

$$H_2O_2 = \frac{\text{Mol. wt.}}{\substack{\text{Total valency}\\ \text{of } 2H^+(=2)}} = \frac{34}{2} = 17]$$

Hence molarity of H_2O_2 = 0.1 M **Ans.**

28.6 AIEEE PATTERN EXAMPLES

Example 26. *The hardness of water containing 24 ppm of $MgSO_4$ is :*

(a) 10 ppm	*(b) 20 ppm*
(c) 30 ppm	*(d) 40 ppm*

Solution. Mol. wt. of $MgSO_4$

$$= 24 + 32 + (4 \times 16) = 120\ \text{g mol}^-.$$

Mol. wt. of $CaCO_3$ = 40 + 12 + (3 × 16) = 100 g mol^-

We know that : 1 g mol

$$\begin{array}{rl} MgSO_4 & \equiv 1 \text{ g mol } CaCO_3 \\ 120\text{ g} & 100\text{ g} \\ 120\text{ ppm} & 100\text{ ppm} \end{array}$$

Since the hardness of water is expressed in terms of $CaCO_3$, thus :

$$120 \text{ ppm } MgSO_4 \equiv 100 \text{ ppm } CaCO_3$$

$$24 \text{ ppm } MgSO_4 \equiv \frac{100}{120}\times 24 = 20\,\text{ppm}$$

So, the correct answer is (*b*).

Example 27. *The temporary hardness of water containing 20 ppm of Ca $(HCO_3)_2$ and 10 ppm of $MgSO_4$ is :*

(*a*) *8.2 ppm* (*b*) *9.2 ppm*

(*c*) *12.3 ppm* (*d*) *24.6 ppm*

Solution. Mol. wt. of

$$Ca\,(HCO_3)_2 = 40 + 2\,[1 + 12 + (3 \times 16)]$$
$$= 162 \text{ g mol}^-$$

Mol. wt. of $CaCO_3$ = 40 + 12 + (3 × 16) = 100 g mol$^-$

Since temporary hardness of water is due to $Ca(HCO_3)_2$ only and it is expressed in terms of $CaCO_3$, so we have :

g. mol. of $Ca(HCO_3)_2 \equiv$ 1 g. mol $CaCO_3$

162 g 100 g

162 ppm 100 ppm

162 ppm $Ca(HCO_3)_2 \equiv$ 100 ppm $CaCO_3$

$$\therefore\ 20 \text{ ppm } Ca(HCO_3)_2 \equiv \frac{100}{162}\times 20 = 12.3\,\text{ppm}$$

So, the correct answer is (*c*).

Example 28. *The permanent hardness of water containing 12 mg of $MgCl_2$ and 24 ppm of $Mg(HCO_3)_2$ per 1/2 kg of water is :*

(*a*) *25.2 ppm* (*b*) *12.6 ppm*

(*c*) *126 ppm* (*d*) *1.26 ppm*

Solution. Out of $MgCl_2$ and $Mg(HCO_3)_2$, the permanent hardness is due to $MgCl_2$ only.

Mol. wt. of $MgCl_2$ = 24 + (2 × 35) = 95 g mol$^-$;

Mol. wt. of $CaCO_3$ = 40 + 12 + (3 × 16) = 100 g mol$^-$

Since the hardness is expressed in terms of $CaCO_3$, so, we have :

$$\text{Wt. of } MgCl_2 = 12\text{mg}\times\frac{1\text{g}}{1000\,\text{mg}} = 12\times10^{-3}\text{g}$$

$$\text{No. of mol. of } MgCl_2 = \frac{\text{wt.}}{\text{mol. wt.}} = \frac{12\times10^{-3}\text{g}}{95\text{g mol}^-}$$
$$= 1.26 \times 10^{-4} \text{ mol}$$

But, 1 g mol $MgCl_2 \equiv$ 1 g mol $CaCO_3 \equiv$ 100 g $CaCO_3$

1.26×10^{-4} mol $MgCl_2$ = $1.26 \times 10^{-4} \times 100$ g $CaCO_3$

= 1.26×10^{-2} g $CaCO_3$

$$\text{Wt. of hard water} = \frac{1}{2}\text{kg} = \frac{1}{2}\times 1000 = 500\,\text{g}.$$

∴ 500 g hard water contains $MgCl_2$ equivalent to $CaCO_3$ = 1.26×10^{-2}g $CaCO_3$

∴ 10^6 g (= one million) water contains $MgCl_2$ equivalent to $CaCO_3$

$$= \frac{1.26\times10^{-2}\text{g}}{500\,\text{g}}\times10^6\text{g} = 25.2\text{g}.$$

∴ Permanent hardness of water = 25.2 ppm. So, the correct answer is (*a*).

Example 29. *The 'volume strength' of 1.5 N H_2O_2 solution is :*

(*a*) *4.8* (*b*) *8.4*

(*c*) *3.0* (*d*) *8.0*

(CBSE, 1997, IIT, 1991)

Solution. g. eq. wt. of

$$H_2O_2 = \frac{\text{Mol. wt.}}{2} = \frac{(2\times1)+(2\times16)}{2} = 17\text{g}$$

1N H_2O_2 contain

H_2O_2 = 1 g eq. wt. of H_2O_2= 17 g

1.5 N H_2O_2 contain H_2O_2 = 17 × 1.5 = 25.5 g

$$\underset{\substack{2[(2\times1)+(2\times16)]\\=68\,\text{g}}}{2H_2O_2} \rightarrow \underset{22.4\text{L}}{O_2} + 2H_2O$$

68 g H_2O_2 liberate O_2 = 22.4 L

$$25.5 \text{ g } H_2O_2 \text{ liberate } O_2 = \frac{22.4}{68}\times 25.5 = 8.4 \text{ L}$$

So, the correct answer is (*b*).

Example 30. *The amount of H_2O_2 present in one litre of 2.2 N H_2O_2 solution is :*

(*a*) *74.8* (*b*) *37.4*

(*c*) *18.7* (*d*) *9.35*

Solution. g. eq. wt. of

$$H_2O_2 = \frac{\text{Mol. wt.}}{2} = \frac{(2\times1)+(2\times16)}{2} = 17\text{g}$$

1 N H_2O_2 contain H_2O_2 = g. eq. wt. of H_2O_2 = 17 g

2.2 N H_2O_2 contain H_2O_2 = 17 × 2.2 = 37.4 g

So, the correct answer is (*b*).

Example 31. *20 volume of H_2O_2 solution has a strength of about*

(*a*) *30%* (*b*) *6%*

(*c*) *3%* (*d*) *10%*

Solution. $\underset{\substack{2[(2\times1)+(2\times16)]\\=68\,\text{g}}}{2H_2O_2} \rightarrow 2H_2O + \underset{22400\,\text{mL}}{O_2}$

20 volume H_2O_2 solution means that 1 mL H_2O_2 liberate 20 mL oxygen.

22400 mL O_2 is liberated from H_2O_2 = 68 g.

$$20 \text{ mL } O_2 \text{ is liberated from } H_2O_2 = \frac{68}{22400}\times 20 = 0.06$$

$$\%\text{ age of } H_2O_2 = \frac{0.06}{1}\times 100 = 6\%$$

So, the correct answer is (*b*).

Example 32. *Commercially 10 volume H_2O_2 is a solution with strength of approximately*

(*a*) *30 gL$^-$* (*b*) *6 gL$^-$*

(*c*) *3 gL$^-$* (*d*) *10 gL$^-$*

(BET, 2003)

Solution. 10 volume H_2O_2 means that :

1 mL of H_2O_2 at N.T.P. gives O_2 gas = 10 mL

Reaction : $\underset{\substack{2[(2\times1)+(2\times16)]\\=68\,g}}{2H_2O_2} \rightarrow 2H_2O + \underset{22400\,mL}{O_2}$

22400 mL O_2 at N.T.P. ≡ 68 g H_2O_2

$\therefore$ 10 mL O_2 at N.T.P. = $\dfrac{68}{22400}\times10 = 0.0303\,g$

$\therefore$ 1mL of H_2O_2 (volume) weighs
= 0.0303 g

$\therefore$ 1000 mL of H_2O_2 (10 volume) weighs
= 0.0303 × 1000 = 30.3 ≃ 30 gL^-.

So, the correct answer is (*a*).

Exampe 33. *The percent strength (W/V) and normality of 15 mL of a 40 volume H_2O_2 solution is respectively.*

(*a*) *6%, 6.1 N* (*b*) *7%, 9.2 N*
(*c*) *12.13%, 7.14 N* (*d*) *20%, 2N*

Solution. 40 volume H_2O_2 means that :

1 mL of 40 volume H_2O_2 produces O_2 = 40 mL

$\therefore$ 15 mL of 40 volume H_2O_2 produces

$$O_2 = \frac{40\,mL}{1\,mL}\times15\,mL = 600\,mL$$

Reaction : $\underset{\substack{2[(2\times1)+(2\times16)]\\=68\,g}}{2H_2O_2} \rightarrow 2H_2O + \underset{22400\,mL\,at\,N.T.P.}{O_2}$

22400 mL of O_2 at N.T.P. is obtained from
H_2O_2 = 68 g

$\therefore$ 600 mL of O_2 at N.T.P. is obtained from

$$H_2O_2 = \frac{68g}{22400\,mL}\times600\,mL = 1.82g$$

(*i*) 15 mL of given H_2O_2 solution contains
H_2O_2 = 1.82 g

1000 mL (or 1L) of given H_2O_2 solution contains H_2O_2

$$= \frac{1.82g}{15\,mL}\times1000\,mL = 121.3\,gL^-$$

$\therefore$ Strength of given 40 volume
H_2O_2 solution = 121.3 gL^-

Similarly : 15 mL of given H_2O_2 solution contains
H_2O_2 = 1.82 g

$\therefore$ 100 mL of given H_2O_2 solution contains

$$H_2O_2 = \frac{1.82\,g}{15\,mL}\times100\,mL$$

= 12.13 g per 100 mL

$\therefore$ Percent strength of given
H_2O_2 = 12.13 % (W/V)

(*ii*) Eq. wt. of H_2O_2 = $\dfrac{\text{Mol. wt. of } H_2O_2}{2}$

$$= \frac{(2\times1)+(2\times16)}{2} = 17$$

$[\because H_2O_2 \rightarrow 2H^+ + O_2 + 2e^-]$

$$\therefore \quad \text{Normality} = \frac{\text{Strength in gL}^-}{\text{Eq.wt.}} = \frac{12.13}{17}$$

= 7.14 N **Ans.**

So, the correct answer is (*c*).

Example 34. *7.5 cm^3 of '10 volume' H_2O_2 solution was acidified with dil. H_2SO_4 and titrated with N/20 $KMnO_4$ solution. It was found that 15 cm^3 of N/20 $KMnO_4$ was needed to exactly oxidise the given H_2O_2 solution. The % age of H_2O_2 in the solution is :*

(*a*) *20%* (*b*) *21%*
(*c*) *17%* (*d*) *0.17%*

Solution. For H_2O_2 ,
N_1 = ?, V_1 = 7.5 cm^3; For $KMnO_4$,
N_2 = 1/20, V_2 = 15 cm^3.

Using normality equation, we have:

$$\begin{aligned} &H_2O_2 \quad KMnO_4 \\ N_1V_1 &= N_2V_2 \\ N_1\times7.5\,cm^3 &= \frac{1}{20}\times15\,cm^3; N_1 \\ &= \frac{1}{20}\times\frac{15\,cm^3}{7.5\,cm^3} = 0.1N \end{aligned}$$

H_2O_2 (reductant) was oxidised by $KMnO_4$ according to the reaction:

$$H_2O_2 \rightarrow 2H^+ + O_2 + 2e^-$$

$\therefore$ Eq. wt. of H_2O_2 = $\dfrac{\text{Mol. wt.}}{2} = \dfrac{(2\times1)+(2\times16)}{2} = 17$

$\therefore$ Strength of H_2O_2 = Normality × Eq. wt.
= 0.1 × 17 = 1.7 g L^-

Hence,% age of H_2O_2= $\dfrac{1.7\times100}{1000} = 0.17\%$

So, the correct answer is (*d*).

Example 35. *The normality of 30 volume H_2O_2 is:*

(*a*) *2.678 N* (*b*) *5.35 N*
(*c*) *8.034 N* (*d*) *6.685 N*

(WB-JEE, 2011)

Solution. We know:
Volume strength = 5.6 × normality
$\therefore$ 30 = 5.6 × Normality;
Normality = 30/5.6 = 5.35

So, the correct strength is (*b*).

Example 36. *An ion exchange resin RH_2 displaces Mg^{2+} ions in hard water as:*

$Mg^{2+} + RH_2 \rightarrow R\,Mg + 2H^+$

When exact one litre of hard water was passed through the resin, the water was found to have pH = 3. So, the hardness of Mg^{2+} in ppm will be:

(*a*) *4 ppm* (*b*) *8 ppm*
(*c*) *12 ppm* (*d*) *16 ppm*

(PSEB, 2012)

Solution. pH = 3. So, $[H^+] = 10^{-3}$ and $[Mg^{2+}] = 10^{-3}/2$

$= \dfrac{24 \times 10^{-3}}{2}$ g L^- ($\because$ at. wt. of Mg = 24 amu.). Hence:

$$\text{Hardness} = \frac{24 \times 10^{-3}}{2 \times 1000} \times 10^6 = 12 \text{ ppm.}$$

[$\because$ 1 L = 1000mL]

Example 37. *150 mL of a given hard water (density 1 g cm^{-3}) needs 31.2 mL of 0.04 N H_2SO_4 for complete reaction. The hardness of water will be:*

(a) *208 ppm* *(b)* *416 pm*
(c) *624 pm* *(d)* *832 ppm*

(H.P. Board, 2012)

Solution. The hardness is calculated in terms of $CaCO_3$, mol. wt. = 100 [*i.e.*, 40 + 12 + (3 × 16) = 100] and equivalent weight = 100/Valency of Ca^{2+} = 2

= 50. Thus:

Milliequivalents of H_2SO_4 = Milliequivalents of $CaCO_3$.

$$31.2 \times 0.04 = \frac{\text{wt. of } CaCO_3\ (= w)}{\text{Eq. wt. of } CaCO_3} \times 1000 = \frac{w \times 1000}{50}$$

$$\therefore w = \frac{31.2 \times 0.04 \times 50}{1000} = 0.0624$$

$$\text{Hence hardness} = \frac{0.0624 \times 10^6}{150} = 416 \text{ ppm}$$

So, the correct answer is (*b*).

Example 38. *Calculate the degree of hardness (in ppm) of a sample of water containing 6 mg of $MgSO_4$ per kg of water. (Mol. wt. of $MgSO_4$ = 120 g mol^-)*

Solution.

Mol. wt. of $MgSO_4$ = 120 g mol^- = 1 g mol^- of $MgSO_4$

(*i*) 120 g $MgSO_4 \equiv$ 1 g mol of $CaCO_3$ or 100 g $CaCO_3$

$$6 \times 10^{-3} \text{ g } MgSO_4 = \frac{100 \times 6 \times 10^{-3}}{120} = 5 \times 10^{-3} \text{ g } CaCO_3$$

$$\left[\begin{array}{l} \because \text{Mol. wt. of } CaCO_3 = 40 + 12 + 3\,(16) = 100 \\ \text{Also, } 6 \text{ mg} = 6 \times 10^{-3} \text{ g} \\ \quad 1 \text{ kg} = 1000 \text{ g} \end{array}\right]$$

(*ii*) 1000 g water contains $MgSO_4$ equivalent to 5×10^{-3} g $CaCO_3$

$$\therefore 10^6 \text{ g of water will contain } CaCO_3 = \frac{5 \times 10^{-3}}{1000} \times 10^6$$

$= 5$ g $CaCO_3$

$\therefore$ Hardness of water sample = **5 ppm** **Ans.**

PROBLEMS FOR PRACTICE

1. Volume strength of hydrogen peroxide is 22.4. What volume of this sample is required for the oxidation of 3.4 g of hydrogen sulphide?

(*a*) 50 mL (*b*) 200 mL
(*c*) 100 mL (*d*) 5 mL **Ans.** (*a*)

2. The normality of 30 volume H_2O_2 is:

(*a*) 1.1 (*b*) 2.2
(*c*) 5.36 (*d*) 6.2 **Ans.** (*c*)

3. A sample of water contains 30 ppm of $CaCl_2$. Find the degree of hardness of this water.

Ans. (27.03 ppm $CaCO_3$)

4. Calculate the molarity of 10 volume H_2O_2.

Ans. (3.57 M)

5. What volume of 30 volume H_2O_2 be decomposed to get 100 mL of oxygen at N.T.P.?

Ans. (3.33 mL)

6. Calculate the strength in volumes of a solution containing 60.7 gL^- of hydrogen peroxide.

Ans. (20 Volume)

7. The temporary hardness of water containing 15 ppm of $Ca(HCO_3)_2$ and 10 ppm of $MgSO_4$ is:

(*a*) 9.26 ppm (*b*) 1 ppm
(*c*) 2 ppm (*d*) 1.97 ppm

Ans. (*a*)

8. The hardness of water containing 10 ppm $MgSO_4$ is:

(*a*) 5.1 (*b*) 7.7
(*c*) 8.33 (*d*) 2.67 **Ans.** (*c*)

9. Calculate the volume strength of 0.16 N H_2O_2.

Ans. (0.896)

10. Find the volume strength of 0.2 M H_2O_2.

Ans. (2.24)

Note: For more numericals on hard water, see chapter 23, page.. 662.

29

CHAPTER

Polymers, Co-ordination Compounds and Surface Chemistry

29.1 POLYMERS

These are the high molecular mass compounds, obtained by joining to-gether a large number of simple molecules through covalent bonds in a regular fashion. The simple molecules which combine to form a polymer are called monomers. The process of the formation of polymers from the simple starting materials is called polymerisation.

29.2 NUMBER AVERAGE MOLECULAR WEIGHTS ($\overline{\mathbf{M}}_\mathbf{n}$)

It is defined as the total mass (or weight) of the material of a polymer sample divided by the number of moles of various polymer molecules present in the sample.

$$\overline{M}_n = \frac{n_1M_1 + n_2M_2 + ... n_iM_i + ...}{n_1 + n_2 + ... n_i + ...}$$

$$= \overline{M}_n = \frac{\sum_i niM_i}{\sum_i n_i}$$

Where $n_1\ n_2\ .....\ n_i$ ..... are the number of moles of the polymer molecule of molecular weight M_1, M_2 ..... M_i respectively.

Or $$\overline{M}_n = \frac{\text{wt. of polymer sample}}{\text{Total number of moles of various molecules present in the sample}}$$

In other words, $\overline{M}_n$ is simply the arithmetic mean of molecular weights of all molecules in a sample.

If *xi* is the mole fraction of polymer species '*i*', with molar mass 'M_i' then :

$$\overline{M}_n = \sum_i xiMi$$

29.3 WEIGHT AVERAGE MOLECULAR WEIGHTS ($\overline{\mathbf{M}}_\mathbf{w}$)

It is defined as the total contribution of various weight fractions of molecules to-wards the total molecular mass of the polymeric sample. *i.e.,*

$$\overline{M}_w = \sum_i w_iM_i = w_1M_1 + w_2M_2 + ...w_iM_i + ... \qquad (1)$$

Where w_i is the weight or mass fraction of polymeric species with molecular mass M_i *i.e.,*

$$w_i = \frac{\text{Mass of species '}i\text{'}}{\text{Total mass of polymer sample}}$$

$$= \frac{m_i}{\Sigma m_i} = \frac{n_iM_i}{\Sigma n_iM_i} \qquad ...(2)$$

Combining equations (1) and (2), we get :

$$\overline{M}_w = \frac{n_1M_1 \times M_1}{\Sigma n_iM_i} + \frac{n_2M_2 \times M_2}{\Sigma n_iM_i} + ... \frac{n_iM_i \times M_i}{\Sigma n_iM_i}$$

Or $$\overline{M}_w = \frac{\Sigma n_iM_i^2}{\Sigma n_iM_i}$$

29.4 CO-ORDINATION OR COMPLEX COMPOUNDS

These are such compounds which retain their identities even when dissolved in water or any other solvent and having properties completely different from those of the constituents. The branch of inorganic chemistry which deals with the study of co-ordination compounds is called co-ordination chemistry.

In co-ordination or complex compounds, the ligands that are written along with the central metal in square brackets *i.e.,* [] are non-ionisable while those which are written outside the square brackets are ionisable. *e.g.,*

(*i*) When the complex $[Co(NH_3)_6]Cl_3$ is dissolved in water, we get three Cl^- ions as shown below.

$$[Co(NH_3)_6]Cl_3 \rightleftharpoons [Co(NH_3)_6]^{3+} + 3Cl^-$$

(*ii*) When the complex $[Co(NH_3)_5Cl]Cl_2$ is dissolved in water, we get two Cl^- ions as shown below.

$$[Co(NH_3)_5Cl]Cl_2 \rightleftharpoons [Co(NH_3)_5Cl]^{2+} + 2Cl^-$$

Adsorption. The phenomenon of higher concentration of molecular species (gases or liquids) at the surface of a solid than in the bulk is called adsorption.

Freundlich adsorption isotherm. The curves obtained by plotting the amount of gas adsorbed ($a = x/m$) against gas pressure at a constant temperature are called adsorption isotherms. Mathematically, $\frac{x}{m} = a = kp^{1/n}$. This relation is called Freundlich isotherm. $\frac{x}{m}$ is the amount of gas adsorbed per gram of the adsorbent at a pressure P. K and n are the constants depending upon the nature of the gas and the adsorbent.

Example 1. *A sample of human blood plasma contains 40.0 g albumin with molecular weight, $M_1 = 69000$ and 20.0 g of globulin with molecular weight, $M_2 = 162000$. Calculate $\overline{M_n}$ and $\overline{M_w}$.*

Solution. Wt. of albumin, $W_1 = 40.0$g ; mol. wt, $M_1 = 69000$. So, no. of moles of albumin, $n_1 = \frac{40}{69000}$; Wt. of globulin, $W_2 = 20.0$g ; mol. wt., $M_2 = 162000$. So, $n_2 = \frac{20}{162000}$.

Hence (*i*) $\overline{M_n} = \frac{\sum_i niMi}{\sum_i ni}$

$$= \frac{[(40/69000) \times 692000 + [(20/162000) \times 162000]}{(40/69000) + (20/162000)}$$

$$= (40 + 20)/(5.7971 \times 10^{-4}) + (1.2346 \times 10^{-4})$$

$$= 60/10^{-4}(5.7971 + 1.2346) = \frac{60 \times 10^4}{7.0317} = 85328$$

(*ii*) $\overline{M_w} = \sum_i niM_i^2 / \sum_i niMi.$

$$= \frac{(40/69000) \times (69000)^2 + (20/162000) \times (162000)^2}{(40/69000) \times 69000 + (20/162000) \times 162000}$$

$$= 6 \times 10^6/60 = \mathbf{10^5}$$ **Ans.**

Example 2. *Calculate the number average molecular mass $\overline{M_n}$ and weight average molecular mass ($\overline{M_w}$) of a polymer in which 30% molecules have a molecular mass 20,000; 40% have 30,000 and the rest 30% have 60,000.*

Solution. The polymer contains $n_1 = 30, M_1 = 20{,}000$; $n_2 = 40, M_2 = 30{,}000$ and $n_3 = 30, M_3 = 60{,}000$.

So, $\overline{M_n} = \frac{n_1M_1 + n_2M_2 + n_3M_3}{n_1 + n_2 + n_3}$

$$= \frac{30 \times 20{,}000 + 40 \times 30{,}000 + 30 \times 60{,}000}{30 + 40 + 30}$$

$$= \frac{10{,}000\,(60 + 120 + 180)}{100} = 36{,}000$$ **Ans.**

$$\overline{M_w} = \frac{n_1M_1^2 + n_2M_2^2 + n_3M_3^2}{n_1M_1 + n_2M_2 + n_3M_3}$$

Substituting the values, we get ;

$$\frac{30(20{,}000)^2 + 40(30{,}000)^2 + 30(60{,}000)^2}{30 \times 20000 + 40 \times 30{,}000 + 30 \times 60{,}000}$$

$$= \frac{10^8(120 + 360 + 1080)}{10^4(60 + 120 + 180)}$$

$$= 10^4(1560/360) = 43333$$ **Ans.**

Example 3. *1 kg of a polymer with molar mass 10,000 g and the same amount of polymer with molar mass 20,000 g are mixed. Calculate $\overline{M_n}$ and $\overline{M_w}$.* **(GNDU 1998)**

Solution. (*i*) Wt. of one polymer, $W_1 = 1$ kg $= 1000$ g ; molar mass of one polymer, $M_1 = 10{,}000$ g.

So, n_1 = no. of moles of one polymer

$$= \frac{\text{wt.}}{\text{molar mass}} = \frac{1000\text{g}}{10{,}000\text{g}} = 0.1$$

(*ii*) Wt. of second polymer $W_2 = 1$ kg $= 1000$ g ; molar mass. of second $M_2 = 20{,}000$g.

So, n_2 = no. of moles of second polymer

$$= \frac{\text{wt.}}{\text{molar mass}} = \frac{1000\text{g}}{20{,}000\text{g}} = 0.05.$$

$\therefore$ $\overline{M_n} = \frac{\sum_i n_iM_i}{\sum_i n_i}$

$$= \frac{0.1 \times 10000 + 0.05 \times 20000}{0.1 + 0.05} = \frac{2000}{0.15}$$

$$= \mathbf{13333}$$ **Ans.**

Also, $\overline{M_w} = \frac{\sum_i n_iM_i^2}{\sum_i n_iM_i}$

$$= \frac{0.1 \times (10000)^2 + 0.05 \times (20{,}000)^2}{0.1 \times 10{,}000 + 0.05 \times 20{,}000}$$

$$= \frac{10^7 + 2 \times 10^7}{2000} = \frac{10^7(1 + 2)}{2000} = \frac{3 \times 10^7}{2 \times 10^3}$$

$$= \mathbf{15{,}000}$$ **Ans.**

Example 4. *A solution containing 4.22 g $PtCl_4.5NH_3$ was passed through a cation exchanger. The solution so obtained was treated with $AgNO_3$ solution. As a result 4.305 g of AgCl precipitate was obtained. Calculate the formula of the complex. (Molar mass of $PtCl_4.5NH_3$ = 422 g mol^{-} ; at. wt. of Ag = 108, Cl = 35.5).*

Solution. (*i*) Molar mass of AgCl = 108 + 35.5 = 143.5g mol$^-$; wt. of AgCl ppt = 4.305g.

We know that :

$$AgCl \equiv Cl$$
$$143.5 \text{ g} \quad 35.5 \text{ g}$$

143.5 g AgCl contain Cl = 35.5 g

$$4.305 \text{ g AgCl contain Cl} = \frac{35.5}{143.5} \times 305 = 1.065 \text{ g}$$

(*ii*) Let *n* = no. of Cl$^-$ ions (ionisable) outside the coordination sphere. Hence

422 g of $PtCl_4.5NH_3$ contain ionisable

Cl$^-$ ions = $n \times 35.5$ g

∴ 4.22 g of $PtCl_4.5NH_3$ contain ionisable

$$Cl^- \text{ ions} = \frac{n \times 35.5}{422} \times 4.22$$

$$\text{Hence} \quad \frac{n \times 35.5 \times 4.22}{422} = 1.065$$

$$\therefore \quad n = \frac{1.065 \times 422}{35.5 \times 4.22} = 3.0$$

∴ no. of Cl$^-$ ions outside the co-ordination sphere = 3

∴ Formula of the complex = **$[Pt(NH_3)_6]Cl_3$** **Ans.**

Example 5. *A solution containing 1 g of the complex $[Co(NH_3)_6]Cl_3$ was passed through a cation exchanger. The acid liberated was made up to one litre. Find out the strength of the acid solution. (At. wt., Co = 58.9, Cl = 35.5, N = 14, H = 1)*

Solution. Molar mass of complex $[Co(NH_3)_6]Cl_3$ = 58.9 + 6[14 + (3 × 1)] + 3 (35.5) = 266.4 g mol$^-$.

When solution of above complex is passed through cation exchanger, HCl is produced according to the following reactions.

$$\underset{1 \text{ mol}}{[Co(NH_3)_6]Cl_3} \rightleftharpoons \underset{3 \text{ mol}}{[Co(NH_3)_6]^{3+}} + \underset{3 \text{ mol}}{3Cl^-}$$

$$\underset{\text{(From cation exchanger)}}{3H^+} + 3Cl^- \longrightarrow \underset{3 \text{ mol}}{3HCl}$$

∴ 3 mol of HCl are produced from 1 mol of the complex *i.e.*,

$$[Co(NH_3)_6]Cl_3 \equiv 3HCl$$
$$266.4 \text{ g} \quad 3(1 + 35.5) = 109.5 \text{ g}$$

266.4 g complex liberated HCl = 109.5 g

$$1 \text{ g complex liberated HCl} = \frac{109.5}{266.4} \text{g} = 0.411 \text{ g}$$

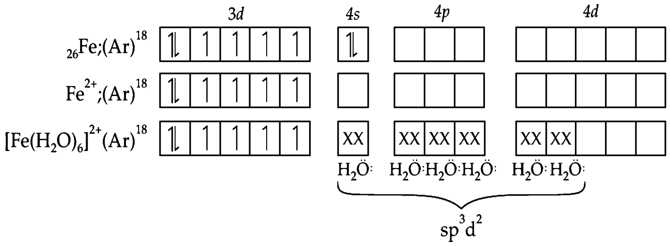
Hence one litre solution contain HCl = **0.411 g** **Ans.**

Example 6. *Describe for any two of the following complex-ions, the type of hybridisation, shape and magnetic properties.*

(*i*) $[Fe(H_2O)_6]^{2+}$ (*ii*) $[Co(NH_3)_6]^{3+}$

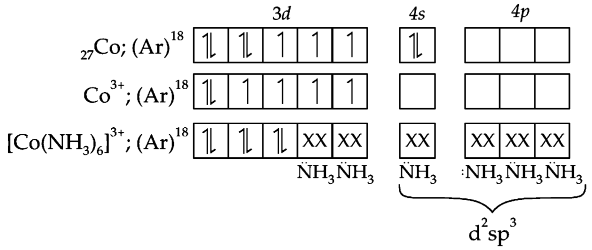
(At. no. Fe = 26, Co = 27, Ni = 28) **(CBSE, 2007)**

Solution. (*i*) $[Fe(H_2O)_6]^{2+}$. Here, oxidation state of Fe = +2



The complex has sp^3d^2 hybridisation and hence has octahedral shape. It is paramagnetic due to four unpaired electrons.

(*ii*) $[Co(NH_3)_6]^{3+}$. Here oxidation state of Co = +3

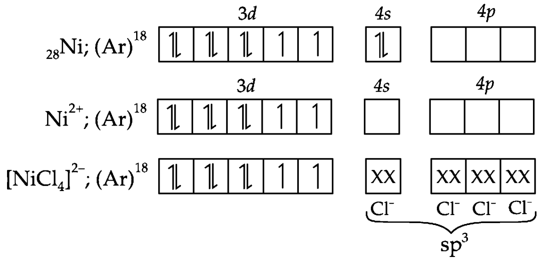


The complex has d^2sp^3 hybridisation and hence has octahedral shape. It is diamagnetic because all electrons are paired.

Example 7. *The magnetic moment (spin only) of $[NiCl_4]^{2-}$ is.*

(*a*) 1.82 BM	(*b*) 5.46 BM
(*c*) 2.82 BM	(*d*) 1.41 BM **(AIEEE, 2011)**

Solution. $[NiCl_4]^{2-}$. Here oxidation state of Ni = + 2



The complex has sp^3 hybridisation and hence has tetrahedral shape. It is paramagnetic due to two unpaired electrons. *i.e.*, $\mu_{BM} = [n(n + 2]^{1/2} = [2\ (2 + 2)]^{1/2} = 8^{1/2} =$ 2.82 B.M.

So, correct answer is (c)

Example 8. *A decapeptide (mol. wt. 796) on complete hydrolysis gives glycine (mol. wt. 75), alanine and phenylalanine. Glycine contributes 47.0% to the total weight of the hydrolysed products. The number of glycine units present in the decapeptide is :* **(IIT-JEE, 2011)**

Solution. Given : Decapeptide + $9H_2O$ → glycine + alanine + phenylalanine. Thus total wt. of amino acids after addition of 9 mol H_2O = 796 + (9 × 18) = 958. Let *n* = no. of units of glycine. So:

$$\frac{n \times 75}{958} \times 100 = 47.0 \; ; n = \frac{47 \times 958}{75 \times 100} = 6.003 \simeq 6$$

Example 9. *In a coagulation experiment, a sol of As_2S_3 is mixed with distilled water and 0.2 m solution of an electrolyte,* *AB so that total volume is 20 mL. It was found that all solutions containing more than 4.5 mL of AB get coagulated within two minutes. What is the flocculation value of AB for As_2S_3 ?* **(PSEB, 2008)**

Solution. Given : Concentration of AB = 0.2 m; Volume needed to coagulate 20 mL solution = 4.5 mL.

wt. of AB needed to coagulate 20 mL solution

$$= \frac{4.5 \times 0.2}{1000} \text{mol}$$

$$= \frac{4.5 \times 0.2}{1000} \times 1000 \text{ millimol}$$

$$= 0.9 \text{ millimol}$$

∴ Millimole of AB needed to coagulate 1 L (= 1000 mL)

$$\text{solution} = \frac{0.9 \times 1000}{20 \text{ for } As_2S_3} = 45$$

Hence flocculation value of AB = 45

Example 10. *On the addition of 2 mL of 5% NaCl to 10 mL gold sol in the presence of 0.025 g starch, the coagulation is just prevented. What is the gold number of starch ?* **(PSEB, 2008)**

Solution. Given : 2 mL of 5% NaCl solution means 1 mL of 10% NaCl solution. Thus:

0.025 g of starch just prevents the coagulation of 10 mL of gold sol on the addition of 1 mL of 10% NaCl.

∴ Milligram of starch which just prevent the coagulation of 10 mL gold sol on the addition of 1 mL of

$$10\% \text{ NaCl} = 0.025 \text{ g} \times \frac{1000 \text{ mg}}{1 \text{g}} = 25 .$$

∴ Gold number of starch = 25.

29.5 AIEEE PATTERN EXAMPLES

Example 11. *The number average molecular mass and mass average molecular mass of a polymer are respectively 30,000 and 40,000. The polydispersity index of the polymer is :*

(a) < 1 *(b)* > 1

(c) 1 *(d)* 0

(e) – 1 **(Kerala, PET, 2005)**

Solution. $\overline{M_n}$ = Number average molecular mass = 30,000

$\overline{M_w}$ = Mass average molecular mass = 40,000

$$\therefore \text{ polydispersity index (PDI)} = \frac{\overline{M_w}}{\overline{M_n}} = \frac{40{,}000}{30{,}000} = 1.33$$

So, the correct answer is **(*b*)**.

Example 12. *Which of the following complexes exhibits the highest paramagnetic behaviour?*

(a) $[Co(ox)_2(OH)_2]^-$ *(b)* $[Ti(NH_3)_6]^{3+}$

(c) $[V(gly)_2(OH)_2(NH_3)_2]^+$

(d) $[Fe(en)(bpy)(NH_3)_2]^{2+}$

Where gly = glycine, en = ethylenediamine and bpy = bipyridyl moities (At. no., Ti = 22, V = 23, Fe = 26, Co = 27) **(CBSE-PMT, 2008, Prelims)**

Solution. (*a*) Oxidation state (O.S) of Co is $[Co(ox)_2(OH)_2]^-$:

$x + 2(-2) + 2(-1) = -1; x - 4 - 2 = -1; x = 5$. or $_{27}Co^{5+} = (Ar)^{18}\, 3d^4$. The +5 oxidation state of Co is not possible because O.S. of Co is usually +2, +3 or +4.

(*b*) O.5 of Ti is $[Ti(NH_3)_6]^{3+}$. $x + 6 \times 0 = +3; x = +3$.

So, $_{22}Ti^{3+} = Ar^{18}\, 3d^1$, So, no. of unpaired electrons = 1.

(*c*) O.S of V is $[V(gly)_2(OH)_2(NH_3)_2]^+$. $x + (2 \times 0) + 2 \times (-1) + 2 \times 0 = +1; x - 2 = +1; x = +3$, So, $_{23}V^{3+} = (Ar)^{18}\, 3d^2$. So, no. of unpaired electrons = 2.

(*d*) O.S of Fe is $[Fe(en)(bpy)(NH_3)_2]^{2+}$. $x + 0 + 0 + 2 \times 0 = +2; x = +2$.

So, $_{26}Fe^{2+} = (Ar)^{18} 3d^6$ with 4 unpaired electrons ($3d^{2+1+1+1+1}$).

Since (*d*) has maximum no. of unpaired electrons, correct answer is (*d*).

Example 13. *Excess of silver nitrate solution is added to 100 mL of 0.01 M pentaaquachlorochromium (III) chloride solution. The mass of silver chloride obtained in gram is : (atomic mass of silver is 108).*

(a) 287×10^{-3} *(b)* 143.5×10^{-3}

(c) 143.5×10^{-2} *(d)* 287×10^{-2}

(Karnataka CET, 2011)

Solution.

$$[Cr(H_2O)_5Cl]Cl_2 \xrightarrow[\text{of } AgNO_3]{\text{Excess}} [Cr(H_2O)_5Cl]^{+2}_{+2NO_3^-} + 2AgCl\downarrow$$

2 mol, Cl 2 mol, Cl

∴ milliequivalents of Cl^- in complex = Milliequivalent of Cl^- in AgCl

But number of mol of Cl^- ions in 100 mL of 0.01 m complex.

$$= (2 \times 100 \times 0.01)/1000 = 0.002 \text{ mol.}$$

$$\therefore \text{Mass of AgCl} = 0.002 \times 143.5 \; [\because \text{Mol. wt. of AgCl} = 108 + 35.5 = 143.5]$$

$$= 0.287 \text{ g} = 287 \times 10^{-3} \text{ g.}$$

So, the correct answer is (*a*)

Example 14. *The volume (in mL) of 0.1 M $AgNO_3$ required for complete precipitation of chloride ions present in 30 mL of 0.01 M solution of $[Cr(H_2O)_5Cl]Cl_2$ as silver chloride is close to ml :* **(IIT-JEE, 2011)**

Solution. (*i*) The precipitation reaction is :

$$[Cr(H_2O)_5Cl]Cl_2 + 2AgNO_3 \rightarrow 2AgCl\downarrow + [Cr(H_2O)_5Cl](NO_3)_2$$

Here, the number of ionisable Cl^- ions =2. Thus :

No. of millimoles = 2 × molarity × volume (in mL)

$$= 2 \times 0.01 \times 30 = 0.6$$

∴ Ag^+ ions needed for precipitation = 0.6 millimoles.

But Millimoles = molarity × volume (in mL)

∴ 0.6 = 0.1 × volume ;

or volume = 0.6/0.1 = 6 mL

Example 15. *What is the equation form of Langmuir isotherm under high pressure?*

(a) $\frac{x}{m} = \frac{a}{b}$ *(b)* $\frac{x}{m} = aP$

(*c*) $\frac{x}{m} = \frac{1}{aP}$ (*d*) $\frac{x}{m} = \frac{b}{a}$ **(Gujarat, 2006)**

Solution. According to Langmuir adsorption isotherm,

$$\frac{x}{m} = \frac{aP}{1+bP} \qquad ...(A)$$

Where x = mass of gas adsorbed on mass m g of the adsorbent. a and b are constants while p is the pressure of the gas. At high pressure, $bP >>> 1$.

So, Equation (*A*) changes to

$$\frac{x}{m} = \frac{aP}{1+bP} = \frac{a}{b}$$

So, the correct answer is (***a***).

Example 16. *The volume of a colloidal particle, Vc as compared to the volume of a solute particle in a true solution Vs could be :*

(*a*) $\frac{Vc}{Vs} \simeq 1$ (*b*) $\frac{Vc}{Vs} \simeq 1023$

(*c*) $\frac{Vc}{Vs} = 10$ to 3 (*d*) $\frac{Vc}{Vs} \simeq 1003$ **(AIEEE, 2005)**

Solution. (*i*) For a true solution, the diameter of the solute particle ranges from 1 to 10A° and for colloidal solution, the diameter of colloidal particle range is 10 to 1000 A°. Taking the lower limits :

$$\frac{Vc}{Vs} = \frac{\frac{4}{3}\pi r_c^3}{\frac{4}{3}\pi r_s^3} = \left(\frac{rc}{rs}\right)^3$$

Substituting the values of diameters in place of rc and rs, we have

$$\frac{Vc}{Vs} = \left(\frac{10}{1}\right)^3 = 1000 \simeq 1003.$$

So, the correct answer is (*d*).

Example 17. *1 g of charcoal adsorbs 100 mL of 0.5M CH_3COOH to form a monolayer, and thereby the molarity of CH_3COOH reduces to 0.49. The surface area of charcoal is 3.01×10^2 m²/g. The surface area of the charcoal adsorbed by each molecule of acetic acid is :*

(*a*) 2.5×10^{-19} (*b*) 5.0×10^{-19}

(*c*) 13.2×10^{-18} (*d*) 1.32×10^{-19}

(IIT 2003 modified)

Solution. (*i*) At start, no, of millimol of CH_3COOH adsorbed = 100 × 0.5 = 50

(*ii*) At the end, no. of millimol of CH_3COOH adsorbed = 100 × 0.49 = 49

∴ no. of millimole of CH_3COOH actually adsorbed = 50 – 49 = 1

But $1 \text{ millimol} = \frac{1}{1000} \text{ mol} = \frac{1}{10^3}$

∴ no. of molecules of CH_3COOH that adsorbed

$$= \frac{6.02 \times 10^{23}}{10^3} = 6.02 \times 10^{20}$$

Area of 1 g charcoal = 3.01×10^2 m²

6.02×10^{20} molecules of CH_3COOH get adsorbed in area = 3.01×10^2 m²

∴ 1 molecule of CH_3COOH get adsorbed in area

$$= \frac{3.01 \times 10^2}{6.02 \times 10^{20}} = \mathbf{5.0 \times 10^{-19}} \qquad \textbf{Ans.}$$

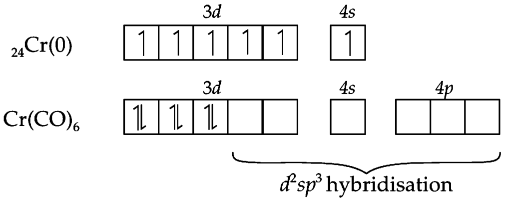
Example 18. *The spin only magnetic moment value (in Bohr magneton units) of $Cr(CO)_6$ is :*

(*a*) 0 (*b*) 2.84

(*c*) 4.90 (*d*) = 5.92

(AIEEE, 2006; IIT-JEE, 2009)

Solution. In $Cr(CO)_6$, Cr (at. no. 24) has 24 e^- and CO is a neutral strong ligand. So, CO causes pairing of electrons.



∴ number of unpaired electrons, $n = 0$

∴ Magnetic moment, $\mu = [n(n+2)]^{1/2}$

$= [0(0+2)]^{1/2} = 0$

So, the correct answer is (*a*)

Example 19. *There are 20 naturally occurring aminoacids. The maximum number of tripeptides that can be obtained is :*

(*a*) 6470 (*b*) 7465

(*c*) 5360 (*d*) 8000. **(Karnataka CET, 2009)**

Solution. Given: no. of naturally occurring amino acids is 20. So, the maximum number of tripeptides that can be obtained = $(20)^3$ = 8000. So, the correct answer is (*d*).

Example 20. *The magnetic moment of a transition metal ion is $\sqrt{15}$ B.M. Therefore, the number of unpaired electrons in it is :*

(*a*) 4 (*b*) 1

(*c*) 2 (*d*) 3 **(Karnataka CET, 2009)**

Solution. We know that magnetic moment, $\mu = [n(n+2)]^{1/2}$ where n is the number of unpaired electrons. Since:

$$\mu = (15)^{1/2}, \text{ so, } \sqrt{15} = \sqrt{n(n+2)};$$

$$15 = n(n+2)$$

or $n^2 + 2n - 15 = 0$. After factorising, we get $n = 3$.

So, the correct answer is (*d*).

Example 21. *The spin only magnetic moment of Fe^{3+} ion (in BM) is approximately*

(*a*) 4 (*b*) 7

(*c*) 5 (*d*) 6 **(Karnatka CET, 2011)**

Solution. ${}_{26}Fe = (Ar)^{18}3d^6 4s^2; Fe^{2+} = (Ar)^{18} 3d^{2+1+1+1+1}$. So, Fe^{2+} has 4 unpaired electrons. Hence its magnetic moment, $\mu = [n(n+2)]^{1/2} = [4(4+2)]^{1/2} = (24)^{1/2} = 4.899 \simeq 5$. B.M. So, the correct answer is (*c*).

Example 22. *When 0.01 mol of a cobalt complex is treated with excess silver nitrate solution, 4.305 g silver chloride is precipitated. The formula of the complex is :*

(*a*) $[Co(NH_3)_3Cl_3]$ (*b*) $[Co(NH_3)_5Cl]Cl_2$

(*c*) $[Co(NH_3)_6]Cl_3$ (*d*) $[Co(NH_3)_4Cl_2]NO_3$

(*e*) $[Co(NH_3)_4Cl_2]Cl.$ **(Kerala PET, 2011)**

Solution. Wt. of AgCl = 4.305 g; mol. wt. of AgCl =108 + 35.5 = 143.5 g mol^{-}.

No. of mol of 4.305 g AgCl

$$= \text{wt./Mol.wt.} = \frac{4.305}{143.5} = 0.03 \text{ mol}$$

It shows that one mol of compound gives 3 mol of Cl^- ions in solution. So, the correct answer is (c) because when this compound is dissolved in water, 3 mol of Cl^- ions will be formed.

Example 23. *50 mL of oxalic acid is shaken with 0.5 g of wood charcoal. The final concentration of the solution after adsorption of the solution is 0.5 M. Amount of oxalic acid adsorbed per gram of charcoal is:*

(*a*) *3.15 g* (*b*) *3.45 g*

(*c*) *6.3 g* (*d*) *none of these*

(M.P. PMT, 2004)

Solution. 50 mL of 1M oxalic acid contains oxalic acid

$$= \frac{50 \times 1}{1000} = 0.05 \text{ mol}$$

∴ 50 mL of 0.5 M oxalic acid contains oxalic acid = 0.05 × 0.5 = 0.025 mol

Amount adsorbed = 0.05 – 0.025 = 0.025 mol

$$\text{Amount adsorbed per gram} = \frac{0.025}{0.5} \times 1 = 0.05 \text{ mol}$$

= 0.05 × 126 (= mol. wt. of oxalic acid)

= 6.3 g **Ans.**

∴ (*c*) is correct.

Example 24. *On addition of 1mL of 10% NaCl solution to 10 mL gold sol in the presence of 0.25 g of starch, the coagulation is just prevented. Starch has gold number*

(*a*) *0.025* (*b*) *0.25*

(*c*) *2.5* (*d*) *none of these*

(M.P. PMT, 2004)

Solution. 0.25 g of starch just prevents the coagulation of 10 mL of gold sol on adding one mL of 10% NaCl.

$$\therefore \text{Gold number} = 0.25 \text{ g} \times \frac{1000 \text{ mg}}{1 \text{ g}} = 250 \text{ mg} = \mathbf{250}$$

So, the correct answer is (*d*).

Example 25. *10^{-4} g of gelation is required to be added to 100 cm^3 of a standard gold solution to just prevent its precipitation by the addition of 1 cm^3 of 10% NaCl solution to it. Hence the gold number of gelation in mg is:*

(*a*) *10* (*b*) *1.0*

(*c*) *0.1* (*d*) *0.01*

(Kerala PMT, 2005)

Solution. $10^{-4} \text{ g} = 10^{-4} \text{ g} \times \frac{1000 \text{ mg}}{1 \text{ g}} = 0.1 \text{ mg}$

Gelatin required to prevent the coagulation of $10cm^3$ of gold sol $= \frac{0.1 \times 10}{100} = 0.01$ mg

[$10cm^3$ sol. = 0.01 mg = gold number]

∴ Gold number = **0.01.**

Example 26. *1 g of charcoal adsorbs 100 mL of 0.5 M CH_3COOH to form a monolayer, and thereby the molarity of CH_3COOH reduces to 0.49. Calculate the surface area of the charcoal adsorbed by each molecules of acetic acid. Surface area of charcoal is 3.01×10^2 m^2/g.* **(I.I.T. 2003)**

Solution. No. of moles of CH_3COOH in 100 mL before the addition of charcoal

$$= \frac{0.5 \times 100}{1000} = 0.05$$

No. of moles of CH_3COOH in 100 mL after adding charcoal

$$= \frac{0.49}{1000} \times 100 = 0.049$$

∴ No. of moles of CH_3COOH adsorbed on the surface of charcoal

= 0.050 – 0.049 = 0.001

No. of molecules of CH_3COOH adsorbed on the surface of charcoal

$= 0.001 \times 6.02 \times 10^{23} = 6.02 \times 10^{20}$

(∵ 1 mol = 6.02×10^{23} particles)

Surface area of charcoal = 3.01×10^2 m^2

∴ Area occupied by single acetic acid molecule on the surface of charcoal $= \frac{3.01 \times 10^2}{6.02 \times 10^{20}} = 5 \times 10^{-19}$ m^2.

Example 27. *20% of the surface sites are occupied by N_2 molecules. The density of surface site is 6.023×10^{14} cm^{-2} and total surface area is 1000 cm^2. The catalyst is heated to 300 K while N_2 is completely desorbed into a pressure of 0.001 atm and volume of 2.46 cm^3. Find the number of active sites occupied by each N_2 molecule.* **(I.I.T. 2005)**

Solution. Total number of surface sites = [Total surface area × density]

$= 1000 \times 6.023 \times 10^{14} = 6.023 \times 10^{17}$

Sites occupied by N_2 molecules

$$= \frac{6.023 \times 10^{17} \times 20}{100} = 12.04 \times 10^{16}$$

Pressure of desorbed N_2 = 0.001 atm, Temperature = 300K

Volume = 2.46 cm^3 = 2.46×10^{-3} L, R = 0.082 1 L atm K^- mol^-

But $PV = nRT$. Hence,

$$n = \frac{PV}{RT} = \frac{0.001 \text{ atm} \times 2.46 \times 10^{-3} L}{0.0821 \, L \text{ atm } K^- \text{ mol}^- \times 300 \, K} = 10^{-7} \text{ mol}$$

$\therefore$ No. of N_2 molecules $= 10^{-7} \times 6.023 \times 10^{23}$

$= 6.023 \times 10^{16}$

$\therefore$ No. of sites occupied by each molecule

$$= \frac{12.04 \times 10^{16}}{6.023 \times 10^{16}} = 2$$ **Ans.**

EXAMPLE 28. *The mass (m) of an adsorbed solute on a solid is given by a form of the Freumdlich isotherm as, $m = kC^n$ where C is the concentration in molarity and the values of k and n that give m in units of (g acetic acid, HAc) and (g blood charcoal)$^{-}$ are k = 0.160 and n = 0.431. Calculate the amount of acetic acid that 1 kg of charcoal would adsorb from0.837 M vinegar (acetic acid) solution.* **(PSEB, 2012)**

SOLUTION. $m = 0.160\ (0.837)^{0.431} = 0.148$ (g HAc) (g charcoal)$^{-}$

[Hint. Use log on both side to solve]

= 148 (g HAc) (kg charcoal)$^{-}$

$$= \frac{148 \text{ (g HAc) (kg charcoal)}^{-}}{60.05 \text{ g mol}^{-} \text{ (= mol wt. of HAc)}}$$

= 247 (mol HAc) (kg charcoal)$^{-}$ **Ans.**

EXAMPLE 29. *The adsorption of a dye from a solution on charcoal is governed by Freundlich isotherm as, $m = kC^n$ where C is the concentration in millimoles per c.c., m in millimoles per g, n = 2 and k = 6.8. If 10 g of charcoal is shaken with a 0.1 M solution of a dye, what will be the equilibrium concentration of the solution?* **(H.P.Board, 2012)**

SOLUTION. Given: $\frac{x}{m} = k\,C^n$; Initial concentration = 0.1 mol L^{-} = 0.1 millimol (cm^3)$^{-}$.

Let x millimoles have been adsorbed.

$\therefore$ Equilibrium conc. = 0.1 – x millimoles

But $\frac{x}{10} = 6.8 \times (0.1 - x)^2$ or $x = 68 \times (0.1 - x)^2$

Or $x^2 = 462.4 + 4624\,x$ Or $x = 0.09$

Hence eqm. conc. = 0.1 – 0.09 = 0.01 mollimoles /c.c = 0.01 M **Ans.**

EXAMPLE 30. *Low spin complex of d^6–cation in an octahedral field will have the following energy?*

(a) $\frac{-12}{5}\Delta_0 + P$ (b) $\frac{-12}{5}\Delta_0 + 3P$

(c) $\frac{-2}{5}\Delta_0 + 2P$ (d) $\frac{-2}{5}\Delta_0 + P$

(H.P.Board, 2012)

SOLUTION. Since it is low spin octahedral complex, the distribution of electrons in t_{2g} and e_g orbits = $t_{2g}^{2+2+2}\,e_g^{\,0}$.

So, total number of pairs of electrons, $P = 3$. But:

CFSE = $(-\,0.4\,x + 0.6\,y)\,\Delta_0 + zP$ ...(1)

x = no. of electrons occupying t_{2g} orbitals, y = no. of electrons occupying e_g orbitals and z = no. of pairs of electrons. Substituting these values in equation (1), we get:

$$\text{CFSE} = [(-\,0.4 \times 6) + (0.6 \times 0)]\,\Delta_0 + 3P \text{ or } \frac{-12}{5}\Delta_0 + 3P.$$

So, the correct answer is (*b*).

EXAMPLE 31. *The spin only magnetic moment of $(CrF_6)^{4-}$ (at. no. of Cr = 24) is:*

(a) 0 (b) 1.73 BM

(c) 2.83 BM (d) 4.9 BM

(J&K CET, 2012)

SOLUTION. Cr in $[CrF_6]^{4-}$ is Cr^{2+}.

$_{24}Cr = (Ar)^{18}\,3d^5\,4s^1$; $Cr^{2+} = 3d^4 = 3d^{1+1+1+1}$ *i.e.*, four unpaired electrons. So, $n = 4$

Magnetic moment = $(n\,(n + 2))^{1/2} = [4\,(4 + 2)]^{1/2} = (24)^{1/2}$ = 4.9 BM. So, the correct answer is (*d*).

EXAMPLE 32. *The effective atomic number of the central metal ion, Pt, in the complex $[Pt\,(NH_3)_6]^{4+}$ is: (at. no. of Pt = 78):*

(a) 74 (b) 90

(c) 86 (d) 84

(AMU (medical), 2012)

SOLUTION. Effective at. no. (EAN) = At. no. of metal + no. of $\bar{e}$s gained from donor atoms of the ligands –no. of $\bar{e}$s lost in ion formation.

$\therefore$ EAN of Pt in $[Pt(NH_3)_6]^{4+} = 78 + (6 \times 2) - 4 = 86$.

So, the correct answer is (*c*).

PROBLEMS FOR PRACTICE

1. The number average molecular mass and mass average molecular mass of a polymer are 20,000 and 30,000 respectively. The polydispersity index of the polymer is :

(*a*) > 1 (*b*) 1

(*c*) < 1 (*d*) 0 **Ans** (*a*)

2. On the addition of 2 mL of 5% NaCl to 10 mL gold sol in the presence of 0.04 g of a compound, the coagulation is just prevented. What is the gold number of the compound ? **Ans.** (40)

3. What is the type of hybridisation of Ni in nickel carbonyl ? **Ans.** (sp^3)

4. A polymer sample contains 25% molecules of molar mass, 20,000, 30% molecules of molar mass 30,000 and 45% molecules of molar mass, 40,000. Calculate $\overline{M_n}$. **Ans.** (32,000)

5. One kg of a polymer with molar mass, 20,000 g and 500 g of another polymer with molar mass, 25,000 g are mixed. Calculate $\overline{M_w}$. **Ans.** ($\simeq$ 21667)

6. The magnetic moment (spin only) of $[Fe(H_2O)_6]^{2+}$ in B.M. is :

(*a*) 4.89 (*b*) 3.99

(*c*) 1.5 (*d*) 4.01 **Ans.** (*a*)

7. The magnetic moment of a transition metal ion is $\sqrt{35}$. Therefore, the number of unpaired electrons in it are :

(*a*) 3 (*b*) 4

(*c*) 5 (*d*) 6 **Ans.** (5)

8. Excess of silver nitrate solution is added to 200 mL of 0.05 M pentaaquachloridochromium (III) obtained in gram is :

(*a*) 0.175 (*b*) 1.9

(*c*) 1.1 (*d*) 0.287 g **Ans.** (*d*)

9. The volume (in mL) of 0.2 M $AgNO_3$ needed for the complete precipitation of chloride ions present in 40 mL of 0.01 M solution of $[Cr(H_2O)_5Cl]Cl_2$ as silver chloride is close to :

(*a*) 2 mL (*b*) 3 mL

(*c*) 4 mL (*d*) 5 mL **Ans.** (*c*)

10. Suppose there are x naturally occurring aminoacids. Calculate the maximum number of tripeptides that can be obtained. **Ans.** (x^3)

30

CHAPTER

Distribution Law

30.1 SOLVENT EXTRACTION

Solvent extraction or liquid - Liquid extraction is a partitioning process which involves the distribution of a solute between two immiscible liquid phases. It is a standard method of purification of organic compounds and for quantitative separation of both inorganic and organic compounds.

30.2 NERNST DISTRIBUTION LAW

This law states that 'When a solute (liquid or solid) is added to a heterogeneous system of two immiscible liquids (in both of which solute is soluble), the solute distributes itself between the two solvents in such a way that the ratio of the concentrations in the two liquid phases is constant at a constant temperature provided the solute has same molecular weight in each phase and this ratio is independent of the amount of solute or solvent.

Mathematically, when a solute does not undergo dissociation or association in a solvent, then:

$$\frac{\text{Concentration of solute } x \text{ in phase } A \text{ or solvent, } A}{\text{Concentration of solute } x \text{ in phase } B \text{ or solvent, } B} = \frac{C_1}{C_2} = K$$

where **K** is constant called **Partition co-efficient** or **distribution-co-efficient.**

30.3 WHEN THE SOLUTE NEITHER UNDERGOES DISSOCIATION NOR ASSOCIATION IN THE SOLVENTS

Use : $\frac{C_1}{C_2} = K$

Note: When K is required in favour of solvent A (or phase A), the concentration of solute in solvent A should be taken in the numerator.

EXAMPLE 1. *When boric acid was shaken with a mixture of water and amyl alcohol solvents at constant temperature, the following data was recorded.*

	I	*II*	*III*
Equilibrium conc. of boric acid in H_2O	*0.087*	*0.54*	*0.90*
Equilibrium conc. of boric acid in amyl alcohol	*0.024*	*0.15*	*0.25*

Show that the data illustrates the distribution law considering distributing co-efficient in favour of amyl alcohol.

SOLUTION.

$$\frac{C_{\text{Boric acid} - \text{amyl alcohol}}}{C_{\text{Boric acid} - \text{water}}} = K$$

$$\textbf{I. } \frac{0.024}{0.087} = \mathbf{0.276}; \quad \textbf{II. } \frac{0.15}{0.54} = 0.278; \textbf{III. } \frac{0.25}{0.90} = 0.274$$

Since the value of K is constant, the distribution law is obeyed.

EXAMPLE 2. *When a mixture of 70cm^3 ether and 150 cm^3 water was shaken with succinic acid, at equilibrium, water layer contained 3.0g while ether layer contained 0.2 g of succinic acid. Calculate the partition co-efficient in favour of ether.*

SOLUTION.

$$C_{\text{succinic acid} - \text{ether}} = \frac{0.2}{70} \text{ g cm}^{-3} = C_1$$

$$C_{\text{succinic acid} - \text{water}} = \frac{3}{150} \text{ g cm}^{-3} = C_2$$

$$\therefore \quad \frac{C_1}{C_2} = K; \ \frac{0.2/70}{3.0/150} = \frac{0.2 \times 150}{3.0 \times 70}$$

Or $K = \mathbf{0.1428}$ **Ans.**

EXAMPLE 3. *The partition co-efficient of boric acid between water and amyl alcohol in favour of water is 3.3. How much amyl alcohol is needed to decrease the concentration of boric acid in 50 ml water from 6% to 2%?*

SOLUTION.

(*i*) Conc. of boric acid in H_2O = 6%

$\therefore$ Wt. of boric acid in 50 ml water $= \frac{50 \times 6}{100} = 3.0g$

(*ii*) Conc. of boric acid in H_2O after the use of amyl alcohol = 2%

$\therefore$ Wt. of boric acid in 50 ml

$$H_2O = \frac{50 \times 2}{100} = 1.0 \text{ g}$$

Let volume of amyl alcohol required = V mL

$\therefore$ At equilibrium, wt. of boric acid in

H_2O = 1.0 g per 50 mL H_2O

Wt. of boric acid in ether = 3.0 – 1.0

= 2.0 g per VmL ether

But $$K = \frac{\text{Conc. of boric acid in water}}{\text{Conc. of boric acid in amyl alcohol}}$$

$$3.3 = \frac{1/50}{2/V};\ 3.3 = \frac{1}{50} \times \frac{V}{2};$$

$V = 3.3 \times 50 \times 2 =$ **330 mL** **Ans.**

Example 4. *25 mL of ether was shaken with 100 mL of M/10 aqueous solution of quinine ($C_{20}H_{24}O_2N_2$) till equilibrium was established. If distribution co-efficient of quinine is 22 in favour of ether, find the concentration of quinine in the ether layer.*

Solution. Conc. of quinine in

$$H_2O = \frac{1}{10}\ M = \frac{1}{10} \text{ mol L}^{-}$$

Thus : Conc. of quinine in 1000 mL

$$H_2O = \frac{1}{10}$$

Conc. of quinine in 100 mL

$$H_2O = \frac{1}{10} \times \frac{100}{1000} = \frac{1}{100} = 10^{-2}$$

Let quinine extracted in 25 mL ether = a mol

$\therefore$ Conc. of quinine in 25 mL ether = $\frac{a}{25}$

At equilibrium, conc. of quinine in

$$100 \text{ mL water} = \frac{10^{-2} - a}{100}$$

But $$\frac{\text{Conc. of quinine in ether}}{\text{Conc. of quinine in } H_2O} = K$$

$$\frac{a/25}{\left(10^{-2} - a\right)/100} = 22;\ \frac{a}{25} \times \frac{100}{10^{-2} - a} = 22$$

$$22(10^{-2} - a) = 4a;\ 0.22 = 26a$$

$\therefore$ $a = \frac{0.22}{26} =$ **0.00846 mol per 25 mL Ans.**

Example 5. *10 mL of CCl_4 was shaken with 100 mL of a saturated solution of I_2 in water to attain equilibrium. The solubility of I_2 in water is 0.7g L^-. Calculate the amount of I_2 in CCl_4 if partition co-efficient of I_2 in favour of CCl_4 is 85.*

Solution. Solubility of

I_2 in H_2O = 0.7g L^- = 0.7g (1000 mL^-)

1000 mL H_2O contain I_2 = 0.7 g

$$100 \text{ mL } H_2O \text{ contain } I_2 = \frac{0.7}{1000} \times 100 = 0.07 \text{ g}$$

Let wt. of I_2 extracted by

10 mL CCl_4 = a g

$$\therefore \text{Conc. of } I_2 \text{ in 10 mL } CCl_4 = \frac{a}{10} \text{ g} (\text{mL})^- = C_1$$

Wt. of I_2 in 100 mL H_2O = $(0.07 - a)$g

$\therefore$ Conc. of I_2 in

$$100 \text{ mL } H_2O = \frac{0.07 - a}{100} \text{ g} (\text{mL})^- = C_2$$

But $$\frac{C_1}{C_2} = K;\ \frac{a/10}{(0.07 - a)/100} = 85$$

Or $$\frac{a}{10} \times \frac{100}{0.07 - a} = 85;$$

$$10\,a = 85(0.07 - a) = 5.95 - 85a$$

or $$95\,a = 5.95;\ a = 5.95/95$$

= **0.0626 g in 10 mL CCl_4 Ans.**

Example 6. *Benzoic acid exists as a monomer in water but gives a higher value in benzene. Calculate the complexity of benzoic acid in benzene from the following distribution experimental data.*

	I	*II*	*III*
$C_1(H_2O)$	*0.015*	*0.022*	*0.029*
$C_2(C_6H_6)$	*0.24*	*0.55*	*0.93*

Solution. Suppose n = complexity of benzoic acid in C_6H_6

$$\therefore \quad K = \frac{C_1}{(C_2)^{1/n}}$$

Taking logs of both sides, we get :

$$\log K = \log C_1 - \frac{1}{n} \log C_2 \quad ...(i)$$

Substituting the values in equation (*i*), we get :

I $$\log K = \log 0.015 - \frac{1}{n} \log 0.24$$

$$= -1.82 - \frac{1}{n}(-0.62)$$

$$= -1.82 + \frac{0.62}{n} \quad ...\text{(ii)}$$

II $$\log K = \log 0.022 - \frac{1}{n} \log 0.55$$

$$= -1.66 - \frac{1}{n}(-0.26)$$

$$= -1.66 + \frac{0.26}{n} \quad ...\text{(iii)}$$

III $$\log K = \log 0.029 - \frac{1}{n}\log 0.93$$

$$= -1.54 - \frac{1}{n}(-0.032)$$

$$\log K = -1.54 + \frac{0.032}{n} \quad \ldots (iv)$$

(*a*) Equating equation (*ii*) and (*iii*), we get

$$-1.82 + \frac{0.62}{n} = -1.66 + \frac{0.26}{n};\ \frac{0.62}{n} - \frac{0.26}{n}$$

$$= 1.82 - 1.66 = 0.16$$

or $$\frac{0.36}{n} = 0.16.\ \text{Hence } n = \frac{0.36}{0.16} \approx 2.$$

(*b*) Equating equation (*iii*) and (*iv*), we get

$$-1.66 + \frac{0.26}{n} = -1.54 + \frac{0.032}{n};\ \frac{0.26}{n} - \frac{0.032}{n}$$

$$= 1.66 - 1.54 = 0.12$$

or $$\frac{0.228}{n} = 0.12.\ \text{Hence } n = \frac{0.228}{0.12} \approx 2.$$

Since the value of n is almost equal to 2, benzoic acid exists as a dimer in benzene.

EXAMPLE 7. *5.0g of oxalic acid is distributed between* ***a mixture*** *of one litre water and 100 mL of ether. If partition co-efficient of* ***oxalic acid*** *in water and ether is 10, find the* ***concentration*** *of oxalic acid in both the solvents.*

SOLUTION.

Suppose, wt. of oxalic acid in ether = x g

Total wt. of oxalic acid added = 5 g

∴ Wt. of oxalic acid in H_2O phase = $(5 - x)$ g.

Volume of ether = 100 mL

∴ Conc. (C_1) of

acid in ether layer = $\frac{x}{100}\text{g}(\text{mL})^{-}$

Also, conc. (C_2) of acid in water layer

$$= \frac{5-x}{1000}\text{g}\,(\text{mL})^{-}$$

[∵ 1L = 1000 mL]

But $\frac{C_1}{C_2} = K$ (By Nernst distribution law)

$$\therefore \quad \frac{x/100}{(5-x)/1000} = 10;\ \frac{x}{100} \times \frac{1000}{5-x} = 10$$

$$10x = 10(5 - x);\ \boldsymbol{x = 2.5\ \text{g}}$$

(*i*) wt of acid in 100 mL ether = 2.5 g

∴ conc of acid in 1000 mL ether

$$= \frac{2.5}{100} \times 1000 = \mathbf{25\ gL}$$ **Ans.**

(*ii*) wt of acid in

1000 mL water = $5 - x = 5 - 2.5 = 2.5$ g

or wt of acid in H_2O = **2.5 gL^{-}** **Ans.**

EXAMPLE 8. *The solubility ratio of an organic substance in between water and benzene is 4.1. 100 cm^3 of an aqueous solution having 0.75 g per 500 cm^3 of the substance is shaken with 50 mL of benzene till equilibrium is attained. Calculate the amount of substance extracted by benzene from aqueous solution.*

SOLUTION.

(*i*) *Aqueous solution.*

500 cm^3 solution contain substance = 0.75 g

100 cm^3 solution contain substance

$$= \frac{0.75 \times 100}{500} = 0.15\ \text{g}$$

(*ii*) *C_6H_6 solution.*

Let wt. of substance extracted in

50 cm^3 benzene = xg

∴ Wt. of substance extracted in

100 cm^3 H_2O = $(0.15 - x)$g

Conc. of substance in benzene = $\frac{x}{50} = C_1$

Conc. of substance in H_2O

$$= \frac{0.15 - x}{100} = C_2 \quad \text{But } \frac{C_1}{C_2} = K.\ \text{So,}$$

$$\left(\frac{x}{50}\right)\Big/\left(\frac{0.15 - x}{100}\right) = 4.1;\ \frac{x}{50} \times \frac{100}{0.15 - x} = 4.1;$$

$$2x = 0.615 - 4.1x$$

$$\therefore \quad x = \frac{0.615}{6.1} = \mathbf{0.1g}$$ **Ans.**

30.4 WHEN THE SOLUTE DISSOCIATES

In case, a solute dissociates in solvent 1 and α_1 is the degree of dissociation of the solute in solvent, then :

$$K = \frac{C_1(1-\alpha)}{C_2}$$

Where C_1 and C_2 are the concentrations of the solute in solvent 1 and solvent 2 respectively.

30.5 WHEN THE SOLUTE DISSOCIATES IN BOTH OF THE SOLVENTS

In case, a solute dissociates in both the solvents 1 and 2, and α_1 and α_2 are the degrees of dissociation of the solute in solvent 1 and 2 respectively, then :

$$K = \frac{C_1(1-\alpha_1)}{C_2(1-\alpha_2)}$$

where K is the partition co-efficient or distribution co-efficient.

Type: *To calculate degree of dissociation.*

EXAMPLE 9. *An organic compound is five times more soluble in water than in a solvent, X. When 10.0 g of the compound was mixed with 50 mL water and 40 ml of X, 0.5 g of the compound* *was found to be present in 20 mL of X. Find the degree of dissociation of the compound in water.*

Solution.

$$\frac{\text{Solubility in } H_2O}{\text{Solubility in solvent}, X} = K;\ K = \frac{5}{1} = 5$$

Suppose degree of dissociation of compound in

$H_2O = \alpha$

Compound present in

20 mL of X = 0.5g

∴ Compound present in 40 mL of X

$$= \frac{0.5}{20} \times 40 = 1.0 \text{ g}$$

Total compound mixed = 10g

∴ Compound present in 50 mL H_2O

= 10 – 1 = 9g

Conc. of compound in

$$H_2O = \frac{9(1-\alpha)}{M \times 50} = C_1$$

Conc. of compound in solvent,

$$X = \frac{1.0}{M \times 40} = C_2$$

But $\frac{C_1}{C_2} = K$. So, $\dfrac{\dfrac{9(1-\alpha)}{50M}}{\dfrac{1}{40M}} = 5$

$$\frac{9(1-\alpha) \times 40}{50} = 5;\ 1 - \alpha = \frac{5 \times 50}{40 \times 9} = 0.69$$

∴ $\alpha = l - 0.69 = 0.31$

Or $\alpha = 0.31 \times 100 = $ **31%** **Ans.**

30.6 WHEN THE SOLUTE ASSOCIATES IN ONE OF THE TWO SOLVENTS

Suppose a solute (molecular formula, X) exists as such (i.e., X) in solvent I but is associated in solvent II as $(X)_n$. Then :

$$(X)_n = nX$$

where n is the degree of association. Then according to distribution law

$$K = \frac{C_1}{(C_2)^{1/n}}$$

Example 10. *Using the following data, prove that acetic acid exists as a dimer in CCl_4 if it exists as single molecules in water.*

$C_1(H_2O)$	2.51	3.99	5.45
$C_2(CCl_4)$	0.146	0.362	0.705

Solution.

$$\frac{C_1(H_2O)}{[C_2(CCl_4)]^{1/2}} = K \qquad \left[\because \frac{C_1}{(C_2)^{1/n}} = K\right]$$

I $\quad \dfrac{2.51}{(0.146)^{1/2}} = K;\quad K = \dfrac{2.51}{0.382} = 6.57$

II $\quad \dfrac{3.99}{(0.362)^{1/2}} = K;\quad K = \dfrac{3.99}{0.62} = 6.44$

III $\quad \dfrac{5.45}{(0.705)^{1/2}} = K;\quad K = \dfrac{5.45}{0.839} = 6.49$

The constant value of K indicates that acetic acid exists as a dimer in CCl_4.

Example 11. *Phenol was shaken with a mixture of water and $CHCl_3$. Their distribution ratio gave the following results.*

	I	*II*	*III*
$C_1(H_2O)$	0.188	0.508	0.872
$C_2(CHCl_3)$	0.508	3.70	10.86

What conclusion can be drawn from above results regarding molecular condition of phenol in $CHCl_3$.

Solution. (*a*) Suppose phenol exists as a monomer. Then :

I $\quad \dfrac{C_1(H_2O)}{C_2(CHCl_3)} = K;\quad \dfrac{0.188}{0.508} = K;\quad K = 0.37$

II $\quad \dfrac{C_1(H_2O)}{C_2(CHCl_3)} = K;\quad \dfrac{0.508}{3.70} = K;\quad K = 0.137$

III $\quad \dfrac{C_1(H_2O)}{C_2(CHCl_3)} = K;\quad \dfrac{0.872}{10.86} = K;\quad K = 0.08$

Since the value of K is not constant, phenol does not exist as monomer or normal molecule in $CHCl_3$.

(*b*) Suppose phenol exists as a dimer in $CHCl_3$. Then :

$$\frac{C_1(H_2O)}{[C_2(CHCl_3)]^{1/n}} = K \quad \text{where n is the degree of association}$$

I

$$\frac{C_1(H_2O)}{[C_2(CHCl_3)]^{1/n}} = K;\ \frac{0.188}{(0.508)^{1/2}} = K;\ K = \frac{0.188}{0.712} = 0.26$$

II

$$\frac{C_1(H_2O)}{[C_2(CHCl_3)]^{1/n}} = K;\ \frac{0.508}{(3.70)^{1/2}} = K;\ K = \frac{0.508}{1.923} = 0.26$$

III

$$\frac{C_1(H_2O)}{[C_2(CHCl_3)]^{1/n}} = K;\ \frac{0.872}{(10.86)^{1/2}} = K;\ K = \frac{0.872}{2.295} = 0.26$$

Since the value of K is constant, phenol exists as a double molecule or dimer in $CHCl_3$.

30.7 SOLVENT EXTRACTION METHOD.

It has been found experimentally that the process of extraction is very economical if carried out in several operations with the given volume of solvent than by using the same volume in one lot.

Consider a mixture of two immiscible solvents containing a solute.

Let Wt. of the solute = Wg; Volume of the mixture solution = V_1 mL

Volume of the pure immiscible solvent shaken repeatedly for extraction = V_2mL

No. of extractions done = n

Then :

(*a*) **Wt. of solute left unextracted** after the end of n extractions = W_n. Then :

$$W_n = W\left[\frac{KV_1}{KV_1 + V_2}\right]^n$$

(*b*) Wt. of solute extracted will be :

$$W - W_n = W - W\left[\frac{KV_1}{KV_1 + V_2}\right]^n = W\left[1 - \left(\frac{KV_1}{KV_1 + V_2}\right)^n\right];$$

where K = Partition co-efficient

Example 12. *12 g of hydrogen peroxide is present in a 140 mL solution of hydrogen peroxide in amyl alcohol. The partition co-efficient of hydrogen peroxide between amyl alcohol and water is 1:7. Calculate the amount of H_2O_2 extracted out with 90 mL of H_2O (i) in one lot and (ii) in three lots of 30 mL each.*

Solution.

(*i*) Volume of mixture solution, V_1 = 140 mL

Volume of pure solvent used, V_2 = 90 mL

Wt. of H_2O_2 = 12 g

Partition co-efficient,

$$K = \frac{C_1 \text{ of } H_2O_2 \text{ in amyl alcohol}}{C_2 \text{ of } H_2O_2 \text{ in water}} = \frac{1}{7}$$

Wt. of H_2O_2 extracted when extraction is done in one lot of 90 mL will be given by the relation :

$$W_n = W\left[1 - \left(\frac{KV_1}{KV_1 + V_2}\right)^n\right]$$

$$W_1 = 12\left[1 - \left(\frac{\frac{1}{7}\times 140}{\left(\frac{1}{7}\times 140\right) + 90}\right)^1\right]$$

$$= 12\left[1 - \frac{20}{110}\right] = 12 \times \frac{9}{11} = \mathbf{9.82\ g\ Ans.}$$

(*ii*) wt. of H_2O_2 extracted when extraction is done in three lots of 30 mL each i.e., when V_2 = 30 mL

$$W_n = W\left[1 - \left(\frac{KV_1}{KV_1 + V_2}\right)^n\right]$$

$$= 12\left[1 - \left(\frac{\frac{1}{7}\times 140}{\left(\frac{1}{7}\times 140\right) + 30}\right)^3\right]$$

$$= 12\left[1 - \left(\frac{20}{50}\right)^3\right]$$

$$= 12\left(1 - \frac{8}{125}\right) = 12 \times \frac{117}{125}$$

= **11.23 g** **Ans.**

Example 13. *The solubility of a substance (A) is two times more in other liquid than in water. Compare the quantities of A extracted from 120 mL of aqueous solution by (i) 100 mL of CCl_4 in one operation and (ii) four extractions using 25 mL in each extraction. Also calculate the amount of A unextracted in each case.*

Solution.

Volume of mixture solution,

V_1 = 120 mL

Volume of pure solvent,

V_2 = 100 mL

Wt. of substance,

$$A = W; K = \frac{1}{2}.$$

(*i*) Wt. of A unextracted when extraction is done in one lot of 100 mL will be given as :

$$W_n = W\left(\frac{KV_1}{KV_1 + V_2}\right)^n;$$

$$W_1 = W\left(\frac{\frac{1}{2}\times 120}{\left(\frac{1}{2}\times 120\right) + 100}\right)^1$$

$$W_1 = W\left(\frac{60}{160}\right) = \frac{3}{8}\times 100$$

= **37.5% of W** **Ans.**

(*ii*) Wt. of A unextracted when extraction is done in four lot of 25 mL each will be given as:

$$W_n = W\left(\frac{KV_1}{KV_1 + V_2}\right)^n;$$

$$W_4 = W\left(\frac{\frac{1}{2}\times 120}{\left(\frac{1}{2}\times 120\right) + 25}\right)^4$$

$$W_4 = W\left(\frac{60}{85}\right)^4 = 0.2489\,W \quad \text{(See below)}$$

$$= 0.2489 \times 100$$

$$= \mathbf{24.89\%\ of\ W} \qquad \textbf{Ans.}$$

Let $x = \left(\frac{60}{85}\right)^4$. Taking logs of both sides, we get:

$$\log x = \log\left(\frac{60}{85}\right)^4$$

$$= 4[\log 60 - \log 85]$$

$$= 4[1.778 - 1.929]$$

$$= 4 \times -0.151$$

$$= -0.604 = -1 + 1 - 0.604$$

$$= \bar{1}.396.$$

Taking antilog of both sides, we get $x = 0.2489$

Example 14. *2.0 grams of a solute are contained is 100 ml of an aqueous solution. Determine the quantity of the solute left in aqueous phase after :*

(i) single extraction with 90 ml of an organic solvent with appropriate reagents;

(ii) a single extraction with 30 ml solvent and

(iii) three successive extractions with 30 ml of solvent, assuming that the distribution ratio of solute between ether and water is 10 : 1.

Solution. Weight (W) of solute in 100 ml of aqueous solution = 2.0 gm

Volume (V_1) of solution containing the solute = 100 ml

Volume (V_2) of extracting solvent in (*i*) 90 ml (*ii*) 30 ml (*iii*) three successive extractions of 30 ml.

Number (n) of extractions in (*i*) 1, (*ii*) 1, (*iii*) 3.

Let weight of solute left after the extraction with V_2 ml of solvent = W gm.

Distribution co-efficient

$$(K) = \frac{1}{10}.$$

We know that $W_n = W\left[\frac{KV_1}{KV_1 + V_2}\right]^n$

$\therefore$ For (*i*) $W_1 = 2.0 \times \left(\frac{\frac{1}{10}\times 100}{\left(\frac{1}{10}\times 100\right) + 90}\right)^1$

$$= 0.20 \text{ gm}$$

(*ii*) $W_1 = 2.0 \times \left(\frac{\frac{1}{10}\times 100}{\left(\frac{1}{10}\times 100\right) + 30}\right)^1$

$$= 0.50 \text{ gm.}$$

For (*iii*) $W_3 = 2.0 \times \left(\frac{\frac{1}{10}\times 100}{\left(\frac{1}{10}\times 100\right) + 30}\right)^3$

$$= 0.0312 \text{ gm.}$$

Hence percent solute extracted in (*i*) = $\frac{2-0.2}{2} \times 100 = 90$; percent solute extracted in (*ii*) = $\frac{2-0.5}{2} \times 100 = 75$; percent solute extracted in (*iii*) = $\frac{2-0.0312}{2} \times 100 = 98.4$

Example 15. *100 ml of 0.01 M solution of NH_3 in chloroform was shaken with 10.0 ml of H_2O until distribution equilibrium was attained at 291 K. Calculate the number of moles of NH_3 left in the chloroform layer after extraction ($K_e = 27.5$).*

Solution. Volume of

$$NH_3 = 100 \text{ mL} = \frac{100}{1000} \text{ L} = 0.1 \text{ L};$$

molarity of $NH_3 = 0.01\ ML^-$

$\therefore$ No. of mol of

NH_3 = [Volume of NH_3] × [Molarity of NH_3]

$= 0.1\ L \times 0.01\ mol\ L^- = 0.001$ mol

Suppose x = no. of mol of NH_3 left in the chloroform layer after extraction.

$\therefore$ No. of mol of NH_3 extracted by water

$$= 0.001 - x$$

$\therefore$ Molarity of NH_3 in aqueous layer

$$= \frac{(0.001 - x) \text{ mole}}{0.01 \text{ litre}}$$

$$= 0.1 - 100x \text{ mole litre}^-$$

$$= [NH_3]_{H_2O}$$

Molarity of NH_3 in chloroform layer

$$= \frac{x}{0.1} \text{ mole litre}^- = 10x \text{ mole litre}^-$$

$$= [NH_3]_{CHCl_3}$$

Assuming that the volumes of the two liquid phases are unaffected by transfer of NH_3, the equilibrium condition is :

$$27.5 = \frac{[NH_3]_{H_2O}}{[NH_3]_{CHCl_3}}$$

$$= \frac{0.1 - 100x \text{ mole litre}^-}{10x \text{ mole litre}^?};$$

$$\therefore \quad x = 2.67 \times 10^{-4} \text{ mole.}$$

30.8 DISTRIBUTION RATIO

A different term, the distribution ratio, D is more meaningful than distribution co-efficient. It is because it does not account for any equilibrium steps which might take place in either of the two phases. **Due to this reason, the distribution law is redefined in terms of distribution ratio, *D* as follows :**

"It is the ratio of the concentration of all the species of solute in each phase. The concentrations in the two phases are expressed as total concentrations rather equilibrium concentrations".

EXAMPLE 16. *40 ml of an aqueous solution of 0.20 M butanoic acid are shaken with 20 ml of ether. After the aqueous and ether layers separated, it was found by titration that 1.0 millimoles of butanoic acid remained in the aqueous layer. Find the distribution ratio (D) and percent of solute extracted.*

SOLUTION. Number of moles of butanoic acid

$$= 40 \text{ ml} \times 0.20 \text{ M} = 8.0 \text{ millimoles.}$$

Number of millimoles of butanoic acid left in aqueous solution = 1.0

∴ Number of millimoles of butanoic acid extracted in ether = 8.0 – 1.0 = 7.0

Concentration of the acid in ether layer

$$= \frac{7.0 \text{ mil lim oles}}{20\text{ml}} = 0.35\, M$$

Concentration of the acid in aqueous layer

$$= \frac{1.0}{40} = 0.025\, M$$

∴ Distribution ratio,

$$D = \frac{\text{Concentration of acid in ether layer}}{\text{Concentration of acid in aqueous layer}}$$

$$= \frac{0.35}{0.025} = 14$$

Since 7.0 millimoles of the acid were extracted in ether; the percent extracted (% E) $= \frac{7}{8} \times 100 = 87.5\%$

or % $E = \dfrac{100D}{D + V_\alpha / V_o}$ where V_α = volume of aqueous solution and V_0 = volume of ether solvent $= \dfrac{100 \times 14}{14 + 40/20}$

$$= \frac{1400}{16} = 87.5\%.$$

EXAMPLE 17. *An aqueous solution of an organic compound contains 10 g of solute per litre. When one litre of this solution is treated with 100 mL of ether, 6g of the organic solute is extracted. How much of the solute will be extracted from the aqueous solution by adding further 100 ml of ether? (Assume that molecular state of the solute is the same in ether and water). (ISC, 2007)*

SOLUTION. $k_d = \dfrac{C_e}{C_w} = \dfrac{w/100}{(a-w)/100}$

$$= \frac{6/100}{(10-6)/1000} = 15$$

Let, w_1 = Amount extracted with further 100 mL of ether.

$$\therefore \quad k_d = \frac{C_e}{C_w};\ 15 = \frac{w_1/100}{(4-w_1)/1000}$$

$$= \frac{10w_1}{4-w_1};\ 60 - 15\, w_1 = 10\, w_1;$$

$$25\, w_1 = 60$$

$$\therefore \quad w_1 = 60/25 = 2.49$$ **Ans.**

30.9 AIEEE PATTERN EXAMPLES

EXAMPLE 18. *The concentrations of iodine between CCl_4 and water solvents in g/200 mL are 10.2 and 0.12 respectively. The value of partition co-efficient in favour of water will be :*

(*a*) 85 (*b*) 0.01176

(*c*) 42.5 (*d*) 21.25

SOLUTION. According to distribution law.

$$\frac{C_{I_2 - H_2O}}{C_{I_2 - CCl_4}} = K;\ \frac{0.12}{10.2} = K$$

∴ $K = 0.01176$. So, the correct answer is (*b*)

EXAMPLE 19. *The partition co-efficient of I_2 in-between CCl_4 and H_2O is 85 in favour of CCl_4 solvent at 298 K. If solubility of I_2 in CCl_4 at 298 K is 28.05 gL^{-}, the solubility of I_2 in water at 298 K will be :*

(*a*) 33.0 gL^{-} (*b*) 0.66 gL^{-}

(*c*) 0.33 gL^{-} (*d*) 66 gL^{-}

SOLUTION. Let solubility of I_2 in water = $x\, gL^{-}$

$$\text{But} \quad \frac{C_{I_2 - CCl_4}}{C_{I_2 - H_2O}} = K;\ \frac{28.05}{x} = 85$$

$$\therefore \quad x = \frac{28.05}{85} = 0.33 \text{gL}^{-}.$$

So, the correct answer is (*c*)

EXAMPLE 20. *The distribution co-efficient of lactic acid between water and chloroform in favour of chloroform is 0.02. Half litre of aqueous solution of lactic acid in water having 25 g was mixed with 250 ml of chloroform. The concentration of lactic acid in gram in chloroform will be :*

(*a*) 0.02 (*b*) 0.01

(*c*) 1.5 (*d*) 0.247

SOLUTION. $K = 0.02$ in favour of chloroform ($CHCl_3$)

Let lactic acid comes out in $CHCl_3$ at equilibrium = xg

∴ Conc. of lactic acid in

$$CHCl_3 = \frac{x}{250} \text{g}(\text{mL})^{-}$$

Conc. of lactic acid in

$$H_2O = \frac{250 - x}{500} \text{g}(\text{mL})^{-} \quad \left[\because \frac{1}{2} \text{L} = 500\text{mL}\right]$$

$$\text{But} \quad \frac{\text{Conc. of lactic acid in } CHCl_3}{\text{Conc. of lactic acid in } H_2O} = K$$

$$\frac{\frac{x}{250}}{\frac{25-x}{500}} = 0.02 \quad \text{Or} \quad \frac{x}{250}\times\frac{500}{25-x} = 0.02;$$

$$\frac{2x}{25-x} = 0.02;\ 2x = 0.5 - 0.02x$$

Or $2.02x = 0.5$

Hence $x = (0.5/2.02) = 0.247$ g

So, the correct answer is (*d*).

EXAMPLE 21. *A mixture of equal volumes of bromoform and water was thoroughly mixed with 7.52g of Br_2 till equilibrium was attained. Now, excess of phenol was added to bromoform layer after separation. As a result, 10.2 g of tribromophenol, $C_6H_2Br_3OH$ (mol. mass = 331 g mol⁻) precipitate was obtained. The partition co-efficient in favour of water is :*

(*a*) 0.0162 (*b*) 4.21

(*c*) 1.24 (*d*) 0.0531

SOLUTION. Given, $C_6H_2Br_3OH = 3Br$

$$331 \text{ g} = 3 \times 80 = 240 \text{ g}$$

331 g $C_6H_2Br_3OH$ has Br_2 = 240 g

10.2 g $C_6H_2Br_3OH$ has $Br_2 = \frac{240}{331}\times 10.2 = 7.4$ g

$\therefore$ Br_2 in $C_6H_2Br_3OH$ = 7.4 g

Total Br_2 = 7.5 g (given)

$\therefore$ Br_2 in aqueous layer

$= 7.52 - 7.4 = 0.12$ g

Volume of bromoform

= Volume of H_2O = V (say)

But $$\frac{\text{Conc. of } Br_2 \text{ in } H_2O}{\text{Conc. of } Br_2 \text{ in bromoform layer}} = K$$

Or $$\frac{0.12/V}{7.4/V} = K; \quad K = 0.0162$$

So, the correct answer is (*a*)

EXAMPLE 22. *When benzoic acid was shaken with a mixture of water and benzene, following data was obtained.*

	I	*II*	*III*
Concentration of benzoic acid in water (C_1) in g/100 cm^3	0.016	0.024	0.03
Concentration of benzoic acid in benzene (C_2) in g/100 cm^3	0.242	0.56	0.95

The above data indicates that in benzene, benzoic acid exists as :

(*a*) monomer (*b*) dimer

(*c*) trimer (*d*) tetramer

SOLUTION. (*i*) *For monomer :*

I $$\frac{C_1}{C_2} = K; \quad K = \frac{0.016}{0.242} = 0.066$$

II $$\frac{C_1}{C_2} = K; \quad K = \frac{0.024}{0.56} = 0.043$$

III $$\frac{C_1}{C_2} = K; \quad K = \frac{0.03}{0.95} = 0.0316$$

Since the values of K are not constant, benzoic acid does not exist as a monomer.

(*ii*) *For dimer :*

I $$\frac{C_1}{(C_2)^{1/2}} = K; \quad K = \frac{0.016}{(0.242)^{1/2}} = \frac{0.016}{0.49} = 0.0326$$

II $$\frac{C_1}{(C_2)^{1/2}} = K; \quad K = \frac{0.024}{(0.56)^{1/2}} = \frac{0.024}{0.748} = 0.0321$$

III $$\frac{C_1}{(C_2)^{1/2}} = K; \quad K = \frac{0.03}{(0.95)^{1/2}} = \frac{0.03}{0.97} = 0.031$$

The constant values of K suggest that benzoic acid exists as a dimer in benzene solvent.

EXAMPLE 23. *An organic compound containing nitrogen was shaken with a mixture of water and ether at 273K. The following data was obtained.*

C_1(Conc. in H_2O layer)	*0.042*	*0.047*	*0.051*
C_2(Conc. in ether layer)	*0.913*	*1.028*	*1.1208*

If the organic compound exists as monomer in ether it will exist as one of the following in water.

(*a*) *trimer* (*b*) *dimer*

(*c*) *monomer* (*d*) *tetramer*

SOLUTION.

I $$\frac{C_1}{C_2} = K; \quad K = \frac{0.042}{0.913} = 0.046$$

II $$\frac{C_1}{C_2} = K; \quad K = \frac{0.047}{1.028} = 0.046$$

III $$\frac{C_1}{C_2} = K; \quad K = \frac{0.051}{1.1208} = 0.0455$$

Since the values of K are constant, the organic compound exists as a monomer in water. So, the correct answer is (*c*).

EXAMPLE 24. *The distribution co-efficient of an organic compound in ethoxyethane and water is 3:1. The weight of organic compound extracted from 200 mL of aqueous solution containing 20 g of organic compound by 100 mL ethoxyethane is :*

(*a*) *0.0012 g* (*b*) *1.2 g*

(*c*) *6 g* (*d*) *12 g*

SOLUTION.

Volume of mixture solution,

$$V_1 = 200 \text{ mL}$$

Volume of pure solvent (ethoxyethane) used

$$V_2 = 100 \text{ mL}$$

Wt of organic compound,

$$W = 20 \text{ g}$$

Distribution co-efficient,

$$K = \frac{C_1(H_2O)}{C_2(\text{ethoxyethane})} = \frac{1}{3}$$

We know that :

$$W_n = W\left[1-\left\{\frac{KV_1}{KV_1+V_2}\right\}^n\right]$$

$$= 20\left[1-\left\{\frac{\frac{1}{3}\times 200}{\left(\frac{1}{3}\times 200\right)+100}\right\}^1\right]$$

$$= 20\left[1-\frac{200/3}{500/3}\right] = 20(1-0.4)$$

$$= 20 \times 0.6 = 12 \text{ g}$$

So, the correct answer is (*d*)

EXAMPLE 25. *100 mL of an aqueous solution contains 5.6 g of an organic compound. The partition co-efficient of this compound between water and $CHCl_3$ is 1:5. The weight of organic compound extracted by 120 mL of $CHCl_3$ in four separate extractions using 30 ml of $CHCl_3$ for* each extraction will be:

(*a*) 5.6 g (*b*) 4.6 g

(*c*) 5.46 (*d*) 1.2 g (**Ans.** (*c*))

SOLUTION.

Hint. Consult example, 24.

EXAMPLE 26. *The partition co-efficient of iodine between CCl_4 and H_2O in favour of CCl_4 is 85. When 15 g of I_2 is shaken with the mixed solvents, the approximate ratio between the volumes of CCl_4 and H_2O if 8 g of I_2 is left in aqueous layer will be:*

(*a*) 85 : 1 (*b*) 1 : 85

(*c*) 97 : 1 (*d*) 1 : 97

SOLUTION.

Wt of I_2 in mixed solution = 15.0 g

Wt. of I_2 in water layer = 8.0 g

∴ Wt. of I_2 in CCl_4 layer = 15 – 8 = 7 g

Let Volume of H_2O taken = *a* litre

Volume of CCl_4 taken = *b* litre

∴ Conc. of I_2 in CCl_4 = $\frac{7}{b}\,\text{gL}^{-} = C_1$

Conc. of I_2 in H_2O = $\frac{8}{a}\,\text{gL}^{-} = C_2$

$$\therefore\ K = \frac{C_1}{C_2};\ 85 = \frac{7/b}{8/a};\ \frac{a}{b} = \frac{85\times 8}{7} = 97$$

∴ Ratio between volumes of H_2O and CCl_4 = 97 : 1; between CCl_4 and H_2O = 1 : 97

So, the correct answer is (*d*).

EXAMPLE 27. *One gram of silver gets distributed between 10 cm^3 of molten zinc and 100 cm^3 of molten lead at 800°C. The percentage of silver still left in the lead layer is approximately : Partition co-efficient of Ag in Zn and Pb = 300*

(*a*) 2 (*b*) 5

(*c*) 3 (*d*) 1 **[Karnataka CET 2011]**

SOLUTION. Let mass of Ag in Zn at equilibrium = *x*

Mass of Ag in Pb = 1 – *x*

$$\text{But partition co-efficient} = \frac{\text{Conc. of Ag in molten Zn}}{\text{Conc. of Ag is molten Pb}}$$

$$\text{or} \qquad 300 = \frac{x/10}{(1-x)/100} = \frac{10x}{1-x};$$

$$30(1-x) = x;\ 30 - 30x = x \text{ or } 31x = 30;$$

x = 30/31. So, mass of

Ag in Pb = 1 – 30/31 = 1/31

or % age of Ag = 1/31 × 100 ≃ 3.2% ≃ 3

So, the correct answer is (*c*).

PROBLEMS FOR PRACTICE

1. When a solute A was shaken with a mixture of water and an alcohol solvents at constant temperature, the following data was recorded.

	I	II	III
Equilibrium concentration of solute A in H_2O	0.174	1.08	1.80
Equilibrium concentration of solute A in alcohol	0.048	0.30	0.50

Show that the data illustrates the distribution law considering distribution co-efficient in favour of alcohol

2. Using data of above question 1, show that the data illustrates the distribution law considering distribution co-efficient in favour of water.
3. When a mixture of 60 cm^3 ether and 120 cm^3 water was shaken with succinic acid, at equilibrium, water layer contained 2.5 g while ether layer contained 0.15 g of succinic acid. Calculate partition co-efficient in favour of ether. (**Ans.** 0.1202)
4. Calculate partition co-efficient in favour of water in the above question, 3. (**Ans.** 8.32)
5. 20 mL of ether was shaken with 80 mL of M/5 aqueous solution of an organic compound till equilibrium was established. If distribution co-efficient of compound is 18 in favour of ether, find the concentration of organic compound in ether layer. (**Ans.** 0.013)
6. An organic compound is six times more soluble in water than in a solvent, S. When 9.0 g of the compound was mixed with 40 mL water and 30 mL of S, 0.4 g of the compound was found to be present in 18.0 mL of S. Find the degree of dissociation of the compound in water. (**Ans.** 35.65 %)
7. Using following data, prove that benzoic acid exists as a dimer in C_6H_6 if it exists as a single molecule in water.

$C_1(H_2O)$	5.02	7.98	10.90
$C_2(C_6H_6)$	0.146	0.362	0.705

8. 1.0 gm of a substance is dissolved in 100 ml of water. This solution is shaken repeatedly with 10 ml of $CHCl_3$ four times. The distribution ratio of the substance is 10 in favour of $CHCl_3$. Calculate the amount of substance left in water after four shakings and left if only once with 40 ml of $CHCl_3$. The substance has same molecular weight in both the solvents.

Ans. (*i*) 0.0625 g (*ii*) 0.20 g]

Hint. Consult example 1, 2.

9. 1.0 gram of a solute is contained in 100 ml of an aqueous solution. Calculate the quantity of solute left in aqueous phase after single extraction with 70 ml of an organic solvent (*ii*) two successive extractions with 35 ml of solvent assuming that the distribution ratio of the solute between organic solvent and water is 10. Also calculate the percent solute extracted.

Ans. (*i*) 0.125 gm left and 87.5% extracted (*ii*) 0.049 gm left and 95.1% extracted]

Hint. Consult example 14.

10. 20 mL of an aqueous solution of 0.1 M organic acid are shaken with 10 ml of chloroform. After the layers are separated, it is found by titration that 0.5 millimoles of the organic acid remains in the aqueous layer. Calculate the distribution ratio and percent of organic acid extracted. **Ans. D = 6.0%; extracted = 75%**

Hint. Consult example 16.

Appendix (i)

Hints and Answers to Practice Problems

CHAPTER – 1

1. **Hint.** $\left(\text{Speed} = \frac{1.60 \times 10^3\ \text{m}}{1\ \text{mile}} \times \frac{1\ \text{hr}}{3.6 \times 10^3 \text{s}} \times \frac{100\ \text{miles}}{\text{hr}}\right)$

   [**Ans.** 44 ms^{-}.]
2. Pm = petameter = 10^{15}; 41 $pm = 41 \times 10^{15}\ m$
3. 1 pico, $p = 10^{-12}$; $7p = 7 \times 10^{-12}\ m$
7. $2 \times 10^{-2}\ m^3 = (1L/10^{-3}\ m^3) \times 2 \times 10^{-2}\ m^3 = 20\ L$
8. $(10^{-10}\ m/\text{Å}) \times 0.50\ \text{Å} = 5.0 \times 10^{-11}\ m$.
9. $-25°\text{C} = 273 - 25 = 248\ K$
10. 1 yotta, $Y = 10^{24}$. So, $2Y = 2 \times 10^{24}$ cm.

CHAPTER – 2

3. 8.01 + 10.11 + 9.123 = 27.243 = 27.24 (up to least no. of decimal places in given data) = 4 significant figures.
4. $2.1\ \text{m} \times 1.50\ \text{m} = 3.15\ \text{m}^2 = 3.2\ \text{m}^2$
5. 0.1246 ÷ 3.6 = 0.03461 = 0.034 i.e., upto least no. of significant figures in question.
6. Significant figures in 2.2315 are four because preceding digit to 5 is odd. Thus, we have 2.232.
7. Significant figures in 1.12225 are five because preceding digit to 5 is even. Thus, we have 1.1222.
8. 1.1 × 1.111 = 1.2221 = 1.2 because significant figures the least precise factor 1.1 is 2.
9. $4000 = 4.0 \times 10^3$. No. of significant figures in 4.0 are two when the value is determined up to two significant figures.
10. 245 × 0.0125 + 55 = 3.062 + 55 = 58.062 = 58 since 55 contains only number up to two decimal places.

CHAPTER – 3

1. $2\text{Fe}^{2+} \rightarrow 2\text{Fe}^{3+} + 2\text{e}^-$; or $\text{Fe}^{2+} \rightarrow \text{Fe}^{3+} + 1\text{e}^-$.

   Eq. wt. of Fe SO_4 = Mol. wt. of
   Fe SO_4 (= 56 + 32 + (4 × 16) = 152)/(no.
   of e^- s = 1) = 152 ; $\text{Cl}^{5+} + 6e^- \rightarrow \text{Cl}^-$;
   Eq. wt. of KClO_3 = Mol. wt. of KClO_3
   [= 39 + 35.5 + (3 × 16)
   = 122.5/no. of e^{-s} (= 6)] = 20.42
2. Eq. wt. of Na_2HPO_4 = Mol. wt. of Na_2HPO_4
   = (2 × 23) + 1 + 31 + (4 × 16)
   = 142/no. of replaceable H-atoms
   (= 1) = 142.
3. $\frac{E_1}{E_2} = \frac{\text{wt. of metal, 1}}{\text{wt. of metal, 2}}$; $\frac{E_1}{E_2} = \frac{x}{y}$; $E_1 = \frac{x\,E_2}{y}$
4. $\text{I}_2 + 2e^- \rightarrow 2\text{I}^-$; Eq. wt. of
   I_2 = [Mol. wt. of
   I_2 (= 2 × 127)/No. of e^-s gained (= 2)]
   = 127
5. Eq. wt. of metal = [(wt. of metal/wt. of H_2)] × Eq.
   wt. of H_2 = (2.5 × 1.008)/0.21 = 12
6. Eq. wt. = At. wt./valency = 40/2 = 20
7. Eq. wt. = (strength in g L^-/normality) = 5.3/0.1 = 53
8. In $\text{NaOH} + \text{HCl} \rightarrow \text{NaCl} + \text{H}_2\text{O}$, no. of H^+ ions that react with one molecule of NaOH is 1. So, equivalent wt. of NaOH = mol. wt. of NaOH (= 23 + 16 + 1 = 40)/1 = 40
9. Eq. wt. of KHCO_3 = [mol. wt. of KHCO_3/no. of
   replaceable H-atom] = $\frac{100}{1} = 100$
   [∵ Mol. wt. of KHCO_3 = 39 + 1 + 12 + (3 × 16) = 100].
10. 1 mol HCl = 1 mol H^+ ions. So, eq. wt. of
    HCl = mol. wt. of HCl = 1 + 35.5 = 36.5
    ∴ Milliequivalents of
    HCl = (wt./eq. wt.) × 1000
    = (3.65/36.5) × 1000 = 100.

CHAPTER – 4

1. Mol. wt. of KClO_4 = m + 35.5 + (4 × 16)
   = m + 99.5;
   m = at. wt. of K. Hence,
   28.26 = m/(m + 99.5) × 100; m = 39
2. At. wt. = $23 \times 1.66 \times 10^{-24} \times 6.023 \times 10^{23} = 23$
3. Mean at. wt. of Cl = [(35 × 3) + (37 × 1)/3 + 1] = 35.5
4. App. at. wt. = 6.4/0.05 = 128;
   1/3 = E/E + 80 [∵ at. wt. of Br = 80]
   ∴ E = 40; valency = 128/40 = 3.2 = 3;
   at. wt. = 40 × 3 = 120
5. wt. of metal/wt. of oxygen
   = Eq. wt. of metal/Eq. wt. of

oxygen; 60/40 = E/8
∴ E = 12; Mol. wt. of MClx
= $E_x + 35.5x$ where x is valency.
So, $12x + 35.5\,x = 2 \times 47.5$; $x = 2$;
At. wt. = 12 × 2 = 24

6. At. wt. = $3.82 \times 10^{-23} \times 6.023 \times 10^{23} = 23$

7. 1120 mL weighs 3.55 g. So, 22400 mL weighs (3.55/1120) × 22400 = 71 g mol. wt.
But mol. wt. = Atomicity of Cl_2 × at. wt.
So, 71 = 2 × at. wt. Thus, at. wt. = 35.5

8. E = Eq. wt. of Mg ; (Wt. of Mg/wt. of MgO) $= \dfrac{\text{Eq. wt. of Mg (E)}}{\text{Eq. wt. of MgO}}$
$\dfrac{1.2}{2} = \dfrac{E}{E+8}$; E = 12 ; At. wt. of Mg
= E × valency = 12 × 2 = 24.

9. γ = Cp/Cv
= 1.33. So, atomicity of gas is 3.
So, at. wt. of gas = Mol. wt./atomicity = 48/3 = 16

10. Cp − Cv = R ; Cp − 24.6 = 8.3 ; Cp = 32.9;
Cp/Cv $= \dfrac{32.9}{24.6} = 1.33$
So, gas is triatomic. So, at. wt.
= (Mol. wt./atomicity) = 48/3 = 16

CHAPTER – 5

1. Volume = $4/3\, \pi r^3 = 4/3 \times 22/7 \times (8.8/2)^3$
= 357 mm^3; density = mass/volume
= 2.0 g/357 mm^3
= 2.0×10^{-3} kg/357×10^{-9} m^3
= 5.602×10^3 kg m^{-3}.

2. Volume = (Mass/density)
= 18kg × (1000g/1kg) × (1cm^3/1.5g) × 1L/1000cm^3 = 12 L

3. V.D. = 11200 mL of H_2 × sp. gr ;
V.D. = $11200 \times 1.29 \times 10^{-3} = 14.48$

4. Density = Mass/volume
= 1500 g/10 × 8 × 1.5 cm^3
= 12.5 g cm^{-3}.

5. wt. = vol. × density
= 15 cm^3 × 1.1 g cm^{-3}
= 16.5 g; %age by wt. of HNO_3 = (5.2 g/16.5 g) × 100 = 31.5%

6. 500 mL = (500/1000) L
= 0.5 L ; d = 1.18 g cm^{-3}
= 1.18 kg L^{-}.

Pure HCl $= 0.5\text{L} \times \dfrac{1.81\text{ kg}}{1\text{L}} \times \dfrac{28\text{ kg acid}}{100\text{ kg acid}} = 0.344$ g

7. Density = mass/volume
= 120 g / 100,000 mL
= 1.2×10^{-3} g mL^{-1}

8. wt. of KOH = Molarity × mol. wt.
= 5.6 × 5.6 = 313.6 of L^{-}
1000 mL solution contain alkali = 313.6 g.
100 mL solution contain alkali = (313.6/1000) × 100
= 31.36 g
[∵ wt. = 25 g, volume is 100 mL]
∴ 31.36 g alkali is present in solution
= (100/25) × 31.36 = 125.44 g

9. wt. of liquid = 25 g; wt. of solution
= 100 g . 45 g of liquid is present
in solution = (100/25) × 45
= 180 g. So, volume
= (mass/density)
= 180/1.09 = 165.1 mL

10. Density = (1.9 g/cm^3) × (1 kg/1000 g) × (100 cm/1 m)^3 = 1900 kg m^{-3}

CHAPTER – 6

1. Molar mass of base
= $n/2\,[(195\, m_1/m_2) - 410]$
= 1/2 [(195 × 100)/33.4] − 410]
= 86.9 g mol

2. Molar mass = 2 [(108 × 0.8/0.51) − 107]
= 124.8 g mol^{-}.

3. 1000 mL of 1 N NaOH neutralise acid
= (0.24 × 1000)/30 × 0.1
= 80 g = g. eq. wt. of acid
∴ Molar mass = Eq. wt. × basicity
= 80 × 2 = 160 g mol^{-}

4. 1000 mL of 1 NHCl neutralise base
$= \left[(0.12 \times 1000)/\left(10 \times \dfrac{1}{2}\right)\right]$
= 24 g = g. eq. wt. of base.
So, molar mass = Eq. wt. × acidity
= 24 × 1 = 24 g mol^{-}.

5. 300 mL weighs = 0.368 g. So, 22400 mL weighs
= (22400 × 0.368)/300 = 27.5 g

6. $V_2 = (P_1V_1T_2/T_1P_2)$
= [(750 mm × 0.056 dm^3 × 273 K)/
(25 + 273 = 298 K) × 760 mm]
= 0.05 dm^3; 0.05 dm^3 weighs 0.073

g. So, 22.4 dm^3 weighs equal to $(0.073\ g \times 22.4\ dm^3)/0.05\ dm^3$ i.e., 32.7 g mol^-

7. $V_2 = (P_1V_1T_2/T_1P_2)$
$= [(1.1\ atm \times (36\ L/1000) \times 273\ K/$
$(107 + 273 = 280\ K) \times 1\ atm]$
$= 0.038$ L. So, wt. of 0.038 L H_2
$= 0.09\ g \times 0.038 = 3.42 \times 10^{-3}\ g$
$\therefore$ $V.D. = 36$; Mol. wt. = 2 × V.D.
$= 2 \times 36 = 72\ g\ mol^-$.

8. $P_1 = 35/76$ atm.,
$V_1 = 72/1000 = 0.072$ L,
$T = 25 + 273 = 298$ K.
But $PV = nRT$ or $PV = wRT/M$.
So, $M = WRT/PV$
$= (0.059\ g \times 0.0821\ L\ atm\ K^-mol^- \times 298\ K \times 76)/35\ atm \times 0.072\ L)$
$= 43.5\ g\ mol^-$

9. 0.4 L of a gas weighs 0.57 g. So, 22.4 L of gas weighs equal to $(0.57 \times 22.4/0.4) = 31.92\ g\ mol^-$.

10. $P_1 = 755.7 - 26.7 = 729.0$ mm,
$V_1 = 20.8$ mL, $T_1 = 27 + 273 = 300$ K;
At NTP, $P_2 = 760$ mm, $V_2 = ?$, $T_2 = 273$ K. So,
$V_2 = (P_1V_1T_2/T_1P_2)$
$= (729\ mm \times 20.8\ mL \times 273\ K/\ 300$
$K + 760\ mm) = 18.16$ mL;
V.D. $= (0.054/18.16 \times 0.00009)$
$= 33$; Mol. wt. = 2 × V.D. = 2 × 33
$= 66\ g\ mol^-$

CHAPTER – 7

1. $Zn + CuSO_4 \longrightarrow ZnSO_4 + Cu$;
0.65 g 1.5 g x 0.635 g
Using law of conservation of mass, 0.65 + 1.5
$= x + 0.635$. So, $x = 1.515$ g.

2. (*i*) Ratio of I : Cl = 3.5 : 1; K : I = 1 : 3.237; K : Cl
= 1 : 0.923. Keeping wt. of K constant,
I : Cl = 3.237/0.923 : 0.923/0.923
= 3 . 5 : 1 which is same as of (*i*).
So, correct answer is (*b*).

3. (*i*) wt. of CO_2 = (44 × 1120)/22400)
= 2.2 g ($\because$ mol. wt. of CO_2 = 44 g);
wt. of oxygen = 2.2 – 0.6 = 1.6 g;
So, C : O = 0 . 6 : 1.6 = 3 : 8 ...(1)
(*ii*) C = 27.3%, O = 100 – 27.3 = 72.7 %.
Thus C : O = 27.3 : 72.7 or (27.3/27.3)
: (72.7/27.3)
= 1 : 2.66 or (3 × 1) : 3 × 2.66
= 3 : 8 ...(2)
the ratio in (1) and (2) is same.

4. When 5 mL of O_2 are treated with 10 mL of H_2, water is formed. When 100 mL of H_2 at N.T.P are passed over heated cupric oxide, the cupric oxide loses 0.072 g of its weight. Show that the results are in agreement with the law of constant composition.

(**Ans.** In both experiments, the ratio by wt. of $H_2 : O_2$ to form H_2O is 1 : 8. So, the law of constant composition is obeyed).

Hint. wt. of 5 mL

$$O_2 = \frac{32}{22400} \times 5\ g = 71 \times 10^{-4}\ g;$$

$$\text{wt. of } H_2 = \frac{2 \times 10}{22400}\ g = 8.9 \times 10^{-4}\ g.$$

$$\text{wt. of 100 mL } H_2 = \frac{2 \times 100}{22400} = 8.9 \times 10^{-3}\ g$$

$$\text{wt. of } O_2 = 0.072\ g = 72.0 \times 10^{-3}\ g$$

Ratio by wt. of H : O in both cases is same *i.e.*, 1 : 8.

5. In H_2O, ratio by wt. of H : O
= 11.2 : (100 – 11.2 = 88.8) = 1 : 7.92
In H_2O_2, the ratio by wt. of H : O
= 5.93 : (100 – 5.93 = 94.07)
= (5.93/5.93) : (94.07/5.93)
= 1 : 15.86. Keeping wt. of H
= 1 fixed, the ratio by wt. of O in H_2O and H_2O_2 is 7.92 : 15.86 or 1 : 2 which is simple multiple ratio.

6. (*i*) 0.2/0.2 : 0.4/0.2 = 1 : 2 (*ii*) 6/6 : 24/6 = 1 : 4 (*iii*) 20/20 : 120/20 = 1 : 6. Keeping wt. of A = 1 fixed, wts. of B are multiple of each other, 2 : 4 : 6 or 1 : 2 : 3

7. $CH_4 + 2O_2 \longrightarrow CO_2 + 2H_2O$
1L 2L
1L CH_4 uses O_2 = 2L. So, 6 L CH_4 uses
O_2 = 6 × 2
= 12 L. So, volume of air used
= (12 × 100/20.9) = 38.27 L.

8. $NaHCO_3 + CH_3COOH \longrightarrow \underbrace{CH_3COONa + H_2O} + 2CO_2$
2.1 g 1.5 g 2.05 g x
$\therefore$ 2.1 + 1.5 = 2.05 + x ;
x = 2.1 + 1.5 – 2.05
= 1.55 g
(law of conservation of mass)

9. (*i*) In PCl_3, P : Cl = [(22.57/22.57) : 77.43/22.57]
= 1 : 3.43; (*ii*) In PH_3, P : H

= [91.18/91.18 : 8.82/91.18]
= 1 : 0.096
In (*i*) and (*ii*) ratio of H : Cl
= 0.096 : 3.43 = 1 : 35. In (*iii*) H : Cl
= [2.77/2.77 : 97.23/2.77]
= 1 : 35.
In both cases, the ratio is same.

10. (*i*) In NH_3, N : H = (82.35/17.65 : 17.65/17.65)
= 4.66 : 1 (*ii*) In H_2O, O : H
= (88.9/11.1 : 11.1/11.1) = 8 : 1. So,
in (*i*) and (*ii*) N : O = (4.66/4.66 : 8/4.66)
= 1 : 1.71. In (*iii*), N : O
= (36.85/36.85 : 63.15/36.85)
= 1 : 1.71. In both cases, ratio is same.

CHAPTER – 8

20. $n = PV/RT$
$= 3170\ \text{Pa} \times 1\ \text{dm}^3/8.314 \times 10^3\ \text{Pa}$
$\text{dm}^3\ \text{K}^-\ \text{mol}^- \times 300\ \text{K} = 1.27 \times 10^{-3}$ mol.

21. $P_A = d_A\, RT/M_A = 2d_B\, RT/M_{B/2}$
$= 4\, d_B\, RT/M_B$;
$P_B = d_B\, RT/M_B$.
So, $P_A/P_B = [4\, d_B\, RT/M_B]/d_B\, RT/M_B] = 4/1$

22. Vol = mass/density
= (144 – 50 = 94 g)/0.47 g mL^-
= 0.2L ; PV = nRT
= (m/M)RT. So, 1 atm × 0.2 L
= (0.5 g/M) × 0.0821 L atm $\text{K}^-\ \text{mol}^-$
× 300 K. So, M = 61.575 g mol^-.

23. $U_{rms}(H_2) = (3RT/M)^{1/2} = (3R \times 300/2)^{1/2}$
$= 1.9 \times 10^3\ \text{ms}^-$; $U_{rms}(O_2)$
$= (3RT/M)^{1/2} = (3R \times 1200/32)^{1/2}$
$= (3R \times 4 \times 300/16 \times 2)^{1/2}$
$= \dfrac{2}{4}\ (3R \times 300/2)^{1/2}$
$= 0.95 \times 10^3\ \text{ms}^-$

24. $P_1V_1/T_1 = P_2V_2/T_2$; [1.5 atm × V_1/15 + 273
= 298 K] = 1.0 atm × V_2/288;
$V_2 = 1.55\ V_1 \simeq 1.6\ V_1$.

25. $PV = nRT = mRT/M$; 1 atm × 22.4 *L*
= (4.4 g/M) × 0.0821 L atm $\text{K}^-\ \text{mol}^-$
× 273.15 K; *M* = 44.05 g
[∵ *p* = 101.325 *k* Pa = 101325 Pa = 1 atm].
So, gas is C_3H_8 (3 × 12 + 8 = 44).

26. Greater the volume of vander Waal constant, '*a*' stronger will be the intermolecular forces and easily that gas will liquify. So, the correct answer is (*d*).

27. Average velocity of gas = $(8RT/M)^{1/2}$, On doubling the temperature, the average velocity will be $(2)^{1/2}$ i.e., 1.414 times.

28. $r_{HCl}/r_{NH_3} = (M_{NH_3}/M_{HCl})^{1/2} = (17/36.5)^{1/2} = 1/1.46$.

29. $r_{H_2}/r_{H.C.} = (M_{HC}/M_{H_2})^{1/2} = 3(3)^{1/2}$;
$(M_{HC/2})^{1/2} = 3(3)^{1/2}$;
$M_{HC} = 2 \times 27 = 54$.
So, the hydrocarbon (H.C.)
= C_4H_6 i.e., 54/12
= 4C + 6H = C_4H_6.

CHAPTER – 9

11. 22.4 L SO_2 at N.T.P.
= 6.023×10^{23} molecules; 5.6 L SO_2
= $6.023 \times 10^{23} \times 5.6/22.4$
= 1.5×10^{23} molecules.

12. 11.2 L (= 22.4/2) $O_2 \equiv (6.02 \times 10^{23}/2)$
= 3.01×10^{23} molecules; 8 g (= 32/4)
O_2 = $(6.02 \times 10^{23}/4)$ or 1.505×10^{23}
molecules; 0.1 mol O_2 = $0.1 \times 6.02 \times 10^{23}$
= 6.02×10^{22} molecules ;
2.24×10^4 mL of O_2 = $6.02 \times 10^{23} \times 2.24 \times 10^4/22400$
= 6.02×10^{23}.

13. Molarity of acid = Normality/basicity ;
Molarity = 0.02/2 = 0.01 M ; 1000 mL
= 0.01 mol, so 100 mL
= 0.01 × 100/1000 mL
= 0.001 mol or $6.02 \times 10^{23} \times 0.001$
= 6.02×10^{20}.

14. 1 mol $(NH_4)_2Cr_2O_7$
= Total no. of atoms × 6.023×10^{23}
= 19 atoms (= 2 N + 8H + 2 Cr +
7O = 19) × 6.023×10^{23}
= 114.437×10^{23} atoms.

15. Time in hours to distribute 10^{20} grains
= $(6.023 \times 10^{23})/10^{20} \times 60 \times 60$
= 1.673 hours.

16. No. of atoms in 0.1 mol of triatomic gas
= $0.1 \times 3 \times 6.02 \times 10^{23} = 1.806 \times 10^{23}$.

17. 1 mol CO_2 = 12 + (2 × 16) = 44 g; 88 g CO_2
= 2 mol ; no. of O-atoms in 1 molecule of CO_2
= 2 ; no. of O-atoms in 2 mol of
CO_2 = $2 \times 2 \times 6.02 \times 10^{23}$
= 24.08×10^{23} ;
One CO molecule contains O-atoms = 1
1 mol CO (= 12 + 16 = 28 g) contain O-atoms
= 6.02×10^{23}.

So, mass of CO containing 24.08×10^{23} oxygen atoms

$= (28/6.02 \times 10^{23}) \times 24.08 \times 10^{23}$

$= 112$ g. So, (*d*) is correct.

18. 22400 cm^3 contain Ar-atoms = Atomicity of Ar × 6.02×10^{23} atoms

∴ 100 cm^3 contain Ar-atoms

$= 1 \times 6.02 \times 10^{23} \times 100/22400$

$= 2.7 \times 10^{21}$. So, (*d*) is correct.

19. wt. of A $= 20 \times 10{,}000 = 20{,}000$ g; 1 g atom

of A $= 6.02 \times 10^{23}$ atoms. So, g. atoms of

A $= 3.01 \times 10^{-23} \times 6.02 \times 10^{23}$

$= 18.1$ g; 18.1 g of A

$= 1$ g atom of A. So, 20,000 g of A

contain g atoms $= 20{,}000/18.1 = 1105$ g atoms.

20. $V_2 = (P_1V_1T_2/P_2T_1)$

$= (2 \times 400 \times 273/1 \times 273)$

$= 800\ cm^3$. 22400 cm^3 gas weighs (1 g × 22400/800) = 28 g ; wt. of one atom of gas = [1 g. mol. wt. of gas/ atomicity of gas × 6.02×10^{23}]

$= [28\ g/2 \times 6.02 \times 10^{23}]$

$= 2.3 \times 10^{-23}$ g.

CHAPTER – 10

2. Suppose no. of O^{2-} ions = 30. So, no. of octahedral voids = 30.

∴ Ratio of $Al^{3+} : O^{2-} = (30 \times 2/3) : 30 = 20 : 30 = 2 : 3$

∴ Formula $= Al_2O_3$.

3. **AB:** $r^+/r^- = 1/1 = 1$. So, b.c.c. struture ;

$2 \times (r_A^{\ +} + r_B^{\ -}) = \sqrt{3} \times a$.

∴ $a = (2/\sqrt{3})\ (1 + 1)$

$= 4/\sqrt{3}$; vol. $a^3 = (4/\sqrt{3})^3$

$= 12.32\ cm^3$.

AC : $r^+/r^- = 1/2 = 0.5$; so octahedral structure ; $a = 2\ (r^+/r^-) = 6$ pm. So, volume, $a^3 = (6\ pm)^3$

$= 216\ pm^3$.

4. $d = [(4 \times 58.5)/6.023 \times 10^{23} \times (0.5627 \times 10^{-7})^3] = 2.1805\ g\ cm^{-3}$;

Due to misssing of some ions, observed density 2.164 $g\ cm^{-3}$ is less than calculated 2.1805 $g\ cm^{-3}$. Thus:

$Z = 2.164 \times 6.023 \times 10^{23} \times (0.5627 \times 10^{-7})^3/58.5 = 3.969$; missing units

$= 4 - 3.969 = 0.031$; % missing

$Na^+, Cl^- = 0.031 \times 100/4 = 0.775$.

5. (*i*) Length, *a*. $4r = \sqrt{2}.a$; $4 \times 130 = \sqrt{2}\ .\ a$

So, $a = 367.64$ pm; (*ii*) volume

$= a^3 = 4.94 \times 10^{-23}\ cm^3$ (*iii*) for fcc,

$Z = 4$ (*iv*) $d = [(4 \times 63.54)/6.023 \times 10^{23} \times (3.67 \times 10^{-8})^3] = 8.54\ g\ cm^{-3}$.

6. For fcc, Z = 4; for bcc, Z = 2. Use

$d = n$ M/No. a^3. So, d_{fcc}/d_{bcc}

$$= 4/2 \times \frac{3^3}{(3.5)^3} = 1.259$$

7. $2r^+ + 2r^- = 600$ pm, $r^+ + r^-$

$= 300$; For octahedral, r^+/r^-

$= 0.414$. From r^+/r^-

$$= 300,\ r^-\left(\frac{r^+}{r^-} + 1\right) = 300;$$

r^- of $A^- = 212.164$ and r^+ of M^+

$= 212.164 \times 0.414 = 87.84$ pm.

8. $n\lambda = 2d \sin\theta$; $d = n\lambda/2 \sin 60$

$= 2 \times 1\ Å/2 \times \sqrt{3}/2 = 1.15Å$.

9. Radius ratio $= r^+/r^- = 88/200$

$= 0.44$. So, co-ordination number

$= 6$.

10. $a = 2d/\sqrt{3} = 2 \times 452/1.732$

$= 522$ pm; for bcc, $Z = 2$. So,

$d = Z\ M/N_c \times a^3 \times 10^{-30} = 910\ kg\ m^{-3}$.

So, (*c*) is correct.

11. For fcc, $r^+/r^- = a/2 = 508/2 = 254$ pm.

So, $r^- = 254 - 110 = 144$ pm.

CHAPTER – 11

1. Use example, 1 at page, 182.

2. $CO_2 \equiv C$; H_2O : 2H

44 g   12 g   18 g   2 g

wt. of H_2 in 0.69 g H_2O

$= [(2 \times 0.69)/18] = 0.0767$ g

wt. of carbon in 3.38 g CO_2

$= (12 \times 3.38/44) = 0.9218$ g; mass

of fuel gas $= 0.9218 + 0.0767$

$= 0.9985$ g; mass percent of carbon

$= (0.9218 \times 100/0.9985)$

$= 92.32\%$; mass percent of H_2

$= (0.0767 \times 100/0.9985)$

$= 7.68\%$. To find E.F. we have:

Element	*% age*	*At. mass*	*relative no. of atoms*	*simple ratio*	*whole no. ratio*
C	92.32	12	92.32 = 7.69	7.69/7.69 = 1	1
H	7.68	1	7.68/1 = 7.68	7.68/7.68 = 1	1

So, E.F. = CH

3. 10 L gas weighs = 11.6 g. So, 22.4 L gas weighs
= (11.6 × 22.4/10) = 26 g

4. M.F. = n × E.F.; n = [molar mass/E.F. mass of CH (= 12 + 1 = 13)] = 26/13
= 2. So, M.F. 2 × CH = C_2H_2

5. $H_2 + Br_2 \longrightarrow 2HBr$
1 vol 1 vol 2 vol
3L 3L 2 × 3 = 6L

Vol. of H_2 gas taken = 3.2 L ; Vol of H_2 gas used is 3.0 L. So, vol. of H_2 gas left behind = 3.2 – 3.0 = 0.2 L; vol of HBr formed = 2 × 3 = 6 L. Here, Br_2 being less, is limiting reagent.

6. $2\,Na + 2HCl \longrightarrow 2NaCl + H_2$
2 vol 1 vol
Decrase in volume = 2 – 1 = 1V. Actual decrease in vol
= 48 – 40 = 8 mL. Vol of HCl in 48 mL
mixture = 8 × 2 = 16 mL; vol of
H_2 = 48 – 16 = 32 mL; 98 mL of mixture
contain HCl (g) = 16 × 2 = 32 mL and
H_2 = 98 – 32 = 66 mL.
$NH_3(g) + HCl(g) \rightarrow NH_4Cl(s)$; [32 mL NH_3 = 32 mL HCl]
32 mL 32 mL
Residual NH_3 = 48 – 32 = 16 mL ; residual
H_2 = 98 – 32 = 66 mL

7. $C_xH_y + (x + y/4)\,O_2 \longrightarrow x\,CO_2 + y/2\,H_2O.$
250 mL 250 $(x + y/4)$ 250 x 250 × y/2
= 125 y
= 1250 mL = 1500
[∵ 1.5 L = 1.5 × 1000 = 1500 mL]
250 x = 1250; x = 5 ; 125 y = 1500.
So, y = 1500/125 = 12 .
Thus, the formula of hydrocarbon = C_5H_{12}.

8. Use example 23 for calculations.

9. Use example 27 for calculations.

10. $CH_4(g) + 2O_2(g) \longrightarrow CO_2(g) + 2H_2O(l)$
22400 mL 2 × 22400 mL
22400 mL CH_4 use O_2 = 2 × 22400 mL
112 mL CH_4 use O_2 = [2 × 22400 × 112/22400] = 224 mL. So, (b) is correct.

CHAPTER – 12

1. No. of atoms in NH_3
= 1 N + (3 × 1) H
= 4. Mol. wt. of NH_3
= 14 + (3 × 1) = 17 g mol⁻
17 g NH_3 ≡ 4 × 6.023 × 10^{23} atoms
4.25 g NH_3 ≡ [4 × 6.023 × 10^{23}/17] × 4.25
= 6.023 × 10^{23} atoms.
So, correct answer is (a).

2. 22400 mL H_2O ≡ 6.023 × 10^{23} molecules.
1 mL H_2O ≡ (6.023 × 10^{23}/22400) = 20 drops.
∴ 1 drop H_2O ≡ [6.023 × 10^{23}/22400 × 20]
= 1.344 × 10^{18} molecules.

3. $(NH_4)_2Cr_2O_7$ contains atoms
= 2N + 8H + 2Cr + 7O
= 19. So, 1 mol contains 19 × 6.023 × 10^{23} = 114.437 × 10^{23} atoms.
So, (c) is correct.

5. no. of emitted spectral lines when electron jumps from n_2 to n_1 orbit
= $[(n_2 - n_1)(n_2 - n_1 + 1)/2]$
= (5 – 1) (5 – 1 + 1)/2 = 10

6. $\bar{v} = R_H\,[1/n_1^2 - 1/n_2^2]$
= 8/9 R_H; $1/n_1^2 - 1/n_2^2$
= 8/9. So, n_1 = 2, n_2 = 3.
So, (a) is correct.

7. n = no. of photons ;power
= 600 W or 600 J s^{-}; E = n hc/λ
= 600 Js^{-}.
600 = [n × 6.626 × 10^{-34} × 3 × 10^8/331.3 × 10^{-9}]; n = 1 × 10^{21} photons.

8. ΔE = $N_A\,hc/\lambda$; 242 × 10^3
= [6.02 × 10^{23} × 6.62 × 10^{-34} × 3.0 × 10^8/λ]
or λ = 4.94 × 10^{-7} m = 494 nm.

9. Z for He = 2; for Li = 3. I.E. of He^+
= I.E. of H × Z^2 ; I.E. of H
= 19.6 × 10^{-18}/Z^2 = 4
= 4.9 × 10^{-18} J atom⁻. I.E. of Li^{2+}
= I.E. of H atom × Z^2 = 4.9 × 10^{-18} × $(3)^2$ = 4.41 × 10^{-17} J
= – 4.41 × 10^{-17} J.

10. $_{24}Cr = 1s^2\,2s^2\,2p^6\,3s^2\,3p^6\,4s^2\,3d^4$.
So, 19th electron goes to 4s-energy level.

CHAPTER – 13

1. $_{27}Co = (Ar)^{18}\,3d^7\,4s^2$; $Co^{3+} = (Ar)^{18}\,3d^6$

2. $_7N = (He)^2\,2s^2\,2p^1_x\,2p^1_y\,2p^1_z$ **Ans.** Try others yourself e.g. ; $_{12}Mg^{2+} = (Ne)^{10}$ has no unpaired electron.

3. $\chi_B - \chi_A$ = 1.0. Use the calculations of example 25, page 258 to get the result.

4. Extra ionic resonance energy
= 103.2 – $[104.2 \times 58]^{1/2}$
= 103.2 – $(6043.6)^{1/2}$
= 103.2 – 77.7 = 25.5 cal mol⁻

5. %age ionic character

$= 16\,\Delta x + 3.5\,(\Delta x)^2$

$= 16\,(3.0 - 2.8) + 3.5\,(3.0 - 2.8)^2$

$= 3.34.$

6. $\Delta H = E.A. + I.P. = -3.7\text{ eV} + 4.3\text{ eV}$

$= 0.6\text{ eV}.\ \Delta H\text{ mol}^{-}$

$= 0.6 \times 6.02 \times 10^{23}\text{ eV} \times 1.602 \times 10^{-19}$

$\times 10^{-3}\text{ kJ/1 eV} = 57.86\text{ kJ}.$

7. I.P. of K $= 4.3\text{ eV atom}^{-} \times 6.023 \times 10^{23} \times 1.602 \times 10^{-19}\text{ J mol}^{-}/1\text{eV atom}^{-}$

$= 414.9 \times 10^{3}\text{ J mol}^{-}$. For 3.0 mol K,

I.P. $= 3 \times 414.9 \times 10^{3} = 1244.7 \times 10^{3}$ J.

8. Bond length = 0.28 Å + 0.99 Å = 1.27 Å.

9. ${}_{19}K = 1s^2\,2s^2\,2p^6\,3s^2\,3p^6\,4s^1$. Highest no. of shell = no. of period = 4.

CHAPTER – 14

1. $4Al + 3O_2 \longrightarrow 2Al_2O_3$

4 × 27 = 108 g   3 mol

3 mol O_2 ≡ 108 g Al ; 1.5 mol O_2

≡ (108 × 1.5)/3 = 54 g

2. 1 kg sea water ≡ 10^6 mg; 10^6 mg H_2O contain dissolved O_2

= 6 mg. So, concentration of O_2

$= 6 \times 10^6\text{ ppm}/10^6 = 6$ ppm.

3. Mol. wt. of Na_2CO_3

= 106; Molarity

$$= \frac{25.3 \times 1000}{106 \times 250}$$

= 0.955 M;

$Na_2CO_3 \rightleftharpoons 2Na^+ + CO_3^{2-}$

∴ $Na^+ = 2 \times 0.955 = 1.910$ M;

$CO_3^{2-} = 0.955$ M.

4. $NaCl + AgNO_3 \longrightarrow NaNO_3 + AgCl$

23 + 35.5	108 + 14 + 48	108 + 35.5
= 58.5	= 170	= 143.5
5g	20 g (given)	
5g	14.5g (see (*i*) below)	
5 – 5 = 0	20 – 14.5 = 5.5 (difference)	
Less	more	

= Limiting reagent

(*i*) 58.5 g NaCl ≡ 170 g $AgNO_3$

5 g NaCl = 170 × 5/58.5 = 14.5 g

(*ii*) 58.5 g NaCl ≡ 143.5 g AgCl

5 g NaCl = (143.5 × 5/58.5) = 12.26 g

5. $NaHCO_3 + HCl \longrightarrow NaCl + H_2O + CO_2\uparrow$

23 + 1 + 12 + (3 × 16) = 84 g   22400 mL

84 g $NaHCO_3$ form CO_2 = 22400 mL

8.4 g $NaHCO_3$ form CO_2 = (22400 × 8.4/84) = 2240 mL

6. $Pb(NO_3)_2 + 2NaCl \longrightarrow PbCl_2 + 2NaNO_3$

207 + 2 (14 + 148)	2(23 + 35.5)
= 331 g	= 117 g
3.31 g	1.0 g (given)
3.31 g	1.17 (Calculated)
0	– 0.17 Difference

Since – 0.17 < 0, NaCl is the limiting reactant.

3.31 g Pb $(NO_3)_2$ ≡ 117 g NaCl

3.31 g Pb $(NO_3)_2$ = 117 × 3.31/331 = 1.17 g

7. Acidity of Ca $(OH)_2$

= 2; Molarity of Ca $(OH)_2$

= Normality/acidity = 0.2/2 = 0.1

$[M_1\,V_1\,(H_2SO_4)/M_2V_2\,Ca(OH)_2]$

= no. of mol of H_2SO_4/no. of mol. of Ca $(OH)_2$; 0.4 × V_1/0.1 × 20

= 1/1 ; V_1 = 20 × 0.1/0.4 = 5 mL

$Ca(OH)_2 + H_2SO_4 \longrightarrow CaSO_4 + 2H_2O$

1 mol   1 mol

8. $Mg + H_2SO_4 \longrightarrow MgSO_4 + H_2$

1 mol   1 mol

0.1 mol   0.1 mol

Moles of Mg = (wt/g at. wt.) = 2.4/24 = 0.1

1 mol   1 mol

Vol of H_2SO_4 in litre = Mol/molarity

= 0.1/0.4 = 0.25 L

9. Consult example 70.

10. Consult example 68.

CHAPTER – 15

11. At equilibrium, ΔG

= 0; ΔG (= 0) = ΔH – TΔS ; T

$= \Delta H/\Delta S = (-743.1\text{ J mol}^{-}/$

$-17\text{ J k}^{-}\text{ mol}^{-}) = 43.7$ K

12. $\Delta S = \Delta H v/T$;

$\Delta S = (-35.3 \times 1000\text{ J mol}^{-}/273 + 80$

$= 353\text{ K}) = -100\text{ JK}^{-}\text{ mol}^{-}$

13. $\Delta S^\circ = S^\circ(XY_3) - 1/2\,S^\circ(X_2) - 3/2\,S^\circ(Y_2)$

$= 50 - 1/2(60) - 3/2(40) - 40\text{ JK}^{-}\text{mol}^{-}$

$T = \Delta H^\circ/\Delta S^\circ = (-30 \times 10^{3}\text{ J mol}^{-}/$

$-40\text{ JK}^{-}\text{ mol}^{-}) = 750$ K.

15. For $1/2\ H_2\ (g) + 1/2\ Cl_2\ (g) \rightarrow HCl\ (g)$,
$\Delta_r H = \Delta H$ (Products) – ΔH (reactants) ;
$\Delta_r H = (-92.3) - ((1/2 \times 218) + 1/2 \times 121.68) = -262.14$ kJ mol$^-$

16. Moles of HCl; $= 0.1 \times 500/1000 = 0.05$ mol; mol of NaOH $= 0.2 \times 200/1000 = 0.04$ mol
0.04 mol NaOH $\equiv$ 0.04 HCl ; Heat of neutralisation $= 0.04 \times 57.1 = 2.284 \simeq 2.29$ kJ.

17. $H-H + O=O \rightarrow H-O-O-H$;
$\Delta_r H$ = B.E. (reactants) – B.E. (Products) $= (438) + (498) - [2\ (464 + 138)] = -130$ kJ mol$^-$.

18. Given equations are (*i*) $1/2\ N_2\ (g) + 3/2\ H_2\ (g) \rightarrow NH_3\ (g)$;
$\Delta H = -46$ kJ (*ii*) $2\ H\ (g) \rightarrow H_2(g)$;
$\Delta H = -436$ kJ; (*iii*) $2N\ (g) \rightarrow N_2(g)$;
$\Delta H = -712$ kJ. In order to get equation,
$NH_3(g) \rightarrow N(g) + 3/2\ H\ (g)$,
we have, 1/2 equation (*iii*) + 3/2 × equation (*ii*) –equation (*i*), we get
$\Delta H = 1056$ kJ for three N-H bonds.
So, average bond energy (N – H) = 1056/3 = 352 kJ.

19. At equilibrium $\Delta G = 0$; $\Delta G\ (= 0) = \Delta H - T\Delta S$;
$\Delta S = \Delta H/T = [21.3 \times 1000$ J mol$^-/82 + 273 = 355] = 60$ JK$^-$ mol$^-$

20. External pressure, $P = 0$; $W = P \times \Delta V = 0 \times \Delta V =$ zero.

CHAPTER – 16

6. H_2SO_4. 2 × O.N. of H + O.N. of S (= x) + 4 × O.N. of O = 0; $(2 \times +1) + x + 4\ (-2) = 0$; $x = +6$

7. Let O.N. of I $= x$; (*c*) IO_3^-; $x + 3\ (-2) = -1$; $x = +5$; IO_4^- ; $x + 4\ (-2) = -1$. So, $x = +7$; $K^+ I^-$; $x = -1$; I^0_2 ; I = 0.

8. $Ag^+ + e^- \rightarrow Ag$, $E° = +0.80$ V; $Cu^{2+} + 2e^- \rightarrow Cu$, $E° = +0.34$. Since E° (reduction) value + 0.80 V > + 0.34 V, Ag^+ is stronger oxidant than Cu^{2+}.

9. $Zn^{2+} + 2e^- \rightarrow Zn$, $E° = -0.76$ V ; $Cu^{2+} + 2e^- \rightarrow Cu$, $E° = +0.34$ V.
Since E° (reduction) value – 0.76 V < + 0.34 V, Zn is stronger reducing agent than Cu.

10. $MnO_4^- + 8H^+\ 5e^- \rightarrow Mn^{2+} + 4H_2O] \times 2$
$\underline{FeC_2O_4 \rightarrow Fe^{2+} + 2CO_2 + 2e^-] \times 5}$
$5\ FeC_2O_4 + 2\ MnO_4^- + 16\ H^+ \rightarrow 2Mn^{2+} + 8H_2O + 5\ Fe^{2+} + 10CO_2$
$\therefore$ 5 mol $FeC_2O_4 \equiv$ 2 mol MnO_4^-. So, 2 mol FeC_2O_4 $\equiv$ 2/5 or 0.6 mol MnO_4^-.

11. $Mn^{7+}\ O_4^- + N^{3-} \rightarrow N^{5+} + Mn^{4+}$. Here O.N. of Mn $= +4 - 7 = -3$; O.N. change of N $= +5 - (-3) = +8$. So, $x = 8$, $y = 3$.

12. Let x = O.N. of Hg. So, in Hg_2Cl_2, $2x + 2$ (O.N. of Cl) = 0; $2x + 2\ (-1) = 0$; $x = +1$.

13. (*i*) PO_4^{3-} ; $x + 4\ (-2) = -3$. So, $x = +5$ (*ii*) SO_4^{2-} ; $x + 4\ (-2) = -2$. So, $x = +6$ (*iii*) $Cr_2O_7^{2-}$; $2x + 7\ (-2) = -2$. So, $x = +6$.

14. (*c*) $Cl^{+1}\ O^- + Cl^{+1}\ O^- \rightarrow Cl^{+5}\ O_3^- + Cl^-$. Here one Cl^{+1} is oxidised to +5 while the second Cl^+ is reduced to Cl^-.

15. In Mohr's salt, $FeSO_4\ (NH_4)_2\ SO_4$. 24 H_2O, oxidation state of Fe in $FeSO_4$ is + 2 i.e., x + O.N. of $SO_4^{2-} = 0$; $x - 2 = 0$; $x = +2$

CHAPTER – 17

1. Molarity of solution = (25.3 × 1000/106 × 250) = 0.955 M; $Na_2CO_3 \rightleftharpoons 2Na^+ + CO_3^{2-}$
$\therefore$ $[Na^+] = 2 \times 0.955 = 1.910$ M; $CO_3^{2-} = 1 \times 0.955 = 0.955$ M.

2. 0.08 g S is present in insulin = 100 g; so, 32 g S (at. wt. of S = 32) is present in insulin = (100 × 32/0.08) = 40,000.

3. Mass of NO_2 gas = (46 × 112/22400) = 0.3 g; Volume of liquid = 0.23/1.15 = 0.20 mL; no. of molecules = no. of moles × Avogadro's no. $= (0.23/0.46) \times 6.02 \times 10^{23} = 3.01 \times 10^{21}$.

10. Mole fraction $I_2 = 0.2$; $C_6H_6 = 0.8$. Mass of C_6H_6 (mol. wt. 78) = 0.8 × 78 = 62.4. So, molarity of I_2 = (0.2 × 1000/62.4) = 3.2.

CHAPTER - 18

3. $\Delta T_f = i\ k_f \times m$. For $Na_2SO_4 \rightleftharpoons 2Na^+$ (2 mol) + SO_4^{2-} (1 mol), $i = 2 + 1 = 3$.
Molality, m = (0.01/1 kg) = 0.01 m;
$\Delta T_f = 3 \times 1.86$ K kg mol$^- \times 0.01$ mol kg$^-$ = 0.0558.

4. $x_{\text{solute}} = (p^{\circ} - p/p^{\circ}) = (0.8 - 0.6/0.8) = \mathbf{0.25}.$

5. $\pi = \text{CRT}$

$= 0.002 \times 1000 \text{ mol m}^{-3} \times 8.314 \text{ JK}^{-}$

$\text{mol}^{-} \times (273 + 20 = 293 \text{ K})$

$= 4872.004 \text{ J m}^{-3} = 4872.004 \text{ Pa}$

6. Molality, m = [mol. of solute/mass of solvent

(g)] $= [(1/250)/51.2] \times 1000 = 0.078$

$\therefore \quad \Delta T_f = k_f \times m = 5.12 \times 0.078 = 0.4$

7. Electrolytes with maximum degree of dissociation in diluted solution have maximum van't it off value. So, correct result is (*a*).

8. Relative lowering of V.P., $(p^{\circ} - p_s/p^{\circ})$

$= (w_A/m_A) \times (m_B/w_B)$; $(10/100)$

$= [x/60)/(180/18)]$

$\therefore \quad x = 60$. So, 60 g of solute should be added.

9. (*i*) Osmotic pressure, π

$= hdg = (2.6/10 \text{ cm}) \times 1 \text{g cm}^{-3} \times 980$

dynes cm^{-2} (*ii*) $\pi = \text{WRT/V}m$. Hence $(2.6 \times 1 \times$

$980/10) = 0.75 \times 8.314 \times 10^7 \times (273 + 4$

$= 277)/125 \times m$. So, $m = 5.4 \times 10^5$.

10. Such solutions are isotonic which have same molar concentration.

In 0.1 M Ba $(NO_3)_2$, $Ba(NO_3)_2 \rightleftharpoons Ba^{2+}$ (0.1 M) + 2 NO_3^- (0.2 M).

$\therefore$ Molar concentration of 0.1 M $Ba(NO_3)_2$ = 0.1 + 0.2 = 0.3 M. In 0.1 M Na_2SO_4, Na_2SO_4 (0.1 M) $\rightleftharpoons$ 2 Na^+ (0.2 M) + SO_4^{2-} (0.1 M).

$\therefore$ Molar concentration of 0.1 M Na_2SO_4 = 0.1 M + 0.2 M = 0.3 M. Since molar concentrations are same, (*d*) is correct.

11.
$$\begin{array}{cccc} \text{Na I} & \rightleftharpoons & \text{Na}^+ & + \quad \text{I}^- \\ 1 - \alpha & & \alpha & \alpha \end{array}$$

Total no. of mol $= 1 - \alpha + \alpha + \alpha$

$= 1 + \alpha$; Observed osmotic pressure,

$\pi_{\text{obs}} = \pi_{\text{Theoretical}} \times (1 + \alpha)$

$= 0.01 \text{ RT } (1 + \alpha)$; π_{glucose}

$= 0.016$ RT. So, $0.01 \text{ RT } (1 + \alpha)$

$= 0.016$ RT. Hence, α

$= 0.6$ or $0.6 \times 100 = 60$ %.

12. $\Delta T_b = K_b \times W_2/M_2 \, W_1$ in kg

$= [0.513°\text{C kg mol}^{-} \times 20 \text{ g}/78 \text{ g mol}^{-} \times 400/1000 \text{ kg}]$

$= 0.329°$C. So, b. pt. of solution

$= 99.834°\text{C} + 0.329°\text{C} = 100.163°\text{C}.$

CHAPTER – 19

19. Resistivity = 1/conductance = 1/18.5 ;

$\lambda_0 = 438 \text{ ohm}^{-} \text{ cm}^2 \text{ eq}^{-1}$

$\lambda_c = K \times 1000/C = (1/18.5 \times 1000)/15/49;$

$$\alpha = \lambda_c/\lambda_0 = \frac{1 \times 1000 \times 49}{18.5 \times 15} \times \frac{1}{438} = 0.403$$

$\therefore \quad \alpha = 0.403 \times 100 = 40.3\%.$

So, correct answer is (*d*).

20. 0.1 millifaraday $= (0.1 \times 1/1000)$ F

But 1 Faraday = 1g equivalent of Al

$$= \frac{\text{At. wt. of Al}}{\text{Valency}} = \frac{27}{3} = 9$$

$= 9 \times 1000 \text{ mg} = 9000 \text{ mg}$

$= 0.1 \times \dfrac{1}{1000} F = 9000 \times 0.1 \times 1/1000$

$= 0.9$ mg

So. the correct answer is (*d*).

21. $E_{\text{cell(2)}} = E°_{\text{Cell}} - (0.059/1) \log (0.0025/1)$

$= -\,0.059 \log 0.0025;$

$E_{\text{cell(1)}} = E°_{\text{cell}} - (0.059/1) \log (0.05/1)$

$= -\,0.059 \log 0.05;$ $(E_{\text{cell(2)}}/E_{\text{cell(1)}})$

$= [-0.59 \log 0.0025/-0.59 \log 0.05]$

$= (-\,2.6/-\,1.3) = 2$. So, $E_{\text{cell (2)}}$

$= 2 \times 70 \text{ mV} = 140 \text{ mV}.$

22. W = Z It; $Z_H = 1/96500$;

$Z_{\text{oxygen}} = 8/96500$;

$W_H = 0.504$ g, t = 2 hrs, W_{oxygen} = ?

$(W_H/W_{\text{oxygen}}) = Z_H \text{ It}/Z_{\text{oxygen}} \text{ It} = Z_H/Z_{\text{oxygen}}$;

$(0.504/W_{\text{oxygen}}) = (1/96500)/(8/96500)$

$\therefore \quad W_{\text{oxygen}} = 4.032 \simeq 4\text{g}$

23. g eq. wt. of Cu = At. wt/Valency

= 63.5/2 g i.e., 0.5 mol ;

1 mol Cu = 63.5 g; 0.5 mol Cu is deposited

from = 1Faraday.So,1molCuisdeposited

from = $(1/0.5) \times 1 = 2$ **Ans**

24. $\lambda_\infty = \lambda_c + \lambda_a = 315 + 35$

$= 350 \text{ mho cm}^2 \text{ eq}^-.$

25.
$$\begin{array}{lll} Al^{3+} + 3e^- \rightarrow Al \,; & Cu^{2+} + 2e^- \rightarrow Cu \,; & Na^+ + 1e^- \rightarrow Na \\ 3F \quad 1 \text{ mol} & 2F \quad 1 \text{ mol} & 1F \quad 1 \text{ mol} \\ 1F \quad 1/3 \text{ mol} & 1F \quad 1/2 \text{ mol} & \end{array}$$

$\therefore$ Mole ratio = 1/3 : 1/2 : 1 or 2 : 3 : 6

26. Percent ionisation, $\mu = \Lambda_c/\Lambda_\infty = (14/238) \times 100 = 5.9$

27.
$$\begin{array}{ccccc} Cu^{2+} & + & 2e^- & \rightarrow & Cu \\ 1 \text{ mol} & & 2 \text{ mol} & & 1 \text{ mol } (63.5 \text{ g}) \end{array}$$

Charge to deposit 2.0 g Cu

= (2 × 96500 × 2.5/63.5)
= 7598.4 Coulomb ;
t = (no. of coulombs/current in
ampere) = [7598.4/2.5] = 3039.36 s/60 × 60
= 0.844 hours.

28. 1 coulomb = 3×10^9 esu. So, electrostatic
charge on Na^+ ions = (96500 coulomb/6.023×10^{23})
= [96500 × 3 × 10^9 e.s.u./6.023×10^{23}] = 4.8×10^{-10} e.s.u.

CHAPTER – 20

3. ΔH = E_a (forward) – E_a (back ward) for a reversible reaction
∴ ΔH = 150 –260 = – 110 kJ mol^-

4. $2\,A(g) + B(g) \rightleftharpoons 3C(g) + D(g)$

	2 A(g)	B(g)	3C(g)	D(g)
Initial :	1 mol	1 mol	0	0
At eqm	1 – (2 × 0.25) = 0.5	1 – 0.25 = 0.75	3 × 0.25 = 0.75	0.25

∴ Eqm. constant, K= $[C]^3\,[D]/[A]^2[B]$
= $(0.75)^3\,(0.25)/(0.5)^2\,(0.75)$

5. k = (2.303/t) log $a/a - x$ and
k = $0.693/t_{1/2}$; $t_{1/2}$ = 69.3 min.
∴ k = 0.693/69.3
= 2.303/t log 100/10. So,
t = 230.3 min.

6. A + 2B → C
1 mol 2 mol 1 mol

8 mol of B need 4 mol of A, so B, is limiting reagent. 2 mol B give 1 mol of C, so 8 mol of B give 1/2 × 8 = 4 mol of C.

7. k = (2.303/t) log $a/a - x$; 4.5×10^{-3}
= (2.303/60) log $1/a - x$
∴ $a - x$ = 0.7634, So, rate after 1 hr (= 60
min) = $k\,(a - x) = 4.5 \times 10^{-3} \times 0.7634$
= 3.4354×10^{-3}

8. Rate = k (A) ; 0.08 = $k\,[A]_{15}$;
0.06 = $k[A]_{25}$; $[A]_{15}/[A]_{25}$
= 0.08/0.06 = 4/3.

For first order reaction,
t = 2.303 log $[A]_{15}/[A]_{25}$. But
t = 25 – 15 = 10 min. So,
10 = 2.303/k log 4/3. So,
k = 0.0288 min^{-}. Hence,
$t_{1/2}$ = 0.693/k = 0.693/0.0288
= 24.06 min.

9. log $k(s^-)$ = 12.14 – (1.41×10^4/T) (given).
Also, log k = log A – E_a/2.303 RT.

Comparing both equations, we have (E_a/2.303 RT)
= 1.41×10^4. So,
E_a = $1.41 \times 10^4 \times 2.303 \times 8.314 \times 10^{-3}$
= 269.97 kJ mol^-
∴ log $k\,(s^-)$ = 12.14 – (1.41×10^4/800)
= – 5.485. So, k = antilog – 5.485
= 3.27×10^{-6}.

10. $t_{1/2}$ = 0.693/0.03465 = 20; concentartion,
C = $C_0(1/2)^n$; $n = t/t_{1/2}$, so, n = 40/20
= 2; C_0 = 2M. Hence, C = 2 × $(1/2)^2$
= 1/2 M; rate of reaction in the
beginning = $k_1 \times C_0$ = 20 × 0.03465 × 2
= 1.386 M min^- ; rate after 40 min
= k_1 C = 0.03465 × 1/2 = 0.017325.

11. Arrhenius parameters are activation energy, E_a and pre-exponential factor, A.
log k_2/k_1 = $E_a/R\,[T_2 - T_1/T_1T_2]$.
E_a = [2.303 $RT_1T_2/T_2 - T_1$] log k_2/k_1
= [2.303 × 8.314 × 10^{-3} × (273 + 20
= 293) × (273 + 45 = 318)/ 318 – 293
= 25] log $1.2 \times 10^{-2}/3.0 \times 10^{-3}$
= 3 × 10^{-3} × 1/2.303 antilog 42.96/8.314 × 10^{-3} × 293
= 3 × 10^{-3} × 1/2.303 antilog 17.43
= 3 × 10^{-3} × (1/2.303) × 2.69 × 10^{17}
= 3.5 × 10^{14}

12. E_a'/T_1 = E_a/T_2 ; (20/273 + 25 = 298)
= $30/T_2$; T_2 = 447 K

CHAPTER – 21

12. ${}^{x}_{y}A \rightarrow {}^{m}_{n}B + a\,{}^{4}_{2}He + b\,{}^{0}_{-1}\beta$;
$x = m + 4a + (b \times 0); a = x - m/4;$
$y = n + 2\,a - b;$
$y = n + (2 \times x - m/4) - b\,;$
$b = n + (x - m/2)\; - y.$

13. ${}^{235}_{92}U \rightarrow {}^{142}_{54}Xe + {}^{90}_{38}Sr + x\,{}^{1}_{0}n$;
235 = 142 + 90 + x ; x = 3

14. Rate of decay of Ra
= λ × no. of nuclei of Ra in 1 g
$$= \frac{0.693}{1600 \times 365 \times 60 \times 60} \times 1.6023$$
10^{23}/226 [∵ $t_{1/2}$ = 0.693/λ] = 3.7×10^{10} dps.
= ($3.7 \times 10^{10}/10^6$) = 3.7×10^4.

15. Ac : $\frac{227}{4}$ = 56 + remainder, 3. So, it belongs to 4n + 3 series.

16. $^{39}_{19}K \rightarrow {}_{+1}^{0}\beta + {}^{39}_{18}A$;
= [At. mass of A/at. no. of A]
= 39/18 = 2.16

17. Amount left = 100 – 93.75 = 6.25 ;
N/N_0 = 6.25/100 = 1/16. So, 1/16
= $(1/2)^n = (1/2)^4$; $n = 4$;
$t_{1/2}$ = 30 min/4 = 7 min. 30 seconds.

18. Radius of $_{40}Ar$ = $(40)^{1/3} \times 1.4 \times 10^{-15}$ *m*
= 5.1×10^{-15} *m*.

19. Packing fraction = $(34.96903 - 35) \times 10^4/35 = -8.848$

20. Half-life is independent of initial concentration of radioactive subtances of first order reaction. So, half-life of 1 g = half-life of 15 g = 25 days.

21. No. of half-lives = 18 days/6 days
= 3. So, amount of radioactivity left
behind = $2 \times (1/2)^3$ = 1/4 millicurie.

CHAPTER – 22

1. $40V_1/V_2 - 17$. Where V_1 = volume of hydroxide taken for each titration and V_2 is volume of HCl used for neutralising V_1 ml of given hydroxide solution.

2. Mol. wt. of hydrated oxalic acid found experimentally {*i.e.* 6.3 × basicity of oxalic acid (2)/Normality of oxalic acid} (–) Mol. wt. of anhydrous oxalic acid *i.e.* 90/18

3. RCOOH + NaOH $\longrightarrow$ RCOONa + H_2O; find normality (N_1) of organic acid ; then Eq. wt. of org. acid = $5.25/N_1$ = *a* (say) ; basicity of org. acid = 126/*a*]

4. $MHCO_3$ + HCl $\longrightarrow$ MCl + CO_2 + H_2O ; find normality (N_1) of $MHCO_3$; Eq. wt. of
$MHCO_3$ = $10/N_1$ = *a* (say) ; Eq. wt. of
$MHCO_3$ = at. wt. of M (*i.e. m*) + 1 + 12 + (3 × 16) or *m* + 61; *a* = *m* + 61 ; ∴ *m* = *a* – 61]

8. Eq. wt. of Mg $(OH)_2$ = (Mol. wt. of Mg $(OH)_2$/no. of replacement OH^- groups) = 24 + 2(16 + 1)/1 = 58

9. Total volume = 1/2 L = 1/2 × 1000
= 500 mL; NaCl $\rightleftharpoons$ $Na^+ + Cl^-$
No. of m. mol of NaCl
= (2.0 m. mol/mL) × 200 mL
= 400 m. mol; Na^+ = 400/500
= 0.8 M.

10. KOH $\rightleftharpoons$ $K^+ + OH^-$. One OH^- gives valency factor
= 1; $H_2SO_4 \rightleftharpoons SO_4^{2-} + 2H^+$ (two H^+
give valency factor = 2). N_1 KOH
= 1 M × valency factor
= 1 × 1 = 1 ; $N_2(H_2SO_4)$
= 2 M × Valency factor
= 2 × 2 = 4 M. Thus:
$N_1 V_1$ (KOH) = N_2V_2 (H_2SO_4); 1 × 20
= 4 × V_2 ; V_2 = 5 mL

11. Molarity = Normality/valence factor; For $H_2SO_4 \rightleftharpoons SO_4^{2-} + 2H^+$ (Valency factor = 2); Molarity = 1.5/2 = 0.75 M

12. Wt. of NaOH = 40 g, wt. of solution
= 100 g; vol of solution
= 100/density, *d*.
Molarity = (40 × 1000 d/40 × 100) = 5.1 ;
d = 0.51 g $(mL)^-$

13. Molarity of H_2O = (wt. of H_2O × 1000)/(mol. wt. of
H_2O × Vol in mL) = [100 g × 1000/18 g mol^- × 1000]
= 55.6.

CHAPTER – 23

1. $Kp = Kc\,(RT)^{\Delta n(g)}$. *Kp* will be equal to
Kc; if Δn(g) = 0.
In reaction (*a*), Δn(g)
= no. of mol of products – no. of
mol of reactants = 2 – 2 = zero. $Kp = Kc\,(RT)^{\circ}$;
Kp = *Kc*. So, correct answer is (*a*).

2. $Kp = Kc\,(RT)^{\Delta n(g)}$; $\Delta n(g) = n_p - n_r$
= (2 + 1) – 2 = 1; 1.8×10^{-2}
= *Kc* (0.0821 L atm K^- mol^- × 500).
So, *Kc* = $1.8 \times 10^{-2}/0.0821 \times 500$
= 4.38×10^{-4}

3. $Kp = Kc\,(RT)^{\Delta n(g)}$;
$\Delta n(g) = n_p - n_r$ = (1 + 0) – 0 = 1;
$Kp = Kc\,(RT)^{\Delta n(g)}$
∴ *Kp* = $1.87\,(0.0821 \times 1073)^1$ = 164.73

4. Molar mass of
CH_3COOH = 12 + (3 × 1) + 12 + 2 (16) + 1
= 60 g mol^-, wt. of CH_3COOH
= 30 g. No. of mol of CH_3COOH
= 30/60 = 0.5. Hence, active mass
= no. of mol / vol in litre
= 0.5 mol/1 L = 0.5 mol L^-.

5. Calculate the percentage dissociation of H_2S (g) if 0.1 mol of H_2S is kept in 0.4 litre vessel at 100 K. For the reaction $2H_2S\,(g) \rightleftharpoons 2H_2(g) + S_2\,(g)$ the value of K_p is 1.0×10^{-6} **(Roorkee, 1994)**

Ans. Vol = 0.4 L.

	$2H_2S$ (g) ⇌	$2H_2$ (g) +	S_2 (g)
(*i*) n mol at start	0.1	0	0
(*ii*) Change by reaction	$-0.1x$	$0.1x$	$\frac{0.1x}{2}$
(*iii*) *n* mol L^- at equilibrium	$\frac{0.1-0.1x}{0.4}$	$\frac{0.1x}{0.4}$	$\frac{0.1x}{2\times 0.4}$
	$= \frac{0.1\,(1-x)}{0.4}$	$= \frac{x}{4}$	$= \frac{x}{8}$
	$= \frac{1-x}{4}$		

$$\therefore \quad K_c = \frac{[H_2]^2[S_2]}{[H_2S]^2} = \frac{\left(\frac{x}{4}\right)^2 \times \frac{x}{8}}{\left(\frac{1-x}{4}\right)^2} = \frac{\frac{x^2}{16} \times \frac{x}{8}}{\left(\frac{1}{4}\right)^2}$$

[∵ if x is very small, $1 - x \simeq 1$]

$$\therefore \quad K_c = \frac{x^3}{16 \times 8} \times \frac{4 \times 4}{1}$$

$$= \frac{x^3}{8};\ 1.0 \times 10^{-6} = \frac{x^3}{8};$$

$$x^3 = 8 \times 10^{-6}$$

Or $\quad x = (8 \times 10^{-6})^{1/3} = 2 \times 10^{-2}$

∴ % age dissociation

$= 2 \times 10^{-2} \times 100 =$ **2 %** **Ans.**

7. *15 g mol of H_2 reacts with 5.2 g mol of I_2 to give 10 g mol of HI. Calculate the equilibrium constant of the reaction $H_2 + I_2 \rightleftharpoons 2HI$.* **(UP, 1980)**

Ans. Reaction :	H_2	+	I_2	$\rightleftharpoons$	2 HI
(*i*) *n* mol at start	15		5.2		10
(*ii*) Change by reaction	$-x$		$-x$		$2x$
(*iii*) *n* mol at equilibrium	$15 - x$		$5.2 - x$		$2x$

$2x = 10.$ So, $x = 10/2 = 5$

$\therefore \quad [H_2] = 15 - x = 15 - 5 = 10;$

$[I_2] = 5.2 - x = 5.2 - 5.0 = 0.2,\ [HI] = 10$

Applying law of chemical equilibrium, we get :

$$K = \frac{[HI]^2}{[H_2][I_2]} = \frac{10 \times 10}{10 \times 0.2} = 50$$

$\therefore \quad$ **$K = 50$** **Ans.**

9. If the weight of KI and KI_3 at equilibrium in the reaction $KI + I_2 \rightleftharpoons KI_3$ are 1.326g and 0.105g respectively, then calculate the value of K_C. The number of mol of free I_2 at equilibrium is 0.0025 and the volume of solution is 10^3 cm³. (At. wt. K = 39, I = 127).

Hint and Ans.

$$\begin{array}{lccc} & KI\,(aq) & + \ I_2(s) \rightleftharpoons & KI_3(aq) \\ \text{no. of mol at } t = 0 & \frac{1.326}{166} & & 0 \\ \text{no. of mol at equilibrium} & \frac{1.326}{166} - \frac{0.105}{420} & 0.0025 & \frac{0.105}{420} \\ & = 7.738 \times 10^{-3} & 0.0025 & 2.5 \times 10^{-4} \end{array}$$

$$\therefore \quad K_c = \frac{[KI_3]}{[KI][I_2(s)]} = \frac{2.5 \times 10^{-4}}{7.738 \times 10^{-3}}$$

$=$ **0.0323** **Ans.**

Since KI has fully reacted with I_2 and free I_2 will be in the solid state, so $[I_2]$ is taken as constant.

10. Consider the equilibrium reaction $X + Y \rightleftharpoons P + Q$. X and Y are mixed in a vessel at temperature, T. The concentration of X at $t = 0$ is twice the concentration of Y. After the equilibrium has been reached, the concentration of P was three times the equilibrium concentration of Y. Find the value of K_c.

Hint and Ans.

	X	+	Y	$\rightleftharpoons$	P	+	Q
no. of mol at $t = 0$	$2a$		a		0		0
no. of mol at equilibrium	$(2a - x)$		$a - x$		x		x

But $\quad [X] = 2\,[Y] = 2a$

$$\text{Hence} \quad K_c = \frac{x \times x}{(2a - x)(a - x)} \qquad \text{... (1)}$$

At equilibrium, $\quad [P] = 3\,[Y]$

$$x = 3\,(a - x)\,;\ x = \frac{3a}{4} \qquad \text{...(2)}$$

Putting $\quad x = \dfrac{3a}{4}$ in equation (1),

$K_c = 1.8$ **Ans.**

11. When an equation for a reaction is multiplied by a factor '*n*' , then the new equilibrium constant (k') becomes $k''$and also if the reaction is reversed, the value of equilibrium constant gets inverted. Thus:

$k_2 = 1/k_1^2$. So, (*a*) is correct.

12.

A	+	2B	→	C
1 mol		2 mol		1 mol
5 mol		5 × 2 = 10 mol		5 mol

Since 8 mol of B are given instead of 10 mol, so, B acts as a limiting reagent. Since;

2 mol of B give mol of $C = 1$

∴ 8 mol of B give mol of

$C = 1/2 \times 8 = 4$ mol.

So, the correct answer is (*d*).

CHAPTER – 24

16. Molarity, M $= [0.023 \times 1000/(23 \times 100)]$

$= 0.01$ M; $NaOH \rightleftharpoons Na^+ + OH^-$.

So, $[OH^-] = 0.01 = 10^{-2}$ M;

$p_{OH} = -\log 10^{-2} = -(-2)\log 10$

$= 2.\ p_H + p_{OH} = 14;\ p_H = 14 - 2 = 12.$

17. $p_H = pKa + \log\,[\text{salt}]/[\text{Acid}]$. So, [salt]

$= [0.1 + 0.1/1000 \text{ mL}] = \dfrac{0.2}{1\text{L}} = 0.2$

mol L^-. [Acid] $= 0.1/1000 \text{ mL} = 0.1/1\text{L} = 0.1 \text{ mL}^-$.

Hence, $p_H = pKa + \log 0.2/0.1 = pKa + \log 2.$

18. Ionic product of AgCl

$= 10^{-4} \times 10^{-5} = 10^{-9}$; ionic product

of $Ag_2CrO_4 = 10^{-8} \times 10^{-5} = 10^{-13}$; Ionic product of AgCl > *Ksp*, so AgCl will precipitate. Ionic product of Ag_2CrO_4 < *Ksp* of Ag_2CrO_4. So, it will not precititate.

19. $p_H = -\log\,[H^+]$ (*a*) $p_H = -\log\,(0.1)$

$= 1$ (*b*) $p_H = -\log\,(2 \times 0.05)$

= 1 (*c*) p_H of CH_3COOH is not equal to one because it is a weak acid and does not ionise completely (*d*) Milliequivalent of acid
= 50 × 0.4 = 20; milliequivalent of
NaOH = 50 × 0.2 = 10. So, acid left behind
= 20 – 10 = 10 milliequivalent.

20. $Ksp\ [Mg(OH)_2] = [Mg^{2+}]\ [OH^-]^2;\ 10^{-11}$
$= (0.001)\ [OH^-]^2;\ [OH^-]^2$
$= (10^{-8})^{1/2};\ [OH^-] = 10^{-4}$
$\therefore\quad p_{OH} = -(-4) \log 10 = 4;\ p_H + p_{OH}$
$= 14 \therefore p_H = 14 - 4 = 10.$

21. $Mg(OH)_2 \rightleftharpoons Mg^{2+} + 2OH^-.$
Let s = solubility of $Mg(OH)_2$ in mol L^-
$k_{sp} = [Mg^{2+}]\ [OH^-]^2 = s \times (2s)^2 = 4s^3;\ s$
$= (K_{sp}/4)^{1/3} = (4 \times 10^{-12}/4)^{1/3}$
$= 10^{-4}$ mol L^-.

22. $p_{OH} = -\log [OH^-] = (-) \log 10^{-3}$
$= -(-3) \log 10 = 3;\ p_H = 14 - p_{OH}$
$= 14 - 3 = 11$

23. $\because [H^+] = C\alpha = 0.1 \times 0.02$
$= 2 \times 10^{-3}$ M
($\because$ degree of dissociation = 2 % = 2/100 = 0.02)
Hence, $[OH^-] = 10^{-14}/2 \times 10^{-3} = 5 \times 10^{-12}$ M

24. $p_H + p_{OH} = 14;\ 12 + p_{OH} = 14;\ p_{OH} = 14 - 12$
$= 2;\ [OH^-] = 10^{-2}$
$Ba(OH)_2 \rightleftharpoons Ba^{2+} + 2OH^-;$
$\qquad\qquad s \qquad 2s$
$2s = [OH^-] = 10^{-2};\ s = 10^{-2}/2 = 5 \times 10^{-3}$
$Ksp = [Ba^{2+}]\ [OH^-]^2$
$= (5 \times 10^{-3}\ M) \times (10^{-2}\ M)^2$
$= 5 \times 10^{-7}\ M^3.$

25. $p_{OH} = pK_b + \log [B^-]/[HB]$. Since $[B^-]$
= [HB] (given), the $p_{OH} = pK_b$ or p_{OH}
$= -\log 10^{-10} = -(-10) \log 10$
$= 10;\ p_H = 14 - p_{OH} = 14 - 10 = 4.$

CHAPTER – 25

1. An organic compound contains carbon, hydrogen and oxygen. In a Liebig's method, 0.2475g of it was analysed. The increase in the weight of U-tube and the potash bulb at the end of operation was found to be 0.2025g and 0.4950g respectively. Calculate the percentage composition of the compound.

wt. of compound = 0.2475g; wt. of CO_2
= increase in the wt. of potash
bulb = 0.4950g; wt. of H_2O
= increase in the wt. of U-tube
(containing $CaCl_2$) = 0.2025g.

(*i*) *To find % age of carbon.* $\underset{12+(2\times16)=44g}{CO_2} \equiv \underset{12g}{C}$

44g CO_2 contain carbon = 12g

0.495g CO_2 contain carbon $= \dfrac{12}{44} \times 0.495g$

$$\%\text{ age of C} = \frac{\text{wt. of C}}{\text{wt. of substance}} \times 100$$
$$= \frac{12 \times 0.495}{44} \times \frac{100}{0.2475}$$
= 54.54% **Ans.**

(*ii*) *To find percentage of hydrogen.* $\underset{(2\times1)+16=18g}{H_2O} \equiv \underset{2\times1=2g}{2H}$

18g H_2O contain hydrogen
= 2g

0.2025 g H_2O contain hydrogen $= \dfrac{2}{18} \times 0.2025g$

$$\therefore\ \%\text{ age of hydrogen} = \frac{\text{wt. of hydrogen}}{\text{wt. of substance}} \times 100$$
$$= \frac{2 \times 0.2025}{18} \times \frac{100}{0.2475} - 9.09\%$$ **Ans.**

$\therefore$ % age of oxygen = 100−(54.54+9.09)=36.37% **Ans.**

2. 0.2 g of an organic compound on combustion with CuO, gave 30.1 cm^3 of moist nitrogen at 15°C and 730.7 mm pressure. Calculate the percentage of nitrogen in the compound. (Aqueous tension at 15°C = 12.7 mm).
Wt. of organic compound = 0.2 g.
P_1 = 730.7 – 12.7 = 718 mm,
V_1 = 30.1 cm^3, T_1 = 15 + 273
= 288 K; at NTP, P_2 = 760 mm,
V_2 = ?, T_2 = 273 K.

We know, $\dfrac{P_1V_1}{T_1} = \dfrac{P_2V_2}{T_2}$ (Gas equation)

$$\therefore\quad V_2 = \frac{P_1V_1T_2}{T_1 \times P_2}$$
$$= \frac{718\,\text{mm} \times 30.1\,\text{cm}^3 \times 273\text{K}}{288\,\text{K} \times 760\,\text{mm}}$$
= 29.96 mL But, 22400 mL of
N_2 weighs = g. mol. wt. of
N_2 = 28g

26.96 mL of N_2 weighs $= \dfrac{28}{22400} \times 26.96$ g

$$\therefore\quad \%\text{ age of } N_2 = \frac{28 \times 26.96}{22400} \times \frac{100}{0.2} = \mathbf{16.85\%}$$ **Ans.**

3. An organic compound having molecular formula C_4H_9N was analysed by Duma's method for the estimation of nitrogen in this compound. Calculate the volume of nitrogen liberated at N.T.P. from 2.1 g of the substance (at. wt., C = 12, H = 1, N = 14).
Mol. wt. of C_4H_9N = (4 × 12) + (9 × 1) + 14 = 71
Reaction :

$$\underset{1\,\text{mol}=71\,\text{g}}{C_4H_9N} \xrightarrow[\Delta]{CuO} 4CO_2 + \frac{9}{2}H_2O + \underset{\frac{1}{2}\text{mol}=\frac{1}{2}\times 22400=11200\,\text{mL at NTP}}{\frac{1}{2}N_2}$$

71g of C_4H_9N produce N_2 at NTP= 11200 mL

$\therefore$ 2.1g of C_4H_9N would produce N_2 at NTP

$$= \frac{11200}{71} \times 2.1 = \mathbf{331.3\ mL}$$

Volume of N_2 at N.T.P. = **331.3 mL Ans.**

4. 0.45g of an organic compound on Kjeldahl's analysis gave enough ammonia to just neutralise 20mL of 0.1 M H_2SO_4. Calculate the percentage of nitrogen in the compound.

Wt. of organic compound = 0.45 g.

Volume of 0.1 M H_2SO_4 required to neutralise

NH_3 = 20 mL.

$$\underset{\substack{2\,\text{mol}\\2\,\text{vol}}}{2NH_3} + \underset{\substack{1\,\text{mol}\\1\,\text{vol}}}{H_2SO_4} \rightarrow (NH_4)_2SO_4$$

20 mL of 0.1 M H_2SO_4

$= 2 \times 20$ mL of 0.1 M NH_3

$= 40$ mL of 0.1 MNH_3

$$= \frac{40 \times 0.1\text{M}}{1\text{M}} = 4\,\text{mL of } 1\text{M}\,NH_3$$

But 1000 mL of 1 M NH_3 = 14 g N

$$\therefore 4\text{ mL of 1 M } NH_3 = \frac{14}{1000} \times 4\,\text{gN}$$

$$\therefore \%\text{ age of nitrogen} = \frac{14 \times 4}{1000} \times \frac{100}{0.45} = \mathbf{12.4\%} \qquad \textbf{Ans.}$$

or 1000 mL of 1 M

NH_3 = 14 g N

$$40\text{ mL of 0.1 M } NH_3 = \frac{14}{1000} \times 40 \times 0.1 = 0.056\,\text{g of N.}$$

$$\therefore \%\text{age of nitrogen} = \frac{0.056}{0.45} \times 100 = \mathbf{12.4\%} \qquad \textbf{Ans.}$$

5. An organic compound weighing 0.354g on analysis by Kjeldahl's method gave ammonia which was absorbed in 70mL of M/10 H_2SO_4. The excess of the acid required 40 mL of M/5 NaOH for complete neutralisation. Calculate the per*centage of nitrogen in the compound.*

Volume of H_2SO_4 of molarity M/10 taken = 70 mL.

$$\frac{(M_1V_1)\text{ Residual } H_2SO_4}{(M_2V_2)\text{NaOH}} = \frac{1}{2}$$

$$\left(\because\ \underset{2\,\text{mol}}{2NaOH} + \underset{1\,\text{mol}}{H_2SO_4} \rightarrow Na_2SO_4 + 2H_2O\right)$$

$$\frac{\frac{1}{10} \times V_1}{40 \times \frac{1}{5}} = \frac{1}{2};$$

$$V_1 = 40 \times \frac{1}{5} \times \frac{10}{2} = 40\,\text{mL}$$

$\therefore$ Volume of M/10 acid left unused = 40 mL

Volume of M/10 H_2SO_4 used = 70 – 40 = 30 mL

$\therefore$ 30 mL of $\frac{M}{10}$ $H_2SO_4 \equiv 2 \times 30$ mL of $\frac{M}{10}$

NH_3 = 60 mL of $\frac{M}{10}$ NH_3

$(\because 2\,NH_3 + H_2SO_4 \rightarrow (NH_4)_2\,SO_4)$

But, 1000 mL of 1 M NH_3 contain nitrogen = 14 g

60 mL of $\frac{M}{10}$ H_2SO_4 contain nitrogen

$$= \frac{14}{1000} \times 60 \times \frac{1}{10}\,\text{g}$$

$$\therefore \%\text{ age of nitrogen} = \frac{14 \times 60}{1000} \times \frac{1}{10} \times \frac{100}{0.354}$$

$= \mathbf{23.73\%}$ **Ans.**

6. An organic compound weighing 0.4g was Kjeldahlised and ammonia gas produced was absorbed in 50 mL of M/4 H_2SO_4. The residual acid solution was diluted with distilled water and the volume was made up to 150 mL. The 20mL of this diluted solution required 31mL of 0.05M NaOH for complete neutralisation. Calculate the percentage of nitrogen in the compound.

Wt. of compound = 0.4g.

Volume of $\frac{M}{4}$ H_2SO_4 required to absorb ammonia = 50 mL

(*i*) $\underset{2\,\text{mol}}{2NaOH} + \underset{1\,\text{mol}}{H_2SO_4} \rightarrow Na_2SO_4 + 2H_2O$

$$\frac{M_1V_1\text{ (diluted acid)}}{M_2V_2\text{ (NaOH)}} = \frac{1\,\text{mol}}{2\,\text{mol}};\quad M_1 \times 20 = \frac{0.05 \times 31}{2};$$

$$M_1\text{ (dil. acid)} = \frac{0.05 \times 31}{2 \times 20}$$

(*ii*) To find volume of $\frac{M}{4}$ original H_2SO_4 left used

M_3V_3 (dil. acid) = M_4V_4 (original acid)

$$\frac{0.05 \times 31}{2 \times 20} \times 150 = \frac{1}{4} \times V_4;$$

$$V_4 = \frac{0.05 \times 31 \times 150 \times 4}{2 \times 20} = 23.25\,\text{mL}$$

$\therefore$ Volume of $\frac{M}{4}$ H_2SO_4 used = 50 – 23.25 = 26.75 mL

Now, 26.75 mL of $\frac{M}{4}$ H_2SO_4 = 2 × 26.75 mL of $\frac{M}{4}$ NH_3

$$\left(\because\ \underset{2\,\text{mol}}{2NH_3} + \underset{1\,\text{mol}}{H_2SO_4} \rightarrow (NH_4)_2SO_4\right)$$

But, 1000 mL of 1M NH_3 contain nitrogen = g. at. wt. of N = 14 g

$\therefore$ 2 × 26.75 mL of $\frac{1}{4}$ M NH_3 contain nitrogen

$$= \frac{14}{1000} \times 2 \times 26.75 \times \frac{1}{4}\,\text{g}$$

$$\therefore \%\text{ age of nitrogen} = \frac{14 \times 2 \times 26.75}{1000 \times 4} \times \frac{100}{0.4}$$

= 46.81% **Ans.**

7. In a carius method, 0.24 g of an organic substance was heated with fuming nitric acid and solid $AgNO_3$. As a result, 0.31 g of dry silver chloride was obtained. Calculate the percentage of Cl in the given substance. (at. wt., Ag = 108, Cl = 35.5).

Wt. of organic substance = 0.24 g.

Wt. of AgCl ppt = 0.31 g. We know, $\underset{108+35.5=143.5\,g}{AgCl} \equiv \underset{35.5\,g}{Cl}$

143.5 g AgCl contain

$$Cl = 35.5\ g$$

$$0.31\ g\ AgCl\ contain\ Cl = \frac{35.5}{143.5}\times 0.31\,g$$

$$\%\ age\ of\ Cl = \frac{\text{wt. of Cl}}{\text{wt. of substance}}\times 100$$

$$= \frac{35.5\times 0.31}{143.5}\times\frac{100}{0.24}$$

$$= \mathbf{31.95\%} \qquad \textbf{Ans.}$$

8. In a carius method, 0.31 g of an organic compound yielded 0.296 g of silver bromide. Calculate the percentage of bromine in the organic compound. (At. wt. Ag = 108, Br = 80).

Wt. of organic substance = 0.31 g.

Wt. of AgBr ppt = 0.296 g

We know : $\underset{108+80=188\,g}{AgBr} \equiv \underset{80\,g}{Br}$

188 g AgBr contain Br = 80 g;

$$0.296\ g\ AgBr\ contain\ Br = \frac{80}{188}\times 0.296\,g$$

$$\%\ age\ of\ Br = \frac{\text{wt. of Br}}{\text{wt. of substance}}\times 100$$

$$= \frac{80\times 0.296}{188}\times\frac{100}{0.31} = \mathbf{40.63\%}\ \ \textbf{Ans.}$$

9. An organic compound weighing 0.197 g was heated with fuming nitric acid and solid $AgNO_3$ in a carius tube. As a result, 0.3525 g of dry silver iodide was obtained. Calculate the percentage of iodine in the given compound. (At. wt. Ag = 108, I = 127).

Wt. of organic compound = 0.197 g;

Wt. of Ag I ppt = 0.3525 g

We know : $\underset{108+127=235\,g}{Ag\,I} \equiv \underset{127\,g}{I}$

235 g Ag I contain I = 127 g

$$0.3525\ g\ Ag\ I\ contain\ I = \frac{127}{235}\times 0.3525\,g$$

$$\therefore\quad \%\ age\ of\ I = \frac{\text{wt. of I}}{\text{wt. of substance}}\times 100$$

$$= \frac{127\times 0.3525}{235\times 0.197}\times 100 = \mathbf{96.7\%\,Ans.}$$

CHAPTER – 26

1. (*i*) MF. = n × E.F; C_6H_6 = 6 × CH. So, E.F = CH (*ii*) N_2O_4 has E.F. = NO_2 (*iii*) and

(*iv*) E.F. and M.F. are same as their atoms do not have comman factor for division.

2. Mol. wt. of

Na_2CO_3 = (2 × 23) + 12 + (3 + 16)

= 106 g mol^{-}. % age of Na

= (2 × 23/106) × 100 = 43.39 %.

3.

Element	*% age*	*At. mass*	*Relative no. of atoms*	*Simple ratio*	*whole no. ratio*
C	75	12	75/12 = 6.25	6.25/6.25 = 1	1
H	25	1	25/1 = 25	25/6.25 = 4	4

So, E.F. is CH_4.

4. $M_2O_x \xrightarrow{\text{Reduction}} M$; eq. wt. of

M_2O_x = eq. wt. of metal; wt. of M_2O_x/Eq.

wt. of M_2O_x = wt. of metal/Eq. wt. of metal;

$4/(2 \times 56 + x \times 16/2x) = 2.8/(5.6/x)$

On solving, we get x = 3. So, oxide is M_2O_3.

5. %age of Fe = (0.2014/1.0) × 100

= 20.14. Similarly,

S = 11.53%, O = 23.1%, H_2O = 45.32%

Element	*% age*	*At. mass*	*Relative no. of atoms*	*Simple ratio*	*whole no. ratio*
Fe	20.14	56	20.14/56 = 0.3596	0.3596/0.3596 = 1	1
S	11.53	32	1253/32 = 0.3603	0.3603/0.3596 ≃ 1	1
O	23.1	16	23.1/16 = 1.4438	1.4438/0.3596 = 4	4
H_2O	45.32	18	45.32/18 = 2.518	2.518/0.3596 = 7	7

∴ E.F. = $FeSO_4 \cdot 7H_2O$.

6. wt. of H_2O = 2.875 g – 1.615 g

= 1.260 g. %age of H_2O

= (1.260 × 100)/1.165 = 78%

Use method of question 5 and get $ZnSO_4 \cdot 7H_2O$.

7. %age of Pt = 100 – 42.1 = 57.9%.

Now find M.F. as Pt Cl_4.

9. %age of Cu = (1.89/4) × 100

= 47.25%; %age of Cl

= 2.11 × 100/4 = 52.75%.

Try yourself.

CHAPTER – 28

1. H_2S + H_2O_2 $\longrightarrow$ $2H_2O + S$

$(2 \times 1 + 32)$ $(2 \times 1) + (2 \times 16)$

$= 34$ g $= 34$ g

34 g H_2S react with $H_2O_2 = 34$ g

3.4 g H_2S react with $H_2O_2 = (34/34 \times 3.4 = 3.4$ g)

Volume strength 22.4 means : $22.4 \times 3.035 = 67.98$ gL⁻

67.98 g are present in volume = 1000 mL

3.4 g are present in volume $= 1000 \times 3.4/67.98$

$= 50.00$ mL

2. Volume strength = 5.6 × normality. Thus, 30 = 5.6 × normality

So, normality = 30/5.6 = 5.36. So, the correct answer is (*c*).

3. $CaCl_2$ ≡ $CaCO_3$

$40 + (2 + 35.5)$ $40 + 12 + (3 \times 16)$

$= 111$g $= 100$g

111 ppm $CaCl_2$ = 100 pm $CaCO_3$

30 ppm $CaCl_2$ = 100 × 30/111 = 27.03 ppm

4. Volume strength = 5.6 × normality.

So, 10 = 5.6 × Normality

∴ Normality = 10/56. But Molarity

= Normality × Eq. wt./Mol. wt.

So, Molarity = (10/5.6) × 17/34 = 3.57.

5. 30 mL O_2 is produced from 30 volume

H_2O_2 = 1 mL; 100 mL O_2 is produced from

30 volume H_2O_2 = 1 ×100/30 = 3.33 mL

6. $2\,H_2O_2$ $\rightarrow$ $2H_2 + O_2$

$2[(2 \times 1) + (2 \times 16)]$ 22.4L at NTP

$= 68$ g

68 g H_2O_2 produce

O_2 = 22.4 L; 60.7 g H_2O_2 produce

O_2 = 22.4 × 60.7/68

= 20 L; 1 L O_2 is produced from

H_2O_2 = 1 volume; 20 L O_2 is produced

from H_2O_2 = 20 volume

7. Ca $(HCO_3)_2$ ≡ $CaCO_3$

$40 + 2\,(1 + 12 + 48)$ $40 + 12 + 48$

$= 162$ g $= 100$ g

162 ppm 100 ppm

162 ppm Ca $(HCO_3)_2$ ≡ 100 ppm $CaCO_3$

15 ppm Ca $(HCO_3)_2$ ≡ 100 × 15/162 = 9.26 ppm.

Note. Temporary hardness is only due to $Ca(HCO_3)_2$

8. $MgSO_4$ ≡ $CaCO_3$

$24 + 32 + 64$ $40 + 12 + 48 = 100$ g

$= 120$ g

120 ppm 100 pm

120 ppm $MgSO_4$ ≡ 100 ppm $CaCO_3$

10 ppm $MgSO_4$ ≡ 100 × 10/120 = 8.33 ppm

9. Volume strength = 5.6 × normality = 5.6 × 0.16 = 0.896

10. $$\text{Volume strength} = 5.6 \times \frac{\text{Molarity} \times \text{Mol. wt.}}{\text{Eq. wt. of } H_2O_2}$$

$= 5.6 \times 0.2 \times 34/17 = 2.24$

CHAPTER – 29

1. Polydispersity index = $\overline{M_w}/\overline{M_n}$ = 30,000/20,000 = 1.5

2. 2 mL of 5% NaCl means that 1 mL of 10% NaCl solution. Thus, the milligram of compound which prevents co-agulation = 0.04 g × 1000 mg/1 g = 40 mg.

3. In $Ni(CO)_4$, Ni is in zero oxidation state. $_{28}Ni^0 = (Ar)^{18}$ $3d^{2+2+2+1+1}\,4s^2$. In $Ni(CO)_4$, we have $(Ar)^{18}\,3d^{2+2+2+2+2}\,4s^0\,4p^0$. So, Ni is sp^3 hybridised.

4. $\overline{M_n}$ = 25 × 20,000 + 30 × 30,000 + 45 × 40,000/(25 + 30 + 45) = 32,000.

5. $w_1 = 1$ kg $= 1000$ g; $n_1 = 1000/20{,}000$

$= 0.05$; $w_2 = 500$ g; n_2

$= 500/25000 = 0.02$

$\overline{M_w} = 0.05 \times (20{,}000)^2 + 0.02 \times (25{,}000)^2/(0.05 \times 20{,}000) + (0.02 \times 25{,}000) = 21667$

6. $_{26}Fe = (Ar)^{18}\,3d^6\,4s^2$;

$Fe^{2+} = (Ar)^{18}\,3d^{2+1+1+1+1}\,4s^0$

= 4 unpaired electrons

$= n$; $\mu_{B.M.} = (n\,(n + 2))^{1/2}$

$= [4\,(4 + 2)]^{1/2} = 4.89$ B.M.

7. $\sqrt{35} = \sqrt{n\,(n + 2)}$. So, $n\,(n + 2) = 35$; $n^2 + 2n - 35 = 0$. After factorising, we get $n = 5$.

8. $$[Cr\,(H_2O)_5\,Cl]\,Cl_2 \xrightarrow[AgNO_3]{\text{Excess}} [Cr\,(H_2O)_5\,Cl]^{2+} + 2\,NO_3^- + 2AgCl$$

2 mol Cl^- 2 mol Cl

∴ Milliequivalent of Cl^- in complex = milliequivalent of Cl^- in AgCl

But no. of mol of Cl^- ions in 200 mL of 0.05 M complex = 2 × 200 × 0.05/1000 = 0.02; mass of AgCl (mol. wt. = 108 + 35.5 = 143.5) = 0.02 × 143.5 = 0.287 g

9. See reaction of question no. 8 above. The number of ionisable Cl^- ions = 2. Thus, no. of millimoles = 2 × molarity × volume (in mL) = 2 × 0.01 × 40 = 0.8. But : millimoles = molarity × volume (in mL) ; 0.8 = 0.2 × volume ; volume = 0.8/0.2 = 4 mL

10. Maximum no. of tripetides = $(x)^3 = x^3$.

CHAPTER – 30

1. $K = C_{\text{solute – alcohol}}/C_{\text{solute – water}}$;
I . 0.048/0.174 = 0.276 ; II. 0.3/1.08
= 0.277 III. 0.5/1.8
= 0.277. Since value of K is constant, the data obeys distribution law.

2. $K = C_{\text{solute – water}}/C_{\text{solute – alcohol}}$;
I = 0.174/0.048 = 3.6;
II. 1.08/0.3 = 3.6 ;
III. 1.8/0.5 = 3.6. Value of K is constant = 3.6.

3. C_1 = Csuccinic acid-ether
= 0.15/60 g cm^{-3} = 0.0208 g cm^{-3};
$C_1/C_2 = 2.5 \times 10^{-3}/0.0208 = 0.1202 = K$.

4. C_1 = Csuccenic acid-water/Csuccinic acid-ether = 2.5/120 = 0.0208 g cm^{-3};
C_2 = Csuccinic acid-ether = 0.15/60
= 2.5×10^{-3} g cm^{-3} ;
$C_1/C_2 = 0.0208/2.5 \times 10^{-3} = 8.32$

5. Conc. of compound in 80 mL
H_2O = $1/5 \times 80/1000$
= 0.016. Let compound extracted
in 20 mL ether = a mol. So, conc. of compound in
20 mL ether = $a/20$. At equilibrium, conc. of compound in 80 mL water
= $0.016 - a/80$. Hence,
$K = (a/20)/0.016 - a/80$. Hence,
$a = 0.013$ **Ans.**

6. $K = 6/1 = 6$. Let degree of dissociation
= α; compound present in 30 mL
of S = $(0.4/18) \times 30 = 0.67$ g; Total
compound mixed = 9 g. Compound present in 40 mL
H_2O = 9 – 0.67 = 8.33 g
Conc. of compound in water = $8.33\,(1 - \alpha)/M \times 40$
= C_1 ; conc. of compound in
solvent, $S = 0.67/M \times 30 = C_2$; $C_1/C_2 = K = 6$.
$\therefore$ $6 = [8.33\,(1 - \alpha)/40\,M]/0.67/30M$.
So, α = 0.3565 or 0.3565 × 100 = 35.65%.

7. $C_1(H_2O)/C_2\,(C_6H_6) = K$. I. $5.02/(0.146)^{1/2}$
= 13.1; II. $7.98/(0.362)^{1/2} = 12.9$
III. $10.90/(0.705)^{1/2} = 13.0$. Value of K being constant, benzoic acid exists as a dimer.

Appendix (ii)

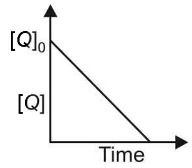
Appendix (viii)

Solutions to Numericals set in JEE-Advanced, 2013

1. *In the reaction, $P + Q \rightarrow R + S$, the time taken for 75% reaction of P is twice the time taken for 50% reaction of P. The concentration of Q varies with reaction time as shown in the figure. The overall order of the reaction is :*



(a) 2 (b) 3 (c) 0 (d) 1

Sol. Let $t_{50\%} = x$ for P. So, $t_{75\%} = 2x$. Thus, the order with respect to $P = 1$. From the given graph, it is clear that the concentration Q decreases linearly with time. Hence, order with respect to Q is zero. The rate law expression will be :

$$r = k\,[P]^1\,[Q]^0$$

$\therefore$ Order of reaction = 1 + 0 = 1. So, the correct answer is (*d*)

2. *Consider the following complex ions, P, Q and R. P is $[FeF_6]^{-3}$, Q is $[V(H_2O)_6]^{2+}$ and $R = [Fe(H_2O)_6]^{2+}$. The correct order of the complex ions according to their spin-only magnetic moment values (in B.M) is:*

(a) $R < Q < P$ (b) $Q < R < P$ (c) $R < P < Q$ (d) $Q < P < R$

Sol. $P = [Fe\,F_6]^{3-}$. Here, oxidation state of Fe is + 3

$[\because$ Fe + 6 F$^-$ = – 3 ; Fe = – 3 + 6 = + 3$]$

$\therefore {}_{26}Fe^{3+} = (Ar)^{18}\ \boxed{\uparrow}\boxed{\uparrow}\boxed{\uparrow}\boxed{\uparrow}\boxed{\uparrow}\ 3d^5$

($\because$ Fe^{3+} has e^-s = 26 – 3 = 23)

Here no. of unpaired electrons = 5

Magnetic moment, $\mu = [n(n + 2)]^{1/2}$ B.M.

$= [5(5 + 2)]^{1/2} = (35)^{1/2} = 5.92$ B.M.

$Q = [V(H_2O)_6]^{2+}$; Oxidation state of $V = +2$

$[\because V + 6H_2O = +2 ; V + 6(0) = +2$; So, $V = +2]$; ${}_{23}V^{2+}$ has e^-s= 23 – 2 = 21.

$\therefore {}_{23}V^{2+} = (Ar)^{18}\ \boxed{\uparrow}\boxed{\uparrow}\boxed{\uparrow}\boxed{\ }\boxed{\ }$ 3*d*

$\therefore$ No. of unpaired electrons = 3

Magnetic moment = $[3(3 + 2)]^{1/2} = [15]^{1/2} = 3.87$ B.M.

$R = [Fe(H_2O)_6]^{2+}$; Oxidation state of Fe = +2

$[\because$ Fe + 6H$_2$O = + 2 ; Fe + (6 × 0) = + 2 ; Fe = + 2$]$; ${}_{26}Fe^{2+}$ has e^-s = 26 – 2 = 24

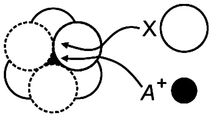
$\therefore {}_{26}Fe^{2+} = (Ar)^{18}\ \boxed{\uparrow\downarrow}\boxed{\uparrow}\boxed{\uparrow}\boxed{\uparrow}\boxed{\uparrow}\ 3d$

No. of unpaired electrons = 4

Magnetic moment = $[4(4 + 2)]^{1/2} = (24)^{1/2} = 4.90$ B.M.

$\therefore$ The correct order of values of spin-only magnetic moment is : $Q < R < P$. So, the correct answer is (*b*)

3. *The arrangement of X^- ions around A^+ ions in solid AX is given in the figure (not shown to scale). If the radius of X^- is 250 pm, the radius of A^+ is :*



(*a*) 104 pm (*b*) 125 pm (*c*) 183 pm (*d*) 57 pm

Sol. From the figure it is clear that the cation A^+ occupies octahedral void. Hence :

$$\frac{r_{A^+}}{r_{X^-}} = 0.414\ ;\ \frac{r_{A^+}}{250\text{ pm}} = 0.414\ \ (\because \text{given } r_{X^-} = 250\text{ pm})$$

$\therefore r_{A^+} = 0.414 \times 250\text{ pm} = 103.5 \simeq 104$ pm. So, the correct answer is (*a*).

4. *The standard enthalpies of formation of $CO_2(g)$, $H_2O(l)$ and glucose (s) at 25°C are –400 kJ/mol, –300 kJ/mol and – 1300 kJ/mol, respectvely. The standard enthalpy of combustion per gram of glucose at 25°C is :*

(*A*) + 2900 KJ (*B*) –2900 KJ (*C*) –16.11 KJ (*D*) +16.11 KJ

Sol. Given reactions are :

(*i*) $C(s) + O_2(g) \rightarrow CO_2(g)$; $\Delta H = -400$ kJ mol$^-$

(*ii*) $H_2(g) + \frac{1}{2}O_2(g) \rightarrow H_2O(l)$; $\Delta H = -300$ kJ mol$^-$

(*iii*) $6\,C(s) + 6\,H_2(g) + 3\,O_2(g) \rightarrow C_6H_{12}O_6(s)$; $\Delta H = -1300$ kJ mol$^-$

Required equation is :

$C_6H_{12}O_6(s) + 6O_2(g) \rightarrow 6CO_2(g) + 6H_2O(l)$; ΔH = ? ...(A)

(6 × 12) + (12 × 1) + (6 × 16)

= 180 *g* = 1 mol

In order to get equation (*A*), we have :

– Equation (*iii*) + 6 × equation (*i*) + 6 × equation (*ii*).

Thus :

$$\left.\begin{array}{l} -6\,C(s) - 6\,H_2(g) - 3\,O_2(g) \\ +6\,C(s) + 6\,O_2(g) + 6\,H_2(g) \\ +3\,O_2(g) \end{array}\right] \rightarrow \begin{array}{l} -C_6H_{12}O_6(s) + 6CO_2(g) \\ +\,6\,H_2O(l) \end{array}$$

ΔH in kJ is

– (–1300) = + 1300 kJ

+ 6(– 400) = – 2400 kJ

+ 6(–300) = – 1800 kJ

Total = – 2900 kJ

OR

$C_6H_{12}O_6(s) + 6\,O_2(g) \rightarrow 6\,CO_2(g) + 6\,H_2O\,(l)$;

$\Delta H = -2900$ kJ

180 *g* of $C_6H_{12}O_6$ produce heat = 2900 kJ

$\therefore$ 1g of $C_6H_{12}O_6$ produce heat = $\frac{2900}{180}$ = 16 kJ

or $\Delta H = -16$ kJ

So, the correct answer is (*c*)

5. *The initial rate of hydrolysis of methyl acetate (1M) by a weak acid (HA, 1M) is 1/100th of that of a strong acid (HX, 1M) at 25°C. The Ka of HA is :*

(a) 1×10^{-4} *(b)* 1×10^{-5} *(c)* 1×10^{-6} *(d)* 1×10^{-3}

Sol. (*i*) Rate with respect to weak acid :

$$r_1 = k\,[H^+] \text{ weak acid}$$

(*ii*) Rate with respect to strong acid :

$$r_2 = k\,[H^+] \text{ strong acid}$$

Hence : $\frac{r_1}{r_2} = \frac{k\,[H^+] \text{ weak acid}}{k\,[H^+] \text{ strong acid}} = \frac{1}{100} = 0.01$ M

$\therefore$ $[H^+]$ weak acid = 0.01 M

$$HA \rightleftharpoons H^+ + A^-$$

$$1 - 0.01 \simeq 1M \quad 0.01 \quad M \; 0.01 \; M$$

$$\therefore Ka = \frac{[H^+][A^-]}{[HA]} = \frac{0.01 \times 0.01}{1} = 1 \times 10^{-4}$$

So, the correct answers is (*a*).

6. *The atomic masses of He and Ne are 4 and 20 a.m.u respectively. The value of de Broglie wavelength of He gas at – 73°C is M times that of the de Broglie wavelength of Ne at 727°C. M is.......*

Sol. We know that de Broglie wavelength,

$$\lambda = \frac{h}{(2\,m \times K.E)^{1/2}} \; ; \frac{\lambda_{He}}{\lambda_{Ne}} = \left[\frac{m_{Ne} \times K.E._{Ne}}{m_{He} \times K.E_{Ne}}\right]^{1/2}$$

$$\text{or } \frac{\lambda_{He}}{\lambda_{Ne}} = \left[\frac{m_{Ne} \times T_{Ne}}{m_{He} \times T_{He}}\right]^{1/2} \quad [\because K.E. \propto T]$$

$$= \left[\frac{20 \times (727 + 273)\,K}{4 \times (-73 + 273)\,K}\right]^{1/2} = \left[\frac{20 \times 1000}{4 \times 200}\right]^{1/2} = 5$$

$\therefore$ $\lambda_{He} = 5 \times \lambda_{Ne}$ **Ans.**

7. *The K_{sp} of Ag_2CrO_4 is 1.1×10^{-12} at 298 K. The solubility (in mol/L) of Ag_2CrO_4 in a 0.1 M Ag NO_3 solution is :*

(a) 1.1×10^{-11} *(b)* 1.1×10^{-10}

(c) 1.1×10^{-12} *(d)* 1.1×10^{-9}

Sol. $Ag_2CrO_4 \rightleftharpoons 2\;Ag^+ + CrO_4^{2-}$ (ionisation)

Solubility $\quad 2S \quad S$

$$Ag\,NO_3 \rightleftharpoons \underset{0.1\,M}{Ag^+} + \underset{0.1\,M}{NO_3^-} \text{ (ionisation)}$$

$\therefore$ $[Ag^+] = 2S + 0.1 \simeq 0.1$ M ; $[CrO_4^{2-}] = S$

$\therefore$ $K_{sp} = [Ag^+]^2\,[CrO_4^{2-}]$

or $[CrO_4^{2-}] = \frac{K_{sp}}{[Ag^+]^2} = \frac{1.1 \times 10^{-12}}{(0.1)^2} = 1.1 \times 10^{-10}$ mol L^-

$\therefore$ S = 1.1×10^{-10} mol L^-. So, the correct answer is (*b*).

8. *The **standard** reduction potential data at 25°C is given below.*

E°(Fe³⁺, Fe²⁺) *= + 0.77 V ; E° (Fe²⁺, Fe) = – 0.44 V*

E°(Cu²⁺, Cu) *= + 0.34 V ; E° (Cu⁺, Cu) = + 0.52 V*

E°[O₂(g) *+ 4H⁺ + 4e⁻ → 2 H₂O] = + 1.23 V*

E° (O₂(g) *+ 2H₂O + 4e⁻ → 4OH⁻ = + 0.40 V*

E°(Cr³⁺, Cr) *= – 0.74 V ; E° (Cr²⁺, Cr) = – 0.91 V*

Match *E° of the redox pair in list 1 with the values given **in list II** and select the correct answer using the code given below the lists.*

	List I		*List II*
P.	*E° (Fe^{3+}, Fe)*	*1.*	*–0.18 V*
Q.	*E° ($4H_2O \rightleftharpoons 4H^+ + 4OH^-$)*	*2.*	*–0.4 V*
R.	*E° ($Cu^{2+} + Cu \rightarrow 2\,Cu^+$)*	*3.*	*–0.04 V*
S.	*E° (Cr^{3+}, Cr)*	*4.*	*–0.83 V*

	P	*Q*	*R*	*S*
(a)	*4*	*1*	*2*	*3*
(b)	*2*	*3*	*4*	*1*
(c)	*1*	*2*	*3*	*4*
(d)	*3*	*4*	*1*	*2*

Sol. **P :**

$$\begin{array}{l} Fe^{3+} + 1e^- \rightarrow Fe^{2+} ; \Delta G_1^\circ = -\,1F \times 0.77 \\ Fe^{2+} + 2e^- \rightarrow Fe \; ; \Delta G_2^\circ = +\,2F \times 0.44 \\ \hline Fe^{3+} + 3e^- \rightarrow Fe \; ; \Delta G_3^\circ = -\,3F \times E^\circ_{Fe^{3+}/Fe} \end{array}$$

But $\Delta G_3^\circ = \Delta G_1^\circ + \Delta G_2^\circ$

$\therefore$ $-3F \times E^\circ_{Fe^{3+}/Fe} = -\,0.77\,F + 0.88\,F$

or $-3\,E^\circ_{Fe^{3+}/Fe} = 0.11\,V$ (After dividing both sides by F)

$\therefore$ $E^\circ_{Fe^{3+}/Fe} = -\frac{0.11}{3}\,V = -\,0.036\,V \simeq 0.04\,V$

Q : $2H_2O \rightarrow O_2 + 4H^+ + 4e^-$; E° = – 1.23 V

$$\text{Add : } \begin{array}{l} 2H_2O + O_2 + 4e^- \rightarrow 4OH^- ; E^\circ = +\,0.4\,V \\ \hline 4H_2O \rightarrow 4H^+ + 4OH^- \; ; E^\circ = -\,0.83\,V \end{array}$$

R : $Cu^{2+} + 2e^- \rightarrow Cu$; E° = + 0.34 V

$$\text{Add : } \begin{array}{l} 2Cu \rightarrow Cu^+ + 2e^- \; ; E^\circ = -\,0.52\,V \\ \hline Cu^{2+} + Cu \rightarrow 2\,Cu^+ \; ; E^\circ = -\,0.18\,V \end{array}$$

S :

$$\begin{array}{l} Cr^{3+} + 3e^- \rightarrow Cr \; ; \Delta G_1^\circ = +\,3 \times F \times 0.74 \\ Cr \rightarrow Cr^{2+} + 2e^- \; ; \Delta G_2^\circ = +\,2 \times F \times 0.91 \\ \hline Cr^{3+} + 1e^- \rightarrow Cr^{2+} \; ; E^\circ = -\,0.4\,V \end{array}$$

So, the correct answer is (*d*).

Appendix (ix)

Solutions to Numericals set in NEET, 2013

1. *At 25°C, molar conductance of 0.1 molar aqueous solution of ammonium hydroxide is 9.54 ohm^{-} cm^{2} mol^{-1} and at infinite dilution, its molar conductance is 238 ohm^{-} cm^{2} mol^{-}. The degree of ionisation of ammonium hydroxide at the same concentration and temperature is :*

   (*a*) 4.008 % (*b*) 40.800% (*c*) 2.080% (*d*) 20.800%

Sol. Molar conductivity at conc., c (λ^{c}_{m}) = 9.54 ohm^{-} cm^{2} mol^{-}. Molar conductivity at infinite dilution,

$$\lambda^{\infty}_{m} = 238 \text{ ohm}^{-}\text{cm}^{2}\text{ mol}^{-}$$

$\therefore$ Degree of dissociation,

$$\alpha = \frac{\lambda^{c}_{m}}{\lambda^{\infty}_{m}} = \frac{9.54 \text{ ohm}^{-}\text{ cm}^{2}\text{ mol}^{-}}{238 \text{ ohm}^{-}\text{ cm}^{2}\text{ mol}^{-}}$$

$$= 0.04008$$

$$= 0.04008 \times 100 = 4.008\%$$

So, the correct answer is (*a*).

2. *A metal has a fcc lattice. The edge length of the unit cell is 404 pm. The density of the metal is 2.72 g cm^{-3}. The molar mass of the metal is : (Avogadro's constant = 6.02 × 10^{23} mol^{-})*

   (a) 27 g mol^{-} (b) 20 g mol^{-} (c) 40 g mol^{-} (d) 30 g mol^{-}

Sol. For fcc structure, $Z = 4$; $N_A = 6.02 \times 10^{23}$ mol^{-} ; $a = 404$ pm = 404×10^{-10} cm ; Molar mass ; M = ?. We know that :

$$d = \frac{Z\,M}{N_A\,a^3} \text{ or } M = \frac{d\,N_A\,a^3}{Z}$$

$$\therefore \frac{2.72 \text{ g cm}^{-3} \times 6.02 \times 10^{23} \text{mol}^{-} \times (404 \times 10^{-10})^3 \text{ cm}^3}{4}$$

$= 26.99 \simeq 27$ *g* mol^{-}

$\therefore$ The correct answer is (*a*).

3. *What is the activation energy for a reaction, if its rate doubles when the temperature is raised from 20°C to 35°C (R = 8.314 JK^{-} mol^{-})*

   (a) 34.7 kJ mol^{-} *(b) 15.1 kJ mol^{-}*
   (c) 342 kJ mol^{-} *(d) 269 kJ mol^{-}*

Sol. Here $k_2 = 2k_1$; $T_1 = 20 + 273 = 293\ K$; $T_2 = 35 + 273 = 308\ K$; $R = 8.314$ JK^{-} mol^{-}. Substituting these values in :

$$\log \frac{k_2}{k_1} = \frac{Ea}{2.303\,R}\left[\frac{1}{T_1} - \frac{1}{T_2}\right], \text{ we get :}$$

$$\log \frac{2k_1}{k_1} = \frac{Ea}{2.303 \times 8.314 \text{ JK}^{-}\text{ mol}^{-}}\left[\frac{1}{293\ K} - \frac{1}{308\ K}\right]$$

$$\log 2 = \frac{Ea}{2.303 \times 8.314 \text{ J mol}^{-}} \times \frac{15}{293 \times 308}$$

$$0.3010 = \frac{Ea}{2.303 \times 8.314 \text{ J mol}^{-}} \times \frac{15}{293 \times 308}$$

$$\therefore Ea = 0.3010 \times 2.303 \times 8.314 \text{ J mol}^{-} \times \frac{293 \times 308}{15}$$

= 34673 J mol^{-} $\simeq$ 34.7 kJ mol^{-}. So, the correct answer is (*a*)

4. *A magnetic moment of 1.73 BM will be shown by one among the following*

   (a) Ti Cl$_4$ *(b) [Co Cl$_6$]$^{4-}$*
   (c) [Cu (NH$_3$)$_4$]$^{2+}$ *(d) [Ni (CN)$_4$]$^{2-}$*

Sol. Magnetic moment, $\mu = (n\,(n + 2))^{1/2}$ where '*n*' is the number of unpaired electrons.

(*a*) In TiCl$_4$, oxidation state of Ti = + 4 [$\because$ Ti + 4 Cl^{-} = 0; Ti + 4 (–1) = 0. Hence, Ti = + 4]

$_{22}$Ti^{4+} = 22 – 4 = 18 *e*$^{-}$*s*. So, Ti^{4+} = (Ar)^{18}. It has no unpaired electron.

(*b*) [Co Cl$_6$]$^{4-}$. In this complex, oxidation state of cobalt is + 2 [$\because$ Co + 6 (–1) = – 4 ; Co = – 4 + 6 = + 2]

$_{27}$Co^{2+} = 27 – 2 = 25 *e*$^{-}$*s* ; electron configuration

$$= (\text{Ar})^{18}\ \overset{3d}{\boxed{\uparrow\downarrow}\boxed{\uparrow\downarrow}\boxed{\uparrow}\boxed{\uparrow}\boxed{\uparrow}}$$

So, there are three unpaired electrons. Hence, $\mu = [3\,(3 + 2)]^{1/2} = (15)^{1/2} = 3.87$ BM.

(*c*) (Cu (NH$_3$)$_4$)$^{2+}$, In this complex, oxidation state of Cu = +2 [$\because$ Cu + 4(0 of NH$_3$) = + 2 ; So, Cu = +2]

$_{29}$Cu^{2+} = 29 – 2 = 27 *e*$^{-}$*s* ; electron configuration

$$= (\text{Ar})^{18}\ \overset{3d}{\boxed{\uparrow\downarrow}\boxed{\uparrow\downarrow}\boxed{\uparrow\downarrow}\boxed{\uparrow\downarrow}\boxed{\uparrow}}$$

So, there is one unpaired electron or $n = 1$

$\therefore \mu = [n\,(n + 2)]^{1/2} = [1(1 + 2)]^{1/2} = (3)^{1/2} = 1.73$ BM.

(*d*) In [Ni (CN)$_4$]$^{2-}$, oxidation state of Ni = +2. So, $_{28}$Ni^{2+} = 28 – 2 = 26 *e*$^{-}$*s* ; electron configuration is (Ar)^{18} 3$d^{2+2+2+1+1}$ with two unpaired electrons So, $\mu = [2(2 + 2)]^{1/2} = (8)^{1/2} = 2.82$ BM.

So, the correct answer is (*c*)

5. *Number of carbon atoms per unit cell of diamond unit cell is :*

   (a) 6 *(b) 1* *(c) 4* *(d) 8*

Sol. Diamond has zinc blende (ZnS) like structure. Carbon forms ccp (fcc) and also occupies half of the tetrahedral voids.

∴ Total number of carbon atoms per unit cell =

$$\underset{\text{(corners)}}{(8 \times 1/8)} + \underset{\text{(Face centred)}}{\left(6 \times \frac{1}{2}\right)} + \underset{\text{(Tetrahedral voids)}}{4} = 8$$

So, the correct answer is (*d*).

6. *A button cell used in watches functions as follows :*

$$Zn_{(s)} + Ag_2O_{(s)} + H_2O_{(l)} \rightleftharpoons 2\,Ag_{(s)} + Zn^{2+}(aq) + 2OH^-(aq)$$

If half-cell potentials are

(i) $Zn^{2+}(aq) + 2e^- \rightarrow Zn_{(s)}$; $E° = -0.76$ V

(ii) $Ag_2O(s) + H_2O(l) + 2e^- \rightarrow 2\,Ag(s) + 2\,OH^-(aq)$; $E° = 0.34$ V

The cell potential will be :

(a) 0.84 V (b) 1.34 V (c) 1.10 V (d) 0.42 V

Sol. Required reaction is :

$Zn(s) + Ag_2O(s) + H_2O(l) \rightleftharpoons 2\,Ag(s) + Zn^{2+}(aq) + 2OH^-(aq)$; $E° = ?$

In order to get above equation, we have :

Given equation (*ii*) – given equation (*i*). Thus :

$$\left.\begin{array}{l} Ag_2O(s) + H_2O(l) + 2e^- \\ -Zn^{2+}(ag) - 2e^- \end{array}\right] \begin{array}{l} \rightarrow 2Ag(s) + 2OH^-(ag) - Zn(s); \\ E^\circ = 0.34 - (-0.76) = 1.10\text{ V} \end{array}$$

or $Zn(s) + Ag_2O(s) + H_2O(\underline{l}) \rightarrow 2\,Ag(s) + Zn^{2+}(aq) + 2OH^-(aq)$

So, the correct answer is (*c*).

7. *6.02×10^{20} molecules of urea are present in 100 mL of its solution. The concentration of this solution is :*

(a) 0.001 M (b) 0.1 M (c) 0.02 M (d) 0.01 M

Sol. Mol of urea $= \dfrac{6.02 \times 10^{20}}{6.02 \times 10^{23}} = 0.001$

∴ Concentration of solution $= \dfrac{0.001}{100} \times 1000 = 0.01$ M

So, the correct answer is (*d*)

8. *How many grams of concentrated nitric acid Should be used to prepare 250 mL of 2.0 M HNO_3 ? The concentrated acid is 70% HNO_3.*

(a) 70.0 g conc. HNO_3 (b) 54.0 g conc. HNO_3

(c) 45.0 g conc. HNO_3 (d) 90.0 g conc. HNO_3

Sol. We know molarity,

$$M = \frac{\text{Mass of solute} \times 1000}{\text{Mol. Wt. of solute} \times \text{vol in mL}}$$

$$\therefore 2 = \frac{\text{Mass of solute} \times 1000}{63 \times 250} \quad \left[\begin{array}{l} \because \text{Mol.wt. of } HNO_3 = \\ 1+14+3(16) = 63\text{ g mol}^- \end{array}\right.$$

$$\therefore \text{Mass of solute} = \frac{63 \times 250 \times 2}{1000} = 31.5\text{ g}$$

$$\therefore \text{Mass of acid} \times \frac{70}{100} = 31.5$$

$$\text{Or Mass of acid} = \frac{31.5 \times 100}{70} = 45\text{ g}$$

So, the correct answer is (*c*)

9. *The value of Planck's constant is 6.63×10^{-34} Js. The speed of light is 3×10^{17} nm s^-. Which value is closest to the wave length in nanometer of a quantum of light with frequency of $6 \times 10^{15}\ s^-$?*

(a) 50 (b) 75 (c) 10 (d) 25

Sol. $\lambda = ?$; $C = 3 \times 10^{17}$ nm s^- ; $\nu = 6 \times 10^{15}\ s^-$. We know that :

$$\lambda = \frac{C}{\nu} \quad \therefore \lambda = \frac{3 \times 10^{17}\text{ nm } s^-}{6 \times 10^{15}\ s^-} = 50\text{ nm}.$$

So, the correct answer is (*a*)

10. *A hydrogen gas electrode is made by dipping platinum wire in a solution of HCl of pH = 10 and by passing hydrogen gas around the platinum wire at one atm. pressure. The oxidation potential of the electrode would be*

(a) 0.118 V (b) 1.18 V (c) 0.059 V (d) 0.59 V

Sol. $$\underset{1\text{ atm}}{H_2(g)} \rightarrow \underset{10^{-10}}{2H^+} + \underset{n=2}{2e^-} \quad \left[\begin{array}{l} \because pH = -\log(H^+) \\ \quad 10 = -\log(H^+) \\ \therefore [H^+] = 10^{-10} \end{array}\right.$$

Using Nernst equation, we have :

$$E_{H_2/H^+} = 0 - \frac{0.059}{2} \log \frac{(10^{-10})^2}{1}$$

$$\text{or } E_{H_2/H^+} = \frac{-0.059}{2} \times 2 \log 10^{-10} = (-)\ (-10) \times 0.059$$

log 10 = 10 × 0.059 × 1 = 0.59 V

So, the correct answer is (*d*).

Pauling electronegativity 257
Percentage composition 848
Period number prediction 253
Pfund series 227
pH of buffers 769
pH of mixtures 400, 766
(of weak acid + salt of weak acid with a strong base 767, weak acid + weak acid 768, pH of one solution + pH of second solution 835)
pH of salts and solutions of hydrolysis 784
(salts of weak acids and strong bases 784, 785, salts of strong acids and weak bases 788,
pH of solutions 748
(of strong acids 400, 749, strong bases 400, 750, weak bases 750, weak acids 751, strong acid + weak acids 753, weak acid + strong base 754, strong acid + strong base 756 834, strong acids + strong base + weak bases 758, weak acid + strong alkali 778, 782, strong alkali + strong alkali, 834, strong acid + strong acid, 834, Common ion effect 766
Common ion concentration 766
Photoelectric effect 213
Photon numbers 209
Physical and chemical equilibrium 661, 666
Physical constants 4
(conversion factors 4, 5
pi (p)-mesons 556
Planck's quantum theory 208
Planck's relation 208
POH 748
Polymers 945
Potassium dichromate titrations 606
Potassium permanganate titrations 603, 606
Potential difference 463
Precipitation prediction 796
Precision 8
Primary standard 596
Primitive cubic lattice 152
(no. of atoms per unit cell 153)
Proton 204

R

Radiant energy 207
Radioactive disintegration series 570
Radioactive equilibrium 582
Radioactive substance in solution, 576
Radioactivity 563
(units Becqueral, rutherford, millirutherford, curie, millicurie, micro curie 563)
Radius of atom 155
(relation with distance between nearest neighbours 155)
Radius of orbit 224
Radius of oxygen atom 250
Radius ratio 164
Raoult's law 401

(relation with Dalton's law of partial pressures 401, 402)

Rast's camphor method 425

(relation with depression in f.pt. 424)

Rate constant 514

Rate of disappearance of a compound 510

Rate of disintegration 563

Rate of reaction 510

(average 511)

Reaction quotient, Q 662

Redox reaction 360

(Method to balance by oxidation number change method 360. for neutral medium 362; for acidic medium 363; for alkaline medium 364;

Reducing agent (prediction) 465

Reductant or reducing agent 360 (method to know in a redox reaction 360)

Reduction 359

Reduction half-reaction 462

Reduction potential 463

Regnault's method 58

Relative density 48

Relative lowering of vapour pressure 401 (to find mol. wt. of solute 403)

Resistance 458

Resistivity 458

Resonance energy 259, 318

Reversible Process 297

Root mean square velocity 96

Rounding off figures 15

Rutherford's model of atom 201

Rydberg constant 227

S

Salt buffer 769

Scientific notation 15

Second order reactions 514

Secondary standard 596

Shortest wave length in H-atom 227

Sign convensions (in thermodynamics 299)

Significant Figures 14

(rules, 4, addition and subtraction 16, multiplication and division 16)

Silver salt method 55

Simple cubic lattice 152

S.I. Units (Basic) 1

Soddy-Fajan-Russel's— article No. 12.6

Solubility 741

Solubility 793

(of salt of strong base and strong acid 793, of salt of a strong base and strong acid containing common ion 793, salt of weak acid and strong base 794, salt of a salt of a weak acid and a strong base in acidic buffer solution 794, salt of a weak acid and a strong base in a basic buffer 974, salt of a weak acid with a weak base 794, salt of a weak acid and weak base in acidic buffer 794 and in basic buffer 795)

Solubility product 793

Solution 373

Solutions to problems 963

Solvent extraction 953

Solvent extraction method 957

some typical facts 866,

Space lattice 152

Specific activity 563

Specific conductance 458, 459 conductivity 458

Specific gravity 48

(determination 48)

Specific heat 326

Specific resistance 458

Spectral lines 227, 399

Spectral lines, minimum number 232, 399

Standard solution 596

Standard states 299

Steno's law of constancy of interfacial angles 153

Stoke's law 113

Strength of solution 596

Structure of organic compounds 862

Basic concepts 862,

Surface tension 114

Symmetry laws 153

T

Terminal velocity 113

Tetrahedral voids 154

Thermal capacity 326

Thermal decomposition 683

Thermal dissociation 683

Thermal equilibrium 111

Thermodynamics 297

Third order reaction 514

Thomson's model of atom 201

Thorium series 570

Threshold energy 539

Threshold frequency 213

Titrations 597

(of acid-base 597, involving molarity 601, redox titrations 602, potassium paramagnate 603, 606 Potassium dichromate titrations 606)

Trailing zeros 14

Translational K.E change 111
Transport number 459
Types of reactions 299
    (Enthalpy of formation 299, 307, combustion, 299, 312,transition, hydration 299, 321, neutralization 299, 323)

U

Uncertainty in momentum of particle 221
Uncertainty in position of particle 221
Unit cell 152 (no. of atoms per unit cell 153)
Units contrary to S.I. units 2
    (physical quantities, distance, time, temperature 2; pressure, mass, volume, energy, force, density, work, velocity, momentum, radioactivity, electrical charge 3.
Uranium series 570

V

Valency (from Dulong and Petit's Law, 36
Van't Hoff factor, i 423, 429
Vander Waal constants 102
Vander Waal equation 102
Vapour density 48
    (determination of a gas 50, from Victor Meyer method 60)
Vapour pressure 402
    (of water above solution 403
Vapour pressure lowering, 406
Velocity 207
    (of electron 225)
Velocity of particles 561
Viscosity 113
Voltaic cell 462
Volume occupied by particles 155
Volume percentage 373
Volume-volume relationship 274
Volumetric analysis 596

W

Water 933
Water equivalent of calorimeter 326
Watt relation with joule 216
Wave length 207
    (relation with velocity and wave length 207)
Wave number 207
    (of spectral line 227)
Weight-weight relationship 268 (successive reactions 269)
Weigth- volume relationship 270
Work (W) 297 (of expansion 297)
Work done (in isothermal reversible process 298, 303, in adiabetic reversible process 298)
Work function 213
Work to heat n mol of a substance 302

X

X-ray diffraction 169

Z

Zero order reaction 531
